provided with 1200 ships of war, and 3000 ships of burthen, for his intended expedition: and his army consisted of seventeen hundred thousand infantry, and four hundred thousand cavalry, and these, joined to those who manned his fleet, amounted to near two millions of fighting men. In the year 480 B.C. he passed the Hellespont, and the vain-glorious monarch had the pleasure of reviewing the whole fleet and army near Doriscus, a city of Thrace, at the mouth of the river Hebrus. In the mean while those Grecians, who, unmoved by the terrors of invasion, obeyed the voice of liberty and their country, had sent deputies to the illustrious of Corinth, to deliberate about the common safety. A general union prevailed, and the general danger seemed to harmonize the most discordant members of the common council. The Grecian fleet sailed to Artemisium, patiently expecting the arrival of the barbarians. The straits of Thermopylae, 15 miles distant from the station of the Grecian fleet at Artemisium, and deemed the gate or entrance into Greece, was guarded by troops, consisting chiefly of Peloponnesians, under the command of Leonidas, the Spartan king. Xerxes having made his previous arrangements, sent messengers to treat with the Spartans, and to desire them to lay down their arms; to which they replied, "Let him come and take them." The messengers then offered them lands, on condition of their becoming allies to the great king, but they answered: "That it was the custom of their republic to conquer lands by valour, not to acquire them by treachery." Xerxes waited four days after the return of the messengers, expecting the Grecians to retreat into their own country, or surrender their arms. On the fifth day he determined to chastise their insolent opposition. The attack was ordered, and the Persians were repelled: it was renewed the next day with the like result.

The Greeks, however, were betrayed by Epialtes, a perfidious wretch of their own nation, who conducted a body of twenty thousand Persians through a passage in the mountains of Oeta, several miles to the west of that guarded by Leonidas. The Athenian general had prudently guarded this important but unknown pass, which, as he conceived, chance or treachery might discover to the Persians. A body of 1000 Phocians had been appointed to this service; upon the approach of the Persians they instantly flew to their arms, and determined to resist the progress of the enemy or to die in the attempt. Expecting to be pursued, they retired to the highest part of the mountain; but the Persians, declining to follow them, seized the passage which they had abandoned, and marched down the mountain in order to accomplish the design which had been preconcerted by the traitor Epialtes. Leonidas, apprized of this act of treachery, called a council of war; when all the confederates of Peloponnesus, except the Spartans, determined to abandon a post which they deemed to be untenable. Leonidas, however, with 700 Thebians, 400 Thebans, and 300 Spartans, remained in the post of danger and of glory. In the dead of night the Spartans, headed by Leonidas, marched in a close battalion towards the Persian camp, with resentment heightened by despair. The conflict was ardent and destructive, whilst the Greeks were favoured in their attack by the darkness of the night; but at the approach of day the Persians, who had previously fled, discovered that their fears had multiplied the number of the enemy; and therefore rallying their scattered forces, Xerxes gave orders to pursue the Greeks, who had retreated in close order to the straits of Thermopylae. The shock was dreadful; and the battle was maintained on the side of the Greeks with persevering intrepidity and desperate valour. At length a barbarian dart pierced the heart of Leonidas; nevertheless the Lacedaemonians and Thebians,

though ingloriously deserted by the Thebans, maintained their firmness to the last; and they were finally not destroyed or conquered, but buried under a trophy of Persian arms. (See LEONIDAS and THERMOPYLÆ.) During the military operations at Thermopylae, the Grecian fleet was stationed in the harbour of Artemisium, the northern promontory of Eubœa, and the numerous one of the Persians had anchored on the road that extends between the city of Caranava and the promontory of Sepias, on the coast of Thesalia. Here it suffered calamities, of which Xerxes had been forewarned, but which he disregarded. Themistocles, by his address, prevailed on the Athenian commander to remain at Artemisium; and as soon as the Persians recovered from the terrors of the storm, the effects of which they had suffered, both sides prepared for a battle, for the result of which see ARTEMISIUM. The Persians were again totally defeated near Salamis (which see); upon which Xerxes determined to leave Greece. Of the conduct of Themistocles on this occasion, see his article; and for an account of the battle of Plataea, see PLATÆA. The event of this bloody engagement not only delivered the Greeks from the danger of servitude, but gave them possession of greater wealth than they could ever have expected to possess. In his precipitate retreat from Greece, Xerxes left behind him all his riches and magnificence. The battle of Plataea was succeeded by that of Mycale, in which the Greeks were again victorious. About 40,000 Persians perished in the field, many fell in the pursuit, and the remainder fled in disorder, nor thought themselves secure till they had reached the walls of Sardis. Their ships, their camp, the freedom of Ionia, and the undisturbed possession of the Asiatic coast, formed the inestimable prize of the victors; and thus the expedition of Xerxes, undertaken with a view to enslave Europe, restored liberty to the fairest portion of Asia. The beginning of the 5th century B.C. forms the most glorious era in the history of Greece. It is, however, the peculiar glory of the Athenians that, during their rapid career of military and naval triumphs, they cultivated, with a generous enthusiasm, the arts which adorn peace as well as war. It is observable that in the single life-time of Pericles, the republic of Athens produced those inestimable models of poetry, eloquence, and philosophy, which, in every succeeding age, the delighted portion of mankind hath invariably regarded as the best standards, not merely of competition and style, but of taste and reason. The name of Greek seemed thenceforth to be sunk in that of Athenian. (See ATHENS, and SPARTA.) For an abstract of the further history of this period of Alexander's history and exploits, we have given a brief sketch under his article; we shall here observe, with Dr Gillies, that during the later years of his reign the Greeks, deprived of the honour and delivered also from the cares of independent sovereignty, and undisturbed by those continual and often bloody dissensions, which deform the annals of their tumultuous liberty, indulged their natural propensity to the social embellishments of life; a propensity by which they were honourably distinguished above all other nations of antiquity. Their innumerable shows, festivals, and dramatic entertainments, were exhibited with more pomp than at any former period. The schools of philosophers and rhetoricians were frequented by all descriptions of men. Painting and statuary were cultivated with equal ardour and success. Many improvements were made in the sciences, and the Greeks, particularly the Athenians, still rivalled the taste and genius, though not the spirit and virtue, of their ancestors. Yet even in this degenerate state, when patriotism and true valour were extinct, and these vasquished republicans had neither liberties to love, nor country to defend, their

martial honours were revived, and brightened by an association with the renown of their conqueror. Under Alexander, their exploits, though directed to very different purposes, equalled, perhaps excelled, the boasted trophies of Marathon and Plataea. By a singularity peculiar to their fortune, the era of their political disgrace coincides with the most splendid period of their military glory. Alexander was himself a Greek; his kingdom had been founded by a Grecian colony; and to revenge the wrongs of his nation, he undertook and accomplished the most extraordinary enterprises recorded in the history of the world.

The *fourth* period of the history of Greece, commencing with the death of Alexander, 323 B.C. and terminating 146 B.C. when the Achaean league was dissolved, and Greece became a Roman province, under the name of Achaia, comprehends an interval of 177 years. After various changes and revolutions, for an account of which, see ACHAEANS and ATHENS, it became subject to the Turks.

GRÆCIA, *Magna*, a name given to the southern part of Italy, comprehending Apulia, Lucania, and the country of the Brutii, and also to Sicily and several of the adjacent islands. The name of *Græcia* was derived from the Greek colonies, which migrated hither at different periods, and the epithet *magna*, or great, was derived from mere ostentation, as Pliny informs us (l. iii. c. 5.). This migration and settlement took place at a very early period, about 1055 years B.C. The most numerous colonies, the migration of which was occasioned by intestine faction, foreign invasion, or the restless spirit of adventure and rapine, occupied the isles of the Ionian and Ægean seas, the southern coast of Italy almost intersected by the former, and the winding shores of Asia Minor so beautifully diversified by the latter. The larger islands of Sicily, Sardinia, and Cyprus were very anciently planted by Greeks.

Whoever has observed the desolate barbarity of Calabria, or reflected on the narrow extent and present weakness of Sicily, will scarcely believe, that five centuries B. C. those countries contained above 20 warlike communities, several of whom could send into the field 100 thousand fighting men. In order to account for this wonderful population, we must look back to the period above mentioned in the heroic ages; and consider likewise that the greater number of Greek colonies in those parts were planted during the eighth century before the Christian era, and chiefly, 1. By the Eubœans, whose principal city Chaleis, usually furnishing the conductor of the colony, gave the epithet of Chalcidian to the new settlements; 2. By the Achæans of Peloponnesus, who were of the Eolian tongue and lineage; and 3. By the Dorian states of that peninsula, especially Corinth. Besides their powerful colonies in Coreyra, Lencas, Anactorium, Anibracia, whose transactions form such an important part of the history of ancient Greece, the Corinthians founded Syracuse, which soon became, and long continued, the capital of Sicily; and in the sixth century B. C. the Syracusans had extended their settlements over all the southern coast of the island. By means of these and similar establishments of a powerful kind, the Dorians acquired, and always maintained, an ascendant in Sicily; but the Achæan colonies, who were of the Æolian blood and language, commanded the Italian shore. Crotona, the most considerable city of the Achæans, and of all Italy in ancient times, was built 710 years B. C. Sybaris, its rival, was founded about the same time. The former sent colonies to Tirina, Cephalonia, and Pandosia; the latter built Laus, Metapontum, and Posidonia, or Præstum, whose admired ruins attest the ancient wealth and grandeur of the Greek cities of Italy. We may here remark, that the Ionians,

who came from Eubœa, and settled chiefly near the eastern shore of Sicily, never rivalled the power and fame of their Dorian and Æolian neighbours, but fell short of those nations in Magna Græcia, as much as they surpassed them on the shores and islands of Asia. In order to account for the flourishing situation of Magna Græcia about the year 500 B. C., many causes may be assigned, besides those of a physical and moral nature, which usually contribute to the rapid growth of newly-established colonies. We might mention the natural fertility of Magna Græcia, and particularly of Sicily, which in many places produced an hundred fold; and in this connection observe, that the Greeks who sailed thither from Peloponnesus, carried with them the knowledge and practice of agriculture, which had early attained a high degree of perfection in their peninsula; and that the exuberant soil of Sicily, improved by cultivation, soon exhibited a picture of that rich abundance, which, in later times, made that beautiful island be entitled the granary of Rome. Besides, the peculiar situation of the Achæans and Dorians, from whom chiefly the colonies in Magna Græcia derived their origin, had a considerable influence in accelerating the population and grandeur of these new establishments. The impartial and generous spirit of the Achæan laws early compensated the natural defects of their territory, which was a long, but narrow, strip of ground, not more fertile than extensive, along the Corinthian gulf. They, however, were the first, and long the only republic of Greece, who admitted strangers into their community on equal terms with the ancient citizens. The equitable and generous policy, which they transported with them into Magna Græcia, could not fail to promote the happiness and prosperity of that delightful country. The condition of the Dorians, at the time when they planted colonies in Italy and Sicily, is not less worthy of consideration. The Dorian states of Peloponnesus were then universally subject to the gentle government of limited but hereditary princes, or to magistracies chosen from the descendants of their ancient royal families; and who, thus adorned by birth, were sometimes still more ennobled by wisdom and virtue. Moreover, the colonies in Magna Græcia, enjoying a wide extent of territory before them, were not retarded in their advancement by interference of interest on the part of neighbouring states, but they found sufficient employment in subduing the original inhabitants of that country, without commencing hostilities either against their neighbours or against each other. The kings or nobility of Magna Græcia, secure of their own pre-eminence, felt nothing of the republican jealousies which prevailed in the mother country. They received with pleasure new citizens, or rather subjects, from whatever quarter they might come. The states of Italy and Sicily, thus increasing by degrees, could soon boast, the former of Crotona, Tarentum, Sybaris, Rhegium; the latter of Syracuse, Agrigentum, Messenæ, Himera, and several other cities, which rivalled or surpassed the wealth of Athens or Corinth, and the populousness of Thebes, Argos, or Sparta. The wars, conquests, or oppressions, and, above all, the civil dissensions, which in the sixth century B. C. disturbed and deformed the coast of Ionia, and the other Grecian colonies in the islands and continent of Asia, brought frequent accessions of inhabitants to the shores of Magna Græcia. Nevertheless, the Ionians, along with their poetry, music, and painting, communicated also their dissolute and artificial appetites to the Greeks of Italy and Sicily. It is a fact, however, that Magna Græcia, having obtained opulence by industry, dissipated it in idleness and licentiousness: inasmuch that the Greek cities of Italy, and particularly Sybaris and Crotona,

fell a prey to the most dangerous errors and vices, when Pythagoras came to their relief about 550 years before the Christian era. His philosophy and legislation reformed and improved the manners and policy of Magna Græcia, and contributed, in an eminent degree, not only to the quiet and happiness, but to the industry, power, and splendour of that celebrated country. (See PYTHAGORAS.) The concurring testimony of historians assures us, that the school of Pythagoras flourished above 40 years to the unspeakable benefit of Magna Græcia when a war arose between Crotona and Sybaris, the latter of which had ever contemptuously rejected the Pythagorean institutions.

Having traced the progress towards prosperity and renown of Magna Græcia, it is natural to state the causes of its decay. In Italy, the citizens of Crotona had too soon reason for lamenting their insurrection against their magistrates, and their dereliction of the discipline of Pythagoras. The other Greek cities of Italy, which are said to have imitated the fatal example of Crotona, were harassed by wars against each other, or against their barbarous neighbours. In 60 years after the death of Pythagoras, an attempt was made to revive his institutions; but in less than 40 years a new persecution entirely drove the Pythagoreans from Italy, and completed, according to Polybius (i. 403.) the confusion and misery of that once happy country. Gillies's Hist. of Greece, vol. ii.

GRÆCINUS, JULIUS, in *Biography*, a Roman senator, who flourished in the reign of Caligula, was son of a Roman knight, and greatly distinguished for eloquence, and for the study of philosophy, and he carried into practice the moral lessons which his studies led him to contemplate. He refused to obey the command of the emperor to appear as the accuser of Marcus Silanus, and suffered death in consequence. Seneca says of him, that he was put to death for the sole reason, that he was too good a man to be permitted to live under a tyrant. He is mentioned by Columella, as having written a treatise concerning agriculture and the management of vines. He was the father of the illustrious Cn. Julius Agricola. Univer. Hist.

GRÆDÈR FIORD, in *Geography*, a bay of West Greenland. N. lat. 63° 50'. W. long. 49° 30'.

GRAEMSAY, one of the Orkneys, a flat, fertile island, $1\frac{1}{2}$ mile in length, and a mile in breadth, containing 32 families and 179 inhabitants; $1\frac{1}{2}$ mile S. of Stromness, near the northern extremity of Hoy. The soil of the interior part is thin and fertile; but the coast is a chain of broken and pointed rocks. It contains a bed of slate, but no fuel.

GRAEN, a town of Hindoostan, in Vishapour; 24 miles S. of Curer.

GRAESATZ, a town of Croatia; 30 miles S. of Bihacs.

GRÆVIUS, JOHN-GEORGE, in *Biography*, an eminent critic; was born at Naumberg, in Saxony, in 1632. Having acquired a good knowledge of the learned languages in Germany, he went to Leiphe and studied under Rivinus and Strauchius. After this he passed two years at Deventer, intimately connected with the celebrated Gronovius, to whom he acknowledged himself indebted for a considerable part of his acquisitions, and whom he after succeeded in his professorship. (See GRONOVIVS.) His great reputation induced the States of Utrecht to invite him to their university, and during forty-one years he instructed the young men there in politics, history, and eloquence, refusing various invitations to other seminaries. He died in the year 1703, at the age of seventy-one. He was the editor of many of our best classical authors, as Hesiod, the greater part of the works of Cicero, Florus, Cæsar, Suet-

tonius, &c. He compiled also "Thesaurus Antiquitatum Romanorum," in 12 vols. fol. and "Thesaurus Antiquitatum Italicorum," in 6 vols. fol. This work was continued by Burman to the forty-fifth volume. Grævius, as a critic, was modest, and free from pride and pedantry, which are said too frequently to accompany this character. Moreri.

GRAF, in *Geography*, one of the smaller Western islands of Scotland, on the W. coast of Lewis. N. lat. 58° 14'. W. long. 6° 53'.

GRAFFENBERG, a town of Germany, in the territory of Nuremberg; 11 miles S. E. of Forchheim.—Also, a town of Upper Carniola; 19 miles S. E. of Laybach.

GRAFFENECK, a town of Austria; 10 miles S. W. of Sonneberg.

GRAFFER, from the French *greffier*, i. e. *scriba*, a notary, or *scrivener*. It is used in the stat. 5 Hen. VIII. cap. 1.

GRAFFIGNY, FRANÇOIS D'ISSEMBOURG D'HAIPOUCOURT DE, in *Biography*, a literary lady, daughter of a major of the gendarmerie of the duke of Lorraine, was born at Nanci about the year 1694. She married de Graffigny, chamberlain to the duke, a man of violent passions and most brutal disposition, from whom she obtained, after living with him many years, a legal separation. She now went to Paris with mademoiselle de Guise, who was espoused to marshal Richelieu, and soon made her merit known to the wits of the capital. In 1745 she was announced as the author of a Spanish novel. This was followed by the "Lettres d'une Peruvienne," in two vols. 12mo. which were much read and admired, though defective in point of style, and in the metaphysical manner of treating of the passion of love. One of her best pieces was entitled "Cénie," a drama in five acts, which was written in prose. She wrote another, which was entitled "La Fille d'Aristide," and which obtained a much less share of public approbation. This lady was of a truly estimable character in private life, and had many respectable friends, even in the highest ranks of society. The emperor and empress honoured her with particular notice, and made her frequent presents. She was an associate of the academy of Florence; and died at Paris in 1758, at the age of sixty-four. Gen. Biog.

GRAFFIO, or GRAVIO, in our *Old Writers*, denotes a *landgrave* or *earl*. "Nec princeps nec graffio, hanc lenitatem mutare audeat."

GRAFFIUM, is used for a writing-book, register, or chartulary of deeds and evidences.

GRAFT, in *Gardening*, a name applied to the shoot or scion that is to be inserted into the stock or branch of the tree, in the operation of grafting. It has occasionally the vulgar term of *graft* given it by gardeners.

The word is formed of the French *graffe*, which signifies the same thing; and *greffe*, in this sense, is supposed to have been derived from the resemblance the shoot bears to the point of a penknife, which was anciently called *greffe*. Du Cange goes farther, and derives the ancient *greffe* from *graphium*: Menage, from *graphium*, a Latin word, signifying a little style, or iron bodkin, one end whereof was pointed, and served to write on waxen tablets; and the other flat, serving to efface or rub out what was written.

There are several circumstances to be attended to in choosing the grafts. The shoots or scions that are to be employed in this way, should be selected and cut in the manner that will be directed in speaking of grafting: but they should never be taken from such as have a too rapid growth, or are in the least degree infected with disease of any kind. See GRAFTING.

In the conducting of this process, though the wits of the stock, and those of the shoot or graft are.

GRAFTING.

sure, brought into contact and thereby united, as well as those of the latter supplied with nutritious matters from the former, yet their economy remains still the same. Mr. Bradley has considered it as a sort of planting; the shoot or scion rather taking root in the stock or tree into which it is inserted, than uniting itself with it, as is seen by its preserving its natural purity and utility, although fed and supported merely by a crab-stock; which it is supposed depends upon some difference in the vessels of the shoot or scion from those of the stock or tree.

GRAFTING, the act of inserting a shoot or scion taken from one tree, into the stem or some other part of another, in such a manner as to unite and constitute a perfect plant of the same kind as that from which the branch was taken.

It is by this practice that particular sorts of curious fruit-trees of different kinds are capable of being raised with a certainty of their being the same, or not degenerating. It has been observed, that though the plants raised from seed are liable to run from their kinds, and afford such fruits as are not worth the trouble of cultivation; those procured from shoots taken from such trees as produce good fruit, never alter from their kind, whatever the stock or tree on which they are grafted may be; as notwithstanding the grafts receive their nourishment from the stocks, their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken: the only alteration which they undergo is, that when the stocks on which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they do not make so great a progress as they otherwise would do, nor is the fruit they produce so fair, or sometimes so well flavoured, or so large.

This process has the advantage, probably from the supply of nutritious matter being not only more abundant but more regular, of rendering the plants or trees which are thus raised more quick in their arriving at the state of maturity, or that of bearing.

It is on these different accounts that the practice of grafting is principally had recourse to, in raising different sorts of fruit trees, as well as some particular sorts of ornamental plants of the tree and flower kinds. It also affords the means of growing different kinds of fruits and flowers of the same sort, in the same stock or tree, as several varieties of pears and apples, &c.

There are different methods of performing this operation, and which are distinguished by different terms or names, as below.

Rind, Shoulder, or Crown Grafting.—This is that mode in which the grafts are set in a sort of circle or crown, upon the top of the cut-off stem or branch.

It is chiefly practised on large trees, when either the head or the large branches are cut off horizontally, and two or more shoots or scions put in, according to the size of the branch or stem: in performing which, the scions are cut flat on one side, with a shoulder to rest upon the crown of the stock; then the rind of the stock is raised up, to admit them between the wood and the bark of the stock, which must be inserted about two inches, so as that the shoulders may meet, and closely join the crown of the stock; and after the whole of the shoots or scions are inserted, all the crown of the stock should be well clayed over, leaving two eyes of them uncovered with it, which will be sufficient for shooting. It is a method of grafting that was much more in practice formerly than at present, owing to the bad success with which it has been attended; for, as the scions are placed between the rind of the stock and the wood, they are frequently blown out by strong winds after they have

made large shoots, sometimes after five or six years growth. Where this method is practised, there should therefore always be some stakes fixed, so as to support the scions until they have almost covered the stock or branch. It is usual to perform the operation in this mode of grafting about the beginning of April, or sometimes a little later.

Stock, Cleft, or Slit-Grafting.—This is a mode which is practised upon stocks, trees, or branches, of a smaller size, as from one to two inches in diameter, and may be used with success where the rind of the stock is not too thick, by which the inner bark of the scion will be prevented from joining to that of the stock. In performing it the head of the stock or branch must be cut off with a slope, and a slit be made the contrary way, in the top of the slope, deep enough to receive the scion, which should be cut sloping like a wedge, so as to fit the slit made in the stock; care being taken to leave that side of the wedge which is to be placed outward, much thicker than the other: and in putting the scion into the slit of the stock, great care must be taken to join the rind of the scion exactly to that of the stock; for if these do not unite perfectly, the grafts will not succeed: when this method of grafting is used to stocks that are not strong, it will be proper to make a ligature of bafs, to prevent the slit of the stock from opening: after which the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the scion above the clay for shooting. It is usually performed about the beginning of March, or sometimes a little later.

Whip, or Tongue-Grafting.—This is most generally practised by nursery-men, especially for small stocks, or branches of an inch, half an inch, or less, as the scions much sooner cover the stocks in this method, than in the other. It is performed by cutting off the heads of the stocks sloping; then making a notch in the slope towards the upper part downwards, a little more than half an inch deep, to receive the scion, which must be cut with the slope upward, and a slit made in this slope like a tongue, which tongue must be inserted into the slit made in the slope of the stock, and the scion be placed on one side of the stock, so as that the two rinds of the scion and stock may be equal, and join together exactly; after which, there should be a ligature of bafs put round to fasten the scion, so as that it may not be easily displaced, the whole being afterwards clayed over as in the former methods. It may be performed in the early spring months, with most success.

There are, besides these, some other modes of performing the business.

Grafting by Approach, or Inarch-Grafting.—This is sometimes called ablation. It is performed where the stocks that are designed to be grafted, and the trees from which the graft is to be taken, stand so near together, as that their branches may be bent and united. It is most commonly practised on tender exotic plants, and some other sorts which do not succeed in any of the other methods. In performing the work, a part of the stock or branch is slit off about two inches in length, a smooth part of the stock being always chosen for the purpose; then a small notch is made in this slit downward, in the same manner as directed for whip-grafting; the branch of the tree designed to be inarched having a part slit off in the same manner as the stock, and a slit made upward in it, so as to leave a tongue, which tongue should be inserted into the slit of the stock, joining their rinds equally, that they may unite well together; after which a ligature of bafs should be made, so as to keep them exactly in their situation, and afterwards this part of the stock clayed over well to keep out the air. In this method of grafting, the scion is not separated from the tree until

GRAFTING.

Until it is firmly united with the stock, nor is the head of the stock or branch, which is grafted, cut off till the same time, and only half the wood pared off with a slope, about three inches in length, and the same of the scion or graft. But in this method of grafting, the operation is not performed so early in the season as the others; it being done in the month of April, when the sap is flowing, at which time the scion and stock will join together, and unite much sooner than at any other season or period of the year. It is principally employed in raising jasmimes, oranges, and other exotic trees of the harder kinds.

By experience it has been found, that the walnut, fig, and mulberry will take by this method of grafting, while neither of them succeed in any of the other modes. Several sorts of evergreens may likewise be propagated by this method of grafting; but all the trees that are grafted in this way are weaker, and never grow to the size of those which are grafted in the other methods; therefore it is rarely practiced, except on such sorts of trees as will not take by the other methods of performing the operation.

Root-Grafting.—This, which is a late improved mode, is performed by cutting the clean smooth roots of the stocks in pieces of five or six inches long, and as large, or a little larger, than the graft; then they are whip-grafted, and tied together very close, so as to prevent the wet from affecting the wounded parts, planting them so deep as that the graft, which should be four or five inches long, may be about half buried. In this way, the grafts themselves will root, and a nearer similitude be preserved to the tree, whence the grafts are taken; and after two or three years, the stock may be cut quite away, and the graft left to maintain itself. In practicing this method, the grafts should be an inch or two longer than the others.

Season of Grafting.—The period or season for grafting should always be regulated by the state of the weather. From the climate being so uncertain in the spring, it is best to defer it till the circulation of the sap is brisk, and the buds of the stocks begin to break into leaves, attention being had that the weak shoots of tender trees will not admit of being so long cut as the more hardy, and that the operation should never be performed while it actually freezes or rains, or there is snow upon the ground.

Proper Grafts.—In providing these, care should be taken that they are shoots of the former year, as when they are older they never succeed well; that they be always taken from healthy fruitful trees, as when the trees are sickly from whence they are taken, the grafts often partake so much of the distemper, as not to get the better of it, at least for some years; that they be not taken from young luxuriant trees, whose vessels are generally large, continuing to produce luxuriant shoots, and seldom proving fruitful; and that they be taken from the lateral or horizontal shoots, rather than the perpendicular ones. They should be cut off from the trees before their buds begin to swell, which is mostly three weeks or a month before the season for grafting; consequently when they are cut off, they should be laid in the ground, with the cut part downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood be cut off with the scion, it will preserve it the better, and when they are grafted, this may be cut off; for, at the same time, the scions must be cut to a proper length before they are inserted in the stocks; but, till then, the shoots should remain of their full length, as they were taken from the tree, which will better preserve them from shriveling: when the scions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in

moist, which will preserve them fresh for a month or longer; but these should be cut off from the trees earlier than those which are to be grafted near the place where the trees are growing. It is, however, always the best practice to cut the grafts as near the time of their being inserted into the stocks as possible, as by that means they succeed with much more certainty.

Stocks proper for Grafting upon.—The stocks are the trees or plants for grafting upon; which are either such old trees, as are already growing where they are to remain, but the fruit of which is intended to be changed; or such young trees as have been raised in the nursery as a supply to the garden. In the former case, there is no other choice than that of the branches, which should be such as are young, healthy, well-situated, and have a smooth bark. Where these trees are growing against walls or espaliers, it will be proper to graft six, eight, or ten branches, according to the size of the tree, by which they will be much sooner furnished with branches again, than when a less number of shoots or scions are put in; but in standard trees, four, or at most six scions will be sufficient for the purpose.

In choosing young stocks for grafting upon, such as have been raised from the seed, and that have been once or twice transplanted, should always be fixed upon for the purpose.

After these, those stocks which have been raised from cuttings or layers should constantly be preferred; but those which are suckers from the roots of other trees should be rejected, as they are never so well rooted as the others, and constantly put out a great number of suckers from the roots, by which the borders and walks of the garden will be always pestered during the summer season. These, besides being unprofitably, take off part of the nourishment from the other trees and plants.

And where these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened and more compact than those which have grown close, and have been drawn up to a greater height. The wood of these will be soft, and their vessels large; so that the scions grafted into them will shoot very strong; but they will be less disposed to produce fruit than the others; and when trees acquire a bad habit at first, it is difficult to reclaim them afterwards. The stocks most adapted to each sort will be explained under their particular genera, and in considering the nature of stocks. See STOCKS.

Implements proper for the Work.—These are principally a neat small hand-saw, for cutting off the heads of large stocks; a good strong knife, with a thick back, to make clefts in the stocks; with a sharp pen-knife, or budding-knife, to cut the grafts with; and a grafting chisel and small mallet. Other sorts of implements are sometimes necessary in performing particular sorts of grafting.

But besides these tools, other sorts of materials are wanted in performing the business, such as bass-strings, or woollen yarn, to tie the grafts with; and a quantity of good tough clay, which should be prepared a month before it is wanted, and kept turned and mixed, like mortar, every other day, in the following manner:

A quantity of strong good clay, in proportion to the quantity of trees intended to be grafted, should be provided, and some new well-fed horse-dung broken in among it; and if a little straw or hay be mixed amongst it, it will hold together the better. The addition of a quantity of salt will also prevent the clay from dividing in dry weather. These should be stirred and mixed together, putting water to them occasionally, in the manner of making mortar. The whole should be hollowed like a dish, filled with water, and kept

every

every other day stirred. It should be carefully kept from being exposed to frost or drying winds; and the oftener it is wrought over the better it will become.

Some have lately made use of another sort of composition for grafting, which has been found to answer the intention of keeping out the air better than the clayey mixture. It is composed of turpentine, bees'-wax, and rosin melted together; which, when of a proper consistence, is put on the stock round the graft, in the same manner as the clay is usually applied; and though it be not above a quarter of an inch thick, it keeps out the air more effectually than the clay; and, as cold hardens it, there is no danger of its being hurt by frost, which is very apt to cause the clay to crack, and fall off; and, when the heat of the summer comes on, it melts and falls off without any trouble. In the using it, a tin or copper pot is necessary, with a convenience under it to keep a very gentle fire with small coal; otherwise the cold soon condenses the mixture. It is necessary not to apply it too hot, lest the graft be injured. A person a little accustomed to this composition, applies it very fast; and it is much easier for him to work with than clay, especially when the season proves cold.

In the business of grafting it is found, that in long-continued dry seasons the grafts are liable to fail in taking, which is sometimes probably owing to the improper choice of the grafts, as well as to the dry weather. Great care should of course always be taken not to graft with weak shoots, particularly those taken from near the top, but such as are taken from the lower end of the shoots, and in which the wood is plump and fresh: such as are shrivelled seldom or ever take well. When any have missed in the spring, it has been advised to cut off, about the middle or latter end of June, some fine, healthy grafts of the sorts that are wished to graft with, and to open the bark in the same manner as for budding, inserting the graft with a piece of the former year's wood on it, and after this has been done, to rub in with a brush some of the composition of Mr. Forsyth in a liquid state; then to warp bafs round it, as is done for spring grafting, leaving about three eyes in the shoot, which should be tied on with the bafs as light as possible; then covering the outside of the bafs, thus tied up, with the composition to the thickness of about one-eighth of an inch, as well as the end of the shoot, to exclude the air and wet. In about three weeks or a month, the grafts should be looked over, to see if they have taken. When the graft begins to swell, it will throw off the composition; in which case always remember to apply more to prevent the air from penetrating the incision or wound that has been formed.

About the month of September it should be examined whether the wounds are all healed up, and the two barks perfectly united; which, if they are, slacken the bafs; and when they are perfectly healed up, it may be wholly taken off; but if not, the bafs must be again tied on, and covered with a composition as before, letting it remain till the following spring. It may then be taken off; and if it be found that the two barks have separated during the winter, with the point of a sharp knife, all the brown part of the bark (which, if left, would infallibly bring on the canker) should be cut out, and the composition rubbed into the wound. When the grafts have produced strong leading shoots, the tops of them should be pinched off with the finger and thumb; but if they have not shot strong, they should not be cut till the spring, when they may be cut down to three or four eyes, according to their strength, to make them produce horizontal shoots, and form handsome leads. This sort of grafting should always be performed in moist or cloudy weather, if possible, as under such circumstances the operation mostly succeeds better.

It has been remarked by Mr. Forsyth, that rubbing a little of his composition into the incision will effectually prevent the canker, and in applying it round the graft, a much less quantity is sufficient than of the clay; as it need not be more than three inches round in grafting small stems or shoots, and in proportion for those which are larger. It keeps the scion moist. When used in grafting, it should be of such a consistence as to work easily with the hand, or a knife, or small trowel, rather softer than grafting-clay generally is. This method, on a fair trial, will, he thinks, be found "a sure, neat, and expeditious way of grafting."

In grafting, or budding, they should be performed as near to the upper side of a bud as possible, and the most proper place for inserting the scions or buds is at the joints, a little above the cross shoot.

And in respect to the sorts of trees that will succeed upon one another, it may be observed that all such as are of the same genus, that is, which agree in their flower and fruit, take upon each other; hence all the nut-bearing trees may be safely grafted on each other, as well as all the plum-bearing trees, as the several sorts of plums, almond, peach, nectarine, apricot, &c.; but as many of them are subject to admit gum from the parts wounded, as the peach and nectarine kinds, it is found the surest method to bud or inoculate them.

All such trees as bear cones also do well upon each other, though they may differ in one being evergreen, and the other shedding its leaves in winter; as in the cedar of Libanus, and the larch-tree, which are found to succeed upon each other; but they must be grafted by approach, as they abound with a great quantity of resin, which is apt to evaporate from the graft, when separated from the tree before it is joined with the stock; whereby they are often destroyed. The laurel likewise on the cherry, or the cherry on the laurel. All the mast-bearing trees are also found to take upon each other, and those which have a tender soft wood do well if grafted in the common way; but such as are of a firm texture, and are slow growers, must be grafted by approach.

It is likewise by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; as by being grafted upon stocks of the same kind which are hardy, the grafts are rendered more capable of enduring the cold, and the general effects of the atmosphere.

GRAFTING Wax. See WAX.

GRAFTING Tool, in *Engineering*, signifies a kind of spade, made very strong and curving, used in digging canals, often called only a *tool*; see fig. 50. CANALS, Plate VII.

GRAFTON, in *Geography*, a town of America, in Windham county, Vermont, chartered by the name of Tomlinson, but assuming its new name in 1791. It contains 1149 inhabitants, and lies W. of Rockingham, adjoining.

GRAFTON County, a county of New Hampshire, bounded N. by Canada, S. by the counties of Strafford, Hillsborough, and Cheshire, W. by the state of Virginia, and E. by the district of Maine. It is divided into 50 townships, and 17 locations, and contains 23,093 inhabitants.

GRAFTON, a post-town in the county above-mentioned, 13 miles S.E. of Dartmouth college, and 19 S.W. of Plymouth. It was incorporated in 1778, and contains 682 inhabitants. Lapis specularis, of the best quality, is found in this town; it lies in a mountain about 20 miles E. of Dartmouth college, adhering to the rocks of white or yellow quartz, and lying in laminae, like sheets of paper.

GRAFTON, the *Hoffanamisco* of the Indians, a township in Worcester county, Massachusetts, containing 985 inhabitants; 40 miles S.W. of Boston.

GRAFTON, *Cape*, a cape on the coast of New Holland,

fo called by Cook in 1770. S. lat. 16° 57'. W. long. 214° 6'.

GRAFTON *Island*, the most northerly of the Bashee islands, in the East Indian sea. N. lat. 21° 8'. E. long 118° 14'.

GRAGNANO, a town of Naples, in Principato Citra; 11 miles W.S.W. of Salerno.

GRAHAM'S ISLAND, one of the Aladin islands, in the Mergui Archipelago, about 6 miles in circumference. N. lat. 9° 19'.

GRAIG, or GRAIGNAMANNA, a post-town of Ireland, in the county of Kilkenny. Here is a good bridge over the Barrow, and the tide flows up. It is 58 miles S. by W. from Dublin.

GRAIN, JOHN BAPTIST LE, in *Biography*, was born, in 1565, at Paris, where he was educated with great care, and in early youth he was introduced to court, and attached himself to the service of Henry IV. He was appointed by that prince to the office of counsellor, and master of requests in ordinary to the queen, Mary de Medicis. His employment was in writing, and in attending on the education of his children. On their account he drew up Memoirs relative to the history of France, which remained in MS. till the chancellor de Sillery persuaded him to publish a part of them. His first publication, which he printed in his own house, was entitled, "Decade contenant l'Histoire de Henri le Grand, Roi de France et Navarre, IV. du Nom." fol. 1614, in ten books. It comprizes the period from the peace in 1559, to the king's death in 1610. He published a second decade, including the history of that king's reign, in 1618. The former decade was presented to the young king Lewis XIII. who was highly delighted with the freedom displayed by the author, and it was at his desire that the other was made public. Le Grain, though fortunate in pleasing his sovereign, made himself many enemies by the honesty and candour which he displayed in the narration. Attempts were made to procure a censure upon it from the Sorbonne, but they were unsuccessful, that body declaring that they found nothing in it deserving of censure. The real grounds of the objections to it were that the author had supported the liberties of the Gallican church; that he had censured attempts to introduce into France those articles of the council of Trent, which had been rejected; — that he disapproved the establishment of new religious orders, and was not favourable to the persecution of heretics. For these sentiments, which ought to have endeared him to his countrymen, he was continually harassed by bigots, till at length an order was procured from the king for the suppression of all the copies of his work, which remained in his hands. The treatment which he experienced disgusted him with the court, and he went into retirement on his estate of Montgeron, where he died in 1642. He left in MS. a manifesto relating to all the proceedings respecting his book, which is said to display in glowing colours the discouragements attending honest historians under an absolute monarchy. He left likewise the third decade of his history, and some chronological pieces in MS. Moreri.

GRAIN, GRANUM, primarily denotes a fruit, or seed, growing in a spica, or ear.

In this sense, grain comprehends all sorts of corn; as wheat, rye, barley, oats, &c.

GRAIN, *Structure of*. There are three particulars observable in every grain, whether it be wheat, barley, oat, or whatever else of that kind. These are, 1. The outer coat or pellicle, which contains all the rest. This in the same species of grain is found to be very different in thickness in different ears, and as it has grown in different soils.

2 The germ or bud; this is always hid within the seed or grain, and is the plant in miniature that is to arise from it. (See BUD and GERM.) And, 3. The meal, or that farinaceous matter which is inclosed in the skin, and which surrounds the germ, and serves to give it nourishment when first put into the earth, before it is capable of drawing it from the earth itself. Dr. Grew, in his *Anatomy of Plants*, has treated of this at large. See FERTILIZATION of Plants, GERMINATION, VEGETATION, &c.

The whole structure of the plant which produces these seeds is equally admirable. The chaffy husk is admirably adapted to shield and defend the seed as long as that is necessary, and then to let it fall; and the stalk, formed hollow and round, is necessarily at once light and strong, capable of sustaining the ear, without absorbing too much of the juices destined to its nourishment; and the beards of many kinds are a defence against the birds, that would otherwise destroy the seed before its ripening. The covering of the seed is formed of two membranes, which meeting in a line on one part of the seed, form together that furrow we see on it. This is the place at which the seed is to burst open on being moistened. Had not nature provided this means of the germ's coming out, the toughness necessary to the coat of the seed, as a defence from injuries, would have suffered the farinaceous matter and the germ to rot together, within it, before it would have given them way to come out, and for the germ to grow.

Nor is this the only use of this place of opening. The great Creator of all things has provided these seeds, not only for a supply of the same species of plant, but for our food, and for that of birds, &c. We have art enough to erect machines for the reducing of the farina to powder, and the freeing of it from its covering membrane; but the birds eat it as it is, and it would pass through them whole, and without doing them any good, were it not that the juices of the stomach swelling it up, it bursts open at this furrow, and all the nutritive matter pours itself out. De Lande's, *Trait. Phys.* p. 62. See FARINA, FECULA, FLOUR, BREAD, &c.

For the laws relating to the importation and exportation of several sorts of grain, as wheat, barley, oats, &c. See CORN.

The cleaning and preserving of grain in a proper sweet condition have long been objects of considerable importance, but it is probable that the latter cannot be effected for any great length of time.

Different methods of managing grain, after being threshed out, are practised by farmers; some keeping a large proportion of it in the chaff on the barn floors, while others, after having it cleaned, put it into sacks, and place them in the same situation, or in some room appropriated to the purpose, until they can be sent to the market. But each of these methods is liable to much objection; as when it remains for any length of time on low damp floors, it must obviously soon become musty, however much precaution is taken to prevent it, whether it be in sacks, or in a loose state without being cleaned.

There is another practice sometimes employed in the more northern parts of Scotland, according to the author of "Modern Agriculture;" which is, that of twisting straw into large bands, or ropes, and coiling them up in the manner of the cables of ships, placing the grain, when threshed and cleaned, within the coils, in a sort of well, as it were. But as the grain in this way rests on the ground or floor, and, of course, is liable to imbibe damp, it is not less objectionable than the others, while it is much more troublesome, and more exposed to loss.

It has been advised, in order to preserve grain in a proper state after threshing it out, to have it as expeditiously as possible cleaned from the chaff, when the air is in a dry state, and put into a room, chest, or bin, which is perfectly dry and free from any sort of moisture, until it can be properly placed in the granary, or be sent away for sale. This should always be effected as early as possible, as, by delaying the cleaning of the corn, the sample is very liable to be injured.

The cleaning of the grain is performed in several different ways; but where threshing-machines are in use, they are now mostly contrived in such a way as to execute it at the same time the threshing is going on. The winnowing-machine is also frequently employed for the same purpose, and answers perfectly well. And in some situations the *casting-shovel* and *spry*, or flat broom, as well as the *scuttle*, are made use of, the broom serving to remove the chaffy parts and the more minute strawy particles which are separated from the grain by the wind. This method can, however, only be employed with advantage where there is plenty of barn-room; under other circumstances the winnowing-machine is far more beneficial and proper. The practice of cleaning grain on the barn-floor, by means of the wind, is not only tedious and troublesome, but an extremely imperfect method.

In whatever way the extraneous matters have been removed from grain, it should, as soon as the operation has been performed, especially in barley and wheat, be put through a screen-machine, which, in most of the more improved threshing and winnowing-machines, is provided with this intention, and is thereby rendered free from all sorts of small seeds and other foreign matters. In this way the ova of different sorts of insects are also removed, and the production of the weevil, moth, beetle, &c. prevented, as well as the destruction which they commit while in their vermicular state, guarded against.

Screen machines may be had separately from the others; but the work of cleaning the grain is the most readily, cheaply, and conveniently performed, where they are connected with the other necessary machinery.

It has been suggested, that as the prevention of all sorts of corn from being affected by the different causes that have a tendency to injure it, when laid up for the purpose of keeping, depends upon its being put by in a perfectly dry condition, and on its being afterwards preserved in that situation; it is of much consequence, in these views, to keep it, from the period of its being threshed out of the straw, as much as possible from coming in contact with the earth, stone, or any other sorts of floors that are placed near to, or upon the ground, as they have constantly a great disposition to communicate moisture, and in that way injure the grain that rests upon them.

It is likewise found to be a highly beneficial practice to prevent, as much as possible, the entrance of the atmospheric air, whenever it is much loaded with humidity; as from the vast extent of surface that is exposed to its action, it is easy to perceive that it must be highly prejudicial to the corn, by imparting its moisture to it, as a sort of mucus, or mouldiness, is thereby brought on, that is attended with a musty disagreeable smell, and that prevents its keeping in a proper manner. In regard to the means of prevention, they must be different in different cases; but much may be done in the first of the above situations, by cautiously avoiding the too general practices of permitting the corn to remain upon the threshing-floors in the barns, particularly where they are of the earthy or stoney kinds, too long after it is threshed out, before it is cleaned from the chaff, and other useless

matters: or, after it has been cleaned, by preventing its being deposited upon them, either in the loose state, or in sacks. And farther, by having great regard to the dryness of the air when the business is performed.

In instances of the latter kind much is capable of being accomplished by having proper apparatus, such as slides, shutters, and other suitable contrivances, fixed in the pipes, funnels, and other openings, designed for the purpose of ventilation in the corn-chambers and granaries; which should be preserved, constantly shut in a close manner at all times when the air is much impregnated with watery particles, so as to prove hurtful to the grain. Damp and frosty weather are, of course, always improper for exposing grain to the air in, as it must, in such seasons, do great mischief. But, besides air, light is essential in the preservation of grain in these circumstances, as, where it is not admitted pretty freely, a kind of vegetable mucus, or mould, as already noticed, is liable to fix upon the grain, and injure it greatly. The ingenious author of the "Philosophy of Gardening and Agriculture," has remarked, that this possesses the same property as that of other funguses, of growing where there is scarcely any change of air, and in places where there is little or no light, provided there be the necessary degree of warmth and moisture. On the same principle, with the intention of retaining the grain in a state as free as possible from dampness, it is suggested by the same writer, that it might be useful to have well constructed stoves in the bottom parts of corn-chambers and granaries, for the purpose of occasionally communicating such moderate degrees of heat to the grain as would be sufficient to dry up and expel any injurious moisture that it might have attracted in damp wet seasons. On this idea it has, indeed, long ago been recommended as supported by experience by Mr. Tull, to preserve wheat, by exposing it to the action of a sun-shine degree of heat upon a hair-cloth, in a malt-kiln, produced by the combustion of clean straw, for such a length of time as may be necessary to remove the dampness, as from four or five to ten or twelve hours, according to the proportion in which it may exist. But in this method the heat should be constantly kept so moderate as not to destroy the vegetative property, or life of the grain, as, if that were the case, its putrefaction and decay would be promoted. The degrees of heat that would be the most adapted to answer the purpose, in different cases, would be easily regulated by those instruments which are in general use for measuring the heat and moisture of the atmosphere. These principles assist us much in reconciling the differences of opinion that have so long prevailed in respect to the use of air in the preservation of corn in granaries, as they sufficiently show, that when admitted in its perfectly dry and elastic state, it must be particularly useful in carrying off any moisture or disagreeable smell that the grain may have contracted by remaining closely heaped together for some length of time; as, by the stirring that mostly accompanies the ventilation, it must necessarily operate in a very extensive manner; but that when applied in its moist heavy state, it must be detrimental in an equally proportionate degree, by imparting its humidity to the grain, and thereby causing a sort of mustiness.

It is probable that the ventilation of grain is the most completely effected by stirring it by means of proper slides, doors, or other similar contrivances made in the floors, windows, and other openings of the granaries or corn-chambers; but it is capable of being accomplished in a more slow and less economical manner by shovels, rakes, and other similar tools. And in order that the work may be more readily and more effectually performed, the grain should not be

spread out too thickly over the floors of the granaries and corn-rooms. From one to two feet, or two feet and a half in depth, is considered fully sufficient for the purpose, in proportion as it becomes more dry and the moisture more dissipated. When grain is heaped together to too great a thickness at first, from the natural moisture which it contains, it is frequently apt to heat, and thereby greatly injure the sample. Frequent screening should likewise be had recourse to immediately after its being deposited in the corn-rooms, and occasionally at other times as circumstances may demand.

Other points have been suggested by Doctor Darwin, as necessary to be attended to in this business, in order to perform it in the most effectual manner; such as those of having the doors, windows, and other principal apertures of the buildings placed in such a manner as to face the south, and as close to the ceiling as possible, so that the rays of the sun may enter with the greatest freedom. And in addition, the linings of all such corn-rooms should constantly be formed of such materials, as have no tendency from their coldness to precipitate the moisture from the atmosphere, which is frequently the case with particular substances, when warm, damp, south-west winds take place after cold or east ones, and in that way impart it to the grain that comes in contact with them. It is also equally necessary in all such cases that the entrance of wet and moisture should be prevented in an effectual manner, by having recourse to proper sheltering boards, slides, and other contrivances of the same kind.

There is likewise a particular sort of management necessary in the turning over and stirring of grain in order to its complete ventilation, as when the corn is first placed in the rooms it stands in need of much more frequent turning over than afterwards, when it has parted with a considerable proportion of its moisture and is become somewhat dry. For the first month or six weeks, once or twice in every week or ten days may be sufficient to answer the purpose; but afterwards for four or five months longer, about once in the fortnight may commonly be sufficient, and from that period only once in the month, except when the season proves very moist, warm, and of course improper for keeping the grain well.

In order to accomplish this business different methods are in use; it is the custom in some places to have empty spaces left on the sides of the heaps of grain and other parts into which they may be turned over when necessary; while in others, square holes are formed in the ends of the floors, and round ones in the middle, by which means the grain is thrown from the upper to the lower chambers, and back again, and of course becomes agitated and exposed to the air in a more perfect manner. This is a method that is practised with success in some parts of the county of Kent. As, however, in these modes such frequent turnings are not only extremely troublesome, but expensive, in consequence, especially in the first case, of being performed by the shovel, the plan of having sliding shutters in the middle of the different floors so contrived, as to have an inclination towards the centre of the granaries, has been had recourse to; by the occasional removal of which, and the opening of the windows and ventilators, the grain is turned and exposed to the influence of the air at the same time with great ease, convenience, and dispatch.

This mode of preserving grain was long ago found by Monsieur du Hamel to answer perfectly well, even in cases where it had been laid up in a moist, damp, and improper state.

There can be no doubt, however, but that grain may be preserved without having recourse to the means of ventilation, by depositing it, when in a perfectly dry state, in deep wells, pits, and caverns that are free from any sort of damp and moisture, and so far below the surface of the ground that it cannot be affected by the heat or the changes that take place in the seasons. But though grain has been known to have been preserved in this manner for a great length of time in those countries where it is the practice to have it stored up for times of scarcity, it is by no means either a very safe or convenient method.

It must be observed, however, that in whatever manner grain is secured, it is essentially necessary that care should be taken that such portions as are in a soft damp state, or which have been badly harvested, should not, on any account, be laid up with that which is in a dry condition and perfectly sound; as from the quantity of moisture that is contained in it, and the tendency to germination that takes place in consequence of it, a musty bad smell is liable to be imparted to the whole, and the sample either totally or in a great degree destroyed.

The practice of exposing grain to the free action of the atmospheric air, has been discarded by some in consequence of the ova or eggs of insects being liable in that way to be deposited among the grain, but it would seem more probable, when the economy of such insects is well considered, that their ova were either deposited originally among the grain in such situations, or brought in with different parcels of it from different places. On this account it is evident that great caution should be used in furnishing fresh parcels of grain for being laid up, and that the screen should be constantly employed before putting it into the rooms.

It is, however, pretty certain that where grain is to be preserved for much length of time, though it may without doubt be safely kept in the ways that have been already mentioned; yet it is most probably not only a much better, but more certain and economical method to let it remain unthreshed from the ear in the stacks in which it has been built, particularly where they rest upon saddles that are properly constructed for the purpose.

It may be proper to observe, that where grain is to be long preserved after being threshed out, there should always be proper buildings of the granary kind provided for its reception, the sizes of which should be proportioned to the extent of the farm, being constantly adequate to contain about one-half of the grain-produce after it has been threshed out and cleaned.

In cases where the grain is ground and preserved afterwards in the state of meal, it is the usual and by far the best mode to pack it very closely by means of treading or ramming it into dry, close, small rooms, or large chests, as, in this way, when laid up in a proper condition, it will keep for a very great length of time quite safe and free from mischief.

But, notwithstanding the custom of preserving grain in stacks and granaries, from the convenience of it, may, in some instances, be beneficial, not only to the farmer, but the public, and, consequently, in some measure necessary, it is clear from the trials that have been already made, that the storing of grain in either way should be carried to as small an extent as possible, as it has been ascertained that there is a constant decrease taking place in its weight from the period at which it has been harvested or laid up, but that this loss is far greater at first, than after it has been kept some time.

In the second volume of the new edition of *Georgic*

GRAIN.

Essays, published by Doctor Hunter, the loss is stated by Mr. Holt to be in the following proportions in different sorts of grain :

In Wheat.

	lb. oz. drs.
On being rubbed out in the hot-sun, and weighed the 31st of August, 1789, soon after being cut, afforded	0 2 11
On being weighed again on the 18th of October	0 2 7
Loss of weight, <i>per</i> bushel, of 70lbs. nearly	6 8 3
Or almost one-tenth of the whole in forty days.	
Of this wheat, thirty-two grains weighed one penny-weight.	

It is, however, remarked, that this is the greatest possible loss that the grain can sustain, as though it was in a full state of maturity or ripeness, it had neither had the benefit of being dried by exposure to the sun after being cut, nor undergone the process of fermentation after it was put together.

In Wheat.

	lb. oz. drs.
Another quantity, weighed on the 22d of October, produced	0 6 3
Weighed again 24 days afterwards, afforded	0 6 0
Loss in that time <i>per</i> bushel, at the rate of	2 11 15
A further quantity, weighed on the 8th of January, 1790, produced	0 2 2
Loss <i>per</i> bushel, on being weighed again 32 days afterwards, at the rate of	2 0 15

In Barley.

On being weighed on the 2d of September, under similar circumstances, produced	0 2 2
On being weighed again on October the 18th, afforded	0 1 12
Loss of weight <i>per</i> bushel of 60 lbs. Or about one-seventh of the whole in 47 days.	8 4 22
Twenty-four grains of this barley were found to weigh one penny-weight two grains.	

In Oats.

With this sort of grain no experiment appears to have been made by the writer, but there can be no doubt but that the loss must be equally great as in any of the other sorts.

The results of these trials render it sufficiently evident, that the more expeditiously grain is brought to the market, the less is the loss which is sustained by the cultivator. Of course it should never be laid up or kept in any other way longer than circumstances render it necessary. But in addition to the loss that has been seen to occur from the gradual diminution in the weight of the grain in consequence of the dissipation of the more moist particles which it contains, there are others that arise occasionally from the ravages of different kinds of vermin, and the effects of damps, mildew, and several other causes.

In regard to the preservation of grain from the depredations of insects, and other similar animals, it may probably be the best accomplished by a timely and frequent use of the screen, with proper ventilation, as has been noticed above. Where the injury is produced by the weevil, the moth, or the beetle, it has always ceased at the period when these vermin appear, as they are, when in this state of existence, merely propagators of their several respective kinds of vermiculi, which, while they continued in that state or form, produced the injury.

In their ultimate or insect state they eat or consume very little, their business being principally that of depositing their ova or eggs, which they do by a sort of unerring instinct, in situations where the large collections of grain are sure to furnish food for their successors during the period in which they are in the vermicular state. It is consequently a matter of great moment to prevent the generation of them, by the destruction of the eggs before they are hatched, which is usually the best performed by having recourse to the screen, and exposure to a free air, as has been already shewn. The frequent stirring of the grain breaks the cohesion of their ova, by which the nidus of such minute vermiculi is destroyed, as on hatching they collect together, and spin or weave numerous nests of a cob-web-like substance for their own security and protection. And a great number of grains are attached together by them to these nests, by an infinity of small threads, both for their safety and food. Consequently, when their habitations are broken and separated by the use of the screen, they fall through its small interstices, and are capable of being easily removed with the dust and other refuse matters: and such as escape the early screenings are destroyed by those that follow, and the grain of course little injured by the operation, being only rendered more clean and free from impurities. See *HARVESTING of Grain, REAPING of Grain, and STACKING of Grain.*

GRAIN is also applied to the fruits or seeds of divers plants, as a grain of millet, of pepper, &c.

GRAIN is also extended to a minute body, or parcel of a body pulverized. In which sense we say, a grain of sand, a grain of salt, a grain of gunpowder, &c.

GRAIN denotes also a small weight, used in estimating divers substances.

The grain is the smallest of all weights known in England. It is taken from the weight of a grain of wheat, gathered out of the middle of the ear, and well dried. By stat. 12 Henry VII. cap. 7. every sterling or penny-weight was to weigh thirty-two such grains; but now twenty-four grains make a penny-weight, and twenty penny-weights an ounce. See *PENNY and WEIGHT.*

The grain is troy weight, and used in the weighing of gold, silver, jewels, bread, and liquors.

Among the ancients, the grain was the fourth part of the siliqua, or twelfth of the obolus, and the twenty-second of the drachma. It coincided with lens.

Fernelius, lib. iv. cap. 6. Method. Medend. affirms it as a thing known and certain, that the grain is of the same weight every where: but he is mistaken. Mr. Greaves, in his treatise of the Denarius, in his Miscell. Works, vol. i. p. 276. has shewn, that 179 Dutch grains, which Snellius had found to be the weight of a Philip of gold, only amount to 134½ English grains. Add, that Mons. Perrault has computed the French grain to be less than the English, and yet bigger than the Dutch; to the English, it is as 158 to 134½; and to that of Holland, as 158 to 179. See *WEIGHT.*

The grain used by the apothecaries is the same with that of

of the goldsmiths; though they make a difference in the weights raised from it. Thus, 20 grains, with them, make a scruple, 9; 3 scruples, a drachm, 3; 8 drachms, an ounce, 3, &c.

The carat used in estimating the fineness of gold, as well as in weighing diamonds and precious stones, is also divided into four grains; and the carat is about the one hundredth and fiftieth part of an ounce troy, according to Mr. Jeffreys, in his treatise on Diamonds and Pearls.

Hence, the jewellers' grain is to the troy grain, inversely, as 600 is to 480, that is, directly as four to five.

GRAIN, in English troy and apothecaries weight, is the 480th part of a troy pound = 20 mites = 480 droits = 9600 perits = 230400 blacks, of the assayills, = .820386 French grains = .06475 grammes of the new weights of France = .000142857 pounds avoirdupoise.

GRAIN, a weight in France, = 1.21893 English troy grains = .00017413 English pounds avoirdupoise = .0531217 grammes of the new weights.

GRAIN is also used for the figure or representation of grains on stones, fluffs, leathers, &c. Thus we say, morocco has a bolder and richer, that is, a larger grain, than shagreen.

In some marbles, the grain is very fine; in others coarser. Steel is known by its grain, which is much finer than that of iron.

GRAIN, in *Mining*, is applied by quarry-men and masons to the minute figures in most blocks of stone, by which they are disposed to split most easily in some certain direction, than in any other, as wood is disposed to split in the direction of its grain. Beat, sheet, lamella, and stratula, are other terms of almost similar import. Experienced masons can generally discover the grain of the most homogeneous or perfect free-stone blocks, or such as will cut with equal ease in any direction, and this they often do, by observing the directions of the very minute plates of mica, or silver, as they call it, which are frequently found arranged, in the stone, in the direction of the grain, or beat of the stone; which, it must be observed, is not always that of the beds or stratification, many rocks having stratula which cross their beds obliquely, often at an angle, of from 30° to 45° with the bed or plane of the stratum; and such stratula, not uncommonly, dispose the stone to split into flags or paviers or even tile-stones, or slates for houses, and into the most thin and perfect lamina. Sometimes these oblique stratula cross stone beds of very great thickness, and have been frequently mistaken, by inattentive observers, for the stratification itself, as Mr. Kirwan observes of the argillites or slates, p. 283 of his "Geological Essays." See STRATULA and STRATA.

GRAIN, *Cochineal*. See COCHINEAL.

GRAIN, *Scarlet*. See SCARLET.

GRAIN, *Oily*, in *Botany*. See MYAGRUM.

GRAIN, *Lin*. See STREAMING and PIN.

GRAINS, in the *Materia Medica*, or the seeds of vegetables, are distinguished into emulsive, which yield a considerable quantity of mucilage and oil, which may be separately extracted from them; such are almonds, and the seeds of almost all fruits; and farinaceous, which are entirely composed of a dry substance, easily reducible into a fine powder, called meal. Of this kind are the grains of all graminous and leguminous plants.

GRAINS, in *Rural Economy*, a term applied to the remains of different substances of the grain kind after they have been employed in the brewing of beer, or the distillation of spirituous liquors. They are in much use by the farmers and cow-keepers near large towns for the feeding of various de-

scriptions of domestic animals, such as milch cows, hogs, fowls, geese, ducks, &c. as well as sometimes for the fattening of neat cattle. In this last intention, it is however necessary to mix other substances with them, such as good pollard, coarse ground oatmeal, &c. It must be observed, that these matters can only be made use of while they are in a fresh state with advantage. It is of course necessary, particularly during the more hot summer months, to employ such means as are proper for preventing their running into a state of fermentation, which would render them wholly useless. This is usually effected by having them well pressed and trodden down into large vats and cisterns formed deeply in the ground, and covered from the action of the air. In this way they may be kept perfectly sweet and fit for use for a considerable length of time. See COW-KEEPING and STALL FEEDING.

GRAINS of *Paradise*. See MEDEA.

GRAIN-Coast, *Malaguetta*, or *Pepper-Coast*, in *Geography*, a country of Guinea, extending about 300 miles along the coast of the Atlantic from the vicinity of Cape Palmas to that of the river Mesurada, but its limits are not precisely ascertained; and bounded by the country of the Foulahs, or the Sierra Leona country on the west, and the Ivory Coast on the south-east. It derives its name from the great quantity of Guinea pepper which it produces. The climate is insalubrious, and is found to be particularly noxious to Europeans. The productions of this country are pease, beans, gourds, lemons, oranges, bananas, and a kind of nut with a thick shell, which is a most delicious fruit. The palm-wine and dates are in high perfection; cows, hogs, sheep, and goats, are very plentiful; but this country derives its chief wealth from the abundance of Guinea pepper, or grains of Paradise, called Malaguetta by the Portuguese, which it produces. It supplies also a considerable quantity of pimento. Its commerce has also very much consisted in ivory and slaves. The natives are reckoned temperate and abstemious; but they are said to allow Europeans every kind of familiarity with their females, and to invite them to love-banquets with their own wives and daughters. They are actuated in common with other negroes, by an invincible propensity to steal, not only from strangers and foreigners, but from the nearest of their own kindred. Their language is peculiar to themselves, and difficult of attainment. Their trade is carried on by signs and tokens, some of which are not very decent. The natives are, in general, well-formed, and handsome in their persons and features. Their common dress is a "paan," or unshaped piece of cloth round the waist. They are extremely subject to hernias and ruptures. They have among them some excellent mechanics, some of whom understand and practise the art of tempering steel, making arms, and all steel instruments, and constructing canoes; others have introduced improvements in husbandry, particularly with respect to the method of cultivating rice, millet, and Guinea pepper. Their king, called "taba," "taba scyle," or "taba scil," exercises despotic authority over his subjects, and never appears abroad without the utmost pomp and magnificence; and he receives from the people a degree of veneration and awe, which belongs to superior beings. They are said to be believers in a future state, which appears by the ceremonies performed to the souls of the deceased, and the prayers they offer for a happy meeting in another world. They welcome the new moon with songs, dancing, and every kind of diversion; and their superstitious regard for forerunners is extreme.

The sole employment of many of the negroes, especially about the river Sestos, is fishing, which they perform in their canoes, by a hand-line and hook. The artists of Sestos are

are also peculiarly expert in their manufacture of iron and metals.

The Portuguese possessed for many years an independent and uncontrouled connection with this country; but in the year 1664 the English and Dutch, perceiving the advantages which were derived from their commerce, interfered, and their rivals prevailed to such a degree as to drive the Portuguese settlers into the interior parts of the country, where they united themselves with the natives; and from this intercourse sprung that mixed progeny of Mulattoes, who are more numerous here than in any part of Guinea. The small remnant of trade now possessed by the Portuguese is entrusted with these persons, to whom they give the appellation of the *hidalgos* or gentlemen, having profelyted them to their forms of Christian faith and practice, and initiated some of them into holy orders, whom they employ in propagating their notions of Christianity.

The months most favourable to trade on this coast are February, March, and April; small vessels, which are capable of sailing up the rivers into the country, are more convenient than large ships; and it should be recollected, that the S.S.E. winds begin to blow in the month of May, and they bring with them heavy rains and tornadoes, with terrible thunder and lightning, extremely dangerous to shipping.

GRAINE, an island in the mouth of the river Thames, about $3\frac{1}{2}$ miles long, and $2\frac{1}{2}$ broad, separated from the coast of Kent by a narrow channel, called the "Stray," or "Yenlade." It is low, flat, and marshy, and has upon it only a number of detached huts, with some salt works. N. lat. $51^{\circ} 27'$. E. long. $0^{\circ} 42'$.

GRAINED MEDALS. See MEDAL.

Cross GRAINED Stuff. See CROSS GRAINED.

GRAINGER, JAMES, in *Biography*, a physician and poet, was born at Dunfermline, a small town in the south of Scotland, about the year 1723. After finishing his school education, he was sent to Edinburgh, where he commenced his medical studies under professors who were highly celebrated through the medical world, and in due time he received his degree of M. D. He commenced his professional career as surgeon in the army, and in that capacity he served in Germany, under the earl of Stair, till the peace of Aix-la-Chapelle, in 1748. He afterwards settled in London, and practised as a physician. He here obtained and cultivated the friendship of several distinguished literary men, particularly of Shenstone and Dr. Percy, afterwards bishop of Dromore. While in London he published his translation of the elegies of Tibullus; but this work did not receive the approbation to which he thought it entitled, especially from Dr. Smollet, whose criticisms were the occasion of a long paper-war between them, and produced an irreconcilable difference. Probably his success in practice in London was not great, as he embraced an offer of settling advantageously in the island of St. Christopher, in the West Indies; where, by marriage, he became connected with several of the principal families, and practised his profession with great success. He continued, however, to cultivate his attachment to the muses, and wrote, during his leisure hours, an interesting poem "On the Culture of the Sugar Cane." He likewise composed a treatise "On the Diseases of the West Indies," for the use of the planters. At the conclusion of the war, he paid a visit to his native country, and at the same time published his poem, with copious notes relative to the natural history of the island. He afterward returned to St. Christopher's, and continued to practise till the beginning of the year 1767, when he was seized with a fever, which then raged in the island, and

died. Dr. Grainger was benevolent in his disposition, engaging in his manners, and an able physician: he ranks also considerably above mediocrity as a poet. An "Ode to Solitude," and "A West Indian Ballad," (the latter published in Dr. Percy's collection) have been much admired. He published several medical tracts. Hutchinson, *Biog. Med.*

GRAINGER, in *Geography*, a county of America, in the district of Hamilton, Tennessee, formed of parts of the counties of Knox, Jefferson, and Hawkins, and bounded N. by Virginia and Kentucky. Its chief town is Rutledge. It is very mountainous, interspersed with fertile valleys. It contains 7367 inhabitants, of whom 496 are slaves.

GRAINING, in *Ichthyology*, the name of a fish found in the Mersey, near Warrington; it resembles the dace, but is more slender, and has a straighter back. See DACE.

GRAINING Board is a board used by the curriers, to give the grain to their leather.

It is made with teeth, or notches, running quite across; into which the soft, moistened, suppled leather being pressed, its surface readily takes the impression. See CURRYING.

GRAINVILLE, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton, in the district of Les Andelys. The place contains 393, and the canton 10,846 inhabitants, on a territory of 185 kilometres, in 32 communes.

GRACLE, in *Ornithology*. See GRACULA and PARADISEA.

GRALLÆ, the fourth order of birds, comprising those which have the bill cylindrical, and a little obtuse; tongue entire and fleshy; and the legs naked above the knees.

GRALLATORIÆ. See CLASSIFICATION.

GRAMAT, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton, in the district of Gourdon; 22 miles N.N.E. of Cahors. N. lat. $44^{\circ} 47'$. E. long. $1^{\circ} 49'$. The place contains 1842, and the canton 9888 inhabitants, on a territory of 275 kilometres, in nine communes.

GRAMAYE, JOHN BAPTIST, in *Biography*, a writer of history, was a native of Antwerp, and flourished in the early part of the 17th century. He studied at Louvain, and became professor of rhetoric in that university. He was afterwards historiographer to the Low Countries, and obtained some other offices of trust and honour. He travelled through the greater parts of Germany and Italy, and proceeding from the latter country to Spain, he was made captive by an Algerine corsair and carried to Africa. How he obtained his release does not appear, but his writings prove that he had been an attentive observer of that country. Upon his return to his native land, he travelled into Moravia and Silesia, and in the latter province he was, by cardinal Dietrichstein, placed at the head of a college. He died at Lubec in 1635, leaving behind him many works, which shew that he was unquestionably a man of great learning. He wrote in prose and also in verse. Of the former are "Africa Illustrata, lib. x." 4to. 1622: "Diarium Algeriense;" "Peregrinatio Belgica;" "Antiquitates Flandriae;" and "Historia Namurencis." The first of this list of works contains a history of Africa from the remotest periods to his own times, with geographical details; and the second is the result of local observation during his captivity. Moreri.

GRAMEN, in *Botany*. See GRAMINA.

GRAMEN Murorum, *ſſicalorgiſſima*. See FESTUCA.

GRAMINA, Grasses, a most natural order of plants, the fourth of Linnæus, and the fourth order of the second class in the Genera Plantarum of Jusſieu, who chooses to alter

alter the appellation of it to *Graminea*. The Latin word *gramen* is supposed to be derived from *gradiens*, going or proceeding along, in allusion to the great increase of many of these plants by their creeping roots.

Jussieu's second class consists of monocotyledonous plants with a superior germen. His definition of the present order is as follows.

Calyx, (which he terms *glume*;) single or many-flowered, enclosing, in the latter instance, two or more flowers, disposed in two ranks in a little spike or ear; it is mostly of two valves, rarely of one or of many, or altogether wanting. Each flower has a *corolla*, (called *calyx* by Jussieu,) resembling the before-mentioned calyx, mostly of two valves, rarely of only one, or altogether wanting; the outer valve either beardless or awned. *Stamens* below the germen, of a definite number, except in the *Pariana* of Aublet, generally three, rarely two, or six, or one; their anthers oblong, forked at each end. *Germen* one, superior, accompanied at the base by two little scales, not always evident. *Styls* often two, with two feathery stigmas; sometimes one, with a simple or divided stigma. *Seed* in either instance solitary, naked, or often clothed with the permanent inner valve of the corolla. *Embryo* small, attached below to the side of the farinaceous and much larger *albumen*. The lobe of the embryo in germination is permanent and sessile along with the annexed albumen, attached on one side, at the bottom, to the primary sheath which surrounds the plumula, or bud of the future plant.

The *roots* are fibrous and capillary. *Stems* or *culms* cylindrical, either hollow or filled with pith, jointed or separated into distinct portions by knots, mostly simple and herbaceous. *Leaves* alternate, generally solitary at each knot of the stem, sheathing, their sheath splitting down to the knot. *Flowers* either in dense clusters, or spiked upon a common *rachis*, or paniced, concealed before they arrive at maturity in the sheath of the upper leaf. Some species are monoicous, by an abortion of some of the organs.

Botanists have differed much about the principles on which the genera of Grasses should be founded. Linnæus and Jussieu take into consideration the number of flowers, or rather florets, in each calyx; Haller in a great measure rejects this, paying regard chiefly to the figure of the parts, which indeed is of primary importance. He does not, however, sufficiently attend to other equally important marks, as the distinction, for instance, between *Poa* and *Briza*, consisting in the incorporation of the seed of the latter with the larger valve of the corolla, and its depressed figure. It were to be wished that the awns of grasses were permanent and constant in the same genus, or at least species, but though constant in some, as *Avena*, in others, as *Agrostis* and *Triticum*, they are not sufficient to discriminate species.

In the sexual system Grasses chiefly belong to *Triandria Digynia*. Some few have proper monoecious, none dioecious, flowers, and several are polygamous, having a few male blossoms intermixed with perfect ones furnished with both stamens and pistils, and were therefore referred by Linnæus to *Polygamia*. But this latter circumstance is so common and variable, and causes such unnatural separations of species or genera, that botanists have generally agreed to pay no regard to it in this family, but to class all such grasses by their perfect flowers.

Linnæus remarks that "Grasses are the most general of plants, constituting almost a sixth part of all the vegetables on our globe, especially in open situations. There they multiply, and extend themselves by creeping roots, to a vast extent. In confined and woody places they scarcely creep, but grow erect. They are the most important of plants,

especially as affording the chief sustenance of animals who feed on vegetables. They furnish the verdure of our summers, and spread a carpet over our meadows. Their leaves are not easily damaged, even by our walking over them; and though winter destroys their foliage, and the early spring finds them dry and withered, they revive in a wonderful manner from apparent death. How solicitously has the Author of Nature protected these plants, by giving them such hard stems, while they are perfecting their seed, that cattle cannot readily attack them in that state! Then, on the other hand, they are so constituted, that the more their herbage is cropped, or hardly used, the better they thrive, and extend themselves the more under ground. That they may be able to exist in almost every situation, their narrow spiny leaves are purposely contrived to insinuate themselves between other plants.

"The creeping roots of grasses are formed like a tape-worm; and are mostly fibrous, rarely tuberous or bulbous. They consist of numerous joints and knots, each of which has its bud, capable of producing a new stem, and the more they are separated by the heavy tread of cattle, the more they multiply, thus constituting the strength of the vegetable kingdom.

"Very few grasses have any peculiar taste, most of them having the insipidity of pot-herbs, though some few are fragrant, at least when dry. None are dangerous or poisonous, if we except the intoxicating seeds of *Lolium temulentum*. They are the most simply constructed of all herbs, scarcely any of them having thorns, prickles, tendrils, flings, bractæas, or other appendages. Their stems are with us generally simple; in India frequently branched. Leaves always simple and undivided, mostly quite flat, and if one side be somewhat rounded, it is never that next the stem. The sheath of their leaves is often crowned with a membranous stipula, called by some *ligula*, which closely embraces the stem in growing, to keep out water.

"The fructification of Grasses is so different from other plants that it was judged impossible to reduce them to order. They were first divided into Corn and Grasses, but the former differ from the latter merely in the greater size of their seeds, which compose the basis of our aliment, as the smallest of the grass-seeds nourish small birds. Ray first examined this tribe scientifically, dividing them by their habits or likenesses, but he traced out no just limits. Tournefort, though a most eminent botanist, was not equal to this subject. Monti followed Ray, but examined the grasses of Italy only. John Scheuchzer, at the persuasion of Sherard, undertook ample and minute descriptions of every grass he could procure, but the herbage of all is so similar, that his descriptions, till he comes to the inflorescence, are too little contrasted. They are, however, very exact. Micheli first contrived a method of arrangement founded on the spikelets being simple or compound, with an attention also to the sexual parts; but he subjoined some plants, termed *graminibus affines*, which have really no connection with them. If the sexes of grasses be attended to, their arrangement becomes less difficult. Their inflorescence is either spiked or paniced."

The principal writers on Grasses, besides those above-mentioned, are Schreber, who wrote in German, with fine plates, coloured or uncoloured, and who is very full on their qualities and uses; Rottböll, who described new or rare species, with plates; Linnæus the younger, in a thesis describing new genera of grasses; Host, who has published three folio volumes, with excellent coloured plates in the style of Jacquin, entitled *Gramina Austriaca*; Leers, who in his *Flera Herbortenensis* has delineated and engraved all the grasses

grasses of that Flora, with more exquisite precision than can be found in any similar performance. Stillingfleet, Curtis, and Swayne have in England published botanical and economical remarks on grasses, the latter giving dried specimens to illustrate them. Many species are admirably represented and described in the *Flora Londinensis*, and the second part of the first volume of the *Flora Græca* contains 50 plates of rare and curious grasses, from the drawings of Mr. Ferdinand Bauer, which are among the most beautiful and perfect of their kind.

The number of genera of grasses in Jussieu are 60, arranged in 13 sections, nine of which comprehend grasses with two styles, four those with only one. This distinction however is not one of the most absolute, even in the same genus. His subdivisions are marked by the number of stamens, or of florets, according to what we have mentioned above.

Willdenow has in his *Triandria Digynia* 34 genera, besides five in *Triandria Monogynia*, *Cinna* in *Monandria*, and *Nardus* in *Diandria*; he has moreover, in *Hexandria*, *Ehrharta*, and *Oryza*, in all 43. He has five genera in *Monoecia*, making 48 in the whole, besides the polygamous ones, which after the original plan of Linnæus, he refers to *Polygamia*. We have not yet seen this latter part of his work. In the 14th edition of Linnæus's *Systema Vegetabilium* the genera of polygamous grasses are eight, only, *Holcus*, *Cenchrus*, *Ischemum*, *Manisuris*, *Ægilops*, *Spinifex*, *Andropogon*, and *Apluda*. Willdenow places *Cenchrus* in *Triandria Monogynia*, we believe with great propriety, but the genus appears unnatural with respect to habit, and perhaps requires to be new modelled.

Mr. R. Brown, in his *Prodromus Floræ Novæ Hollandiæ & Insulæ Van-Diemen*, has defined 35 new genera of this natural order; *Sporobolus* separated from the Linnæan *Agrostis*; *Polygogon* of Desfontaines; *Pentapogon* of Billardiere; *Streptachne* very near *Stipa*; *Amphipogon* remarkable for having an awn to each of the five segments of its corolla; *Diplopogon* apparently too nearly akin to the last; *Anisopogon* very near the following; *Danthonia* of Decandolle; *Glyceria* of which we have treated in its proper place; *Triodia* very near *Poa*; *Eriachne* somewhat akin to *Aira*; *Triraphis*; *Eleusine* of Gärtner; *Chloris* of Swartz; *Cælachne* remarkable for having its imperfect flower female, not, as usual in grasses, male; *Chamaraphis* distinguished from *Panicum* chiefly by the peculiarity of three styles; *Orthopogon* formed of Linnæus's *Panicum compositum* and others; *Penisetum* of Richard; *Neurachne* resembling an *Alopecurus*; *Isachne* to which belongs the *Meneritana* of Herman's Zeyl. 24; *Xerochloa* whose seed is inclosed in the inner paper-like valve of the corolla; *Thuarea* of Thuars in Persoon's Synoptis; *Imperata* of Cyrilli, which is *Lagurus cylindricus* of Linnæus; *Dimeria* near *Saccharum*; *Ophiurus*; *Lepturus*; and *Hemarthria*; the three last separated from *Rottböllia*; *Microchloa* which is *Nardus indica* of Linnæus; *Zoysia* recently formed by Willdenow of his *Agrostis Matrella*; *Hierochloa* of Gmelin Sibir. which is *Dicerrenum* of Billardiere; *Tetrarrhena* composed of the *Ehrharta distichophylla* of Billardiere with other species; *Microlena* his *E. stipoides*; *Potamoiphila* a water grass near *Oryza* and *Zizania*; and finally *Leptaspis* which has the aspect of *Pharus latifolius*.—It is not wonderful that a country whose natural productions are all so very anomalous with respect to those of the rest of the world, should afford so many novelties, even in so natural and well-known a family as the grasses.

GRAMINEA, in *Antiquity*, is applied to a crown formed of grass, *gramen*, bestowed by the Romans on certain of their generals, in consideration of their having saved or rescued an army.

The grassy crown, *corona graminea*, was but rarely conferred, and for some signal exploit; when, through the courage or dexterity of a general, an army reduced to the last extremities had been saved, or delivered, and the enemy put to flight.

GRAMINEOUS HERBS, among *Botanists*, are such as have a long, narrow leaf, with no foot-stalk.

GRAMINIFOLIA, a name given by Dillenius to a genus of plants, called by Micheli and Linnæus *zannichellia*.

GRAMMAR, teaches the right use of language, or to speak, to read, and to write a language with propriety. Particular grammar teaches the principles peculiar to any one language. Thus the English grammar ascertains and teaches the principles which exclusively belong to, and which distinguish the English tongue. The French grammar professes the same end with regard to the French; and this is the case with the grammar of any other language.

When grammar is limited to any particular language, it is employed in its humblest province, and may be considered only as a mere *mechanical art*, the rules of which are little investigated, and have no other foundation than the practice of those who speak and write that language. But when grammar, rising above the consideration of any one language, compares many languages together, and by this comparison traces the principles which are common to them, unfolding by that means the nature and origin of speech, the causes by which it is divided into distinct dialects, and the analogies which facilitated the growth and determined the idioms of each: grammar, in this extensive view, assumes the nature of a *science*, and is justly distinguished by the name of *general* or *universal grammar*.

That grammar claims the dignity of a science, in consequence of investigating the general principles of speech, is evident from the slightest consideration. All languages, however different, have many properties in common. They have in general the same parts of speech, because the ideas or things which they express exist with little or no variation in the nature of things. Men also, in all ages and countries, have the same organs of speech, which are similar in structure, however modified by peculiarities of enunciation. Finally, the same great law of association regulates the mind of every man; and the political, moral, and religious institutions, which direct the operations of this law, however remote in age and country, considerably resemble each other. To these causes it is owing, that the languages of all nations, ancient and modern, are marked by a similitude truly surprising; and the more closely they are examined, the more numerous will appear the points in which they all resemble each other. Hence may be justified the conclusion, that as all the tribes of men originated in one family, so all the languages of men are but ramifications of one original tongue.

Grammar has usually been divided into four departments, namely; *orthography*, *etymology*, *syntax*, and *prosody*. Orthography teaches to form and to sound letters, to analyse or combine syllables, or to express words by their proper letters. Etymology comprehends the classification, the properties, or, more properly speaking, the derivation and composition of words. Syntax prescribes the government or the right order of words in a sentence; while prosody directs the just pronunciation, the poetical construction of words, or supplies the laws of versification. But this distribution of the parts of grammar is neither useful nor accurate, as they are not independent of each other. Etymology is a principle necessary to account for phenomena in every department, and is that upon which orthography is chiefly founded. We therefore discard these divisions of grammar, and distribute and confine our observations on this subject

to the origin, nature, classification, and the properties of words.

The Origin, Nature, and Classification of Words.

Words have been defined articulate or significant sounds, formed by the organs of speech, and used by common consent as signs of ideas. The propriety of this definition will appear, if we attend to the mode in which words acquire their signification. The best method to teach a language, with which a youth is yet entirely unacquainted, would, if attended to, clearly unfold the nature and origin of speech in general. Suppose a *book* is held out before him for the first time, an *impression, phantasm, or idea* of that object is thus conveyed to his mind by the organ of sight. While this impression continues, suppose farther that the *sound* book is distinctly uttered; he will then have an impression or idea of the sound conveyed through the sense of hearing, which will be rendered more distinct, if he himself be taught to enunciate it. The two ideas, namely, that of the *object*, and that of the *sound* will then, if long continued, or often repeated, coalesce in his mind, and become so illogically connected, that the idea of the object shall suggest that of the sound, book: and, on the other hand, the sound shall recal the object. The principle on which this coalition is founded, is a law of the human mind, known under the name *association of ideas*; and the progress of the learner in connecting other ideas with other sounds, is only a repetition of the operation, till the whole language is acquired.

From this brief description, naturally follow a few inferences of importance, to be observed on this subject. *First*, sounds, though so closely connected by frequent use with the things signified, as not to be separated from them even in imagination, have no natural affinity with them. Any other sound than *book, moon* for instance, might have been associated with that object in the mind of a learner, and this last name would as naturally, by use, be applied to book, as we now apply it to the object so known in the sky. And this is the reason why the same idea is expressed by different sounds in different countries, where each sound is rendered equally natural and familiar by repeated associations. *Secondly*, as language altogether depends on an arbitrary compact between sound and sense, there exist not, in any regular polished tongue, such words as *natural* articulate sounds. There are, indeed, in all languages, certain sounds indicating desire or aversion, pleasure or pain, but these are natural cries, and not articulate sounds; and they arise more from the structure of man as an animal, than from his rank as an intelligent being, capable of forming distinct ideas, and expressing them by articulate sounds. Hence such sounds are common to him with inferior animals, and abound most among men in the savage state, where language is least formed. The above explanation farther excludes what have been called *factitious* words, or words whose sound bears some resemblance to the sense. Some words indeed, of this kind, are supposed to exist in all languages; but the supposition, we venture to affirm, is erroneous, the imagined similarity being altogether the effect of association. This principle, when a word is heard, instantly suggests its meaning, and while we overlook the suggestion, we ascribe the sense to a fancied similitude between it and the sound. Let an idea be in your mind, when you hear a *cock crow*, or a *bell toll*, and you will immediately suppose, that the sound of the cock, or of the bell, conveyed the entertained idea. This is a delusion precisely similar to that into which we fall respecting the import of factitious words. If there be any word in our language, or in any language naturally indicative of the sense, it is

cuckoo; and yet ask a foreigner, altogether unacquainted with English, what the term means, and he will not by any means be able, from the sound, to ascertain the object denoted. The word is a repetition of *coo coo*, which exists in Greek under the form of *κοο*, and which in Persian signifies the sound made by a strong emission of the breath. Hence the Persians express the *ox-kind* by *caa*, which we have borrowed and confined to the female *cow*, which originally meant a *lowing* animal. In Chaldee, *cuckoo* means a *magpie*, the sound of whose voice is very different from that of the cuckoo. We cannot help remarking, that if a similitude between sound and sense obtained in any part of language, it would appear more manifest and predominant in the most ancient languages, and especially in Hebrew, which we conceive by far the most ancient, even of the Asiatic tongues. But we venture to affirm, that not a single instance of the kind can be produced in that tongue. And this early specimen of human language is a fair presumption, that the principle of factitious sounds did not in the least obtain in the first formation of speech.

From the above explanation we infer, in the *third* place, that the names of things, at first, were names of *individual* objects, and that man learnt in youth, to form *general* ideas, *solely by means of language*. Thus with respect to the above-mentioned youth, when he has connected the sound book with the thing so called, the word is only a sign of the individual book which was first presented to him. Presently, however, he perceives the same sound applied successively to other objects of the same kind; and this application leads, and in a manner *compels* him to note those peculiar circumstances which distinguish each book, and those, on the other hand, which belong to that whole class of objects. As the sound is not repeatedly associated with the former, he *forgets*, and consequently *overlooks* them; while he combines the ideas belonging to the class, and retains them in a closer and yet closer union, under the term which was his instrument in forming those ideas. In this manner are all our *abstract ideas* acquired; and language, as the mind rises by means of it, from the contemplation of one to many objects, from individuals to classes, is the sole instrument in acquiring them. Some indistinct idea of this process was probably the circumstance which led our celebrated grammarian, Mr. H. Tooke, to say, (vol. i. p. 36.) "That the composition of ideas was merely a contrivance of language; that the only composition was in the *terms*, and that they are not ideas, but merely terms which are general and abstract." In another place, he denies the operations of the mind as influencing speech, and talks of the operation of language. These, and such other remarks are, however, so palpably erroneous, that we cannot ascribe it to ignorance or inattention in so enlightened a critic, but suppose them to have proceeded chiefly from a desire which pervades his works, of rejecting the ideas of others as unjust, because they were *known*, and conspicuously displaying his own as right, because they were *new*. The composition of terms in grammar, is merely the derivation or combination of terms, by such laws as custom or analogy have previously determined. Composition of this kind, with which a grammarian, as such, has any thing to do, is as distinct from the composition of ideas, as sound is from sense, or grammar is from logic. Language has no power but what it has derived from *association*; and he who speaks of the operation of language, instead of the operation of the mind, acts the absurd part of a man who ascribes to the pen, the motion of the hand which directs it. If we can judge from his works, Mr. Tooke appears not to have studied the true theory of the human

mind; and from the want of just ideas on this subject, he has, as we shall shew in the sequel, plunged himself and his readers in deep and manifold errors.

As general or abstract ideas, which are the chief materials of science, are formed solely by the instrumentality of language, we may hence see the reason why the study of language ought to form the *basis* in every system of education; and why science can flourish only among a people previously acquainted with the arts of eloquence and composition. The philosophy of grammar, moreover, as it retraces the track of the human mind, in the formation of its ideas, through the medium of speech, is the best guide to the knowledge of its powers and operations, and consequently to their proper direction. Hence the only systems of metaphysics and logic, worthy the attention of a philosophical enquirer, are those which are built on the foundation of grammatical analysis.

But further, as words in the very commencement of every man's education denote individual objects, and become signs of classes or kinds by the successive application of each word to many individuals of that class, we might conclude that in the original language of mankind, if solely the effect of human invention, each term at first was but a proper name of a thing or of a quality, and afterwards represented a greater number of individuals as the mind advanced in the principle of generalization. But this inference is contrary to the fact. The Hebrew tongue carries us back almost to the infancy of human society, and, whether it be the original language of mankind or not, it presents us with much fairer specimens of what language must have been, than we can gather from any modern dialect. The primitive words of that language are founded upon the most comprehensive analogies; and the learner, in acquiring that tongue, instead of being carried up from the individual to the species, and from the species to the genus, finds himself on the top of the most extensive class; and in the formation of words he is made to descend from general to specific terms, and from specific terms to proper names; so that all the proper names which we meet with in the Hebrew records are really derived from general appellations. This phenomenon appears to us completely to annihilate the supposition, that language is solely the fruit of human ingenuity. Moses, in his history, obliquely states, and, with his usual brevity, accounts for the fact: "And out of the ground the Lord God formed every beast of the field, and every fowl of the air, and brought them to see what he would call them: and whatsoever Adam called every living creature, that was the name thereof." The Arabic translation, we apprehend, alone places this verse in its proper light, by rendering *to see*, to cause *to see*, *i. e. to shew*. The author then intimates that God shewed or directed Adam in the application of names to things. And what can be more probable, than that *He*, who formed the organs of man, should at first instruct man in the proper use of them.

Lastly, it follows from the above explanation, that words, as they are at first associated with ideas, are in strict propriety signs of *ideas*, and not signs of *things*. For unless the idea be previously in the mind, there can be no union by association of sense with sound. The association takes place in the mind, and where the idea of the thing, and that of the sound do not meet, there can be no formation of articulate sound. The learner, however, is not sensible of any distinction between his ideas and the external objects which are their origin or prototypes; and he refers the sound immediately to its prototype, without being conscious that an impression or idea of it exists in his mind. As, however, we know nothing of things but through the medium of our ideas, and as ideas must depend for their properties and distinction upon the

things they represent, the above oversight is not productive of any error or inconvenience; and we may say that words are signs of things, or of the ideas of things, without any prejudice to philological accuracy. This leads us to the classification of speech, or its division into parts.

The common distribution in our own tongue is into *nouns, articles, adjectives, pronouns, verbs, participles, adverbs, prepositions, conjunctions, and interjections*. This division has obtained with little variation in other modern languages, and has been derived, on the authority of ancient grammarians, from the languages of Greece and Rome. The above classification, however general and convenient in a popular view, is by no means to be admitted in a philosophical grammar. And the few writers of this kind in English, or other tongues, have been sensible of the inaccuracy of the popular division. The Oriental grammarians admit only *three parts* of speech, the verb, the noun, and particles derived from these. Plato, whose notion of language as a science must have been formed in Egypt, mentions only two, the noun and the verb; tom. i. p. 261. Edit. Ser. And Aristotle mentions no more, where he treats of propositions. (De Inter. c. 2.) But Mr. Harris, Herm. p. 38. thinks that those philosophers were not ignorant of the other parts of speech, but spoke with reference to logic or dialectics, considering the essence of speech as contained in these two, because they alone combined to make a perfect assertive sentence, which none of the rest without them are able to effect. But Aristotle, in his treatise of Poetry, where he was to lay down the elements of a more variegated speech, adds the *article* and *conjunction* to the noun and verb. The latter Stoics, improving on the authority of Aristotle, instead of *four parts*, made *five*, by dividing the noun into the *appellative* and *proper*. Others increased the number, by detaching the *pronoun* from the noun; the *participle* and *adverb* from the verb; and the *preposition* from the conjunction. The Latin grammarians went farther, and detached the interjection from the adverb, within which by the Greeks it was always included as a species.

Mr. Harris, following Aristotle and the elder Stoics, divides speech into words that are significant as *principals*, and those which are significant as *accessories*, including under the former class *substantives* and *attributives*, and under the latter *definitives* and *connectives*. This distribution is set aside and ridiculed by Mr. Tooke, who says, vol. i. p. 47; "In English, and in all languages, there are only two sorts of words, which are necessary for the communication of our thoughts, and they are noun and verb. And as to the parts of speech, they may be either *two* or *twenty*, or more. In the strict sense of the term, both the necessary words and the abbreviations are all of them parts of speech; because they are all useful in language, and each has a different manner of signification. But I think it of great consequence, both to knowledge and to languages, to keep the words employed for the different purposes of speech as distinct as possible. And therefore I am inclined to allow that rank only to *necessary* words: and to include all the others, which are not necessary to speech, but merely *substitutes* of the first sort, under the title of *abbreviations*." In this boasted division, as we shall presently see, there is neither utility nor accuracy, and the author was betrayed to it by a secret wish to place the novelty of his own system in the most conspicuous light, namely, that conjunctions and prepositions are but abbreviations of nouns and verbs.

Now it is singular, that the division which we think the most philosophical, and, therefore, the most simple and useful, is that which is thus proffered in a very laboured

treatise on grammar, in the *Encyclopædia Britannica*, (article 11.) "The division of words into those which are *significant of themselves*, and those which are *significant by relation*, is absolute nonsense, and has been productive of much error and mystery in some of the most celebrated treatises on grammar. It is indeed probable, that any attempt to establish a different classification of the parts of speech, from that which is commonly received, will be found of little utility, either in *practice* or in *speculation*. As far as the *former* is concerned, the vulgar division seems sufficiently commodious; for every man who knows any thing, knows when he uses a noun, and when a verb. With respect to the *latter*, not to mention that all the grammarians, from Aristotle to Horne Tooke, have differed on the subject; it should seem to be of more importance, after having ascertained, with precision, the nature of each species of words, to determine in what circumstances they differ than in what they agree."

If these remarks be just, any attempt at a philosophical arrangement of the parts of language must be frivolous and useless. But we regard the paragraph as a manifest acknowledgment that the writer knew of no such arrangement, and that, as is often the case, he endeavours to console himself and his readers, under the absence of this knowledge, with the consideration that if attained it would not be useful. We shall, however, attempt briefly to do what he thinks unnecessary to be done: but what we think not only useful and necessary, but even essential, in a philosophical treatise. An accurate distribution of our words, is but an accurate distribution of our ideas; and as in logic we cannot think justly, unless we know how to distinguish our thoughts; so we cannot with precision reason in grammar, unless we have previously distinguished the parts of speech. The source of this distinction must be sought in the nature of the ideas expressed by those parts, and the enquiry, how many sorts of words there exist in human language, is merely, when directed to its proper object, how many sorts of ideas there are in human knowledge.

We have then ideas of *things*: we have ideas of the *properties* or *attributes* of things: we have ideas of the *connection* of things, *i. e.* of the arrangement of things, or of their increase or diminution: finally, we have ideas of the *relation* of things. Nor have we an idea which may not rank with one of these classes. And as language consists of terms expressing ideas, it consists of terms which express either ideas of *things* or the *attributes* of things, or the *connection* of things, or the *relation* of things. The terms expressing things are *nouns*, including substantives and the personal pronouns, which are only *substitutes* for nouns, and therefore, in their nature, names of things. *Sweet* is an attribute of sugar, and so is *to think* an attribute of a man; *to fly* of a bird; *to be* of a being that exists, and so, moreover, *loving*, *hating*, are attributes of some creatures susceptible of love and hatred; finally, the circumstances which define things or distinguish them from others, may be considered as attributes or properties of the things so defined. The terms expressing attributes may be called *attributives*; and include adjectives, verbs, adverbs, participles, and definitives. The terms expressing the relations of things are prepositions; while those which express the connection of things are conjunctions. And thus the most comprehensive, and, as we conceive, the most philosophical division of speech is into four parts, *nouns*, *attributives*, *prepositions*, and *conjunctions* or *connectives*; nor is there any language, however few or numerous its terms may be, which is not capable of being distributed into these four classes. As to the *interjection*, it must be regarded as a sound which is either inar-

ticulate, or which, as far as it partakes of articulation, partakes of the nature of a noun or of a verb. Having noted this distribution, we, as not systematically writing on grammar, shall, in our remarks, follow the popular division.

Nouns and attributives, to use Mr. Harris's language, are significant as *principals*, and we do not depart from philosophical accuracy, when we say that prepositions and connectives are significant by *relation*. Our notions of the relations and connections of things arise by the principle of abstraction from our notions of the things themselves to related or connected. If all ideas of things or actions were obliterated from our minds, the ideas of their associated relations would be entirely obliterated with them. And as our notions of relation spring from the objects so related, so language, following the rise and progress of ideas, has derived those terms which express relations and connections, from the terms expressing the things and operations so related and connected. In other words, prepositions and conjunctions are words which, by association, flowed from nouns and verbs as their real sources. If this be correct, what shall we say to Mr. H. Tooke, who affirms prepositions, conjunctions, and other particles, to be substitutes for those necessary words, the noun and verb. If this assertion be put in clear language, it means that the relations of things, or of the operations of things, are *substitutes* for the things so related; that is, the relation of *cause* and *effect* is a substitute for cause and effect; the relation of *beginning* is a substitute for things which begin; the relation of *instrumentality* is a substitute for that which is instrumental; and the relation of *end* is a substitute for that which ends. Moreover, the separation or concatenation of two or more assertions is a substitute for the operations so separated or connected. This is not philosophical reasoning, calculated to throw light on language, but a sophistry calculated to confound the most distinct ideas which the human mind is capable of forming, and a jargon not to be equalled by any error or contradiction, which Mr. Tooke has so severely censured and ridiculed in Mr. Harris. Besides, terms to express the relations and connections of things are not less necessary than those which denote things and their operations. A language without conjunctions and prepositions is not merely a sledge, (to use his own words,) which cannot be drawn along as smoothly, and easily, and swiftly, as a carriage with wheels, but is a sledge which has nothing to connect it with the horse; nothing to direct it in the way along which it should be dragged. The noun and the verb indeed may express a complete proposition; but the instances in which such simple propositions occur are very few, compared with those more complicated cases where the use of prepositions and connectives is absolutely necessary. The distribution of speech into necessary words and abbreviations, is therefore, in this point of view, also frivolous and erroneous.

The Origin and Properties of Nouns.

Nouns are the names of things, or signs of those ideas by which we come to the knowledge of things. The term is a corruption of *nomen*, which is from *νομινα*, while *name* came probably from the Persian *naam*, which seems to be of the same origin with the Greek word. Nouns may be divided into three classes: names of *individuals*, names of *species* or *kinds*, names of *abstract ideas*. To this may be added, as a fourth class, the *pronoun*, which is made the substitute or representative of all other nouns. But we shall consider this in the place usually assigned to it by grammarians. On each of the above classes we beg to make a few brief remarks

Names of individuals do not enter into the composition of language; because individual objects are too numerous to have each a distinct name; and because language would then be changing in endless succession, each term dying away with the object it signified, and another rising to occupy its place. This is the reason why *proper names* cannot be translated from one tongue to another, the individuals specified by them, being confined to one time and one place, are not capable of being the prototypes of words in other times and places. Individuals, however, among men, animals, and places, which the purposes of life render it necessary to specify, have appropriate names given them to distinguish them from all other individuals. And it sometimes happens that when individuals among men become eminent for any attainment or profession, their names are used to designate others who are eminent in the same way. Thus proper names are sometimes converted into common names. The former are called proper, as being peculiar to individuals, in opposition to such names as are common to all the individuals of a class.

The perceptions of the human mind, as we have observed, commence with individual objects; but we are soon induced to compare those objects; and on comparing individuals together, we readily discern a resemblance between them in some things while they differ in others. The mind then separates the particulars in which objects differ, and collects into one idea their points of similitude. Thus it forms ideas of classes, or in logic called *species*, comprehending under them various individuals. After this the species themselves soon become subjects of comparison; and excluding from each its individual qualities, the human mind formed those more general aggregates termed *kinds*, comprehending under them different species, as the species comprehend different individuals. Thus mankind classified all the objects around them, and acquired specific and generic ideas in nature, in art, and in abstract qualities. Having, as it is supposed, first advanced in the classification of their ideas, men gave names to each class, and thus acquired those general terms which are called specific and generic terms. But we have already shewn that the process of the human mind, in the principle of abstraction, is the reverse of this: general terms do not arise, as will appear evident if we attend to the commencement of education in ourselves and others, from general ideas, but, on the contrary, general ideas arise from general terms. The former have no existence till they are generated in the mind solely by the instrumentality of language; the learner being involuntarily and passively led by the successive application of the same word to different individuals of the same class, to compare them, to separate their component parts where they differ, and to combine them where they agree. In this point of view, grammar is the foundation of logic; and language, instead of being the offspring of human invention, is the sole medium of awakening the first dawn of intelligence in the human mind, and points for its existence to some intelligence superior to man.

Specific and generic ideas being thus formed, the subject matter of language is reduced, so as to be commensurate with the limited faculties of man; because, though individual objects are infinite, the classes comprehending them are comparatively few. The subject matter of speech by this means, moreover, is rendered *permanent* and *universal*, or unconfined to points of space and time; because, though particular things are local and transient, the species and kinds of things are universal and eternal. This is the reason why words which are unintelligible in one age and country are understood in other ages and countries; and

may be translated from one tongue into another, without ambiguity or error, where the prototypes exist in common. Farther, though general terms are often indefinite and uncertain, yet whenever they express species or kinds, they may be defined by ascertaining the several ideas which constitute those species or kinds. And as the properties which constitute each class are found complete in each individual of each class, the name of the kind is applied to each of the species; and the name of the species to each individual included under it: and thus generic and specific terms are employed by the assistance of certain adjuncts hereafter to be considered, to denote individuals.

General ideas may be considered as abstract ideas, as they are generated by the mind *separating* or *abstracting* from each object those particularities which constitute individuality. But they are to be distinguished, at least in a grammatical view, from that numerous and important class of ideas which we acquire by the more simple act of separating from a thing the quality which belongs to it. Thus, the attribute *to think* becomes *thought*; and *good* is converted into *goodness*. Abstract nouns of this kind are all, without exception, derived from *verbs* and *adjectives*, and formed by the simple power of withdrawing a property from the subject which supports it, and giving it an independent existence in the imagination. Now, it is a fact worthy of attention, that as general, so abstracted, ideas are formed by the sole agency of language, and would not have existed in the slightest degree, if words had not previously been applied to express the qualities of things. For as soon as a property was marked by an appropriate word, the separate and independent existence of that word, recognized by the eye or by the ear, induced the mind, without an effort and, perhaps imperceptibly, to give the property so designated an independent existence also. Mr. Tooke rejects the principle of abstraction, and would introduce in the room of it what he calls *subaudition*. Thus, according to him, *goodness* is that which is good: *flying* is that which flies: and under this erroneous and circuitous mode of explaining abstract qualities which he has borrowed from the neuter participle in Latin, he has attempted to bury out of sight the operation of the mind in forming abstract ideas. The existence of this operation, however, is too obvious to be denied with effect, and too important, in philosophical grammar, to be abandoned on the authority of any person whose acuteness of intellect may enable him sometimes rather to perplex than to unravel truth. In conformity to his own theory, Mr. Tooke supposes such words as *science*, *diligence*, which are abstract nouns, derived from the Latin *scientia*, *diligentia*, to be neuter participles plural in *entia*, a supposition contrary to the analogy of the Latin tongue, which affords not a single instance of plural adjectives being converted into abstract nouns.

We cannot help noticing in this place an observation in the Encyclopædia Britannica, 13; "As all the objects which exist must be either in the same state in which they were produced by nature, or changed from their original state by art, or abstracted from substances by the powers of imagination, and conceived by the mind, as having at least the capacity of being characterized by qualities; this naturally suggests a division of nouns into *natural*, as *uran*, *vegetable*, *tree*, &c.; *artificial*, as *house*, *ship*, *watch*, &c.; and *abstract*, as *covitiveness*, *motion*, *temperance*, &c." This division has been borrowed from Mr. Harris, in his *Hermes*, and borrowed without consideration. Abstract ideas are the chief materials of science, which, giving birth to art, extended to the productions of art, as its genuine offspring, the use of its own terms. Accordingly, all *artificial* terms are abstract

abstract terms, or terms derived from adjectives and verbs. Thus, *stable* denotes an artificial production, and is at the same time an abstract noun from *stabilis*; and *plough* is taken from the Hebrew פלג, *phalag*, and means an instrument of separation. And even natural objects are often expressed by abstract nouns, as *creation* from the verb *create*. And if abstract nouns are extended by association to designate natural and artificial objects, they cannot with propriety be said to form a class of nouns distinct from nature and art.

Abstract nouns, expressing ideas properly so called, are very numerous in our language, and worthy of attention. They are chiefly taken from the Latin; as those in *tion* or *sion*, *ment*, *ence*, *ty*, or *tude*; as *faction*, *collusion*, *commandment*, *consequence*, *piety*, *alitude*. And all the nouns of this termination, with others in *nse* and *t*, such as *expanse*, *merit*, are also from this source. Many others are derived from the Anglo-Saxon or Gothic, such as all those in *ness*, *some*, and *hood*; as *goodness*, *noisome*, *neighbourhood*. The far greater part of Mr. Tooke's second volume is occupied in tracing nouns of this description. His etymological researches are, in many respects, useful and important; but we cannot help bearing our testimony against his work, as tending to direct the labours of philological enquirers to wrong objects, and to withdraw their attention from those sources, whence English and all other European languages, ancient and modern, have sprung. But let us hear his own words: "The bulk and foundation of the Latin language is Greek; but great part of the Latin is the language of our northern ancestors grafted upon the Greek. And to our northern language the etymologist must go, for that part of the Latin which the Greek will not furnish; and there, without any twisting or turning, or ridiculous forcing and torturing of words, he will easily and clearly find it. We want, therefore, the testimony of no historians to conclude that the founders of the Roman state and of the Latin tongue, came not from Asia, but from the north of Europe. For the language cannot lie. And from the language of every nation we may with certainty collect its origin. In the same manner, even though no history of the fact had remained; and though another Virgil, and another Dionysius, had again in verse and prose brought another Æneas from another Troy to settle modern Italy, after the destruction of the Roman government, yet, in spite of such false history, we should be able, from the modern language of the country, (which cannot possibly lie,) to conclude with certainty, that our northern ancestors had again made another successful irruption into Italy, and again grafted their own language upon the Latin, as before upon the Greek. For all the Italian which cannot be easily shewn to be Latin, can be easily shewn to be our northern language. Mr. Wakefield had, shortly before his death, agreed with me to undertake, in conjunction, a division and separation of the Latin tongue into two parts; placing together in one division all that could be clearly shewn to be of northern extraction." (Vol. ii. p. 140) In p. 299, he gives the following instances, with many others, of Latin words derived from the northern language:

Pinan,	<i>punire</i>	Suegian,	<i>suadere</i>
Pyngan,	<i>pingere</i>	Biddan,	<i>petere.</i>
Fegan,	<i>figere</i>		

According to Mr. Tooke, the words in Roman letters are plainly of northern origin, while those corresponding to them in italics are Latin verbs derived from them. The reverse of this position we can prove to be true. The Anglo-Saxon, or Gothic words, which this author dignifies as northern primitives grafted on the Latin, are no other than Latin words borrowed and corrupted by the northern barbarians when they over-ran the Roman empire. This position, if proved, will render the far greater part of Mr. Tooke's labours perfectly nugatory; and nothing more is necessary to prove it than to shew that the originals of the Latin words exist in Greek, or in one of the Oriental tongues, and exist too in such a form, as to evince that these are the primitives, and consequently that the northern words are only corruptions derived from thence. Thus the Hebrew קַח, *kaph*, is a hand; hence *capio*, to take in hand, and by softening *c* into an aspirate, as is often the case, *habeo*, to hold in the hand, *i. e.* to have. The Greek κρατος, overthrow, is the parent of the Latin *neco*, corrupted into *hæcæc*; εγω, I go, eo, *higan*; χειρα, *hendo*, *henton*, to seize; κυβητος, *volvo*, *wealopian*, to roll; φλου, *fluo*, *fleuan*, to flow; σπυ, *spu*, and שפת, *spu*, signify lips; hence *spuo*, or *sputo*, the action of the lips in throwing out of the mouth, *i. e.* *spue*, *spit*; μαλακω, to soften, *mulceo*, *milefcian*; μιλγω, *molgian*, to milk; ποινω, recompence, punishment, *punio*, *pinnan*, to punish; πονω, a tail, *pongo*, *pyngan*, to act as a tail does, *i. e.* to prick; πηγω, *figo*, *segan*, to fix; λοω, *leo*, *deleo*, to wash down, to obliterate by washing, *dilgian*; μολω, *molo*, Goth. *ma'an*, to mill; Chaldee *ארו*, *aro*, *arian*, to plow; עלו, to rise, *tollo*, *tilian*; סב, to spin, twill, *neflo*, *gniltan*, or *nigtan*; תגו, *tego*, or *tango*, *tekan*, to touch; דממו, *dummo*, *deman*; פרו, *probo*, to taste food, *profcian*, to prove; שפוט, transposing *r*, as is often the case, *rapio*, *reafian*; פטו, to desire, *peto*, to seek in consequence of desiring, *biddan*.

Though this list clearly shews that the Northern language is, in a great degree, a corruption of the Latin borrowed from the Greek, the Hebrew, and other Oriental tongues, yet Mr. Tooke gives it as exhibiting instances of the Northern dialect grafted on the Latin. The primitive language of the North could have been no other than a branch of the primeval language of men, conveyed there by the first emigrants, diversified and enriched by communications with the East on the north of Asia, by early irruptions into Greece, as is mentioned by Herodotus, and, in far later days, by amalgating with the Latin, when in the dark ages the tribes of the North invaded and dismembered the Roman empire. In this state, the Northern language became the parent of the English; and though a multitude of its words, especially monosyllabic words, are, no doubt, immediately from the Anglo-Saxon and Gothic; yet few instances, we believe, can be produced, which may not be traced, by a competent etymologist, through the medium of those corrupt changes, to their primordial purity in Italy, in Greece, and in the East, the sole origin of language and literature. But Mr. Tooke reverses this natural and necessary order; and, without the testimony of historians, without any documents of the language subsisting in the North, antecedent to that which was spoken in the middle ages, he fixes on corruptions borrowed from the Latin, and holds them up as the origins whence Latin, Greek, and English have been derived. His theory, thus far, is ridiculous and mischievous; ridiculous, because it is a palpable error, professing important discoveries; and mischievous, because, while it pretends to trace words

words to their genuine roots, stop up all the true sources of information on the subject of language. As we have passed this censure on his system, we feel ourselves called upon to justify it by more numerous instances. And we think this the more necessary, as subsequent grammarians, and the public in general, seem willing to acquiesce in his positions as incontrovertibly just.

In doing this we shall adopt the words which present themselves, without much selection, referring our readers to the page where they occur in his second volume. It was impossible to err as to the derivation of *right* from *rectum*; but *something ordered* is not the leading idea of the term, though Mr. Tooke employs many quarto pages in explaining it on this principle. The primary sense of *right* is *straight*, a relative term, denoting the means to an end. Thus, *virtue* is *right*, because it is the short or direct road to happiness. That hand is *right*, which does its work in the *shortest* way. Property is *right*, because it is the straight road to the welfare of society. In this sense we may say of God, if we say it with reverence, that it is *right* in him, because, when he has an end to answer, right means the straight way to accomplish it. "The *left-hand* is that which is *leaved*, or which we are taught to leave out of use on such occasion," p. 10. This appears to us nonsense. *Left* is the Greek *λειος*, and Latin *levus*, with *t*, the usual termination of northern words. *Lex*, Fr. *loi*, and our *law*, is from *lego*, and means something *read* or *dictated*, and not *something placed*, p. 8. The Anglo-Saxon, *leagan*, *ponere*, is but a corruption of *locare*, to place. *Iustus*, indeed, means something commanded, *justum*, from *jubeo*. But this last is the Hebrew *יָבֵן*, *gab*, and the Arabic *jaab*, to answer or assent. Hence, in Latin, *jubere legem*, to enact a law, *i. e.* to allow it to pass, and promise to obey it.

"*To cucol* is to do as the cuckow does," p. 21. Few people know how the cuckow does; but all know how a *cock* acts on such occasions. *Kokoraa* is an Eastern word, which, coming into Italy, gave birth to *cicurio*, to crow; and, changing *r* into the connate *l*, as is often the case, to *kokolaa*, which, in Celtic, is *kilog* and *kilogee*, to act as a cock does with a hen. This, we presume, is the origin of *cuckold*. *Hen-pecked* is a figure of the same nature, and from the same source. "*Alert* is *all-cresta*," p. 24. No, we presume it is *all-ert*, or *all-art*, *i. e.* all active. The word *art*, signifying skill, came to signify that diligence by which skill is attained. The opposite, which sanctions this etymology, is *inert*, not active. *A knave*, *i. e.* a man cunningly skilful, came, by the same association, from *gnavus*, diligent. "*Lash*, (French *lâche*) of a whip, *i. e.* that part of it which is *let loose*," p. 32. Rather from *λυσις*, an *osier*. The French *lâche*, or the Italian *lasciare*, is the Latin *lasare*, from *λυγος*, to bend. *To burn*, or *to burn*, gave birth to *brand*, *i. e.* a mark by burning;—*brandy*, *i. e.* spirits which burn;—*brown*, *i. e.* bread burnt;—*brunt*, brunt of the battle, *i. e.* the heat of the battle, or the place where the battle burns. The origin is *furnus*, an oven. *Odd* is not the participle *owed*, *i. e.* something owed to make up a pair, p. 38; but the Hebrew *אָבָד*, *abad*, one, single, singular, *i. e.* one that has no other to make an even number, or pair, with him. Thus we say, an *odd man*, *i. e.* a singular man. *Loud*, p. 39, is, we presume, from *κλυτος*, a voice heard. The Anglo-Saxon, derived from this word, has preserved the *x* aspirated, *blowan*. In Celtic it is *cloed*, that which is heard in praise of a man. The Latin has rejected the guttural altogether in *laudo*. The Greek poets have applied the epithet *κλυτος*; to such animals as *beast*; hence *low*: *shred*, or *sherd*, *shur*, *share*, (as plough share) p. 41, come from *κλιψα*, to clip, by prefixing *s*, a

practice very frequent in Latin; and hence the Anglo-Saxon *scyran*, to shear.

One of those broad analogies by which the Latin separated from the Greek, is to convert a guttural into a labial, as in *χλον*, *flos*, *χλωος*, *floridus*. Thus it may be, *cultus* became, as it were, *fultus*, *fult*, *field*, *i. e.* a cultivated ground, and not a *place felled*, p. 41. *Coward* is the participle of *cower*, to bend; but the parent of this verb is *corruo*, to shrink, p. 42. *Bread* is beared, *i. e.* the produce of the earth, as *bearn*, offspring, is *boren*, something horn, and not from the obsolete *bray*, to pound, which is taken from the Latin *frico* or *frango*; both of which originated in the Arabic *فَرَس*, *pharac*. *Fiend*, *foe*, is the participial termination of *فِيء*, or *فِيء*, *violence*, in which, as Socrates says, there is *cumity*; while *friend* is the same form of *frau*, a woman, (from *φειρα* *i. e.* the bearing animal,) and seems at first to mean a *female loved*. The letter *l*, being of the same organs with *n*, is often changed for it in all languages, as *λυμφα*, *lympa*; *πνευμα*, *pulmo*. On the same principle, the Hebrew *נָאֵף*, *naaph*, to marry, became *leaf*, or *love*. The Hebrew *בְּחִי*, *bhit*, and the Persian *bhod*, *self*, passing to the North, gave birth to the pronoun *hit*, or, as it is farther corrupted, *it*, which, like *id* in Latin, directs the attention to something going before, and is a substitute for it. Gothic *haitan*, Anglo-Saxon *batan*, or *gatan*, to *speak* or *command*, is, perhaps, the Greek *αὐδα*, which, in Celtic, is *gwyd*, in English *quoth*, and in Latin in the compound form of *in-quit*, p. 53.

Tight, *i. e.* tied, and the Gothic *tian*, is from *πυσσα*, to *fold up*, 67. *Twist* is *tortus* or *toftus*, and not that which is *twiced*. *Quilt* is *coiled*, (*κωλις*) *twisted*. *Draught*, *drag*, is *τραχυν*, *traho*. *Tilt* is *tilted*, lifted, from *τελλω*, *tollo*. "*Barren*, *i. e.* *barred*, closed, shut", p. 72. The verbs *φειρα*, *fero*, *bear*, *paro*, *pareo*, *pario*, with the numerous tribes of words derived from these in all languages, owe their existence to the Arabic *barron*, the *earth*, or that which produces all things: and *barren*, we presume, meant primarily an animal having produced; and thence it denoted *infecundity*, consequent on production, or, more generally, incapacity to produce. The Hebrew *שָׁר*, *ster*, denotes any thing *close*, *sharp*, or *hard*. Hence the Greek *σείρος*, *firm*, *rigid*; and our *stern*, p. 73. The same word in Arabic means a harsh or acute sound, and hence seemingly the English *stir*. The Arabic *شَر*, *seer*, which we should pronounce *steer*, denotes to flow, or to move as water does. Hence the Anglo-Saxon *stiran*, which means to cause a ship to move, which is the meaning of the hence-derived *steer*. *Stern* is that part of a ship which is thus moved. The Hebrew *גָּר*, *gur*, to *turn*, has given birth to *cburn*, turning or stirring cream being the means of obtaining butter, which in Anglo-Saxon is *gyran*, 76; to *year*, which is a revolution of time; to *yarn*, which means therefore something *turned* or *twisted*, and not prepared. *Πίλος*, *pilus*, means hair on the head; hence it signified to form hair, or to grow into a head. And this is the origin of our words *pile*, *build*. *Bold* or *bald* originated in *validus*, bodily strength naturally inspiring mental energy, 79; but *bolt*, p. 128, is *βίλος* or *βλητος*, the thing cast, 129. *Boar* is the Hebrew *בָּעַר*, *bacer*, a sturdy stupid animal; but *brawn* we think is not *baeren*, but *pork*, *porken*, *proken*, *brawn*, from *porcus*, and therefore it means the flesh of a pig, 87.

Chop, *chip*, is something cut off, from *κοπιω*. The Anglo-Saxon *plibtan*, to pledge, is from *πλησσω* or *πληγω*, to *strike*, plight being a bargain struck. *Shut* is the same in sense and found with the Arabic *شَد*, *shud*. The Anglo-Saxon *scitan* is nothing but the Hebrew *שָׁט*, *shit*, *nates*; and hence it came to signify the action of the nates in throwing away the excrements. We shall merely add the following list, and all the

words

GRAMMAR.

words in the laboured chapter on *abstraction* are, with few exceptions, capable of being traced in the same manner; and we desire our readers to compare the derivations here given with those of Mr. Tooke in the pages referred to.

Θεωλεια, to divulge or expose; *trull*, a public woman, p. 153. Τροστια, to turn, *drab*, a woman that turns about, a vagabond woman, 154: hence the Gothic *trubian*, to drive about, or turn out, 155. The Arabic *علف*, *alph*, means *food, support*, and hence *loaf*, the means of subsistence. The Anglo-Saxon has preserved the nasal aspirate *blasf*, 157. From Δοφω, a hill, came the Anglo-Saxon *blifian*, to raise to an high place; hence too *lofty, lift*, 162. רען, *rhen*, Anglo-Saxon *grenian*, virefcere, *green*. Γηρασκη, Anglo-Saxon *geregnan*, to decay. *Grey*, 167, the colour of old age. שער, *shair*, *shower*. שירה, *shire*, principality. *Shire, fire, fir*. Ruga, a wrinkle. *Rough*, Anglo-Saxon *rof*, 177. Υφω, *weave, woof*, Anglo-Saxon *wesjan*, 178. Τασσα, to arrange, *bind, command*; hence *taxo*, to weave; *tax*, tribute, i. e. *tag*, the thing fastened, 179. Τελλω, to rise; hence *tollo*, *tall*, i. e. what is raised. Τελλω signifies also to command, and thence it came to denote voice, or found in general; *tell, tale, toll*, the found of a bell. Τηλο, a tribute, *talio*, to pay, *toll*. Δουλεια, to slave, to toil, or, as it was formerly spelt, *tuell, ual*; *tool*, the medium of toil, an instrument. Hence, moreover, Anglo-Saxon *tillian*, *till*, i. e. to slave on the ground, cultivate the ground, 180. בר, *bar*, something added on the outside for the sake of defence, is the origin of *bar*: בריה, *bariech*, is *burgh, borough*, a place barred, i. e. secured, which in Greek is περιγος; a tower, and in English *park*: moreover, the bark of a tree is ברק, *birk*, or that which separates from the tree. The Arabic *borbaan*, a nobleman, is the parent of *baron*, and to this sense of the word St. Paul alludes, in Acts, xvii. "the Bereans were more noble than those of Thessalonica." פלך, *phulk*, in Arabic means a *ship*, and this, by changing *l* into *r*, gave birth to *bark* and *burge*, 182. בור, *bur*, pit or grave, *bury*. Σωρη is *store*, treasure, 185. זרם, to inundate, is the Anglo-Saxon *styrnian*, to rage as a flood, and hence *storni*, 183. א.ד.א, *dana*, in Arabic means a body of people come together; hence *town*, 201. בית, *beet*, means a *house*, a place that holds or contains; hence *bed, abode, pot*, in Greek βεβαι, in Celtic *bedh*, the last abode of man, and *pit*. *Causo*, to plead, to deliberate, gave birth to *choice*, the effect of deliberation, and to *cozen*, i. e. to deceive by pleading. The Persian *shiraub*, is vine, juice; and hence the Latin *forbeo*, and the English *syrup, shrub*, 209. ביהר, *mebur*, *morrow*, Anglo-Saxon *mergen, morn*. מצה, to heat, to dry, to evaporate by heat; hence Anglo-Saxon *drygan*, *drain*, 224. Ρηγο, a garment, *rug, rig*. Τραχων, *trabo*, Anglo-Saxon *drag, dragen, drone*, an insect that drags itself. שכל, *skal*, produced *skill*. The Anglo-Saxon *scylan*, to separate, seems to have come from σκελος, *leg*, i. e. to put the legs in action, to separate one from the other. *Scal*, to disperse, is σκυλλω, *jaſto*; while *scale*, to weigh, is שקל, *skall*, 233. Βερεα, *bercha*, is *brook*. Φανλο; *foul*, Anglo-Saxon *fylan, file, defile*. Γον, genu, *knee*. Νυο, *nutus, nod*, 254. Τηλο; *talio, sole, dote, dollar, deal*, 256. לעג, *glaw*, Anglo-Saxon *hlian* Ταρχο; *salted curds, tart*. Στεγο; a roof, Anglo-Saxon *figan*, to ascend the roof. *Sty*, a place covered for hogs. *Stage*, a place covered for actors to entertain the people. Πλω, *fluo*, by transposing *l*, is *fall, fill*. Ferveo, *fretum*, the boiling sea; hence *bruit*, noise of the boiling waves, and the Celtic *frood*, also *fret*. *Paseo*, to feed, Anglo-Saxon *byfcian*, to be occupied in feeding cattle, *busy*. די, *din, dun, dint*, 305. Κεζμα, a small piece, *crum*, Anglo-Saxon *grymman*, to prepare small pieces by fire. *Dono*,

to produce, yield, is the parent of *do*. דום, *dum, mute, dumb*. Μωρα, *mors*, Anglo-Saxon *myrran, mar*. שטר, *samad, smelitus, finite, smith, finiter*, 416. א.צ, *artz, au* Arabic *aarb, earth*, 417.

These specimens (and they are ample specimens) will be sufficient to enable us to form a just estimate of Mr. Tooke's merit as an etymologist. If the above are well founded, they shew that his labours have been greatly over-rated. His great error is, that by forced analogies, or rather contrary to all analogy, he has yoked together words as of a common origin, which have flowed from very different sources; and this error has arisen from his studied inattention to the operations of the human mind, to his entire want of acquaintance with the Oriental tongues, whence all the European dialects, ancient and modern, have been derived; and to his preposterous attempt to deduce English, Latin, and Greek, from the corruptions of Latin and Greek by a barbarous people in the dark ages. Before we quit this subject, we shall make one or two observations worthy the attention of those who trace the ramifications of modern languages from their ancient stems.

In the Oriental tongues gutturals abounded, which, like other consonants, contained in themselves the vowels necessary to their pronunciation. But it is the tendency of every guttural, when become habitual, to soften down, in the rapidity of utterance, into a mere aspirate, till it at length vanishes. Thus *cornu* has degenerated into *horn*, and *χρυσος* into *humus*, and into *homo*, a creature of earth; so in the Greek, the Oriental *khaan*, a king, became *αισασα*, to reign, which Homer pronounced *φαισασα*. This principle has obtained in the formation of many words, derived into English through the medium of the Anglo-Saxon and the Gothic. And the instances are still more numerous where the aspirate, instead of vanishing, has been converted into the labials *v, f, or y*. Thus *wicked* is the Arabic *هكرك, hegnad*; *warms*, the Persian *garm*; *all, ελε; awhole*, the Hebrew *כל, kal*; *work, εργο*, the Chaldean *ארק, aark*, *cheil, strength*; hence *weal, wealth*, the strength of a state; *wall*, the strength of a town; *beal, health*, the strength of the human body. *הרט, hart, aerie*.

An inattention to this principle has betrayed Mr. Tooke into many errors; thus he derives *field* from *felled*, that is, a piece of ground in which the wood is felled; whereas we conceive it is a corruption of *cultus*; as if *sultus, fild, field*, i. e. a cultivated piece of ground, precisely in the same way as *χολη*, became *slos*, and *χολη, sel, gall*. This substitution of the labial for a guttural or aspirate obtained in an early period of the Greek, and constitutes the origin of what is called the *digamma*. This digamma prevailed in the age of Homer, when the language was chiefly oral. But his poems, as being written, preserved the guttural or aspirate, the true original character, which being studied, caused the aspirate to prevail in time over the digamma; and thus it restored the language to its primitive purity. But the Latin, having flowed from the Greek at an early age, when the caprice of oral sounds spread uncontrolled by written letters, and having no monument of genius like the *Iliad* and *Odysssey* to correct that caprice, as was the case in Greece, adopted the digamma, and thus separated, by a broad line of distinction, from the parent tongue. We now return to the properties of nouns.

The properties of nouns are gender, number, and case. Gender, as meaning the distinction of sex, was by no means a necessary property of nouns, for the signification was sufficient to shew the sex to which it belonged. Thus, as

there-

there were but two sexes, there should have been two genders, masculine and feminine, nouns meaning males being ranked under the former class, those meaning females under the latter; while the *neuter* or neither gender comprehended the names of inanimate things, or such animals as had their sex not discernible, or not necessary to be distinguished. But unfortunately the termination of nouns became a mark of gender independent of their signification; and thus nouns were considered as masculine, feminine, or neuter, as they happened to have the endings which custom usually assigned to either of these three classes. The Hebrew tongue, in its primitive purity, appears to have been exempt from this unhappy embarrassment, and the only languages known to us which have maintained the empire of common sense against the caprice of custom are the English, the Persian, and the Bengalese. In Greek and Latin the dictates of reason have so far prevailed as to cause all those nouns, whatever be their terminations, which mean males and females, to be deemed masculine and feminine; while the names of inanimate objects only are determined by the termination. In other languages, such as the Arabic, French, and Italian, this absurdity has been carried much farther, the names of inanimate objects being said to have gender: the neuter, which is only the negative of sex, is excluded; and the learner has his memory loaded with the gender of nouns which really meant things without sex, and this without any one advantage to counterbalance so much fruitless trouble, and such glaring sacrifice of common sense.

The English language, as conforming to nature in regard to the distinctions of gender, has greatly the advantage over other tongues: when rising to the rhetorical and poetical style it addresses the fancy by personification. This figure is essential to poetry. In order to interest the imagination, the subject of discourse, when inanimate, must be invested with the forms and attributes of living beings. Now, when things are thus personified or spoken of as persons, they must be represented as *male* or *female*. May they be made either? Or is there any analogy to give one the preference over the other? Let us hear what Mr. Harris (Herm. p. 44.) says on this subject. Having observed that some nouns are of such a gender from having such a termination, he thus proceeds: "In others we may imagine a more subtle kind of reasoning, a reasoning which discerns even in things without sex a distant analogy to that great natural distinction which, according to Milton, animates the world. In this view we may conceive those substantives to have been considered as *masculine*, which were conspicuous for the attributes of imparting or communicating, or which were by nature active, strong, and efficacious, and that indiscriminately whether to good or to ill, or which had claim to eminence either laudable or otherwise. The *feminine*, on the contrary, were such as were conspicuous for the attributes either of receiving, of containing, or of producing and bringing forth; or which had more of the passive in their nature than of the active; or which were peculiarly beautiful and amiable; or which had respect to such excesses as were rather feminine than masculine." On this principle the *sun*, as imparting light, is masculine; the *moon*, as receiving it, feminine. The *sky*, or *ether*, *time*, *death*, the *ocean*, the *Supreme Being* are all masculine; while the *earth*, *ship*, *city*, *virtue*, *religion*, are feminine. And yet Mr. Tooke roundly pronounces this reasoning fallacious. "As for Mr. Harris's poetical authorities, the Muses are bitter bad judges in matters of philosophy. Besides, that Reason is an arrant despot, who, in his own dominions, admits of no authority but his own. And he is particularly unfortunate in the very outset: for his very first instances,

the *sun* and the *moon*, destroy the whole subtlety of this kind of reasoning. For Mr. Harris ought to have known that in many Asiatic languages, and in all the northern languages of this part of the globe which we inhabit, and particularly in our mother language, the Anglo-Saxon, *sun* is feminine, and *moon* is masculine," vol. i. p. 54. The author of the learned treatise on grammar in the *Encyclop. Britannica*, 17, resting no doubt on the authority of Mr. Tooke, thus pronounces on the reasoning of Mr. Harris; "Such speculations are wholly fanciful; and the principle on which they proceed are overturned by an appeal to facts. Many of the substantives that in one language have masculine names, have in others names that are feminine, which could not be the case, were this matter regulated by *reason* or *nature*."

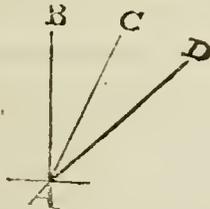

The languages from which the objection to Mr. Harris's theory is derived are *not* regulated in regard to the distinction of gender by reason or nature. And facts borrowed from them are not surely to be admitted as conclusive against a principle in a language which *is* regulated by reason and nature. Mr. Harris deduced his theory from the English, though he has applied it with perhaps more fancy than truth to some instances in the classical languages. Our own tongue, as making all things neuter which have no life, admits the operation of fancy in personifying inanimate objects; and where personification is admitted, the *analogy* to the natural distinction of the sexes must necessarily be admitted also. But, Mr. Tooke and his abettor say, it is *fanciful* because it does not obtain in other tongues. Their argument is briefly this:—The *sun*, by personification, is not made masculine in English, where the consideration of gender is founded on reason, because it is made feminine in some languages where the termination, and not reason, determines the gender. Reasoning of this kind is not only inconclusive, but frivolous; and the analogy stated by Mr. Harris invariably and necessarily operates on our own tongue, and would have operated in *all* tongues, if, like the English, they had conformed to the standard of nature; and we ought no more from their caprice to argue against the dictates of reason and analogy, than we ought to deny a regard to the distinction of sex in the nouns of one language, because the gender of the same nouns in others is regulated by considerations independent of sex.

When a noun represents its object as *one*, it is said to be in the *singular*, and *plural* when meaning more than one. This property also can hardly be said to be necessary to nouns, as its place might have been supplied with greater accuracy by numerical adjectives when extended to express numbers, as *two men*, *three men*, &c. "Bengal nouns," says Mr. Halhed, in his excellent grammar of that tongue, p. 68. "have neither dual nor plural numbers, I may add that neither is wanted. The *dual* is found in no modern language, and probably never existed but in the Arabic and its branches, in the Shanferit and in the Greek. That the idea of multitude is not confined to the plural number, is clear beyond a doubt, because singular nouns are used in all languages with a collective sense, almost as frequently as plurals, thus: *man love to study*, and *man loves to study*, are phrases perfectly equivalent. So also we join to a noun in the singular number an epithet of indefinite plurality to convey a plural meaning: *many a man* is written by the Bengalese *beboot mah-boosb*. Perhaps it might be safely urged that the singular number has more occasion for an accurate specification than the plural; at least this is the only circumstance which can account for the extensive use of the article or representative of unity in most of the modern dialects of Europe."

The plural number in its origin was no other than a noun.

of multitude, annexed to that preceding it, in order to mark its extension from *one* to *many*. Thus in Hebrew, whose high antiquity unfolds to the philosophical enquirer the several steps which mankind took in the formation of speech: **אנוש**, *anosh* *hemon*, a man multitude, became contracted, for the sake of brevity, into **אנשים**, *anoshem*, *men*. In the Chaldean and Syriac the final *m* was changed into *n*. Hence the Hebrew *em* in Chaldean became *en*, in Arabic *oon*, in Persian *aan*, to denote the names of animals, and *an* inanimate things. And from this source are derived the plural terminations in *an* or *a* in the Anglo-Saxon and German tongues. The letters *n* and *s* being of the same organ, the Chaldean *en* became *es* in the formation of the Greek, or *es* in the third declension of Latin nouns. Hence, too, the plural termination *s* in English and French; while the Italian exclusively follows the analogy of the second Latin declension in *i*. Thus the plural termination in all languages, ancient and modern, appears to have been derived from one source: and that consisted of the annexation of a noun of multitude to the singular form of a preceding noun. And it is remarkable that in the Bengalese, which is but a branch of the Shanferit, this mode of expressing plural nouns is preserved to this day; as, *projaa*, a peasant, *projaa-lok*, peasant-people, *projaa-lok*, peasants; *lok* signifying people annexed to the singular noun whatever it might be. We shall only observe, that the names of classes only admit the plural form; while *proper* names in all languages are, by their signification, confined to the singular, unless many individuals by accident have the same name. The names of *families* and *nations* must likewise be excepted, from a regard to their signification, are necessarily plural.

We come next to the consideration of *cases*, which are properties of nouns, perplexed and undefined, as is evident from the different, and we may add, erroneous accounts given of them by most grammarians. The best and surest way to ascertain the nature and origin of cases, is to attend to the manner in which they were at first considered in the Peripatetic school. We adopt the words of Mr. Harris, p. 277. "The Peripatetics held the nominative to be no case, and likened the noun in this, its primary and original form, to a perpendicular line, such for example as the line

A B. The variations from the nominative, they considered as if A B were to fall from its perpendicular, as for example to A C or A D. Hence, then, they only called these variations **πτωσις**, *casus*, *cases*, or *fallings*. The Stoics, on the contrary, and the grammarians with them, made the nominative a case also. Words they considered (as it were) to fall from the mind, or discursive faculty. Now, when a noun fell thence in its primary form, they then called it **πτωσις** *ορθη*, *casus rectus*, an erect or upright case or falling, such as A B, and by this name they distinguished the nominative. When it fell from the mind under any of its variations, as for example in the form of a genitive, a dative, or the like, such variations they called **πτωσις** *παραγυια*, *casus obliqui*, oblique cases or side-long fallings, (such as A C or A D), in opposition to the other (that is, A B), which was erect and perpendicular. Hence, too, grammarians called the method of enumerating the various cases of a noun **κλισις**, *declination*, a *declen-*

sion, it being a sort of progressive descent from the noun's upright form, through its various declining forms, that is, a descent from A B to A C, A D."

We copy this account because it is very plausible, though we regard it as erroneous; the learned author and Anthonius (De Interpret. p. 35.) from whom he derived it, being misled by the figurative language borrowed from geometry. We believe that the nominative is said to be in the right case, not because it is an erect or upright falling from the mind, but because the nominative, the verb, and its object following each other in direct succession, form one simple proposition. The nominative is the leading noun or *agent*, and the accusative is the *effect*, in which the action straightway terminates. And when other nouns are introduced, they are spoken of not directly as the agent or subject, but *collaterally* or *obliquely*, as objects to which the direct noun someway belongs. Thus the accusative as well as the nominative are right cases, or direct parts of a proposition; whereas the genitive, dative, ablative, and vocative are oblique cases, or indirect parts of a proposition.

From this simple statement, which we recommend to our readers as important, we infer, that a case did not at first mean a *change* in the termination of a noun, but the *position* of a noun expressing its relation to some other word in the sentence. And our next object is to ascertain those leading relations which the position of a noun, or some other means more specific, expresses. *God made man* is a sentence in which the agent, the action, and the object follow each other in the order of nature: *God*, as occupying the place of the agent, is the nominative; and *man*, as corresponding to the effect, is the accusative. But in the sentence *God is good*, we cannot say *God* is the agent, because the verb *is* does not express an action, but serves only to connect the epithet *good* with *God*. The nominative, therefore, here expresses not the agent, but the *subject* of the attribute connected to it. The nominative case, then, is that leading state or position which expresses the *subject* of a connecting verb, and the agent of an active verb. And the accusative is that position which expresses the effect of an active verb, and thus far simple position will carry us: and the nominative and accusative have evidently to each other the relation which a cause has to its effect, and that for no other reason, but that their order corresponds to the order of cause and effect.

But suppose that my purpose was not only to express a cause or agent, but the *origin* of that cause, or the *instrument* by which it acts, or the *end* for which it acts. In such cases simple position will be of no avail. I must have recourse to some other expedient, and no expedient so well can serve as suitable words to express origin, instrumentality, and end. "Thus, the *Son of God* redeemed mankind—he redeemed them *by his death*—he redeemed them *for happiness*. In the first sentence, *of* means beginning or origin: and *God*, succeeding it, as being the origin of *son*, is said to be in the *genitive* case. In the second, *by* denotes *instrumentality*, or medium; and as *death* is the instrument or medium by which Christ redeemed man, it is said to be in the *ablative* case, and might more properly be said to be in the *instrumental* or *medial* case. In the third instance *for* expresses the *end* for which Christ redeemed man: the noun happiness succeeding it, is therefore in the *final* case, or as it is commonly, though unmeaningly, called the *dative* case."

The cases, then, or those leading positions of a noun that answer the purposes of speech, are the nominative, accusative, genitive, ablative, and dative. Let it be added, that the nominative, as it implies the name of its object, is often used merely to address a person, and thus to fix his attention. In this state the noun is said to be in the *vocative* case, and is

GRAMMAR.

sometimes preceded by the interjection O! But we have not yet done: the nominative and accusative are expressed by position; while the oblique cases, the genitive, ablative, and dative depend on words expressing beginning, medium, and end. Let us a little contemplate the consequence of these words, or words of the same import, when first introduced into discourse. As the relations of things are in the order of our ideas consequent upon the things so related, prepositions denoting those relations must at first have succeeded the nouns which they now precede and govern. Thus in the above instances, the order would have been *God of—death by—happiness for*. And it is remarkable, that in the Hindoostanic the prepositions to this day generally succeed the dependent nouns, instead of going before them, as in other tongues. The consequence of this was, that the prepositions, abbreviated perhaps into single letters, coalesced with the preceding noun, forming thereby one word with it. Thus *godof, godby, go. for*: and the variety of terminations given by this means to the noun is the origin of cases. Modern tongues, in rejecting this variety, and substituting prepositions, have only recurred to the original purity of language.

Grammarians have generally concurred in defining cases to be changes of termination. In this, if the above account be just, they are mistaken, not only because position is the primary and essential idea of a case; but because while they reject prepositions as marks of cases, the cases defined by them are no other than the prepositions which they reject. Conformably to this notion, they maintain that the English noun has no other than the possessive case: and Dr. Lowth and Mr. Lindley Murray, pursuing the same error to its consequences, comprehend nouns expressing the relation of effect, the relation of beginning, the relation of medium, and the relation of end, under one unmeaning phrase of *objective case*, thus confounding relations the most necessary to the purposes of speech, the most distinct in themselves, and most requisite to be kept distinct in the mind.

The ideas of the most acute and learned grammarians have hitherto been confused and contradictory on the subject of cases, especially the oblique cases. And the author of the treatise in the Encyclop. Britannica has just left the matter obscure and uncertain, as he found it. "The genitive, says he, is the most general of all the cases, and gives notice that some connection indeed subsists between two objects, but does not point out the particular kind of connection. That we must infer, not from the nature or termination of the genitive itself, but from our previous knowledge of the objects connected. That the genitive denotes merely relation in general, might be proved by adducing innumerable examples, in which the relations expressed by this case are different." These observations clearly shew that this writer did not himself understand the meaning of the genitive case, which, instead of expressing *some connection* between two objects, or *mere relation in general*, uniformly expresses one and the same relation, namely, that of *beginning, source, and origin*; and *of*, the mark of it, has uniformly the same sense with *from*. Thus a table *of* wood, a table *from* wood; wood being the origin of the table. Rays *of* the sun, rays *from* the sun, the sun being the origin of the rays. And *beginning* will appear to be the primary idea implied in *of*, if we trace it to its origin; *of, ab, aro, ἄρ, ab, parent, stem, root*. Thus also in Latin *Dei gratia*, the grace of God, the grace from God, the grace of which God is the source. Of the phrase *injuria regis* the writer says, no man can know whether the injury mentioned be an injury *suffered*, or an injury *inflicted* by the king. We deny this: if the terms be used in strict propriety they must mean an injury from the king, an injury of which the king is the source and author; and, if they are intended

to denote an injury received by him, the expression is incorrect and ambiguous, though the ambiguity would be removed by the context: and this leads me to remark, that as the beginning of a thing is the *author* of it; and as the author has a full right to the fruits of his labours, so that state of the noun which expresses beginning came to signify the *owner* or *possessor*. And thus the genitive in Greek and Latin expresses the relation of possession, and answers to what is called in English the *possessive case*. Thus, *my father's will* may mean the will of which my father is owner; it means also the will which originated in my father. The possessive case, in our tongue, is an evident abbreviation of the genitive termination of the third declension in Latin, *father's house, father's house*, the apostrophe above supplying the place of the excluded vowel.

The same writer has not defined the meaning of the *dative*, though the relation denoted by it is the most obvious of any, contenting himself with saying, that it has nearly the same sense with the accusative, 19. No two relations, however, can be more distinct; as the accusative expresses the effect of an action, and therefore stands immediately connected with that action; whereas the dative denotes the *end* to which a motion or action tends, and in which it terminates, or the point to which the attention is directed forward, as that to which something else is related. Thus, in the instance given by him, *comparo Virgilium Homero*. The immediate object of comparison is *Virgil*, and *Homer* is the point, or standard placed before me in making that comparison. The two first words express the action and its effect, the last holds to view the point to which they are directed. It is true that in this and similar instances, the mind brings under one view the person compared and the person to whom the comparison is made; and this proximity or juxtaposition constitutes the affinity which the writer erroneously supposes to be between the two cases. *Antonius lesit Ciceronem*, and *Antonius nocuit Ciceroni*, he farther supposes to be expressions of the same import; but in this he has been misled by the genius of our tongue, which would express each phrase by *Antony hurt Cicero*. But this is the exact meaning of the first clause only. In the second clause *nocuit* expresses not an *action*, but asserts a *quality*. Antony was hurtful to Cicero. Antony was hurtful, and Cicero was a person to whom his hurtful behaviour was directed.

The dative case stands opposed to the genitive as *end* to *beginning*. The latter is the point where motion *begins*, the former where it *terminates*, and the ablative is the medium or instrument between both. In consequence of this connection between the ablative and the genitive, on one hand, it came in Latin, by the mere impulse of repeated associations, to mean in many instances the same relation with the genitive, and this is the reason why the same word often governs a genitive or an ablative, why in our own tongue *of* and *from* have precisely the same signification, and why the French and Italian express the genitive by those prepositions which in Latin govern the ablative. On the other hand, as the instrument or medium is connected with the end, the ablative holds a similar connection with the dative. Hence in Latin these two cases are often used one for the other, which is certainly a great impropriety in that language, and which occasions much perplexity to the learner; while in Greek, which has not a distinct ablative, the relations of instrumentality and end are expressed by the same termination, which is certainly a great defect in that elegant and copious language. Instrumentality implies *concomitancy*; but this is not the primary sense of the ablative, as the author of the above treatise erroneously supposes.

The Origin and Properties of Adjectives.

Things or substances are known and valuable on account of their qualities; the qualities of things therefore first engaged the attention of mankind. And as they perceived that the same quality existed in the same or in a different degree, in different things, men, however rude or uninformed, learned to form ideas of qualities independent of the substances to which they belonged. Hence they acquired that class of words called *adjectives*, which are only the names of qualities. Now as qualities result from things, the names of qualities are derived from the names of things; and, as moreover qualities are constant concomitants of the things they characterize, the names of qualities are constant adjuncts of substantives expressed or implied. Hence they are sometimes called *nouns*, because they have been borrowed from nouns; and always called *adjectives*, because they are always *adjoined* or *added* to nouns, and for this reason they have also the name of *adnouns*. From this account of adjectives we deduce the following inferences, which are worthy of attention.

First, adjectives expressing the simple qualities of natural objects, which do not imply *motion* or *action*, are derived from nouns, by the mind first abstracting the quality from the thing it qualifies, and then generalizing it so as to make it an epithet expressive of a similar quality in different things. Thus in $\pi\epsilon\pi\eta\mu\alpha$, *a sleep rock*, the quality *sleep*, contemplated first as a quality of that particular thing, the mind soon learned to consider as *separate* from the rock, and hence to make it a general term of the like quality in other objects. Thus was derived the adjective $\pi\epsilon\pi\eta\mu\alpha$, *pronus*, *prone*. And in the manner this single adjective is formed, are formed all the adjectives which exist in all languages.

When adjectives became numerous in any language, analogy or custom soon assigned them a particular termination. Hence, on every conversion of a noun into an adjective, that adjective immediately assumed the ending which analogy had appropriated to words of that class. Thus $\phi\alpha\gamma\epsilon\iota\sigma$, *food*, *relish*, was changed into *probus*, signifying agreeable food or wholesome relish. Thus also *wood*, *wind*, became *wooden*, *windy*, in our own tongue. It is obvious from this to observe, that in the earlier periods of human language, adjectives approached nearer in meaning and termination to the nouns whence they were derived; that is, they were less abstracted and generalized. But the principles of abstraction and generalization were greatly facilitated, when a quality was once expressed by an independent word; the eyes and the ears being made by that means to aid the conceptions of the mind. This is the reason why a barbarous people have few or no adjectives; and why, in the more ancient dialects of the East, the use of adjectives is far less frequent than in the more recent languages of Europe.

In speaking of the qualities of things, *similitude* or *resemblance* is an idea of high importance and frequent recurrence. A person discoursing to another of something *unknown*, naturally says, that it is *like* to some other that is known. Thus in Greek $\epsilon\iota\kappa\omicron\varsigma$, *image*; $\epsilon\iota\omicron\varsigma$, *form*; $\epsilon\iota\omicron\varsigma$, *like*; are combined with nouns in order to express *likeness*; $\alpha\theta\eta\tau\omicron\pi\iota\kappa\omicron\varsigma$, *man-like*; $\epsilon\upsilon\kappa\epsilon\tau\epsilon\iota\delta\eta\tau\omicron\varsigma$, *having the form of Hector*, *Hector-like*, i. e. *the son of Hector*; $\alpha\theta\eta\tau\omicron\pi\iota\kappa\omicron\varsigma$, *man-like*. This last termination, by inserting *s*, gave birth to the Latin adjectives in *osus*, and to our adjectives in *ous*; *pecunia*, *pecuniosus*; *glory*, *glorious*. The numerous adjectives and adverbs in English are formed on the same principle. *Earthly*, i. e. earth-like, which is the Greek $\delta\epsilon\gamma\mu\omicron\varsigma$. *Gladsome* is *gladlike*, the *same* with *glad*; *some*, or *same* being, we conceive, corruptions of *similis*. The termination *ish* is originally the Persian $\tau\omega\sigma\iota\sigma$, added to a

noun to express likeness; as $\mu\omicron\sigma\iota\sigma$, *the moon*; $\gamma\omicron\mu\eta\tau\omicron\sigma\iota\sigma$, *moonish*, like the moon; $\gamma\omicron\mu\eta\tau\omicron\sigma\iota\sigma$, *womanish*, like a woman. The termination *en*, derived, it is allowed, from the northern language, is borrowed by that language from the Greek participle in *en*. In the same manner we form some adjectives after the analogy of the past participles in *ed*, as *lovin*, *worsh*; while that of *y* is the Anglo-Saxon *ig*; but this is only the Latin termination *cus*; as *unicus*, Anglo-Saxon *an'g*, *any*.

But it must not be omitted that a very numerous class of adjectives is derived from *verbs*, and that independently of participles. Of this origin are all those adjectives whose qualities pre-suppose *motion* or *action*; and they imply greater power of abstraction than those derived from nouns. Mr. Tooke, indeed, denies this power as a principle influencing language; and by this rejection is led to deny the existence of adjectives as a class distinct from nouns. His definition is the following. "An adjective is *the name of a thing*, which is directed to be joined to some other name of a thing." (Vol. ii. p. 241.)

As his authority on the subject of language is so high in the estimation of many, we shall briefly examine and refute the above definition. His arguments are these; "I think you will not deny that *gold* and *brass* and *silk* is each of them the name of a thing, and denotes a substance. If then I say a *gold-ring*, a *brass-tube*, a *silk-string*, here are the *substantives* used adjectively, yet names of things, and denoting substances. If again I say a *golden ring*, a *brass tube*, a *silk string*, do *gold* and *brass* and *silk* cease to be the names of things, and cease to denote substances, because, instead of coupling them with *ring*, *tube*, and *string* by a hyphen thus (-), I couple them to the same words by adding the termination *en* to each of them? Do not the adjectives which I have made such by the added termination *golden*, *brass*, *silk* convey to the hearer's mind, and denote the same things as *gold*, *brass*, and *silk*? Surely the termination *en* takes nothing away from the substantives *gold*, *brass*, and *silk*, to which it is united as a termination: and as surely adds nothing to their signification, but this single circumstance, *viz.* that *gold*, *brass*, and *silk* are designated by this termination *en* to be joined to some other substantive;" p. 430. Again he says, p. 442, "But if, indeed, it were true that adjectives were not the names of things, there could be no attribution by adjectives; for you cannot attribute *nothing*. How much more comprehensive could any term be by the attribution to it of *nothing*? Adjectives therefore, as well as substantives, must equally denote substances; and substance is attributed to substance by the *adjective* contrivance." He concludes with what Dr. Jonathan Edwards says of the language of the Muhhekanew Indians. "The Mohegans have no adjectives in all their language, although it may at first seem not only singular and curious, but impossible that a language should exist without adjectives, yet it is an indubitable fact."

This account, instead of unfolding that simplicity and precision which mark the process of the human mind in the formation of language, tends to erase the very elements of knowledge, and to confound ideas the most palpable and distinct. Our ideas naturally and obviously divide into two classes, ideas of qualities and ideas of things. The distinction between these classes is universal; it is common to the philosopher and the bulk of mankind; and is most readily comprehended even by children. As we have then *ideas* of qualities, language must have *words* to express those qualities, i. e. it must have *adjectives*; and as our ideas of qualities are in their nature distinct from, though concomitant ideas of things; so adjectives must in their nature be distinct from, though adjuncts of nouns.

The first step in the formation of adjectives is *abstraction*; the mind being led to conceive of the quality independent of the thing, in consequence of perceiving it in *different* things. The frequent recurrence of the quality, which is one and the same, and therefore remembered, while the substances which present it are numerous and successive, and therefore forgotten, greatly facilitates our abstract conceptions. A similar facility, as we have already observed, is afforded by the independent use of words to express qualities. The dependence of adjectives on the principle of abstraction is evident from one circumstance. *Like* is a very abstract quality; and the union of this word with nouns is one copious source of adjectives in most languages of which we have any knowledge.

The next step in the formation of adjectives is *association*. This principle is so powerful and instantaneous, that it changes the nature of a word, in consequence of its connection with other words, and of our previous experience. Thus, "the ladies *fan* themselves"—"The plummy people *eye* the falling verdure." Because we have experienced the middle term of a simple direct proposition to be always a *verb*, we instantly, in the above examples, conclude that *fan* and *eye* do not here denote the things usually meant by them, but the *operations* of those things; that is, association and experience convert the nouns *fan* and *eye* into verbs, without any thing to aid or indicate that conversion but association suggested by the collocation. This conversion of a noun into a verb by simple experience, illustrates the conversion of a noun into an adjective. We place a word signifying a quality before a word denoting a substance; and as we uniformly find that qualities belong to the things which they qualify, and first act upon our perceptions, we instantly infer from the collocation that the first expresses an attribute of the second; and this attribution is not indicated by the termination of the attributive, but an *inference* of the mind founded on experience. The termination *en* signifying *to be added* is a conceit of this grammarian, and has no foundation in truth: for it is the Greek participial termination in *on*, borrowed by the Goths. The formation of language did not require such petty, circuitous contrivances; but points to the broad and simple principles of abstraction and association as the copious sources of all its phenomena.

From this it appears, that a peculiarity of termination is not necessary to form an adjective, the collocation being sufficient to ascertain its character as such. An adjective may have the same ending with any other noun, or with the very noun from which it was derived; and it has this identity of termination in Greek and Latin, and yet no ambiguity arises as to its nature and use. The inference, which we instantly, and we may say, imperceptibly, draw from the *juxtaposition* in our own tongue, and from the similarity of terminations in the classical tongues, is an unerring guide in these respects. And this is the reason why, in a barbarous language, it is possible that the name of a quality may be always the same with the name of the thing to which that quality belongs, and yet abound with adjectives, *i. e.* abound with nouns converted into adjectives by juxtaposition. And this is all that can be meant by the testimony of Dr. Edwards, in regard to the language of the Mohegans. If there existed a language which had no verbs, but nouns converted (as in the above instance of *fan* and *eye*) into verbs without any variation of termination, a person who did not understand the nature of the human mind, and who had been accustomed to classify words only by their endings, might say of that language, that it had *no verbs*.

The foundation of Mr. Tooke's error, is the circumstance

that most adjectives were originally nouns. As they were nouns *in their origin*, and as he rejected the operations of the mind in the construction of language, he inferred with confidence, that they were nouns *still*, thus confounding in one promiscuous mass our ideas of qualities, and our ideas of things; yet, notwithstanding this confusion, he writes thus: "If in what I have said of the adjective, I have expressed myself clearly and satisfactorily; you will easily observe that adjectives, though convenient abbreviations, are not *necessary* to language; and, therefore, are not ranked by me amongst the parts of speech; and, perhaps you will perceive, in the misapprehension of this useful and simple contrivance of language, one of the foundations of those heaps of false philosophy and obscure (because mistaken) metaphysic with which we have been bewildered."

Adjectives, as expressing not things, but their qualities, cannot, in strict propriety, have any *gender*; but, as in Greek and Latin, they have the same terminations with nouns, they are said to be masculine, feminine, or neuter, merely as they have masculine, feminine, or neuter terminations.

In most languages, adjectives vary their endings to correspond with the plural form of nouns; in English they have no such variation, nor is it necessary, since qualities are not susceptible of numerical distinction, being the same, whether applied to one or to many.

There is, however, one variation which adjectives have in all languages, namely, the variation to express the three degrees of comparison. The qualities of things differ in different objects, and they must be expressed with *augmentation* or *diminution*, as they are compared with others more or less intense.

When a quality is expressed without reference to any other, the adjective is then said to be in the *positive* degree. When expressed with reference to the same quality or to another more or less intense, it is said to be in the *comparative* degree; and when in the highest or lowest degree of all, it is in the *superlative*. Different languages have different ways of forming the comparative and superlative; but in almost all, both these degrees are derived by certain syllables added to the positive: the adjective itself, by being thus *lengthened*, is made to correspond with the augmentation in sense, which the quality acquires by comparison. The mode of expressing the degrees of qualities being only *two*, and therefore very general and imperfect, while the qualities themselves vary in endless gradations, a more adequate method is used, by having recourse to those attributes of an inferior order, called *adverbs*, as *much good*, *tolerably good*, *exceedingly good*, *more good*, *most good*.

As it is not our object to detail the minute rules of grammar in our own tongue, we shall conclude this part of the subject with one or two observations on the three degrees of comparison. The positive degree, though not implying an immediate comparison with the same quality in a higher or lower degree, often conveys a *relative* or *comparative* idea; and for this reason may, by the assistance of a preposition, be made to express the comparative or superlative degree, as "Blessed among women, *i. e.* the most blessed of women." And this relative or comparative idea, implied in the positive, is the reason why the positive has sometimes after it the case which is used after the comparative. On the other hand, the comparative and superlative are used in a positive sense, or used to express a high degree without any immediate object of comparison. Thus Virgil speaks of Venus: "Tristior et lacrymis oculos suffusa nitentes."—*Tristior*, more sad than usual, *i. e.* very sad. This is more usual in the superlative degree, *vir doctissimus*, a very learned man. The comparative is used with propriety only when *two* things are compared;

the superlative when a thing is compared with *many*. The elder of the two—the eldest of all. Nevertheless it is to be allowed, that multitude may be the object of the comparative, if preceded by *all* or *whole*, to give it a collective idea; as, “he is wiser than all his teachers, *i. e.* he is wiser than the whole body of his teachers,—he is wiser than them all put together;—or, compared with his teachers one after another, he is wiser than them all.”

The Origin and Properties of Pronouns and Definitives.

Pronouns have been defined substitutes for nouns, to prevent their too frequent recurrence. Mr. Harris accounts for pronouns, or, as he calls them, *nouns of the second order*, in a different way; and, as his explanation is curious, we shall here place it before our readers. “All conversation passes between individuals, who will often happen to be till that instant unacquainted with each other. What then is to be done? How shall the speaker address the other, when he knows not his name? or how explain himself by his own name, of which the other is wholly ignorant? Nouns, as they have been described, cannot answer this purpose. The first expedient on this occasion, seems to have been *pointing* or *indicating* with the finger or hand; some traces of which are still to be observed, as a part of that action which naturally attends our speaking. But the authors of language were not content with this: they invented a race of words to supply this pointing, which words, as they always stood for substantives or nouns, were characterised by the name of *pronouns*. These, also, they distinguished into three several sorts, calling them pronouns of the first, the second, and the third person, with a view to certain distinctions, which may be explained as follows.

“Suppose the parties conversing to be wholly unacquainted, neither name nor countenance on either side known, and the subject of conversation to be the speaker himself. Here, to supply the place of pointing, by a word of equal power, the inventors of language furnished the speaker with the pronoun *I*; *I write, I say, I desire, &c.*; and as the speaker is always principal with respect to his own discourse, this they called, for that reason, the pronoun of the first person. Again, suppose the subject of the conversation to be the party addressed. Here, for similar reason, they invented the pronoun *thou*; *thou writest, thou walkest, &c.*; and, as the party addressed is next in dignity to the speaker, or at least comes next with reference to the discourse, this pronoun they therefore called the pronoun of the second person.

“Lastly, suppose the subject of conversation neither the speaker nor the party addressed, but some third object different from both. Here they provided another pronoun, *he, she, it*, which, in distinction to the two former, was called the pronoun of the third person. And thus it was, that the pronouns came to be distinguished by their respective persons.”

This account, which the author, as he says, received from Apollonius, is arbitrary and erroneous. The use of the pronouns is not to supply the names of persons unknown to each other; nor can they be said to have been *invented*: for though they answer the most useful purposes, they originated in circumstances in which *design* had no concern. The origin of the two first pronouns we conceive to be this. They are the adjectives *one, two*, losing their numeral signification, and coming to mean the speaker and the person addressed, by the mere force of association with the verb. Let us suppose that a person wished, in the infancy of language, to express the proposition *I love thee*. If English were his words, he would have said, *one love two*. This form being repeatedly used, and the person using it accom-

panying the leading term *one* with a consciousness of himself, that term would gradually drop its character of one in opposition to *two*, and derive a new character by association from the verb, namely, one that was speaking in opposition to the other spoken to. Thus the same process which converted *one* in general into *one speaking*, converted *two* into the person addressed.

That the pronouns *I, thou*, were originally *one, two*, will appear probable from hence. In Hebrew, the most ancient language, the pronoun answering to *I* is evidently the parent of the numeral *one*; and *two* has a close resemblance to *thou*. Thus אֲנִי, *ani*, ego, is אֶן in Greek, and *unus* in Latin, and the other form אֶנְכִי, *enki*, is *unicus*. Moreover, אַתָּה, *ato*, by dropping א seems to have produced אַ, *tu, thou*; and *duo, duo, two*. And in other tongues the pronoun *thou* and the numeral *two* have such resemblance as to bespeak one common origin in Hebrew. Besides, the pronouns *I* and *thou* still retain their origin in their names; *I* being the *first* person, *thou* the *second*; not because the former is the first and the latter the second in dignity, but because these were their original meaning. Moreover, the numerals *one, two*, must have been among the first adjectives formed by abstraction from such things as nature produced in pairs, or those which alternately succeed each other, such as *day* and *night*. And as discourse is but an *alternation* or *interchange* of sentiments between *two* persons, the numeral adjectives in question were the most likely to be used on such occasions. Remains of this usage may be still traced in some languages, as we say, *One thinks so*, or in French, *On dit*; *one* being not as Condillac (see his Works, tom. v. p. 184.) asserts, a corruption from *homme*, but of the Latin *unus*, and is not a substantive, but a substitute for a substantive, *i. e.* a pronoun. Finally, we observe that no words but *numerals* were capable of being formed by association into pronouns. The speaker, indeed, might use his own name, and which, when repeatedly used, the verb would convert into the first person. But on the same principle another would employ his own name, and thus the associations of one man would counteract the associations of another; and neither name would be received as the representative of the speaker.

From this statement of the origin of the pronoun, some particulars respecting its nature and use may be deduced with precision. First, the adjective, in being changed into a pronoun, loses the generality of a numeral, and assumes an individual character; that is, the character assigned to it by the verb. But as any other person may use that term in similar circumstances, the pronoun *I*, which was changed into the index of an individual by association, becomes again *general* by succession; each speaker having a right in his turn to use it: and thus the pronouns *I* and *thou* became substitutes for the names of all persons in a change of situation. Secondly, *I* and *thou* are not, as has been supposed, substitutes for the names of the speaker and the person addressed, to avoid their too frequent repetition, nor yet substitutes for those names while yet unknown, but representatives of those persons in that limited or restricted character which they derive from the associated verb. Now as *speakers* there is no difference between a man and a woman. A man that speaks and the woman that speaks, in that particular function, is the same: and the same thing holds in regard to the person addressed. The first and second persons, therefore, have not, in any language, the distinction of gender merely; because they represent human beings in that particular character which excludes the idea of sex. Thirdly, there is, properly speaking, no such thing as a *third* person; this being a *definitive*, marking the subject of discourse, and said to be the third person in refer-

ence to the *first* and *second*, and thus represented as something distinct from them, and not included under them. Thus *בַּיָּמִין*, *boa*, in Hebrew, and *he* in English, were, as we shall presently see, but the article; and so *ἐ, εὐτος, εξωτος, αυτος* in Greek, and *hic, ille, is, ipse*, in Latin, are all a species of restrictive or definitive adjectives, agreeing with the defined noun expressed or implied. As the first and second persons represent two individuals in peculiar circumstances, they comprehend no other noun under them; whereas the third person is only in general a subject of discourse, and therefore it comprehends any noun in the language, excepting the first and second: accordingly every subject or agent in every language is the third person singular and plural, except four, *I, thou, we, and ye*, or their equivalents. The first and second person, we have seen, exclude the idea of sex, whereas it is a character often necessary to be marked in the subject or agent: for this reason pronouns of the third person have the triple distinction of masculine, feminine, and neuter.

All the three persons admit the plural number, as each is capable of representing numbers. In our own tongue *I, we, thou, you or ye; he, she, it, they*. Here it may be observed that *ye* is a corruption of *you* or *you* abbreviated; and as this abbreviation naturally takes place in the nominative or vocative, when the persons addressed are called; and as it is necessary to be distinct when expressing the addressed persons as affected by a verb, *ye* is used with propriety only in the nominative or vocative, and *you* in the accusative. Men of rank being usually surrounded with attendants, it became a compliment to address a person as such; in the same manner as in Greek, *ἐν περι Πριάμου, those around Priam*, was a respectful way of designating Priam. Hence in common discourse we use *you* for *thou*; and on such occasions the verb also should be in the plural; as *you were* and not *you was*. But this complimentary style is not applied to the Supreme Being, who is always addressed by *thou*, from a regard, probably, to his unity, numbers being not able to add to his dignity or greatness. The regal style *we* has respect to the king's counsellors, who are supposed to advise the subject of discourse, and who are responsible for it. With regard to the third person, though it be convenient to mark the gender, it is not essential: for the plural *they* is made to represent men, women, and things, without any inconvenience or ambiguity.

The personal pronouns, contrary to the analogy of nouns, have each three terminations, or three variations, to denote cases. This is owing to their being derived from the Greek and Latin, with their respective inflexions. Their genitive, dropping the primary sense of *beginning*, has uniformly the secondary sense of *possession*. Hence it is called, in our tongue, not improperly, the *possessive case*.

In Hebrew, Arabic, and Persian, the personal pronouns are converted into adjectives, by being annexed to nouns, which, from their position, are called *affixes*. In this state they are somewhat abbreviated and changed: but however changed when connected with nouns, they are always adjectives, but retain their personality when affixed to verbs. In our own tongue the personal pronouns are changed into adjectives from the genitive or possessive case: as *mine, my; thine, thy; hers, ours, yours, theirs; her, our, your, their*. Thus formed, they are properly called *pronominal adjectives*—adjectives, as qualifying nouns, and pronominal, as derived from the personal pronouns. *His* must be considered, by coalescence, as an adjective of this kind, through the genitive *he's*. These pronominal adjectives, as derived from the genitive, may be resolved into the signification of that case: as *my* of *me*; *thy* of *thee*; *his* of *him*, though seldom in English used in their personal form: The reason is, that our tongue has a strong propensity to convert nouns into

adjectives by juxtaposition, and thus to use them for the sake of brevity, instead of the genitive: as when we say *silk-string* for *string of silk*, and *gold-ring* for *ring of gold*. The Greek and Latin do not abound with the same analogy, and therefore frequently use the personal pronoun in the genitive as equivalent to the pronominal adjectives.

The reciprocal or reflex pronoun *self* is added to these pronominal adjectives: as *myself, thyself, &c.* The third person singular and plural by analogy should be *his-self* and *their-selves*: but in order to humour the ear or the organs of speech, these are changed into *himself* and *themselves*. *Self* means an individual in opposition to another, and is derived from the Latin *solus*, alone, through the medium of the Anglo-Saxon *solus, soul*, Anglo-Saxon *safel, self*: hence also *soul*, which means that part of man in which consists the vital principle in opposition to the body: *own*, often used to precede *self*, is a corruption of the Anglo-Saxon *egen*, which by the insertion of the letter *g*, after the analogy of that language, is borrowed from the Latin *unus*. *Ownself*, therefore, is *oneself*.

Mr. Harris gives the following account of that species of adjectives called *definitives* or *articles*: “The visible and individual substances of nature are infinitely more numerous than for each to admit a particular name. To supply this defect, when any individual occurs, which either wants a proper name, or whose proper name is not known, we ascertain it as well as we can, by referring it to its species; or if the species be unknown, then at least to some genus. For example, a certain object occurs with a head and limbs, and appearing to possess the power of self-motion and sensation: if we know it not as an individual, we refer it to its proper species, and call it *dog*, or *horse*, or *lion*, or the like. If none of these names fit, we go to the genus, and call it *animal*.”

“But this is not enough: the thing at which we are looking is neither a species nor a genus. What is it then? An individual. Of what kind? Known or unknown? Seen now for the first time, or seen before, and now remembered? It is here we shall discover the use of the two articles *a* and *the*. *A* respects our primary perceptions, and defines individuals as unknown: *the* respects our secondary perception, and denotes individuals as known. To explain by an example: I see an object pass by, which I never saw till now. What do I say? There goes *a* beggar with a long beard. The man departs, and returns a week after. What do I say then? There goes the beggar with the long beard. The article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual, *once vague*, is now recognized as something known, and that merely by the efficacy of this latter article, which tacitly insinuates a kind of previous acquaintance, by referring the present perception to a like perception already past.

“The truth is, the articles *a* and *the* are both of them definitives, as they circumscribe the latitude of genera and species, by reducing them for the most part to denote individuals. The difference between them, however, is this: the article *a* leaves the individual itself *unascertained*, whereas the article *the* ascertains the individual also, and is for that reason the more accurate definitive of the two.”

We give this statement as that of an eminent grammarian, without subscribing to it as just in all respects. It is not, we conceive, true, to say that the individual defined by *a* is always *unascertained*; nor does *the* necessarily imply a previous acquaintance, by referring the present perception to a like perception already past. And we cannot help observing that, if Mr. Harris and other writers on the subject had traced these words to their sources, and thus ascertained their primary meaning, their readers would have been more inform-

ed in one paragraph, than they otherwise could by the most elaborate treatise.

The article *a* is in truth the numeral adjective *ἓ* in Greek, *unus* in Latin, *een, an, ans*, in Anglo-Saxon: and the import of it precisely corresponds with its original signification of *one*. A book is one book; a man is one man. Hence we may learn with certainty the following particulars. That it is enveloping the word in mystery to call it an *article*, instead of calling it by the more appropriate name of *numeral adjective*, or *definitive*. That as it means *one* it cannot be prefixed to plural nouns, unless those nouns be taken in a collective sense. That the usual rule, *a* becomes *an* before a vowel, should be just reversed in order to be true. "*An* becomes *a* before a consonant." That the equivalent of the article *a* exists in Greek and in Latin, but is rejected as useless in those languages; and that the frequent use of it in English and other modern language is so far from being necessary, that it is an incumbrance and inelegance. *I see man* would be as intelligible as when we say *I see a man*; and *they read book*, as definite, as *they read a book*; and this, from the nature of the case, just as in Latin, *video hominem, legunt librum*, where *unum* would be both unnecessary and inelegant. The English *I see man*, and the Latin *video hominem*, are both equally indefinite in themselves; but they are sufficiently limited by the nature of our perception, and by previous experience. "The indefinite article," says the author of the treatise on Grammar in the Encyclop. Britannica, "is much less useful than the other; and therefore the Greek and Hebrew languages have it not, though they both have a definite article. In languages, of which the nouns, adjectives, and verbs have inflexion, no mistake can arise from the want of the indefinite article; because it can always be known by the terminations of the noun and the verb, and by the whole circumstances predicated of the noun, whether a whole species or one individual be intended. But this is not the case in English. In that language the adjectives having no variation with respect to gender and number, and the tenses of the verbs being for the most part the same in both numbers, it might be often doubtful, had we not the indefinite article, whether the specific name was intended to express the whole species or only one individual." All this reasoning, however, appears to us fallacious, and only shews that even a wise and able man, such as the writer of this article certainly is, will readily think that necessary and useful to which he has been accustomed, and therefore will seldom be at a loss for some plausible reasons to justify it. In truth, the inflexions of adjectives and verbs in the learned languages alluded to, have no influence whatever in defining the extent of the general term, but serve merely to shew that they qualify that term, and depend upon it. The very example adduced by this writer shews the fallacy of his reasoning: *Ἔγνωτο ἀνθρώπος ἀπεσταλμένος πρὸς θεοῦ ὀνόματι Ἰωάννης*. Here *ἀνθρώπος* as clearly denotes not the whole species, but an individual, as if it was written *ἓς ἀνθρώπος*, and that not because of the singular correspondence of *ἔγνωτο*, nor from the termination of *ἀπεσταλμένος*. Of this there is an evident proof; *ἔγνωτο* and *ἀπεσταλμένος* would be still the same, though *ἀνθρώπος* had a specific or collective sense. But the individual sense of the noun appears from the nature of the case, from the context, and especially from the clause, *whose name was John*: and these circumstances, which sufficiently define it in Greek, would be sufficient to define it in English, were it written "Man was sent from God whose name was John." It is impossible to feel in this any ambiguity; and the expression seems uncouth only because we have been accustomed to the use of *a man* was sent from God, &c.

Mr. Tooke derives *the* and *that* from the Anglo-Saxon verb

thean or *thegan*, to take. But these definitives exist in that language, and why should he attempt to derive them from any word, when they are already formed and employed in the same sense? He seems to have been aware of this objection. And he adds, vol. ii. p. 60, "*The* (our article, as it is called) is the imperative of the same verb *thean*, which may very well supply the place of the correspondent Anglo-Saxon article *se*, which is the imperative of *seon, videre*. For it answers the same purpose in discourse to say—*see man*, or *take man*." The English *take*, and the Anglo-Saxon *thegan*, which this writer would lead us to regard as a primitive northern word, is only the Greek *δέχομαι, to accept*—*Take this*, therefore, means, *receive this*.

Light is the medium of sight, and hence, in the most ancient languages, the word signifying light gave birth to verbs signifying to see. Thus the Hebrew *ראה, tsā*, pronounced in Arabic *thao*, but in Persian *seca, light*, is the parent of the Anglo-Saxon *seon* and our *see*, which accords with the Persian pronunciation, and also of the Anglo-Saxon article *se* or *see*, or, as we found it, conformably to the Arabic, *the*. It is remarkable the article *ἓ* in Greek is founded entirely on the same principle, though derived from a very different word. For its original appears to have been the Hebrew article *ה*, which probably was founded *hu* or *ho* short, and which is but an abbreviation of *הוה, ha*. Now the use of this last consists in directing the attention to an object, and answers to *en* or *ecce* in Latin, and *behold* in our own tongue. And as the necessary consequence of looking upon a thing is to see it, as distinguished from other things, hence *ה* in Hebrew, *ἓ* in Greek, *the* in English, from signifying to perceive, through the medium of light, came to signify an effect of perception, namely, the distinction or opposition which the thing to seen has to other things which may be related to it.

From this account we may gather the following particulars respecting the nature and use of the definitive article. Its primary force consists merely in directing the eye or the attention to an object; and the definitive power alligned to it is rather an effect of the sight where the object is present, or of the mind in drawing the necessary inference, where the object is previously described or specified. If this account be just, the assertion of Mr. Tooke, that the article, in combination with a general term, is a mere substitute for a particular term, (see vol. i. p. 69) is erroneous. The article is only an index; having indicated the thing intended it does no more: the eye or the mind does the rest, and the general term is defined or made particular, by being brought under immediate inspection. It is necessary to subjoin the general term to the article, because it is necessary to specify the object intended; but the restriction of the specific or general noun to that individual object is a consequence of the article, rather than a power belonging to it. The article therefore cannot be a mere substitute, to do that which is done by another principle, namely, the eye or the mind.

The article serves as an index to specify an object hitherto unknown, as well as one previously known; and thus Mr. Harris's distinction, that *a* respects our primary perception, and denotes individuals as unknown; *the* respects our secondary perception, and denotes individuals as known, is unfounded. The index indeed may be directed to a past event or object, thus to make it the subject of inspection a second time. In this view Mr. Harris's position is true, but the use of the article is far more general, and by no means confined to such cases.

The article *the* is the same in origin, and often in use the same with *that*, and indeed in the Anglo-Saxon *that* is only the neuter gender of *the*; and Mr. Tooke ought to have made this remark instead of representing each as independent of the other.

This

This definitive is in our tongue variously applied; and the objects of its application are so distinct and different, that it has been thought to change its nature, and to belong to different parts of speech. And Mr. Tooke has the merit of being the first to shew that in all circumstances, *that* retains one and the same character. Let us briefly consider its various applications. And *first*, it is used to bring under the eye of the mind, *i. e.* to define individual objects; as *that* book. In this sense it is opposed to *this*, answering to *ille* as opposed to *hic* in Latin. *Ille, that*, denotes the remoter of two objects; *hic, this*, the nearer. "Alexander and Julius Cæsar were great commanders, *that* (ille) conquered Asia; *this* (hic) subdued the Gauls—*that*, meaning Alexander as the farthest off; *this*, Julius Cæsar, as the nearest." In such a sentence it would be more usual to say the *former* and the *latter*. *Secondly, that* is frequently used to characterize a *whole clause*, which is the object of a transitive verb, thus serving to fix the attention on what is going to be said, and by that means to render it emphatic and prominent. Thus, "I wish you to believe *that* (that thing which I am going to say, namely,) I will not hurt a fly;" which Mr. Tooke thus resolves, "I would not willingly hurt a fly; I wish you to believe *that* assertion." In this application it answers to *quod* in Latin. *Thirdly, that* is an index to point out the *end* or *purpose* which a person has in view, and as such precedes a verb in the subjunctive mood, expressing that end thus: "Thieves rise in the night *that* they may steal."—"Thieves rise in the night, *that* being their purpose, namely, they might steal." In this sense it corresponds to the Latin conjunction *ut*, which, perhaps, led to the error of considering *that* as a conjunction in the second and third senses. *Fourthly, it* is an index pointing to a noun in the preceding clause, and is a substitute for that noun, or rather it agrees with that noun implied, though never expressed. "The man, *that* hath not music in himself, is fit for treason." Here the first clause, *the man*, is represented as definite, while the reader as yet is not able to recognize it as such. What man is fit for treason? To preclude the necessity of this question, a clause is introduced, *that* man, namely, he who hath not music in himself. In this sentence *that* is thought to be a relative equivalent to *who*, which may be substituted for it. But in reality it is still a definitive, used to ascertain the preceding specified noun, which has the form of being definite without being really so; and the preceding noun is to be repeated, or, as *that* is *descriptive*, a generic or specific noun of the same import is understood to be introduced. Thus the man, namely, *that sort of man*, who hath not music in himself, is fit for treason. The subject of discourse may be *plural*, and yet the singular form of *that* may, on this supposition, be used. "The men *that* have not music in themselves, are fit for treason," *i. e.* the men, *that sort of men*, namely, who have not music in themselves, are fit for treason: and this is the solution of the apparent anomaly of *that* being used in both numbers, without variation, when taken relatively.

We come next to speak of the *relative pronoun*, which Mr. Harris thus explains, p. 77. "But besides those there is another pronoun (in Greek $\epsilon\sigma\tau\iota$, in Latin *qui*, in English *who*, *which*, *that*), a pronoun having a character peculiar to itself, the nature of which may be explained as follows. Suppose I was to say *light* is a body,—*light* moves with great celerity. These would apparently be two distinct sentences. Suppose, instead of the second *light*, I were to place the prepositive pronoun *it*: *Light* is a body; *it* moves with great celerity; the sentence would be still distinct and two. But if I add a connective (as for example an *and*) saying *light* is a body, and it moves with great celerity; I then by connec-

tion make the two into one, as, by cementing many stones I make one wall.

"Now it is in the united powers of a connective and another pronoun, that we may see the force and character of the pronoun here treated. Thus, therefore, if in the place of *and it* we substitute *that* or *which*, saying *light* is a body, *which* moves with great celerity; the sentence still retains its unity and perfection, and becomes, if possible, more compact than before. We may with just reason, therefore, call this pronoun the *subjunctive*, because it cannot, like the prepositive, introduce an original sentence; but only serves to subjoin one to some other which is previous."

This account, though elegant and specious, we nevertheless deem erroneous; because the relative pronouns in all languages are the same in their origin and use with the articles or definitive pronouns. In Greek $\epsilon\sigma\tau\iota$ is only the article $\epsilon\sigma\tau\iota$ with ϵ annexed after the analogy of that termination in Greek nouns. Hence the reason why ϵ and $\epsilon\sigma\tau\iota$ are, by the more ancient writers, such as Homer and Herodotus, used for one another, either as demonstrative or relative pronouns. The Latin *hic* is also the article ϵ with a guttural annexed—*hoc*; while *qui*, which Scaliger, and after him Mr. Tooke, derive from $\kappa\alpha\iota$ ϵ , is no other than the Persian *ke* or *che*, *who*, *which*. Moreover, *quis* is the Oriental *kis*, *who* or *what*; and it is remarkable that in Hindoostan *kis* is redoubled *kis kis*, and this has been imported into Latin *quisquis*. Finally, our *who* is the Greek ϵ , having the labial ω substituted for the aspirate, which is a broad and general analogy, by which words in Latin and the Anglo-Saxon are formed from Greek or from the Oriental tongues. *Which* is the neuter termination of ϵ , formed on the same principle as *hoc* in Latin, that is, a guttural is annexed to ω , *whoc*, *which*. And this is the reason that, while *who* is applied to persons, *which* is made to stand for inanimate things.

As the relative and definitive pronouns have the same origin, they are also the same in use. For in Latin the relative always supposes the antecedent to be repeated, and is repeated when obscure or doubtful. In our own tongue, indeed, *who* never coalesces with the antecedent noun, and is therefore a *substitute* for it, and this peculiarity in our own tongue has caused *who*, with its other cases *whose*, *whom*, to drop its nature as a definitive, and to become really a *pronoun*, *i. e.* a substitute for a noun. This peculiarity has also obtained in regard to *he*, which was the Hebrew and Greek article η , *ha*, or ϵ . And this is the reason why the article in Homer may be often rendered by *he* in our own tongue. Dr. Middleton, not perceiving this circumstance, was led, in a voluminous work published on the Greek article, to suppose that the Greek article is in its nature a *personal pronoun*, and may be always resolved into a pronoun. The foundation being thus fallacious, the whole super-structure, however learned and elaborate, is frivolous and useless.

We observe farther that *hic*, *ille*, and *is*, which are really definitives, often refer, like *qui*, to a preceding noun, and for this reason have a claim equally just to be called relative pronouns. Thus, "Dens nobis hæc otia fecit; namque erit ille mihi semper Deus; illius aram sæpe tener nostris ab ovilibus imbuet agnus." Here the first *ille* is *ille homo*, or *ille juvenis*, meaning *Augustus*, elegantly kept out of sight, the reader being left to conceive of him only as a *god*; while *illius* is *illius dei*, of *that god*. "Tres littore cervos prospicit errantes, hos tota armenta sequantur, *i. e.* hos cervos." "Cognoscimus Deus ex operibus ejus," we know God from the works of the same—*ejus dei*.

Because the relative *qui* is thus a definitive, the defined noun, when not antecedent, is made to succeed it in Latin, and

and in Greek, as "Maximis laboribus consequuntur eam, quam ex discendo capiunt, voluptatem;"—literally, with the greatest toil they pursue that, which pleasure, (for that pleasure, which) they derive from study. "Quas condidit arces, ipsa colat,"—let her inhabit which citadels she built, for, let her inhabit the citadels which she built. In our own tongue such an arrangement is not allowed, or even intelligible, because here the relative is really a substitute for the noun preceding it, and refuses to coalesce with it as an adjective. And it is obvious to remark in this place, that with the exception of *who* in English, the articles or definitives are not *pronouns*, but *adjectives*, numeral or restrictive, agreeing with a noun expressed or understood, and to be supplied from the context or the preceding clause. We remark, finally, that as articles are definitives, the Latin tongue has not only *one* but several articles, which it is erroneously supposed to want. Thus, hic homo, *this man*, ille homo, *that man*, is homo, *the same man*, ipse homo, *that very man*, are phrases, either of which is equally definite and emphatic with our *the man*, and on many occasions precisely the same with it.

Before we quit this subject we shall advert to a question proposed and solved by Mr. Tooke, vol. i. p. 273. "What is *as*?—The truth is that *as* is also an article; and however, and whenever, used in English, means the same thing as *it*, or *that*, or *which*. In the German, where it still evidently retains its original signification and use, (as *so* also does,) it is written *es*." Now, if Mr. Tooke had properly understood the nature of the article, he would not have made this assertion. *As* indeed, like the article, is an *index*, but it is an index directing the mind from one object to another, and the consequence of its being so directed is the perception of some *resemblance* between them. Accordingly *as* is *is*, an adverb of similitude in Greek, which being inverted (as is often the case with monosyllabic words), has become *so*. On the other hand, the consequence of the indication conveyed by the article is not to the observance of some likeness between the objects specified, but the limitation of the general term to the individual object, circumscribed by the eye or the mind by being so indicated.

In a note this writer adds: "Dr. Lowth, amongst *some* false English which he has recommended, and *much* good English which he has reprobated, says, *so-as*, was used by the writers of the last century to express a consequence instead of *so-that*. Swift, I believe, is the last of our good writers who has frequently used this manner of expression." If *that* denote *end* or consequence, the third sense we have assigned to it in the preceding page, and if *as*, on the other hand, signify *similitude* between two objects, *so as* is, as Dr. Lowth states, very improper; while *so that* alone is good English and good sense: and Mr. Tooke is himself guilty of the charge he brings against Lowth, namely, of recommending *some* false, and reprobating *much* good English. We cannot help observing that the object of comparison marked by *as* is often implied, and is to be gathered from the context; as in the following stanza:

Save that from yonder ivy-mantled tower,
The moping owl does to the moon complain
Of *such as*, wandering near her secret bower,
Molest her ancient solitary reign.

i. e. complain of *such persons*, as *those who* wandering, &c.

The Origin and Properties of Verbs.

We shall begin this part of our subject also with an extract from Mr. Harris, because his opinion, though plausible, is erroneous, and has been the means of leading other

grammarians, who followed his authority, into error. "We are now," says he, "to descend to the common herd of attributes, such as *black* and *white*, *to write*, *to speak*, *to walk*, &c. among which, when compared and opposed to each other, one of the most eminent distinctions appears to be this. Some, by being joined to a proper substantive, make, without farther help, a perfect assertive sentence; while the rest, though otherwise perfect, are in this respect deficient. To explain by an example, when we say *Cicero eloquent*, *Cicero wise*, these are imperfect sentences, though they denote a substance and an attribute. The reason is, that they want an assertion to shew that such attribute appertains to such substance. We must therefore call in the help of an assertion elsewhere, an *is* or *was*, to complete the sentence, Cicero *is* wise, Cicero *was* eloquent. On the contrary, when we say *Cicero writeth*, *Cicero speaketh*, in instances like these there is no such occasion, because the words *writeth* and *speaketh* imply, in their own form, not an attribute only, but *assertion* likewise. Hence it is they may be resolved the one into *is* and *writing*, the other *is* and *walking*.

"Now all these attributives, which have this complex power of denoting both an attribute and an assertion, make that species of words which grammarians call *verbs*. If we resolve this complex power into its distinct parts, and take the attribute alone, without the assertion, then have we *participles*. All other attributives, besides the two species before, are included together in the general name of *adjectives*; and thus it is that all attributives are either *verbs*, *participles*, or *adjectives*. Besides the distinctions above-mentioned, there are others which deserve notice. Some attributes have their essence in motion; such are *to walk*, *to fly*, *to strike*, *to live*. Others have it in the privation of motion; such are *to stop*, *to rest*, *to cease*, *to die*. And lastly, others have it in subjects which have nothing to do with either motion or its privation; such are the attributes of *great* and *little*, *white* and *black*, *wise* and *foolish*, and in a word the several *quantities* and *qualities* of all things. Now these last are *adjectives*; those which denote *actions* or their privation are either *verbs* or *participles*."

"Of all the constituent parts of speech," says the writer in the Encyclop. Britannica, 58, "none has given the grammarians greater trouble than the verb. The vast variety of circumstances which it blends together in one word, throws very considerable difficulties in the way of him who attempts to analyse it and ascertain its nature; at the same time that by its eminent use in language, it is entitled to all the attention which can be bestowed upon it. It should seem that the first object of our investigation ought to be the *characteristic* of the verb, or that which all these words have in common, and which constitutes them verbs, distinguishing them from every other species of words. Now it is obvious to the slightest attention, that every verb, whether active, passive, or neuter, may be resolved into the substantive verb *is*, and another *attributive*: for *loveth* is of the same import as *is loving*; and *amans* with *amans est*."

"But *loving* and *amans* are not verbs; whence it follows that the characteristic of the verb, that which constitutes it what it is, and cannot be expressed by other words, must be that which is signified by the word *is*; and to us that appears to be neither more nor less than *assertion*."

"Assertion therefore, or predication, is certainly the very essence of the verb, as being that part of its office, and that part only, which cannot be discharged by other kinds of words. Every other circumstance which the verb includes, such as *attribute*, *mode*, *time*, &c. it may be possible to express by adjectives, participles, and adverbs; but without a verb it is impossible to *predicate*, to *affirm*, or *deny*."

any one thing of any other thing. The office of the verb, when stripped of all accidental circumstances, seems to be merely this: to join together the subject and predicate of a proposition; its powers are analogous to those of the sign + in algebra, which does not affect the separate value of the quantities between which it is placed, but only indicates their union or coalescence." The writer then, in illustration of this theory, takes the examples used by Mr. Harris, and then adds, "in resolving every verb, whether active, passive, or neuter, into the substantive verb *is*, and another attributive, we have the honour to agree with all the grammarians."

We respect the opinion of other grammarians, and that of this writer in particular, but we cannot think it an honour to agree with him and his predecessors on this subject; but we rather think it an honour to differ with them, because we conceive them to be in an error. Now the most sure way to ascertain the characteristic of a verb; or that which constitutes its essence, is to attend to that operation of the human mind by which verbs have been formed. But as the affirmative *is* is thought essential to all others, we shall begin with this. And Mr. Harris thus explains it, p 88, "Previous to every possible attribute, whatever a thing may be, whether black or white, square or round, wife or cloquent, writing or thinking, it must first of necessity exist, before it can possibly be any thing else. For existence may be considered as an *universal genus*, to which all things, of all kinds, are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being essential to the very being of every proposition, in which they may still be found either expressed or by implication; expressed, as when we say "the sun is bright;" by implication, as when we say "the sun rises;" which means, when resolved, "the sun is rising."

According to this explanation *existence* is the primary idea of *is*; and Mr. Harris is little consistent with himself when, in resolving active verbs into this and another attributive, he supposes it to mean *assertion*. But let us deduce a more adequate idea of it from examples—*God is good; His food was locusts and wild honey; If we be virtuous we shall be happy.* In the first of these examples *is* connects *good* with *God*; so in the second *was* connects *locusts and wild honey* with *food*, and asserts, that with regard to John they were the same. In the third instance, *happy* is, by *shall be*, represented a quality of *we*. For this reason the following terms would be more appropriate than any other. The leading noun the *subject*, the thing connected the *predicate*, and the verb connecting them the *connecting verb*. Thus, *God* is the subject, *is* the connecting verb, and *good* the predicate; and so in all other instances.

If then *is* be the characteristic or essential idea of every verb, and if farther, as appears from fact, the primary idea of *is* denotes *connection*, it follows that not *assertion*, as the grammarians have hitherto supposed, but *connection*, is that which constitutes verbs, or that which distinguishes them from other species of words. But the connecting verb itself will not appear necessary, if we judge of its use in the ancient languages, the juxtaposition of the subject and predicate being sufficient to supply its place. Thus *μακαριος ει ελεημονη*; *blest the merciful*. Here *μακαριος*, being placed by the side of *ει ελεημονη*, suggests that it belongs to it, and by virtue of this suggestion conveys to the mind as full and complete a proposition as though the connecting verb had been inserted. Thus too in Latin, *Homo precipuum opus Dei*, man the principal work of God, meaning man is the principal work of God. Thus also in Hebrew, "And Moses said unto the Lord, I not eloquent, *i. e.* I am not eloquent, Exod. iv. 10. And Moses

said unto God, who I, that I should go unto Pharaoh; and God said, certainly I will be with thee, and this token unto thee, *i. e.* this *shall be* a token unto thee," iii. 11, 12. In this tongue, indeed, the substantive verb is comparatively of rare occurrence, and its place is supplied by the collocation of the terms to be connected, a principle in itself extremely simple, and suggested by the great law of the human mind. In Greek and in Latin its use indeed is more frequent; and it is remarkable that where it does occur, it generally occurs either in the beginning or the end of the clause, and not in the middle, a circumstance which arose from a desire of keeping together words that are related as subject and predicate. Now Mr. Harris and other grammarians, overlooking the force of juxtaposition, and judging of the importance of the substantive verb from its frequent use in modern speech, have hence supposed that it is absolutely necessary to the existence of language, and that no proposition can be communicated without it. And what is more remarkable still, "they have represented a word as essential to a verb, which, so far from being necessary to a verb, is not necessary even to language."

Verbs express the operations or the active qualities of things; and as the growth of words corresponds to the growth of our ideas, it follows that verbs originally were the names of things; but by combining them with the personal pronouns, they became, in consequence of the association of ideas, to express not things, but their operations.

The conversion of nouns into verbs we will illustrate by an example in the Greek tongue, Mr. Jones, in his Grammar of that language, has shewn that the personal terminations of the Greek verbs are but corruptions of the personal pronouns, and all the variations of mood, tense, number, and persons have originated in these six elementary principles, thus:

εγω	ω, I,	ημεις	ομεν, we,
συ	ει, thou,	υμεις	εστε, ye,
ου	ει, he,	ουτοι	ουσι, they.

Now let these in their corrupted state be annexed to any noun, for instance to *οινο-ς*, wine; and we shall have *οινο-ω*, wine I; *οινο-ει*, wine thou; *οινο-ει*, wine he; *οινο-ομεν*, wine we; *οινο-εστε*, wine ye; *οινο-ουσι*, wine they. When the attention of the speaker or hearer was fixed on the first of these combinations, the union of the two words which signified *himself* and *wine* could not fail of bringing to his mind the circumstances which he had *previously experienced or observed* in regard to that liquid; and hence he necessarily recalled the idea of *making or tasting wine, or drinking wine*. Consequently, the two terms thus combined he naturally employed to express one of those notions. A similar process took place with regard to the remaining five combinations. And thus have we in Greek, and other languages, verbs diversified by *six persons*. This extension of the names of things to signify the actions which those things have been observed to perform, is, it is obvious, founded on the law of association, and may be illustrated by many instances in all languages. But the principle is not so clear in any tongue as it is in Hebrew, where the personal pronouns annexed to the verb are preferred with little variation from what they are in their independent state.

In the above, and similar other examples, the agent, and that which is the effect or object of the action, combine to express that action; but in other instances, the name of the agent alone is sufficient to express its operation. Thus, "the ladies *fan* themselves;" "the plummy people *eye* the falling verdure." Now having previously observed the use or action of the *fan*, and learnt in ourselves the *effect* of the eye, being also previously aware that in a simple direct proposition,

position, the second usually denotes operation, we should immediately infer that *fan* and *eye* here express not the things meant by them but their active qualities; in other words, our previous associations would instantly convert those nouns into verbs, though we had never seen them so used before.

From this account of the deduction of verbs from nouns and pronouns, we may ascertain their nature and properties. A verb is a word borrowed from a thing to express the action of that thing. It implies *connection*, the connection of an agent and its object, or more generally the connection of cause and its effect. But this connection is not expressed by an independent word but by the juxtaposition, or the combination into one word of the agent and its object. On the other hand, it does not imply *affirmation* or *assertion*, as grammarians have hitherto supposed, because no word expressive of this enters into its composition. The operation of a verb is indeed positive; and therefore that implication which writers on this subject call *assertion* may be considered to belong to it, but this is rather an inference formed by the mind than a property inherent in the verb; and is confined to a certain mood or form of it. We understand the *indicative* to assert, but this assertion is lost in the *imperative*, *subjunctive*, and *infinitive*. So that if *assertion* be essential to a verb, a verb ceases to be a verb in these moods.

A verb implying an abstract idea, and therefore often indefinite and obscure, may be ascertained in regard to its meaning by recurring to the noun from whence it has been derived. This noun, which probably is the name of some sensible object, suggests its *primary sense*, a circumstance of great importance in the construction of a *philosophical dictionary*, a work existing in no language, and much wanted in every language. "The most necessary verbs," says Dr. Crombie in his English grammar, p. 81. in every language, are those, the signification of which is the most extensive, and which would originally be of most general use, such as verbs denoting existence, possession, acting and being acted upon. Of this kind in our language, are the verbs *to be*, *to do*, *to have*."

We will take these, which this grammarian has cited, as examples to illustrate our theory. In the Great Indian language, *baa-o* is *air*, and *air* is the medium of existence; it gave birth to the verbs of *being* in most languages. Hence *bodan* in Persian; *be* in Anglo-Saxon and English; *βίωω* in Greek, and the digammated *vivo* in Latin, and *bwoy* in Celtic. On the same principle the Hebrew אָוֵר, *awer*, *light*, *air*, is the parent of our words *are*, *were*, *was*, and of the Latin *ero*, *eram*. *To do* is to put forth power: and this, with other verbs of the same kind, are borrowed from such objects as put forth their fruits, such as herbs, trees, the earth. Thus, *πρωι*, the *grass*, gave birth to *πρωω*, *to produce*. Hence such phrases as *πρωω ακακρω*, *to produce fruit*; *δενς*, is the *oak*; and hence *δενω*, *to bring forth as the oak*; *βεεω*, the *beech*, hence *facio*, *to yield fruit as the beech*; פָּרַח, *pharag*, means *a flower*; hence *פָּרַח* or *פָּרַח*, *to effloresce* or *fructify*. In Chaldee אָרַק, *aruk*, is the *earth*; hence in Greek *εργω*, *εργω*, and our verb *work*. In the same way *δω*, *do*, *to give*, *yield*, is the real source of the English *to do*.

Now, it is very evident that the principle which converted one of these nouns into a verb, is that which converts all other nouns into verbs. If this be the case, Dr. Crombie and other followers of Mr. Horne Tooke are mistaken, when they supposed that the junction of one of these verbs to a noun, caused that noun in process of time to assume the character of a verb. And here we may observe that an infinitive verb, as separated from its agent or subject, is in reality an *abstract noun*. In this state the preposition *to* is prefixed to it, and its use is to be ascertained from its etymology. In Ara-

bic אָרַק is a verb which signifies motion to a place or object. Hence in Celtic (*atto*, it) became a preposition denoting an *end*, or the point to which motion tended. In passing to Persia it dropped the initial vowel, and in the form of *taa* it denotes, in Persian, the interval in which motion reaches its object, or that object itself, and thus became the parent of our *to*, which it perfectly resembles in sound and sense. *To* then denotes that point of time or place to which motion or action tends, and in which it terminates; and prefixed to an infinitive verb, thus converted by abstraction into a species of verbal nouns, holds it forth as the object to which the preceding verb is directed; thus, *I desire to learn*, *I desire*, and the object or end of that desire is *learn* or *learning*. He commanded me to tell you, he commanded, and the object which that command respects, is, that I should tell you. This explanation appears just, from the circumstance that when the infinitive verb is the immediate subject of action rather than a more remote object to which an action tends, the preposition *to* is dropped; as *I do plow*, *i. e.* I use the plough, or act the plough.

Let us next see what Mr. Tooke says on this subject. "The preposition *to*," says he, vol. i. p. 350, "is the Gothic substantive *taui*, or *taubts*, *i. e.* *act*, *efficit*, *reficit*, *consummat*. Which Gothic substantive is, indeed, itself no other than the first participle *tauid*, or *tauids*, of the verb *taugan*, *agere*. And what is done is *terminated*, *ended*, *finished*. After this derivation, it will not appear in the least mysterious or wonderful that we should, in a peculiar manner in English, prefix this same word *to* to the infinitive of our verbs. For the verbs in English not being distinguished, as in other languages, by a peculiar termination, and it being sometimes impossible to distinguish them by their place, when the old termination of the Anglo-Saxon verbs was dropped, this word *to*, *i. e.* *act*, became necessary to be prefixed, in order to distinguish them from nouns, and to invest them with the verbal character. For there is no difference between the noun *love*, and the verb *to love*, but what must be comprized in the prefix *to*." And he goes on, p. 355, "*Do*, the auxiliary verb, as it has been called, is derived from the same root, and is, indeed, the same word as *to*. The difference between a *t* and a *d* is so very small, that an etymologist knows by the practice of languages, and an anatomist by reason of that practice, that, in the derivation of words, it is scarce worth regarding. And, for the same reason that *to* is put before the infinitive, *do* used formerly to be put before such other parts of the verb which likewise were not distinguished from the noun by termination. As we still say—I do love, instead of I love. And *I do'd*, or *did* love, instead of I loved. But it is worth our while to observe, that if a distinguishing termination is used, then the distinguishing *do* or *did* must be omitted, the termination fulfilling its office. And, therefore, we never find—I *did* loved, or he *doth* loveth. But I did love, *he doth* love."

It is necessary briefly to expose what we conceive to be the fallacy and absurdity of this reasoning. *To*, in sound and sense, is the farthest possible from the Gothic *taugan*, which is only the Greek *τεταω*, *to fabricate*, the true origin of *to* being the Persian *taa*, which has precisely the same meaning with it. It is altogether unnecessary to prefix the *to*, in order to distinguish the verb from its corresponding noun, because this is done by the context, or the collocation of the verb; and what is most remarkable, when *to* is prefixed, the verb loses its verbal character, and becomes a noun by abstraction. That an infinitive verb has the nature of an abstract noun, is manifest from this. In all languages it may be made the subject or object of discourse; and, in Greek, it admits of the article before it, as nouns do; and in all instances what-

ever, an abstract noun, where such exists, may be substituted for it.—I desire to learn, *i. e.* I desire learning.—To excel in learning is honourable, *i. e.* excellence in learning is honourable. So then, according to Mr. Tooke, *to* is put before a verb to distinguish it as a verb when it has ceased to be a verb—when, from a verb, it is become a noun. And the reason why we say *he doth love*, instead of *he doth loveth*, is not that the termination supplies the place of *to*, but because *loveth* and *love* are one a verb, the other a noun, which last does not admit such a termination.

The conversion of *to* into *do*, so as to become a verbal index, is a conceit of this writer, equally unwarrantable. *Do*, as we have shewn, is the identical Latin *do, to give, to place, to produce, or put forth*, where it has such meaning, in the following phrase—*dare operam*, to put forth exertion, *i. e.* to exert, endeavour. And yet Mr. Tooke has been followed and supported by all subsequent grammarians in the above incorrect and inconclusive reasoning. “The form,” says Dr. Crombie, p. 83, “of the infinitive *to love*, is, doubtless, the same as *do love*, thus denoting the simple energy of the emotion, signified by the noun, *d* and *t* being kindred letters, and easily convertible. To love, therefore, means *ad love, do love*, the word *do* or *to* investing the noun with a sort of verbal character. The infinitive, then, expresses simply the action or energy of that attribute which is denoted by the verb, un-compounded with the various accidents of mood, tense, number, and person.” This last sentence is a just description of the infinitive mood which Dr. Lowth very properly calls the *substantive mood*; and it is a correct description of an abstract verbal noun. How then can *to* or *do* invest the noun with a sort of verbal character; when, if it be an index of any thing, it is an index of a verb changed into a noun? A respectable writer on grammar, in the New British Encyclopædia, p. 31, following the tract which Horne Tooke has pointed out, thus adds: “The infinitive mood, as it is commonly called, is the verb divested of its peculiar force, *viz.* of affirmation, and un-compounded with those words which render it expressive of person, number, &c. and in the modern languages of time: but it seems erroneous to consider this as the fundamental form of the verb, where it has any distinguishing termination; it is then the *noun state* of the word, with a termination added to it, to shew that it is to be employed as a verb. Thus, in the Anglo-Saxon *þeacn*, *the* is the fundamental form of the verb, and *an* is the *verbalizing adjunct*. Now, as the imperative form of the verb is nothing more or less than the simple verbal name, unattended with the inference of affirmation, this may be considered the fundamental form: and in the Latin in particular the variations of flexion are traced with the greatest advantage from this source.”

It is curious to observe the contradictions and absurdities into which writers plunge themselves, when they have adopted erroneous positions to account for the phenomena of language. Mr. Tooke, assenting to the ancient Stoics, thinks the purest state of the verb to be the infinitive, and yet agrees with his followers in making *affirmation* or *assertion* to be the essence of a verb. But it is allowed that a verb drops its affirmation in the infinitive; so that, according to this reasoning, a verb is in its purest state when without its essence. Again, the infinitive is here not improperly called the *noun state*, *i. e.* an abstract noun, with the prefix *to* in our tongue; but in the Anglo-Saxon with the affix *an*, to shew that it is a verb: and as this is a new idea, *an*, in a new language, is called the *verbalizing adjunct*. But what evidence is there for saying that *an* performs this office? No evidence at all, but a false assumption. We have already said that the Gothic and Anglo-Saxon *an* is but the Greek in-

finite *ων*, or (in verbs in *αα*), *α*, which is the same without the change of a letter. We have this further evidence of the derivation of the Northern language from the Greek, in this respect, that in this latter the imperative, instead of being the fundamental form of the verb, is, by corruption, derived from the infinitive. Thus, $\gamma\epsilon\gamma\alpha\tau\epsilon\upsilon$ was the old infinitive; $\gamma\epsilon\gamma\alpha\tau\epsilon\upsilon$ was also the imperative; but the final *ν* being, by degrees, dropped, it became $\gamma\epsilon\gamma\alpha\tau\epsilon$. And it is remarkable, that in the Anglo-Saxon the imperative is derived from the infinitive, in the same manner precisely as the imperative is from the infinitive in Greek; and this correspondence, added to the identity of the termination, we deem a sufficient proof that the Northern, in this respect, is no other than the Greek tongue. The Latin imperative is borrowed from the Greek, as is evident on inspection;— $\gamma\epsilon\gamma\alpha\tau\epsilon$; $\gamma\epsilon\gamma\alpha\tau\epsilon\upsilon$; *scribe, scribeto*. And the position, that the variations of inflexion may be traced with advantage from the Latin imperative, is a fancy, which is contradicted by that broad analogy by which the Latin verbs are formed from the present tense. It is worthy of remark, that the old Greek accords with the Hebrew, where the imperative is the same with the infinitive, and succeeds it in the paradigm of verbs. We shall only, on this subject, express our surprize that, if these sensible men were deceived by adopting the notions of Mr. Tooke, they were not repelled by what appear to us to be contradictions. This grammarian gravely tells us that deliberate art had no concern in the formation of language: yet, in examining its phenomena, he recurs to minute mechanism and petty artifices, which, as being unwilling to allow the agency of a rational law in the human mind, he calls the *contrivances of language*.

We now proceed to consider briefly the usual divisions of verbs into *active, passive, and neuter*: and this division of verbs we pronounce to be extremely unphilosophical. And first, as the expression of active qualities is essential to verbs, there is no such thing as a *neuter verb*. There are, indeed, verbs which denote *rest*, or the cessation of *motion*; but we cannot use even these without connecting with them positive ideas: and as action is necessary to destroy or support action, we can resolve all apparent neuter into active verbs. Thus *to stand*, is *to cause to stop*; *to sleep*, is *to enjoy repose*; *to sit*, is *to hold one's seat*. Secondly, the division of verbs into active and passive, though convenient in some languages, is incorrect and even absurd in our own tongue. For all active verbs imply passion; while all passive verbs on the other hand imply action. Hence the one may assume the form of the other without altering its nature. Thus, *ille amat parentes*, he loves his parents, is the same in sense as *parentes amantur ab illo*, his parents are loved by him. The only difference is that, in the first instance, the agent is nominative, and the object accusative: in the second, the object, becoming the subject of the verb, is put in the nominative, and the agent in the ablative. An agent, while it acts, is acted upon. Every active verb, therefore, has the compound sense of active and passive. Thus, in the above sentence, *he loves his parents*, the first part, *he loves*, is active; the last, *loves his parents*, is passive. In the same sentence, converted into the passive form, *his parents are loved by him*; the first part is passive, and the last active. In the infancy of language, the distinction of active and passive was in all probability not known. In Hebrew, the difference but imperfectly exists, and in the early periods of it probably did not exist at all. In Arabic, the only distinction which obtains, arises from the vowel points, a late invention, compared with the antiquity of that language. And in our own tongue the names of active and passive would have been unknown, if they had not been imported from the Greek and Latin

Latin grammars. In English the passive form of the verb is expressed by the connecting verb *to be*, and the perfect participle; and in converting an active into a passive proposition, we need only change the verb to its perfect participle, and subjoin it to the connecting verb in the same mood and tense, and annexing the agent with its correspondent preposition in the ablative case. Thus, we worship God, becomes *God is worshipped by us*. Hence it appears that verbs which are transitively active can be made passive, because they have an object, which, in the passive form, is made the subject of discourse; and that verbs intransitively active cannot have a passive form, because they have no object.

The passive voice, in all languages, is expressed by the connecting verb, and the perfect participle for its predicate; and it is curious to observe, that this combination is its origin in the Greek tongue, the subject of discourse being combined with the personal pronouns in the dative case. Thus, οἶκος μοι, *house for me*, which do not, as before, coalesce as a subject with an agent; but as a subject with the person to whom it belongs, and for whom it was intended. Hence their combination came to convey the idea *I am housed, I am built*: for the auxiliary *am* serves only to assert that *housed* or *built* belongs to the pronoun preceding it, and to cement their union in the mind as subject and predicate. In the same manner, if σὺ, τοι, be annexed to the word οἶκος, we have οἶκος σοι, οἶκος τῷ, *house for thee, house for him*. And these contractions, by slight changes, became οἰκίζομαι, οἰκίζῃσαι, οἰκίζῃται, *I am built, thou art built, he is built*.

A verb, if its operation pass over to another thing, or if it have an object to express the effect of that operation, may be called *transitive*; but if its influence do not pass over, or if it have no object, it is *intransitive*. Verbs, on the other hand, not expressing action, but *being, positure, continuance*, and serving to associate two things, as a subject and predicate, may with propriety be called *connecting* verbs. Of this class is *am*, with all its branches, or the corresponding verbs in Latin and Greek. And here it is proper to observe that verbs of motion came in all languages to signify *continuance, positure*, and the like, because we can measure *duration*, or even *rest*, and privation of motion, only by ideas consequent on motion. Thus, in our own tongue, "a diligent boy will become a learned man." "By thee disposed into congenial soil, stands each attractive plant," *i. e. is disposed*. So in Latin, "Quam placidum ventis flaret mare," when the sea stood (*i. e. was continued*) tranquil from the winds. Veniet lenior, she will come milder, *i. e. will be or become milder*. Vixisset inmundus sus, he would have lived, *i. e. he would have become a filthy pig*. Ego incedo regina, I walk a queen, *i. e. I am a queen*. Theocritus, speaking of the irascibility of *Pan*, writes καὶ ἐν αὐτῷ δριμύτη χόλα ποτὶ μῦν καθύεται, *keen anger always sits in his nose, i. e. the breath of anger always continues in his nostrils, or, he is ever irascible*. On this principle it is that εἶμι, in Greek, as implying continuance or positure, came to have the sense of *am*—εὖλας εἶμι, *I am well*; and that εἶ, *I am*, and ἵμι, *I go*, were originally the same. And in Latin *eaco* became, for a similar reason, into *esco*, which occurs in Lucretius in the sense of *est*. From *exire* the Italians have derived *uscire*, to go out, end, and *uscio*, *exitus*, a door, or avenue. Hence we have derived to *usher*. The Italian *stato*, *been*, owes its derivation from *sto*, to the same mode of thinking. All verbs, then, are either transitive or intransitive, or connecting verbs. And this division appears to us obvious, useful, and philosophical.

The properties of verbs are mood, tense, number, and person. On these properties, as they are discussed in all grammars, (see L. Murray's valuable Grammar of the English Tongue; Dr. Crombie on Etymology and Syntax;

Dr. Priestley's Philosophical Grammar, and particularly Mr. Pickbourn's excellent Dissertation on the English Verb,) we shall content ourselves with a few observations. Mr. Tooke, vol. ii. 473, says that mood, tense, number and person are no parts of the verb. But this opinion will appear to be erroneous, if we reflect on the manner in which verbs are derived from nouns. For the personal pronouns in each number enter into the composition of a verb in the ancient languages, where it is distinguished by personal termination; though we acknowledge the assertion to be just in English, where the verb is known only from the annexed pronoun, or its connection with the agent and object. Again, if we reflect on a verb in its formation, we perceive it to contain an idea, the result of observation and experience, which, as *pass*, is *certain, absolute, and unconditional*. This certain, absolute, and unconditional form is essential to the verb, and it constitutes that *mode or manner* called the indicative mood. As the indicative mood respects the past time; so the subjunctive, in respect to it, regards the future. And as all future events, at least with respect to man, are *uncertain, relative, and conditional*, all verbs, expressing an uncertain, relative, or conditional sense, are in the *subjunctive*, so called from its being *subjoined* to a verb in the indicative. All verbs, moreover, expressing an *end or intention*, as being from their nature uncertain, are used in the subjunctive; and for this reason it might be called the *final mood*. In this view it has a close affinity to the *infinitive*, which, as we have already observed, is only an abstract noun with the preposition *to*, denoting the end or object to which the preceding verb is directed. Accordingly, they may be substituted one for the other, in all instances. Thus, *I desire to learn*; I desire, the object of my desire being learning; I desire that I should learn; I desire, *that* being my end, I should learn. Hence it follows that the subjunctive mood is not essential to language, and for this reason it does not exist in Hebrew and some other tongues. As a command is necessarily given in the time *now*, the imperative has no tense but the present, nor can it, in strict propriety, have a first person, singular or plural; because it would be absurd in a person to command himself. *Let me love*, then, is not the *first* but the *second* person, as may appear by substituting *permit* for its equivalent *let*, *Permit thou me to love*.

Finally, if we reflect on the verb in its element, we shall find that *time past* is essential to it, because the conversion of a noun and the annexed pronoun into a verb is in consequence of past experience or observation. But as present feeling or consciousness coalesce with our reflection on the past, the verb, which owes its existence to the past, comes to signify also the present. And this is the reason why in Hebrew, the most ancient language, the same form of the verb expresses the past and the present time; and this, too, appears to be the reason why in English and all other languages a verb in the present tense is often used, in an extended sense, to comprehend all time, present and past. As, *the sun rises every day; birds fly; truth is always one*. In these and similar instances no reference is made to the *future*; unless the future, by association, insensibly in our minds coalesce with the past. But men soon became sensible of the necessity of limiting the verb in regard to time. They soon acquired a distinct notion of the three divisions of time into present, past, and future; and in order to vary the terminations of the verb, so as to correspond to these divisions, nothing more was necessary than to follow the impulse of association acting on accidental corruptions. Hence the origin of tenses, which, as the word implies, are the *extension* of the verb by distinguishing terminations to express the divisions of time. And here we cannot help observing, how improper it is to call tenses,

and similar contrivances, *abbreviations*, (as is done by Mr. Tooke,) a name, the very reverse of what a tense purports to be. The formation of the tenses in Hebrew is worthy of attention, and shews that the human mind, under the influence of a rational law, without perhaps the express exertion of reason, may produce a contrivance for its beauty and simplicity truly admirable. In that language the distinguishing termination is the personal pronoun, annexed or prefixed. Now, suppose תי, *ti*, a fragment of the first personal pronoun, to mean *I*. It will also become a natural index of the time now, whenever the speaker uses it in connection with a verb, because he measures the present moment by the use of it, or by reflecting on himself when using it. This being the case, a verb preceding תי will be a past verb, by pointing, as it were, the attention backward, as *Pegod-ti, visited I, or I visited*; while a verb succeeding the same particle expresses the future time: the pronoun, being the index of the present time, points now the attention forward, as *ti-pegod, I visit, (meaning I will visit)*. But for *tia*, the other fragment of the personal pronoun, is used *apegod*. In modern languages which have no distinguishing terminations, the notification of time future is but an inference drawn from verbs of volition or desire, in consequence of the constant association of the object of that volition or desire with time to come: as *I will learn*, which meant, at first, *I am resolved to learn*, and then the time when the resolution is to be performed. Thus *shall* and *will*, which are the Hebrew שאל, *shaal*, and the Greek βουλω, *volo*, in a secondary sense become indices of time to come. It is here of importance to remark, that though *shall, will*, with *do, may, have, &c.* are called auxiliaries, they are still leading verbs, and govern those, which they are supposed to subserve, in the infinitive mood.

The Greek has been represented as very like the Shanferit; but in truth, the old *Aeolic* dialect, whence the Latin is derived, claims a much closer affinity with the great Indian language; and in that dialect of it which is spoken in Bengal, the mark of the future tense is *bo*. Thus *hoibo, I shall be*, is the future of *hona*; just so is the Latin *amabo*, the future of *amo*; *abo* being originally *awo*, a form of the verb denoting *causative*, and thence *succession*, or transition in regard to time. Mr. Tooke, indeed, in his usual manner, supposes *amabo* to be an abbreviation of *amaboule, amaboul, amabo*, see vol. ii. 434. But the primary sense of βουλω is *to will, or deliberate*; and upon the same principle that this verb became an index of future time, any other verb or form of a verb would be made an index of it by associating its object with futurity. The ideas which this grammarian had of language are altogether mechanical; and by rejecting the principle of mind, while continually hunting after blind mechanism, he seems to us not to have sustained the character of a philosopher in explaining its phenomena.

The Origin and Properties of Participles.

Mr. Harris's account of participles is as follows: Every complete verb is expressive of an *attribute of time*, and of an *assertion*. Now if we take away the assertion, and thus destroy the verb, there will remain the attribute and the time, which make the essence of a *participle*, p. 184. This statement has conciseness and simplicity to recommend it, though we do not regard it as correct. Mr. Tooke gives us the following account of participles. "This sort of word is by no means the same with a *noun adjective*. The participle has all that a noun adjective has; and for the same reason, *viz.* for the purpose of *adjection*. But it has likewise something more than a noun adjective has; because the *verb* has some-

thing more than the noun. And that something more (as Perizonius proceeds to assert) is not only the adsignification of time, for every verb has a signification of its own, distinct from *manner* and *time*. And language has as much occasion to *adjective* the distinct signification of the verb, and to adjective also the *mood*, as it has to adjective the time. And it has, therefore, *adjectived* all three—the distinct signification of the simple verb, and the verb with its moods, and the verb with its tenses. I shall at present notice only six of these verb-adjectives, which we now employ in English, *viz.* the simple verb, itself adjective; two adjective tenses, and three adjective-moods.

"We had formerly in English only the simple *verb-adjective*, and the past tense adjective. In addition to these two, we have now the convenience of four others, which I must call the *potential mood active adjective*; the *potential mood passive adjective*; the *official mood passive adjective*; and the *future tense active adjective*. As the noun adjective always signifies *all* that the unadjectived noun signifies, and no more, except the circumstances of adjection; so must the verb adjective signify *all* that the unadjectived verb signifies, and no more, except the circumstance of adjection. But it has been usual to suppose, that with the indicative mood, as it is called, is conjoined also the signification of the present time, and, therefore, to call it the indicative mood present tense. And if it were so, then indeed the word we are considering, besides the signification of the verb, must likewise adsignify some manner and the present time; for it would be then the present tense adjective as well as the indicative mood adjective. But I deny it to be either. I deny that the present time, or any time, or any *manner*, is signified by that which is called improperly the indicative mood present tense. And, therefore, its proper name is merely the verb—*indicative*, if you please, *i. e.* *indicative* of being merely a verb."

Our readers, we are sure, will not be able to peruse this account without surprise; and we shall endeavour to set it aside by a more simple and rational account of the participle. The *present participle* denotes the operation of a verb without regard to any agent; the *perfect participle* denotes the state, power, or habit, generated by that operation in a person or thing which is the object of it. If this statement be just, the participle in its genuine state is rather a verbal *noun* than a verbal *adjective*, and has a close affinity to the infinitive mood. Hence, we can account for the origin and use of the participle. The Hebrew, and more especially the Arabic, form their verbal nouns by what is called *nunation*, or the syllable *on* added to the verb; and this is the Greek participle in *ov*, which the Latins have converted into *ens*; but which we, by giving *n* a nasal sound, have corrupted into *ing*.

As the participle is a verbal noun, we see the reason why in all languages it is either used as a noun, or gives birth to various classes of abstract nouns. The present participle, as expressing an operation, naturally coalesces with an agent, and this is the reason why in Hebrew, in Greek, and sometimes in Latin, it denotes a doer, or a person who acts; as *ὁ γράφων, he writing, the writer*; *ὁ ἀμῶν, he loving, the lover*. From its facility to coalesce with a noun, the participle loses its nominal character, and becomes an *adjective*; and as it denotes an active quality, or a power in energy, it forms, with the connecting verb *to be*, the three active compound tenses—*I am writing—he was writing—they shall be writing*.

Farther, as all operations are in *time*, and we acquire the idea of time present by reflecting on successive operations, the present participle implies *time* unlimited, and in its associated

ciated effect *time present*, i. e. time present, not absolute, but *relative*. Thus, *I am writing*, i. e. I am *now* writing; I was writing, i. e. I was writing *at the time then* present. And, in general, the participle is defined by the concomitant verb in the sentence which may be either present, past, or future. If the verb be past, it marks the past time as then present; if future, it marks the future as hereafter present. And thus is refuted the opinion of Mr. Tooke, that there is no *adsignation of time* in the present participle. But as he may pronounce this argument a mere evasion, I will illustrate it by a parallel instance in Greek. The subjunctive verb *τοῦτο, τοῦτε, &c.* is thought to be the *first aorist*; but it is really the *first future*, and this is proved by its signification as well as by analogy, for in all instances this expresses a *future* time, not indeed absolutely so, but future in regard to another verb connected with it in the sentence. For example, "and they asked him, saying, if it be lawful to heal on the sabbath-day, that they might accuse him," *ἵνα κατηγορήσουσιν*. To accuse him was their end in asking, and in regard to that act was *future*, though now long past. Finally, things which act in consequence of acting, acquire a *disposition* to act, just as bodies when moved have a tendency to move. Repetition, moreover, imparts to the acting quality additional strength, protension, and permanence. To express it with the propensity and vigour thus attained by use the participial termination *ων* in Greek is added to a noun or to an adjective, which, as receiving an additional meaning, is called an *augmentative*. Thus, *εἰςων*, *speaking*, means also one who is prone to speak, which is the character of the scolder or dissembler; *απατων*, *deceiving*, one given to deception, a great deceiver; *κλιος; κλιων*, *more wicked, increasing in wickedness*. And from this the Italians have derived one way of augmenting their nouns. Hence, our *saloon*, (a great hall), *balloon*, and, perhaps, *postroom*, the augmentative of *paltry*.

The perfect, or past participle, is certainly derived, as Mr. Tooke represents, from the past tense.—*Amavit, amavitus, amatus*;—*docuit, docuitus, doctus*;—*legit, legitus, lectus*;—*audivit, audivitus, auditus*. *Us*, which is the Greek *ος*, is added to the third person as the analogical termination of nouns, to shew that the verb is now abstracted into a verbal noun, denoting the effect of the action. Accordingly *amatus, doctus, lectus, auditus*, and the like, are every one either abstract nouns of the fourth declension, or verbal adjectives coalescing with another noun. And here we shall quote a passage from the *Encyclopædia Britannica*, (p. 86.) to shew into what errors grammarians have fallen, by not having attended to the *nominal character* of the participle: "From these observations and examples," says the writer, "we shall be able to understand the two uses of the adjective. It is either employed to *restrict* or *modify* a *general term*; or the abstract substantive contained in the adjective is modified by the noun with which, in the concrete or adjective form, that abstract substantive is joined. The first may be called the *direct*, the second the *inverse* acceptance of adjectives. Livy, speaking of the abolition of the regal authority at Rome, says; "Regnatum est Romæ ab urbe *condita* ad *liberatam* annos ducentos quadraginta quatuor:" Monarchy subsisted at Rome, *not* from the city built (which would convey no meaning,) but *from the building* of the city, to its deliverance. Both the participles *condita* and *liberatam* are here used inversely, i. e. the abstract substantives contained in *condita* and *liberatam* are modified and restricted by the substantives *urbe* and *urbem*, with which they unite. Again, Ovid, speaking of the contest between Ajax and Ulysses for the arms of Achilles, has these lines:

"Qui licet eloquio fidum quoque Nestora vincat
Haud tamen efficiet, desertum ut Nestora crimen
Nullum esse reor."

Here also the adjective or participle *desertum* is taken inversely, and the general notion of *desertion* contained in it is modified or rendered particular, by being joined with the substantive *Nestora*. The meaning of the passage is, "I will never be induced to believe, that the desertion of Nestor was not a crime." Were *desertum* to be taken directly as an adjective, modifying its substantive, the sentence must be translated, "I cannot believe that Nestor deserted was not a crime." But it is evident that this is nonsense; as Nestor, whether deserted or not deserted, could not be a crime."

This writer was led by Mr. H. Tooke to consider every adjective as a noun in its nature: he then makes a discovery in which he seemingly blames himself, which is this: instead of the adjective qualifying its noun; the noun inversely qualifies its adjective! This able writer would not have used this language, if he had trusted to his own understanding, and had not allowed himself to be misled by his guide. The participles *condita* and *liberatam*, though they here coalesce with another noun, still retain their original character of a substantive, and the historian has apprized his readers of this character by the *collocation*, where *condita* is rendered prominent and emphatic by succeeding the qualified *urbe*. The same observation applies to *desertum Nestora*, which is equivalent to *desertionem Nestoris*.

As the past participle expresses the effect of an operation, it has been called the *passive participle*; but when the subject of an operation is a moral agent, that effect is *habit*, or a voluntary principle of action. And thus it is, that the perfect participle often expresses or implies action; as, *admiratus, having admired*; *locutus, having spoken*. Sometimes in Greek and Latin it conveys a reflex sense; as, *stratus membra, having prostrated his limbs*; *πιστευωμενος, αγγειωμενος, having the gospel entrusted to me*. And lastly, as the perfect participle is derived from a past verb, and, as it signifies an effect already produced, it points to time past; nevertheless, as that effect is a habit or power capable of action, it implies time present, and thus the past participle, comprehending both times, answers to the denomination of *perfect present*.

The Origin and Properties of Prepositions.

Mr. Harris defines a preposition to be a part of speech, devoid itself of signification, but so formed, as to unite two words that are significant, and refuse to coalesce or unite of themselves. This definition is undoubtedly erroneous, and has been justly censured by Mr. H. Tooke. We venture, however, to affirm, that the account given by the last-mentioned writer, is by no means such as a philosopher, who accurately understood his subject, would give of prepositions. "As the necessity, says he, vol. i. p. 319. of the article, or of some equivalent, follows from the impossibility of having in language a distinct name or *particular term* for each particular individual idea; so does the necessity of the *preposition*, (or of some equivalent invention) follow from the impossibility of having in language a distinct complex term for each different *collection of ideas*, which we may have occasion to put together in discourse. The addition or subtraction of any one idea, to or from a collection, makes it a different collection: and if there were degrees of impossibility, it is still more impossible to use in language a different and distinct complex term for each different and distinct collection of ideas, than it is to use a distinct particular term for each particular and individual idea. To supply, therefore, the place of the complex terms which are wanting in a language, is the preposition employ-

ed, by whose aid complex terms are prevented from being infinite or too numerous, and are used only for those collections of ideas which we have most frequently occasion to mention in discourse. And this is obtained in the most simple manner in the world. For having occasion, in communication, to mention a collection of ideas, for which there is no one single complex term in the language, we either take that complex term which includes the greatest number, though not *all* of the ideas we would communicate, or else we take that complex term which includes all, and the fewest *more* than those we would communicate; and then, by the help of the preposition, we either make up the deficiency in the one case, or retrench the superfluity in the other. For instance, "A house *with* a party wall," "A house *without* a party wall." In the first instance, the complex term is deficient. The preposition directs to add what is wanting. In the second instance, the complex term is redundant. The preposition directs to take away what is wanting."

Now this statement appears to us to be more properly descriptive of *conjunctions* than of prepositions, it being made altogether in reference to *with*, which has, in the above instance, only a *conjunctive* sense; as, a house *and* a party wall, *i. e.* a house *add* a party wall, or, as Mr. Tooke explains, *with* a house *join* a party wall. The following we deem a more full representation. Prepositions express the relations of things; and, as our ideas of relations are associated effects, arising from our ideas of things, so the words expressing relations are borrowed from the things related, that is, prepositions originated in nouns and verbs. But we have seen, that the relations of things are also expressed by *cases*. Cases, therefore, and prepositions, have the same meaning; the former, indeed, being no other than the latter combining with nouns, and thus giving them different terminations, bearing distinct senses. The three leading relations we have farther seen expressed by cases, are *beginning*, *instrument* or *medium*, and *end*. Those prepositions, then, which signify *beginning*, require the noun succeeding them to be in the *original* state or position, or, agreeably to the usual language, govern the *genitive* case. Those signifying *instrument* or *medium* govern their dependent nouns in the *instrumental* or *medial*, or, as it is commonly called, the *ablative* case; while those denoting the object or end to which an action or motion relates, to which it tends, and in which it terminates, have their governed nouns in the *final* or *dative* case.

We now proceed to ascertain the meaning of the leading prepositions, by deducing them from their origin. And we shall find that Mr. Tooke, as his ideas are unsatisfactory and unappropriate in regard to the use of prepositions, is mistaken in almost every instance, in respect to the sources in which they originated. And here we must premise, that our ideas of beginning, medium, and end, are so palpable and distinct, and so essential to distinctness in our other conceptions, that they are nearly *coeval* with our ideas of things and of motions; and consequently must have existed in the language of men, as soon as it reached a form deserving of that name. And as we maintain, that all the varieties of human speech which now exist, or have ever existed, are but branches propagated by various causes, (like the human race itself,) from a few parental stems in the one primeval language of mankind; so we maintain, that most prepositions in different languages, are but the same original words, differently corrupted, agreeably to the genius of the people who borrowed them from their ancestors; and that the English prepositions, in particular, are antecedent to Anglo-Saxon and Gothic corruptions, or, as Mr. Tooke would say, *abbreviations*, and originated in oriental words, derived in many instances through the medium of Greek and Latin. The derivation of the con-

junctions and prepositions is, indeed, the most specious part of Mr. Tooke's system; and not only in his own opinion, but in the opinion of the public, he lies so strongly fortified, that no adversary can dislodge him. We shall, however make an attempt for this purpose.

"I imagine, says he, p. 367, that *of* (in the Gothic and Anglo-Saxon *af*) is a fragment of the Gothic and Anglo-Saxon *afara* or *afora*, *posteritas*, *offspring*, that it is a noun substantive, and means always *consequence*, *offspring*, *succession*, or *follower*." Now as to *afora* it is nothing but the Greek $\alpha\phi\omicron\sigma\omicron\upsilon$, *produce*, from $\alpha\phi\epsilon\upsilon$, and the meaning of *of* is quite the reverse of *consequence*, &c. Thus, in the phrase *rays of the sun*, *of* points to the sun as the origin of rays. It means, therefore, *source*, *origin*, and its derivation is $\alpha\phi\epsilon\upsilon$, *ab*, root, stem, $\alpha\phi\epsilon\upsilon$, *ab*. The genitive case, which corresponds to *of*, further proves this, *Solis radii*, where *is*, annexed to *sol*, surely does not mean that the sun is a consequence of the rays, but that it is the origin of the rays. The source or cause of a thing is before that thing in the order of nature. Hence, according to the usual arrangement in Latin, the noun in the genitive is put *before* that which proceeded from it, and this is the reason why in English we always say *father's house*, (*father is house*;) and never *house father's*, having copied not only the genitive termination of the third declension, but also the collocation of the noun affected by it. Moreover, not *of* but *after* came from the Gothic *afara*, because this, meaning *offspring*, came also to denote *succession*, or that which comes after those who gave it birth. And in the Gothic it is used as a preposition signifying *past*, *after*, where the *t* is introduced to humour the pronunciation, as δ is inserted in $\alpha\phi\epsilon\upsilon\sigma\omicron\upsilon$ for $\alpha\phi\epsilon\upsilon\sigma\omicron\upsilon$, or $\alpha\phi\epsilon\upsilon\sigma\omicron\upsilon$.

As *of* means beginning, it has the same sense with *from*; which last Mr. Tooke derives from the Gothic and Anglo-Saxon *frum*, meaning *first*, *beginning*. This may be admitted. But whence did *frum* originate? The Latins, it is well known, converted the Greek termination ν into *m*. Thus the accusative ν became *im* or *em*; the genitive plural ω , *um*, and the neuter ending \omicron , is also *um* in Latin. On this principle $\pi\epsilon\upsilon\upsilon$ is the parent of *primus*. This last the Goths of Wallachia, where, as Michaelis observes, a Latin colony had been established, and whose language, after thus blending with the Latin, is the only specimen of the Gothic preserved in modern days, have borrowed and corrupted in the form of *frum*, which retains the original sense of *initium*, *principium*. But we are not yet arrived at the origin of the word. The Arabic $\mathfrak{P}\mathfrak{R}\mathfrak{S}$, *phra*, among other meanings, denotes *the head of a family*; which being rendered more general and abstract, gave birth to the Greek $\pi\epsilon\upsilon\upsilon$, $\pi\epsilon\upsilon\upsilon$, to the Latin *præ*, to *fra* in the Icelandic, Norse, Danish, Swedish, to *fry* in Frisch, and *fræ* in Scotch. And thus the Arabic origin of the word accounts for the different forms of *from*, *fra*, *fry*, *fræ*, in the Northern dialects, the first being derived through the medium of Greek and Latin; the others immediately from Asia. Mr. Tooke happens to be right in the meaning of *from*, merely because the Gothic corruption of *frum* has correctly retained the original sense of *primus*. He thus illustrates its signification. Figs came from Turkey; lamp falls from cieling; lamp hangs from cieling. Figs came, beginning Turkey, that is, Turkey the place of beginning to come. Lamp falls, beginning cieling; cieling the place of beginning to fall. Lamp hangs, beginning ceiling; ceiling the place of beginning to hang. This explanation is rational and just: but when he adds came is a complex term for one species of motion; falls is a complex term for another species of motion; hangs is a complex term for a species of attachment, though very true, this is nothing to the purpose. *Came*, *falls*, *hangs*, imply each motion or direction,

direction, and *from* points to the origin of the motion or direction in each, without any reference whatever to their peculiar meaning.

To the prepositions *of* and *from*, stand opposed *to*, *till*, and *for*. Mr. Tooke might, with equal propriety, derive *to* from his own name, as derive it from the Gothic *taugan*, to act, which is but the Greek *τεχνειν*, to fabricate. Equally absurd is it to say, that the Latin *ad* is from *adum*. The parent word, as we have seen, is the Arabic *اتا*, *ata*, to move to a thing. In Celtic, the word has preserved its original form (*atto*,) in the exact sense of *to*. But in Persian, losing the initial vowel, it became *taa*; whereas, in Latin, retaining the first and dropping the last, it exists under the form of *ad*, and in English under that of *at*. *To* and *at* have a signification corresponding to their kindred origin, the former denoting the object of motion, the latter coalescence with that object after its reaching it. "That *till* should be opposed to *from*, says he, only when we are talking of time, and upon no other occasion, is evident for this reason, *viz.* that *till* is a word compounded of *to* and *while*, *i. e.* time. And you will observe, that the coalescence of these two words *to*, *while*, took place in the language long before the present wanton and superfluous use of the article *the*, which, by the prevailing custom of modern speech, is now interposed. So that when we say, "From morn *till* night," it is no more than if we said, "From morn *to* *time* night." When we say, "From morn *to* night," the word *time* is omitted as unnecessary. So we might say, "From Turkey to the place called England, or to *place* England," p. 363. But *while*, or, as it is in the Anglo-Saxon, *hwile*, does not mean time but a *period*, or *revolution* of time, such as a day, week, &c. and is derived from the Hebrew *גול*, *gul* or *geel*, to revolve, and *year*, or, as our ancestors spelled it, *gear*, is derived from *גור*, *gure*, or in Greek *γυρον*. The Hebrew *geel* is also the parent of our *wheel*. *To* points to a final object either in place or time, while *till*, in strict propriety, is applied to time only, and is derived from *עלה*, *to rise*, and was at first expressive of the rising sun. Thus, "I will wait *till* morning," *i. e.* I will wait the rising morning. As *till* denotes time, rising, or alternation of time, the word is always understood to be followed by some change implied in the context, but never expressed: thus, "We are always insensible of a blessing, *till* (or *until*) we lose it," then, "we *are* sensible of it," is a clause implied. "They will slay *till* morning;" and they will then depart, is to be understood. *Till* exists in the Cimbric language, and this is an additional proof, that the uncouth composite to *while* is a mere fiction of Mr. Tooke.

Mr. Tooke takes *for* to signify *cause*, as opposed to *of*, signifying consequence, from the Gothic substantive *serina*, a *cause*, p. 367. He thus illustrates them, I am sick *of* my husband, and *for* my gallant. Love makes her sick *of* and lick *for*. Here *of* and *for* seem almost placed in opposition. At least their effects in the sentence are most evidently different: for by the help of these two prepositions alone, and without the assistance of any other words, she expresses the two contrary affections of loathing and desire. Her disgust was the offspring of her husband, proceeded from her husband. Her gallant was the *cause* of her love. But if her disgust proceeded from her husband, he was the *cause* of her disgust: and *of* and *for*, instead of being opposed to each other, as they certainly are, mean just the same thing, namely, *cause*, and not *cause* and *consequence*. But in truth, the matter is just the reverse of what our grammarian represents. *Of* means *cause* or *origin*, and *for* means *consequence* or *end*. She is sick *of* her husband—she is sick, her husband is the source of it—she is sick *for* her gallant, and the object to which she looks with desire is her gallant. Accord-

ingly, *for* always supposes the attention not directed *backwards*, as to the cause, but *forwards*, as to some end; and its etymology is this, *περα*, to pass over, *περ*, or *per*, the medium of passing to an object: the French *pour*, *for*, the object or end to which passage is made. Johnson gives *for* forty-six different meanings. But there is not one instance in which it does not bear a sense deducible from its primary signification of *end* or *object*. Thus, Christ died *for* us; Christ died, *us*, (*i. e.* our redemption,) being the end or object of his death. To fight *for* the public good; to fight, the public good being the end or object of fighting. He does all things *for* the love of virtue. He does all things, the love of virtue being the end or motive of all his actions, and so in all other instances.

By (in the Anglo-Saxon *bi*, *be*, *big*) is the imperative of *byth* of the Anglo-Saxon verb *beon*, to be. And our ancestors wrote it indifferently *be* or *by*. So then, according to this, our auxiliary *be* and the preposition *by* are of the same origin: and what analogy in the name of common sense is there between them, excepting the accidental resemblance of sound. Let us apply this etymology to the solution of some example, "He was slain *by* the sword," *i. e.* he was slain *be* a sword, or, "let a sword *be*." We might ask let a sword be what? Mr. Tooke has anticipated the question by saying this preposition is frequently, but not always, used with an abbreviation of construction: *subauditur*, *instrument*, *cause*, *agent*, &c. Really it appears to us surprising, that a man of taste and understanding should write thus. In Hebrew *בא*, *baa*, is *to pass*, and is the parent of *βασ* in Greek. In Arabic and Persian it became a preposition, signifying the medium of motion. In this sense it gave birth also to the Latin *via* and to the English *way*, *bye*, and also to the Anglo-Saxon preposition *bi* or *be*, and the English *by*, which last was used by our old writers to signify the interval of time during which motion is continued; as, "By so long a time," *i. e.* for so long a time—By his life. *i. e.* during his life.

Then it came to signify the medium or instrument by which any action in general was performed. He was slain *by* the sword—He was slain, the sword being the medium or instrument of his slaughter. The derivation of *with* from *wythan* is no less absurd. What has *with* to do with *wyr*, or, as we have it, *were*? The parent of this verb, which signifies *to exist*, is the Hebrew *אור*, *awar*, *light*, *air*, the medium of existence. The Greek *ωπερ*, denoting *connection*, *concomitance*, *instrumentality*, has passed into the Anglo-Saxon in the form of *mid*, where it is corrupted into *with*, and exists in the same sense in both forms. The letters *m*, *w*, *u*, are of the same organs, and often change one for another. Many Greek words are borrowed from the Hebrew, by changing *מ* into *ו*; as *מלך*, *malal*, is *βασιλευς*, *to rule*; and all the Welsh words borrowed from Latin have *m* corrupted into *w*, *arma arve*; *mare uoar*; *me w*. Instances of this species of corruption occur in Anglo-Saxon and Gothic. Thus, the Gothic *weis* is the Greek *ωεις*; and hence the Anglo-Saxon, and the English *we*. Even *withan*, from which Mr. Tooke also derives *with*, is only the Latin *mitti*, *to seat*, *to put*. And not *withan*, as he says, but *ga withan* signifies *to join* or *put together*.

"The English preposition *through*, says our author, is no other than the Gothic *þ* substantive *durra*, or the Teutonic substantive *thuruh*, and like them means *door*, *gate*, *passage*, p. 334." And he adds in the next passage, "After having seen in what manner the substantive *bois* became a preposition in the French, you will not wonder to see *door* become a preposition in the English; and though in the first instance it was more easy for you to see the nature of the French *chez*; because having no preposition corresponding to it in English; yet I am persuaded you will not charge this to me as a fan-

taistical or far-fetched etymology, when I have placed before you at one view the words employed to signify the same idea in those languages to which our's has the nearest affinity." After doing this, he adds, "Though it is not in Asia or its confines that we are to seek for the origin of this part of our language, yet is it worth noticing here, that the Greek, to which the Gothic has in many particulars a considerable resemblance, employs the word *θυρα* for *door*." All this is very specious, and being confidently advanced, it has the aspect of truth, though it be misrepresentation. The preposition *through* exists, as Mr. Tooke has shewn, in all the collateral languages; and it may be observed, what he has not, that there is a guttural annexed to the word in all. Thus in English *through*, Anglo-Saxon *thurub* or *thurh*, Gothic *therb*, German *durch*, Teutonic *duruc* or *durub*, &c. This uniformity in retaining a guttural, shews that a guttural was an original part of the word. And it is no other than the Hebrew דָּרַךְ , *dark*, *road*, *passage*, which has given birth not only to this preposition, but to a multitude of other words in all languages. He came *through* Greece, he came, Greece being the *road*, a *passage* of his coming. The genial sun warms *through* the air; the genial sun warms; the *medium* or *passage* by which it does this, is the air. We shall only add on this subject, that the prepositions *down*, *neath*, *beneath*, exist in the Arabic, with little or no variation, and in the same sense; while *among* is the Persian *mecan*, in the *midst*, the same with the Celtic *mecan*. In the Hindoostanic it is founded with a nasal guttural, as if written *meng*, and by the same analogy that *mid* became *amid*; *bove*, *above*; *bout*, *about*; *meng* became *among*. The corresponding word in Hebrew is בֵּין , *bin* or *been*, which means *separation*, *distinction*, an idea the very reverse of that contained in *mengan*, *to mix*, from which Mr. Tooke derives it. From signifying *separation*, it came to signify the *interval* between two things separated, and hence the Hebrew *bin* (or written with the *minn*ation *binon*) is the parent of the Anglo-Saxon *binnon*, *between*, *within*. The Greek ἐπιθρῶ , *to overturn*, is in Latin *verto*, *to turn*, which the Anglo-Saxons have further corrupted into *weard-an*, *to turn to*. Hence, in the form of *weard* it came to signify the object to which the attention is directed; as *eastward*, *i. e.* *east prospect*. We add only the genealogy of *over*, Anglo-Saxon *ofer*; Greek ὕπερ ; Hebrew עָבַר , *ober*, *to pass over*.

We have already observed, that Mr. Tooke's description of the nature and use of prepositions belongs more properly to the conjunctions. But we ought rather to say that it belongs to neither. Prepositions express the relation of things, and those relations are the same, whether things or the complex names of things are few or many: and the necessity of prepositions arises not from the impossibility of having a distinct complex term for each different collection of ideas, but from the necessity of those ideas we have of things and their operations. It is therefore utterly croneous to say, that the preposition is employed to supply the place of complex terms. On the other hand, the conjunctions serve to propose or to compare our ideas, to combine or to separate them: and this use is entirely independent of the number or variety of complex terms. If the complex terms of a language be few, they cannot be so few as not to need being separated; and if they be ever so numerous, they cannot be so numerous as not to need being joined in composition. Indeed what Mr. Tooke says on this subject is indistinct, inappropriate, and even nugatory; though some subsequent grammarians have gravely copied his reasoning as oracular wisdom.

The prepositions and conjunctions in English exist in the Anglo-Saxon and Gothic. But this circumstance Mr. Tooke has kept out of sight. He knew it would appear strange to deduce words of this kind from verbs and nouns in the pa-

rent tongue, while the very same words existed in that tongue coeval, and in many instances antecedent to the nouns and verbs represented to be their origin. But whence came those conjunctions and prepositions to the northern language? We have anticipated this question by proofs from fact. These branches of the northern tongue, as the northern tongue itself has done, originated in the oriental languages. The structure of those languages is such, that the verb is the leading part of speech, and not only the subordinate parts, but even the noun is derived from it. This doctrine is inculcated and supported by the most extensive and obvious analogies, and taught in the popular grammar, so that no learner, who has made any progress in them, can be ignorant of the true origin whence those particles including adverbs, prepositions, and conjunctions, are derived. The verbs, from signifying in the Asiatic dialects the *actions* of things, degenerated to express the *relations* and *connections* of those things; and with some necessary variations incidental to sounds, passed into Greek, Latin, and other tongues, in the form of prepositions and conjunctions; and they were thence propagated, with still farther corruptions, into the Gothic, Anglo-Saxon, and other European dialects. Losing much of their primary forms, and changed in signification, European grammarians soon considered them as distinct parts of speech. And much uncertainty, confusion, and obscurity, hung for ages on the subject, till Mr. Tooke rose and dissipated the mist, by asserting their true origin to be nouns and verbs. This he acknowledges, or rather boasts to have been a mere *conjecture* at first: and it has this singular fate, that, while the conjecture itself is perfectly just, almost every influence alleged to support it is erroneous and futile. Having no acquaintance with the oriental tongues, and seemingly little acquaintance with Greek and Latin, but endowed with a powerful mind, as we conceive, under some wrong biases, and actuated by a desire of opening new paths of speculation, he boldly imputes the dignity of an ancient and independent language to oral corruptions, chiefly made by a barbarous people, so late as the dark ages. On some of these corruptions he lays his hands, and holds them forth to the public as the parents of those words which long existed antecedently to those corruptions. This we believe to be a just representation of the question, and our readers will hence be able to appreciate the merits of his system. The following is the table of genealogy, which he gives of the leading conjunctions.

If	} are the imperatives of	Gif	} of their respective verbs	Gifan, <i>to give</i>
An		An		Au-an, <i>to grant</i>
Unlesfs		Onlesfs		Onlesfan, <i>to dismiss</i>
Eke		Eac		Eacan, <i>to add</i>
Yet		Get		Gettan, <i>to get</i>
Still		Stell		Stellan, <i>to put</i>
Else		Ales		Alesfan, <i>to dismiss</i>
Though		Daf		Dasian, <i>to allow</i>
Büt		Bot		Botan, <i>to boot</i>
Büt		Beutan		Beon-utan, <i>to be put</i>
Without		Wyrrhatan		Anan-ad dare conge-
And		An-ad		riem.

We will briefly examine these. Skinner, before Mr. H. Tooke, has derived *gif* from the Anglo-Saxon *gifan*, *dare*; and perhaps this very word is the foundation of his theory, though he has not mentioned (and he may have forgotten) the circumstance which gave birth to his conjecture. It is, however, important to observe, that the use of *gif*, as a preposition, is not of a late origin: for the Anglo-Saxons used it in that sense, and derived it in common with the verb *gifan* from the Hebrew, Arabic, and Persian word קָבַץ , *kaph*, the palm

palm of the hand. Now the action of the hand is two-fold, to give or to receive. In the latter sense it has passed into Latin, and produced *capio, capio*, and even *habeo*, meaning to hold; in the former it has given birth to the Anglo-Saxon verb *gif*, which signifies the action of the hand in imparting. Our word *keep* is apparently of the same origin, meaning to hold. Mr. Tooke observes, that *gin* is used in our Northern countries, and by the Scotch in the sense of *if*, and he justly says, that it is only a contraction of the participle *given*.

An, quoted by old authors, means *if*, as in the following lines, quoted by Johnson :

“ An honest mind and plain : he must speak truth
An they will take it so ; if not, he's plain : ”

That is, *if* they will take it so. This Mr. Tooke derives from *anan*, to grant, which is only the Latin *annuo, to assent to*; whereas *an* is the Arabic particle ان , *an*, which is pronounced as if written *in*, when meaning *if*. We borrowed it from the Gothic, where it is employed, as it is also in Latin, to mark an interrogation. The derivation of *unless*, or, as it was formerly written, *onles*, from *on-les*, seems at first sight not to be disputed. The application of the Anglo-Saxon *onles* does not appear forced; as Troy will be taken, *onles* the palladium be preserved, *i. e.* Troy will be taken, dismiss the palladium be preserved, or, dismiss that circumstance, namely, the preservation of the palladium, and Troy will be taken. And yet we are persuaded that this is not the true interpretation of *unless*. Mr. Tooke is not fair in explaining the words from which he would derive this and other particles; but, in order to answer his own purpose, gives them a meaning which they really do not bear. *On-lesan* is interpreted by *lye, un-lesse* *sc. un-loose, solve*, and it has no other meaning; and in this sense it is incapable of solving the difficulty.—“ Troy will be taken, *unloosed* the palladium be preserved,” which is hardly sense. Mr. Tooke acknowledges that the Anglo-Saxon writers have not given us instances of *onles* in a conjunctive sense: “ but, instead of it,” adds he, “ they frequently employ *nymbe* or *nembe*, which is evidently the imperative *nym* or *nem* of *nyman* or *neman*, to which is subjoined *the, i. e. that*: and *nymbe, take away that*, may very well supply the place of *onles the*, expressed or understood, *dismiss that*. But *nyman* signifies not merely to take, but to take counsel, it being derived from the Greek $\nu\omicron\mu\iota\zeta\omicron$, to consult or deliberate; while the Latin *nempe* is $\nu\omicron\mu\omega\ \pi\alpha$, by law, by right, rightly, truly: *leave* is a security by law, and *unless*, we conceive, is a corruption of *unloosed, i. e. unprovided, unsecured*. Thus, Troy will be taken, *unless* the palladium be preserved, *i. e.* it being unprovided, or it being not provided, that the palladium be preserved; or, provided that the palladium be not preserved, Troy will be taken. This author adds *les*, the imperative of *lesan*, which has the same meaning with *on-lesan*, is likewise used by old writers instead of *unless*; as, “ But will not hide there *les* yourself do bring him.” To this he subjoins, in a note, p. 173, “ It is this same imperative *les*, placed at the end of nouns, and coalescing with them, which has given to our language such adjectives as *hopeless, restless, deathless, motionless, &c. i. e.* dismiss hope, rest, death, motion.” But *les*, we think, which, though not in a comparative form, conveys a comparative idea, is the offspring of the Greek $\lambda\epsilon$, (as little is of $\lambda\iota\tau\omicron$) both signifying *small, slender*. From denoting something minute, it came, as the Latin *minus*, to express *negation*. On this principle, a *sleepless night*, meant at first not absolutely a night without sleep, but a night having less sleep than is necessary, or less than

usual, though in time it came to convey absolutely a negative idea. *Hopeless* without hope; *bottomless*, having no bottom; and we appeal to our readers, whether this explanation be not more simple and natural than *dismiss the labour*. If this derivation be just, *less* or *lest* is not the past participle *less* of *lesan*, to dismiss, but a contraction of *lessert*, the analogical superlative of *less*, and it means the least degree of some consequence that follows the preceding clause; as, “ Let those who stand take heed *lest* they fall;” which means, let those who stand take heed; if not, they will fall, and that is the least that may happen.

Esse, and, in the Latin *ac*, is ultimately derived from the Greek $\alpha\epsilon\zeta\alpha$, or as it is in Latin *augere*, to increase, though it may come more immediately from *cacere*, the Anglo-Saxon offspring of $\alpha\epsilon\zeta\alpha$. An observation of Mr. Tooke goes certainly to prove the latter, if we can depend on its correctness. “ In each language,” says he, “ where this imperative is used conjunctively, the conjunction varies just as the verb does. In Danish, the conjunction is *og*, and the verb *oger*. In Swedish, the conjunction is *och*, and the verb *oka*. In Dutch, the conjunction is *ook*, from the verb *oeken*. In German, the conjunction is *auch*, from the verb *auchen*. In Gothic, the conjunction is *auk*, and the verb is *aukan*.” This example serves to shew how nearly allied these languages are one to another, and how a large portion of them is derived from the Greek and Latin.

Yet is assuredly the Anglo-Saxon *get* or *gut*, *adverb, diav*, though Mr. Tooke has referred it to the verb *to get*. This grammarian seems not to have sufficiently studied those analogies by which the genius of a language is formed. The Anglo-Saxon, delighting in gutturals, forms many of its words by prefixing the particle *ge*, or the letter *g*. Thus, *gefyrn, pridem*, is only the Greek $\pi\epsilon\upsilon$, with *ge*; and *german* is our *among*. This peculiarity gave birth to the German mode of prefixing *ge* to the perfect participle, and is the principle on which the Greek $\epsilon\tau\iota$, in Anglo-Saxon is corrupted into *geta, get*, or *gut*. The Anglo-Saxon *stellan*, the German *stellen*, the Swedish *ställa*, the Danish *stiller*, originated in the Greek $\sigma\tau\alpha\lambda\alpha$, which denoted first to lay down the sails of a ship. Hence in the above mentioned modern tongues, it came to signify, to place, compose, or adjust; but the general consequence of putting down the sails is to give stillness or tranquillity to the ship. Hence $\sigma\tau\alpha\lambda\omega$ gave birth also to the Anglo-Saxon *stillan*, and the English *to still*, and to the conjunction *still*. The Anglo-Saxon and Gothic used it conjunctively in the form of *still*; or *style*, and its immediate parent undoubtedly is *stilian*, and not *stellan*, as Mr. Tooke would have us believe.

Esse, with no less certainty, is the Anglo-Saxon *elles*, the Latin *alias*, and the Greek $\alpha\lambda\lambda\omega\iota$, and has nothing to do with *alesan, to dismiss*, and it means not *exception* or *dismissal*, but a change or difference in the consequence, or in the condition of what is expressed in the preceding clause. Thus, let the derivation be just, *esse* it will not be received, *i. e. otherwise* it will not be received: let the derivation be just; if otherwise than just, it will not be received. On Mr. Tooke's principle the solution stands thus: let the derivation be just, *dismiss* it will not be received, an interpretation at once unnatural and unmeaning; and in order to give it the appearance of sense and coherence, he is forced to suppose a *clause understood*. Let the derivation be just, *dismiss* the derivation being just, or dismiss that circumstance, it will not be received: see his resolution of such examples in vol. i. p. 247. The conjunction $\alpha\lambda\lambda\omega$, like $\alpha\lambda\lambda\omicron$, is a modification of the pronoun $\alpha\lambda\lambda\omicron\iota$, *another*; and may be resolved in the same way as *et* in English. $\text{Οὐκ ἔστιν ἄλλο καταρτισμὸς,}$

οὐκ ἔλθω καταστρεῖν, I came not to destroy, *but* to fulfil—I came not to destroy, another thing, (*i. e.* I came for another thing,) I came to fulfil.

Mr. Tooke derives *but* from two different words *butan*, to *boot*, and *butan*, or *be utan*, to *be out*, or to *except*, and accordingly assigns the word two different senses, as it is taken from the one or the other. In opposition to this, we maintain that *but* is the Anglo-Saxon *buton*, or *butan*, and has the sense which it bears in that language of *except*, *without*, and no other but this, or one resolvable into this. We farther maintain, that the Anglo-Saxon *buton* is the Arabic and Hebrew בָּטַן, *bata*, to *cut*, which, as it exists in the former with the *numnation*, is *buton*; and the principal idea implied in it is *separation*. With *but* have flowed from the same source *bit*, a morsel separated; *bite*, to separate with the teeth. Let us apply the word thus explained. I saw none but two plants—two plants being separated I saw none, or two planted being excepted or taken away, I saw none.

In such instances as these, the negative is often omitted for the sake of brevity; but it must be supplied before the sentence can be explained. Again, "I have much to say on this subject, *but* I must proceed to another." Mr. Locke observed, that in such instances, *but* intimates a stop of the mind, in the course it was going. But, says our grammarian, the truth is, that *but* itself is the farthest of any word in the language from intimating a stop. On the contrary, it intimates something *more*, something to follow. And, therefore, whenever any one in discoursing finishes his words with *but*, the question always follows, but what? p. 205. Now, we hesitate not to say that Locke, though not right, is nearer the truth than Mr. H. Tooke. "I have much to say on this subject, let that however be separated, or that being separated or laid aside, I proceed to another." Here then *but* denotes the *removal* of the thing which already occupied the mind, and the succeeding word or words mark that which is introduced to fill its place. On such a removal the mind naturally looks forward to the introduction of something else; and its expectation in this respect forms no part of the meaning expressed by *but*, but is a habit formed by experience or association. Knott having remarked, that the Catholics prayed, conferred places, and consulted the originals; Chillingworth replies, "you pray, *but* it is not that God would bring you to the true religion, *but* that he would confirm you in your own. You confer places, *but* it is that you may confirm or colour over with plausible disguises your erroneous doctrines; not that you may judge of them and forsake them, if there be reason for it. You consult the originals, *but* you regard them not, when they make against your doctrine or translation." In all these places, *but* does not, as Mr. Tooke asserts, direct something to be *added* or *supplied*, but denotes a separation or removal of something that ought not to be separated or removed. You pray not that God would bring you to the true religion; you pray, motive being apart, that he should confirm you in your own. You confer places, the right object is separated, and you confer them that you may confirm, &c. You consult the originals, and regard them when they make for your doctrine; this regard is separated when they make against your doctrine or translation. Thus, whatever senses may be ascribed to *but*, they are all resolvable into one original signification. Nor have we need with this celebrated grammarian to trace it into two distinct verbs, a thing in itself very improbable and contrary to all analogy, nor would he have adopted so unlikely an hypothesis, if it were not necessary for supporting his system.

On the conjunction *although*, or *though*, we quote the following remark from the learned Dr. Jamieson, in his Etym. Dictionary. "Mr. Tooke derives *though* from the Anglo-Saxon *thafian*, or *thafigan*, to allow. But there is not the same evidence here, as with respect to some other conjunctions illustrated by this acute and ingenious writer. It certainly is no inconsiderable objection to this hypothesis, that it is not supported by analogy in the other northern languages. In Anglo-Saxon, *theab* signifies *though*, Alemannic *thaeb*, Icelandic *tho*. I shall not argue from Moes G. *thau*, in *thaujaba*, which Junius views as synonymous with *though*; because this seems doubtful. In old English *thab* was written about 1264, see Percy's Reliques, ii. 210. which nearly approaches to the Anglo-Saxon *theab*. Instead of *thoeb* in our oldest MSS. we generally find *thoebt*, *alhoebt*. This might seem allied to the Icelandic *thoebt*, quamvis, which, according to G. Andr. is per syncop. for *tho*, *at*, from *tho*, licet, et; Lex. p. 266. But it is more probable, that our term is merely Anglo-Saxon *thobie*. Moes G. *thabta*, cogitabat; or the participle part of the verb from which English *think* is derived; as in latter times *provided*, *except*, &c. have been formed. Resolve *alhoebt*, and it literally signifies "all being thought of," or taken into account; which is the very idea given by the conjunction. The Synon. in German exhibits some analogy; *dachte*, being the imperfect and participle part of *denken doeb*, although, may have been formed from the same verb." Though this etymology be plausible, we do not agree with it, merely because a more just and simple one may be pointed out. *Although* is *though* combined with *all*, as in the verbs *albeit*, *alene*, (for all one), *atene*, at one. And *though* means not *thought*, but *concession* or *allowance*, and is derived from the Greek obsolete *δοω*, to give, to grant; and as this verb is *δοω*, or *δωω*, (which gave birth to the first aorist *εδωκα*), so this derived conjunction is *tho* or *though*. Its resolution may thus be illustrated: "Though the book be long and tedious, I will read it with attention: be it granted, that the book be long and tedious, I will read it with attention." It is observable, that in its simple form the word is hardly capable of being explained on Dr. Jamieson's principle. "Be it *thought* that the book is long and tedious, I will read it with attention;" whereas, on our hypothesis, the compound form is easily susceptible of illustration. Be it all granted, that the book, or grant that the book be all long and tedious, &c. It is observable that the word has spread as is seen above, from the same root into all the kindred northern tongues. So has indeed *to think*, but this comes from *θηνω*, to express, which in its derived form was naturally employed to denote the operation of the mind in supplying the materials of discourse, *i. e.* in thinking. The noun *θηνωσις* is also the parent of our word *thing*, which signifies any object that is the subject of thought. We only add that the Anglo-Saxon *thafian* is certainly of the same origin with *though*, the guttural *gh* being corrupted into the labial *f* in the orthography, as well as in the pronunciation.

Skinner's account of *and* is this. "Nescio an a Lat. *addere*. q. d. *add* interjecta per epenthesin *n*, ut in *render* a reddendo;" which we think a more proper etymology than that of Mr. Tooke, who derived it from *annan-ad congeriem dare*, a combination and a sense of his own invention. But this word exists in Anglo-Saxon and Gothic, not only as a conjunction but as a preposition combined with words. In these characters it signifies *connection*, *union*, *reciprocation*, or *opposition*; and these significations demonstrably shew that its origin is the Greek *αυτι*, so similar to it in sound, and precisely the same with it in sense. When one person or thing meets another to unite or co-operate, *αυτι*, expressing this

this union, or co-operation, is the copulative *and*; but when a person or thing opposes or counteracts another, *and*, in the form of *and*, is combined with another word to express *against* or *in return*; as *andwyrd*, a word in return for a word, *i. e.* an answer; *andfelis*, against the sun, see Hicks's Anglo-Saxon Grammar, p. 87. When objects act upon the organs of sense, the mind is supposed in return to act upon the impressions of those objects in order to perceive them, and the perception so acquired is called in Greek *συναισθησις*. Hence, in Anglo-Saxon *andgit*, if we attend to the composition of the word, means that sense which the mind *acts* or acquires by a reciprocal action on its own organs.

The conjunction, according to Mr. Harris and other grammarians, connects not *words* but *sentences*, so as out of two to make one sentence. Thus, you and I and Peter rode to London, is one sentence made of three. But this notion Mr. Tooke refutes by the following example: two *and* two are four, A B *and* B C *and* C A form a triangle. John and Jane are a handsome pair. Does A B form a triangle, B C form a triangle? Is John a couple? Is Jane a couple? Are two four? p. 221. In truth, conjunctions as well as prepositions affect words and not sentences, and their office is to combine the words succeeding to the words going before them, *i. e.* to combine a verb coming after with a preceding verb; a noun coming after with a preceding noun, an adjective coming after with a preceding adjective, &c.

Mr. Tooke has not given the etymon of *than*, though it exists only in Anglo-Saxon under the form of *thonne*, and in Gothic under that of *thana*. But in order to come at its origin, we must attend to the effect which external objects produce on the organs of sense. When two qualities, unequal in degree, are compared, that which exceeds appears to receive by means of the contrast an immediate augmentation; while on the other hand, the less seems to diminish. This being the case, and human nature being the same in all ages and countries, the same form of expressing the degrees of comparison has obtained in all languages. Thus in Hebrew *tub nua kberust*, good from gold, *i. e.* better than gold. The Arabs borrowed the Hebrew *min* to express their comparative; and the Persians denote it by *az*, a word of the same import. The Latin tongue in this instance is founded on the same general principle—*Clarius sole*, brighter from the sun. The French *de* and the Italian *di* are taken from the Latin *de*; and as the use of cases in these languages has for the most part given way to prepositions, they express their degrees of comparison by these particles in the sense of *from*. In our own tongue the mode of expressing the comparative seems alone unintelligible. But by tracing *then* to its root the mystery vanishes; and we recognize the same great principle of nature. The imperative of the Hebrew *נָתַן*, *nattan*, which has given birth to corresponding verbs in all other languages, is *תֵּן*, *than*, which is precisely our English *than*, retaining not only its original sound, but moreover its original sense of *give*, *put*, *place*. Thus, his face was brighter *than* the sun. *Put* the sun (namely by the side) his face was brighter. Lighter *than* gold. *Put* gold, it is lighter. From the juxtaposition of gold it becomes lighter; or as in other languages lighter *from* gold. I shall only add that *von*, *from*, of the Germans, is a corruption of the Hebrew *מִן*, *min* or *mon*, *m*, *b*, *v*, being interchangeable letters. Accordingly the Germans say in the superlative, der beste *von* seinen brudern, the best *from* his brothers, the best of his brothers.

It still remains that we notice the *adverbs* and *interjections*, but as we have already occupied so much of our readers attention in discussing the other parts of speech, we shall dis-

patch these by one or two general remarks. Adverbs, or as Mr. Harris describes them, attributes of a secondary kind, are corruptions from nouns, adjectives, pronouns, and verbs. The name of *adverbs* given to such corruptions is not, it should be observed, descriptive of their nature, as distinct parts of speech, but of their use in modifying the verb or adjective to which they are annexed. An adverb is often a substitute for a whole clause, as *here*, for *in this place*; *then*, for *at that time*. In this view, adverbs are the only words which properly come under the denomination of *abbreviations*, a term of which Mr. Tooke is so fond, and to which he so improperly refers several other parts of speech. As to *interjections*, it may be questioned whether or not they can be considered as *articulate* sounds, though they have been usually honoured with a distinct department in language. One consideration, however, is calculated to leave them in possession of their hitherto enjoyed honours. Interjections, it is true, are not distinct names of our feelings and passions, and therefore they have not, like other words, derived articulation from the association of sense with sound; nevertheless they consist of certain *expressions* or *cries*, which, as founded in nature, are as well calculated to recal to our minds ideas of certain emotions, as if, like other words, they had been by common consent made the signs of those emotions.

GRAMMAR is also used for a book concerning the rules of grammar, which obtain in any language. See LANGUAGE.

The ancient grammars are: for the Hebrew, that of rabbi Juda Ching, which is commonly held the first Hebrew grammar that appeared; though it is certain, rabbi Saadiah Haggaaon, who lived before rabbi Juda, composed two works of the same kind: one expressly of grammar; and the other of the elegancies of the Hebrew tongue.

For the Greek, the oldest grammar is that of Gaza: the Latin ones are the works of Martianus Capella, Priscian, and Aconius Pedianus.

The modern grammars are; 1. For the Hebrew, that of Pagninus, the edition of Hen. Stephens, or le Preux; at Geneva, in 1592; that of Petrus Martinus at Rochel 1592; that of Buxtorf; that of Ludovicus Deus, in three languages; that of Sixtinus Amama, which is a collection from Martinus and Buxtorf; that of Bellarmine, with the notes of Muis; those of F. Sglanther, of W. Schickard, and of Visé. Bythner, to the latter of which is annexed a brief account of the Chaldee, are useful for beginners; and those of Gronovius, Schultens, Schroeder, Bayly, Bennet, Robertson, &c.; and for the Hebrew, without the Massoretic points, the excellent grammar of Mafeseh, to the second edition of which, published at Paris in 1743, are annexed Chaldee, Syriac, and Samaritan grammars; those of Sharp, Wilford, Bates, Parkhurst, &c. 2. For the Chaldee, the best are those of Martinus, Buxtorf, and Lud. Deus, in three languages. 3. For the Syriac, those of Amira, Myricæus, Waterus, and Beveridge; with the Chaldee and Syriac ones of Buxtorf, of Lud. Deus in three languages, and that of Lemben. 4. For the Coptic, the Prodromus Coptus, and Lingua Ægyptiaca Restituta of Kircher. 5. For the Arabic, that of Erpenius, and that of Golius, which is only Erpenius's a little augmented. 6. For the Ethiopic, that of J. Ludolphus. 7. For the Persian, that of Lud. Deus, and that of sir William Jones. 8. For the Sancerit, those of Wilkins and Carey. 9. For the Armenian, those of Schroeder and Galanus. 10. For the Greek, those of Mart. Rulandus Sylburgius, F Moquet, Vossius, Gaza, Herman, Busby, Port Royal, Manutius, Bell, Milner, Moor, Parkhurst, Valpy, Jones, &c. 11. For the Latin, those of Diomedes, Despauter, the Minerva of Sanctius, those of Vossius, Ward, Clarke, and Sprat; that of Port Royal, which

is only a collection from the rest ; those of Lowe, of Eton, of Jones, &c. 12. For the Italian, those of Berger, Lanfredini, Port Royal, and Veneroni, Baretti, &c. 13. For the Spanish, those of Salazar, Port Royal, the abbot de Vairac, &c. 14. For the Portuguese, that of Pereira. 15. For the French, those of the abbé Regnier, and F. Buffier, &c. 16. For the High Dutch, those of Claius, Hertfburgensis, Schottelius, Boedicher, and Steinbach. 17. For the German, that of Wendeborn, &c. 18. For the English, those of Wallis, Brightland, Greenwood, Lowth, Pricstley, Murray, Crombey, &c.

GRAMMAR is also used in the same sense with elements ; as geographical grammar.

GRAMMAR, *Philosophical*, is that which, without regarding the several idioms of particular languages, only respects those principles that are essential to them all. One of this kind was proposed by lord Bacon ; not upon the analogy of words, but such as should diligently examine the analogy or relation between words and things. He disapproves too curious an enquiry about the original imposition and etymology of names. This he thinks an elegant, and, as it were, a waxen subject, that may be handsomely wrought and twisted, but is attended with little truth and advantage. But, says he, it would be a noble kind of grammar, if any one well versed in languages, both the learned and the vulgar, should treat of their various properties, shewing wherein each of them excel and fall short : for thus languages might be enriched by mutual commerce, and one beautiful image of speech, or one grand model of language, for justly expressing the sense of mankind, be formed like the Venus of Apelles, from the excellencies of several. And thus, at the same time, we should have some considerable marks of the genius and manners of people and nations, from their respective languages. See Bacon's Doctrine of Delivery, § 7. and De Augm. Scient. vi. 1.

The object of philosophical or universal grammar is speech or language, as divided into its constituent parts, as a statue may be divided into its several limbs ; or else, as resolved into its matter and form, as the same statue may be resolved into its marble and figure : and thus it is distinguished from the art of logic, which considers speech as combined or compounded ; so that by this synthesis, simple terms are combined to produce a truth, and two truths are combined to produce a third, &c. In this kind of grammar, the design is to point out the several powers and modes of expression which sounds are capable of, to trace their connections with, or relation to the ideas they represent ; and to shew the actual variety of the external expressions of the same mental conceptions which different languages exhibit. By this comparison we shall be enabled to judge which is the most adequate and convenient method of expression, what is defective and what is redundant in the structure of any particular language, and direct to the most proper method of supplying the defect, or lessening the inconveniencies arising from the superfluity. (See LANGUAGE.) See an excellent and well-known work of this kind, by the ingenious and learned Mr. Harris, called the *Hermes*, or a Philosophical Enquiry concerning Universal Grammar, 2d ed. 1765. See also Tooke's *Diversions of Purley*, and the preceding article GRAMMAR.

GRAMMAR, *Characters in*. See CHARACTER.

GRAMMARIAN, GRAMMATICUS, a person well versed in grammar ; or who teaches grammar.

The denomination grammarian is, like that of critic, frequently, though unjustly, used as a term of reproach ; a mere grammarian ; a dry, plodding grammarian, &c. The grammarian is conceived as a person wholly attentive to the minutiae of language ; industriously employed about words and phrases ;

and incapable of perceiving the beauties, the delicacy, fineness, extent, &c. of a sentiment.

Scaliger, however, considered grammarians in another light. " Utinam essem," says he, " bonus grammaticus ? fuscit enim ei, qui omnes auctores probe vult intelligere, esse grammaticum."

The title grammarian, it is certain, was anciently a title of honour ; being given not only to such as applied themselves to grammar, or excelled in philology ; but to all who were reputed learned in any art or faculty whatever, as is shewn by Ger. Vossius, in his book of grammar.

The word was properly a title of literature and erudition, and was frequently given to persons who excelled in all, or many arts, called also *polybiflores*.

Thus, Philoponus, a famous philosopher in Justinian's time, remarkable for the extent and variety of his knowledge, was surnamed *Grammaticus*, as appears from Photius's Bibliothec.

So Saxo, the Danish historian, in the 13th century, got the appellation *grammaticus* : and as late as the year 1580, Thomas d'Averla, a celebrated Neapolitan lawyer, was surnamed the Grammarian.

The title grammarian was anciently bestowed on those we now call *critics*, men of learning, erudition, letters, &c. and particularly such as wrote well, and politely, in every kind.

It is in this sense that Suetonius intitles his book which he wrote on the best Latin authors, " Of the celebrated Grammarians ;" and that Cornelius Nepos calls the commentators on the orators and poets, grammarians ; and lastly, it is in this sense the appellation is attributed by the ancients to Apion, Philoponus, and Solinus.

The most celebrated grammarians of the second century were Aper, Pollio, Eutyclus, Proculus, Athenæus, Julius Pollux, Macrobius, and Aulus Gellius : the works of these last authors are an assemblage of abundance of very different things, and subjects relating to the criticism of the ancient writers, and the polite literature.

If the name have lost its ancient honour, it is through the fault of those who have assumed it ; by their treating of grammar in a low, pedantic, dogmatic manner ; reducing it to words and syllables ; and dwelling altogether on trifling puerile remarks and censures : whereas its ancient office was to make an accurate and thorough examen of an author ; to enter into all his views ; to point out the beauties, and the defects thereof ; to distinguish the true beauties from the false ; and the genuine productions of an author, from the supposititious ; that is, a grammarian was then, what we call a critic now.

Those who only taught to read, understand, and explain authors, were called grammatists, grammaticistæ ; in contradistinction from grammatici ; though, in course of time, the grammaticistæ have risen in the place of grammatici, who are now preferred to that of critics.

GRAMMATICAL, something relating to grammar.

We say, grammatical construction ; grammatical signification, &c. Idioms, as Anglicisms, Latinisms, Grecisms, Gallicisms, &c. deviate from grammatical strictness. Such a phrase is not grammatically just ; it is an idiom.

GRAMMATICAL *Criticism*. See CRITICISM.

GRAMME, in the new weights of France, is the weight of a centimetre of distilled water at its maximum of density, = 18.8247 French grains = 15.444 English grains = .0022063 English avoirdupoise pounds.

This weight is the standard, or unit, of the new system of weights ; 10, 100, 1000, and 10,000 times its weight, being expressed by the prefixes, *deca*, *hecto*, *kilo*, and *myria*, respect-

respectively; and $\frac{1}{10}$ th, $\frac{1}{100}$ th, and $\frac{1}{1000}$ th, by the prefixes *deci*, *centi*, and *milli*. Thus, hectogramme signifies 100 grammes, and centigramme signifies the 100th part of a gramme.

GRAMMELOUC, in *Natural History*, the name of an East Indian shrub, very common in the woods and forests. It grows to five or six feet high: its leaves are very long and narrow, and terminate in a point; they are of a lively green; the fruit is carried in a bag of a triangular shape, of the size of a hazel-nut, but something longer; on opening this there appear three cells, in each of which is contained one fruit, resembling the seed of the palma Christi, but covered with a transparent pellicle, and a black one under that: the inside of the fruit is white, and is of a sharp and pungent taste. It is a very violent medicine, operating both by stool and vomit, and that often, so as to endanger the life of the person who has taken it. They allay its operation by eating betel. Mem. Acad. Par. 1609.

GRAMMICA, in *Botany*, from $\gamma\rho\rho\mu\mu\alpha\sigma$, *linear*, alluding to its slender thread-like form, Loureir. Cochinch. 170, appears evidently by his description to be a species of *Cuscuta*, or Dodder. See *CUSCUTA chinensis*, n. 6, which is probably the very plant.

GRAMMITIS, from $\gamma\rho\rho\mu\mu\alpha$, *a line*. Swartz. Fil. 21. Class and order, *Cryptogamia Filices*; sect. *Annulate*. Nat. Ord. *Filices*.

Est. Ch. *Capsules* in straight feathered lines. Cover none.

This genus differs from *Polypodium*, in having its capsules disposed in straight continued lines, instead of round dots. The *involuterium* is wanting in both. Dr. Swartz defines twelve certain species. Of these such as have a simple undivided frond, like *G. lanceolata*, Swartz. t. 1. f. 4, form the most natural assemblage. The genus has, however, the advantage of admitting some ferns, which preceding writers did not well know how to dispose of, as *G. Ceterach*, (*Asplenium Ceterach*; Linn. Sp. Pl. 1538. *Scolopendrium Ceterach*; Sm. Fl. Brit. 1134. Engl. Bot. t. 1244.) and *G. leptophylla*, Swartz. t. 1. f. 6, which Linnæus and other botanists had hesitated whether to reckon a *Polypodium* or an *Asplenium*.

Dr. Swartz mentions two doubtful species; the *Polypodium graminum* of Lamarck, perhaps his own *Grammitis linearis*; and the *Asplenium subsessile*, of Cavanilles lectures, n. 627, a native of the Philippine islands.

GRAMMONT, in *Geography*, a town of France, in the department of the Scheldt, and chief place of a canton, in the district of Audenarde, built at the foot of a mountain by the Goths, and thence called "Gotteghem." When Baldwin de Mons, count of Flanders and Hainaut, purchased the lordship of one Gerard, in 1068, he built a town, calling it after the name of the former lord, Gerardmont; and hence, by corruption, Grammont. It is partly situated on a hill; and the river Dender, which runs through it, divides it into the Higher and Lower Town; 20 miles W. of Brussels. The place contains 5948, and the canton 16,000 inhabitants, on a territory of $92\frac{1}{2}$ kilometres, in 17 communes.

GRAMMUM, a town of Hindoostan, in Mysoor; 44 miles N. of Seringapatam.

GRAMPIAN HILLS, a range of mountains, extending from E. to W. through almost the whole breadth of the kingdom, from Loch Lomond to Stonehaven, and deriving their name from one of them, the "Mons Grampius" of Tacitus, where Galgacus waited the approach of Agricola, and where was fought the battle so fatal to the brave Caledonians. This chain of hills forms the southern boundary

of the Highlands; though four or five counties on the N.E. of that chain have, in their eastern and northern parts, the name of Lowlands. The transition to the Grampians is gradual; the first chain, according to general Roy, consisting of the Sadley-hills on the E., the Ochills in the middle, and Campsie-hills on the W. To the Grampian chain belong Ben Lomond, 3262 feet high; Ben Ledy, 3009; Ben More, 3903; Ben Lawres, the chief summit, 4015; Schellallen, 3564; Ben Verlich, 3300; and other less considerable elevations on the east.

GRAMPOUND, a small borough and market town, in the hundred of Powder, and county of Cornwall, England, is situated on the banks of the river Fal or Pale, in the parishes of Creed and St. Probus, the eastern part of the borough being in the former parish, and the western in the latter. Grampound is supposed, by Borlase, to stand on the site of the Voliba of Ptolemy. Extensive privileges were conferred on this town by king Edward I., particularly a freedom from toll throughout Cornwall; and the remains of a Caedefula, or Felon Wood, granted with all the lands in it by this monarch, are still extant. The right of holding a market was a grant from John of Eltham, earl of Cornwall, and brother to Edward III., who, after the death of earl John, confirmed the first charter, and made the town a borough: but no representatives were returned to parliament till the reign of Edward VI. Two members are now elected by the magistrates and inhabitants paying scot and lot; but the whole number of voters is only 25. The corporation consists of a mayor, eight magistrates, a recorder, and a town-clerk. The church is about half a mile from the town, in the parish of Creed; but a small chapel of ease stands near the centre of the borough. Grampound is 263 miles S.W. from London; has three annual fairs, and a weekly market on Saturdays. In the return under the late act, the inhabitants amounted to 525, the houses to 80. Polwhele's History, &c. of Cornwall. Beauties of England and Wales, vol. ii.

GRAMPUS, in *Ichthyology*, the DELPHINUS *orca* of Linnæus; which see.

GRAMZOW, in *Geography*, a town of Brandenburg, in the Ucker Mark; 8 miles S.E. of Prenzlau.

GRAN, or ESZTERGON, or *Strigonia*, a town of Hungary, situated near the conflux of the rivers Gran and Danube; the see of an archbishop; 55 miles S.E. of Presburg. N. lat. $47^{\circ}44'$. E. long. 18° .

GRAN, a small island on the W. side of the gulf of Bothnia. N. lat. $62^{\circ}1'$. E. long. $17^{\circ}22'$.

GRANA, a sea-port of Spain, in Galicia; 2 miles W. of Ferrol. N. lat. $43^{\circ}29'$. W. long. $8^{\circ}15'$.

GRANA *Figlia*, in the *Materia Medica*, the fruit of a species of ricinus.

GRANA *Paradis*, or *Greater Cardamoms*, are the seeds of the amomum of Linnæus.

GRANA *Regia*, the seeds of the common ricinus, called by some palma Christi.

GRANADA, or GRENADA, sometimes called *Upper Andalusia*, in *Geography*, a kingdom or province of Spain, occupying half of the eastern extremity, and all the southern part of Andalusia as far as the straits of Gibraltar, has the form of a pyramid with its base to the east, on the kingdom of Murcia, and its apex to the south-west towards the Straits. Its length is 58 leagues from the E. to the S.E.; the breadth at its apex seven from the S.W. to the N.E., and at its base 28 from S. to N. To the E. and N.E., it is bounded by the kingdom of Murcia; to the S. and S.E. by the Mediterranean; to the W., by the kingdom of Seville; to the W. and N.W. by that of Cordova;

and

and to the N.W. and N., by that of Jaen. It lies between $36^{\circ} 20'$ and 38° N. lat. and between $5^{\circ} 5'$ and $1^{\circ} 30'$ W. long.; and contains about 661,600 inhabitants. This province has three sea-ports on the Mediterranean; viz. that of Amunécar, defended by three forts of little importance; that of Almería, which was celebrated under the Arabs; and that of Málaga, now the most flourishing and most frequented. Its principal towns are Granada, the capital, Málaga, Almería, Guadix, Motril, Marbella, Velez-Málaga, Baza, Vera, Ronda, Loja, Santa-Fé, Huelva, Antequera, and Alhama. Its rivers are the Verde, Xenil, Las Feguas, Guadalentia, Guadavar, Guadalmeja, Rio de Almería, Rio Frio, Guadalmerina, Darro, Andaraye, Guadix, Bravata, Marehan, Almarcara, Aguas, Culebras, and Guadalete. This province is very mountainous; its chief mountains being the following, viz. the Sierra Vermella or Vermeja, i. e. red mountain, so called from the colour of the soil, the Sierra de Filabre, the Sierra de Bujo, the Sierra Blanquilla, or white mountain, denominated from its appearance at a distance, and the Sierra de Javal-Cohol. The Sierra Nevada is a grand and beautiful mountain situated nearly in the centre of the province: it takes its name from the snow that remains on it through the year. It is very lofty, can be seen at a very great distance, and is well known to mariners, who discover it far out at sea. The Sierra Alpuxara, likewise in this province, is formed by the contiguity of several lofty mountains, and generally called the Alpuxaras. These afforded a retreat to a considerable number of Moors driven from Granada, who remained there 120 years, till their total expulsion from Spain. The Sierra de Ronda lies on the southern and eastern part of the province of Granada; stretching N. and E. in that of Seville, and running S. towards the straits of Gibraltar. Granada, although mountainous, contains plains of considerable extent, and pleasant valleys abounding in springs.

Granada, as a part of Andalusia, was first known to the Phœnicians and then to the Carthaginians, who were expelled by the Romans; and they also were expelled, in the fifth century of the Christian era, by the Vandals; and the Goths, led by Euric, afterwards took possession of the country. The Arabs entered Spain by Andalusia in the year 711; and after the battle of Xeres, which decided its fate, as well as that of Spain, it belonged to the caliphs of Damascus, and then to those of Bagdad; till at length Abdal-rahman, or Abderame, a prince of the blood-royal of the Omniades or Almohades, seized on the throne of Spain in 755. In the year 1027 the empire of the Moors in Spain was dismembered; and in 1221 the kingdom of Granada was dissolved. Soon after this period, viz. in 1236, Mahomed Almir, or Alhamar, founded anew the kingdom of Granada; and his descendants preserved for about $2\frac{1}{2}$ centuries the throne, which he transmitted to them. It was reserved for Ferdinand V. and Isabella his queen, to give the last blow to the power of the Moors, by depriving them of the kingdom of Granada at the end of the 15th century. The capture of Málaga, Aug. 18th 1487, facilitated the siege of Granada, the capital of the province, into which the Moors had collected their whole force. They were attacked in 1491, and after a siege of upwards of a year, the town was obliged to surrender to the Catholic armies; and thus in 1492 the Moorish empire in Spain terminated. The extent of Granada at this time was 70 leagues long and 30 broad; it contained, as it is said, 32 great towns, 97 smaller ones, upwards of 2000 boroughs and villages, and 3,000,000 of inhabitants. The revenue derived from it amounted annually to 700,000 ducats; and gold and silver abounded more in this kingdom than in any other country of Europe.

But the astonishing fertility and wealth of this country passed away with its old inhabitants, and were succeeded by a deplorable degree of indolence, poverty, and misery.

GRANADA, or *Grenada*, the capital of the province above described, and an archbishop's see, is a large city, which was entirely built by the Moors in the tenth century; and in 1235, after having previously belonged to the dominions of the kings of Cordova, it became the capital of a new empire, and soon acquired great celebrity in the Moorish annals. This town, which in a short time became important for its extent, population, wealth, and power, and the magnificence of its buildings, became, in process of time, the ultimate resource and last bulwark of the authority of the Moors in Spain. We have already given an account of its surrender to the Catholic kings. At that period it was three leagues in circumference, its ramparts were defended by 1030 towers; its walls inclosed 70,000 houses, and a population of 400,000 inhabitants. It had an army of 60,000 men; and the number that defended its ramparts in 1491 and 1492 amounted to 100,000. It was protected by two fortresses, each of which was large enough to contain 40,000 men.

This town stands on two hills, at the end of the plain called Vega de Granada, near the Sierra Nevada, on the banks of the Darro which runs through it, and of the Xenil which bathes its walls. The two fortresses just mentioned are on the summits of the hills on either side, thus commanding the town, which itself commands the beautiful adjacent country ten leagues round; and its situation is delightful. The plain, at the extremity of which it stands, is somewhat sloping; its diameter is from nine to ten leagues, and its circumference 30: on the N. it is bounded by the Sierra Nevada and the mountains of Elvira, and on the other sides by successive and varied amphitheatres of hills agreeably planted with vines, olives, mulberry, lemon, and orange trees, &c.; it is watered by five rivers, intersected by various canals, supplied from limpid rivulets with a number of springs; and it is covered with meadows, forests of oak, woods of orange-trees, orchards, sugar-canes, corn, flax, and in short all kinds of fruits and vegetables.

Granada was formerly divided into four quarters, viz. Granada, Alhambra, Albayzin, and Antiquerula. Of these, the first, or Granada, is the handsomest, most important, most agreeable, best built, and best inhabited part of the town. It occupies the commencement of the plain, and a part of the valleys between the two mountains; it is embellished with a number of fountains, large gardens, handsome squares, and fine buildings: it is inhabited by the nobility, clergy, magistracy, and the richest of the citizens; and the principal markets are situated in it. The quarter of Alhambra, properly speaking, is only a great fortress, situated on a mountain, called Sierra del Sol, or mountain of the sun; it was the residence of the kings, whose palace still possesses great beauties. (See the description of it under ALHAMBRA.) The quarter of Albayzin resembles a fauxbourg raised on a hill, where was formerly a fort, which commanded and protected the town, from which it is separated by a rampart. It contains about 400 houses. Antiquerula has the appearance of another fauxbourg built upon the plain; it was peopled by settlers from Antequera, and is at present chiefly inhabited by dyers and silk weavers. Among the numerous squares of Granada we may specify as the handsomest, El Campo, in which is a hospital; the Plaza Mayor, which is spacious, and used for public shows, particularly the bull-fights; and the Bivarambla, embellished by a beautiful jasper fountain, and by the two fine edifices of the Alcazaria, which was used by the Moors

Moors as a bazar, and still appropriated to the purpose of a market-place, and containing about 200 shops; and the palace of the chancery. To these two buildings we may add an ancient mosque, now a parish-church, the cathedral, two hospitals, and the two palaces of the Alhambra. The cathedral is not large, but has a handsome dome, resting on twelve arches, supported by as many large pilasters; the vault is full of paintings and richly gilt, and two rows of gilded balconies run round it over the arcades. Statues of the twelve apostles in bronze, gilt, and as large as life, are placed against the twelve columns. The vault of the church of the Chartreux is covered with fine paintings in fresco, by Antonio Palomino. In many of the houses are found remains of baths, constructed by the Moors; and most of the houses are embellished with fountains, which supply water not only for domestic purposes, but for moderating by its coolness the heat of a climate extremely warm in summer.

Granada is an archbishopric, worth 25,000*l.* a year, containing a cathedral chapter, six collegiate chapters, and 194 parish churches. This city is the seat of a royal chancery, divided into six chambers, and composed of a president, twenty-five counsellors, two solicitors, and one alguazil mayor. The intendant of the province resides here; and the town has a criminal judge, two alcaldes mayores for the administration of justice, a municipality composed of a certain number of regidores, a war auditor, and a tribunal of the inquisition. The Alhambra has a jurisdiction peculiar to itself. The city is divided into twenty-three parishes, with forty convents, three beatarios, seventeen hermitas or chapels, nine hospitals, and eight colleges. Granada has an university, founded A. D. 1531; and an academy for painting, sculpture, and architecture, conducted at the king's expence, and free for all. The extent of Granada is nearly the same as it was under the Moors; but its population is very much diminished. In 1614, at the period of the total expulsion of the Moors from Spain, a very considerable number of the families of that people left it. The town, which had counted 400,000 individuals within its walls, and which had armed 100,000 warriors in its defence, is now reduced, according to the government returns stated by Mr. Townsend, (*Travels in Spain*, vol. iii.) to 52,325 souls; although, upon good authority, he says, they may be reckoned 80,000. Under the Moors, Granada carried on a great trade, and was famous for its own productions; it manufactured cloths, various kinds of woollen stuffs, and a great quantity of silks. Indeed, it is not possible to think of manufactures in Granada, without calling to mind the expulsion of the Moors, and pausing to examine the policy of that strong measure. They were numerous, and, in consequence of their industry, accompanied with frugality, they had acquired opulence and power. It is said, (see Townsend, *ubi supra*.) that of 100,000, condemned by the inquisition for apostatizing from the Christian faith, 4000 had been burnt without any good effect. Philip III., in the year 1609, banished to Africa 140,000 out of the kingdom of Valencia; and in the three years following, 600,000 from Seville, Murcia, and Granada. If to these we add the multitudes that perished by famine, and by the sword, we shall be inclined to state the loss to Spain at one million of its most active subjects. This loss, added to what the country had sustained by the previous expulsion of 800,000 Jews, with all their wealth, in the reign of Ferdinand and Isabella, was, under such a government as that of Spain, irreparable. The Moors are acknowledged by the best Spanish writers to have excelled in agriculture, particularly in watering their lands, in the cultivation of mulberry trees, the sugar-cane,

rice and cotton, all introduced by them; in their practice of breed of horses; and in the manufactures of silk, of paper, and of gun-powder, first brought into Europe by them. The manufactures of Granada, however, continued to be somewhat flourishing about the middle of the sixteenth century. Some regulations, favourable to them, were adopted and established in 1552. At that time great attention was paid to the production of silk in Andalusia, and the trade in it was prosperous. But, in process of time, as the consequence of the expulsion of the Moors, the privileges and immunities granted to the hidalgos or knights, bearing in the kingdom of Granada the proportion of 1979 to 652,990, the whole number of inhabitants, and various oppressive restrictions and burthens, agriculture languished, silk was neglected, the manufactures decayed, and in the seventeenth century few or none remained. Some attempts have been lately made to revive them; some new ones have been established, in which ribbons and silk stuffs are made; but they have not been very prosperous. There is a manufacture of gun-powder on the king's account. In the production of nitre, at the salt-works near this town, about 100 men are employed in summer, and 26 in winter; and from these government obtains 3000 quintals annually. In the vicinity of Granada are some considerable plantations of the sugar-cane.

The environs of Granada are delightful; the public walks, of which the most frequented are those on the banks of the Xenil with cooling shade and refreshing fountains, and another, more wild and romantic, by the side of the Darro, are pleasant; and the country all round the city appears to be well cultivated. The market gardens appear like a wilderness of fruit trees, and yet are covered with the most luxuriant crops of all kinds of vegetables. Every cottage has a little court, or bower, formed by a lattice frame, and wholly shaded by the vine; under which, in the evening, the peasant assembles his family to take refreshment; whilst the nightingale from every tree is uttering his plaintive note. These gardens are all plentifully watered. Granada abounds in marbles, remarkable for their variety, and fineness of grain and beauty; and it has also a variety of alabasters, jaspers, and other precious stones. Its mineral waters are also various and abundant.

GRANADA, a small town in the province of Nicaragua, seated at the S.E. extremity of the lake of Nicaragua. It has considerable commerce in indigo, cochineal, hides, and sugar. In the year 1680, this town, and also Leon, the capital of the province, were pillaged by the buccaneers of America. N. lat. 11° 15'. W. long. 86° 15'.

GRANADA, *Nova*, a viceroyalty of the dominions of Spain, in South America, extending from the river Tumbez to the Caribbean sea; that is, from S. lat. 3° 30', to N. lat. 12°, or about 930 geographical miles; its medial breadth may be stated at 4° or 240 geographical miles. This grand and opulent viceroyalty, though it dates its origin from the year 1718, was, after a long suppression, only established finally in 1740. It is sometimes called from its capital Santa Fé, and comprises the following provinces: viz. Jaen de Bracamoros, Loja, Cuença, Macas, Riobamba, Guayaquil, Quito, Tacames, Pastos, Barbacoas, Popayan, Raposo, Novita, Antioquia, Santa Fé, San Juan de los Llanos, Merida, Santa Marta, Carthagena, Zinu, Choco, and the Tierra Firme, including the three districts of Darien, Panama or Tierra Firme proper, and Veragua. The ample provinces which form this viceroyalty were mostly discovered and annexed to the dominions of Spain about the year 1536, by Sebastian de Benalcazar, and Gonzalo Ximenes de Quesada, two of the bravest officers employed

in the conquest of America. The former, who commanded at Quito, made an attack from the south, and the latter from Santa Marta on the north. As the original inhabitants of this region were farther advanced in improvement than any people of America, but the Mexicans and Peruvians, they defended themselves with great resolution and good conduct. The abilities and perseverance of these two officers ultimately prevailed, after encountering many dangers, and reduced the country into the form of a Spanish province. The kingdom of New Granada was at first governed by the royal audience founded in 1547, and by its president the captain-general. In 1718 this arrangement was changed, and the viceroyalty was established; but it was suppressed in 1724, and finally established in 1740. When the conquerors first took possession of this country, it was more populous than the generality of the other states; and its want of population at this time prevents its being rendered one of the richest in America. The government resembles that of the other viceroyalties; with a royal audience at Santa Fé, the capital, a tribunal of accounts, a treasury, and a royal mint. The royal audience sits in the same hall for civil and criminal causes; there being five judges, a fiscal, a protector of the Indians, and other officers. The governments, comprehended in the royal audience, are Cartagena, Panama, Santa Marta, Maracaibo, and Porto Bello, with the district of the river Hacha; in the interior are Antioquia, Choco, Veragua, Mariquita, Giron, Neiva, and the Llanos. There is also a royal audience at Quito, and a governor and president, who rules the southern provinces in subordination to the viceroy of New Granada. But Quito remains a bishopric while Santa Fé is an archbishopric, founded in 1562, with Popayan and Cartagena as suffragans. In 1783 the archbishop was named viceroy. There are also several missions in the country called Los Llanos, and on the Apari, Meta, and Casanari, with some little villages or stations. Those on the Upper and Lower Orinoco, and river Negro, assigned to the Capuchins in 1769, belong to the government of Caraccas.

The population of this viceroyalty has not been accurately ascertained; but if the general population of Caraccas amounts to 728,000, it is probable, says Mr. Pinkerton, that rather more than one million may be allowed for that of Granada. Of the amount of its revenues we have no certain documents; but from the amount of the annual coinage at Santa Fé and Popayan, and allowing a tenth to the king for the expences of government, they cannot be less than 220,000 pounds. The state of the military force is inconsiderable; nor would it be easy in these distant provinces to collect an effective force of five or six thousand men. The capital of this viceroyalty is BOGOTÁ, or *Santa Fé de Bogota*, for an account of which see those articles. Of the other principal cities and towns notice is taken in the progress of this work. The commerce of this viceroyalty has very much suffered by the suppression of the galleons; and though it has been encouraged by the freedom granted in 1779, it is not yet recovered. The contraband trade, carried on by the English on the Musquito shore, and from the Portuguese settlements in Brazil, and the Caribbean sea, has impeded the exertions of the Spanish colonists. Its commerce is allowed to be very disproportioned to the distinguishing advantages of this territory. Its existence almost depends on the gold from the mines, a few manufactures, and some native products. The manufactures are carried on chiefly at Tunja, Socorro, Velez, and other towns and villages towards the plains; and they consist of cotton cloths, carpets, counterpanes, and woollens of various descriptions, that support internal trade. The northern provinces pro-

duce excellent wood for the construction of ships; and the dyeing woods are superior to those of Campechy. The mahogany of Panama is exquisitely beautiful, and superior to all others. The chocolate from the banks of the Magdalena is esteemed equal to that of Caraccas; and vast harvests of cotton and tobacco might be gathered, while the navigable rivers Magdalena and Atrato, and the ports of Cartagena and Santa Marta, offer easy and commodious outlets to the European markets. Its intermediate mart of Havana presents another convenience to the traffic of this viceroyalty. The culture of coffee and chocolate is in a prosperous state in the province of Guayaquil. The salutary and useful vegetable productions of these extensive provinces are so numerous and diversified, that industry alone is wanting to open all the sources of commerce.

The climate of this extensive viceroyalty presents great variety; for though it lies under the equator, and in its vicinity, the enormous and sublime chain of the Andes, running N. and S. from the Table land of Quito and Cuenca to the Caribbean sea, and environs of Santa Marta, occasion every diversity from the snow and ice of the poles to the rain and heat of the tropics. The great rivers Magdalena and Cauca rise and terminate in this province. The animals are in general such as are common to the whole continent of S. America; and the inhabitants breed a number of horses and mules which they send to Peru. The mineralogy of New Granada cannot be reckoned unimportant; Alcedo, cited by Pinkerton, observes, that gold is here more abundant than in any other part of America. The richest provinces in this respect are those of Choco and Antioquia; and they are easily accessible by the rivers Atrato and Guacuba, which enter the gulf of Darien, and are navigable for a considerable extent. Silver is also remarkably pure; and the mines of Marquetones, in the district of Pamplona are so rich, that if they had a sufficient number of labourers, they might rival those of Potosi, as they sometimes yield eight marks of silver in the hundred weight. Copper and lead also abound, but they are not much valued; and the various kinds of precious stones are plentiful. Platina has been thought to be the peculiar product of Choco. Salt is obtained in great abundance. The natives use maize, or the Cassava root, instead of bread. Game is abundant; and the rivers and lakes furnish an ample supply of fish. The natives are tall; and wear thick, white, or variegated cloaks, which they tie round the waist with a sash. They adorn their heads with strings of painted flowers very ingeniously made of cotton. Robertson's America, vol. iii. Pinkerton's Geog. vol. iii.

GRANADIER, GRENADIER, or *Granadier*, a foot-soldier, who is armed with a firelock, bayonet, and in some services a hanger, and a cartridge-box that will hold 36 rounds. They wear a high cap, fronted with a piece of brass, on which the king's arms is generally represented, &c. and a piece of cloth upon their shoulders, called a wing. In some armies they have better pay than a common soldier. They were first established in France in 1667, and soon after formed into companies: they were first known in England in 1685.

GRANADIERS, or *Grenadiers, Horse*, called by the French *grenadiers volans*, or flying grenadiers, are such as are mounted on horseback, but fight on foot and on horseback. These were first established in France by Lewis XIV. in 1676, and formed into squadrons.

Every battalion of foot has generally a company of grenadiers belonging to it; which generally take the right of the battalion; and, being the tallest and stoutest men, frequently are the first in attacks.

We have had in England two troops of horse granadier guards; the first raised in the year 1693, and the second in 1701.

GRANADILLA, in *Botany*, the diminutive of the Spanish name of the Pomegranate. *Granada*, used in the West Indies, and retained by Tournefort and Adanson, for the *Passiflora* of Linnæus. This appellation is particularly applied to the fruit of *Passiflora quadrangularis*, much esteemed by West Indians, and sometimes ripened in England.

GRANADO, GRANADA, or *Grenade*, in the *Military Art*, a hollow ball or shell, of iron, brass, or even glass, or potter's earth, filled with gun-powder, and fitted with a fuzee to give it fire.

The name granado takes its rise hence, that it is filled with grains of powder, as a pomegranate is with kernels.

Of these there are two kinds; the one large, the other small: the first are to be thrown at the enemy by a mortar, properly called *bombs*, or *shells*. The latter to be cast with the hand, and thence denominated *hand-granados*.

The best way, Casimir observes, to secure a man's self from the effect of a granado, is, to lie flat down on the ground, before it burst.

The common, or hand granado, is a little, hollow ball of iron, tin, wood, pasteboard, or other matter, filled with strong powder, lighted with a fuzee, and thus thrown by hand into places where men stand thick; and particularly into trenches and lodgments. These are now sunk into disuse.

Their composition is the same with that of *bombs*; which see. For size, they are usually between two and three inches in diameter, about the bigness of a common iron bullet, and weigh about three pounds; as to dimensions, they are commonly in thickness one-eighth, one-ninth, or one-tenth of their diameter; their aperture, or orifice, about $\frac{1}{2}$ wide, as prescribed by Casimir.

Thuanus observes, that the first time granados were used, was at the siege of Wachtendonck, a town near Gueldres; and that the inventor was an inhabitant of Venlo; who, in making an experiment of the effect thereof, occasioned two-thirds of that city to be burnt; the fire being kindled by the fall of a granado.

Bombs were known long before the invention of granados. The ancients had a sort of ollæ, or fire-pots, somewhat of the same nature with our granados, but they were much less perfect.

Casimir mentions a sort of blind granados, without any aperture, or fuzee, as not needing to be lighted; but being thrown with a mortar, they take fire of themselves whenever they fall on any hard solid object.

GRANARD, in *Geography*, a neat, new built market and post town of Ireland, in the county of Longford. Adjoining is a remarkable hill or mount called the *Moat of Granard*, thought to be artificial, and the site of a Danish fort, which commands from its summit a most extensive prospect into six or seven adjoining counties. It is 52 miles from Dublin, and 12 from Longford.

GRANARY, in *Agriculture*, a building contrived for laying up and storing corn, in order to preserve it for a length of time. They have, near Grand Cairo, magazines or granaries, called "Joseph's granaries," defended with wooden walls, in which vast quantities of grain are annually preserved; and many parts of Africa abound with granaries of this kind. They are frequently deep pits made in the solid rock; the descent into them being just large enough for a man to go down; but they grow larger as soon as the person is in, and are usually square, from thirty to forty

feet in diameter. In these the great men of the country preserve their corn; they first cover over the floor with straw, then they lay on the corn, still, as the heap rises, placing a thin bed of straw between the corn and the floor, as they did at the bottom. In this manner they proceed till the whole cavity is filled; when this is done they cover the mouth or entrance with a sort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickness of sand, and over this raise a ridge of earth, well beaten together, in order to throw off the rain both ways, that none may settle on the place and soak into the magazine. The corn thus stored up keeps three, four, or more years very good; and, not infrequently, the proprietor being taken off by the severity of the eastern governments, under which they live, the magazine is forgotten, and some accident discovering it many years afterwards, the corn is almost always found perfectly good in it. All the care they take, in regard to the grain, is to expose it two or three days to the sun's heat, to dry it thoroughly, before they carry it into the magazine.

It may be stated further, that in the duchy of Lithuania, and in the Ukraine, the people also preserve their corn in the same manner, in wells or pits made in dry places: but in these countries great care is to be taken in the opening of these store-rooms; for, if people descend into them before they have had sufficient communication with the fresh air, they are often killed by the damps; this, however, is easily guarded against. By these, and numerous other instances of the practice of other countries, it appears evident that subterranean granaries may occasionally be highly useful for the purpose of preserving grain in particular situations and circumstances.

But the common granaries may, with proper care, be rendered much more useful than they are at present. The grand caution necessary to this purpose is, to guard against the too great humidity, which is often the case in places where there is a great number of doors and windows. A too free access of the external air is also to be guarded against; as this has not only a tendency to produce the above effect, but is liable to bring in with it the ova or eggs of a number of different insects, which prey upon and destroy the corn. A third caution is, when the corn is the produce of the country where it is preserved, not to fill the place with the crop of one place only, but to mix the harvests of two as different provinces as may be, the one dry, the other moist, or otherwise differing as much as may be; thus the contrary qualities of the one may prevent the destruction of the other. These are the principal rules to prevent the corrupting of corn: but when the mischief is once begun, it will be very difficult to stop it; all the care that can be employed should, of course, be taken in regard to these as speedily as possible.

It may be observed, that the chief points to be attended to in the erecting of granaries, are to make them sufficiently strong, and to give them such a situation as may expose them to the most drying winds. But in constructing a granary merely for the accommodation of a farm, it is unnecessary, Mr. Batefon observes, in the second volume of Communications to the Board of Agriculture, to attend to all those circumstances respecting strength, situation, &c. which ought to be observed in building an extensive granary, where large quantities of grain are sometimes deposited. A farmer seldom wishes to have a great deal of his thrashed corn on his hands at once; nevertheless there ought, on every farm, to be a place of security, capable of containing, at least, one-third or one-half the grain produced

duced annually on the farm. Where the practice of housing corn is followed, there is little or no room, he remarks, within the barn for a granary; but where this is not the practice, particularly where there is a thrashing mill, the granary may be easily made over the barn; which, with proper tackle for hoisting the sacks from below, is, he thinks, the most convenient and least expensive place a farmer can have it in.

The ordering of the corn in many parts of England, after being separated from the chaff, dust, and other impurities, and well screened, is this: after bringing it into the granaries, it is spread about half a foot thick, and turned from time to time, about twice in a week; once a week they also repeat the screening. This sort of management is continued two months, and after that it is laid a foot thick for two months more, and during this time turned once a week, or twice, if the season be damp, and now and then again screened over. After about five or six months, it is raised to five or six feet thickness in the heaps, and then turned once or twice in a month, and screened now and then. When it has lain two years, or more, it is only turned once in two months, and screened once a quarter; but how long soever it is kept, the oftener the turning and screening are repeated, the better the grain will be found to keep. It is proper to leave an area of a yard wide on every side the heap of corn, and other empty spaces, into which it may be turned and tossed as often as there may be occasion. In Kent they make two square holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their screens are made with two partitions, to separate the dust from the corn, which falls into a bag; and when sufficiently full, this being removed, the pure and good corn remains behind.

By these means corn has been kept in granaries thirty years; and it is asserted, that the longer it is kept the more flour it yields, in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only having been evaporated in the keeping. At Zurich, in Switzerland, it is said that corn has been kept eighty years, or longer, by the same methods of management.

It is stated that the public granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the midst of every floor, to let down the corn from one to another. They are built so securely, that, though every way surrounded with water, the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians preserve their corn in subterranean granaries, of the figure of a sugar-loaf, wide below and narrow at top: the sides are well plastered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these store-houses, and often dry it by means of ovens, their summer dry weather being too short to effect it sufficiently for the purpose.

Different contrivances have been proposed by M. Du Hamel and Dr. Hales, for ventilating or blowing fresh air through corn laid up in granaries or ships, in order to preserve it sweet and dry, and to prevent its being devoured by weevils or other insects. This may be done by nailing wooden bars or laths on the floors of the granary, about an inch distant from each other, when they are covered with hair-cloth only; or at the distance of two or three inches, when coarse wire-work, or basket-work of osier, is laid under the hair-cloth, or when an iron plate full of holes is laid upon them. These laths may be laid across other laths,

nailed at the distance of fifteen inches, and two or more deep, that there may be a free passage for the air under them. The under laths must come about six inches short of the wall of the granary at one end of them, on which end a board is to be set edgeways, and sloping against the wall: by this disposition a large air-pipe is formed, which, having an open communication with all the interstices between and under the bars, will admit the passage of air below forcibly through a hole at the extremity of it, into all the corn of the granary, that will consequently carry off the moist exhalations of the corn. The ventilators for supplying fresh air may be fixed against the wall, on the inside or outside of the granary, or under the floor, or in the ceiling; but wherever they are fixed, the handle of the lever that works them must be out of the granary, otherwise the person who works them will be in danger of suffocation when the corn is fumed with brimstone, as is sometimes done for destroying weevils. Small moveable ventilators will answer the purpose for ventilating corn in large bins or in small granaries, and may be easily moved from one bin to another. If the granary or corn-ship be very long, the main air-pipe may pass lengthwise along the middle of it, and convey air, on both sides, under the corn. In large granaries, large double ventilators, laid on each other, may be fixed at the middle and near the top of the granary, that they may be worked by a wind-mill fixed on the roof of the building, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the several floors to the bottom of the granary, with branching trunks on each floor, by means of which the air may be made to pass into a large trunk along the adjoining cross walls: from these trunks several lesser trunks, about four inches wide, are to branch off, at the distance of three or four feet from each other, which are to reach through the whole length of the granary, and their farther ends to be closed: seams of one-tenth or one-twelfth of an inch are however to be left open at the four joinings of the boards, where they are nailed together, that the air may pass through them into the corn. In some of these lesser trunks there may be sliding shutters, in order to stop the passage of the air through those trunks which are not covered with corn; or to ventilate one part of the granary more briskly than others, as there may be occasion. There must also be wooden shutters, hung on hinges, at their upper part, so as to shut close of themselves; these must be fixed to the openings in the walls of the granary on their outside: by these means they will readily open to give a free passage for the ventilating air, which ascends through the corn, to pass off, but will instantly shut when the ventilation ceases, and thereby prevent any dampness of the external air from entering: to prevent this more fully, the ventilation should be made only in the middle of dry days, unless the corn, when first put in, is cold and damp.

But in smaller granaries, where the ventilators must be worked by hand, if these granaries stand on staddles, so as to have their lower floor at some distance from the ground, the ventilators may be fixed under the lower floor, between the staddles, so as to be worked by men standing on the ground without or within the granary. A very commodious and cheap ventilator may be had for small granaries, by making the door of the granary serve the purpose, which may be easily done by making a circular screen, of the size of a quarter of a circle, behind it; but in order to this, the door must open not inwards but outwards, of the granary, so that, as it falls back, it may be worked to and fro in the screen; which must be exactly adapted to it in all parts of the circular side of the screen, as well as at the top and bottom.

GRANARY.

bottom. But there must be a step at about eight or ten inches distance from the wall, to prevent the doors falling back farther, that there may be room for a valve in the screen to supply it with air: which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there must be another valve over the hole in the wall, to prevent the return of the air from within.

But with the view of facilitating the labour of frequently stirring and ventilating the grain, and of lessening the expense of such buildings, a member of the Society for the Encouragement of Arts, Manufactures, and Commerce, in a letter to Dr Templeman, recommends a new-invented granary, of which the following description is given. It consists, he says, of seven stories of floors, and may be built of any dimensions, provided proper proportions are adhered to. The form of it is square, suppose fourteen feet square within the rooms or cells. The distance from the floor of one cell, to the floor of that above, is five feet; and the whole building should stand on strong posts, more or less in number, according to the dimensions, at the distance of six feet from the ground. The small stairs, or rather ladder, to go to the several cells, must be fixed on the outside of the building sideways, with a leading rail, or rope, to prevent falling. The whole granary to be built of what is generally called brick noggin; that is, it is first framed in strong timber work, and the interstices filled up with brick. The floors, beams, and joists, are to be made strong to bear the weight of the corn; and the inside of the cells well lined with dry oak-board, close jointed, and the outside weather-boarded, the boards being strongly nailed to the timber-work of the frame, and afterwards payed over with pitch. The floors of the cells are to be so contrived, as to slide towards the middle, in which part is to be an aperture six inches square, to be opened or closed by means of a sliding shutter, which must have a long handle, reaching in a groove, without the granary. On three sides of the rooms there should be windows strongly latticed, covered with wire, to keep out large insects and birds, and with strong shutters, to defend the corn from the weather. On the fourth side is a door to each room, to open from without. The windows are to be small, and as close as possible to the ceiling. Over the upper room or cell is a loft, on the outside of the door of which is fixed a crane, to be worked within by a winch and fliers. The use of the windows in the sides of the rooms, is to give the corn all the benefit it can receive from the wind and fresh air. The door, when the cell is empty, admits the workman to sweep, dust, and clean it. The method of managing corn in this sort of granary is as follows: when the wheat is properly cleaned, it is hoiled in sacks to the loft above, and emptied through a hole for that purpose in the floor. The apertures in the floors of the cells being all open (except the two undermost, which are closed by the sliding shutters), the grain falls through till it reaches the undermost cell but one: when this is filled to the height of about two feet, which may be seen through the windows, the aperture in the floor of the next cell above is shut by its slider. This being filled in the same manner, the next above it is also shut, and so on till the whole are filled, if required, except the undermost, which is left empty. In this condition the corn is left for a week or more, if it was got in very dry. When it is to be stirred, the floor of the undermost cell is to be swept very clean, the door is again shut, and the slider in the floor above drawn back, which allows the corn to fall through into that cell. When the cell above is empty, the slider is again shut, the floor swept very clean, and the slider in the next floor over that is opened. In this

manner they are all managed, till at last the uppermost cell remains empty; and the windows having all been open while the corn was falling from one cell to another, render great benefit thereto, by admitting a current of air to pass through. Under the aperture in the floor of the lower cell, a proper screen is fixed; at the end of this screen is fixed a conductor or spout, to which a sack is hung, its bottom resting on a miller's hand-barrow; the slider is then drawn, and the corn let fall on the screen, from which it runs into the sack: when the sack is full, the slider is for a moment shut, till another sack, on another barrow, is put under the conductor; the workman then wheels the first sack to the outside of the granary, and, fastening the crane rope to it, it is drawn up by another workman in the loft. The same method is pursued till the lower cell is emptied. If it is necessary to screen all the corn at this time, a small screen is fixed under the aperture of the next cell to be emptied, so contrived, as to have a box at the back of it for receiving all the dust, seeds of weeds, &c. that pass between the wires; and this screen is successively fixed under every aperture as the cells are successively emptied. After the first month, the corn need be stirred in this manner only once a fortnight, and after the first six months, only once a month, unless the weather should prove in autumn very hot and damp. The advantages of this granary, as described by the inventor, are, that it is built at a small expense; that it contains a great deal of grain in a small compass; and that the grain is easily sifted and ventilated, without the tedious mode of turning it with shovels, or other similar means.

However, the plan of a granary, taken from one built on his own estate, by a very respectable and intelligent gentleman in Cheshire, who has found it to answer extremely well, it is conceived, by an able writer, will perhaps be preferable to the above, not only from its cheapness, but from its simplicity, and the easy mode by which the whole body of grain is stirred, and the air conveyed and circulated through every part of it, at whatever thickness or depth it is laid, and one floor only is necessary, however high the building may be. There can be no doubt, but that a granary of this nature may be very useful and convenient in many cases.

This sort of granary is shewn in *Plate Granary on Agriculture*, in which *fig. 1.* displays the front elevation of the building: *a* is the door into the lower part; *b*, the door into the loft above, to ascend to which a ladder is necessary; *c*, a crane for hoisting sacks up from below; *d, d, d,* are air-holes for ventilation. At *fig. 2.* is seen a section or view of the inside of the building; *a, a, a, a, a,* are wooden spouts, which reach from the air-holes on one side of the granary to those on the other. These spouts are formed of inch deal, about six inches broad, and made with an angle similar to those spouts that are employed to convey off the rain water from the eafings of houses. They are placed across the granary with the angle upwards, as represented at *fig. 3*; *b, b, b,* are the ends of similar spouts, which cross the others, and also reach betwixt the air-holes on the other two sides of the building, as seen at *fig. 4*; *c, c, c,* are half spouts, extending in the same manner to air-holes on each side. It is necessary that the air-holes should decline outwards, in order to prevent the entrance of rain or snow in stormy weather; and they should likewise be secured from insects and vermin by wire cloth; *d d,* the floor of the granary, which is three yards square, and divided each way into three hoppers, *e, e, e,* of one square yard each, making in the whole nine hoppers, as seen at *fig. 5*; *f* is a large hopper, that encompasses all the rest, and has a slider at *g* for opening occasionally, as may be necessary in taking out the grain. And there is another smaller hopper *i*, which is suspended to this by four iron haps,

hasps *k, k, k*, that may be readily unfastened when required, from the square deal box *o o*, fixed to the large hopper. Through the side of this box, the handle *b* of the slider must extend. This hopper is principally used for the convenience of taking out a small quantity of grain, but is removed when a large quantity is to be taken from the granary; *m* is a small loft into which the sacks of grain are hoisted, and emptied over the sides or rails *n, n*, from which it falls down, and passes through the hopper *e, e*, till *f* is filled (the slider *g* being closed); and as the corn continues to be emptied from the loft, the granary is gradually filled until it is up to the top if necessary. The spouts being all inverted, as noticed above, and open below, it is obvious that, although the granary be filled to the top, the corn will not, like a fluid, rise within the spouts above the level of their lower edges; and thus there will be a vacuum left within every spout, through which the air will freely pass. These spouts are placed three feet distant from each other, horizontally from angle to angle, and eighteen inches vertically; that is, from those in one tire, to those in another, which is the next, and crosses it. The holes in the bottoms of the hoppers *e, e, e*, should be so proportioned, that one may not give vent to the grain faster than another; for which reason, the aperture of the middle one *a*, *fig. 5*, should be the smallest, because there is the least obstruction there. The apertures *b, b, b, b*, ought to be somewhat larger, as the grain will meet with some little obstruction there; by the sides of the large hopper; and the apertures or openings *e, e, e, e*, should be the largest, as the obstruction in the angles will be greater than in any other part of the work.

GRANASUOLA, in *Geography*, a town of Italy, in the department of the Amona; 6 miles N. of Faenza.

GRANATAN, a town of Saxony, in the circle of Erzgebürg; 12 miles N. E. of Freyberg.

GRANATARIUS, in *Middle Age Writers*, an officer in monasteries who took care of the provisions.

GRANATE, popularly called garnet, in *Natural History*. See GARNET.

GRANATE *Paste*. The counterfeit garnet in paste, is formed with three different proportions of the ingredients, which are these:

Take prepared crystal two ounces, common red-lead six ounces, manganese sixteen grains, zaffer three grains; mix all well together; and put them into a crucible: cover it with a late, and set it in a potter's kiln for twenty-four hours.

Or, take crystal two ounces, minium five ounces and a half, manganese fifteen grains, zaffer four grains; mix them well together, and leave room for their swelling in the pot; bake them twenty-four hours in a potter's kiln.

The last method is this: take crystal prepared two ounces, minium five ounces; mix them, and add manganese fifty-two grains, zaffer six grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty-four hours.

The first of these makes a very handsome garnet of the common tinge; the second, a deep one, with something of a violet tinge, as many of the natural garnets have; but the third makes much the finest and brightest. *Neri's Art of Glass*, p. 134. See GLASS and PASTE.

GRANATINE, a name given by Kirwan to several triple compounds, professedly of the granitic kind; but as it includes also combinations that have no more than one essential ingredient of granite (such as the combination of quartz, jade, and garnet), it is obvious, that many rocks, thus united into one class, are far from having all the characters of granitic compounds.

GRANATITE. See STAUROLITE.

GRANATRISTUM, in *Surgery*, denotes a boil, or a carbuncle.

GRANATUM, in *Botany*, and the *Materia Medica*. See PUNICA.

GRANBY, in *Geography*, a township of America, in Essex county, Vermont, containing 69 inhabitants.—Also, a township in Hampshire county, Massachusetts, E. of S. Hadley, about 9½ miles W. of Boston; incorporated in 1768, and containing 768 inhabitants.—Also, a township in Hartford county, Connecticut, on the line which separates Connecticut from Massachusetts; 18 miles N. of Hartford, and containing 2735 inhabitants.—Also, a small town on the Congaree, in South Carolina; a place of considerable commerce, having a curious bridge, the arches of which are supported by wooden pillars, fixed by iron-work, in the solid rock, 40 feet high above the level of the water, with the centre arch 40 feet in the clear, for admitting the passage of large trees brought down by the flood.

GRANBY Bay, a bay on the N. coast of the island of Dominica. N. lat. 15° 42'. W. long. 61° 25'.

GRANCEY-EX-MONTAGNE, a town of France, in the department of the Coté-d'Or, and chief place of a canton, in the district of Dijon; 21 miles S. E. of Chatillon-sur-Seine. The place contains 687, and the canton 4071 inhabitants, on a territory of 210 kilometres, in 11 communes.

GRAND, a term rather French than English, though used on many occasions in our language. It has the same import with *great*, being formed of the Latin *grandis*.

In this sense we say, the grand master of an order, the grand master of Malta, of the free-masons, &c.

So also, the grand signor, the grand visier, &c. grand-father, grand-mother, &c.

In the French polity and customs there are divers officers thus denominated, which we frequently retain in English; as grand almoner, grand ecuyer, grand chambellan, grand voyer, &c.

GRAND, ANTHONY LE, in *Biography*, who flourished in the 17th century, was a native of Douay, and is denominated by some writers the “abbreviator of Descartes.” He was author of many works on the subject of philosophy, the chief of these are, “*Institutio Philosophiæ secundum Principia Ren. Descartes*,” 4to. “*Curiosus Naturæ Arcanorum Persecutor*.” Notes on the *Physics of Rohault*, which have gone through many editions; and “*Historia Sacra a Mundo condito ad Constantinum magnum*,” which is said to be his best performance. *Moreri*.

GRAND, JOACHIM LE, a French political and historical writer, was born in 1653 at Thorigny, in Normandy. In early life he entered into the congregation of the Oratory, which he quitted in 1676, and went to Paris, where he engaged in the education of two young men of rank, and at the same time applied himself with all diligence to the study of history under the direction of father Le Cointe. He first appeared as a writer in the year 1688, in “*A History of the Divorce of Henry VIII. and Catharine of Arragon*,” in three vols. 12mo. The main object of this work is to refute certain facts and arguments contained in the two first books of Burnet's *History of the Reformation*. This produced a controversy between Le Grand and the English prelate, which has long since ceased to be interesting. In 1691 he addressed three letters to the bishop, on his critique of Bossuet's *History of the Variations of Protestants*. After this Le Grand was taken from his literary pursuits by the appointment of secretary to the abbé d'Estrees, in his embassy to Portugal. In this situation he continued till

the year 1697. The leisure which his diplomatic functions allowed was employed in translations of *Voyages and Travels* from the Portuguese. In 1702 he accompanied the same minister in Spain, where he remained about two years as secretary. Soon after this the marquis de Torci, minister of state, took him into his service, and employed his pen in drawing up several memorials concerning the Spanish monarchy, and other political topics, in which he was of great use to his patron, and acquitted himself with great ability. As an author his last printed work was a treatise "On the Succession to the Crown of France." This was given to the world in 1718, and is reckoned a curious and useful performance. He died at the age of 80 in the year 1733. He had been possessed of church preferment, and had held, for a time, the office of censor royal of books. Moreri.

GRAND, in *Geography*, is a denomination applied to a variety of places, as in the following instances.

GRAND *Anse*, or *Jeremie*, a well-built town in the western part of the island of Hispaniola; the road of which is so bad, that vessels, in order to escape the wind, are compelled to take shelter behind Cape Donna Maria. N. lat. 18° 15'. W. long. 74° 5'.

GRAND *Bay*, a bay on the S.W. coast of Newfoundland, somewhat S. of Cape Ray.

GRAND *Bourg-Salagnac*, a town of France, in the department of the Creuse, and chief place of a canton, in the district of Guéret. The place contains 2525, and the canton 7828 inhabitants, on a territory of 215 kilometres, in eight communes.

GRAND *Canal*, in Ireland, is an establishment of which we have given some account in our article CANAL, and have here to correct an error which crept into that account, in stating that the canal terminates in the Shannon at Tarmonbury, instead of Shannon-harbour, two miles above Banagher. The branch to the Barrow joins that river at Athy; with a collateral branch from Low-town near Monasterven to Portarlinton.

When the new part of the canal was finished in 1804, from Tullamore to the Shannon, a general repair and deepening of the old parts took place, in which 3000 men were employed for expedition, and the whole line was scoured out, so that 60 ton boats might pass. At Tullamore there are wharfs and warehouses for goods, and also at Shannon-harbour, with inns and other accommodation for persons on business.

The Doonare and Boulavoneen collieries in Queen's county, belonging to this company, were in February 1809 worked by 100 men, and they advertised for 200 more, in order to work 100 acres of a coal three feet four inches thick, which had then recently been laid dry: the canals and river navigations admitting of their being conveyed to Dublin, Limerick, Waterford, Athlone, &c.

Kildare aqueduct, eight miles from Dublin, is 100 feet high, according to M. De Luc, *Geology*, p. 320.

GRAND *Champ*, a town of France, in the department of Morbihan, and chief place of a canton, in the district of Vannes; seven miles N.N.W. of Vannes. The place contains 4139, and the canton 7850 inhabitants, on a territory of 202 kilometres, in four communes.

GRAND *Couronne*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Rouen. The place contains 8000, and the canton 12,795 inhabitants, on a territory of 182½ kilometres, in 13 communes.

GRAND *Fathers*, several large detached mountains of America, in the S.E. corner of Tennessee, in which are the head-waters of French Broad, and Cataba rivers.

GRAND *Foro*, a town of Africa, on the Slave Coast.

GRANDE *Island*, an island in the Atlantic, on the coast of Brazil; 16 miles long and two broad. S. lat 23° 15'.

GRAND *Island*, an island of America, in lake Superior, on the N. side of the lake.—Also, an island in Niagara river, about six miles long and three broad; its S. end is four miles N. of Fort Erie.—Also, an island at the mouth of lake Ontario, within the British territories; 20 miles long and at its greatest breadth four miles.

GRAND *Isle*, a new county of America, in the N.W. corner of the state of Vermont, incorporated in 1802, and including the towns of North Middle and South Hero, Vineyard (late Isle Motte), and Alburgh.

GRAND *Isles*, two large islands in lake Champlain, each about eight or ten miles long, and forming a township belonging to Vermont.

GRAND *Junction Canal*. To the full account which we gave of this very important inland navigation in our article CANAL, we have here merely to add a few particulars which have occurred since that account was printed. The act of the 50th Geo. III. for the Grand Union canal provides, that a canal with locks is to be substituted for the railway-branch from Gayton to Northampton, in order to open a communication by water, from the head of the new navigation, the design for the continuation of the Leicestershire and Northamptonshire Union canals further south than Market Harborough, where it now terminates, being dropt, in consequence of the adoption of the Grand Union above-mentioned, which will connect the above canal with the Grand Junction. The three aqueduct arches over the Ouse at Wolverton having been made flat elliptical, instead of the curves of equilibration, and the foundation also insufficient, they gave signs of great insecurity immediately on their centres being struck, and in February 1808 two of them actually fell in and emptied the canal, as far as the stop-gates: fortunately, the old line of locks across the valley had not been disturbed, and the trade has suffered no interruption in consequence. A cast-iron aqueduct on brick and stone piers is now substituting for these three arches, under the direction of Mr. Benjamin Bevan, who is now the engineer to the company. In 1807 a new reservoir was completed near the side-ponds on the northern side of the Tring summit, for supplying water to the locks below the side-ponds in dry seasons.

In examining the strata and springs on the north side of the chalk summit, between Tring and Wendover, with a view to better supplying the Wendover branch and summit-level with water, Mr. Bevan discovered, that different water-tight beds in the lower chalk held up springs a considerable height above the canal, owing to their dip to the southward; and in order to avail himself of this water, a fough or tunnel was began in the upper bank of the canal near Wendover, and has been driven about half a mile southward, intersecting different strata of chalk from beneath, and increasing in its supply of water as it proceeded: but observing that the principal vent of this water was in the winter and early spring months, when the other sources were more than sufficient for the supply of the canal, it occurred to that ingenious gentleman to place a strong and water-tight valve in the most favourable part of this tunnel, which, as soon in the autumn as the canal is amply supplied from its other feeders, is shut, and kept so, until these begin again to slacken in their supply; the water in the immense planes of these beds of chalk, in the mean time accumulating, as in a vast subterranean reservoir, the springs rise to the level which they originally did before this tunnel was begun, about 20 feet above the canal; and for many weeks

alter the opening of the valve, in the beginning of summer, they pour forth a most surprising stream of water into the canal, which otherwise would have vented miles off in the chalk vallies, or slowly have made its way down through the joints and fissures in the strata to springs at the bottom of the chalk, which vent below the level of the canal.

In 1808 a twelve-horse single Bolton's steam-engine was erected near Nash-mill, in Hertfordshire, to lift the water again, the rise of four locks, for better supplying the mills during seven or eight months of the year. The company, in 1806, caused boats to be fitted up for conveying fat sheep alive, in tiers one above another, from distant places in the county, to the London markets, instead of fatiguing them by driving along the roads, the scheme of thus bringing oxen having been previously tried, and found not to answer; but after a fair trial, the expences were found to over-balance the advantages expected from this also; we are sorry also to add, that the cattle-market at Paddington has failed, and that the pens erected for it by the company have been fold and removed.

The limited quantity of coals brought to Paddington, or within 20 miles of London by this canal, now pay a duty of 10s. 9 $\frac{3}{4}$ d per ton (of 20 \times 112lb.), which is equivalent to the duty on Newcastle coals in the Thames: in consequence of this heavy and oppressive duty, many waggons and carts are employed in fetching coals by land, from the next wharf beyond the limited distance, near Watford. The Grand Union canal above-mentioned is begun, and is to join this canal near the S.W. end of the Braunston tunnel. The design of a branch from near Tring, through Aylesbury and Thame, to the Thames and Isis navigation and Wilts and Berks canal near Abingdon, has been again revived, and it seems probable, that an act for that purpose will pass in the ensuing sessions of parliament (1811).

Towards supplying water to the inhabitants near Paddington, a transfer of the company's rights has been made to a separate water-company, which is expected to be confirmed by parliament in the ensuing sessions.

In November 1806, the company declared the first yearly dividend of 1 $\frac{1}{2}$ per cent. on the original shares, which has regularly increased to 3 per cent. half-yearly, exclusive of property tax. The affairs of the company seem now fast retrieving from the effects of their great mismanagement for many years after its establishment, and to be now in a very prosperous state; the shares (of 100*l.*) were, in September 1810, reported to be currently sold at 30*l.* each! although, at one period, the same could with difficulty be disposed of at 65*l.* to 70*l.* each: such are the effects of good or bad management, and of abilities and integrity in those entrusted with the direction and management of an immense concern like this, in inspiring confidence in commercial men to enter into trade and speculations connected with the canal, and in capitalists to invest their money in the company's shares. A resolution of the general assembly of proprietors, on the 7th of June 1803, for appointing a general superintendant of their concerns, principally led to this beneficial change. On the 11th of June following, Charles Harvey, esq. was appointed to this office by the committee, and, after much opposition from certain powerful individuals, was, on the 11th of July, confirmed therein, by a general assembly called for the special purpose.

GRAND Key, a small island among the Bahamas. N. lat. 26° 54'. W. long. 77° 48'.

GRAND Lake, a lake of Louisiana. N. lat. 32°. W. long. 93° 5'.—Also, a lake in the province of New Brunswick, near the river St. John's, said to be 30 miles

long, eight or ten broad, and in some places 40 fathoms deep.

GRAND Luce, Le, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Saint-Calais; 14 miles S.E. of Le Mans. The place contains 2045, and the canton 10,493 inhabitants, on a territory of 227 $\frac{1}{2}$ kilometres, in 8 communes.

GRAND Maen Island, an island of the Atlantic ocean; 6 miles S. by S.E. of Campo Bello island, opposite to Papamaquoddy bay on the eastern border of the United States.

GRAND Ridge, is a term often used, (see our article CANAL,) for the water-head, or summit line, across an island or continent, from whence the rain waters fall by opposite courses to the ocean. It results from the admirable system of vallies, which the great Creator has spread over the whole face of the earth, leaving no part, perhaps, originally of the surface, without a descent and out-fall to the sea; that the ridges, or summit-lines, form a system not less beautiful and perfect than the vallies; and whence it happens, that, from any hill whatever, it is practicable to mark on a good map, and to travel to every other hill in the same island or continent, however large, without crossing any running water, however small, but constantly to pass along a ridge or watershed; whence the waters on the surface fall opposite ways from your route. It seems surprising, that no one has attempted to illustrate this subject by a good map, shewing all the connections and windings of these ridges in England, or even any local district, until of late, that Mr. Farey has prepared a square of map, including Derbyshire, shewing the ridges, and the situation of all the hills and principal eminences upon them, which is intended to accompany his report to the Board of Agriculture on that interesting district.

The triangular form of the British island, and the situation of the two principal rivers, the Thames and the Severn, (or rather the Bristol channel,) occasion the grand ridge of England to divide into two branches on the Chalk Downs, a few miles N.E. of Devizes; one of which, (the south-western,) proceeds to Rundaway-hill, and crosses the deep cutting of the Kennet and Avon canal, near to Devizes, near East Lavington, Warminster, Wincanton, Beaminster, Crewkerne, Chard, &c. by a most circuitous route, passing almost to the north and to the south coasts alternately, until it reaches the Land's End in Cornwall: having, in this long route, probably descended to no lower strata than the red ground or marl, of which we shall speak further presently.

The other, or south-eastern branch of the grand ridge, proceeds along the chalk and the clays and sands above it, across the deep-cutting of the Kennet and Avon canal, near Burbage, by High-clere, (near which it probably occupies the highest stratum in the whole British series,) near to Alton and Haslemere, when it soon descends off the chalk into the great southern denudation, (see Philosophical Magazine, vol. xxxv. p. 130.) and pursues the under measures, through the wealds of Suffex and Kent, by Alford, Leith-hill, Handcross, (on the London and Brighton roads, being there on the lowest stratum but one which appears in that road,) by Turner-hill, Nutley, Crowborough, Rotherfield, Wadhurst, Tenterden, Shadoxhurst, Lyme (near Hythe), where it again ascends the edge of the chalk, and proceeds on it by Paddlesworth, Swingfield, and Lydden, to the coast at King's Down, near Walmer castle.

From the point of branching, N.E. of Devizes, as above described, the grand ridge follows the chalk northward by White-horse hill, near Cherhill, &c. till within a few miles

of Swindon, when it turns to the N.W., and descends to the marl, and other strata below the chalk, crossing the Woburn sand stratum, not far from Wooton-Basset: and, passing to the Bath free-stone range, it crosses the Salperton tunnel, on the Thames and Severn canal, and proceeds near to the western edges of the same strata, by Charlton-Kings, near Cheltenham, Stanway-hill, Broad-way-hill, Lemington-hill, Long-Compton-hill, and Epwell; soon after which, the grand ridge begins to leave the free-stone, and take to the dark blue clays, &c. under it, except crossing some points of the stone, and traverses the Fenny-Compton tunnel, on the Oxford canal; thence by Heliidon, and near Daventry, it crosses the Brunston tunnel, on the Grand Junction canal, at West-Haddon, and at Husband's-Bosworth, the tunnels of the Grand Union canal; when, turning north-west, the ridge passes Gilmorton; and not far from Lutterworth it crosses the Lias clays and lime-stone strata, and descends to the red marl (above mentioned), and quickly, by a great fault, or sudden lift of the strata, is brought upon the coal-measures of the Bedworth-field, and crosses the deep cutting of the Coventry canal, through Bedworth town, across the late Sir Roger Newdigate's canal, and sweeps round to the west, south-west, and south, to Kenilworth; when, having crossed another fault, and got again upon the red marl, it crosses the deep-cutting of the Warwick and Birmingham canal, near Baddesley-Clinton, and of the Stratford canal, near Hoekley; thence by Ashley-heath, and crosses the West-heath tunnel of the Worcester and Birmingham canal, and the Lapal tunnel of the Dudley canal: after which, the grand ridge crosses the basaltic hills between Rowley and Dudley, (which belong to the red marl strata,) and, descending to the coal-measures, crosses the Dudley tunnel N.W. of that town, and proceeds by Sedgley; then crossing an erect and denuded patch of the yellow lime-strata, it crosses the deep-cuttings of the Old Birmingham canal, the Wyrley and Essington canal, and of the Staffordshire and Worcestershire canal, all near Wolverhampton town; then by Taterhall, Wrottesley, Blimhill, Cowley, Wooton, (near Eccleshall), Broughton, Ashley, Maer, Madeley-park, to Keefe, (near Newcastle-under-line,) where it has again got upon coal-measures, by Bignole-hill, and across the Harecastle tunnel, on the Trent and Mersey canal, by Golden-hill, Wickinton rocks, and, crossing an immense fault, descends to the lime-stone shale, (see Mr. Farey's section in *Plate II.* vol. xxxi. of the *Philosophical Magazine*;) on Biddulph Moor; thence passes the top of the Great Rudyard reservoir, to Gun-hill, and crossing to High Roches rocks, it there ascends the first grit; then crosses a small trough of the first coal-shale and second grit, and descends again to the first grit, or Ramshaw rocks, and still further, on the lime-stone shale, at the Royal Cottage, along which it proceeds to the N.W. side of Flash, and then ascends the first grit again, on South-Axe-edge-hill; it again descends to the shale lime-stone in crossing Middle and Great Axe-edge-hills; from whence it ascends across the first grit and first coal-shale, and ascends the second grit on Thatch Marsh; this it pursues to the north of the Macclesfield and Buxton road, and then turning N.E. again descends to the lime-stone shale, and follows it across the Manchester and Buxton road; soon after, it ascends the first grit and first coal-shale, on Comb's-moss, and again descends to the shale, passes Sitting-low, (1½ mile S.E. of Chapel-en-le-Frith,) when, turning eastward, it crosses the Great lime-stone fault, (N of Dove-holes,) and is found upon the third lime-stone, on which it crosses the quarries and rail-way of the Peak-Forest canal; soon after, it passes over the basset-edge of the third coal-stone,

and descends to the great fourth lime-stone in Peak-Forest, which is probably the *lowest* stratum, to which the grand ridge passes in its route through England; this lime-rock having been estimated to be four miles at least of perpendicular thickness below the top of the chalk, from whence we commenced our description; much the greater part of this vast series of strata having in this route along the grand ridge been lost suddenly by perpendicular lifts of the strata or faults, which, in proceeding to this point by more favourable routes, might have been seen basseting in succession. For about one and a half mile the ridge proceeds upon the fourth lime, then again ascends a point of the third coal-stone and third lime, to the village called Sparrow-pit, in the Manchester and Castleton road, where it again crosses the great fault and ascends to the lime-stone-shale on Rushop-edge, whence it proceeds northward, and after crossing the Liddle-road from Hayfield to Edale-chapel, it ascends the first grit on Edale rock, and proceeds across the moor on Kinder-scout hills; thence it leaves at their N.W. corner, and crosses the moor on the shale, and the ancient Bridle-road called Doctor-Gate, from Glossop to Ashop-Dale; it then ascends the first grit again on shelf-stones, and follows the same to Wain-flores and Blakelaw-flores, which seems to be the highest land in Derbyshire, it then passes N. E. by Round-hill, and ascends to the first coal-shale, crosses the Manchester and Penistone-road at Lady-croft; where, turning N.W. it ascends the second grit rock, and proceeds by Dean and Bretland Edges, to cross the Glossop and Huddersfield road, on the bogs upon the rock on Helme moss; from hence the ridge, after some distance, again descends to the first coal-shale, the first grit, and to the limestone-shale, crossing the Stanage tunnel on the Huddersfield canal near Marston; the ridge then proceeds across Black-flores-edge, and crosses the deep-cutting of the Rochdale canal, near the village of Huddersfield, (which has improperly been said in the population accounts of 1801, to be a town containing 10,671 persons!) the ridge then passes Holme on the Burreley and Halifax road, whence it proceeds, and near Colne comes again upon coal-measures, which are, however, lost again at the great fault, in which part of the Foulridge tunnel on the Leeds and Liverpool canal was driven, and which occasioned the extraordinary trouble and expence attending that tunnel, which is mentioned in our article CANAL. From hence the grand ridge proceeds, by Barnoldswick, West Marton, near the Cold-Comitora, E. of Settleton lime-stone, over Pernigant-hill, Snays-fell, Nine-standards, Kelton-fell, Lunc-forest, Scordal-head, Milbom-forest, Aldstone-moor, lime, Hartside-croft, Gelsdale-forest, Talkin, and crosses the Roman or Pict's wall on the E. side of Upper Denton, and soon after it enters Roxburghshire in Scotland; through which it is much easier to trace this grand ridge than in England, it forming often the boundaries between the Scotch counties, to which this ridge and its collateral ridges are much better adapted than the rivers and brooks, which have generally been chosen as boundaries, both as being more permanent, and not liable to the changes which streams of water are undergoing in the bottoms of vales, and avoiding those disputes respecting, and the delay of making and improving bridges, fords, navigations, &c. owing to the rivers being part in one county and part in another, and by which also many of the most considerable towns are split into two or more counties, to the no small inconvenience of their inhabitants, in judicial and other county matters.

GRAND RIVER. See OTTAWA and OUSE.—Also, a river of Africa which runs into the Indian sea, S. lat. 2° 8'.

—Alfo, a river of Sicily, which runs into the Mediterranean on the N. fide of the ifland, N. lat. $38^{\circ} 3'$. E. long. $14^{\circ} 54'$.

—Alfo, a river of America, which runs into the Miffouri, N. lat. $38^{\circ} 56'$. W. long. $93^{\circ} 25'$.—Alfo, a broad river of America, which difcharges itfelf into lake Michigan, N. lat. $43^{\circ} 25'$. W. long. $85^{\circ} 35'$.—Alfo, a river of America, which runs into lake Erie, N. lat. $41^{\circ} 55'$. W. long. $81^{\circ} 8'$.—Alfo, a river of Canada, which runs into the Detroit, N. lat. $42^{\circ} 34'$. W. long. $82^{\circ} 42'$.—Alfo, a river of Canada, which runs into the St. Laurence, N. lat. $47^{\circ} 3'$.

GRAND River, or *Rio grande*, a river of Africa, which runs into the Atlantic, near the Biffagos ifles, N. lat. 11° . W. long. $14^{\circ} 30'$.

GRANDE Seauv, an Indian nation, inhabiting a territory of the Miffouri, and able to furnifh 800 warriors.

GRAND Sarry-Canal. This canal is yet in the fame ftate, nearly, as when our account of it in the article CANAL was written, in 1805, except, that about two miles in length of it, at its N. E. end, has been brought into ufe, fince the Croydon canal has been completed; and that the dock for fhips, at its entrance from the Thames, was completed and opened in June 1807, and has answered fo well to the proprietors, that in the laft feffions of parliament, they made an unfulleffful attempt to obtain power for a further extenfion of them. In February, 1809, this company determined on erecting a ten-horfe ftream engine on the banks of the canal, by the Deptford road, for fupplying the neighbouring inhabitants with water, intending to let the furplus power of this engine to fome manufacturers.

GRAND Traverfe, a range of iflands, confifting of huge rocks in lake Michigan.

GRAND Trunk Canal, is a name commonly applied to the Trent and Merfey canal, which fee in our article CANAL.

GRAND Union Canal. In the feffions of parliament, 1810, (50 Geo. III.) an act paffed for making the Grand Union canal, the general direktion of which is about S. W. $23\frac{1}{2}$ miles, in the counties of Leicefter and Northampton, being confiderably elevated, and croffing the grand ridge of the ifland twice, by tunnels, its middle part for about half its length fkirting near to the ridge on its western fide, and the two ends being on the eastern fide of the ridge. Its objects are the completing of the long-defired water-communication between the Trent river and the many canals which connect therewith, in Derbyfhire, Nottinghamfhire, and Leicefterfhire, and the Grand Junction canal, and through it to the metropolis, without making the enormous circuit by Burton, Fradley-heath, near Litchfield, Tamworth, Atherftone, Nuneaton, and Braunftone, which at prefent goods, coming by water from Leicefter, Nottingham, and Derby muft do; it is intended alfo to fuperfede the neceffity for the fouthern part of the Leicefterfhire and Northamptonfhire Union canal, between Market-Harborough and Northampton, which on account of its difficulties has never been attempted; the prefent rail-way branch between the Grand Junction and Northampton is intended to be changed for a canal with locks, by which means the people of Northampton will have a water-communication with Market-Harborough, Leicefter, &c. with only about 14 miles longer diftance than the Leicefterfhire and Northampton Union would have been, if the fame had been completed according to its original act. Market-Harborough and Daventry are the only confiderable towns near the line of this canal, which commences in the Leicefterfhire and Northamptonfhire Union canal near Gumley, and termi-

nate in the Grand Junction canal near Buekby-wharf, near the S. E. end of the Braunftone tunnel. From Gumley in $\frac{1}{4}$ mile is a rifc of 76 feet by 12 locks, and thence to Watford, 20 miles are level, then in $\frac{1}{2}$ mile is a fall of 53 feet by eight locks, and thence to the Grand Junction canal about three miles are level; near Husband's Bosworth is a tunnel of about 1120 yards long, and near Crick another of about 900 yards long. Near Crick it is propofed to make a refervoir of 60 acres above the canal, but below its level, fo that the furplus water collected from other parts of the canal in rainy feafons can be here referved, to be pumped up when wanted.

The width of the canal at top is 42 feet and 14 at bottom, and its depth of water five feet; the locks are 82 feet long and feven wide, calculated for 25 ton boats. This line was firft furveyed by Mr. James Barnes in 1803, and by Mr. Benjamin Bevan in 1808 and 1809, and the latter is appointed engineer for the execution of the work.

GRAND Weftern Canal, is fo denominated in an act which paffed in the year 1796, as mentioned in our article CANAL, but under which no progrefs had then been made. In April 1810, it was reported, that a beginning had at length been made on the fummit level, in Holcomb, Devon. A much larger canal, capable of conveying fhips from the Brifol channel to the fouth coaft, has been fome time in agitation, for avoiding the very circuitous and tedious navigation round the Land's End; which, however defirable, is fearcely practicable, we incline to think, for want of water.

GRAND Affife, in Law. See ASSISE.

GRAND Cape. See CAPE and ATTACHMENT.

GRAND Couftumier, le, an ancient book of very great authority, which contains the dual cuftoms of Normandy.

GRAND Days. See DAY, in Law.

GRAND Diftreff, diftrictio magna; a writ of diftreff, fo called on account of its extent, which reaches to all the goods and chattels of the party within the county.

This writ lies in two cafes: either when the tenant or defendant is attached and appears not, but makes default: or where the tenant or defendant hath once appeared, and after makes default. On fuch occasions, this writ lies by common law, in lieu of a petit eape.

GRAND Elixir, guard, jury, larceny, prior, provost of France, ferjeanty. See ELIXIR, GUARD, &c.

GRAND Guffo, in Painting. See GUSTO.

GRANDE, in Geography, a town of Norway, in the diocefe of Drontheim; 21 miles N. W. of Drontheim.

GRANDEE is underftood of a lord of the firft rank or prime quality.

In Spain, the term grandees is ufed abfolutely to denote the prime lords of the court, to whom the king has once given leave to be covered in his prefence: there are fome grandees for life only; made by the king's faying fimply, be covered. Others are grandees by defcent; made by the king's faying, be covered for thyfelf and heirs. Thefe laft are reputed far above the former.

There are fome who have three or four grandceffhips in their family.

GRAND-GOR. A Scotch appellation for the venereal difeafe.

In the Philofophical Tranfactions, N^o 469. fekt. 5. we have a proclamation of king James the IVth of Scotland, ordering all who had this difeafe, or who had attended others under it, forthwith to repair to an ifland in the Frith of Forth. If the grand-gor was the pox, and this diftemper came into Europe at the fidge of Naples in 1494, it muft have made a

very quick progress to cause such an alarm at Edinburgh in 1497.

GRANDI ERCOLE, in *Biography*, whom Vasari calls Ercole da Ferrara, was a painter of the early ages in the art after its revival. He was a disciple of Lorenzo Costa, whom he afterwards surpassed in excellence, and at whose death he was appointed to complete the work of the Crucifixion, begun by the former for Domenico Garganelli, in the church of St. Pietro in Bologna, by which he gained great reputation for the excellence of the colour, and the truth and force of expression; although it is wrought in the dry style of Mantegna and P. Perugino. When unfortunately the chapel was destroyed, that part of the picture which was preserved was placed in the palace Tanara. His peculiar shyness of manner made him many enemies in Bologna. He therefore quitted it and went to Ferrara, where he produced many works which are very scarce now. His fondness for wine shortened his life, and he died at the age of 40 in the year 1531.

GRANDI, FRANCIS LEWIS, who flourished in the latter end of the 17th, and the commencement of the 18th centuries, was born in 1671 at Cremona. He was disposed to a studious life, and chose the profession of theology, in order that he might freely indulge his inclination. He entered into the religious order of Camaldolites, at Ravenna, at the age of 16; and on this occasion he relinquished his own Christian name, and received that of *Guy*. He became, in the early progress of his studies, distinguished for his proficiency in the different branches of literature and science, and being dissatisfied with the Peripatetic philosophy of the schools, he was ambitious of contributing to introduce a more rational system. With this view he offered himself as a candidate for the vacant professorship of philosophy in the school of Florence, and obtained his object, though not without the most determined opposition from the prejudiced adherents to the old opinions. He now applied himself to the introduction of the Cartesian philosophy, while, at the same time, he became zealously attached to mathematical studies. The works of the great Torricelli, of our countryman Wallis, and of other celebrated mathematicians, were his favourite companions, and the objects of his familiar intercourse. He published a treatise to resolve the problems of Viviani on the construction of arcs, which he dedicated to the grand duke Cosmo III., who was so delighted with the performance, that he appointed the author professor of philosophy in the university of Pisa. From this time Grandi pursued the higher branches of mathematics with the utmost ardour, and had the honour of ranking the ablest mathematicians among his friends and correspondents. Of the number may be named the illustrious Newton, Leibnitz, and Bernouilli. By his life of St. Peter Damiano, published in 1702, and his examination of the legends of St. Romauld, he gave offence to the bigots of his community, and was deposed from the dignity of abbot of St. Michael at Pisa; but the grand-duke had too liberal a mind to be offended; and to shew the estimation in which he held the philosopher, he immediately appointed him his professor of mathematics in the university, which, perhaps, led to his re-instatement in the abbacy. He now resolved some curious and difficult problems for the improvement of acoustics, which had been presented to the Royal Society in Dublin, and having accomplished his object, he transmitted the solutions, by means of the British minister at the court of Florence, to the Royal Society at London. The principal work of Le Grandi was "A Treatise on Series and Infinitimals." He appeared likewise as the defender of Galileo's doctrine respecting the earth's motion, and obtained a complete victory

over those who opposed it. He was deeply versed in subjects of political economy, and various disputes were referred to his decision respecting the rights of fishery, &c. He was appointed commissioner from the grand-duke and the court of Rome jointly, to settle some differences between the inhabitants of Ferrara and Bologna, concerning the works necessary to preserve their territories from the ravages of inundation. For these and other important public services he was liberally rewarded by his employers. Reverting to his literary labours, Le Grandi engaged in a contest with Le Ceva, on the subject of the philosophy of the ancients and moderns. This discussion was occasioned by a preface to a Latin poem by Le Ceva, in which he maintained that none but heretics would renounce the philosophy of Aristotle. The remainder of his life this great man spent in mathematical pursuits, and in the publication of works of science, which are too numerous to be recited here. He died at the age of seventy-two in the year 1742. *Moreri*.

GRANDIER, URBAN, was born in the latter part of the 15th century. His father, a notary-royal at Sable, gave him a good education, and introduced him while young among the Jesuits at Bourdeaux, to whose friendship he recommended himself, as well by his natural genius and fine understanding, as by his diligence and proficiency in his studies. Conceiving highly of his talents, the fathers of the college gave him the living of St. Peter, at Loudun, of which they were the patrons, and procured him a prebend in the church of the Holy Cross. These benefices rendered him the object of jealousy with ecclesiastics, which was still farther heightened by the accomplishments of his person and the elegance of his manners. With his friends he was easy, facetious, and agreeable, but extremely haughty towards those whom he regarded as his enemies. Some of his brethren of the clergy he had exasperated, by the arrogance with which he triumphed over them, upon gaining certain suits in the ecclesiastical court, and he raised a host of foes by his reported successful gallantries with the ladies, to the great mortification of disappointed rivals, incensed fathers and husbands. A league was formed with a view of driving him entirely out of Loudun: a heavy charge of debauchery, irreligion, and impiety was laid against him, in the bishops' court of Poitiers, which produced, first, a suspension of the priests' functions; and afterwards he was condemned to resign his benefices, and to the practice of penance and mortification. From a sentence so severe, Grandier appealed to the archbishop of Bourdeaux, by whose means he was acquitted, and even allowed to sue for the recovery of damages, and the restitution of the profits of the benefices during his suspension. The archbishop, a friend to peace, earnestly recommended him to change his residence, but he was incapable of renouncing his favourite passion, revenge. He returned to Loudun, bearing in his hand a branch of laurel, and in his mind a fixed resolution of humbling his enemies. They were equally bitter, and smarting under the lash of the victor, they set about means to compass his destruction. A priest, named Mignon, devised a plan, which ultimately enabled them to gratify all their malignity. He trained up nuns in the Ursuline convent at Loudun, to act the part of women possessed with evil spirits; these were instructed to accuse, in their frantic fits, Grandier of having subjected them to demoniacal influence. At first he was indifferent to the reports, considering the business as a mere farce. It had, however, a most tragical conclusion. Grandier, at length, finding, from the effects produced upon the credulous devotees, that matters were taking a serious turn, appealed to the magistrates, conscious of his own innocence, and requesting them to take cognizance of the affair. They

began the investigation, and were satisfied that the whole was the effect of trick, but when they attempted to interpose their authority, and prohibit the continuance of such disgraceful proceedings, the priests who had patronized and instructed the women, and who were bent upon the destruction of Grandier, disowned their jurisdiction and defied their power. An application was made to the archbishop of Bourdeaux, who employed physicians to examine into the case, and by their reports no doubts were left in the mind of the prelate, that the business was founded on the most gross and scandalous imposture. Upon this the archbishop issued an order, the severity of which put the whole legion of devils to flight. After a time the scheme was renewed, and the authors of it contrived to engage cardinal Richlieu to favour their malignant designs. For this purpose the monks of Loudun wrote to father Joseph, one of their fraternity, informing him that Grandier was author of a satire, entitled "The Shoemaker's wife of Loudun," containing reflections on the cardinal's birth and person, which had excited in the bosom of the cardinal the sharpest stings of resentment. Believing that the information was correct, he determined to make the satirist feel the full weight of his vengeance. Grandier was arrested and brought to trial, and after a tedious process, in which the farce of exorcising the possessed was several times repeated, and the judge's partiality and tyranny displayed in the most glaring light, "upon the deposition of Ashtaroth, a devil of the order of Seraphim, and the chief of the possessing demons, and upon the depositions of the nuns, who pretended to be possessed of devils, the commissioners gave judgment, declaring Grandier duly attainted and convicted of the crime of magic, forcery, and possession, happening by his means in the persons of some of the Ursuline nuns, &c. for the reparation of which he was condemned to an amende honourable, and to be burnt alive with the magical characters." Grandier, innocent of the charge, heard the sentence without any emotion, and afterwards sustained the torture, ordinary and extraordinary with astonishing fortitude, never suffering one repining expression against his enemies to escape him through the whole scene. The last words which he was heard to utter previously to the flames reaching his vital parts, were in supplication to God, to whose mercy he recommended himself. Such was the fate of Urban Grandier, whose pride and passions appear to have been causes of the conspiracy to which he fell a victim, and whose history exhibits a memorable example to shew to what pitch of folly and madness the fury of an incensed cabal, the revenge of a minister, and the prostitution of a judge, may be wrought up. The relations of the case is given in "The History of the Devils of Loudun," first published at Amsterdam in 1693, and which has been frequently reprinted. As an author Grandier is known by a funeral oration for Scavola de St. Martha, which is highly commended for the matterly strokes of eloquence interspersed through it. Moreri.

GRANDINES, in *Surgery*, small tumours on the eyelids.

GRANDMONT, in *Geography*, a town of France, in the department of the Upper Vienne, near which was an abbey, suppressed in 1769; 15 miles N.E. of Limoges.

GRANDOLA, a mean town of Portugal, in the province of Estramadura, containing 800 houses, situated between Cadaon and the sea-coast. Behind it is the Sierra de Grandela, that proceeds in two ranges, one behind the other, from east to west; the town is 27 miles S.E. of Setuval.

GRANDPRE, a town of France, in the department of the Ardennes, and chief place of a canton, in the district

of Vouziers; 33 miles E. of Reims. The place contains 1350, and the canton 8617 inhabitants, on a territory of 242½ kilometres, in 14 communes.

GRANDRIEUX, a town of France, in the department of the Lozere, and chief place of a canton, in the district of Mende; 10 miles N.W. of Langogne. The place contains 1657, and the canton 5389 inhabitants, on a territory of 235 kilometres, in 7 communes.

GRAND-SERRE, LE, a town of France, in the department of the Doubo, and chief place of a canton, in the district of Valence. The place contains 1491, and the canton 6189 inhabitants, on a territory of 232½ kilometres, in 10 communes.

GRANDVILLE, or **GRANVILLE**, a town of France, in the department of the Channel, and chief place of a canton, in the district of Avranches, 12 miles N.W. of it. The place contains 5454, and the canton 12,290 inhabitants, on a territory of 80 kilometres, in 8 communes. The harbour can receive only about 60 small vessels. The town is seated on a sharp rock, forming a peninsula of an oval form, and surrounded with walls; it has two gates, and two faubourgs. Near it is an oyster-fishery, and on the land side quarries of large and very hard stones. N. lat. 48° 50'. W. long. 1° 32'.

GRANDVILLIERS, a town of France, in the department of the Oise, and chief place of a canton, in the district of Beauvais; 14 miles N.N.W. of Beauvais. The place contains 1633, and the canton 12,655 inhabitants, on a territory of 167½ kilometres, in 22 communes. N. lat. 49° 39'. E. long. 2° 2'.

GRANDWALDEN, or **GRAN**, a town of Norway, in the diocese of Christiania; 26 miles S. of Christiania. The town stands on an eminence in the midst of an extensive plain, looking down on several conical rocks, covered with firs, and remarkable for two churches in the same church-yard, called the "Two Sisters."

GRANGE, an ancient term for a barn, or place wherein to lay up and thresh corn.

The word is formed of the Latin *granea*; or of *granum*, grain, corn, &c. Hence also *granger* or *grangier*, a grange-keeper or farmer.

Hence *grange* is a name which was formerly much applied to such farm-houses as were provided with large barns, granaries, and other similar offices, for the preservation of grain, &c.

CRANGE is also used, in a more extensive sense, for a whole farm, with all the appendages of stabling for horses, stalls for cattle, &c. and for an inn.

GRANGE, JOSEPH DE CHANCEL DE LA, in *Biography*, born in 1676 of an ancient French family, at Antoniat in Perigord, exhibited from his boyish days a singular passion for poetry and romance. He was educated among the Jesuits at Bourdeaux, and when he was only nine years old, he composed a comedy in three acts, which was represented by his school-fellows. His early talents seemed to have marked him out for distinction, and his mother took him to Paris, and obtained for him the place of page to the prince of Conti. Before he was sixteen, his tragedy of Jugurtha was represented in the capital, and was applauded as a most extraordinary effort of such a stripling. He continued to write pieces for the stage, which were productive of reputation and pecuniary advantages; but the work which rendered him famous, though it exposed him to much mortification and suffering, was entitled "Philippiques," a satire in verse, directed against Philip, the regent duke of Orleans. This appeared in 1718, and it charged the duke with the crime of poisoning several branches of the royal family.

The

The author attempted to escape, but, falling into the hands of his pursuers, he was committed to the prison of St Marguerite. It appears that he was not brought to trial, and that he contrived to effect an escape from prison and the country, but upon the death of the regent he returned to France, where he lived unmolested. He died at his family seat of Antoniast in 1758. His works were collected in five vols. 12mo. and, with his own corrections, published the year after his decease. They consist chiefly of tragedies, operas, and miscellaneous poems. The tragedies are most esteemed: they are said to be "artful in the contexture of the plot, and abounding in interesting situations, but feebly written, and trite in language and sentiment." In his latter years he employed his time on a history of Portugal. In manners he had all the fire and vanity of a Gascon: he had few friends, and seems to have been more feared on account of his satirical powers, than beloved for his virtues.

GRANGE, in *Geography*, a town of Sweden, in the province of Dalecarlia; 33 miles S S.W. of Falun.

GRANGE, *La*, a cape on the N. coast of the island of Hispaniola. N. lat. 19° 55'. W. long. 72° 30'. This cape, with Point de Dunes, forms the mouth of the bay of Monte Christi, in the county of Stirling.

GRANGE Point, a cape on the S. coast of the Isle of Wight. N. lat. 50° 38'. W. long. 1° 15'.

GRANGE River, a river of Upper Canada, which empties itself into a bay of the same name on the N. shore of lake Superior, W. of the Cris. This river leads to Nipigan, a place which formerly furnished the best beaver and martin, and was the farthest advanced post of the French traders, at the time when Great Britain conquered Canada.

GRANGEA, in *Botany*, Adanson, v. 2. 121. Juss. 184. Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ discoides*, Linn. *Corymbif. rz.*, Juss.

Gen. Ch. *Common calyx* imbricated, spreading; its scales oblong, obtuse. *Cor.* compound; the united florets of the disk very numerous, tubular, five-cleft, regular; females fewer, in the circumference, tubular, three-cleft. *Stam* in the united florets, filaments five, capillary, very short; anthers united into a cylinder, with five teeth. *Pyl.* Germen small; style thread-shaped, the length of the filaments; stigma undivided in the united florets, cloven in the female ones. *Peric.* none, except the permanent calyx. *Seed* solitary to both kinds of florets, obovate, compressed, crowned with a toothed border. *Recept* hemispherical, naked.

Ess. Ch. Receptacle hemispherical, naked. Seed-crown membranous, toothed. Calyx imbricated, spreading. Florets of the radius three-cleft.

We have alluded to this genus under ETHULIA, from which it differs in having a crown to the seed, florets of the radius three-cleft, and scales of the calyx obtuse. It most approaches *Tanacetum* in character, but is sufficiently distinct. The following are the only species we have been able certainly to determine.

1. *G. maderaspatana*. (*Artemisia maderaspatana*; Linn. Sp. Pl. 1190. *Tanacetum Ægyptiacum*; Jacq. Hort. Vind. v. 3. 46. t. 88. *Abinthium maderaspatanum*, *fenecionis incani folio*, *corymbis solitariis in ramulorum fastigio speciosis*; Pluk. *Amalth* 3. t. 353. f. 3. *A. minus odoratum gangeticum*, *floribus chamameli foliariis e foliorum alis*; Pluk. *Almag.* 2. *Phyt.* t. 1. f. 2.)—Leaves sinuated, somewhat lyrate, hairy. Flower-stalks elongated.—Native of the East Indies. *Root* annual, tapering, branched. *Stems* procumbent, a span or more in length, subdivided, leafy, downy. *Leaves* alternate, sessile, deeply pinnatifid, in a lyrate form, and sinuated, clothed with soft whitish hairs, their segments rather rounded. *Flowers* yellow,

almost globular, near half an inch in diameter, on axillary, solitary, simple, hairy stalks, half as long as the leaves. Linnæus in both editions of Sp. Pl. quotes Plukenet, t. 357. f. 3. Adanson, his professed critic, seems to have augmented the error in copying him, and cites t. 257. f. 3; which has given us a great deal of trouble; more especially as we have a plant from the Paris garden for Adanson's *Grangea*, which proves *Hippia integrifolia*, Linn. Suppl. 389, and does not answer to the character or habit of *Grangea*. Nevertheless, as it came with such authority, we have laboured in vain to find any thing like it in Plukenet, and thought for a while we had found it in t. 45 f. 3, which bears a rude resemblance to our specimen, but is *Parthenium Hysterochorus*. Finally, Burmann's *Sphæranthus africanus*, Fl. Ind. t. 60. f. 2, which is not that of Linnæus, and which Jussieu suspects may be a *Grangea*, is not unlike this *Hippia*. If it be our plant, his suspicion is refuted. The leaves in our specimens are occasionally undivided or lyrate, more cut than in Burmann's plate, and less so than in Plukenet's t. 45. f. 3. The calyx, however, which is well expressed in the latter for the *Parthenium*, does not accord with our's.

2. *G. minima*. (*Artemisia minima*; Linn. Sp. Pl. 1190. Burm. Ind. 177. t. 58. f. 3.)—Leaves wedge-shaped, bluntly toothed, smooth. Flowers nearly sessile.—Native of China, and the East Indies. We received it in 1803, from the stove of the late right honourable Charles Grey at Paddington, where it was preserved rather for its rarity and singularity than beauty. It is an annual plant, much smaller in all its parts than the foregoing, smooth, prostrate, of a light green colour. *Flowers* the size of a small pea, axillary, nearly sessile, whitish, sometimes with a purple tinge. Their structure is extremely minute.

We scruple to admit *Ethulia dicaricata* into this genus, though somewhat similar in habit, because of its naked seed, and sharp calyx. See ETHULIA.

GRANGEMOUTH, in *Geography*, a village of Scotland, of considerable extent, founded by sir Lawrence Dundas, upon the angle formed by the junction of the river Carron and the canal. It deserves mention as a place of considerable trade. Vessels bring into this port timber, hemp, flax, deals, and iron, from the Baltic, Norway, and Sweden, and grain from foreign markets, as well as from the coasts of England and Scotland. The trade to London is carried on by the Carron shipping company; 3 miles E.N.E. of Falkirk.

GRANGERIA, in *Botany*, so named by Commerçon in memory of M. Granger, a surgeon, who travelled into Egypt and Judea between the years 1730 and 1736, from whence he sent numerous seeds to enrich the botanic garden at Paris. He published, in 1745, in 12mo. *Relation du voyage fait en Egypte en 1730*, according to Haller, who mentions him as "not a trifling man, though he touched but slightly upon botany. He greatly depreciates the wonders and fertility of Egypt." Juss. 240. Lamarck, *Illustr.* t. 427. Class and order, *Isosandria Monogynia*. Nat. Ord. *Pomaceæ*, Linn. *Rosaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, with five ovate, acute, permanent segments. *Cor.* Petals five, roundish, scarcely longer than the calyx, inserted into its rim. *Stam.* Filaments fifteen, awl-shaped, longer than the petals, inserted into the calyx; anthers roundish. *Pyl.* Germen superior, obovate, woolly; style one, thread-shaped; stigma obtuse. *Peric.* Drupa obtuse, somewhat triangular. *Seed.* Nut triangular, of one cell.

Ess. Ch. Calyx five cleft, inferior. Petals five. Germen woolly. Drupa with a triangular nut.

1. *G. lucifolia*.—A tree, native of the Isle de Bourbon, where

where it is called *Arbre de buis*, or Box tree, from the similitude of its *leaves* to the *Buxus*. These are about an inch long, ovate, acute, entire, veiny, smooth on both sides, nearly sessile, with a pair of small awl-shaped *stipules*. *Flowers* small, in terminal or axillary clusters. *Fruit* somewhat like that of an olive, but smaller, and rather angular.

GRANHULT, a town of Sweden, in the province of Smaland: 35 miles N. W. of Calmar.

GRANI, in our *Ancient Writers*, mustachoes or whiskers of a beard.

The word seems formed from the ancient British or Irish, *greann*, a beard.

It is given for a reason why the cup is refused to the laity, "Quia barbati, & prolixos habent granos, dum poculum inter epulas fumunt, prius liquore pilos inficiunt, quam ori infundunt."

GRANIFEROUS, producing or bearing any sort of grain.

GRANIFEROUS *Pods*, a term signifying such pods as contain small seeds of some of the grain kinds.

GRANILITE. Under this denomination Kirwan comprehends all varieties of granite that contain more than three ingredients, such as quartz, feldspar, mica, and garnet: such supernumerary ingredients, however, must be considered as accidental, and of too little importance to confer the distinction of a particular name on the granite in which they occur.

GRANINGE, in *Geography*, a town of Sweden, in Angermannland, on a lake; 40 miles N. W. of Hernosand.

GRANITE, an aggregate rock, the essential ingredients of which are feldspar, quartz, and mica, being the same as those of gneiss, from which granite differs chiefly in the arrangement of the three component parts: their being mingled without order or regularity, produces a granular structure, while that of gneiss is generally slaty. (See GNEISS.) It is, probably, this granular nature of the rock in question which has procured it its name; though some authors are of opinion that the word *granite* is nothing but a corruption of *geranites*, a name mentioned by Pliny, as that of a stone of the colour of a stork's neck. The fact is, that the word *granite*, which is now adopted by almost all European nations, originated with Italian antiquaries, and Tournefort was not the first writer who makes mention of it.

The three constituent parts of granite vary with regard to their colour, size, relative quantity, form, and freshness.

The colour of this rock is generally more or less reddish, because the feldspar, usually the predominating part, is oftener of that than of any other colour. Sometimes the feldspar is greyish and yellowish-white, and so like the admixed quartz, that it can be distinguished only by its peculiar fracture and lustre. It has been observed that the red colour occurs more frequently in the newer, while the greyish-white appears to be more characteristic of the older formation of granite. Also long continued exposition of granite to the action of the atmosphere contributes to render its feldspath pale or grey. Yellow and green feldspar seldom occur as ingredients of granite.—The colour of the quartz is usually greyish; sometimes this part is perfectly colourless and transparent, in which case, as the grains cannot be viewed by transmitted light, it appears deep grey or black.—The mica is much more frequently black or grey, than brown or perfectly white.

The absolute size of the ingredients of granite is subject to considerable variation; they are seen from very large to very fine granular, the latter being more frequent in the newer formation. With regard to the relative size of its constituent parts, we distinguish equally mixed from une-

qually mixed granite; the former being that in which the magnitude of the three ingredients is nearly the same.

The quantity of these parts is equally various: so that sometimes one, sometimes two of them predominate: upon the whole it is the feldspar that is found in the greatest proportion, and the mica in the least. There are, indeed, some varieties of granite in which the quartz or mica are entirely wanting. Such binary aggregations of the granitic kind have received distinct appellations by some authors. Those of quartz and feldspar, or feldspar and mica, were called simple granites by Wallerius; semi-granites by Blumenbach; and Kirwan proposes to denote all these duplicates in general by the name *granitell*, specifying, when necessary, the constituent peculiar parts of each. The aggregate of quartz and mica is called *gestell-stein*, or *stell-stein*, by some of the older German writers; and that of feldspar and mica, especially when the latter is of a brown or brownish-red colour, and forms the predominant ingredient, has obtained the Finlandic name of *Rapakivi*. Such distinctions, however, are unnecessary and inapplicable, since often in one and the same granitic mass the proportion and number of the component parts are seen considerably to vary. Besides, there are many rocks enumerated by authors as granitels, which cannot, with any propriety, be referred to granitic compounds; such as feldspar with hornblende, with nephritic stone, with garnet, scapolite, or the same separately combined with quartz or mica.

There is but very little variety in the form of the component parts: they are almost always massive and indistinctly angular, and seldom occur in the form of regular crystals. The feldspar is found crystallized in Bohemia, at Schlackenwalde, near Carlsbad; at Tzeidler, in the Saatz district; also near Hohenwalde, in Upper Palatinate; at Ochsenkopf and Kessein, on the Fichtel-gebirge; at Schneeberg, in Saxony; in England; in the island of Arran, &c. The granite in which these feldspar crystals are seen, is often of such fine grain, and the quartz and the mica are so intimately united with each other, that they form, as it were, a matrix for the crystals: such granite is called *porphyritic* granite. Part of the pavement on Westminster and Blackfriars' bridge consists of this species of granite. Something like crystallization of the quartz is now and then observed in granite, but it is always irregular. In the variety, called graphic or Portsoy granite, in which the feldspar constitutes by far the greatest part of the mass, and which contains mica in small groups, at great distances from each other, the quartz is disposed in such a manner, that when the rock is cut in a certain direction, it exhibits forms which bear some distant resemblance to written characters: whence it has obtained its name. But by some, neither the Portsoy nor Siberian graphic stones are considered as true granites.—Also, the mica is now and then found crystallized in granite, such as in Siberia, at Waldheim, Metweida, Johan-georgenstadt, in Bohemia, &c. In a variety of granite of Mount St. Gothard, all the three constituent parts are said to occur crystallized together.

The feldspar is also sometimes found in the shape of coniform concretions, representing on their fracture a surface comparable to the paws of some animals, or to the petals of flowers: this singular variety comes from the neighbourhood of Breitenbrunn, in the Upper Ertzgebirge.

With regard to the *freshness* or state of preservation which these three ingredients exhibit, we have to observe that the feldspar, which, in general, has a vitreous lustre and a perfectly foliated fracture, is also seen in various stages of decomposition; it occurs dull, earthy, friable, and even entirely disintegrated, in which state it is known by the name of porcelain-earth. This disintegration takes place chiefly near the surface

GRANITE.

face of granitic mountains, and in the immediate vicinity of veins. Granite, with feldspar thus converted into an earthy state, is found in Cornwall, on the Hartz, at Burkardgrün in Saxony, &c.; and it is probable to Mr. Emmerling that the giefs-stein, (*Saxum fulviorum*, Linn) which, on account of its loose texture, is made use of in the brads foundries of Sweden and France, may be granite in a similar state of incipient decomposition. Also, the mica is subject to disintegration, especially when acted upon by subterraneous water and vapours; the mass into which it is thus converted is considered as being of the nature of steatite. In this state it is found at Fichtelberg, in the Upper Palatinate, and in the vicinity of Tornitz, near Carlsbad, in Bohemia.

Besides feldspar, quartz, and mica, other fossils are found admixed, which, not being considered as essential, are generally distinguished by the appellation of *accidental ingredients*. They are, 1. Shorl; the most frequent of all. It occurs massive and disseminated, sometimes also crystallized, and appears principally to belong to the old granite-formation: it is found in several parts of Saxony, in Lower Bavaria, Upper-Palatinate, Wirtenberg, Transylvania, Cornwall, &c.; 2. Garnet: mostly in small grains. It occurs but rarely; but has been found near Leipzig (in boulders), at the Greifenstein, and in the neighbourhood of Voigtsdorf, in the vicinity of Freiberg, in Saxony, in Lower Bavaria, &c. An aggregate of quartz, mica, and garnets, is by the Swedes called *norka* or *murkiten*. 3. Tinstone; frequent in the granite of Geier, Zinnwald, &c. 4. Nephrit or jade appears to occur not only in gneiss, but also with real granite, in Switzerland. 5. Rock crystal. 6. Beryl; in the island of Alba, and perhaps also in Siberia. 7. White common opal, sometimes occurs in the granite of Eibenslock in Saxony. 8. Topaze is sometimes seen, together with tinstone, in the granite of Zinnwald. 9. Calcareous spar, very seldom. 10. Fluor-spar, the same; in Siberia, at Geier in Saxony. 11. Barytes, equally seldom; in Switzerland.

Foreign beds are less frequently met with in granite than in other rocks. The more remarkable ones are those of tin-stone, galena, and blende at Zinnwald on the Bohemian frontiers; the beds of mica, particularly in Silesia and Lusatia; of quartz, and rock crystal in Switzerland. Also beds of feldspar are said to occur in it. The green feldspar, called Amazon stone, is found in large masses in the granite of the Ural mountains of Siberia.

Stratification of Granite.—Though granite occurs frequently as widely-extended masses, in which the eye is unable to discover any continued traces of parallel separation; yet there can be no longer any doubt that those geologists, who absolutely denied the existence of stratified granite, were either entirely unacquainted with the structure of many of the European granitic mountains, or too much influenced by the principles of their favourite theories, to allow the observed traces of demarcation to be any thing but irregular and accidental rents and fissures. Pini even endeavours, by mathematical figures, to prove the impossibility of stratification in granite. Notwithstanding all this, the observations of the most eminent geologists appear to prove that such stratification, even in the strictest sense of the word, is not uncommon; but it is often a matter of great difficulty, for an eye, unaccustomed to viewing the structure of mountains on a large scale, to distinguish the parallelism, or to follow the obscurely marked progress of the line of separation of the strata, especially when they are of considerable thickness.

But in many cases, it would appear that this stratification

is too distinct to leave any doubt upon the mind of the observer. Nothing can be more convincing than the account given by Gruber of the stratified nature of the granite composing the Riesengebirge, that separates Silesia from Bohemia. The rocks that chiefly compose this celebrated range of mountains are granite and gneiss, which, on the highest points, such as the Riesen and Schnee-kuppe, are seen in fourfold alternation. Mr. Gruber has ascertained the dip and direction of the strata in eight places, and proved them to be perfectly distinct from the rents which are frequently seen nearly at right angles with the lines of stratification.

From Saussure's observations, made on the several granitic pyramids or "aiguilles" of the Mont-Blanc, it would appear that all the parts of this mountain are composed of vast layers of granite perpendicular to the horizon, and directed from N.E. to S.E. Still more distinct this stratification appears on Mount St. Gotthard. (See GOTTHARD.) According to Charpentier, Leske, and others, also the granite of the whole of Upper Lusatia, and of several parts of Saxony, affects the stratified structure.

In a similar manner Mr. Gruber observed the regular stratification near Carlsbad and Teplitz; and Dr. Reufs found the same in several other parts of Bohemia; such as in the Eger district, where the strata dipped north at an angle of 18°; in the Saatz district at Lefchkau; in the Leutmeritz district on the Saxon frontiers; at the Wolfsberg, where the strata run from two to six feet in thickness; as also in several places in the district of Buntzlau, towards the Riesengebirge. La Perouse describes the granite of part of the Pyrenees as disposed in layers or beds.

In the north of Europe, similar regularity appears to prevail in the stratification of granite; thus, according to Cronstedt and others, in Sweden, on the Kinnekulle and Billing, in West Gothland, the granite (consisting mostly of red feldspar, white quartz, and black and greenish mica, in nearly equal proportion) is observed in distinct layers, with superincumbent strata of rocks of subsequent formation.

Pallas followed vast and continuous layers of granite through whole tracts of mountains in Siberia: indeed, part of the granitic Ural mountains, in the neighbourhood of the lake Kolywan, are described as having the appearance of huge artificial structures, in which the layers appear to be loosely piled on one another.

Dr. Hutton supposed granite, when not shiftose in its structure, to be altogether unstratified; professor Playfair, however, in his exposition of the Plutonic system, so far differs from the opinion of his ingenious friend, that he allows granite to form strata also where it has no character of gneiss; and he thinks that this admission does not embarrass the theory with any new difficulty; but, on the other hand, he suspects that the stratification ascribed by the Neptunists to the granite mountains is, in many instances, either an illusion, or at least something very different from what, in other stones, is accounted stratification. Professor Playfair found stratified granite, in England, at Chorley Forell, in Leicestershire, where, particularly near Mount Sorrel, beds of granite are seen, holding the same direction with those of the subjacent "horn-stone schistus;" and likewise at Fasset-water in Berwickshire, where the beds of granite run from about S.W. to N.N.E. conformable to the schistus on either side of them. Respecting the granite mountains of Arran, we have it observed by the same philosopher that this stratification appears doubtful. The mountain of Goathead, in that interesting island, appeared, contrary to what Mr. Jameson had advanced in his "Mineralogy of the Scottish Isles," without any vestige of stratification in its granitic part, as did also the whole

whole group of mountains to which it belongs; for though he saw large tabular masses, sometimes nearly vertical, separated by fissures, they appeared to him to be much too irregular, too little extended in length and height, and vastly too much in thickness, to be reckoned the effects of stratification. As in the third volume of Jameson's "System of Mineralogy," Arran is not mentioned among the localities where stratified granite occurs, it would appear as if that geognostian does not lay any stress upon his first remark on the nature of the above-mentioned mountain.

The relative age of the different varieties of granite has engaged the attention of several writers on geology; but it must be said, that most of the opinions that have been broached on this subject, and the various ideas entertained by theorists respecting what they call regeneration of granite, are too vague, or at least too little founded on actual observation, to be entitled to particular notice. Some geologists on the other hand have absolutely denied the existence of a second and third granite-formation. The Wernerian school admits three distinct formations of granite. The *first* or *oldest* is that which, of all rocks we are acquainted with, is sunk the deepest into the interior of the earth, and which therefore may with propriety be considered as the fundamental rock. This oldest granite also constitutes the highest parts of the surface of the earth, and, thus elevated, is generally surrounded, and, as it were, enveloped by other primitive rocks. It is frequently coarse-grained and porphyritic. It occurs both stratified and unstratified; and it is the latter which is often seen in large globular distinct concretions of considerable dimensions, such as in several parts of Bohemia, in the Fichtelgebirge, in the island of Arran, &c.

This formation is, of course, far more widely extended than those of a more recent origin. The *second granite formation* is considered as occurring only in veins which never reach any of the newer rocks, but are confined to the oldest formation. Such granite is marked with less regularity of structure, than what is observed in the older formation; at the same time that it surpasses the newest granite, both with regard to the regularity of arrangement, and superior firmness of the constituent parts. The *third*, or *newest granite-formation*, is always found super-incumbent on older primitive rocks, often in an unconformable and over-lying position: it also occurs in veins, which have been seen to intersect or traverse veins of the second granite formation; as a certain criterion of the greater relative age of the latter. Its structure, according to the characteristic given of it by professor Jameson, is very irregular; it has a deep red colour, and contains sometimes grains of garnet, and often fragments of various primitive rocks of various magnitude. When it occurs in veins, these are, according to the same author, not connected with any rock beyond the strata which they traverse. Examples of this newest formation are, that at Greifenstein, a large group of steep rocks between Ehrenfriedersdorf and Geier in the Saxon metalliferous mountains, where the coarse granular and irregularly aggregated granite, composed principally of feldspar and quartz, with but a small portion of mica, occurs resting on mica slate, in an unconformable and over-lying position: it contains nests of quartz and feldspar, as also fragments of gneiss and mica slate, from the size of a cubic each, to that of 100 cubic feet and upwards. Another instance of this formation we have in the tin stockwork at Geyer, where it is contained in a hollow of gneiss, and agrees in its characters with that of Greifenstein. Another portion of the same formation, is that at Johannegeorgenstadt, Auerberg, and Eibenstein, where, however, it occurs only in veins, which are from a foot to several fathoms wide, and are usually traversed by metalli-

ferous and other veins. Mr. Mohs has given a very good characteristic of this newer granite. Veins of the same kind occur also in Bohemia, Upper Lusatia, at Minella in the Alps, in the Shetland islands, in Glen Morison, and in the Highlands.

The nature of the just mentioned *granitic veins* is considered in a different light by Dr. Hutton, according to whom all veins, whether they are obviously connected, or whether they have no apparent connection, with any large mass of granite, are coeval with, and constitute a part of the main body of what is called the oldest granite by the followers of the Neptunian system. Mr. Playfair has given several examples of veins invisibly connected with larger masses; in those at the isle of Coll, in the Hebrides, at Portsoy, in Cornwall, in Glen Tilt; and of such as are visibly connected with the main granitic body, in those occurring in the island of Arran, in Galloway, in Inverness-shire, St. Michael's Mount, Cornwall. Mr. Jameson, however, says that he has convinced himself, after a very careful examination of the rocks of the island of Arran and of Galloway, that they do not afford a single instance of granite veins, nor of veins traversing newer primitive rocks, as it has been insinuated to be the case with the granite veins in Glen Tilt. The same author observes on this occasion, that veins of feldspar have been frequently confounded with granite veins, and he subjoins some observations on this subject communicated by the late Dr. Mitchell, according to which there is a most palpable difference between supposed and genuine granite veins; the former being frequently narrower than one inch, and commonly much ramified, and sometimes tortuous; but they constantly adhere most firmly to the adjacent stone, and when they contain apparent fragments, the stony structure of these is ever conformable to that of the contiguous rock; while genuine granite veins never fall short of some inches, are always pretty straight, seldom giving off branches: they have a distinct separation, and contain fragments of the adjacent rock, which lie promiscuously; the granite is constantly uniform, containing the three ingredients equally mixed; and Dr. Mitchell has always found it small-grained. The supposed granite, according to him, consists of feldspar, of a very unequal grain, inclosing sometimes spots of mica, and rarely specks of quartz. From all which this mineralogist concludes, that the last mentioned veins are nearly of contemporaneous origin with the rocks in which they are contained, and ought, therefore, to be considered as, and called, feldspar veins.

Although granite is the hardest, and one of the most durable rocks we are acquainted with, it is, nevertheless, subject to *disintegration*, which manifests itself not only in the crumbling of the surface of the exposed parts of granitic beds, but likewise in the separation of vast masses, which, being divided by the enlargement of the rents and fissures that generally traverse the granitic mountains, or cross the strata in a nearly vertical direction, are partly precipitated from their high situation, partly displaced in various manners, so as to produce the appearance of huge artificial structures, and of other objects to which the fancy of the beholder may compare them.

M. De Luc has seen on the Riesenbirge, in Silesia, a number of pillars produced by such disintegration, both solitary and grouped together, in a straight line, and, at a distance, presenting the appearance of many high piles of gourds.

The Adon-sholo mountains in Dauria, which consist of granite, are, according to Pallas, in many parts broken into all manner of shapes, representing vast ruins, grottos, and immense flat masses piled on one another in all directions.

Several

—Several of the mountains are, as it were, strewed with blocks of granite, which, at a distance, appear as numerous herds of cattle; and it is this circumstance which is said to have procured this ridge the name of Adon-sholo, a Mongole word, denoting herd-like mountains. All these detached rocks are fragments of the vast strata of granite that compose the greatest part of the Dauric mountains. The summits of the Goatfield and other mountains of Arran have the appearance of huge walls composed of large granitic masses. At Huelgouet, in Lower Brittany, we are informed by Monnet, as also in the Vosges, enormous masses of granite are seen piled on one another, and forming most extraordinary groups. The granite being here divided into masses by fissures, which are filled up with granite possessing less solidity, this latter is sooner acted upon by atmospheric agency, whence, by its disintegration, the masses become perfectly detached, and adopt various positions. But besides the accidental groups formed by the rolling down of the rocks, there are other groups of granitic rocks at Huelgouet, that appear to be in their natural position, and many of them form an assemblage of rock masses, which have a perfectly rhomboidal form, and are regularly joined to each other by means of their corresponding planes. One of the insulated rocks in a group at Huelgouet, is called *Pierre branlante*, or the rocking stone: it is 21 feet long, seven feet high, and eight feet wide, and its cubical content is 1160 feet: it is so accurately poised on the edge of another rock, which serves for its base, that the strength of a few men suffices to change its centre of gravity, and to communicate an oscillatory motion to it. The phenomenon of the *rocking stones* is not unknown in this country; the largest is that seen at the Land's End in Cornwall, where they are called Logan-stones; it weighs upwards of sixty tons, resting on another rock of granite of considerable height close on the sea-shore. "The two stones," says Mr. Playfair, who avails himself of this phenomenon among others to explain the migration of stony masses, "touch but in a small spot, their surfaces being considerably convex towards one another. The uppermost is so nearly in an equilibrium, that it can be made to vibrate by the strength of a man, though to overset it entirely would require a vast force. This arises from the centre of gravity of the stone being somewhat lower than the centre of curvature of that part of it on which it has a tendency to roll; the consequence of which is, that any motion impressed on the stone forces its centre of gravity to rise, (though not very considerably,) by which means it returns whenever the force is removed, and vibrates backward and forward, till it is reduced to rest. Were it required to remove the stone from its place, it might be most easily done, by cutting off a part or blowing it away by gun-powder; the stone would then lose its balance, would tumble from its pedestal, and might roll to a considerable distance. Now, what art is here supposed to perform, nature herself in time will probably effect. If the waste on one side of this great mass shall exceed that on the opposite in more than a certain proportion, and it is not likely that that proportion will be always maintained, the equilibrium of the Logan-stone will be subverted, never to return. Thus we perceive how motion may be produced by the combined action of the decomposition and gravitation of large masses of rock."

It was probably from seeing the fantastical and imitative forms produced by granitic cliffs, and by the disintegration of granite, that M. Vitte framed his unfortunate hypothesis respecting the pyramids of Egypt, and the ruins of Persepolis, Paimyra, and Balbec, all which, together with the temple of Jupiter at Girgentum, the palaces of the Incas in

Peru, &c. &c. were considered by that antiquary as productions of nature.

Granite is much less *metalliferous* than gneiss and other primitive mountains; but tin and iron abound in it. Besides these, several other metals occur in it in small proportion, *viz.* gold, though very rarely, in Peru; native silver, almost equally seldom, at Wittichen and Alt Wolfach, in the Black Forest, near veins of silver and cobalt; copper; galena, for instance, at Schreibershausen, at the foot of the Schneekuppe, in Silesia; bismuth, zinc, cobalt, manganese, molybdena, arsenic, tungstein, and wolfram, all which occur generally in small veins; but tin, galena, and blende, are found in beds at Zinnwald in Saxony, and in Bohemia.

As to the *extent* of granite over the world, it may be said that scarcely any country we are acquainted with is entirely destitute of that rock. In Asia we have the Uralian and Altaic mountains, with the Caucasus; in Africa, the Atlas, several mountains of Egypt, those of the Cape of Good Hope; in North America, some mountains of New York, Pennsylvania, and Virginia; in South America, great part of the Andes, the mountains de los Mariches in the Carracas, the Cordilleras of Parima, Sierra Nevada de Merida, &c.; in Europe, the Seewoga mountains of Scandinavia, those of Finland, the Carpathes, the Hartz, the Riesen-gebirge, the mountains of Upper Lusatia, a part of the Saxon metalliferous mountains, (especially Eibenstock, Johangeorgensladt, Schwartzenberg, Schneeberg, Ehrenfriedersdorf, Geier, Nauendorf, Altenberg, and Zinnwald,) the Fichtel-gebirge, the Odeawald and Schwartzwald, the Alps of Switzerland and Savoy, the Apennines, Pyrenees, the mountains of Cornwall, &c. all which have granite for their principal constituent rock.

The *use* made of granite is manifold: it is employed for building, paving, steps, for troughs in stamping mills, for millstones, &c.

The use of granite for architectural and economical purposes is perhaps no where more amply displayed than at Petersburg, where not only the imperial and other palaces, but even ordinary dwelling houses, have their lower parts lined with slabs of granite. The left bank of the great Neva, from the foundery to the gulf of Cronstadt, and both banks of the Fontanka and of the Catharine canal, are lined by high walls constructed of such slabs of granite; as are many bridges over the Neva, balustrades, &c. The pillars, stairs, balconies, &c. in the palace of Cronstadt, are almost all of the finest kinds of granite. Those employed for ornamental architecture are cut and polished by lapidaries; but those intended for less delicate purposes, such as common slabs, steps, cylinders, troughs, &c. are worked by peasants, particularly by those of Olonek. The government towns, however, Moscow not excepted, are too distant from the chief granite mountains, to be enabled to make frequent use of that rock for the above purposes.

Granite has been more particularly applied, together with sienite, for the purposes of architecture and statuary, by the ancients, especially by the Egyptians; and many very interesting monuments of their skill and patience are still existing in the collections of antiquities.

M. Brand has divided the different granites used in the arts after their predominant colours; the following are the principal varieties, in which, however, the black and white kind is not included, one of its ingredients being hornblende, which assigns it a place among the sienites. See SIENITE.

Grey Granite of Chessy, in the department of the Rhine; it consists of white quartz and black mica, with large crystals of rose-coloured feldspar. The columns of the Eglise d'Ence

d'Enée (ancient temple of Augustus) at Lyons, are of this kind of granite, which has also been worked by the Romans.

Grey Granite of Thain.—It consists of grey quartz, black mica, and white feldspar crystals, which are sometimes from two to three inches long. The quarries of this granite are on the road from Lyons to Valence, on the right bank of the Rhone. It is very well adapted for the construction of large monuments. The granite of St. Peray, not far from Thain, is exactly like this, except that its feldspar crystals are of a rose-colour.

Grey Granite of Lavazzi.—Found in the small island Lavazzi, near Bonifacio, S. of Corsica, in the straits that separate this island from Sardinia. This granite is composed chiefly of small irregular crystals of feldspar, mixed with a little black mica, besides which it contains also feldspar crystals, of a milk-white colour. In the quarry of that island a large unfinished column is to be seen, which has been relinquished by the Roman workmen.

Grey Granite of Elba.—Its grain is pretty uniform: its colour sometimes approaches to light violet. There are four columns of this variety to be seen in the Musée Napoleon: they were taken out of the church which contained the tomb of Charlemagne, at Aix-la-Chapelle.

The grey granites are much more common than the green or greenish, of which the following deserve to be mentioned.

Antique green Granite.—Its predominant ingredient is white quartz, which contains here and there some light green feldspar. There is a column of it in the Villa Pamfili, near Rome.

Fine grained antique Granite.—(Basalte verd oriental.) The component parts of this work are so minute and intimately blended, that they can scarcely be distinguished by the naked eye. Its colour approaches to deep olive. It is very hard, and takes a fine polish. The Egyptians have much employed it for the construction of monuments; and several statues of it may be seen in the Capitol and the Villa Albani. There is another variety with white spots, which is known at Rome under the name of Basalto Orientale pidochiofo; this is very rare, for there are but two columns of it in existence, namely, in the church of St. Pudenciana at Rome. Some varieties bearing that name are sienite.

Granite of St. Christoph.—composed of violet quartz, white feldspar, and green mica. This magnificent rock is found at Oisans, in the department of the Isère.

Corsican orbicular Granite.—This beautiful rock (which probably belongs to the sienite formation) was discovered by M. Barral, in the island from which it derives its name. Its composition is very extraordinary; it has a basis of ordinary grey granite, which, however, in most parts, exhibits a considerable portion of hornblende. But what more particularly characterizes it, is a number of balls, of from one to two inches in diameter, each composed of several concentric and perfectly parallel layers, the outermost of which, generally white, opaque, and two or three lines thick, is composed of quartz and feldspar, blended in various proportions, and exhibiting a radiated appearance, rather converging towards the centre of the ball. The second layer, which is of a greenish-black colour, and about one line thick, is composed of fine laminar hornblende; and this is succeeded by a white, generally translucent quartz layer, of about four or five lines in thickness, inclusive of two or three very thin layers of hornblende, that are generally seen within the substance of this third principal layer. Each of these layers is generally of equal thickness in the whole of its circumference. These three parts may be considered as the coating: the interior of each ball is less defined than the surrounding

layers; it consists of a blackish and a whitish substance, the former surrounded by, and passing into the latter, the centre of which is usually a dark-grey spot.

The quarry of this rock is unknown, a single block only having been found in the gulf of Valinco, in Corsica: its weight was about 80 pounds; but it was soon broke into small fragments, which are now distributed among collectors. There is a beautiful vase of it, one foot six inches high, in the cabinet of M. Dedrec. The granite of Corsica is figured by M. Faujas de St. Fond, in his "Essai de Géologie," and in Mr. Sowerby's "Exotic Mineralogy."

Among the red granites, we have what is called *red oriental granite*, which, as usually containing hornblende, often in large separate patches, will be described under SIENITE.

The red Granite of Ingria.—This granite, says M. Patrin, is distinguished from others in this, that the feldspar, instead of being in grains, or paralleloiped crystals, as in most other granites, constantly appears in the shape of round or oval pieces of from half an inch to two inches in diameter. This granite takes a very fine polish, and in this state exhibits the feldspar in the shape of white, round, or oval *chatoyant* spots, in a reddish ground. The rock, which serves as a pedestal of the equestrian statue of Peter the Great, at St. Petersburg, is of this granite: the block was originally 32 feet long, 21 feet thick, and 17 feet long; but, in order to give it its present shape, imitative of a picturesque natural rock, it has been much diminished in size. This block was disengaged from a swamp, about forty versts from Peterburgh: its weight was calculated to be above three millions of pounds. We have seen several fragments that were detached from the very block forming the pedestal of the statue; but in none of them did we observe the form ascribed by Patrin to the feldspar.

The public summer promenade-garden at Peterburg is decorated with a superb colonnade of this granite: the columns, which are sixty in number, are of the Tuscan order; their shafts, made of one piece, are about twenty feet high, and three feet in diameter. The island, called Kotlin-Ostrow, on which is the fortress of Cronstadt, is covered with blocks of this granite, the feldspar of which is sometimes of the kind called Labrador-stone.

Red Granite of the Vosges Mountains.—This granite is composed of large laminae of rose-coloured feldspar, grey grains of quartz, and small scales of mica. It has so strong a resemblance to the Egyptian red granite, that it is difficult to distinguish them. Its quarries are on the heights of Montaujeu, near the Papean mountains, in the Vosges.

Violet Granite of Elba.—The feldspar of this variety is in large violet crystals. The pedestal of the equestrian statue, in the Piazza della Santissima Annunziata at Florence, is made of it, as are also the fodes in the chapel of St. Laurence in the same town.

Rose-coloured Granite of Baveno.—This beautiful granite consists of flesh-coloured feldspar, white quartz, and some grains of black mica. Considerable quarries of it are found on the borders of the Lago Maggiore, which are worked, without intermission, for supplying Milan, and the whole of the neighbouring country, with this granite. It takes a very fine polish: here and there it exhibits ribbands, or zones, of a grey colour, which are composed of the same ingredients as the rest of the mass, but reduced into very minute particles. Many columns, porticos, &c. are seen of it at Milan.

The name of *graphic granite* is given to those kinds in which the feldspar forms large concretions, intermixed with grey quartz-crystals, exhibiting, when cut transversely, an-
gular

gular figures, mostly shaped like a 7; while others are less regular, and bear a distant resemblance to rude alphabetical writing. They are not considered to be genuine granite by some mineralogists.

Graphic Granite of Portfoy.—The feldspar is of various tints of pale flesh-red; the quartz dark, but transparent, with now and then some small particles of mica. This rock is minutely described by Dr. Hutton.

Graphic Granite of Siberia.—Its feldspar is of a yellowish-white, or reddish colour; the quartz, exhibiting figures similar to those of the quartz in the preceding sort, is of the variety called smoky topaze. Mica occurs in it in small nells, and black shori in acicular crystals.

Graphic Granite of Autun.—Of a pale rose-colour; quartz-crystals grey, very numerous. It is found in the neighbourhood of Autun, department of Saône-et-Loire, particularly at Marmagne. This, in M. Brand's opinion, is the most beautiful of all graphic granites. Another variety of this stone is found at the same place: its feldspar is white; the quartz grey, in small crystals; it is susceptible of very fine polish.

Graphic Granite of Corsica.—Likewise of a rose-colour; but generally paler than that of Autun, from which it is also distinguishable, by its quartz-crystals being larger, and at greater distance from each other. It contains some thinly disseminated bronze-coloured mica. It takes a fine polish.

GRANIVOROUS, an epithet or denomination given to such animals as feed upon corn, or any other grain or seeds.

Granivorous animals are chiefly of the bird kind. These have a peculiar provision for the digesting of so dry and hard a food.

GRANNA, in *Geography*, a town of Sweden, in the province of Smaland; 18 miles N.N.E. of Jonkioping.

GRANO, in *Biography*, a performer on the trumpet and German flute, and a composer of tunes for those instruments, which had their day of favour in the early part of the last century. He was a kind of mungrel dilettante, who during many years condescended to make concerts and give lessons, en professeur, always insinuating that it was merely for the pleasure of amusing the public and instructing individuals. Grano's trumpet march was long used by the Guards.

GRANON, in *Geography*, a small island on the W. side of the gulf of Bothnia. N. lat. 61° 5'. E. long. 17° 5'.

GRANSEE, a town of the Middle Mark of Brandenburg; 30 miles N.N.W. of Berlin. N. lat. 52° 59'. E. long. 13° 13'.

GRANSO, an island in the Baltic, near the E. coast of Sweden. N. lat. 57° 46'. E. long. 16° 5'.

GRANSON, a town of Switzerland, in a bailliage of the same name, belonging to Bern and Friburg, situated between the lake of Neuchâtel and mount Jura, and remarkable for the battle in which Charles the Bold, duke of Burgundy, was defeated by the Swifs in 1476; 16 miles S.W. of Neuchâtel. N. lat. 46° 50'. E. long. 6° 26'.

GRANT, CONCESSIO, in *Laws*, the regular method by the common law of transferring the property of incorporeal hereditaments, or such things of which no livery can be had. (Co. Litt. 9.) For which reason all corporeal hereditaments, as lands and houses, are said to lie in livery; and the others, as advowsons, commons, rents, reversions, &c. to lie in grant. (Ibid. 172.) The reason is thus given by Bracton (l. ii. c. 18.): "*traditio, or livery, nihil aliud est quam rei corporalis de persona in personam, de manu in manum, translatio aut in possessionem inductio; sed res incorporales, que sunt ipsam jus rei vel corpori inbarens, traditionem non patiuntur.*" These, therefore, pass merely by the delivery of the deed. And in signories, or reversions of lands, such grant, to-

gether with the attornment of the tenant, (while attornments were requisite,) were held to be of equal notoriety with, and therefore equivalent to, a feoffment and livery of lands in immediate possession. It therefore differs but little from a feoffment, except in its subject-matter; for the operative words therein commonly used are "*dedi et concessi*," "have given and granted." For the difference between gifts and grants, see the article GIFT. The king's grants are matter of public record. (See RECORD.) No freehold can be given to the king, nor derived from him, but by matter of record. To this end a variety of offices are erected, communicating in a regular subordination one with another, through which all the king's grants must pass, and be transcribed, and enrolled; that the same may be narrowly inspected by his officers, who will inform him if any thing contained therein is improper, or unlawful to be granted. These grants, whether of lands, honours, liberties, franchises, or aught besides, are contained in charters, or letters patent. (See PATENTS.) The manner of granting by the king does no more differ from that by a subject, than the construction of his grants when made. 1. A grant made by the king, "at the suit of the grantee," shall be taken most beneficially for the king, and against the party; whereas the grant of a subject is construed most strongly against the grantor. It is therefore usual to insert in the king's grants, that they are made, not at the suit of the grantee, but "ex speciali gratia, certa scientia, et mero motu regis;" and then they have a more liberal construction. 2. A subject's grant shall be construed to include many things, besides what are expressed, if necessary for the operation of the grant. Thus, in a private grant of the profits of land for one year, free ingress, egress, and regress, to cut and carry away those profits, are also inclusively granted. (Co. Litt. 56.) And if a feoffment of land was made by a lord to his vassal, this operated as a manumission (Litt. § 206.); for he was otherwise unable to hold it. But the king's grant shall not enure to any other intent, than that which is precisely expressed in the grant. As, if he grants land to an alien, it operates nothing, for such grant shall not also enure to make him a denizen, that he may be capable of taking by grant. (Bro. Abr. tit. patent. 62. Finch. l. 110.) 3. When it appears, from the face of the grant, that the king is mistaken, or deceived, either in matter of fact or matter of law, as in case of false suggestion, misinformation, or misrecital of former grants; or if his own title to the thing granted be different from what he supposes; or if the grant be informal; or if he grants an estate contrary to the rules of law; in any of these cases the grant is absolutely void. (Freem. 172. Finch. 101, 102.) To prevent deceits of the king, with regard to the value of the estate granted, it is particularly provided by the statute 1 Hen. IV. c. 6. that no grant of his shall be good, unless, in the grantee's petition for them, express mention be made of the real value of the lands. Blackst. Com. vol. ii.

GRANTHAM, in *Geography*, a township of Upper Canada, in the county of Lincoln, fronting lake Ontario.

GRANTHAM, a market and borough town in the foke, or wapentake, of the same name, in Kesteven division of the county of Lincoln, England, is situated on the side of the river Witham, on the ancient Roman road called Lrmine street. The town comprises four principal streets. The church is an elegant stone structure, consisting of a nave and two spacious aisles, with large handsome pointed windows, and is celebrated for its lofty spire, which is 273 feet in height. The style of architecture appears to be that of the thirteenth century; though Mr. Gough observes that the church was endowed by Hugh, bishop of Lincoln, A.D.

1100. Beneath the church is a chancel-house, filled with human skulls and other bones. Among several handsome monuments in this edifice, are, one to sir Thomas Bury, chief baron of the exchequer in the time of George I, and one to sir Dudley Ryder, chief justice of the King's Bench, in the succeeding reign. The font exhibits a fine specimen of ancient sculpture.

Grantham was incorporated under a charter granted by Edward IV. in 1463; when it first returned members to parliament; the representatives are chosen by the freemen of the borough. The civil government is vested in an alderman, a recorder, 12 common burgesses, a coroner, an escheator, and twelve second men, who are the common council. The jurisdiction of this corporation extends over the whole soke, comprehending twelve villages, and the alderman acts as sheriff of the town and soke, the sheriff of the county having no authority within the soke and district thereof. The guildhall was rebuilt under an act of parliament in 1787. A free-school was founded here by Richard Fox, bishop of Winchester, and further endowed by king Edward VI.; this school attracts attention, from the circumstance of its having been a place of education to that luminary of science, sir Isaac Newton. Near the south entrance into the town, on St. Peter's hill, formerly stood an elegant cross, erected by king Edward I., in memory of Eleanor his queen, who died in 1290; this being one of the places where the corpse was laid in state in its way for interment in Westminster Abbey. Grantham is distant from London 111 miles N., has a well supplied market on Saturdays, and five annual fairs. In the return under the late population act, the number of houses is 631, occupied by 3303 inhabitants.

A canal has been lately cut from Grantham to the river Trent, an extent of 25 miles. It is supplied with water by means of large reservoirs made for that purpose. The chief articles conveyed by this navigation are corn and coals. Turner's History of the Soke of Grantham, &c. Beauties of England and Wales, vol. ix.

GRANTHAM *Canal*, is the parliamentary name of an inland navigation about 33 miles long, in the counties of Nottingham, Leicester, and Lincoln, of which we gave an account in our article CANAL, and nothing material has occurred to be added thereto.

GRANTOWN, a town of Scotland, in the county of Inverness; 17 miles S. of Fores.

GRANVILLE, GEORGE, baron Lansdown, in *Biography*, a nobleman chiefly remembered as a poet, born in 1667, was son of Barnard Greenville, one of the distinguished family of Greenville or Granville, the latter mode of spelling the name being introduced by the subject of this article, who is thereby separated from the rest of his house. He shewed very early talents, and was entered, in his 12th year, at Trinity college, Cambridge. In the same year, he wrote a copy of verses on the dukes of York's visit to the university, and on the accession of James II. he offered incense to the new prince in three short pieces, of which Dr. Johnson says, "the first is profane, and the two others such as a boy might be expected to produce." In 1688, when an invasion was threatened, he was desirous of devoting his life to the service of James, and requested his father to present him to the king for that purpose. The revolution succeeded, and being possessed of neither interest nor considerable fortune, he lived in literary retirement. During this period his dramatic works were chiefly composed and acted. The first of these was "The Gallants," said by himself, by way of apology, to have been written at an age when some persons are but beginning to spell. This was afterwards

brought forward in a more correct form, under the title of "Once a Lover and always a Lover." His tragedy of "Heroic Love," founded on the fable of Homer's Iliad, was acted the same year with great applause from the wits and critics. On this occasion he was complimented in a copy of verses from the pen of Dryden. When queen Anne came to the crown, Mr. Granville emerged from the political obscurity in which he had lived: his fortune was increased by the death of his father, and that of his uncle, who left him an annuity. He was now elected a member of parliament for the borough of Fowey, and feeling the common ardour of his countrymen of all parties against the ambition of Lewis XIV., he joined other literary persons in a translation of the Philippics of Demosthenes, to rouse the nation to oppose the Philip of modern times. By the death of his elder brother sir Bevil Granville, in 1706, he succeeded to a good estate, and he continued to serve in parliament, sitting as knight of the shire for the county of Cornwall. On the change of administration in 1710, he was appointed secretary of war in the room of sir Robert Walpole. He married in the same year Mary, the daughter of the earl of Jersey, then widow of Thomas Thynne, esq. Shortly after this he was introduced into the house of peers by the style and title of lord Lansdown, baron of Biddeford, at the memorable creation of twelve peers, in one day, viz. December 31, 1711. The elevation, however, of lord Lansdown was not one of those which appeared very extraordinary, as two peerages had become extinct in the Granville family. On account of his principles and conduct he stood high in favour of the queen, who made him a privy counsellor, comptroller and treasurer of the household; but the accession of George I. put an end to the power of his party, and deprived him of his place. He remained steady to his former connections, protesting against measures which he deemed unconstitutional, and in consequence of his zeal he was regarded with a suspicious eye, and was reckoned by people in power as a disaffected man. Upon the breaking out of the rebellion in 1715, he was committed to the Tower, and kept confined in that fortress till February 1717, when he obtained his liberty and resumed his seat in the house of lords. In 1719 he opposed with violence the proposed repeal of the bill to prevent occasional conformity; his speech on the subject he afterwards printed. Subsequently to this a derangement in his private affairs, owing to the want of economy, obliged him to spend some years on the continent. During his absence, the first volume of bishop Burnet's "History of his own Times," making its appearance, lord Lansdown undertook the vindication of the duke of Albemarle and the earl of Bath, from some aspersions thrown upon them in that work. He also took occasion to vindicate his great uncle, sir Richard Greenville, from the unfavourable representations of his conduct by lord Clarendon, and archdeacon Echard. On this occasion he published two tracts in 1732. In the same year he published a splendid edition of his works, leaving out a comedy, which, on account of its licentiousness, had been objected to, and he also omitted to insert his speech against occasional conformity. He now felt reconciled to the measures of government, and to the change in the succession, which formerly he had regarded with horror. He went to court, and was graciously received by queen Caroline, to whom he presented his works, with some elegant lines written in a blank leaf. He died Jan. 30, 1735, in his 64th year. In private life, lord Lansdown was amiable, polite, and candid. He was liberal in patronizing literary merit, and had the credit of being one of the first to recognize the rising powers of Pope, who repaid him for his kindness by his dedication of *Windfor*

Forest. His own talents, as a poet, were not of the first order, but his works are still read with pleasure. He is chiefly known as a writer of amatory pieces, most of which are addressed to Myra, the countess of Newburgh, the object of his youthful passion. These are not either highly poetical nor strongly expressive of feeling. Johnson characterizes his "Essay on unnatural Flights in Poetry," as possessing didactic merit, and his "British Enchanters," as lively and pleasing. He seems to think favourably likewise of his epilogues and prologues. Biog. Brit. Johnson's Lives of the Poets.

GRANVILLE, in *Geography*. See GRANDVILLE.

GRANVILLE, a county of North Carolina, in Hillsborough district, S. of Virginia, containing 14,015 inhabitants, of whom 6106 are slaves. Its chief town is Williamsburg. —Also, a township of the county of Annapolis, in Nova Scotia, N. of Annapolis river, on the bay of Fundy, 30 miles long; first settled from New England. —Also, a township of Hampshire county, Massachusetts, about 14 miles W. of Springfield; incorporated in 1754, and containing 2309 inhabitants. —Also, a post-town in Washington county, New York, containing 3175 inhabitants.

GRANVILLE, or *Greenville*, a flourishing town in Mecklenburg county, Kentucky.

GRANVILLE'S *River*, a river of the island of Egmont, or New Guernsey, which runs into the sea, S. lat. 10° 42'. E. long. 163° 58'.

GRANULATED OIL. See OIL.

GRANULATION, in *Chemistry*, an operation performed on metals, whereby they are reduced into small grains or globules.

It is done by melting them, and when in fusion, casting them from a certain height into cold water; in which they congeal into granules, as required, and are hereby rendered more easy to be dissolved. The best way is to pour the fluid metal through a cullender, or a new birchen broom, or to agitate the water with a broom, thus giving it a circular motion while the metal is poured in. Copper is granulated for making brass in a cylindrical wooden reservoir, four or five feet deep, in which a circular brass or copper bottom may be raised or lowered by means of a chain. The reservoir is covered with a copper lid, in the middle of which is a hole half a foot in diameter, intended to receive an iron ladle pierced with holes and coated with clay. The reservoir being filled with water, the melted copper is poured through the holes in the ladle into the water; where it is broken by its fall into smaller drops or grains, rendered solid by the cold water, and collected in the moveable bottom, which is raised by the annexed chain, that the granulated copper may be taken out. Macquer, Dict. Chem. Eng. edit. art. *Brass*. See BRASS.

Lead, tin, and brass, which are very brittle, when they are so hot as to be almost fused, may be granulated by pouring them, in a state of fusion, into a box, the inner surface of which is rubbed with powdered chalk, and by shaking the box: the metals in the box are no sooner become solid, and consequently very brittle, than they are shivered, by being dashed against the sides of the vessel into a fine dust. Silver and gold, and the more tenacious metals, must be granulated in either of the first methods above-mentioned, with water. Cramer, Art of Ass. p. 70.

The term granulation is also applied to *gun-powder*: which see.

The granulation of common fowling shot consists merely in causing the fused metal to fall in equal spherical drops into water. The lead is melted with the addition of a small

proportion of arsenic, which being reduced to a metallic state, by means of grease stirred in during the fusion, renders it less fluid. An oblong shallow vessel of iron, perhaps 10 inches wide, 14 long, and 2½ deep, called a "Card," whose bottom is pierced with holes, proportionate to the size of the shot, is placed at the height of from one to three inches, over the surface of a tub of water, covered with a thin film of oil. The card is previously heated to the temperature of the metal, by immersing it in the cauldron; and a stratum of soft dross or scoræ, found on the surface of the fused alloy, is then placed on its perforated bottom, and being slightly pressed down with the ladle, forms a kind of filter, which partly chokes up the apertures, and prevents the metal from flowing through them in continuous streams. The fused metal is then poured by ladle-fulls into this vessel, and appears, notwithstanding, to run through it with considerable velocity; so that it seems difficult to believe, that it falls in separate drops, till one is convinced by taking up a quantity of shot from the bottom of the water. The imperfections to which this shot is subject, are remedied in the patent shot, the manufacture of which differs from that of the preceding kind, in the addition of a larger portion of arsenic, which varies according to the quantity of the lead, in dropping it from such a height, that it becomes solid before it enters the water, which is from 40 to 100 feet. Besides, it is first dried and sifted. It is then *boarded*, which consists in scattering it on several polished slabs, or trays of hard wood, with rims in the form of a II, except that the sides converge towards the lower part, to which a slight inclination and alternate motion in their own planes are given by boys employed in the manufacture. The shot, whose form is imperfect, are detected by the sluggishness of their motion, and remain behind, whilst the others roll off from the board. The last operation is the polishing; which is performed by agitating the shot with the addition of a very small quantity of black-lead, not exceeding two spoonfuls to a ton, in an iron vessel, turning on an horizontal axis, like a barrel churn. It does not appear that any higher degree of perfection than that which is thus attained remains to be desired. The argentine brilliancy of the shot when newly made, the beautiful accuracy of its form, and the curious instance of inanimate tactics which it presents when scattered on a plate, renders it even an agreeable object of contemplation. Nicholson's Journal, vol. 1. 4to.

GRANULATION. In *Surgery*, granulations are the small eminences of new animal matter, with which the cavities of sores and wounds become filled up in the process of healing. Granulations, according to Mr. Hunter, are formed by an exudation of the coagulating lymph from the vessels, into which new substance the old vessels very probably extend, at the same time that entirely new ones are generated in it. Hence granulations are exceedingly vascular, perhaps more so than almost any other animal substance. Mr. Hunter informs us, that he noticed upon a sore a white substance, exactly similar in every visible respect to coagulating lymph. He did not attempt to wipe it off, and the next day of dressing he found this very substance vascular; for, on touching it with a probe, it bled freely. He observed the same appearance on the surface of a bone that had been laid bare. He once scraped off some of the outside of one of the bones of the foot, in order to see if the surface would granulate. The following day he remarked, that the scraped part was covered with a whitish substance, having a tinge of blue. When he passed his probe into it, he did not feel the bone bare; but only its resistance. He conceived this substance was coagulating lymph, thrown out in consequence of inflammation,

inflammation, and that it would be forced off when suppuration came on; but on the succeeding day he found it vascular, having all the appearance of healthy granulations.

The vessels of granulations first pass to their basis from the original parts, whatever these may be, and then run in nearly parallel lines to their external surface, where they seem as if they ended.

The surface of the new substance continues to have the same disposition for the secretion of pus, as the parts from which it itself was produced. Granulations are very convex, which is an appearance the very reverse of what happens in ulceration, or while a sore is increasing in size. They appear rough, in consequence of having a great many points or small eminences, and they are deemed the more healthy, the smaller such points are.

Healthy granulations are of a deep florid red colour, a circumstance which might lead one to suspect, that the colour was principally owing to the arterial blood; but Mr. Hunter was of opinion, that this appearance only denoted a brisk circulation in the new-formed substance, the blood not having time to become dark.

When granulations are naturally of a livid red, they are commonly unhealthy, and shew a languid circulation. Such appearances may often be induced by position, and we frequently see it take place on sores of the leg, when the limb is not kept in a horizontal posture. In this circumstance, the new-formed vessels are incapable of supporting the increased column of blood, and of acting upon it. The stagnation allows the change of colour to happen, and the alteration, in all probability, takes place both in the arteries and veins. Here may be seen the reason why sore legs are frequently very backward in healing, when the patient is suffered to put his foot on the ground, or to walk about.

Healthy granulations, situated on an exposed or flat surface, rise nearly even with the surface of the surrounding skin, and often a little higher; and in this state they are always of a florid red colour. When they exceed this height, and assume a growing disposition, they are then unhealthy, and they become soft and spongy, without any disposition to form skin.

Granulations always have the same disposition as the parts upon which they are formed; and take on the same mode of action. If it is a diseased part, they are diseased; and if the disease be of any specific kind, they are also of the same nature, and, of course, produce matter of the same quality.

When granulations are healthy, they are always prone to unite with each other, the great use of which is to bring about the union of parts, somewhat like what is the result of union by the first intention. See WOUNDS.

The disposition which granulations have to unite with each other upon coming into contact, without the appearance of any intermediate animal substance, is perhaps effected, as Mr. Hunter conjectures, in the following manner. When two sound granulations approach together, the mouths of the secreting vessels of the one coming to oppose the mouths of similar vessels of the other, they are stimulated into action, which is mutual; so that a kind of sympathetic attraction takes place, and as they are solids, the attraction of cohesion is established between them. This has been termed inoculation. The vessels thus joined are altered from secreting to circulating. There are some other surmises hazarded by Mr. Hunter respecting the rationale of this minute process of nature; but the curious reader must refer for them to the author's own relation of the subject.

Mr. Hunter informs us, that he has seen two granulations on the head, *viz.* one from the dura mater after trepanning,

and the other from the scalp, unite over the bare one, which was between them, so strongly in twenty-four hours, that some force was required to separate them, and when separated, they bled.

The inner surface of the skin, in cases of abscesses, not only does not readily granulate, but does not readily unite with the granulations underneath. Hence the frequent formation of fistulae and sinuses.

Unhealthy granulations have not an equal tendency to unite with each other: a smooth surface is formed, which continues to secrete matter. Thus, Mr. Hunter regarded the internal surface of a fistulous ulcer as, in some degree, similar to the inner surface of the urethra, when it is forming the discharge commonly called a gleet. Such sores have no disposition in their granulations to unite, and nothing can produce an union between them, but altering the disposition of these granulations, by exciting a considerable inflammation and probably ulceration; so as to form new granulations, and by this means give them a chance of falling into a sound state.

It is also noticed by Mr. Hunter, that granulations are not furnished with so much power as parts possess, which are originally formed. Hence they more readily ulcerate and slough. He states, that they not only shew the condition of the part in which they grow, or the condition in which they are themselves, but also, how the constitution is affected by many diseases.

The same author has made some observations respecting the longevity of granulations. He says, that they often seem to be formed with only stated periods of life, and those much shorter, than the life of the part, on which such granulations are situated. Their life, indeed, does not appear to be so short, when cicatrization can be accomplished; but while a sore is in a granulating state, they frequently perish without any visible cause. Thus, says Mr. Hunter, a person may have on his leg a sore, which granulates well, the granulations have a healthy appearance, the skin is forming round the edges, and every thing promises well, when, all at once, the granulations become livid, lose their life, and immediately slough off. In some instances, they are destroyed, partly by ulceration, and partly by mortification. Then new granulations are frequently produced, and go through similar changes. Sometimes this happens three or four times in the same person. Mr. Hunter in vain tried various methods for rendering the granulations in such cases more durable.

Suppuration and granulation are essential for the cicatrization and union of almost every wound, which has not been united by the first intention: a few small wounds and scratches, which heal under a scab, being the only exceptions.

Our author, in the following section of his treatise on the blood, notices, that cicatrization seems to be in view immediately after the granulations are formed. The parts which had receded, in consequence of a breach being made in them, by their natural elasticity, and, probably, by muscular contraction, now begin to be brought together by this new substance, which soon contracts. The contraction takes place in every joint, but principally from edge to edge, which brings the circumference of the sore towards the centre, so that the sore becomes smaller and smaller, although little or no new skin may be formed.

The tendency in the granulations to contract is, in some degree, proportioned to the general healing disposition of the sore, and the looseness of the parts, on which they are formed. When new skin cannot be produced, the granulations do

do not so readily contract, and, therefore, Mr. Hunter infers, that their contraction and the production of skin are probably effects of one cause. The induration, occasioned by inflammation, retards the contraction of granulations, though Mr. Hunter was inclined to think, that the circumstance did not arise so much from a mechanical principle, as from the diminution of the disposition to the process occasioned by the inflammation itself. Granulations, however, as the same writer explains, are sometimes undoubtedly retarded in their contraction by mechanical causes, when formed on parts naturally fixed, such as a bone; for instance, on the skull, the shin, &c.

When, by reason of a loss of substance, there is a deep hollow sore, and the contraction of the granulations is considerably advanced, before they have had time to rise as high as the skin, the edges of the latter part are generally drawn down, and tucked in by it, in the direction of the excavated surface of the fore.

If it is a cavity or abscess, which is granulating, with only a small opening, as often happens when the surgeon has neglected to make a free aperture, the whole circumference contracts, like the bladder of urine, till little or no cavity remains; and if any cavity is left, when the granulations can contract no further, they unite with such as are opposite to them.

This contraction in the granulations, says Mr. Hunter, is continued till the whole of a fore is healed, or skinned over; but it happens in the greatest degree in the beginning, when there is less resistance in the surrounding parts.

The contraction of granulations may often be assisted by art, namely, by using bandages, which tend to push, draw, or keep the skin near to the fore which is healing.

Besides the contractile power of the granulations, there is a similar power in the surrounding edge of the cicatrizing skin, which assists the contraction of the granulations, and is even more considerable, drawing the mouth of the wound together like a purse, and sometimes, when the surface of the fore is high, grasping the granulations.

The contractile power of the skin is chiefly confined to the very edge, where it is healing. The surrounding old skin either does not contract at all, or not much, as is evident from its being thrown into folds and plaits, while the new skin is smooth and shining. The original skin, having little or no power of contraction, is a reason why round sores cannot so readily heal as long ones.

Mr. Hunter has explained, that the uses, arising from the contraction of granulations, are various. It facilitates the healing of a fore, as there are two operations going on at the same time, *viz.* contraction and skinding. It avoids the formation of much new skin, an effect which is very evident in all sores which are healed, especially in found parts. When a thick thigh, seven or eight inches in diameter, has been amputated, the surface of the fore is of the same width; yet, in the end, the cicatrix will be no broader than a crown-piece, in consequence of the old skin becoming drawn over the ulcer, by the contractile power of the granulations. The advantage of this is considerable, since such parts as are originally formed are always much fitter for the purposes of life than those which are newly formed.

After all, a fore is covered with skin, the substance, which is the remains of the granulations on which the new skin is formed, still continues to contract, till hardly any thing more is left than what the new skin stands upon. This is a very small part, in comparison with the first formed granulations, and, in time, it loses most of its apparent vessels, becoming white and ligamentous. All new-healed sores are at

first redder than the common skin, but afterwards become much whiter.

As the granulations contract, the surrounding old skin is stretched to cover the part which is deprived of integuments. At first, the skin is brought little further than into the position from which it had receded, on the occurrence of the wound; but afterwards it becomes drawn much more considerably, being stretched and elongated. See Hunter's *Treatise on the Blood, Inflammation, &c.* chap. 7.

GRANULES, in *Geology*, is a term which Mr. Whitehurst, ("Enquiry," 1st edit. p. 180.) and others, employ to express the grains or minute lumps of stony matter, composing the sand usually found on the surface of valleys, and which is formed by attrition and the grinding down of stones of different kinds.

GRANULOSE ROOTS, are those composed of smaller knobs than the grumose ones, and resembling so many grains of corn; of this sort is the white faxifrage.

GRANUM VIRIDIS, in *Botany*, a name given by some authors to the turpentine-tree. The fruit of this tree is reddish while unripe; but as it ripens, it becomes of a deep blueish-green colour, and hence the name.

GRANZA, in *Geography*, a town of Africa, in the country of Magadoxa.

GRANZOW, a town of the Ucker-Mark of Brandenburg; 8 miles S. E. of Prenzlau.

GRAO, a port of Spain, in Valencia, which carries on a coasting trade along the Mediterranean; on one side, on the coasts of Catalonia, Roussillon, Languedoc, as far as Marseilles; and on the other side, to Alicant, Carthagena, and Malaga: some vessels even pass the straits of Gibraltar, into the Atlantic, and go to Cadiz; and sometimes they go round Portugal as far as the ports of Galicia. The largest of these ships are from 50 to 60 tons, each having a crew not exceeding 11 men. They carry out wines, silk, wool, dry fruits, and kali; and return with limes, woollens, ironmongery, spices, and corn. Grao is pleasant in summer, on account of the sea-baths, which draw together a great number of people for health or amusement.

GRAPE, the fruit of the vine. See VINE and WINE. See also CURRANTS and RAISINS.

GRAPE Hyacinth. See HYACINTH.

GRAPE, Mangrove or sea-side. See COCCOLOBA.

GRAPES, Wolf. See LYCOSTAPHYLÆ.

GRAPE-galls, in *Natural History*, a name given by authors to a species of protuberances, resembling clusters of grapes, and when ripe of a reddish colour, which are found hanging from the oak at some seasons of the year. These are genuine galls, though of a peculiar kind, and owe their origin to a very small four-winged black fly. See GALLS.

GRAPE-shot, in *Artillery*, is a combination of small shot, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in grape varies according to the service or size of the guns: in sea-service nine is always the number; but by land it is increased to any number or size, from an ounce and a quarter in weight to three or four pounds. In sea-service, the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPE-stone, Botrites, is a sort of stadamites, which effervesces with acids, according to Dr. Grew. "Rarities of Gresham College," p. 324. It is also the name of certain botroidal stalactites, which are sometimes met with, pendant from the roofs of caverns in lime-stone districts.

GRAPES, in the *Manege*, a term used to signify the arrears or many tumours that happen in a horse's legs. See ARRETS.

GRAPHICAL PERSPECTIVE, in *Optics*, is an instrument described by Mr. Martin, consisting of a tube containing two convex lenses, which are placed at twice their focal distance from each other; and in their common focus is another glass, divided into equal parts with the point of a diamond. Though this instrument does not magnify any object, yet the angle under which an object is seen is easily known by it; and since this angle varies with the distance of objects, it is easily applied to the purpose of measuring inaccessible heights and distances; and since the field of view is divided into equal squares, it is useful in drawing the perspective appearance of objects. Moreover, as all foreign light is excluded by the tube in which these lenses are inclosed, pictures seen through it have a fine relief, on which account, and also because objects appear inverted through it, the images of a camera obscura are viewed with it to peculiar advantage. If a lens of a greater focal length be fixed at a proper distance from the centre of the tube, this instrument will be a telescope, and will magnify the prints which are looked at through it; and if a small lens be used, it will be a microscope, and the same micrometer will serve for them both. Martin's *Optics*, chap. xvii. p. 280, &c.

GRAPHIDA, in *Natural History*, a name by which some authors have called the *morochthus*, or French chalk.

GRAPHIS, in *Botany*, from *γραψω*, to write, a name invented by Adanson, who is pleased to spell it *grafis*, and adopted by Ehrhart, for the various species comprehended under the *Lichen scriptus* of Linnæus, and which constitute the very distinct genus of *Opegrapha* in Acharius; see Eng. Bot. v. 25, 26. t. 1753, &c.

GRAPHISCUS, in the *Writings of the Ancients*, a name given to an instrument used for extracting darts from wounds. It is said to have been the invention of Diocles, and is described by Celsus.

GRAPHITE. See PLUMBAGO.

GRAPHOIDES, *γραφοειδης*, in *Anatomy*, an appendage of the bones of the temples, long, small, sharp, and a little crooked, like a cock's spur; called also *styloides*.

The same name is sometimes also applied to the musculus gastricus.

Likewise to an extension of the brain, resembling a writing pen.

GRAPHOMETER, a name which some authors, particularly the French, give to a surveying instrument, by us commonly called a *feméirele*; which see. Mr. Nicholson, in the fifth volume of his "Journal," 8vo. has described, and illustrated by appropriate figures, a subterranean graphometer, invented by M. Komarowski, F. R. S. and presented to the National Institute of France. It is a simple construction of the common *theodolite* (which see), and is calculated to answer the author's intentions in operations like those of mining, where great accuracy is not required. In vol. i. of the same "Journal," we have the description of an instrument resembling a graphometer, invented by Cit. Carangeau, for determining the mutual inclination of the faces of a crystal, or its prominent angles; it consists of two concentric, equal quadrantal arcs joined by a hinge; to which are applied compass-legs or radii, capable of being shortened to apply to small crystals, &c. See **GONIOMETER**. See also *Plate VI. Crystallography*, fig. 93.

GRAPNEL, or **GRAPLING**, on *Ship-board*, a kind of small anchor for boats or galleys to ride by. It differs from other anchors, as having four or five flukes and no snack, though there are some with three flukes, with which they use to sweep for hawfers or small cables. In men of war also, the grapnels, or at least a lighter kind of them, whose

flukes are furnished with strong barbs on their points, are used to be thrown into an enemy's ship, in order to catch hold of some of her gratings, rails, gun-wales, &c. this is done in order to boarding of her. They are particularly useful in fire-ships, and called fire-grapplings.

GRAPPLE, in the *Manege*. A horse is said to grapple with one or both legs, when he catches or raises them more hastily and higher than ordinary, as if he were curvetting.

GRAPTOLITHI, in *Natural History*, are the petrificata ficta of Linnæus and others; as dendritæ, landscape-marble, dendropotamites, &c. all which, according to Mr. William Martin, "Outlines," p. 8. should be excluded from the list of extraneous fossils.

GRASS, **GRAMEN**, in *Botany*, See **GRAMINA**.

To enumerate all the species of grass which are found growing naturally in England, would greatly exceed the bounds which can be allowed for this article; it will suffice, therefore, to mention a few species, which are either used in medicine, or cultivated as a pabulum for cattle; for there is scarcely a pasture in this country where great numbers of different species are not to be found intermixed. Mr. Ray has ranged them in the following order, *viz.* wheat-grass, rye-grass, darnel-grass, panick-grass, canary-grass, fox-tail grass, cat's-tail grass, hedge-hog grass, crested-grass, oat-grass, cock's-foot-grass, buck-grass, and millet-grass. These and other grasses Linnæus has arranged into distinct genera. See the following articles:

GRASS, *Arrow-headed*. See **TRIGLOCHIN**.

GRASS, *Bent*. See **AGROSTIS**.

GRASS, *Bird*. See **BIRD-grass**.

GRASS, *Canary*. See **PHALARIS**.

GRASS, *Capon's-tail*. See **FESTUCA**.

GRASS, *Cat's-tail*. See **PPILEUM**.

GRASS, *Clower*. See **TREFOIL**.

GRASS, *Cock's-tail*. See **DACTYLIS**.

GRASS, *Cotton*. See **ERIOPHORUM**.

GRASS, *Couch*. See **TRITICUM**.

GRASS, *Crested*. See **DOG's-tail-grass** and **CYNOSURUS**.

GRASS, *Dog's*. See **TRITICUM** and **AGROSTIS**.

GRASS, *Sea-dog's*, a name sometimes given to the double spiked fescue, or rye. See **SECALE**.

GRASS, *Dog's-tail*. See **DOG's-tail-grass** and **CYNOSURUS**.

GRASS, *Fescue*. See **FESTUCA**.

GRASS, *Fox-tail*. See **ALOPECURUS**.

GRASS, *Goose*. See **ASPERUGO**.

GRASS, *Hair*. See **AIRA**.

GRASS, *Hare's-tail*. See **LAGURUS**.

GRASS, *Knot*. See **POLYGONUM**.

GRASS, *Knot, German*. See **SCLERANTHUS**.

GRASS, *Knot, Mountain, and Verticillate*. See **ILLECEBRUM**.

GRASS, *Love, or Quaking*. See **BRIZA**.

GRASS, *Meadow*. See **POA**.

GRASS, *Hard meadow*. See **CYNOSURUS**.

GRASS, *Millet*. See **MILIUM**.

GRASS, *Oat*, a name given to a species of the fescue. See also **AVENA**.

GRASS, *Panic*. See **PANICUM**.

GRASS of *Parnassus*. See **PARNASSIA**.

GRASS, *Pepper*. See **PILULARIA**.

GRASS, *Pudding*. See **MENTHA**.

GRASS, *Quaking*. See **BRIZA**.

GRASS, *Rattle*. See **PEDICULARIS**.

GRASS, *Rush*. See **SCIRPUS**.

GRASS, *Rye, or Ray*. See **LOLIUM** and **HORDEUM**.

GRASS, *Scorpion*. See **SCORPIURUS**.

GRASS,

- GRASS, *Scorpion*, *Moufe-ear*. See MYROSOTIS.
 GRASS, *Scurvy*. See COCHLEARIA.
 GRASS, *Shave*. See EQUISETUM.
 GRASS, *Silk*. See APOCYNUM.
 GRASS, *Sword*. See GLADIOLUS.
 GRASS, *Trefoil*. See TREFOIL.
 GRASS, *Vernal*. See ANTHONANTHUM.
 GRASS, *Vetch*. See LATHYRUS.
 GRASS, *Viper's*. See SCORZONERA.
 GRASS, *Whitlow*. See DRABA.
 GRASS, *Whitlow*, *Rue-leaved*. See SAXIFRAGA.
 GRASS, *Warm*. See SPIGELIA.
 GRASS, *Wreck*. See ZOSTERA.

GRASS, in *Agriculture*, a general name applied to those herbaceous plants that are employed in the feeding and fattening of neat cattle, sheep, &c. It has been long since remarked in an able tract on the grasses of this country, "that much of our meadow and pasture-land may be rendered infinitely more valuable than it is at present, by the introduction of some of the best grasses which we possess; and that this is an opinion which has long prevailed among many of the more enlightened agriculturists of the present age, some of whom have endeavoured to excite the husbandman to collect and cultivate seeds of this sort, by writings fraught with the soundest reasoning; while others have attempted to attract him by the offers of well-directed premiums; but that hitherto neither the writings of the one, however convincing, nor the premiums of the other, however alluring, have, as the author thinks, been productive of the desired effect." And "Mr. Stillingfleet says, it is wonderful to see how long mankind has neglected to make a proper advantage of plants of such importance, and which in almost every country are the chief food of cattle. The farmer, for want of distinguishing and selecting grasses for feed, fills his pastures either with weeds, or bad or improper grasses; when by making a right choice, after some trials, he might be sure of the best grass, and in the greatest abundance that his land admits of. At present, if a farmer wants to lay down his land to grass, what does he do? He either takes his seeds indiscriminately from his own foul hay-rick, or sends to his next neighbour for a supply. By this means, besides a certain mixture of all sorts of rubbish, which must necessarily happen; if he chances to have a large proportion of good seeds, it is not unlikely but that what he intends for dry land may come from moit, where it grew naturally, and the contrary. This is such a slovenly method of proceeding, as one would think could not possibly prevail universally; yet this is the case as to all grasses, except the darnel-grass, and what is known in some few counties by the name of the Suffolk-grass (*poa annua*); and this latter instance is owing, it is believed, more to the soil than any care of the husbandman. Now, continues he, would the farmer be at the pains of separating once in his life half a pint or a pint of the different kinds of grass-seeds, and take care to sow them separately; in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds separately over the nation by supplying the seed-shops. The number of grasses fit for the farmer is, he believes, small; perhaps half a dozen, or half a score, are all he need to cultivate; and how small the trouble would be of such a task, and how great the benefit, must be obvious to every one at first sight. Would not any one be looked on as wild, who should sow wheat, barley, oats, rye, peas, beans, vetches, buck-wheat, turnips, and weeds of all sorts together? Yet how is it much less absurd to do what is equivalent in relation to grasses?"

VOL. XVI.

It is also asserted by Mr. Kent, that meadow and pasture-land is oftener neglected than ploughed ground, notwithstanding it generally admits of a much greater proportion of improvement. The best grasses cannot be collected at too great an expence; for he has seen a small spot of land, in the middle of a large piece, which was laid down twelve or fourteen years since, by the writer noticed above, upon an estate in Herefordshire, with some choice seeds, at the same time when the remainder of the field was laid down with common feeds; and that this spot is considerably better than the rest. From these experiments, and his own observation, he is clearly of opinion, that any person who has land calculated for grass may improve it, by this method of laying it down, to a much greater degree than he can in the common way. Dr. Anderson has likewise observed, in the second volume of his essays, that although it is probable, that none of the grasses that have been hitherto cultivated by the farmer are of the most proper kind for a turage; yet there is little reason to doubt but that many of the most valuable kinds for this purpose would admit of being cultivated with the same ease as some of those are with which we are well acquainted, if they were properly separated from others, and cultivated with equal care. But so long as we shall remain ignorant of the peculiar qualities of each kind of grass, so as not to be able to distinguish the good from the bad, it is not surprising, that we should remain firmly persuaded that nature alone can provide valuable pastures, and that agriculture is so essentially necessary for bringing them to their ultimate perfection. For, if we allow our fields to remain uncultivated, without having sowed them with any kind of grass-seeds, it must ever happen, that the seeds of such grasses as are brought by the wind, or otherwise, from the neighbouring fields, will there take root, and in time establish themselves. And as it may sometimes happen, that some of the most valuable pasture-grasses may there abound; the field, in these cases, will become filled with their seeds, and in due time may afford the most valuable pasture. But if bad kinds of grasses should abound in the neighbourhood more than the good, the field will as naturally become filled with the seeds of these useless plants. And as a number of these are hardy and abiding plants, if the field is once filled with them, the pasture will be, of consequence, always of little value, if it should be allowed to remain undisturbed for any length of time. Let the reader, therefore, consider how numerous the circumstances are that must accidentally concur together before it is possible to expect a very fine field of pasture-grass, if left to nature, and then he will perceive how improbable it is that all these should concur to produce their full effect in any one field whatever. There must be no roots of bad grasses, nor seeds of robust annuals, in the soil when it is left out from tillage; and the seeds of the most valuable kinds of grasses must be in the neighbourhood in such abundance as to fill the whole field sufficiently at once. Nor is this all. For as there is, no doubt, a considerable variety of valuable kinds of grass, some of which are naturally fitted to grow to perfection on one kind of soil, or upon that soil when in certain circumstances, while others would thrive best upon another soil, or upon that soil only in certain peculiar circumstances; it must so happen, that the very plants which are best adapted to the soil in the state it may be in at the time, should be found in abundance in the neighbourhood of the field. Neither must there be found near that, any sort of robust quick-growing plant, the seeds of which, by being blown upon that field, might suddenly rush up and suffocate, in their infancy these tender and valuable plants. Nor must there be found any bad kinds of grass, that, by being established along with the good in

any proportion, might tend to diminish the value of the pasture.

“ Now, let any one reflect on the infinite diversity these few particulars may admit of, and think how utterly impossible it is that all the favourable circumstances, without any of those that are unfavourable, should concur in any one case, and he will acknowledge, that those who found their hope of obtaining the most valuable pastures only upon the fortuitous concurrence of all these circumstances, or who imagine that every pasture which is old milt, on that account, of necessity be good, act in direct contradiction to the plainest dictates of reason and common-sense. For, although it should be allowed that the grasses hitherto cultivated are not of the most proper sort for forming good pastures, and that therefore, on some occasions, much better natural pastures may be met with than could be formed by means of any of these; yet it by no means follows from thence, that if the farmer were perfectly acquainted with the value and distinguishing qualities of each kind of natural grass, and knew the soil and culture that best agreed with it, the most proper manner of rearing it, and every other particular relating to the economy thereof, he might not perhaps have it in his power to form artificial pastures as much excelling the natural as these last at present usually exceeded the former. For were he possessed of the knowledge above supposed, he could at once fill the soil with the seeds of those valuable grasses which he knew were best adapted to it, and thus effectually exclude the admission of every useless plant, or pernicious kind of grass, that might be brought from the neighbouring fields by the wind, or other accidental causes.

“ Let us, therefore, instead of contenting ourselves on all occasions with such pastures or grass-lands as nature may afford, rather study to improve those that are indifferent, by endeavouring to obtain a knowledge of such plants as might afford the most valuable pasture, and cultivating these with assiduity and care. The inattention of the improving farmers in Great Britain to this subject has been truly amazing. But it is hoped the attempts that have been made by some late writers may have the effect of turning their attention to a subject of such great importance; with regard to which, they will then doubtless make many valuable improvements. It is, however, to be feared, that till some attempt shall be made to ascertain the particular qualities and peculiarities of the different kinds of grasses, the public will be often imposed upon by specious accounts of new grasses, which may be really possessed of few valuable qualities, and may very much tend to discourage the inquirer. It is consequently necessary, to strenuously endeavour to discover what are the particular purposes for which any one plant could be deemed valuable, and in what respects it might be looked upon as of no value at all: For, as there is no plant that can be alike useful on all occasions, if we lose sight of this most necessary distinction, it may often happen, that we may attempt to rear a particular plant for purposes which it was never fitted to answer; and our want of success in these trials may make it be entirely rejected, even in cases for which it was extremely proper and beneficial.

It is stated that ray-grass continues to be the only grass whose seeds can be purchased for the purpose of laying down meadow and pasture-land; and how inadequate that grass is for such a purpose is known to every intelligent farmer. Why indeed the *lolium perenne* (ray or rye-grass) should originally have been made use of in preference to all the other grasses, cannot, perhaps, be satisfactorily accounted for: most probably it owes its introduction to accident, or to its being a common grass whose seeds were easily collected, rather than to its being preferred from any investigation of

its merits compared with the others. However this may be, there appears to be no reason for excluding the others; for it would appear exceedingly improbable, that of upwards of a hundred grasses, taking the word grass in its strict sense, that are growing wild in this country, the Author of nature should have created only one as suitable to be cultivated for pasturage or fodder. Since this period, however, most of the natural grasses have been cultivated for the purpose of affording feed, which may be procured genuine from many feedsmen in most places. Taking it for granted then, that there are other grasses superior in many respects to the ray-grass, this question naturally arises—How comes it that they have not found their way into general use? To this it may be answered, improvements in any science, but more especially in agriculture, are slow in their advances; and perhaps no class of men adheres more pertinaciously to old prejudices than that of farmers, and the difficulty of distinguishing the grasses from each other has, too, no doubt, proved one grand obstacle: many of these plants are so much alike, that the most discerning botanist is often at a loss to know some of them apart: if so, how easily may the husbandman be deterred from the arduous task! There is another cause also which may have operated against their introduction: grasses, as well as other plants, have been frequently recommended from a partial and limited observation of them, by persons who neither knew them well as botanists or agriculturalists, or who have recommended them, merely to gain by the credulity of the public. But, perhaps, the chief reason has been, that persons who might be expected to make the improvements, have not had the means fairly put into their hands to make the experiment, there not having been any easy means of obtaining such sorts of grass-seeds as may be most suitable for the purpose. It appears, however, that in the herbage of good meadows, or grass-lands, there should be a combination of produce, late-ripeness, and early growth. The first is, in most cases, the agriculturalist's grand object—and no wonder, since it is the quantity chiefly which enables him to pay his rent, and support his cattle: to obtain this, the judicious husbandman spares no expence in labour or manure. But it does not follow that produce is to be attended to solely, or that, for its sake, we are to cultivate rough cock's-foot grass, meadow-sweet, and such coarse plants. Grasses which have been recommended for being remarkably grateful to cattle, as the sheep's-fescue grass, or for the sweetness of their foliage merely, if they are found to be deficient in the grand article of produce, will never answer the farmer's or grazier's purpose, since to be a good meadow it must be productive. Cattle, in regard to food, doubtless have their particular likings, though we cannot properly judge of it, in which it may be necessary sometimes to indulge them; but this practice must not be carried too far; for as the farmer cannot afford to feed his ploughmen on pigs and poultry, neither can he indulge his cattle in general with the finer or more delicate hay or herbage. By the bye, we do not know but that the most productive grasses may also be the most nutritious, or that cattle will not as eagerly eat the herbage or hay made of the meadow fox-tail grass, as of the fine bent (*agrostis capillaris*), and procumbent trefoil (*trifolium procumbens*). Moreover, cattle are known frequently to thrive on food to which they are habituated by necessity, though at first they could scarcely be prevailed on to touch it. Persons, in making experiments, are very apt, as has been already observed, to conclude too hastily from the appearance which a plant assumes on its being first planted or sown; the most insignificant vegetable will often make a great show, when its fibres have fresh earth to shoot into;

but the trial comes when the object of our experiment has been in a meadow or pasture several years, when its fibres from long growth are matted together, and it meets with powerful neighbours to dispute every inch of ground with it: if it then continues to be productive, it must have merit. We see that lucern, when left to itself, is soon overpowered; if we sow broad-leaved clover, which is most undoubtedly a perennial, the first year we shall have a great crop of clover; let this field be left to itself, and the clover, like the lucern, will yearly diminish, not because it is a biennial, as some have supposed, but because plants hardier or more congenial to the soil usurp its place: this shews, then, that at the same time that we introduce a good plant, that plant must also be a powerful one, able to keep possession, and continue to be productive.

With regard to the second quality, or that of the cattle's thriving on the food they eat; this is, undoubtedly, of great consequence, and it is to be regretted that our knowledge of the most nutrient herbage is so limited: of those plants which have been cultivated, we are able to speak with some certainty; it is well known that clover, lucern, saintfoin, tares, and several other plants, have a tendency to fatten cattle; but what grasses, or other plants, which have not been subjected to a separate cultivation, have this particular tendency, remains to be ascertained by experiment. But as leguminous plants, in general, are found to agree with cattle, we may reasonably conclude that a certain quantity of them must be proper in pastures. Certain pastures are found to be more bateable or feeding than others; but whether this arises from situation, or their particular produce, remains also to be discovered by further observation.

Respecting the third quality, or the early growth of plants, as the farmers and graziers unitedly complain of the want of early herbage in the spring; those plants, therefore, which are found to put forth early foliage, and to be grateful to cattle, are deserving of great attention. As far as grasses are concerned, the sweet-scented vernal, the meadow fox-tail, the smooth and rough-stalked meadow-grass, will effect all that can be expected from those of British growth: much, very much, however, will depend on seasons: if the winter be very severe, or north-easterly winds prevail in the spring, grassy herbage will be backward: to counteract the bad effects of such seasons, our pastures should be warmly situated, not drenched with moisture, sheltered by thick hedges, and divided into small enclosures: in short, a set of enclosures should be formed for this very purpose, where there is a prospect of its answering the designs of the cultivator. But where early pasturage is the desideratum, other plants, as well as grasses, may deserve a place amongst them, as rib-wort, or rib-grass (*plantago lanceolata*), dandelion (*leontodon taraxacum*), broad-leaved clover (*trifolium pratense*), with many others of the same kind. And as an early herbage, though it is valuable for pasturage, is no less so for hay; by the middle of May at furthest, a meadow of this sort would be fit for mowing, and the second hay-making might commence by the time that hay-making usually takes place in the country. The writer has sometimes thought, but perhaps the idea is too speculative, that we ought to have two sorts of meadows, one for hay, the other for pasture; that our hay-meadows should consist entirely of grasses, and chiefly for this reason, that the hay would on that account be much sooner made; an object of consequence at all times, but more so when the process commences in May. In June and July the more powerful heat of the sun is able to exsiccate the thick leaves and stalks of the more succulent plants; but, in the necessary prolongation of this business, the grasses must materially suffer. But

for the purpose of pasturage, the attention of the agricultor should be chiefly directed to such sorts of grasses as have the propensity of running to leaves, in preference to such as abound more in flower-stalks or stems.

The same writer states, that if we examine our meadows, pastures, and downs, we shall find them pretty much in a state of nature, and, excepting those pastures which of later years have been sown with ray-grass and clover, full of an indiscriminate mixture of plants, some of which afford good, others bad food, some good crops, others scarcely any crops at all: but that he may not be thought to speak at random on this subject, he will state a few facts to corroborate what he has asserted. His worthy and much-esteemed friend, Thomas White, esq. with a view to ascertain the produce of several downs and commons fed on by sheep, procured, from each of those under-mentioned in Hampshire and Suffolk, a turf, which, though not more than six inches in diameter, and chosen indiscriminately, produced, on being planted in his garden, as follows:

Different Turfs.

Turf from Selborn-Common.—*Plantago lanceolata*, *agrostis capillaris*, *avena flavescens*, *dactylis glomerata*, *festuca duriuscula*, *poa annua*, *cynosurus cristatus*, *trifolium repens*, *crepis tectorum*, *achillea millefolium*, *galium verum*, *hypochæris radicata*, *hieracium pilosella*, *thymus serpyllum*.

Turf from Oakhanger.—*Trifolium repens*, *holcus lanatus*, *poa annua*, *agrostis capillaris*, *agrostis palustris*.

Turf from Deortun.—*Ranunculus repens*, *lolium perenne*, *holcus lanatus*, *prunella vulgaris*, *festuca duriuscula*, *agrostis palustris*, *trifolium repens*, *crepis tectorum*, *achillea millefolium*.

Turf from Glynd-hill.—*Medicago lupulina*, *achillea millefolium*, *poa pratensis*.

Turf from the same.—*Avena flavescens*, *festuca duriuscula*, *festuca ovina*, *hieracium pilosella*, *agrostis capillaris*, *trifolium repens*, *thymus serpyllum*.

Turf from Short-Heath.—*Festuca bromoides*, *aira præcox*, *juncus campestris*, *poa annua*, *agrostis capillaris*.

Turf from Mount Cabron.—*Rumex acetosa*, *daucus carota*, *medicago lupulina*, *poterium sanguisorba*, *festuca duriuscula*, *avena flavescens*.

Turf from Ringmer-Down.—*Linum catharticum*, *scabiosa columbaria*, *ornithopus perpiuillus*, *avena flavescens*, *festuca duriuscula*, *trifolium repens*, *hypochæris radicata*, *crepis tectorum*, *lotus corniculatus*, *juncus campestris*, *hieracium pilosella*, *festuca ovina*, *thymus serpyllum*, *poa pratensis*.

It is, perhaps, no small recommendation to the *poa trivialis*, that it is a principal grass in that uncommonly productive meadow near Salisbury, mentioned by Stillingfleet, and more particularly described in the first volume of the Memoirs of the Bath Agricultural Society. And that the account given of the extraordinary fertility of this meadow excited his curiosity, and induced him to request a gentleman residing near the spot to favour him with six small turfs, cut up in different parts of the said meadow, and which being planted in his garden, at Lambeth-Marsh, produced as follows:

Different Turfs.

Turf 1.—*Poa trivialis*, *ranunculus acris*, *triticum repens*, *agrostis palustris*.

Turf 2.—*Poa trivialis*, *alopecurus pratensis*, *triticum repens*.

Turf 3.—*Poa trivialis*, *agrostis palustris*.

Turf 4.—*Poa trivialis*, *triticum repens*, *peucedanum silaus*.

Turf 5.—*Poa trivialis*, *alopecurus pratensis*, *agrostis palustris*, *avena elatior*, *triticum repens*.

This experiment proves, in a great degree at least, what he long before suspected, that the extraordinary fertility of this meadow arose not from any new grass peculiar to it, but from several unusual circumstances concurring and favouring in an uncommon degree the growth of certain well-known grasses, especially the *poa trivialis* and *agrostis palustris*; consequently, in the forming and improving of grass-lands, the most certain plan will be to cultivate the seeds of such grasses as may be most adapted to them, and afterwards sow them at proper seasons upon the lands, when they have been put into a suitable condition for their reception.

The directions given are, that if a piece of ground can be had that is neither very moist nor very dry, it will answer for all the seeds; they may then be sown on one spot: but if such a piece cannot be obtained, they must be sown on separate spots, according to their respective qualities, no matter whether in a garden, a nursery, or a field, provided it be well secured and clean. Dig up the ground, level, and rake it; then sow each kind of seeds thinly in a separate row, each row nine or twelve inches apart, and cover them over lightly with the earth; the latter end of August or beginning of September will be the most proper time for this business. If the weather be not uncommonly dry, the seeds will quickly vegetate; and the only attention they will require will be to be carefully weeded: in about a fortnight from their coming up, such of the plants as grow thickly together may be thinned, and those which are taken up transplanted, so as to make more rows of the same grass. If the winter should be very severe, though natives, as seedlings, they may receive injury; therefore it will not be amiss to protect them with mats, fern, or by some other contrivance. Advantage should also be taken of the first dry weather in the spring, to roll or tread them down, in order to fasten their roots in the earth, which the frost generally loosens; care must still be taken to keep them perfectly clear from weeds. As the spring advances, many of them will throw up their flowering stems, and some of them will continue to do so all the summer. As the seed in each spike or panicle ripens, it must be very carefully gathered, and sown in the autumn, at which time the roots of the original plants, which will now bear separating, should be divided and transplanted, so as to form more rows: the roots of the smooth-stalked meadow-grass in particular, creeping like couch-grass, may readily be increased in this way; and thus, by degrees, a large plantation of these grasses may be formed, and much seed collected for the use of the agricultor. But a more ready way, according to a late writer, is, for the farmer to notice that species of grass most affected by his soil, and carefully to gather the seed from a piece of old meadow, purposely left three or four weeks longer than common, or at least long enough to become sufficiently ripe. He should not scruple the trouble of selecting the heads as they lie in the swath; but they who desire not to be so particular, will thresh out the seed together, either in the field or before it shall have heated in the mow. And good seeds of different sorts of grasses may now also be procured from different seedsmen in large towns and other places; but the collection sold under the title of hay-seeds should never be trusted to in any respect. Mr. Curtis, from the numerous applications that were made to him by gentlemen for grass-seeds, was induced to select such as appeared to him the most useful, and thereby rendered the public an essential service. He wished at least to put it in their power to decide on a matter which had been long agitated, and from

which he was far from being the only one that entertained the sanguine hopes of its proving a great national advantage. The grasses he has recommended will, he is confident, do all that our natural grasses can do: they are six of those which constitute the bulk of our best pastures; most of them are early, all of them are productive, and they are adapted to such soils and situations as are proper for meadows and pastures. But, let no one expect them to perform wonders; for after all they are but grasses, and as such are liable to produce great or small crops, according to particular seasons, or to the fertility or barrenness of the soil on which they are sown and cultivated.

This list comprehends the *anthoxanthum odoratum*, or sweet-scented vernal-grass; the *alopecurus pratensis*, or meadow fox-tail grass; the *poa pratensis*, or smooth-stalked meadow grass; the *poa trivialis*, or rough-stalked meadow grass; the *festuca pratensis*, or meadow-fescue grass; and the *cynosurus cristatus*, or crested dog's-tail grass; of which representations may be seen at *figs. 1, 2, 3*, in *Plate Grasses, Agriculture*, and *figs. 1, 2, 3*, in *Plate Grasses*; but more full accounts of them may be found by referring to their different botanical titles, in different parts of the work.

But of the above grasses, the meadow fox-tail and rough-stalked meadow grass are fittest for moist land; the meadow-fescue, or sweet-scented vernal, are the most proper for land either moist or moderately dry; and the smooth-stalked meadow-grass and crested dog's-tail are those that are best suited for dry pastures and other similar lands.

It is, however, supposed, that in the more southern parts of the kingdom we may in vain expect to clothe dry soils with the constant verdure of grasses; they will not stand the drought of hot parching summers: in such seasons, they are only plants which send down roots to a great depth that can be expected to look green or be productive, as the *lotus corniculatus*, *medicago falcata*, and some others.

The order of flowering in the above grasses is: 1. Sweet-scented vernal. 2. Meadow fox-tail. 3. Smooth-stalked meadow. 4. Rough-stalked meadow. 5. Meadow-fescue. 6. Crested dog's-tail.

It is observed that many more grasses might be added to this list, and those too which perhaps might be highly deserving of it; but he has his doubts, whether by recommending more he might not increase the difficulty of introducing grass-seeds without any adequate advantage in return.

But besides these, the *festuca ovina*, or sheep's-fescue grass; the *festuca duriuncula*, or hard-fescue grass; the *poa compressa*, or flat-meadow grass; the *poa palustris*, or marsh-meadow grass; the *plebeum nodosum*, or knot-grass; and the *lolium perenne*, or rye-grass, which is an useful grass in many cases; may all be employed with advantage. They may be seen at *figs. 1, 2, 3*, in *Plate Grasses*, and at *figs. 1, 2, 3*, in *Plate Grasses*.

And in the second volume of his *Essays on Rural Affairs*, Dr. Anderson has likewise given descriptions of many others, which, he conceives, may be beneficially employed in forming grass-lands, such as the *alopecurus bulbosus*, or bulbous fox-tail grass; the *festuca rubra*, or purple fescue-grass; the *holcus mollis*, or creeping soft grass; the *plantago angustifolia* and *tennifolia*, or narrow-leaved and small grass-leaved plantain or rib-grass; and the *poa procumbens*, or creeping-meadow grass.

In a valuable "Essay on the Conversion of Grass-Land into Tillage," inserted in the Communications to the Board of Agriculture, vol. iii. part 1. the following detail of several plants of the grass kind is given, with the soils they

are most proper for, or on which they succeed to the greatest advantage.

“Ray-grass (*Lolium perenne*). This grass, which for many purposes is a very valuable one, is chiefly to be recommended for the two divisions of soil distinguished under the titles of loam and sand. It will flourish on any land, except stiff clay, and will grow even on that; but, upon rich sands and loams, it becomes not only a good spring-grass, but, if properly managed by due mixtures, turns out well as a permanent pasture-land; always, however, most valuable by being sheep-fed, for which it is singularly adapted. Mr. Peacey’s two varieties of it are said, by some persons who have tried them, to be superior to the common sort. Mr. Professor Martyn, he says, states the *Cynosurus ceruleus*, *Poa nemoralis*, *Bromus mollis*, *Alopecurus*, *Anthoxanthum*, and *Poa pratensis*, as all being earlier than the *Lolium perenne*, or ray.” See *LOLIUM Perenne*.

“Yorkshire white (*holcus lanatus*). This, he observes, flourishes well on any moist soil, and grows very generally, except on the most dry and barren ones, where, however, it is also found. It should be sown chiefly with a view to sheep, for it is not equally good for other stock: many acres of it have been cultivated on his farm for sheep, and it has answered greatly when kept close fed. Mr. Marshall, in his Midland Counties, mentions it as a good grass for cows and other cattle, but bad for horses. In his York Economy he, however, condemns it in toto; probably from not then having so closely remarked its qualities.” See *HOLCUS Lanatus*.

“Meadow-fescue (*festuca pratensis*). This is an excellent grass for good loams and clayey soils, and he has found it abound largely on dry loams. He has laid down some parts of fields with it for comparison with other grasses on wet sandy loams on a clay marle bottom, worth 14s. or 15s. an acre; but has found it giving way in four years to the plants more indigenous to the soil. He does not think there is any better grass for either hay or pasturage, and it yields feed in great abundance. He adds, that colonel St. Leger was, he believes, the first who entered largely into the culture of this grass: and Mr. Majendie, of Essex, revived it, and began with the *alopecurus*.” See *FESTUCA Pratensis*.

“Meadow fox-tail (*alopecurus pratensis*). He thinks that for moist loams and clays, there cannot be a better grass than this: it is very early, and it abides on his farm after nine or ten years on the soils upon which the meadow-fescue gives way to others. It has also been found, by Mr. Majendie, hardier against frosts than the *poa trivialis*: the greatest objection to it is the difficulty of getting the feed in any degree of plenty; there is an insect that feeds on it, and occasions much disappointment. Mr. Professor Martyn, in his excellent “*Flora Rustica*,” speaks, he observes, highly of this grass, and says the seeds may be collected without much difficulty; but he does not there advert to the insect which is so pernicious, as noticed by Mr. Majendie, and by the ingenious Mr. Swayne, in his “*Gramina Pascea*.” In a field on his farm, where it is very well established, and the herbage thick, it produces very few seed-stalks.” See *ALOPECURUS Pratensis*.

“Crested dog’s-tail grass (*Cynosurus cristatus*). It is remarked, that to judge from the appearance of the beats of this grass in poor upland but moist pastures, a man would think it a very unpromising plant; but the rich marshes of Bridgewater and Boston, the famous pasturages of Painton in Devonshire, and those close to Mr. Buller’s cattle near Lestcard in Cornwall, Mr. Thorne’s bullock-grounds on a limestone bottom near Tavilock, Mrs. Williams’s at Little Malvern in Worcestershire, (which are among the richest

pastures in the kingdom), all abound, he asserts, very greatly in this grass; in some of them it is the predominant herbage. Mr. Marshall, in his *York Economy*, places it as the most prevailing plant in the best grass-meadows of the vale of Pickering, some of which will feed a large cow from May-day to Michaelmas. Very fortunately it abounds much with seed, so that he has had many bushels gathered in a season by poor women and children, at one shilling a pound, and laid down many acres with it successfully. Attention should be paid to its being ripe; for he observed eight bushels to be sown on eight acres, and it failed from deficiency in ripeness.” See *CYNOSURUS Cristatus*.

“Roughed-stalked meadow-grass (*poa trivialis*). It is observed that Mr. Boys, of Bethanger, in Kent, has been the largest cultivator of this grass in the kingdom, and sold large quantities of the seed, but gave it up for want of a demand. It is, he asserts, an excellent grass on good, found, and moist loams. It is accounted in Lombardy ‘the queen of meadow plants (*la regina dell’ erbe*),’ whether for dry pastures or water meadows; multiplying itself much by seed, and little by the root: so that, if attention be not paid to permit some seed to fall, its quantity will sensibly diminish. Excellent for all sorts of cattle.”

“This hint concerning the seed is worth attention in England. Major Cartwright has found the *poa pratensis* to be an excellent grass on rich loams; and both succeeded well with sir William Clayton, of Harborough.” See *POA Trivialis*.

“Cock’s-foot (*dasylis glomerata*). This grass has been largely cultivated over the farm he now manages, and to his satisfaction on wet loams on a clay marle bottom, upon which the finer grasses are apt to give way in a few years to the indigenous produce. If suffered to rise high, it is very coarse; but, fed close, is a very valuable sheep-pasture. Women and children make good earnings in gathering it at 4s. a bushel. He has sown two bushels an acre, and tells, common red clover; and when the clover wears out, the grass fills the land, and abides well in it. It grows well in winter. It has been found highly useful as an early sheep feed.”

It is stated in the Norfolk Report on Agriculture, that “sir Mordaunt Martin, in 1788, observing, by an experiment, that this grass grew four inches in less than three days, determined to attend more particularly to it: he remarked, that when sheep were let out of a fold, they ran over every thing, to get at a bank that was full of it, and there ate it in preference to other grasses. In some parts of Norfolk it is called cows’ grass, from their being very fond of it. He began to cultivate it in 1794. It grows at Midsummer, in a drought, when every thing else is burnt up. He sows it with no seed, instead of ray-grass, and finds it much more profitable.” And “Mr. Overman, also, observing the eagerness with which the sheep ran into a field at Burnham-market that had some cock’s-foot grass in it, ran over ray-grass, and every thing else, to get a bite of this plant, thought it worth cultivating, and sowed about an acre, on the dry gravelly part of his farm, just above the marsh. This spot was the only one, in a large field, that did not burn in the severe drought of 1800, and convinced him of the excellence of the grass.” He also shewed the writer “a beautiful crop of drilled wheat, which could scarcely be estimated at less than four quarters and a half per acre, pointed out a part of the field, superior, if any thing, to the rest; and said it was an experiment on the cock’s-foot grass; he had found it an excellent plant for sheep, but having examined the roots, perceived them to be so strong, that he had some suspicion they might exhaust the

the land, and therefore sowed this piece for a trial: the result has satisfied him that all apprehension of the kind was ill-founded, and he intends substituting it for ray-grass." The author has also "cultivated this grass on a large scale for many years, and has found it of great use. It is a most valuable plant when kept close fed." See *DACTYLIS Glycerata*.

"Tall oat-grass (*avena elatior*). This is another coarse grass, profitable when kept close fed: the seed might be had in any quantity from France, or gathered by hand in England. In the Rev. Mr. Swayne's experiment, it yielded a greater weight than any other grass." See *AVENA Elatior*.

"Timothy grass (*phleum pratense*). This grass is represented by all travellers in America, he observes, as the great support of cattle, &c. wherever meadows are found; and it is asserted to have considerable merit. He has several times made the trial of keeping it close fed by sheep on a moist loam, upon a clay marl bottom. The success was very encouraging; enough, he thinks, to prove that it is an object, in this line of husbandry, which merits considerable attention; and the more, as the seeds are to be had, very clean dressed, in any quantity from America, at about a guinea a bushel; which is sufficient, with other plants, for four or five acres of land. He believes it is well adapted to clay, moist loams, and especially peat." See *PHLEUM Pratense*.

"Yarrow (*achillea millefolium*). This, he asserts, is one of the most common and most valuable plants that is to be met with in England. On his farm the cultivation of it has been carried on with success as a sheep-pasture for some years. It is found on moist loams almost equally with dry burning sands, gravels, and chalks. It has a singular quality of resisting drought on the most arid soils; so that, if you see at a distance a green spot on a burnt-up, close-fed pasture, twenty to one but it is clothed with this plant. It is found in the richest meadows and bullock-pastures. Five shillings per bushel are given for gathering the seed in October: it is a plant deserving great attention. Sheep are very fond of it. It is said to form a fourth-part of the herbage of some of the fine meadows of Lombardy."

"Burnet (*poterium sanguisorba*). It is remarked that there are large tracts of the finest parts of the South Downs upon which this plant forms half the indigenous pasture. It abounds much also on all other chalk downs; but it will flourish on any soil, on sand, clay, peat, &c. Some writers speak of it for cows: it has been cultivated on his farm these five and twenty years for sheep, for which animal it is very useful. The seed is to be bought almost every where." See *BURNET*.

And it is observed in the Agricultural Survey of Norfolk, that this plant was "introduced at Stoke 35 years ago, as the writer then registered, with great success; but it never made any progress, though it yielded luxuriant food for many horses in February." However, "the reputation of this plant attracted the notice of Mr. Coke, who formed an experiment at Holkham, to examine carefully its merits, and, with the spirit that characterizes his husbandry, sowed 40 acres, mixing a small quantity of white clover and rib-grass with it. The result was as decisive as can be imagined; the field has been fully and incessantly stocked with sheep, and was constantly pared as close to the ground, as a favourite spot in a pasture is by horses." And in other respects it is also valuable, as "Mr. Bevan has found it to be the most wholesome food for sheep in a wet spring, and a certain remedy for the flux." And he: "is never without twenty acres of it."

"White clover (*trifolium repens*). It is asserted that this plant has hitherto been the main dependence of those who have laid down land to grass; and though, for sheep, it has not the sweetness of some other plants, or of red clover, yet upon the whole, it is one of the best that can be relied on for all rich or dry loams, sands, &c. and also for rich and drained clays and peats; but on poor wet loams and clays it will not abide, but gives way to the water-grass (*agrostis flouluifera*) and noxious plants, or other indigenous grasses. There is no better test of good land, than its running spontaneously to this plant; from the fine loams on rock, upon the Tamar, to the deep friable ones of Leicestershire, red-clover, left unploughed, gives way to a thick covering of this plant. Whatever seeds be sown, this clover should form a part of the dependence for success. Mr. Bakewell, Mr. Wright of Norfolk, and several other practical farmers, made this observation, that stock has been known to do badly, though there was much food on the ground; perhaps that is precisely the reason; and that this plant, like so many others, demands very close feeding to discover its merit." See *CLOVER*.

"Trefoil (*medicago lupulina*). It is observed that, though only a biennial, it is sure to shed so much seed that it rarely wears out of land. It is a good plant, not at all nice in soil, and the seed cheap." See *TREFOIL*.

"Cow-grass (*trifolium medium*). An excellent plant for clays and strong loams. It is said, in the Lincoln Report, that Mr. Ancel got good crops on a rabbit sand; the lint is worth pursuing, but he has not seen it cultivated on such soils. It is much more abiding than common clover. The seed is always to be had: it is known also under the name of marle grass. Mr. Bakewell's method of laying down was, by common red clover and ray grass, being sure of plenty of white clover and good grasses coming; but he prepared by two crops of turnips in succession, and sowed with the barley following. On such land as his, the practice is not to be condemned, but on other soils it would fail entirely."

"Rib-grass (*plantago lanceolata*). It is asserted that upon rich sands and loams this plant gives a considerable herbage, and on poorer and drier soils it does well for sheep; but that it is inferior to some others. Mr. Marshall observes, that it has stood the test of years' established practice in Yorkshire, and is in good estimation; though not well affected by horses, and bad for hay, from retaining its sap. The eminent Haller informs us, that the astonishing richness of the famous dairies of the Alps, described by Scheuchzer, is attributed entirely to the plenty of this plant, and the *alchemilla vulgaris*. The seed is always plentiful." See *PLANTAGO*.

"Lucern (*medicago sativa*). This is more confined than any of the other plants. A landlord should, he thinks, only stipulate for it on very rich, deep, friable, dry, sound, mellow loams, and fertile sands, worth 30s. an acre. Upon such lands, he cannot do better than to encourage it among the tenantry, to be sown broad-cast, 20lbs. an acre, and to remain while productive, which will be from twelve to fifteen years. On such soils it will, he says, support more cattle than any other plant." See *LUCERN*.

But more full accounts of these grasses will be found under the different heads which are referred to.

With respect to *hay-seeds*, it is stated that the only case in which these are admissible is, when a person has a very clean and valuable meadow or pasture which he saves with a view for seed; drawing out the bad plants whilst the crop is on the swath, and threshing the produce on a cloth, after standing till the seeds be ripe. Thus managed, excellent seed may

may be procured with ease, and be beneficially employed in the forming of grafs-lands.

In regard to the arrangement of these different graffes, as they relate to, or are proper for different sorts of foil, it is fully shewn in speaking of the methods of bringing land into the state of grafs or sward. See *Laying LAND down to Grafs*.

But besides the plants that have been noticed above, it "is remarked that there are many others, some of which have been tried under his direction, which deserve much attention; but he has not named them in the above-mentioned list, because the seed cannot be procured but with difficulty: some perennial vetches, clovers, melilots, lotuses, &c. &c. And several others are highly spoken of by some writers; yet as his own trials have not been equally successful, he is not authorized to recommend them. He never tried the *vicia sepium* sufficiently, to give an opinion of it; but, by Mr. Swayne's account, it deserves much attention."

However, in considering the modes of laying lands to the state of sward, lists containing the proportions or quantities of different sorts of grafs-seeds suitable for different sorts of land, are offered to the attention of the cultivator. See *Laying LAND down to Grafs*.

It is remarked in a general way by the same writer "that if the land laid to grafs be intended for sheep, it is not an object of very great consequence to sow only the finer graffes; as close feeding after the first year will make any grafs named in the lists fine, sweet, and productive; but this effect depends altogether on its being constantly fed close, that is, all feed-stems being prevented from rising. Every good farmer is sensible of the necessity of this with ray-grafs, but most unaccountably does not extend a similar concern to other graffes. Above 200 acres under the author's management have been laid down to grafs, chiefly for sheep; and he has stocked the fields so early in spring, and so thickly, as just to keep down the feed-stems: the cock's-foot, oat grafs, and Yorkshire white, with this management, have proved sweet feeding graffes, not at all rejected, even in fields where the flock had a choice. Several writers seem to have been very sensible of the consequence of close feeding. Mr. Davis, in the Wilshire Report, says, "the sweetness of the feeds on the downs of Wilts depends much more on its being kept close, and eaten as fast as it shoots, than on any particular good quality of the grafs itself; for there are many downs that, when close fed, appear to be a very sweet pasture, but which, if suffered to run a year or two without a full stock on them, will become so coarse, that sheep will almost as soon starve as eat the grafs."

And in the Survey of the County of Stirling in Scotland, it is stated, that, upon Benlomond, &c. the pasturing of sheep has evidently, in the course of twenty years past, improved the quality of the herbage so as to raise grafs of a good species, and in very considerable abundance, where nothing formerly prevailed but bad kinds of grafs, and these in no great plenty: and the practice bids fair to banish heath from all the places that are pastured by sheep."

Further, Little, who was the best writer on husbandry we had for many ages, also remarks, "that there are poor soils which require a much longer time to grow a second inch than the first, and that consequently on such it is much more profitable to keep sheep than cattle." The writer, on first reading this passage, made the experiment on land of 12s. and 15s. an acre, clipping the plants with scissars, and carefully measuring and weighing the produce, and comparing it with neighbouring plants left to perfect the feed-stem; the superiority was proportioned to the times of cutting. Sheep-feeding not only, he says, ameliorates, by enriching the foil

and sowing the herbage, but also by destroying weeds. Ragwort, with which the bullock-grounds of Limerick, in Ireland, are overrun for want of sheep is, it is observed, much affected by them: and Mr. Marshall, in his York Economy, gives an instance of a meadow, foul in the extreme with knobweed, cured by pasturing it repeatedly in the spring with sheep. But here, a counter remark must be made, which is, that after a field has been pastured long with sheep, and close fed, it becomes unable to yield a growth of hay: the plants, by being constantly cropped down, acquire a dwarfish habit, however quick the growth in that early stage. There is a small field on the estate which he manages, which has been under grafs, time immemorial, and kept fed for the last forty years at least, except one year in which it was mown, expecting a vast crop: the season was very favourable, but he was utterly disappointed, for the produce was small. He has known the same thing happen on inclosing an old common. In Scotland a similar remark has been made by Mr. Wight. "Two inclosures of the same foil were laid down together with grafs-seeds of the same kind: after two years' hay, the one was surrendered to pasture; from the other a crop of hay was taken every other year. After seven years' absence, the proprietor returned home, and wanting more hay, mowed both, and that which had been pastured gave the worst crop." Something like the same thing has been observed in Switzerland, as stated in the Transactions of the Berne Society. It has occurred also in other instances.

With regard to the forming of grafs or sward, the procuring of good seed has been found, from long experience in every part of the kingdom, to be of all other works the worst executed by tenants: they sow the cheapest seeds which can be procured, that is, common clover or ray, or the rubbish of their hay-lofts: the clover gives a crop the first year; but, as it wears out, all sorts of trumpery succeed, if the foil be not good enough to run spontaneously to white clover. Great care should therefore be taken by the owners of lands, which are to be brought into a state of grafs, to have proper sorts of grafs-seeds provided. About 25s. will purchase the seeds in most instances: the expence may be reckoned from 20s. to 30s. per acre; but depending on various circumstances, as the state of markets, and the price of labour. Of the seeds recommended, the following are to be bought in any quantity: cow-grafs, Yorkshire white, Timothy from America, white clover, trefoil, ray, burnet, rib. And dog's-tail and cock's-foot are easily gathered by hand. Most of the grafs-seeds that have been recommended as useful in forming good grafs-lands may indeed, now, we believe, be had of the different seedsmen in London, and other places, as already noticed.

And the best methods of preparing the land, sowing the seeds, and managing the new grafs-lands, are considered in treating of the practice of restoring arable lands to grafs. See *Laying LAND down to Grafs*.

GRASS, Artificial, a term signifying that kind of grafs that is produced by the sowing of the seeds of different sorts of plants that have a quick and luxuriant growth on arable land; as those of the *red or broad clover, joint-fair, lucern, trefoil, tare, rye, grafs*, and other similar kinds. They are shewn at *figs. 1, 2, 3, in Plate Graffes* and at *figs. 1, 2, 3, in Plate Graffes, in Agriculture*.

There are likewise several other plants of this nature, that may in all probability be employed with great advantage in the same intention. And it has been stated by a late practical writer, that "though the chief hinge on which modern husbandry has been made to turn is that of the introduction of these sorts of graffes, it is extraordinary that they have yet, in but few districts, been made to constitute a part of the

the course of cropping on arable land. In all well cultivated districts, they, however, form a considerable proportion of the crops. The first of the above is a most invaluable plant, whether it be mown and used green, pastured, or made into hay. By its long tap-roots it resists the effect of excessive drought on the driest soils, and increases the quantity of vegetable mould in all. It will grow on moist soils, but is not equally productive; and whether it be mown and used in the green state, pastured, or made into hay, it generally produces four or five times the quantity of fodder that the same land would have done with common grasses. Further, in good rotations, it frequently makes the second crop, in lieu of white corn mown once, and the after-grass eaten off with horses, beats, or sheep, and the land sown with wheat. In that case, two pecks of the best ray-grass, mixed with fourteen pounds of the clover-feed, should be sown upon an acre, which not only increases the quantity, but also greatly improves the quality of the hay. If the clover is for stall-feeding, the ray-grass should be omitted. But in poor light soils, the better way is to take two or three crops of corn, and then to lay the land down to rest, three, four, five, or six years. In this case, it is advised that the farmer should sow the following seeds, in these proportions per acre:

Names of Seeds.	Quantities.
Of Burnet	4 pounds
— Cow red-clover	4 ditto
— White clover	8 ditto
— Trefoil	4 ditto
— Ray-grass	2 pecks
— Vernal grass	$\frac{3}{4}$ ditto
— Sheep's-fescue grass	$\frac{1}{2}$ ditto
— Crested dog's-tail grass	$\frac{1}{2}$ ditto.

"It is supposed, that by this management, the soil would acquire a vast increase of vegetable mould, and, by the pasture maintaining one-fourth more stock than it did before, it would be greatly charged with manure; by which means the land would be kept in perpetual good condition: and, when brought under tillage, produce one-fourth more corn than it did under other circumstances." And it is remarked, in the Norfolk Survey, that "Mr. Purdis, of Eggmore, was recommended by a friend, whose management he had seen and approved, to sow his seeds at twice: half of each sort (white and red clover, and ray) at the time of sowing barley; and the other half before the rollers in going over the young crop: and this practice he intends to pursue in future. He thinks it will give them a better chance of succeeding. He has 600 acres of seeds: he sows the great quantity of 14lb. an acre of white clover, 8lb. of red, and one bushel of ray-grass. The last he esteems much in spring; and, when an observation was made against it, said, that in April and May he had three thousand sheep that found the excellence of it." This should be attended to by the farmer. It is also further stated, that, "in 1784, in registering the husbandry of that spirited cultivator of Holkham, it was remarked, that 'those who have been conversant in the husbandry of old improved countries, know that a common complaint is the failure of red-clover. It has been sown so repeatedly, that the land is said to be surfeited with it. In the same district it comes to nothing on the old improved lands, yet yields immense crops on any accidental spot, where never, or rarely, sown before.' The observation is so common, that no doubt can remain of the fact; however, it may be attributed to certain methods in management pursued in this county. Peas and tare had been tried as substitutes, but they are tillage-crops, and what these thin soils, harassed with the plough, want, is rest. Mr. Coke, it is added,

turned his views to a different and better quarter, to other artificial grasses, which would answer the same purpose as clover and ray-grass. He had recommended to him, on a former occasion, trefoil, white clover, cow-grass, rib-grass, and burnet. Mr. Coke applied them with no inconsiderable sagacity to the present purpose, and, that the experiment might not be delusive, tried them spiritedly upon 30 acres in the middle of a large piece, laid with clover and ray-grass. The quantities of seed he has found will vary according to circumstances; but, in general,

Names of Seeds.	Quantities.
Of Cow-grass	8 to 10lb.
— White clover	5 to 8lb.
— Rib	5 to 8lb.
— Burnet	5 to 12lb.
— Trefoil	5 to 8lb.

according to the price, and also the intended duration of the lay. The success of the first trial induced him to lay down a yet larger space the second year. And the third (with the barley of the last spring), no fewer than 221 acres; this is, in truth, says the writer, doing justice to a new husbandry. Mr. Coke has found that those seeds fill the land completely with plants, which are abiding two and even three years: and how much longer they may last, is more than he can pronounce, as their appearance is yet as good as ever. The author rode over all the pieces, and never saw a finer or more regular plant than they exhibited. And he has, on several occasions, remarked, that sheep give a preference to these grasses, whenever sown in the same field with clover and ray-grass." And it is added, that "in regard to the continuance of these trials, some of the pastures now remain, and are as fine as the soil will yield: thick, clean, and sweet." And it is here remarked in regard to land being tired of this plant, that the observation he made, "during nine years that he was in the constant habit of viewing the farm of Mr. Arbutnot, in Surrey, merits some attention. When he began to farm, the land was sick of clover, inasmuch, that it was almost sure to fail, from having been, perhaps for a century, sown every four or five years. His friend adopted the course of—1. Beans; 2. Wheat; 3. Clover, in which it occurred once in three years, and the farmers predicted an absolute failure: he viewed three courses, and better crops, of pure red clover, were never gained. He began with ploughing treble the depth of that to which the land had been usually stirred, and he manured very amply for every crop of beans, partly with night-soil, from London. In what degree the success arose from depth of tillage, and what degree from a variation in manuring, cannot be ascertained; but the experiment proved that these agents were equal to the cure of the malady." It is also further noticed, that "some farmers in Norfolk have moved out of the common sphere, and ventured to plough deeper than their predecessors; nor have they found any inconvenience in so doing. It merits consideration, whether this practice will not prove in some measure a remedy to the failure of clover. As to manuring, and especially in great variations, the means are generally limited, and a change in this respect, however desirable, is rarely in their power." But, "the only effective remedy hitherto practised, is that of omitting clover altogether, for one or two rounds, which points out the great importance of introducing as many new artificial grasses as possible." See *Red Clover*.

The red-cow clover is another plant of the clover kind, which has been found very useful as an artificial grass. According to Mr. Amos it is perennial, and grows naturally in high chalky fields, and in gravelly fields with clay beneath. In the most improved part of the country, when the land is

to rest for some years, this seed is sown along with the white clover, as it continues in the ground much longer than the meadow-trefoil, and is nearly as productive, especially on chalky and poor sorts of land. And that where a crop of any of those clovers is taken in lieu of a crop of corn, the grain should be sown first, but less in quantity than if no seeds were sown with it; and, after the land has been made fine by harrowing and rolling them, fourteen pounds of clover-feed, and two pecks of best ray-grass, should be sown upon an acre bush-harrowed the length-way, and rolled the cross way of the ridges: afterwards the whole must be well gripped or drained. Nothing more is necessary to be done, on account of the seeds, till the next spring, when the land should be well dressed with the sward-dresser or harrows, drawn with long bushy thorns, the latter end of March, or the beginning of April; then cleaned and rolled the cross way again. In all these operations, the land should be neither too wet nor too dry, but in a due medium with respect to both these extremes, as, under other circumstances, they do not succeed so well.

The time for cutting those two grasses is, when they are in full flower, and rather shewing evidences of declining or passing their maturity. See CLOVER.

And the white clover is, in Mr. Amos's opinion, the sweetest grass for all sorts of stock yet known, and makes the closest sward, and is very productive of foliage. Hence it is, he conceives it most peculiarly adapted to laying down land to pasture. It flourishes most upon rich, dry, warm soils; yet it will accommodate itself to most kinds. It is seldom sown alone, unless it be to raise the feed; nor should it ever be mown for hay. In laying down rich soils, which are intended to remain in pasture for many years, this seed should predominate in the composition that is made use of. But in the Agricultural Report of Norfolk it is stated, that "Mr. Wright, of Stanhow, does not like white clover; he thinks it a bitter food, and that sheep do not eat it kindly; so that while much food seems to be on the ground, stock do badly. This is an uncommon opinion, but the writer remembers Mr. Bakewell starting the same idea." See *White Clover*.

The procumbent or hop-trefoil, is another plant of this sort, which is not very productive, and thrives best upon dryish gravelly fields, and pastures which have the same nature. They are both perennial. See TREFOIL.

Saintfoin is a plant of the artificial grass kind, which produces, Mr. Amos says, the best crops upon light rich land; but it will thrive upon the thinnest lime-stone, gravelly, and chalky soils, with great luxuriance, even where these are so poor as to afford a very scanty crop of any of the other sorts of grasses. It thrives best when sown alone, though it is frequently sown with barley and oats, by cultivators that have not much experience of it. And it is advised, that upon whatever soil it is sown, the land should be brought into a very fine and clean tilth by culture. And, that about the latter end of March, or beginning of April, it should be ploughed, and if it is roughish, be harrowed once in a place; then upon every acre, sixteen pecks of saintfoin seed should be sown; then harrowing the land well, and sowing eight pounds of common red-clover or trefoil, upon every acre afterwards, the land should be bush-harrowed and rolled. And, where weeds appear, they must be destroyed as they come up, by hand, or other means. It is recommended, that no stock be suffered to graze upon the seeds the first year; and, that if it be top-dressed with one quarter of rape or bone-dust to an acre, about old Michaelmas, the plants are greatly invigorated and benefited by the application.

VOL. XVI.

It is further stated, that, upon such lands as the above, it furnishes a crop of hay in summer of greater consideration than any other of the artificial grasses. The hay is excellent for all kinds of stock, and the after-math very good for cattle in autumn, and for sheep in winter, till Candlemas. Hence, saintfoin is a most invaluable grass on lime-stone, gravelly, and chalky soils; but it requires three years in coming to perfection; hence the propriety of sowing common red-clover or trefoil along with it. And it should be mown before it is in full blossom, otherwise there may be loss in that way. See SAINTFOIN.

Lucern is asserted, by the above writer, to be the most productive, and that which comes into use sooner than any other of the artificial grasses. Horses, beasts, sheep and pigs, are very fond of it, when it is mown and given them green, which is the most useful application of it. It is found to thrive best on rich, dry, loamy soils, which should be made deep, fine, and clean of weeds by culture. And, he advises, that about the middle of April, ten pounds of seed should be drilled on an acre, in rows of eighteen inches asunder, and one inch deep, with a row of common red-clover between each; then bush-harrowed and rolled. Nothing more is necessary to be done till weeds appear, when it should be hand-hoed well, and the weeds in the rows pulled out by the hand. As soon as more weeds appear, it must be hand-hoed and hand-weeded a second time, and even a third time, if necessary; when this is done, great care should be taken not to tread upon the young lucern. And as soon as it begins to blossom it should be mown, carried off, and given to the stock green. By this mode of application, it will, he says, keep more stock than any of the other grasses.

But this plant also requires three years in coming to perfection; hence the propriety of sowing common red-clover along with it. After that time, it may be mown three, four, or five times in a season. But, between every mowing, it should be well hand-weeded, and made quite clean of weeds. And every third year it should have a covering of rotten dung, after the rate of eight or ten tons to the acre, applied over it about Martinmas. See LUCERN.

Burnet is a grass of the artificial kind, of which there are several varieties; but the only one worth cultivation in this country is the common sort. This plant, though little cultivated, is highly valuable, either green or in hay for horses and cattle, and is an excellent winter food for sheep. It delights most in a dry, clean, light and deep soil; but it will grow very well on poor, gravelly, and chalky soils, which must be made clean and fine by culture. And it is advised by Mr. Amos, that, "about the middle or latter end of July the land should be ploughed for the last time, and harrowed well: after these operations, four pecks of seed should be sown broad-cast upon every acre, and then bush-harrowed and rolled. And it is suggested, that as the proper season for sowing it is the latter end of July, it becomes an excellent succedaneum to turnips, when they have been destroyed by the fly, which is often the case." And it is stated, that "the most profitable way of cultivating burnet is by sowing it with other seeds, when the land is to be laid down in these proportions:

Names of Seeds.	Quantities.
Burnet-feed	1 peck
White clover	10 pounds
Trefoil	4 ditto
Vernal-grass	$\frac{1}{2}$ peck
Ray-grass	1 ditto
Crested dog's-tail	$\frac{1}{2}$ ditto
Sheep's-fescue	$\frac{1}{2}$ ditto

4 M

The

The land should be bush-harrowed and rolled, and afterwards kept clean of luxuriant weeds. It is, however, remarked, that "much as this has been extolled, yet it is seldom sown either alone, or with other grass-seeds, since the introduction of red and white clover; though its greatest excellence is for winter-pasture in the feeds of sheep, &c." See BURNET.

Chicory is likewise a plant of this description, which may be found highly beneficial on many poor sandy or gravelly soils, where other sorts of grasses cannot establish themselves. It is asserted, in the Norfolk Report, that "Mr. Bevan sowed an acre of poor land, worth not more than 2s. 6d. rent, with chicory in 1793, and that the next year it produced 7l 10s. in feed." And the writer says, that he has taken several opportunities of recommending this grass in that district. On large tracts of poor land, he is confident it would increase the produce tenfold; and it well merits trial, he thinks, on every soil in it. The objection which has been founded on its not being easily extirpated, is, he contends, of no importance, for tares should be sown after it on some soils, and turnips on others, in which system, its distinction is unquestioned. This hint should not slip the notice of cultivators in other districts.

Summer Tare.—This is a plant of the kind, which is much employed as summer herbage, either pastured or mown green, as soiling for horses, &c.; for hay, as a substitute for red clover (on land that has been tired of growing it); for manure to be buried in by the plough: and for seed: hence the season for sowing the seed of this tare will depend upon the use it is intended for. When for summer herbage, &c. it matters not how early the seed is sown, provided no hard frost ensue. The first sowing may be as early in February as the season and condition of the soil will allow, and to continue the sowing at due intervals through the months of March and April, which will give a good opportunity for successions of them, to the great convenience of summer-feeding, but when for depasturing, it will be prudent to wait till the tares have gained a sufficient increase of haulm, before the stock are turned in upon them. And when for soiling horses, &c. they should be mown before they flower; and in no instance should the haulm be suffered to become rotten near the surface of the ground, which frequently happens on rich soils and moist seasons. If for hay, as a substitute for red-clover, the seed should be sown as early in March as circumstances will allow; but the time of mowing is more optional. Some mow them when the blossoms are fuller; others, just before they are quite ripe. But, in either case, the same caution is necessary, as in making faint-foin and clover into hay; and that is, to avoid breaking off the leaves, in which a great part of their virtue resides. When they are intended for manure, the seed should be sown as early in February as the season and condition of the soil will permit, and at the rate of four bushels to the acre. For this use they should be ploughed in before they get too long in their growth. But whatever is the intended use in cultivating this tare, the preparation of the land is the same; and this plant delights most in light sandy soils: and, in every case the land should be ploughed and harrowed once in a place, before the seed is sown; then sow the seed broadcast at the rate of three bushels an acre for the first and second uses, harrow the land well afterwards, and then lay it dry.

"The great objects in cultivating this tare are, 1st, spring-food and summer-herbage for cattle and sheep, especially ewes and lambs. 2d, Hay, as a substitute for red-clover. 3d, Manure, to be buried in by the plough. And 4th, Seed. But whatever is the intended use of this tare, Au-

gust and September is the prime season for sowing the seed of it. As soon, therefore, as the ground can be cleared of its crop, the land should be ploughed and harrowed once in a place before the seed is sown upon it." And it answers extremely well simply as a spring-food, when sown with rye, in the proportion of six pecks of each to the acre. See TARE.

Where they can be cultivated, crops of this sort should never be neglected. See ARTIFICIAL Grasses.

Grass-Ground, in Gardening, the parts of ornamented grounds which are kept in the state of lawn short grass or sward. Those spaces which are extended in the fronts of the houses or habitations, and are termed lawns, are mostly kept in short grass, which, by their constant verdure, summer and winter, and open rural appearance, exhibit a fine imitation of nature at all seasons, especially when the side boundaries terminate in rural plantations in various natural curves and bendings. This mode of laying out pleasure grounds prevails much at present. But besides these it is the practice to have rural short grass openings continued between the plantations throughout the different districts of ground of this sort, separating and bounding the shrubbery clumps, borders, and other parts, in some places widely spreading, in others more contracted; but, in either case, extending to the boundaries of the several plantation compartments, in various bendings, sweeps, and curves; by which the whole is rendered rurally ornamental, and at the same time more agreeable and easy to walk on than gravel between the plantations, when the weather is dry and hot during the summer season. In the ancient style of gardening, it was much the custom to have straight short grass-walks, both for ornament and common walking upon: but for ornament, unless elegantly wide and spacious, they have a littleness in their general appearance, as may be seen where long narrow slips of short grass-ground are extended to some distance, in the way of walks; and for the latter purpose they are very improper in winter and all moist weather; and even in summer in the mornings and evenings, as being always damp and dewy. Walks of this kind should therefore be but sparingly introduced; and where any are made for variety, ornament, or summer's walking, they should be as spacious as the situation admits, not less than from ten to fifteen feet wide, and even twenty feet wide or more, when the walk is considerably extended in length.

The method of forming short grass-ground work is either by sowing the parts with grass seeds, or by laying them with turf cut from a fine field, common, or down; the latter of which, where it can be obtained at a moderate expence, is greatly preferable, as it not only at once forms a complete sward, but is generally more close, even, and smooth, as well as less apt to run up to benty grass, grow rank, or rise in tufts, than by the sowing method. The sowing method is, however, much less expensive.

Preparations.—In preparing the ground either for sowing grass seeds upon or laying with turf, the whole must be broken up equally to a moderate spade's depth, clearing out all the roots of perennial weeds and other coarse materials. When this has been done, stakes or wooden pegs with notches, for making the level, according to the position of the ground, must be driven in; then proceed with line and spade to rough-level the ground according to the marks or levels on the pegs, afterwards treading, rolling, or ramming the whole down equally, that it may nowhere sink in hollows afterwards. When this has been finished, the levels should be wrought up more accurately, and the whole finished with a neat raking, clearing off all large stones, and making an

even and smooth surface; in this state it may either be sown with grafs seed, or laid down with turf.

For the first method the proper seasons for sowing are either February, March, and April, or in August or September in moist weather. In moist wet soils the former is probably the best, but in those of a dry gravelly nature, the latter. In this business it is of the utmost consequence to procure good seeds; those from hay-stacks or out of hay-lofts are often used, which may answer well, where the hay was the growth of some fine pasture free from weeds, and naturally afforded fine turf when grazed and mowed; but in other cases there is often a mixture of various sorts with weeds, by which the sward is rendered irregular and foul, and never makes handsome short grafs-grounds. If you are not furnished with seeds of your own, they must be obtained from the seedsman, and should be of those kinds which strike deep root, spread out laterally in their tops, are permanent, and capable of resisting the effects of heat; there are many of this kind. (See *Laying LAND down to Grafs.*) The seed must be sown broad-cast, very thick and regular over the surface, and directly raked or harrowed in; and when the surface is dry it should be rolled with a wooden roller, to bury the seeds more effectually, and make a smooth surface: when the grafs comes up, all weeds should be removed; and the same season, when the sward is become thick and green, and advanced some inches in growth, it should be mowed, rolling it well afterwards, and continue mowing it and rolling two or three times the first summer, especially if it were sown in spring, as, the oftener it is mowed and felled, the thicker and finer it will grow; and if it be intended to keep the grafs tolerably fine, mowing will be requisite once a week or fortnight, according to the growth from April to October, and rolling once a week or fortnight in moderately dry weather, and occasionally in the winter season. In this way a good turf may be formed in a few years.

In the second method, which should always be employed where it can with convenience, the best turf is that of a fine pastured common or down, where the sward is fine and short, with considerable closeness.

The best season for laying the turf is from September till March or April, though it will grow at almost any time of the year, even, if there be occasion, in the summer months.

The turf for this use is mostly cut or flayed with an iron instrument called a turving iron; all the turfs being cut of an equal width, length, and thickness; the proper size is a foot wide, a yard long, and about an inch in thickness. They should be first marked by a line the proper width, length, and depth, and then cut with a racer or cutter, first longways a foot wide, then across in yard lengths, proceeding afterwards to cut them up; having particular regard to cut them level, and all of an equal thickness, otherwise it will be impossible to lay them level. As they are cut they should be rolled each up close and tight, the grafs side inwards, and piled up by tens, especially if they are cut by the hundred, which is mostly the case. This is usually done at from about a shilling to fifteen pence the hundred, according to the nature of the soil, as, whether soft and easy to cut, or hard and stony. A man will cut from three to five, six, or seven hundred a day, with a person to trace them out and roll them up as they are cut from the surface.

The method of laying them is very easy: they are placed regularly turf and turf, unrolling them as they are laid, joining them up quite close edge to edge, and making good all deficiencies of broken parts as the work proceeds; and

as soon as laid, they should be well beaten with broad heavy wooden beaters, as flat pieces of elm or oak plank two inches thick, fifteen or eighteen inches long, and a foot broad, having long handles fixed slanting in the middle of the upper sides. With these beat the grafs regularly all over, and then roll it well with a heavy iron or stone roller, repeating these operations in moist weather as there may be occasion.

When very dry hot weather succeeds, so as to occasion the turf to shrink and open at the joints, a good watering is of much advantage to it.

The management of short grafs-ground, after it has been thus laid down, is that of mowing it in summer frequently, to keep it short and fine, like a pastured down; pulling occasionally with a long pole, to scatter the worm-casts, which greatly deface all short grafs, and rolling it frequently both to take up the scattered worm-casts to make the surface clean, and to render it smooth, firm, and even in its appearance.

Mowing once a week, ten days, or a fortnight, or, according to its general growth, during the summer, is necessary, especially for the principal home lawns, and other short grafs-grounds, in the most conspicuous parts; which parts should always be kept very close and fine, like the sward of a fine pastured down or common: it is performed with a short grafs-scythe; and dewy mornings, or moist weather, must always be chosen for the work, as it will be impossible to mow short grafs properly in dry weather. Previous to mowing, it is of advantage sometimes to pole and roll the grafs the day before it is intended to mow. In performing the work of mowing, proper attention is necessary not to score or leave the marks of the strokes of the scythe, which has a very unightly appearance; to prevent which, as much as possible, the point of the scythe should be laid out rather wide, an inch or two beyond the measure of heel and point, especially for very short grafs, keeping the point rather out, and not drawing that part too fast inwards, gathering the grafs neatly to the left in a range; and after having mowed thus to the end of the sward, to mow it lightly back again, in order to trim off all scores, and other irregularities, unavoidably left the first time in executing the work.

After it has been all thus mown over, proceed to sweep up the mowings of each sward regularly, by standing in the middle, sweeping it along alternately to the right and left, to the end of the sward, forming all the grafs in a range on each side; then sweep up the ranges in large heaps, and carry the whole off directly in a wheel-barrow, large basket, or other contrivance for the purpose.

The business of poling is performed by a long, taper, pliable, ash pole, fifteen or eighteen feet long, by passing it backwards and forwards, in rather dry weather, so as to break and scatter the worm-casts about. The grafs should be afterwards rolled with a wooden roller, when the surface is a little moist, but not too wet, by which the earth will all adhere to the roller, and render the surface perfectly clean, the work being repeated, as there may be occasion, the year round; and in mowing-time, if the surface is foul, it is particularly necessary to pole and roll on the day previous to mowing, by which a clean smooth surface will be provided, so as to be able to mow close, even, and more expeditiously. See *POLING*.

In the rolling of short grafs-ground, it should be performed occasionally with a wooden roller, and a heavy iron or stone roller: the wooden roller is proper after poling, to clean up the worm-casts and smooth the surface, being performed when the surface is not very wet, especially if full of worm-casts, as it would otherwise plaster and daub

the grass, and render it unfitly; the heavy iron, or stone roller, should be used occasionally, when the surface is dry, to press down all inequalities, so close as to preserve a firm, even, smooth surface. And in fine-kept short grass-grounds, the rolling should be performed occasionally a day or two before mowing, to settle the surface firm and smooth, which greatly contributes to the easy and exact performance of the work: the business of rolling in small, or but moderately large short grass-grounds, is mostly performed by men; but in very extensive grounds, it is sometimes done by a horse; having a large roller for the purpose, with shafts like a cart, and the horse at the time wearing a sort of leathern shoes, very broad at bottom, made so as to lace on occasionally, like mens' half-boots, to prevent his feet cutting the surface in holes, and rendering it uneven, and of a bad appearance.

Where short grass-grounds are defaced by wild daisies, dandelion, or other weeds, the first may be removed by having the blade of an old broad-sword fixed in the end of a long pliable pole, which, as it cuts both ways, by sweeping it backwards and forwards, it will head down the daisies at a great pace; which may be repeated two or three times a-week, or as often as there may be occasion for it.

The others should be extirpated by means of an iron for the purpose, made in the form of a small docking-iron.

In the autumnal finishing mowings, the grass should be generally cut down as close and even as possible, that the sward may remain in a neat even surface over the winter season, and appear well in the early spring.

These directions for the management of short ornamental grass-grounds, regard only such as are required to be kept constantly short, close, and even in the surface, as is necessary in the principal lawns, plats, walks, and other divisions, situated within the limits of the main pleasure-ground. In the outward considerably extended districts, continued into fields, parks, &c. it is not necessary to have them cut so frequently; two or three common mowings in a summer, with occasional rollings afterwards, may be sufficient.

Grass-hearth, in our *Customs*, grazing, or turning up the earth with a plough. Hence the customary service for the inferior tenants of the manor of Amerfsden in Oxfordshire, to bring their ploughs to do one day's work for their lord, was called *grass-hearth*, or *grass-hunt*.

Grass Husbandry, that sort of husbandry which has a relation to the management of grass-land, or such as are under the condition of sward. This, in a great measure, consists in the proper clearing, manuring, pasturing, or feeding down, shutting up, cutting or mowing, and the preservation of the crops. This sort of management is far from being perfectly understood in many parts of the kingdom, and consequently the grass-land is frequently in the most coarse and wretched state, being over-run with various kinds of coarse and aquatic plants, as well as those of the moss, and other descriptions. See *HUSBANDRY*, *GRASS*, *MEADOW*, and *PASTURE*.

Grass-land, that sort, or description of land, which is mostly preserved in a state of herbage or sward. The sorts of land that are the most adapted for this purpose are, according to some late writers,

1st. Such as are situated near large populous towns, where manure is cheap and plentiful, and where the produce of grass-land is constantly on demand, and, of course, dear.

2dly. Such lands as are placed on the banks of rivers and brooks, that may be improved by irrigation to a much higher value than can possibly be done under any other method of cultivation.

3dly. Such lands as lie in vallies of mountainous countries, especially chalky soils, where old meadow-land is

scarce and valuable, and the greater part of the arable land is of that nature and quality, that it is impossible to convert it to good sward-land. And

4thly. All such cold strong ground of the grass kind, which, if ploughed up, would not be applicable to the purposes of the turnip-husbandry, or those of modern farming, and which, under the best practice of wheat-husbandry, would not be so valuable as they are at present in the condition of sward.

The forming of grass-ground is effected with different degrees of difficulty in different instances; in some parts of the island it is accomplished, in general, with great ease and facility, the soil having a natural tendency to the production of grass herbage, when left in an unploughed state, reverting to pasture without labour, expence, or even the sowing of seed; while, in other cases, all the art of man has been found ineffectual, to make good grass-land. Even after 20 years fruitless expectation and expence, the land-holders have often been obliged to restore the ground again to a state of tillage-husbandry.

It is remarked, that consequently the great difficulty in this business is to discriminate what sort of land is suitable and proper for grass, and that which is improper for the purpose. The best meadow-land does not always make the best tillage-land, nor does the best arable-land always make the best pasture, but frequently the reverse. To make this discrimination, it is necessary to consider well the process of nature in propagating and perpetuating grasses. The great object of nature is to perpetuate all her species; but upon the plants created for the support of animals intended for the food and use of man, she seems to have bestowed more than ordinary care. Different kinds of animals propagate in different modes, some oviparously and some viviparously. Plants having no locomotive motion are endowed with a power of propagating in both modes. In trees and shrubs, and many kinds of plants, the assistance of man is required to obtain viviparous production, by grafting, budding, &c. But, in grasses, nature does her own work, and that in both modes. We have only to attend to her examples, and we shall seldom err. In trees and shrubs, the bud is the viviparous production; in grasses, the root performs the same office. Grasses are as much the offspring of roots as of seeds. Every new root contains the germ of a future plant; and, as the seed-stalks of grasses must necessarily be frequently cropped by animals, nature makes up the deficiency by an increase from the roots. Most of the best grasses are, in their nature, biennial; but nature, by giving them the power of propagating by the root, has in effect made them perennial: a much more certain mode of propagation than by seed, as being increased instead of being injured by the biting and treading of animals, and by the produce being perfect in one year instead of waiting two, as in the production by seed. But this process does not go on successfully, unless the land is peculiarly apt for the production of grasses. If it is too wet, the grasses will be injured in the winter by rain and frost, and will soon be superseded by rushes and other aquatic plants: if too dry, they will be killed by the summer's heat, and give place to mosses, fern, heath, &c. No land will, it is conceived, make a good meadow, unless it is deep enough to admit the roots of grasses to run down out of the reach of the summer's heat, and that it be retentive enough to hold water just so long as to produce fermentation, with such an absorbent under-stratum as will drain it before putrefaction takes place.

Some proportion of grass-land should always be attached to every farm, in order that a proper and suitable supply of winter and summer food may be provided for such animals as

may be requisite in managing them, and also that adequate proportions of good manures may be raised; as, where this is not the case, it is impossible that farms can be well managed. And on all sorts of grass-lands, it is of much consequence to keep them as clear and free as possible from the growth of all sorts of coarse plants, those of the aquatic kind being removed by suitable drainage, and the application of different substances of the absorbent description to the surface of the land. They should likewise be carefully eradicated from the hedge-rows of grass-fields annually, and by that means be prevented from spreading themselves over the ground by their seeds. By this practice, the hedge-plants would also be greatly benefited. These sorts of lands should also be kept as clear as the nature of their application will admit, of all kinds of obstacles that impede the production of perfect sward, such as the growth of moss on their surfaces, and the continuance of cattle dung-hills, ant and mole hills, as well as those of sticks, stones, and other similar substances. The proper methods of removing these are noticed under their particular heads, and in speaking of meadow-lands, and pastures.

According to the Agricultural Survey of the County of Hertford, in harrowing, with a view to destroy moss, no benefit has been found to be produced, though the mossy material has been well torn up. It is advised that manure should be laid on at the same time: but that where ashes are spread out over the surface without harrowing, the moss plant is destroyed, and the grass greatly improved. And in other cases, much advantage has likewise been experienced from the application of fine sand over the sward, in an even but not too thick a manner. But the dung of animals should never be suffered to remain any length of time in heaps upon the surface of grass-lands, without being beat out small, and dispersed over the surface; as, wherever that is the case, the sward in the places becomes tender, and the grass comes up coarse and in tufts, which are not eaten by cattle stock, and of course much injury sustained.

In respect to the prevention of the rising of ant-hills on grass-lands, they may be in a great measure, if not wholly, guarded against, by having recourse to frequent heavy rolling; as, in the rolling down of ant-hills, instead of cutting them up, in an experiment made by the duke of Grafton, it was found to be attended with complete success, on a large pasture which had been very much infested with ants, and which they had almost covered with hills. But in such cases the rollings should be performed both in the autumn and spring seasons, when the lands are in such states of moisture as just to admit the impression of the roller without receiving injury from the feet of the horses; as, where such operations are executed when the grounds are in a state of considerable dryness, the benefits are comparatively small. The beneficial effects that are produced in this way depend much upon the degree of consolidation that is effected; as it is only by this means that the insects can be prevented from carrying on their operations; a certain state of lightness as well as fineness in the mould being essential to the execution of their labours in a perfect manner. But besides these, attempts have been made in other ways to prevent the formation of these hills. For as it has been seen that "the economy of the ant requires the situation and soil to be dry, light, and friable, in order to carry on their works, it is probable that, in lands that will admit of the practice, it may be an easy and convenient method of destroying them, and preventing the bad consequences which their labours produce on the surface sward, to conduct water over them; and thus, at the same time, exterminate the colonies of ants,

and irrigate the ground; by which two improvements may be effected at once,—the land being cleared from ant-hills, while its fertility is considerably increased." And the use of night-soil, in combination with various sorts of earthy matters, has been advised with the intention of destroying such insects; but this is probably a practice that can only be depended upon in slight cases. See *Ant-hill*.

Upon stiff yellow clays, a Hertfordshire farmer has found the practice of draining, according to the Essex mode of carrying off the surface-water, useful, though this practice is totally unused by his neighbours in the same parish. Experience has convinced him, that dressing a cold tenacious clay not previously drained is an absurd waste of time, money, labour, and every thing most valuable. Having obtained a tolerably dry surface, his next object (with meadow-land) is to deepen the staple of the soil, and this he does by every kind of compost carried on it for two or three years together, which he finds establishes a better sort of grass than dressing once in three years on the surface.

It is suggested that the custom of feeding the first year, instead of mowing, is a practice that must be preferable or not according to the nature of the soil, and the object of converting it into grass-land. With respect to the former, he has found, that if he was to allow even the treading of sheep the first year after the grass-feed is sown, he should fill the surface with receptacles for water, and should have very little, if any, grass of a coarse quality, notwithstanding his drains; because the sheep or cattle would press the clay soil so close, that the water could not penetrate into them; whereas, if he shuts up his field, suffering the grass to stand till it sheds the seeds, he finds the following season that he is enabled, by giving only a slight dressing, to cut a good crop of hay from it. And in cases of old worn out thin patches or mossy grass-lands, the practice of scarifying or cutting the surface sward, in different directions, by implements for the purpose, has been lately advised as very beneficial in promoting their improvement, especially where they are afterwards manured, and have suitable grass-seeds sown over the thin or patchy parts, as in this way the grass-plants become more strong and vigorous. In performing this business, Mr. Amos has advised the use of a machine for scarifying and dressing grass-land, whether it is to be mown or depastured with animals. And he conceives that the best time of performing this operation, is from the middle of February to the middle of April. And that, in general, dressing the land one way is sufficient; but, if the sward be very mossy or adhesive, it should, he thinks, be dressed length and cross ways, cleaned, and then rolled, the coulters of the implement being occasionally cleaned from the rubbish. It is also suggested, that if the sward be thin, it may be thickened very much by laying eight or ten tons of rotten dung upon it, and sowing seven pounds of white clover, four pounds of wild or cow-clover, four pounds of trefoil, four pounds of rib-grass, and one peck of best rye-grass seeds, per acre, previous to its being dressed or bush-harrowed, and then cleaned and rolled. It is supposed that by dressing land in this way, moss is torn up, ant and mole-hills levelled and destroyed, the roots of the grass cut and horse-hoed, which causes them to throw out fresh lateral shoots or stems, the sward thickened, and the surface made so clean as to put on the appearance of a perpetual spring when close fed down. And that, by such management, and grazing as much stock as will keep the grass in a young succulent state, and hobbing or mowing all the tufts and weeds three times in the course of the summer, the grazier will be enabled to receive every benefit from his land, and likewise

prevent the stems of several grasses from running into seed, and being injured in consequence of it.

But another method of improving grass-lands, practised by Mr. Salter of Norfolk, is said to be original, and of great importance. It is stated in the Norfolk Survey lately published, that "upon his large farm of above 800 acres, he found 3 or 400 acres of old meadows entirely poisoned by springs, which, from every sort of impediment that neglect could cause, had formed bogs and moory bottoms, famous for rotting sheep and miring cows; with blackthorns and other rubbish spread over large tracts. His first operations were, to grub and clear the land, and open all ditches to the depth of four or five feet, and to cut open drains in almost every direction for laying them dry; burning the earth, and spreading the ashes on the ground: so far, the reporter says, all was no more than common good husbandry; but he applied a thought entirely his own: as he found that the stinty gravel, marl, and other earths, but especially the gravel, was very beneficial to the herbage, he thought of sowing winter tares and white clover upon the places wherever any earth was spread, or any other operation had laid bare the surface, harrowing in those seeds. The writer had the pleasure of seeing several of these crops growing: the success has been uncommonly great; for the land thus sown not only has given large and very profitable crops of hay, but has also received a rapid improvement in the herbage; the cover and shade of the tares, so beneficial to all land, mellowed the surface, and seemed to draw up as well as protect such of the old plants as received improvement from the manure, and exhibited a much superior fleece of grafs to any spots where this singular management had not taken place. So that nothing can be clearer, on viewing this large tract of meadow, than the superiority of the improvement resulting from the growth of the tares; the effect of the manure is much accelerated and rendered greater."

The reporter further hints, that "the idea is certainly applicable to many of the grass-lands of the kingdom, especially such as are improving by the addition of chalk, marl, clay, loam, sand or gravel: 40 loads an acre of any of these bodies will much improve coarse or wet, or moory grass-lands; and then to add tares secures an immediate profit, and makes the manure work much sooner and more powerfully. He sows some so late as the middle of May." An idea here strikes the writer, which he shall venture to add; that "if he was to scarify any mossy, hide-bound, or poor pastures, &c. it should be with a drill-scarifier, drilling in winter tares by every tooth of the scarifier; and he has no doubt but the tares would take well, and effect a considerable improvement, even without manuring." It is stated in addition, that "Mr. Salter has practised the tare husbandry on meadows for ten years, but his first beginning was seventeen years ago, at Ellingham: the cockchafer-grubs had destroyed a part of a meadow; he harrowed in tares and seeds, and the success was great." It is also stated, that "tare-seed running short, he this year sowed peas and oats mixed on some spots, and they are found to do well; and this husbandry he pursues, whether he intends mowing or pasturing. The writer considers this a discovery of vast advantage to grass husbandry in general.

And it is likewise observed, that "Mr. Bevan's arable land, at Riddlefworth, joining to his low boggy meadows, gave him the power of carting sand down hill at an easy expence; and thus he improved some parts of those meadows to great effect: from 100 to 150 loads an acre were spread at the expence of 4*l.* or 5*l.*

Statement of Expence.

In 1802 this method answered very greatly: these meads were then not capable of irrigation, but one meadow has since been watered, and the water has taken much greater effect on account of the sanding, than if that operation had not been performed. The sand has all been laid on the most boggy meadows. This hint should not escape the notice of the practical farmer in other districts, as there are many where it may be had recourse to, with the greatest advantage and success. There is likewise a similar method of improving old rough and boggy meadow-land described, with a plate, by a writer, under the title of *Agricola Norfolkensis*, in the first volume of the second series of the *Agricultural Magazine*, as practised by Mr. Rix, of the same county. "This meadow was situated at Clifton, near Fakenham, in the occupation of the above, and the property of T. W. Coke, esq." of Holkham. It is noticed that "this meadow, from the neglect of former tenants, and want of judgment in cutting what few open drains or ditches were attempted, had become very rotten in many places, and at least three parts of the four so over-run with sedge and rushes, that its utmost annual value could scarcely be estimated at more than eight shillings per acre. The lands contiguous to it are of a light friable nature, inclining to sand, by spots, and fall with a gentle declivity towards it from each side, the meadow being the basin and receiver of the numerous springs which rise in the upper fields, and which, in course of time, had rendered some parts of it utterly impassable for an horse, and scarcely safe for a man at certain seasons. It is observed that the first step the present occupier took was, as soon after Michaelmas as he could, to cut the drains, as he has shewn in the plan; all of which are covered, except the main drain, and the two ditches. These latter are cut both wide and deep, and are the chief operating checks to the springs above. And as soon as the weather permitted, he next set the teams to work (which were enabled to enter, even upon the most unsoft parts, very shortly after the first process was concluded), to level the hills, fill up the hollows, and to cart all the superfluous mould he could collect within the boundary of the meadow, (such as came out of the new-cut ditches and main drain principally), to the amount of 1000 loads, over the surface of the whole. About the last week of March he drill-rolled; and where the roller could not work, from little inequalities of ground, he dibbled the seeds mentioned in the annexed statement, harrowing the small seeds in afterwards; and, in July last, he cut and stacked the produce, which the writer has seen, and can witness to be excellent hay.

It is added that the present appearance of the meadow, after being fed down very close by more than fifteen score of sheep, exhibits, notwithstanding the very wet season we experienced, one uniformly dry, firm, and smooth surface, completely covered with a short turf, consisting of ray-grass, Dutch-clover, and good natural grasses. There are certainly some rushes yet, but far less numerous and strong than heretofore, and which it may justly be expected a few sweepings with the scythe, and hard stocking with sheep, will in time wholly destroy. But though there may not be

much novelty in the scheme of draining, the writer is of opinion, that very great merit is due to Mr. Salter, for the introduction of vetches, which he apprehends was never before tried on pasture-grounds, or indeed on any ground whatever unbroken by the plough. It certainly answers several admirable purposes, one is, that it gives a prospect every year of a bulky crop of hay, which otherwise must have been very scanty. And being sown with oats, the vetches afford that hovering kind of shade and protection to the young grasses in which they most delight. The eddish is of course also worth more.

But he is not quite sure, whether Mr. Salter's experiment gave rise to the following practice, which he is informed daily gains ground. Where the clover plants fall partially, or by spots, on a new layer, spring vetches are often drill-rolled upon the surface, not ploughed. The few clover-plants are thus left to grow with the vetches, and both together, in due season, form nearly as good a sward, as if the clover had not died away. Mr. Rix is so thoroughly convinced of the utility and advantage of the method he has pursued, that he is now preparing a second meadow, lying at the foot of the one just improved, for a similar process of improvement.

In cases where pasture-land can be spared for mowing, Mr. Salter seems to be of opinion, that vetches may be profitably employed, even a second year, upon new improved meadows. He has had some experience of such a repeated trial, and the writer believes he thinks favourable of it. He dibbles the seed upon the unbroken surface, after feeding it down as close as he can with sheep or other stock.

It is stated that the above meadow of Mr. Rix's cannot be over-rated, if it be said that it is, at this moment, more worth thirty shillings per acre to a tenant, than, in its former state, it was eight shillings the acre.

It is also necessary that care be taken to keep grass-lands in a proper state of production, by the judicious use of top-dressing, and by observing suitable methods of mowing and feeding them down by flock, and it becomes of course requisite in the view of keeping such lands in the most proper condition for the production of plentiful crops, as well as that of altering and improving the nature of the herbage, to have recourse to the occasional application of manure; as by this means the staple and depth of the vegetable mould are not only much increased, but the land brought into such a state of fertility, as that it may afterwards be kept up with much less expence and trouble than before.

A late writer has stated, that "it is a circumstance well known to grass-farmers in the best cultivated districts, that when lands of this sort are suffered to get much out of condition, it is a much more difficult business to restore them to the proper state of productiveness, than to preserve them in it. From the constant decomposition and decay of various vegetable materials on the surface of grass-lands, new portions of vegetable mould are constantly added, that improve the quality of the lands, and at the same time afford a more suitable and fertile bed for the establishment of the different kinds of grass-plants. It is chiefly, perhaps, on these accounts that old grass-lands are superior to new ones, and it explains the reason of the greater utility of earthy composts with dung in the latter than the former cases. However, with respect to the most proper periods of making such applications, there is much difference of opinion; but it should, probably, be regulated by circumstances; such as the state of the land in regard to dryness, its situation, the heat of the season, and its nature and condition in respect to soil and fertility. Where the land is such as not to admit the dung-cart in the early spring-months, without the danger of injuring the surface by poaching or breaking the texture of the sward, the most proper period would seem to be in the beginning of the autumn, before the heavy rains fall, as at this period the dressing may be laid on with the greatest convenience and safety; and from the after-grass being chiefly consumed with the stall-los in that particular. It is, however, recommended to be performed by some immediately after the land has been mown and cleared from the hay, in which method there may be an advantage in some cases, as the growth of the after-grass may thereby be rendered more abundant." But, in other respects, it has been observed by the author of *Practical Agriculture*, that, "it must often be not only inconvenient, but uneconomical, as, from its happening at a season when much other business is to be performed, it can seldom be attended to in such a manner as is necessary; and when the season at this period is hot, and there is much sun, as in general is the case, there must be considerable loss sustained in the extrication and dissipation of the finer and more enriching particles, such as become more immediately the food of plants, from their being in a condition nearly suitable for being absorbed and taken up by the roots of the grasses. The extent of the loss incurred in this way is much more considerable than is commonly supposed, as must appear evident from the great exhalation and constant evaporation that is often kept up for many days, or even weeks,

weeks, as the very offensive smell that issues fully proves. In this district, where we have occasionally witnessed the practice, with some of the less intelligent farmers, the moisture of the manure has been so much forced off and dissipated, especially when there is much wind, as to leave the materials in nearly a perfectly dry state. The sudden drying up of large ponds, at such seasons, shews in a more striking manner the extent of the injury that the farmer sustains in choosing this season for the application of his manure upon his grafs-lands. And, it still further states, that "there is another way in which a vast loss of manure may take place when applied at either of the periods that have been just noticed, especially where the lands lie in sloping directions, as is frequently the case, which is by the heavy rains in the autumnal season carrying down the more fine and rich parts of the manure, in a state of solution, into the ditches and runlets on the sides or other parts of the fields. Of the great waste of manure occasioned in this way any one may convince himself, by attending to the state of the water as it drains off from the higher grounds into these places, after the land has been previously dressed, as it will be found highly coloured, and loaded with the enriching carbonaceous particles of the manure." And "after frosts, when sudden thaws occur, the same thing happens" in a still more extensive degree than in the other cases.

In cases where the natural dryness and open texture of the soil admit of the manure being applied in the early spring months, there will be less danger of waste in the above manner, and at the same time greater advantage obtained in the growth of the produce; as, from the moderate heat and quickness of the vegetation at this period, the grafs will soon over-shade and conceal the dung, where laid on in a suitable state of reduction or fineness, without suffering much exhalation to take place; and the enriching material be conveyed to the roots of the grafs-plants at the time in which it may be the most useful in promoting their growth. Where the principal object of the farmer is a large produce, and the nature of the soil will admit of the manure's being applied without injury, this is unquestionably the most suitable as well as most beneficial time of putting the dung upon grafs-lands. The earlier, however, it can be performed the better. See MANURE.

But it has been stated by some, that manure produces the strongest effects upon the land when applied early in the autumn, or in meadows as soon as possible after they have had the hay taken off from them. And others suppose this last as the most proper season for having the business performed in of any.

In regard to the kinds of manure that are most proper, there is scarcely any sort that will not be beneficial when laid upon grafs-lands; in general, however, the more rich animal kinds will be the most suitable for the older sorts of sward-land; and dung, in combination with fresh earthy materials, the more proper on the new lays or grafs-lands, as by this means a fine earthy bed will be prepared for the roots of the grafs-plants to shoot and spread themselves into, and a better sward formed in consequence of such applications. See *Laying LAND down to Grafs.*

It is the practice of the best farmers in the hay-district of Middlesex to use the richest dung they can procure, without mixing it with any sort of earthy material, as they find it answer best in the quantity of produce, which is the principal object. The lands on which this system is pursued, are mostly such as have been long under sward, and where the soils are chiefly of the more tenacious, loamy, or clayey kinds. It cannot, however, be doubted, but that

earthy composts in the proportion of a third or fourth of such materials may, in many cases, according to the nature and circumstances of the land, be had recourse to with great and beneficial effects, both in rendering the land more productive, and in bringing the herbage into a finer state, as well as in bettering the surface for the purpose of mowing. See MANURE.

It may be observed, that whatever the nature of the material may be that is employed in combination with dung, or the sort of manure that is used, it should invariably be brought into a rather fine state. It is the practice, in the districts mentioned above, to turn over the dung that is brought from London in a state of tolerable rottenness once, chopping it well down in the operation, so as to be in a middling state of fineness when put upon the land. It is necessary, however, that it should be in a more rotten and reduced state when applied in the spring, than when the autumn is the time of putting it upon the land.

In respect to the proportion of manure made use of at once, it should be, in some measure, suited to the state of the land, but, in general, such as to afford a good even covering to the surface of the ground. Where the manure is of a very good and enriching quality, the quantity may be from four or five to six or seven loads on the acre, of such as are drawn by three or four horses. But where the manure is of an inferior quality, a much larger proportion may be requisite and proper.

The frequency of dressing grafs-lands, in so far as it respects the soil, should constantly be performed at such distances of time, as that the fertility of the lands may not be suffered to decline, but be preserved in an equal or increased state of heart; in which the manner and frequency of cutting, or otherwise consuming the produce, must be considered; as, where crops are more frequently taken off, the land must be prevented from being injured, by the great loss of fertility that must arise in this way, by the dressings being applied at shorter intervals, or in larger quantities at a time; but the first is by much the best method, as injury may often be done by too great a dressing being given at once. But, in general, where such lands are in a tolerable state of cultivation, every third year may be sufficient; while on such as are of inferior value, it may be a better practice to do it every second year, as by this frequent application of manure, the lands may attain a gradual improvement; whereas, in the contrary case, they would be on the decline, and in time become poor and worn out to the great injury of the farmer. It is a too common practice, in districts where grafs-husbandry is imperfectly understood, to almost wholly neglect the manuring of sward-lands, in order to employ it on those which are under the plough: but this is obviously bad management; as it is only by the raising of full crops of grafs for being converted into hay, and of proper kinds of green food, that a full flock of cattle can be kept, and the largest possible proportions of manure provided for the land. It may be noted there are a few articles made use of as top-dressings to grafs-lands, which cannot, it is said, be frequently repeated with either safety or advantage, such as chalk, marle, chopped woollen rags, and some others. It is stated, that "the first of these kinds, especially when of a soft, unctuous nature, so as to readily fall down in the state of solution to the roots of the grafs-plants, is found to produce the most beneficial effects, in rendering the lands more fertile and productive, and improving the quality of the herbage. It cannot, however, be often repeated in its simple state with advantage, as it is some time in producing its full effects; but in that of compost, it may be applied with success at shorter intervals. Marle is likewise a substance, especially when it is of the rich, soapy kind,

kind, that may be made use of with much advantage as a top-dressing on grass-lands; but as its operation is slow, it cannot be repeated at short intervals, except when employed in the state of a compost with dung-woollen rags, which, rendered small by being chopped into pieces, may be laid on land in the state of sward; but as they require a considerable length of time to sink down and become mixed with the soil, so as to be well covered by the grass, they cannot be repeated at short intervals. After they have been fully incorporated with the land, their beneficial effects are considerable," as have been fully shewn in the trials of different grass-farmers: and there are various other matters that are occasionally applied as top-dressings on grass-lands; such as lime in combination with rich vegetable earth or peat, the ashes derived from the combustion of peaty substances, coal-ashes, malt, dust, and foot. Most of these have been made use of with good effects when thinly spread out over the surface swards of lands in the state of grass. The three last have been found to produce the best effects in being dispersed over the new lays of the artificial-grass kinds. All applications of this sort should be applied in February, being spread over the surface as evenly as possible. "If it can be done before a shower of rain, it will be the better, as it is of advantage to have them carried down to the roots of the grasses as soon as possible after they are laid upon the land." But some advise, in the "management of purchased manures, that experiments should be formed for a year or two, before the practice is extended, to see which, at a given price, will suit the land best. Without this precaution, a farmer may probably expend large sums of money to little purpose. Nor should he trust to the mere appearance of the effect soon after the manuring; for some of them, particularly foot and malt-dust, will shew themselves after the first heavy showers, in a finer green than the rest of the field; but the proof of the effect does not arise from fine greens, but from weight of hay: for it has been found from experience, that the latter is not always an attendant on the former. Contiguous half-acres, or roods, should be marked out, the prices of the manures calculated, and on each piece a separate one spread, all to the amount of 20s. an acre, for instance. At hay-time, the crops should be weighed. It will then be known which manure, at the given prices, suits the soil best. This knowledge will prove true experience, and a very different guide from general ideas."

And here is still another circumstance necessary to be attended to in putting manure upon lands of this kind, which is not to suffer too much to be placed out in any of the heaps, but to have them set out as much as possible in moderate sized portions, and "at regular distances from heap to heap; as, where the contrary is the case, it not only takes up more time, and causes much more trouble to the labourer in spreading them, but does not admit of the work being performed in so regular or so exact a manner. Besides, when the heaps are set out too large, much injury is done to the grass-plants on the surface where they stand, if not soon spread out, which should always be the case, in the quickest manner."

It is also of much consequence, in the execution of this business, to have convenient carts for the purpose, which, in general, are those of the single-horse kind.

Some care is likewise necessary in the scaling or "spreading-out all sorts of top-dressings on grass-lands, to see that the work be performed in an exact and even manner, and that all the clods and lumps be well broken down and perfectly reduced by beating with the fork or shovel. If possible, a dry season should be chosen for this sort of business, as, under such circumstances, it can be executed in the most regular and exact

manner; as when the weather is wet, it is an operation that can never be well performed, as the materials clog round the feet and implements of the workman, and can never be effectually separated or divided so as to be spread out with the necessary degree of evenness." It has been already noticed, that "after the heaps have been set out, they should not be suffered to remain so long, as is often the case, before they are spread out, as the plants underneath them become blanched and tender, and great injury is done to the sward in such cases, all of which may be easily avoided by spreading as soon as possible after the manure is taken out. Inconveniences of this kind may likewise be avoided by spreading the manure from the carts, as is the practice in the midland and some other districts: but in this method it is suspected the work can neither be executed in so exact a manner, or with so much economy of time or labour. In this way hill-steads will not be formed, and, of course, the disadvantage of their getting too large a proportion of the manure prevented," as Mr. Marshall has well observed in his *Economy of the Midland Counties of the Kingdom*.

The usual practice, as soon as "the whole has been spread out, and remained in that state for a fortnight or three weeks, or longer, according to circumstances, and is become in some degree dry and powdery, to apply a bush-harrow over the surface once or twice in a place, in order to reduce the manure into a finer state, and bring it more fully to the roots of the grasses. But this sort of work, as that of spreading, should never be attempted when the season is wet, and the manure in a claggy, adhesive state. As soon as this work has been executed, all the rubbish of every kind should be carefully picked off, in order that the ground may receive the action of the roller," which should be passed over it as frequently as may be thought necessary, when the land is in a suitable condition for receiving it. (See *Rolling*.) This is the principal business which is requisite in the management of grass-lands in general.

In Hertfordshire, "a mode of managing sound meadows and pastures has lately been tried, and attended with great increase of produce. The grass is mown as soon as it is in blossom, and consequently previous to the formation of seed. The after-grass is not grazed until it begins to contract a yellow appearance, in the latter end of October or the beginning of November. In this case the ground remains covered during the winter with a portion of dead herbage, through which the young grass springs with the greatest vigour. Mr. Knight contends, that the sap in all plants ascends through the albuminous vessels of the root, and is dispersed over the leaf, whence it is returned to form new roots and buds, and to prepare them for vegetation. According to this theory, if the leaves be eaten off on mowing ground, as soon as they are reproduced, the roots are deprived of their nutriment, and the plants in consequence vegetate weakly in the succeeding spring. Whether this hypothesis be well or ill founded, it is certain that the ground which is left with this portion of the leaves of grass in the one season, is much more productive, and more early in the next; and close grazing will ever be found to decrease the quantity, although it should improve the quality, of the following crops." It is evident that there is some truth in this, from its having been found that the crops are more early and abundant in different cases, where the after-grass is not set down much in the autumnal season with live flock. See *Mowing and Grazing*.

Comparative Quantity of Food from Grass and Tillage Land.

With respect to the difference in the proportion of human food raised from grass and tillage land, the first circumstance necessary to be attended to, according to a late writer, is that

commonly denominated *Price*. But these inquiries suggest a further idea concerning the part of the produce, of either grafs or arable land, to which that circumstance is attached. It is evident, on the slightest view of the subject, that the portion of the produce consumed in the farmer's family can have little to do with the price of the market: it never finds its way thither: it never comes to be measured with the demand of the consumer, who does not produce. For this reason, in all inquiries that have for their object what is called plenty or scarcity, we never hear of any thing but price; and price is never formed but by the supply of towns from the produce of the country. The larger part of a modern society consists of the inhabitants of those towns, who are supported either by manufactures, or on incomes not derived immediately from the cultivation of the earth. So much for just opening our way in a field rather interesting: but may we not, with equal propriety, extend the circumstance just alluded to, to the labouring families supported by the farmer? His little neighbours in the village who do the work of his husbandry, arrest, if we may so express it, the amount of their subsistence from the crop before it arrives at the market. They must be fed; and though in many cases, by buying their flour of a miller, they seem to class with the inhabitants of a town, yet, perhaps, in more numerous cases they are, in fact, fed immediately from the farmer's stores; and in effect always so: for, if the farmer cannot produce his crops but by their direct assistance, and must multiply them exactly in proportion to the oporofeness of his culture, they cannot be considered in any other light, than mouths attached to the culture of the land, and demanding a deduction from the produce of wheat, before the surplus or market be reckoned, in as direct a deduction as that from his crop of oats for the food of his horses, or other animals. It is added that there are in the Suffolk Report some estimates of what the writer calls produce free in the market, and he makes the grafs-lands yield a greater free produce (horses, labour, &c. &c. deducted) than arable; and he knows not but it may be the same in other counties. Other writers seem also to have had the notion that grafs-land is more beneficial than arable. Bertrand, a Swifs writer, says, that grafs-countries yield more food than arable, and therefore manufactures should be fixed in them. Hartlib seems to be of the same opinion, and quotes those of Europe as the most populous. Fortrey, who wrote in 1663, also says, that our chief care should be to increase our flock of cattle. There is some degree of truth in these sentiments; and they might be considered in relation to the proportionate nourishment, in a pound of animal food compared with that of a pound of vegetable, which some authors have made vastly greater in meat than in bread. These are topics, it is stated, which ought to be thoroughly examined, that the public mind may be free from every erroneous bias upon such points. But further in the dairy countries, where butter is the chief produce, four firkins, or 224 lbs. may be reckoned the average produce per cow; the calf sold at about a week old, may contain about 30 lbs. of flesh; and as the pigs supported by a dairy, used to be reckoned at the rate of 20s. per cow, when pork was 6d. per pound, it implies, that 40 lbs. of pork is the proportion to each cow: but the cow consuming the produce of three acres, the acreable account would of course stand as below:

	<i>Acreable Account.</i>	<i>lbs.</i>
In Butter	- - -	74
Veal	- - -	10
Pork	- - -	13
		—
Total		97
		—

However, in the cheefe counties, the products vary a good deal: in Cheshire 4 cwt. per cow; in Shropshire 2½ cwt.; in Gloucestershire about 2¾ cwt.; in Wiltshire 4 cwt.; in Somersetshire 3½ cwt.; in Warwickshire 3 cwt.: the average of all these is 3½ cwt. and at three acres per cow, 1 cwt. and a small fraction per acre; and as these counties are richer than those applied to the produce of butter, veal may be called 15lbs. and pork 20lbs.; in all 147lbs. per acre, or thereabouts. But as to mear, authorities are not very ample: in the midland counties there is a very general notion, that an acre of grafs, at 40s. rent, will give 200lbs. of mutton. By an experiment made on land of an inferior quality, which is mentioned in the Annals of Agriculture, land of 16s. rent, gave 80lbs.; and he has heard, on good authority, that in Cambridgeshire some observations, carefully made, confirmed this proportion of produce in land fed both with bullocks and sheep; and the produce of beef, &c. in the Lincolnshire marshes, goes even further than this ratio or proportion to the acre.

With respect to the butter dairies, they are on land of about 16s. an acre rent; and if the produce be 97lbs. the proportion will be 6lbs. to every shilling rent. The cheefe dairies, at 25s. rent, yielding 147lbs. are also at about 6lbs. per shilling rent. The meat is 5lbs. per shilling. It is easy then to decide, that dairy counties are more advantageous than grazing ones in weight of produce; but their superiority is far greater in another point of view; their produce comes much more into the consumption of the poor; for, where one poor person eats meat, there are probably forty that consume butter and cheefe. How to compare these products with those of arable land is very difficult; and yet the inquiry is too interesting entirely to be omitted: a long train of investigation might enable one to disentangle difficulties, but it would require much time to go deeply into such a variety of subjects. The produce of a good loamy soil, under the course, 1. Turnips, 2. Barley, 3. Clover, 4. Wheat, may, it is supposed, be calculated in this manner.

“ No. I. *Arable dry Land at 16s. an Acre Rent, five Acres each Crop; twenty Acres in all, in a Course of four Years' Husbandry.*

- | | |
|--|------------------------|
| | <i>Time.</i> |
| | Persons. Years. Weeks. |
| 1. Turnips; eight sheep an acre, at the increase of 5s. each sheep, or 40s.; in mutton 80lbs; and for 5 acres 400lbs. will be sufficient (at 1lb. per person per diem) for two persons, one year and five weeks | 2. 1 5 |
| 2. Barley and oats; suppose an allowance of 1½ acre of oats (at five quarters per acre) for one horse as the proportionate team to twenty acres, and including feeds for 1½ acre: in all sixty bushels; remain 3½ acres for barley, at four quarters an acre; fourteen quarters or 112 bushels; deduct fourteen for seed, remain ninety-eight bushels for malt, &c.; but, if applied in bread, sufficient at nine bushels per head per annum, for eleven persons a year, minus one bushel. | |
| 3. Clover; deduct two acres for the summer and winter food of the horses, remain three acres for sheep, at eight per acre, improved 8s. each, or 3l. 4s.; or (at 6d. per pound) 1.8lbs. of mutton, and for three acres 38½lbs. suffi- | |

cient at $\frac{1}{2}$ a lb. a day for two persons a year: and leaving 20lbs. over; -	2	1	20
4. Wheat; twenty-two bushels per acre, which, after deducting seed, leave twenty, or $2\frac{1}{2}$ quarters, and for five acres $12\frac{1}{2}$ quarters, sufficient for twelve persons a year and two weeks	12	1	2
<i>Whole produce in human food</i> -	16	1	17

The same land, if in grass, would give 80lbs. of mutton per acre, 400lbs. per ann. and for four years 1600lbs. sufficient at $\frac{1}{2}$ lb. a day to support eight persons one year and thirty-six days' - - - - -

8	1	36
---	---	----

Hence, "to make the deduction, before alluded to, of the farmer's family, and his labourers: suppose he farms an hundred acres, which is, probably, above the average size of farms of the kingdom, here are five persons to that extent, or one to twenty acres. If we reckon all sorts of labour at 21s. an acre, we shall, he supposes, not be far from the fact: the pay of a labourer may be reckoned on an average at 25l. which we shall call the food of five persons; setting the earnings of the wife and children against rent, clothes, and other articles; this makes food 5l. a head: for every 5l. therefore that the farmer pays in labour, we may safely, he supposes, reckon that one person is fed from the produce of his farm before it reaches the market: the labour in the twenty acres in the above inserted estimate being 21l. he calls four persons', and the farmer's family one, making five, to be deducted from the acreable amount of the farm."

	Persons.	Years.	Days.
Brought forward - - - - -	16	1	17
Deduct - - - - -	5	0	0
Remains for market - - - - -	11	1	17
And the 20s. excess in the 21l. strikes off - - - - -	0	0	17
	11	1	0

Yet, "in regard to grass land, as it is managed with so much more ease, and farms are generally so much larger, it will be fair to deduct only one person for farmer and labour."

	Persons.	Years.	Days.
Brought forward - - - - -	8	1	36
Deduct - - - - -	1	1	36
Remain for market - - - - -	7	1	36

"It then appears, that under the circumstances of such land thus applied, arable land, on comparison with grass, sends to market in the proportion of 11 to $7\frac{1}{7}$. But if the barley, instead of being drunk, be eaten in bread, it adds to the arable account eleven persons, and the account would then stand nearly twenty-two to $7\frac{1}{7}$, or about three to one.

"But, as the largest part of the kingdom is employed in systems of husbandry very inferior to this excellent one, let us calculate how the comparison will stand with open fields,

and those inclosures which are managed by means of fallows in the ordinary rotation of cropping that is pursued upon them.

"No. II. *Open-field arable—Soil clay or wet—Rent 10s. an Acre, five Acres each Crop; thirty in all, in a Course of Six Years' Husbandry.*

	Persons.	Time.	
		Years.	Weeks.
1. Fallow:			
2. Wheat; produce twenty-two bushels; feed two; for consumption twenty, or $2\frac{1}{2}$ quarters; $12\frac{1}{2}$ quarters for five acres, being food for twelve persons during one year and two weeks -	12	1	2
3. Oats: produce four quarters an acre; feed half a quarter; remain $3\frac{1}{2}$ quarters per acre, or $17\frac{1}{2}$ quarters, or 140 bushels: sufficient, at twenty-five bushels a head, to feed five persons a year and five weeks, if used in bread.			
4. Fallow:			
5. Barley; supposed to be consumed in beer, &c.: but, if eaten by man, at four quarters an acre, deducting half a quarter for feed, remain $3\frac{1}{2}$ quarters or twenty-eight bushels; and at nine bushels a head, sufficient for three persons one year, and one bushel over, and five acres, enough for sixteen persons one year and two weeks.			
6. Beans; for horses equal to the food of $1\frac{1}{2}$ horse (at one horse to twenty acres) for the year.			
	12	1	2

But the same land laid down to grass, and let at 20s. will, he says, feed (on the supposition of an increase 5lbs. per shilling rent) oxen and sheep to the addition in weight of 100lbs. of beef and mutton, or 500lbs. for five acres, and 3000lbs. in six years; which, at half a pound a person per diem, or 182lbs. per head per annum, will feed 16 persons one year. The course here detailed does not feed the horses in summer; but as it affords, perhaps, more horse-food in the beans than to that amount, no other deduction should be made. It appears, that thirty acres of such land, when the oats and barley are eaten by horses, or drunk by men, support twelve persons a year and two weeks; now from this we are to deduct, as in the former case, the population of the farmer and his labourers; the former in the same ratio as before; but 15s. will be enough to deduct per acre in labour, instead of 21s. in the other course. This will, on thirty acres, be 22l. 10s. or 4 persons a year: add one and a half for the farmer, it is six in all.

| 1. Turnips: four sheep an acre, to the increase of 6s. each, or 24s.; in mutton 48lbs.; and for five acres 240lbs.; sufficient, at $\frac{1}{2}$ lb. per diem, for one person one year sixteen weeks and four days - - - | 1 | 1 | 16 | 4 |
| 2. Barley and oats; one horse to thirty acres, which demands $2\frac{1}{2}$ acres of oats, at three quarters (seed deducted); the remainder therefore $2\frac{1}{2}$ acres for barley, at $2\frac{1}{2}$ quarters per acre, being sixteen bushels (seed deducted), and for $2\frac{1}{2}$ acres forty bushels remain for malt; but enough in bread, at nine bushels a head for $4\frac{1}{2}$ persons a year, minus one bushel. | | | | |
| 3. Grasses. | | | | |
| 4. Ditto. | | | | |
| 5. Ditto. | | | | |
| The whole, without any horse account, would feed,
1st year, three sheep per acre, 26 weeks
2d two ditto ditto
3d one ditto ditto to the improvement (or the value in keeping) of 40s., and for five acres in each to 100s.; hence it appears that to keep one horse would almost equal the whole amount. | | | | |
| 6. Rye: $1\frac{1}{2}$ quarter; twelve bushels; seed deducted, ten; sufficient to support one person fifteen months; and for five acres six persons one year and eight weeks - - - | 6 | 1 | 8 | 0 |

Within a small fraction equal to the same land in heath would feed, but not fatten, to the value of 10s. per acre; call this 20lbs. of mutton; 100lbs. for five acres, and 600lbs. in

fix years; sufficient, at $\frac{1}{2}$ lb. per diem, for three persons a year and thirty-six days -

	Persons.	Years.	Weeks.	Days.
Brought forward, arable account -	8	1	5	1
Deduct, as farms on this soil are large, only half a person for thirty acres for the farmer; and reckoning labour at 8s. an acre, it is 12s. for thirty acres, or $2\frac{1}{2}$ persons; in all three - -	3	1	0	0
Remain for market - - - - -	5	1	0	0
Grass for ditto - - - - -	3	1	5	0

But “ a fraction is to be deducted for farmer and shepherd. The difference, therefore, is as five to three. But if the barley be consumed in bread, the account will be,

	Persons.	Years.	Weeks.
Brought down - - - - -	5	1	0
Barley - - - - -	$4\frac{1}{2}$	1	0
Together	$9\frac{1}{2}$	1	0
Grass - - - - -	3	1	5

Consequently the arable is therefore superior as nearly three to one. Upon the whole of these comparisons it is sufficiently clear, that the arable land is, and in every case may be, (by eating barley and oats,) far superior to grass-land in the article of feeding not only the people at large, but also in sending a surplus to market. He cannot, however, let his papers go from his hands without requesting them to be read with candour. He presumes to offer them but as rough sketches, that may approximate to truth, but cannot reach exactness: they may afford hints useful to future inquirers, and the subject is interesting enough to answer well a very careful examination. One observation that goes generally to all is too material to be omitted; the production of meat in England is, it is supposed, of small importance compared with that of corn, because the poor do not live on the former; meat is the consumption, generally speaking, of those who are in very easy circumstances, compared with the great consumers of corn; nor would the times be much complained of, whatever the price of meat might be, provided corn were at a reasonable price. This is a circumstance which should be considered as decisive of the inquiry; and sufficient to prove, that the great interests of the public demand every possible encouragement to tillage for given, as shall preserve corn at a fair price, neither too high for the poor, nor so low as to discourage the cultivation of it by the farmer.

With regard to what ought to be the proportion between the grass and arable land of a farm, errors are, it is observed, extremely common among landlords, and not less to with farmers: in general, however, they both look to their own interest; the first to keep much in grass, and the latter to plough all they can: with short leases, and bad covenants, we are not to be surprized at either. One acre of moderate corn, says Adam Smith, in his *Wealth of Nations*, yields a greater neat profit than an acre of the best pasture. And experience, Mr. Davis of Longleat observes, sufficiently evinces the extreme difficulty of persuading tenants to believe that they get more, generally speaking, by feeding their lands than by ploughing them; yet it requires very

very few arguments to convince a landlord, that in cold wet lands especially, the less ploughed land you have, the less you put it in a tenant's power to ruin your estate. That a tenant of 60*l.* per annum in a dairy-farm will get money, while a corn-farm will starve its occupier (though, perhaps, the former gives 15*s.* an acre for his land, and the other but 10*s.*), is self-evident. Perhaps, says Mr. Billingsley, in the third volume of the Bath Memoirs, there cannot be a stronger proof of the inferiority of the plough, with respect to profit, than the superior punctuality of the dairy-farmer in the payment of his rent. He never met with the steward of a manor devoted partly to corn and partly to dairy-farms, who controverted this statement.

Clay.—Upon “this soil, when tenacious and not easily drained, a larger portion should, it is observed, be kept in grass than perhaps on any other; and for this reason,—green winter food is not to be gained at all, or, if gained, not without great difficulty and expence; consequently, the team, and whatever cattle may be kept for consuming straw and making dung, must depend in a larger measure on meadow hay, than upon soils which admit turnip, cabbage, &c. Clover will do on clay, but it is more hazardous and liable to failure; in which case, without a certain resource in the hay of natural grass, the farmer would often find great inconveniences. He has examined many farms with this object in view, and found that, when half the land has been grass, they have been more profitably conducted than with a less proportion; but on no account with less than one-third.”

Loam.—It is stated that “one-third or one-fourth in grass is a proportion found suitable to various loams; the more they tend to wetness, the larger the portion. It is not, however, essential on these soils, not only because clover and other artificial grasses are less apt to fail; but likewise by reason of their admitting profitably the alternate husbandry of grass and arable.”

Sand.—It is contended “that some rich sands are of so happy a texture, that they do very well in permanent grass, and without burning in slight droughts; but, in general, it may be observed, that sand in its several varieties is, of all other soils, that which pays best in tillage: it is easily worked; expences are light; it manures itself by agreeing well with sheep; and, as the result of the whole, farmers are usually rich upon it. In respect of the proportion, it is best managed, perhaps, when the whole is under the plough; for, by means of cultivated grasses of proper sorts, all the stock of the farm may be profitably supported, and the land rested sufficiently, for ensuring a perpetual production of corn. But, contrary to this maxim, and most unprofitably, large tracts are commonly tied up from the plough, by covenants of leases, under the name of sheep-walk, heath, &c. which would, by alternate tillage and rest, produce more corn, and keep more sheep, than in the present state: this is particularly the case in Norfolk, Suffolk, Nottinghamshire, and some other counties.”

Chalk and Lime-sten: Soils.—“Nearly the same observation is to be made on this class; they are more productive under the plough than in grass. But landlords tie up their tenants from ploughing down in Sussex, Hampshire, Dorsetshire, and Wiltshire; but in Gloucestershire, the East Riding of Yorkshire, and Lincolnshire, they have, on the whole, been less tenacious; still, however, large tracts remain, which would be ploughed were tillage permitted. Rules may be carried too far, and this among the rest. Dorsetshire has its ewe leases, which, in many cases, ought not to be touched; and fine sweet downs, which by very attentive management have been brought to a considerable degree of fertility, are

so useful to sheep in winter, that exceptions must occur. Another motive for ploughing is the peculiar advantage derived on this soil from saintfoin, one of the most useful grasses that we owe to the bounty of Providence, but attainable only by tillage.”

Peat.—Immense regions of moors spread widely through all the northern counties, and even in the most southern, as Devonshire and Somersetshire, Cambridgeshire and Wales; also sedgey bottoms are found every where. They admit and call for a much greater improvement than any other soil, comprehending the larger part of the waste lands of the kingdom. These soils are very rarely brought into the state they are capable of, without tillage, and consequently, to prohibit it, is to pass a decree of perpetual sterility. The obstacle, however, most common on moors is, the rights of commonage, which do not come within the scope of the present inquiries. When improved, they are commonly much more adapted to grass than to tillage, not however without numerous exceptions, as we see by the general practice in the fens of Cambridgeshire and Lincolnshire. The alternate husbandry does well upon them: it is easy, however, to be too busy with the plough; for, when good grass is gained, it is the wiser way to continue it in a productive state.

But it is further stated, that the subject of the proportion between grass and arable requires a word or two, viewed in another light, besides the relation to soil. This is the prevalent application of the land. In the midland counties, where grazing very widely extends, it is common to see entire farms of grass-land, and the tenant prohibited from breaking up an acre; in such cases there is a motive for ploughing not immediately connected with soil. To till a part would be right, whatever the soil may be; straw, in such a country, is not to be bought, and the convenience and profit of having some is no inconsiderable object; it would be carefully used as litter, and the manure arising would improve a portion of the land. Some cabbages, or Swedish turnip, or common turnip, might be raised (which to a certain extent, and for certain objects on such farms, would be highly valuable to the grazier), so as to outweigh large expences in procuring them on soils not quite adapted to their culture. There is not a question but a farmer in such cases could afford to pay more rent for liberty to plough a portion of his land than under the present covenants. This would, it is supposed, extend to a fourth of the farms in soil rather unfavourable to the plough; and to a large proportion in others. But even three or four small fields, though no more than one-fifth, one-sixth, or one-tenth, would be highly advantageous to himself and the public, and not at all injurious to the landlord or owner. And to dairy-farms, when entirely in grass, as many are in Wiltshire, Gloucestershire, and other counties, this remark is yet more applicable, as the produce of tillage, straw, cabbage, &c. is yet more necessary than in a mere fattening system. In this case, and indeed in most others, the quantity might be partly regulated by the team: a dairy-farmer, who keeps four horses to draw his butter or cheese to fairs, &c. ought, without question, to have tillage enough to employ those horses: and it is no difficult matter to ascertain that quantity. If the various works be examined carefully, it will be found, that a horse to twenty acres of tillage is a fair proportion, which will leave time for carting hay in summer, and the products of the farm in winter. He is not speaking here of tillage farms on sands, &c. or with rotations of crops, in which the soil rests for several years: on such the proportion varies: but merely on grass-farms, where some horses must be kept, and are at present unem-

unemployed a large part of the year. But meadow farms, properly so called, are never, to his knowledge, met with but in the vicinity of great cities, where the demand for hay is great and uniform; horses on such are kept only for the purpose of carrying hay to market, bringing dung back, carting the hay to the stack, and the manure to the fields. Straw is wanting for litter and for thatch; but it is questionable whether it is profitable to plough for this object only in any case; a scattering of tillage is in some places found, but not by any certain rule; the necessity is small, and straw usually to be purchased. Such districts, being highly improved, demand very little attention, it is supposed. See *Tillage, Rotation of Crops, and Pasture*.

Grass Lease, in *Agriculture*, a term frequently applied to such sward lands as are appropriated to the purposes of grazing, or the fattening of neat cattle and sheep.

Grass-Seeds, a term often used to signify the several different seeds of grasses that are employed in laying land down to the state of turf. It was, however, formerly, mostly made use of to denote the mixture of all sorts of rubbish that was scraped up from the hay lofts, or collected in the cribs or boxes below the racks in the stables. But, in the improved method of forming new grass lands, the practice of using such mixtures of seeds is almost wholly laid aside, and only such as are really useful and proper, had recourse to, by which the lands are found to be much more valuable and productive. See *Laying Lands down to Grass*.

Grass-fods, in *Rural Economy*, a name applied to such fods or turfs as are pared off from the surface of old sward-lands, whether they be intended for the purpose of burning on the land, for fuel, or for being laid down in order to form a lawn, or small plot of fine even turf. In the former intentions they are generally pared off by ploughs, or spades, contrived for the purpose; but in the latter almost constantly with great regularity and exactness, by a turf spade for the purpose. A tool of the plough kind seems, however, capable of being employed in this way also with advantage. See the next article.

Grass-fod-cutting Plough, the name of a tool of the plough kind, which was invented on the continent by count Van Mattzen, and which has been highly useful in cutting grass-fods in a cheap and expeditious manner. It can also be had recourse to with great advantage in paring the swards off old grass lands, wastes, and commons, previously to their being burnt and brought into the state of tillage-husbandry. It is likewise capable of being converted to the purpose of forming walks in grounds where they may be wanted, as well as in paring the bottoms and sides of them, and of such as have been already made, by which means the gardener will only have the simple business of raking and rolling them to perform.

By some slight alterations in the manner of placing the coulters, grass fods are likewise capable of being cut in a very ready manner, and in any form that may be required, so as to be employed in the construction of banks, fortifications, huts, and other works of a similar kind. It would seem, consequently, to be a very useful tool in the expensive business of constructing embankments against the sea, or other large waters.

The inventor was led to the construction of this plough, in consequence of the want of a more cheap and expeditious method of performing the work than the usual one of the spade, in cutting turfs for forming grass-plats, &c.

It may be observed that in forming the tool, the beam, or fore part of any common plough will answer the purpose; this part is consequently not represented in the figure, the kind or operative parts being simply shewn. The tool is

capable of being managed by any person who is able to direct a common plough.

This plough may be seen at *fig. 7.* in the *Plate on Grazing*, in which the nine holes shewn by A, A, is the beam, serve, as in the common plough, to regulate the length of the beam merely by placing the pin C forwards or backwards, and thereby to make the cutting-iron to work to greater or less depth. The two coulters, E, E, which are placed on each side of it, in front of the cutting-iron D, serve to guide the side cut, preparatory to the separation of the turf or sod. The cutting-iron D may, by means of the screws G, G, be raised or lowered at discretion. And, in order to keep it in its place properly, the two supports at H, are made, and provided with several holes for the purpose at I, formed in the cutting-iron D. The two handles are displayed at K, K, and the frame at L L L L; the whole of the remainder, which in the frame is marked black, is to be formed of iron.

A certain degree of practical experience is necessary, in order to use this plough, so as to form the turfs with exactness; and in the commencement of the work care should be particularly taken that the workman does not cut the turfs too deep, and that the plough be not injured by his inattention. In a very short time, he will, however, be so accustomed to the business as to perform with great exactness. In setting out the work, a breadth equal to the width of the two cutters should be previously cut out, as by that means the cutting-iron takes the sod at a proper depth, and executes the work, as soon as the draught commences, in the team. In the performance of the work, oxen are recommended as preferable to horses, from their drawing more steadily, and being more readily managed on stiff lands; but we apprehend that this will not, in general, be found to hold good, and horse-teams are far more expeditious. See *TEAM*.

Grass, in *Mining*, signifies the natural surface of the earth over a mine; sometimes also it is called "the day," or the top; and a mineral vein appearing on the surface, is said to come, or appear to grass, or to the day. Coals and other stratified minerals, when they come to the surface, are said to basset, crop, burst-out, go-out, to want-cover, to run-out, to out-burst, to head-out, to run-out, &c.

Grass River, in *Geography*, a river of America, in the N.W. part of the state of New York, which rises near the main branch of Black river, and runs N.N.W. about 50 miles, then N.E. 40 miles, and is lost in the river St. Lawrence. N. lat. 45° 12'. W. long. 74° 48'. It is a rapid river, affords many mill-seats, and near the mouth, its banks produce great quantities of hay.

GRASSE, a town of France, and principal place of a district, in the department of the Var. The place contains 12,521, and the canton 13,554 inhabitants, on a territory of 100 kilometres, in four communes. The principal trade of the town consists in dry fruit, olives, oil, perfumes, and tanned leather:—9 miles W.N.W. of Antibes. N. lat. 43° 39'. E. long. 6 59'.

GRASSE, La, a town of France, in the department of the Aude, and chief place of a canton, in the district of Carcassonne; 20 miles S.W. of Narbonne. The place contains 1123, and the canton 4524 inhabitants, on a territory of 292½ kilometres, in 18 communes. N. lat. 43° 5'. E. long. 2 42'.

GRASSES, Petrified. Mr. Whitehurst, in his "Inquiry concerning the Earth," 1st edit. p. 169, mentions grasses among the vegetable remains in the coal-measures of Derbyshire: but the late Mr. William Martin, who was perhaps better acquainted with these strata, says, "Outlines," p. 85, that

that the gramina of these argillaceous strata are of unknown species in the recent state, and appear rather allied to the canes and reeds of the Indies, than to grasses properly so called. Mr. Farey also, in his laborious researches among these carboniferous strata, has seen nothing resembling grasses imbedded in them. See REEDS.

In peat districts, which are of modern or recent accumulation, and within the range of flooded rivers, it is not uncommon to meet with preserved grasses, probably belonging to many of the recent species, at considerable depths below the surface of, or even at the bottom of the peat, or muddy deposits; but such peat fossils should on all occasions be distinguished carefully from stratified, or real fossil remains, as remarked in our article COAL.

GRASSHOPPER, in *Entomology*, a species of *Gryllus*; which see.

GRASSHOPPER, in *Ornithology*, a name given to the *Alauda trivialis*; which see.

GRASSI, CECILIA, in *Biography*, afterwards Mrs. Bach, who performed the first woman's part for several successive years at the opera with Guarducci and Guadagni, was inanimate on the stage, and far from beautiful in her person; but there was a truth of intonation, with a plaintive sweetness of voice, and innocence of expression, that gave great pleasure to all hearers who did not expect or want to be surprised. Her performance of the part of Enridice, in Gluck's "Orfeo," with Guadagni, was perfect in all respects, and gave universal satisfaction.

GRASSWINKEL, THEODORE, a learned lawyer and writer, who flourished in the 17th century, was a native of Delft. He wrote various works upon legal and political subjects, by which he acquired a considerable reputation, and was regarded by the government as a proper person to fill some office in the state; he was accordingly made fiscal of the domains of the states of Holland, and secretary of the bipartite chamber on the part of the states-general. He died in 1666, at Mechlin, and was buried in the great church at the Hague. His works were numerous: of these the following may be noticed, "Libertas Veneta, seu Venetorum in se et suos imperandi Jus." This was published in 1634, and in 1644 he defended the republic of Venice, in a dispute with the duke of Savoy concerning precedence. For these services, that republic created him a knight of St. Mark. Previously to the publication of the last of the two above-named works, he attempted to confute the popular maxims of Buchanan, in a treatise, entitled "De Jure Majestatis." This was dedicated to Christina, queen of Sweden, who was known to be a great assertor of regal privileges. Grasswinkel defended the liberty of the seas against a native of Genoa, in his work "Maris Liberi Vindicte." He was author, likewise, of a treatise in two volumes 4to. "On the Sovereignty of the States of Holland." He was at all times a defender of particular states; but a violent oppugner of the rights of the people. Moreri. Bayle.

GRATAROLUS, WILLIAM, was born at Bergamo, in Italy, in the year 1510. He was educated at Padua, where he took the degree of doctor of physic, and afterwards became professor of the same science, and gained considerable distinction. But having embraced the Calvinistic doctrines, on the persuasion of Peter Vermilli, he fled from Italy, through fear of the inquisition, and retired to Marburg, where he taught medicine for a year. But he was compelled to leave that place also, and repaired to Bale, in the hope of a better fortune, and where, in fact, he taught and practised his profession with success, until May 1562, when he died, at the age of 52. He was author of a great

number of works, some of which are honourable to his talents, and evince a large share of knowledge; but in others he shews an attachment to the absurdities of the alchemist, much superstition, and opinions which do not imply a sound judgment. Eloy. Dict. Hist.

GRATCHI, in *Geography*, a town of Russia, in the country of the Cossacks; 20 miles N.W. of Tzaritzen.

GRATIAN, in *Biography*, a Roman emperor, son of Valentinian I. was born at Sirmium, in 359. He was appointed by his father to a share in the empire when he was but eight years old. He was in his seventeenth year when Valentinian died. At this time Gratian was keeping his court at Treves, and was ignorant of what had happened till he was informed that the officers of the army had appointed as his partner in the throne Valentinian II. the younger son of the late emperor, by his second wife Justina. Gratian, though hurt at the assumption of authority on the part of the army, readily ratified the election, and ever treated his brother with affection and tenderness. The Western empire was nominally divided between them, but the superior age of Gratian gave him all the power. One of his first acts was to recal his mother to court, who had been divorced and banished; and this act of justice was followed by the punishment of certain officers in the state, who had abused their power, by cruelty and injustice. While the emperor is praised for these deeds, he has not escaped blame, and a high degree of censure, for putting to death the renowned general Theodosius, who fell a victim to the jealousy of some rival courtiers. History has also censured him for the indulgence which he afforded to the clergy, and for his severity against those who were denominated heretics, for the gratification of the orthodox. At the head of the Eastern empire was his uncle Valens, who was in 378 attacked by the Goths. Gratian, active and courageous, put himself at the head of an army, and marched to his assistance. He obtained a decisive victory in Alsace, and, pursuing his successes, crossed the Rhine, and penetrated into the heart of the enemy's country, in order to join the forces of Valens. Before, however, he could reach him, that emperor had been defeated and slain at the battle of Adrianople. Gratian now felt that he must take the most vigorous measures against their common enemy, and immediately called from his retreat Theodosius, son of the general who had suffered under his hasty displeasure, and placed him at the head of a separate army, with which he was enabled to destroy a large body of Sarmatians, who were on their march to join the Goths. Gratian himself proceeded to Constantinople, where he recalled those orthodox bishops who had been banished by Valens, and he also issued some edicts relative to the exercise of religion. As Valens had left no male heirs, his nephew, disregarding the suggestions of personal ambition, filled the vacant throne to the satisfaction of all, by raising Theodosius to a station, for which his talents were peculiarly adapted. This was in the year 379, after which Gratian returned to Italy, and in his journey he had an opportunity of being benefited by the instructions of the celebrated Ambrose, at Milan, which proved beneficial to the orthodox, but occasioned new restrictions upon those who were regarded as sectaries. After this he continued for some length of time to attend to the defence and concerns of the empire, and is highly applauded for almost all the amiable qualities which have decorated the best of sovereigns. Still it was feared that his good principles were rather the effect of able and virtuous advisers, than the spontaneous result of fixed habits. What the best friends to their country feared, proved to be the real fact: he suddenly fell into snares of unmanly pleasures, spent much of his time in indolence or

trivels

frivolous amusements, which proved not only injurious to his subjects, but, in the end, ruinous to himself. Hunting became his favourite pastime: to enjoy the pursuits of the chase, he neglected the duties incumbent upon him, as the sovereign of a great people, and those only became his favourites who were skilful in hunting. He offended the more sober part of his subjects, by appearing in the garb of a Scythian warrior, armed with a bow and quivers, and discontents were on the very point of embodying themselves into a serious shape, when a revolt took place among the legions of Britain, who, without hesitation, invested Maximus with the imperial diadem. Gratian attempted an opposition; but his own efforts were feeble, and these even were counteracted by the treachery of some of his officers. He had no sooner unfurled his banners, and put himself in a warlike posture, than he was deserted by his household troops. He had now no hope, and immediately fled with about 300 faithful troops towards the Alps. All the cities on his road manifested evident signs of disloyalty: they even refused him a shelter or admission into their towns, till he arrived at Lyons. Here, indeed, the gates were opened for his reception, but the hearts of the people were estranged to his cause, and upon the arrival of the cavalry of Maximus, the governor of the city betrayed the deposed emperor into the hands of the commander, who caused him to be put to death, as he rose from his supper. This was in the year 383, after Gratian had been on the throne nearly eight years. Gibbon. Univer. Hist.

GRATIAN, a Benedictine monk, who flourished in the twelfth century, was a native of Chiufi, in Tuscany, and embraced the monastic life at Bologna. Before his time, there had been many collections of canons and laws of the church, but they were so defective in matter and form, that they could not be conveniently explained, or even made use of as systems of ecclesiastical polity. Gratian undertook the task of compiling such a system, and after more than twenty years' labour he produced, in 1151, an abridgment of canon law, drawn from the letters of the pontiffs, the decrees of the councils, and the writings of the ancient doctors, which he entitled "Concordantia discordantium Canonum," or as it has been translated, "The Coalition of jarring Canons." In a new edition of this work, it was called "Decretum Gratiani," or "Gratian's Decretal." By this name it is generally known. Upon the first appearance of the work, it received the stamp of approbation from pope Eugenius III., who declared himself so satisfied with its execution, that he commanded it to be publicly read in the schools. The professors of Bologna were the first who unanimously adopted it as a text book in their public lectures, and their example was soon followed by the professors of Paris, and, in short, by those of almost all the European colleges. It is, however, said to be full of errors, and in other respects extremely defective, but as it was calculated to support despotism, and to extend the authority of the Roman pontiffs, it was for four centuries appealed to as the standard of ecclesiastical law, and even in ages succeeding that dark period, it has occasionally been quoted with a degree of veneration and authority, to which it has no just title. It was used in MS. till 1472, when it was printed at Mentz: this edition was followed by impressions at Venice in 1476, and Paris in 1508. Another edition was printed at Rome under the auspices of pope Gregory XIII. in four vols. fol. on which a large portion of labour was bestowed in correcting its numerous imperfections. Anthony Angulin, archbishop of Tarragona, in Spain, published a valuable treatise "De Emendatione Gratiani,"

of which the best edition is that published at Paris in 1672. Moreri.

GRATICULATION, a term some writers use for the dividing a draught or design into squares, in order to the reducing it thereby.

GRATINGS, in a *Ship*, are small ledges of sawed plank, framed one into another like a lattice or prison grate, lying on the upper deck, between the main-mast and fore-mast, serving for a defence in a close fight, and also for the coolness, light, and conveniency of the ship's company.

GRATIOLA, in *Botany*, the diminutive of *gratia*, a grace or favour, the herb to which it is applied having been called, by the earlier botanical or medical writers among the moderns, *Gratia Dei*, the favour of God, because of its eminent virtues, which however are of a violent and cathartic nature. It is one of the plants which have been conjectured to yield the tincture called *eau medicinale*, so famous at present as a cure for fits of the gout, but this opinion, it seems, is contradicted by the proprietor of the secret.—Linn. Gen. 13. Schreb. 17. Willd. Sp. Pl. v. 1. 102. Vahl. Enum. v. 1. 88. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 42. Brown. Nov. Holl. v. 1. 435. Juss. 121. Lamarck. Illust. t. 16. Gartn. t. 53.—Class and order, *Diandria Monogynia*. Nat. Ord. *Personate*, Linn. *Scrophulariæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep, awl-shaped or ovate, upright, permanent segments. *Cor.* of one petal, tubular, unequal; tube longer than the calyx, angular; limb small, in five deep segments, of which the uppermost is broadest, emarginate and reflexed, the rest straight and equal. *Stam.* Filaments four or five, awl-shaped, shorter than the corolla, the two or three lowermost shortest and barren, the two uppermost attached to the tube of the corolla; anthers roundish. *Pist.* Germ. superior, conical; style straight, awl-shaped; stigma with two lips, closed after impregnation. *Peric.* Capsule ovate, pointed, of two cells and four valves, the partition from the inflexed margins at two opposite sides. *Seeds* numerous, small.

Ess. Ch. Corolla irregular, reversed. Two stamens barren. Capsule superior, of two cells and four valves. Calyx in five deep segments. Stigma with two lips.

Linnaeus's *gratiola*, in the first edition of Sp. Pl. 17, chiefly depended on the original and primary species, the *officinalis*, for of the three others there defined, *dubia* is *Capraria gratioloides* of the second edition, and *Lindernia pyridaria* of his Mantissa 252; *virginiana*, though in his possession, was made a *Gratiola* chiefly on Gronovius's authority; and *peruviana*, though a genuine *Gratiola*, had then probably never been seen by Linnaeus at all, but was adopted from Feuillée. In the second edition *G. Monnieria* takes place of the *dubia*, and a wrong East Indian synonym is annexed to *virginiana*, but no further species are added. In the second Mantissa two new ones are described, *rotundifolia* and *hypopoides*, both from the East Indies, so that six species in all are enumerated in Syst. Veg. ed. 14. To these Willdenow has added eight more, chiefly East Indian, prudently declining to adopt three unless ones from Walter's Flora Carolina. Vahl has far outstepped his predecessors, giving 31 species in all. Unfortunately a great share of these were described from dried specimens, their genus determined chiefly by habit, and their flowers or fruit not sufficiently investigated. Indeed several of them evidently differ from the original genus in various respects. Mr. R. Brown, a more critical investigator, has greatly reduced the genus in question, though he has described three entirely

entirely new species from New Holland. We shall confine ourselves to an account of such as are certain, with compendious remarks on a few of the rest.

1. *G. officinalis*. Linn. Sp. Pl. 24. Fl. Dan. t. 363. Woodv. Med. Bot. t. 47. Bulliard t. 130. Ehrh. Pl. Off. 11. (*Gratiola*; Matth. Valgr. v. 2. 53. Rivin. Monop. Irr. t. 106.)—Leaves ovato-lanceolate, serrated, five-ribbed, smooth, somewhat longer than the flower-stalks.—Native of moist places in Denmark, Germany, Switzerland, France, and Greece, flowering in June. The roots are perennial, rather creeping. Whole herb smooth. Stems annual, ascending or erect, twelve or eighteen inches high, leafy, round, pale and very sleek, generally simple. Leaves numerous, opposite, sessile, dotted, above an inch long, ovato-lanceolate, bluntish, with many shallow tooth-like serratures in the upper part, and five, rarely seven, parallel ribs, of which the middle one is the most considerable. Stipules none. Flowers pale lilac, with an orange tube, inodorous, scarcely an inch long, on simple, solitary, axillary stalks, which are generally about half the length of the leaves, often more, and bear a pair of bractæas close to the flower, by some taken for additional parts of the calyx; these are spreading and a little toothed.—This species, a stranger to Britain, is the original one, celebrated for its purgative virtues, whence the French call it Poor-man's herb, on account of its cheapness and efficacy. Indeed its use requires great caution, and a plentiful administration of warm water, butter, or oil, at the same time. A scruple of the dried herb is mentioned as a sufficient dose, but its uncertainty, and its emetic properties, have justly brought this medicine into disuse, there being so many more unexceptionable drugs for the same purpose. Its flavour is nauseous and intensely bitter.

2. *G. pilosa*. Mich. Boreali-Amer. v. 1. 7. Vahl. n. 16. (*G. peruviana*; Walt. Carol. 62.)—Leaves ovate, crenate, hairy as well as the stem. Flowers axillary, nearly sessile.—Native of moist places in South Carolina, flowering in May. Stem simple or branched, near a foot high, square, leafy, very hairy. Leaves ovate, not an inch long, somewhat heart-shaped and clasping the stem with their base, bluntish, with two or three distant teeth on each side, fringed, dotted, and hairy. Flowers nearly sessile, white, with a pair of spreading bractæas, which are fringed like the calyx.

3. *G. peruviana*. Linn. Sp. Pl. 25. (*G. latiore folio*, flore albo; Feuill. Peruv. v. 3. 23. t. 16.)—Leaves ovate oblong, toothed, downy, obscurely five-ribbed. Flowers axillary, sessile.—Native of Peru, Mexico, and the Brazils. The whole herb is more or less downy. Stem a span high, angular, mostly simple. Leaves oblong, somewhat ovate, various in breadth, bluntish, obscurely five-ribbed, the margin furnished with distant teeth. Flowers white, nearly or quite sessile, shorter than the leaves, with a pair of bractæas very like, and about equal to the calyx, strongly countenancing the idea of their being properly calyx-leaves.

4. *G. latifolia*. Brown n. 1.—“Smooth. Leaves ovate, obtuse, obscurely crenate or entire. Flowers sessile.”—Native of the neighbourhood of Port Jackson, New South Wales, and of Van Diemen's land.

5. *G. pubescens*. Brown n. 2.—“Clothed with glandular hairs. Leaves lanceolate, toothed. Flowers nearly sessile.”—Native of Port Jackson, the south coast of New Holland, and Van Diemen's land.

6. *G. p. dunculata*. Brown n. 3.—“Clothed with powdery down. Leaves lanceolate, toothed in their forepart, scarcely longer than the flower-stalk.”—Native of Port Jackson.

Mr. Brown announces the existence of a few unpublished

species, natives of North America, of which we know nothing further. He mentions the Linnean *G. hypopoides* and *rotundifolia* as species of *Lindernia* with two barren flamen, undoubtedly a variable circumstance in this tribe, and constituting no generic distinction. *G. Monnieria* is his *Herpissis*, and has the appearance of a good genus.

With respect to some other species.

G. limifolia. Vahl. n. 4 (*Digitalis limifolia lusitanica pallustris*; Tourn. Inst. 165.)—“Leaves linear, entire. Flower-stalks axillary, the length of the leaves.”—Native of Portugal. This seems an unquestionable *Gratiola*, near the *officinalis*, with which it agrees in qualities, but differs in leaves, and in the flowers not being more than one-third the size of that species.

G. lobeliioides of Retzius, Vahl. n. 10, has neither the habit, calyx, nor bractæas of this genus.

G. trifida. Willd. n. 9, seems to agree in all those points with Mr. Brown's *Limnophila*, the *Hottentia indica* of Linnæus.

G. lucida. Vahl. n. 17. (*Capraria cruceacea* of Linnæus), is referred by Mr. Brown to *Torenia*, a genus hitherto not much understood.

GRATIOLA Officinalis, *Hedge-Hyffops*, in the *Materia Medica*, is a plant to which various medical virtues have been ascribed. The first account of its cultivation in Britain, is that given by Turner in 1568, though it is said that the first botanist who mentioned it was Matthioli. It has a strong bitter nauseous taste, with but little or no odour; and its virtues are extracted more perfectly by aqueous than by spirituous menstrua. It resembles digitalis both in the shape of its flowers, and in its medicinal effects, and hence has been called *Digitalis minima*. It is certainly a powerful and active cathartic, and operates so violently as generally to induce vomiting; and on this account, Chomel thought it to be a medicine adapted only to the more vigorous and robust constitutions. Many others, however, recommend it as a safe and useful purgative. But as its effects are uncertain, it should be administered with the precaution of a gradual increase of its dose. This plant has been commonly used in hydropical cases; and in moderate doses it is said not only to act as a hydragogue, but also to manifest a diuretic character; and instances of its good effects in ascites and anasarca are related by many respectable practical writers. Geher and Bergius found a scruple of the powder to be a sufficient dose, as in this case it frequently excited nausea or vomiting; others have given it to half a dram, two scruples, a dram, and even more. The extract is said to be more efficacious than the plant itself, and exhibited in the dose of half a dram or a dram in dysenteries, produces the best effects. Kofrzewski informs us, that in the hospitals at Vienna, three maniacal patients were perfectly recovered by its use; and in the most confirmed cases of lues venerea, it effected a complete cure. It usually acted by increasing the urinary, cutaneous, or salivary discharges. Woodv. Mat. Med.

GRATIOLA, in *Geography*, one of the smallest Canary islands. N. lat. 29 15. W. long. 13 17.—Also, one of the Azores islands, about 10 miles long and eight broad. It takes its name from its beautiful appearance, and fertility in corn, fruit, pasture, and cattle, with which it supplies Terceira, and several of the other islands. It is well peopled, and has a number of villages; and the coast is defended by forts. The chief place is La Plata. N. lat. 39 2. W. long. 27 56.

GRATITUDE, in *Ethics*, a virtue disposing the mind to an inward sense and outward acknowledgment of benefits

its received. This is a virtue in which the Egyptians pretended to excel all the rest of mankind. See EGYPT.

GRATIUS, in *Biography*, a Roman poet, surnamed from the place of his birth Faliscus, was a contemporary of Virgil. They are both mentioned by Ovid in a single distich. The work by which this author is known, and for which he claims a short notice, is entitled "Cynegeticon," or the Art of hunting with Dogs. It was entirely unknown to the moderns till it was brought to light by Paul Manutius in 1534. This learned editor printed it from a MS. copy brought by Sannazaro from France. It is said to be written with a purity not unworthy of the Augustan age. The best edition is that of Leipzig 1659, 4to. with notes. It has been printed in the collection of "Rei Veneticæ Scriptores," 1728, and in Mattaire's "Corpus Poetarum." Gen. Biog.

GRATTAN, in *Agriculture*, a term applied provincially in some situations to such arable lands as are managed under a commonable state. But in other places, as in Cornwall, it is employed to signify the mowing of grass the first year, after the ground has been manured with sea sand; which is an operation that they denominate mowing in grattan. The stubbles of common fields are also frequently called grattans.

GRATZ, or GRAZ, in *Geography*, a town of the duchy of Stiria, on the river Muchr; containing several churches and convents, an arsenal, a castle on a rock, and an university founded in 1585. In this town is held the assembly of the states; and in 1784, it was erected into an archbishopric on the suppression of that of Goritz. It is surrounded by walls. The French took it in 1797; 70 miles S.S.W. of Vienna. N. lat. 47° 10'. E. long. 15 16'.—Also, a town of Silesia, called also *Hradetz*, in the principality of Troppau, situated on the Mora; four miles S. of Troppau. N. lat. 49 47'. E. long. 17 50'.

GRATZEN, a town of Bohemia, in the circle of Bechin; 37 miles S.S.E. of Bechin. N. lat. 48 47'. E. long. 14 43'.

GRAVA SELE, a town of Naples, in the Basilicata; 15 miles E. of Venosa.

GRAVATTEN, a town of Prussia, on the Curisch Nerung; 20 miles S. of Memel.

GRAUDENTZ, a town of Prussia, in the palatinate of Culm, on an island near the Vitula; anciently called Grolek; 14 miles N. E. of Culm. N. lat. 53° 28'. E. long. 18 28'.

GRAVE, in *Grammar*, a species of accent opposite to acute. The grave accent is expressed thus (`); and shews that the voice is to be depressed, and the syllable over which it is placed pronounced in a low, deep tone.

GRAVE, in *Music*, is applied to a sound which is in a low or deep tone.

The thicker the chord or string, the more grave the tone or note, and the smaller the acuter.

Notes are supposed to be the more grave, in proportion as the vibrations of the chord are less quick. See GRAVITY, in *Music*.

GRAVE is also an ingredient in the composition of divers terms in history and policy. Thus we say *land-grave*, *burg-grave*, *marg-grave*, *pals-grave*, &c.

The word, in this sense, is formed of the German *graf*, signifying *comes*, *count*; called in the barbarous Latin *gravius* and *graphio*.

GRAVE is also used for a tomb, wherein a person deceased is interred.

GRAVE, Ital. (pronounced *gravyay*) an adverb applied to slow movements in the second degree, more quick than *adagio*, and more slow than *largo*. In *adagio* movements,

the time is usually counted by quavers, in grave; by crotchets. *Grave*, Ital. and *gravement*, French, not only imply a slow time, but a certain *gravity* in the execution.

GRAVE, in *Geography*, a strong town of Brabant, belonging to Holland, situated in a marshy country, on the S. side of the Meuse; 34 miles S.E. of Utrecht. N. lat. 51 46'. E. long. 5 41'.

GRAVE CREEK, a creek on the Ohio in Virginia, 12 miles from Wheeling. N. lat. 39 46'. W. long. 80 55'. Near this creek is a mound of earth, evidently the work of art, called an Indian grave. Although no tradition remains, that the Indians buried their dead in this manner, these mounds, on examination, have been found to contain a chalky substance, supposed to be bones of the human kind.

GRAVE *Harmonic*, in *Music*, is a phenomenon thus described by the late Dr. Robison: "The reinforcements of sound, which are called *beatings*, are noises. If any noise whatever be repeated with sufficient frequency, at equal intervals, it becomes a musical note of a certain determinate pitch. If it recurs 60 times in a second, it becomes the note *C-fa-ut*, or the double octave below the middle *c* of our harpichords, or the note of an open pipe eight feet long. Now there is a similar (we may call it the very same) reinforcement of sound in every concord. Where the pulse of one found of the concord bisects the pulse of the other, the two sounds are more uniformly spread; but where they coincide, or almost coincide, the condensation of one undulation combines with that of the other, and there comes on the ear a stronger condensation, and a louder sound. This may be called a *noise*; and the equal and frequent recurrence of this noise should produce a musical note. If, for instance, *c* and *a* are sounded together; there is this noise at every third pulse of *c*, and every fifth pulse of *a*; that is, 80 times in a second. This should produce a note which is a 12th below *c* and a 17th below *a*; that is, the double octave below *f*, which makes 320 vibrations in a second. That is to say, along with the two notes *c* and *a* of the concord, and the compound sound which we call the *concord of the Vith*, we should hear a third note FF in the bass. Now this is known to be a fact, and it is the *grave harmonic* observed by Rameau and Tartini about the year 1754, and verified by all musicians since that time."

Mr. John Gough gives the following account of grave harmonics. "When two sounds are heard in concert, the vibrations producing them are arranged in cycles, no one of which continues for a longer or shorter time than the rest; and their effect is perceived by the ear, which becomes sensible of their presence. For when each cycle of a series, separately considered, exceeds the twelfth part of a second, the sense of hearing recognizes each point of division made by the coincidence of the vibrations which separate the contiguous cycles; this circumstance enables the sense to contemplate these periods apart, and comprehend their origin. On the contrary, when the duration of a cycle belonging to a compound series does not exceed the twelfth part of a second, the interval proves too small to be measured by the ear: it therefore escapes notice in a separate state; for the points of division recur too frequently to be observed. When the auditory organ finds itself in circumstances answering to the preceding description, it has but one method to pursue; which is, to treat these derivative intervals in the same manner it treats all periods, which are singly too small for its comprehension; it therefore reduces them to a simple musical sound, corresponding in pitch to a string which vibrates once in the time of each successive cycle. A grave harmonic is on this account always a lower

note than any of its constituents, seeing the time of a cycle exceeds the greatest vibration that enters into the composition of it. The strength of a grave harmonic is also weak, when compared with the notes composing it, because these secondary sounds, being nothing more than certain unavoidable efforts of the imagination, they assume the character of a feeble sound, which is just strong enough to be heard in the company of one or more louder tones; for the power of the imagination is always inferior to external impressions, except in fits of insanity, when the organs of sense appear to be blunted by physical causes. The grave harmonics always keep the direction of the ears, let the position of the head be changed as often as you please, resembling in this circumstance a shrill piping note, called the ringing of the ears; which every one ascribes to a slight affection of the auditory duct, because it differs from external sounds, in having no fixed direction. The grave harmonics agree with the ringing of the ears in this remarkable particular; which is a strong proof that their immediate cause is seated in the person of the hearer; and it is evident from the nature of things, that this cause originates in the mind." Nicholson's Journal, 8vo. vol. iv. p. 2.

We have been thus particular in quoting from two very able writers on the subject of the grave harmonics, or Tartinian sounds, in order to shew the foundation of the rules which we shall here give, for determining the grave harmonic of any given perfect consonance, viz.

1st. Find the number of vibrations made in one second of time by each of the given sounds: which, supposing *C. sol-fa-ut*, or *c* of the German tablature, or that on which the tenor cleff is placed, to make two hundred and forty complete vibrations, is obtained, by multiplying this number by the larger term of the ratio of the given sounds to *C*, and dividing the product by the smaller term of that ratio, if the given sounds lie above *C*, or the reverse if below it.

2d. Having thus obtained the vibrations of the given consonance, divide the larger number of them, by the larger term of the given consonance, and the smaller number by the smaller term, each of which, if the operation be rightly performed, will give the same result, and shew the number of coincidences of the pulses of the two given sounds in one second, and also the vibrations in that same period, of the grave harmonic sought.

3d. Compare the number of vibrations last found with each of the vibrations of the given consonance, and reduce their ratios to the lowest terms, which will then express the intervals or distances of the grave harmonic, below each of the given sounds.

By way of examples of these rules, we subjoin the following table, shewing the grave harmonic, and several other useful particulars, of the principal consonances in the octave, above *C. sol-fa-ut*.

1	2	3	4	5	6	7	8	9	10	11	12	13

Given Consonances.				Grave Harmonics, or Implied Sounds.								

The experiments of M. Tartini, the discoverer of these sounds, extended to ten of the consonances in our table above, viz. the V, 4th, III, 6th, 3d, VI, II, II', (second minor), 2d, (greater semitone,) and minor semitone ($\frac{2}{4}$), but in all of which he seems to have mistaken an octave, in assign-

ing the place of the harmonic in the scale, and has mentioned each of them as being higher by an octave than in our table. Mr. John Holden, the author of "An Essay towards a rational System of Music," printed at Edinburgh in 1807, p. 352, seems to have been aware of this latter circumstance,

but in page 350, lays down an inapplicable and false rule for calculating the place of the harmonic, or *implied found*, as he calls it; viz. "when two different founds are heard together, their combination always either really produces, or essentially implies, a third found, whose vibrations are equal to the difference of the vibrations of the two founds in the same time." Thus C 240, heard together with G 360, produces 120; which is c an octave below C, &c. Now it is observable, that this empirical rule will give the same results as ours above, only in such cases where the least terms of the ratio (in column 3) differs by *unity*; which is the case in eight of Tartini's examples out of the ten, but not with the VI or the 6th: which, according to Holden's rule, stand thus, $400 - 240 = 160$, and $\frac{160}{400} = \frac{2}{5}$, or the fifth below the key, instead of the XIIth (as Dr. Robison and we have calculated it above); also, $384 - 240 = 144$, and $\frac{144}{384} = \frac{3}{8}$, or the octave and fourth, or eleventh, below the upper note, instead of the XXII. It is not a little surprising that Mr. H. should have overlooked these glaring inconsistencies of his rule, with Tartini's experiments, on which he professes to have founded it; acknowledging, however, (p. 351.) that he is unable to discover any philosophical principles on which these phenomena can be explained, and of course unacquainted with the writings of the two authors, from whence we have extracted as above. We should not perhaps have thus adverted to Mr. Holden's essay, had it not been in other respects a most respectable work, and one through which these errors are likely to be widely disseminated among musicians, and were not the fanciful system of harmony, which he builds solely upon them, calculated to bewilder still further the musical student, who may happen to have but a slight knowledge of mathematics. Among the novelties of Mr. Holden's system, he pretends to prove, by means of the implied founds, (calculated by his rule,) that the minor third, $\frac{1}{3}$, is a "superfluous third," and not the fundamental less third of the scale, which he says is expressed by the ratio $\frac{3}{2}$, (though conceived probably, as he says, p. 371, by the ratio $\frac{16}{9}$;) on which account we have introduced this comma-deficient minor third into our table, and when its harmonic is shewn to be $b c$, five octaves below the upper note of the consonance, instead of $284\frac{1}{2} - 240 = 44\frac{1}{2}$, and $44\frac{1}{2} \div 284\frac{1}{2} = \frac{1}{64}$, which expresses 2 VIII + 6th, or a minor twentieth below the upper note, as Mr. H.'s rule would have given it: whereas, had he used the true method of assigning the place of this harmonic or implied found, his boasted fundamental less third, (besides proving less agreeable to the ear on trial, p. 384, than $\frac{1}{3}$;) must have been degraded from the rank of concords, as having an implied found more than three octaves below the lowest of its notes, which is one of the essential properties of concords, according to their new conceits.

Another result of these false principles in the Essay is, the admission of the integer 7 among harmonic ratios (though to the exclusion of 5×7 ; 7^2 , 7 , &c. 2×7 , $2^2 \times 7$, &c. page 341, and also of page 305, although 7, 11, 13, 19, &c. have real places in the *false* notes of the trumpet, horn, &c.), and the consequent introduction of what the author calls a GRAVE fourth (see that article), in his descending scale, page 316. According to which also, the acute or comma-redundant major sixth ($\frac{5}{3}$), belongs essentially to the scale, instead of the true concord $\frac{5}{3}$! We trust that we shall have performed an acceptable piece of service to the well-wishers to the harmonic science, in pointing out the source of such incongruous absurdities as the above; and hope, that in a second edition of this useful work nearly all which follows page 349 will be expunged, and consigned to its merited oblivion.

The grave harmonics found by the rules and table above, are occasioned by the coincidences of the vibrations of perfect consonances, or the *beats* of Mr. Sauveur, but since the *beats* of Dr. Robert Smith also, or those made by imperfect concords, when they occur oftener than 12 or 13 in a second, occasion a grave harmonic note to be perceived, and no theorems for calculating such beats, except that of Dr. Smith from the fractions of a comma of temperament, and Mr. Emerson's from the lengths of strings, having to our knowledge been published, we shall here supply that defect in our article BEATS, and give theorems for calculating the beats made by imperfect or tempered concords whose vibrations per second are given, viz.

Let N and M be the number of complete vibrations made in one second, by the grave and acute notes respectively, of the tempered concord whose perfect ratio is $\frac{n}{m}$ (n being the least term, in its lowest number), and let b be the number of beats in one second of time.

Then, if the temperament be *sharp*, $b = nM - mN$, the beats required.

Or, if the temperament be *flat*, $b = mN - nM$, the beats required.

Take for example, the 3d in our table above, and we have $N = 240$, $M = 284\frac{1}{2}$, $n = 5$, and $m = 6$: and by the second theorem above $6 \times 240 - 5 \times 284\frac{1}{2} = 17\frac{1}{2}$ the beats in one second: which are, it will be observed, just double the vibrations in column five of the table, and therefore the grave harmonic thus occasioned, is four octaves below the upper note of this comma deficient minor third. The above theorems for beats will be found of like easy application, in almost every instance of musical calculations.

GRAVE Intervals is a term applied by Mr. Maxwell and several other correct writers, to such consonances as are flattened or lowered by a major COMMA (see that article) and it is usual with them to distinguish such intervals by the grave accent thus, II', III', IV', V', VI'; &c.; and on the contrary, to apply the acute accent to such as are sharpened or raised a major comma, as II'', III'', 4'', &c. and to call such acute intervals or comma redundant intervals, while those as much flattened are called COMMA deficient intervals, which see. Mr. Holden, a modern writer, has, however, applied this term to intervals lowered by what he calls a *bearing*, whose ratio is $\frac{96}{74} = 11.94709 \Sigma + m$. See GRAVE fourth, &c.

GRAVE fourth, according to Mr. Holden's system lately published, is an interval less than a perfect fourth, by what he calls a *bearing* (which is $\frac{96}{74} = 13.94709 \Sigma + m$) having the ratio of $\frac{1}{2} \frac{96}{74} = 240.05291 \Sigma + 5f + 21m$ in Mr. Farey's new notation; its common logarithm is .8819006, 8792, its Euler's logarithm or decimal value of the octave is .3923175, and it contains 21.89039 major commas.

GRAVE proper semitone, is an interval in Mr. Holden's System of Music, whose ratio is $\frac{2}{3} \frac{96}{74} = 43.05291 \Sigma + f + 4m$; its common logarithm is .9788107, 1, and Euler's logarithm .070389, and the number of major commas 3.92754 which it contains.

GRAVEDO, in *Medicine*, a Latin term, derived from *gravis*, heavy, signifies that species of catarrh, which is usually called a *cold in the head*; and in which, together with a stuffing of the nostrils, and blunting of the voice, there is a sense of fullness and weight in the forehead. It is, according to Celsus, nearly synonymous with the *coryza* of the Greeks. See CATARRH. Celsus, de Med. lib. iv. cap. 2.

GRAVEDONA, or GRAVIDONA, in *Geography*, a town of Italy, in the department of the Lario, on the lake Como: 42 miles N. of Milan.

GRAVEL,

GRAVEL.

GRAVEL, in *Agriculture*, a term frequently applied to a well known material of the small stony kind, the sizes of the particles of which vary from those of very small peas to cockles, and sometimes larger. They are often intermixed with other matters, such as sand, clay, loam, flints, pebbles, iron ocre, &c. Hence there are *sandy, clayey, loamy, stony, pebbly, ocrey or ferruginous* gravels, &c.

GRAVEL, in *Gardening*, is a small stony substance made use of for the purpose of constructing roads, walks and paths. Walks formed of this material are great ornaments to gardens and pleasure-grounds, as well as useful for common walking upon.

The best gravel for those purposes is that which is naturally composed of irregular pebbles and flints, having a moderate proportion of a yellowish or brownish sandy loam, to make it bind, and give colour. It is obtained in fields and commons, in many parts, at from one, to three or four feet under the surface, though not equally good in all parts, in respect to quality and colour, some having a greater or less proportion of pebbles, a larger or smaller proportion of loam, which is more or less sandy or clayey: it is the colour of the loam, or oxyd of iron, principally, which constitutes the beauty of gravel walks; that of a deepish yellow or reddish colour being the most eligible, as when formed into well-laid walks and rolled, it has an exceedingly beautiful and ornamental effect. Where such gravel can be procured within a moderate distance, and easy expence, it is preferable to all others in some parts. Gravel is of an iron-mould colour, or of a dusky brown hue, which may nevertheless be of a proper quality for walks where the colour is disregarded.

Whatever colour the gravel may have, its proper quality for walks is, a due proportion of moderate, light, sandy loam, to make it bind close and firm at all seasons; but not so redundant, or so clayey, as to be clammy and stick to the feet in wet weather, or so sharp and sandy as to become open and loose in dry weather.

In some places, no other gravel is met with but such as is very loose, sandy, or pebbly, and which has scarcely any binding materials amongst it; which kind never of itself binds, but always remains open and loose, being at all times disagreeable to walk upon; this may, however, be mended by a mixture of light sandy loam, where practicable, adding about one load to every two or three of gravel, calling them together, and turning them over two or three times, that they may be well blended and incorporated; and this, when formed into a walk, will often bind close, firm, and smooth at all seasons of the year.

In preparing the gravel for walks, it should not by any means be finely screened, as is often the practice: as it is dug out of the pit, it is only necessary to call it up in a heap, or long ridge, all such large rough pebbles only as roll down being cleared away; as if screened from the stones, it partakes too much of the loam, so as always to stick to the feet at every flash of rain.

In purchasing gravel for walks, it is mostly from about two to five or six shillings or more per cart-load for three horses; though the price differs greatly in different parts, and according to the nature of the gravel, as well as the goodness of its colour.

In respect to the distribution of gravel-walks in pleasure-grounds, and gardens, for ornament or use, large ones are necessary to proceed parallel to the house, extending each way towards the side districts of the garden and ornamented grounds: according to the former style of gardening, a large walk of this kind was usually extended in a straight line from the front of the habitation along the middle of the pleasure ground, sometimes having grass plats continued on each

side, and sometimes spacious borders furnished with curious shrubs and flowers. But in modern designs these middle walks are rarely admitted, especially in spacious grounds, having nothing in front beyond the parallel habitation walk, but an open rural grass lawn, free from all interfections of walks, &c. However, a good walk closely parallel to the house is indispensably necessary, both for ornament and convenience, and from this side-walks should branch off, communicating with the other parts of the pleasure or garden-grounds; one in particular to be extended in a serpentine manner quite round the ground, others leading in the same manner through the interior parts, so as to have dry firm walking at all times to every part of the ground or garden, without coming upon the grass.

The dimensions for gravel-walks must be regulated according to the extent of the grounds or gardens, as from five to twenty feet or more in width; but all principal walks should be at least eight or ten feet wide; and in large grounds or gardens leading directly from the house, they should be ten, fifteen, or twenty feet wide at least. When the houses and gardens are very large, the main walks contiguous to the mansion are sometimes made thirty or forty feet wide; the boundaries on each side being sometimes in grass widely extended, and sometimes in borders for flowers and other curious plants, having either narrow verges of grass, or edgings of dwarf box, or thurst, on the sides of the walks.

In forming walks of this sort, they should be first staked out to the proper width, and then the boundaries formed, each side of equal level, corresponding to the adjacent ground; the cavity of the walk for the reception of the gravel being afterwards made, the whole space being dug out at least twelve inches deep, to allow for a proper depth of gravel, both to prevent weeds coming from the ground below, and worms from casting up the earth; as also to allow of a proper depth for turning the gravel occasionally when the surface becomes foul; the earth dug out to form the cavity of the walk may be used to raise and form the ground on each side, if necessary, which, and the edgings, should always be completed before the gravel is begun to be laid down into the cavity formed for it.

When the cavity has been thus prepared, any hard rubbishing materials may be laid in the bottom, several inches thick; such as coarse gravel or ballast, rough stony lime, brick, or other rubbish, which will greatly prevent worm-casts, and help to drain the moisture from the top of the walk in wet weather, and in winter preserve a dry surface: the proper gravel is then to be laid six or eight inches thick; in laying, raising the middle higher than the sides, in a gradual rounding form; which is not only necessary to throw off the wet, but also to give the walk a more ornamental appearance; the proportion to be observed in this is, for a walk of five or six feet width, an inch and a half of rise in the middle; for one of ten or twelve feet, two and a half inches; and for one of twenty feet, from three to four or five inches; the same proportion being regarded in other widths. At every ten or fifteen feet, as the work advances in laying, it is proper to tread, rake, and roll the gravel down, as it always rolls more firm and smooth, when fresh stirred; it is also necessary, for fear of rain, especially in loamy gravel; for which reasons, more should never be laid in one day than can be finished off, except the rough laying. The treading should be performed regularly with the feet pretty close, taking short steps; so as to render every part equally firm, and not to sink in holes under the feet, in the work of raking and rolling. The raking should be performed regularly lengthways of the walk; and in the finishing

off

off or smooth raking, a wooden-headed rake without teeth is most eligible, or the back of any common rake; as by any of these, the surface may be rendered more regular and even without drawing off the requisite proportion of top pebbles, or raking them into holes or heaps; as the art of smooth-raking is to leave all the proper-sized top stones equally dispersed over the surface. As soon as any part is thus laid and raked, it should be well rolled both across and lengthways; and when the whole is laid, a good rolling should be given the whole length, repeating it till the surface is rendered perfectly compact, firm, and smooth; and after the first shower of rain, another good rolling should be given, so as to make it bind like a rock. This method should be practised with all walks made with these materials invariably.

The management afterwards is, occasional weeding, sweeping, and good rolling, once or twice a week, especially in the advanced part of spring, and all summer; and also occasionally in winter, in dry open weather; and when the surfaces become very foul, or over-run with small weeds or moss, as is often the case, they must be broken up in spring, and turned the surface to the bottom, and the bottom to the top, by which the weeds and moss will not only be buried, but the walks appear as fresh as when new laid. The custom of breaking up gravel-walks in the beginning of winter, and laying them up in rough ridges, to destroy weeds and moss, is not eligible for general practice, or only occasionally, where any walk is exceedingly overrun; it is mostly more advisable to permit all the principal gravel-walks to remain undisturbed, at least till the spring, when, if it appear necessary, the whole may be broken up, regularly turned, and re-laid in a neat manner.

The turning of gravel is a sort of slight digging, the foul surface being turned down, and the fresh up; some have it performed regularly once a year in the spring, in order to preserve the colour. In these cases, the laying, raking, and rolling, are performed the same as in the first constructing the walks.

The rolling should be performed once a week at least in summer, and if two or three times the more beautiful the walks will appear, and it will tend greatly to destroy weeds and moss; it is mostly a rule among gardeners to sweep and roll every Saturday. During the summer, it is of much advantage to give a good rolling after rain, which affords a compact smooth surface, and preserves the walks in good order.

GRAVEL, in *Geology*, is a term properly applied to those fabulous soils, or assemblages of worn and rounded stones, which are found scattered on the surface of the earth, in almost all situations. It is an essential character of gravel, that it shall contain rounded stones extraneous to the place where they are found, otherwise the breccia, rubble, and loosened rocks and strata near the surface, owing to the action of air, wet, and frosts, &c. will be confounded with it, as too often has happened, in the descriptions of countries. The earthy and smaller matters found among gravels, vary in different situations, in all degrees from clay to sand: and yet, if such alluvial mixtures contain rounded stones, and fragments with evident marks of attrition on them, they should, in describing such soils, all be denominated gravel, adding other words to distinguish the nature and quantity of their earthy mixtures: where rounded stones only are found, with little else among them, as on the sea beach often, and in some gravel-pits, such may be denominated very clean gravel; if a small admixture of sand, loam, (a mixture of sand and clay,) or clay, be found among the stones, such may be denominated clean sandy, clean loamy, or clean

clayey gravel: where a considerable portion of the mass is sand, loam, or clay, such should be called sandy, loamy, or clayey gravel: and lastly, where the earths greatly predominate, the terms very sandy, very loamy, or very clayey gravel should be used; or in place of these last, in extreme cases, alluvial sand, alluvial loam, or alluvial clay may be substituted: the last of which terms would apply to the horizontal earthy deposits or meadow soils, by the sides of rivers, the mud of lakes, &c. We have here made use of the term alluvial, in its strict and proper sense, as denoting matters worn, moved, dispersed, mixed, and deposited in water, in distinction from the regular or undisturbed matters of the terrestrial strata: which, though they shew evident marks of having been deposited in a fluid, the perfect homogeneity of each lamina of the strata, and their vast extension, without rude or accidental mixtures, shew that the laws which governed the two kinds of terrestrial deposit, were not less distinct and marked, than are the processes of the precipitation of matters before mechanically mixed and suspended in a fluid, and the crystallization of substances from menstria super-saturated therewith. During the deposition of the strata, all was tranquil and quiet, except the movements of animated beings, which occupied successively the vast subaqueous plains of strata: during the formation and deposition of the gravels, of all descriptions, all was violence and confusion, and apparently so continued for a long period of time.

No problem is of more practical and theoretical importance in geology, than whether gravel is any where found under regular and undisturbed strata? Were the decision of this question to be referred to the opinions of writers on geology, mineralogy, &c. there would be little room to doubt, from their description, that such is sometimes, nay frequently, the case; but Mr. William Smith, from having devoted great part of twenty years to the accurate discrimination of stratified and alluvial matters, on the principles above stated, after examining vast numbers of the deepest and most extensive wells, shafts, mines, quarries, &c. and conversing with quarrymen, miners, &c. who collectively have made an almost infinite number of observations, is decidedly of opinion, that no such case can be pointed out in England. It is true, that sandy, loamy, and clayey masses occur, with a very few rounded or broken and mixed stony fragments among them, so that the nicest discriminations are necessary to distinguish such, in some places, from stratified sand, loam, (or natural brick-earth) or clay; and under great thickness of such doubtful masses, beds of rounded and mixed stones are found, sometimes at very considerable depths, but in all such instances, the doubtful character has continued from the very surface downward, to such gravel-beds, and no where are regular strata of stone, clay, or sand found upon even these doubtful masses, when due caution is used in making and extending the observations. It is true also, that there are, in various parts of the British series of strata, siliceous, or grit-stone beds, and rocks, composed of distinct grains of flint, or crystallized quartz, of all sizes, from such as require a glass for viewing them, to others the size of a man's fist; and in several instances, contrary to the more common case, of small and sizeable, or uniform grains, which distinguish most of our grit-stones, there are beds in which grains, as fine as possible, are mixed with the largest mentioned above, and have, in the cliffs and places where these coarse stone-beds, or loose blocks of them, are seen exposed, so exactly the appearance, at first sight, of gravel-rock, or indurated sandy gravel, that it is no wonder they should have been so generally classed with the gravels. Those, however,

who, like Mr. Smith, and the writer of this article, will be at the pains to trace the blocks of coarse stone alluded to, to their natural bed, and to examine the newly cut, or broken faces of them, and their beds and accompanying strata, and of comparing them with the heterogeneous mixtures and uncertain and irregular stratification of the real gravel-rocks, of which there are great tracts in Nottinghamshire, Derbyshire, Leicestershire, Staffordshire, Cheshire, and others of the midland counties, in some places of immense thickness, will see abundant cause for distinguishing even the coarsest and most irregular of our grit-stone strata, from the superficial gravel-rocks above-mentioned, and, indeed, from alluvial, or water-worn mixtures of any kind. And such observers will be struck with surprize, that such a regular and constant law, as seems to have regulated the formation of grains of siliceous, of all the sizes mentioned, should not have been observed and resorted to, for explaining the formation of coarse as well as fine grit-stones, and have guarded against our confounding them with the water-worn gravels. Accumulations of gravel are to be distinguished into native and foreign, according as the pebbles and earth and extraneous bodies among them, can be referred to known and adjacent strata, or consists of stones and earths not elsewhere found, or but in very distant countries. For it will be found, that except on the sea shore, where the waves continually carry away, and again throw up the stones, which fall from, or are washed out of the marine cliffs, that the gravel of no spot corresponds with the strata on which it is lodged, and if in any situations in land this should seem to be the case, it will probably be found, that those strata extend far to the east or south-east of the place where their alluvial remains are lodged, and the circumstances appear to be explainable, on the principle of a general moving of native alluvia from the south-east quarter towards the north-west quarter, as observed in the Philosophical Magazine, vol. xxxv. p. 135. It is a remarkable fact, that all the very coarse, and irregular grit-stone strata, which have been noticed by the writer of this article in England, precede or occur beneath a series of carboniferous strata, or coal-measures; the lowest being found in the first and third grit rocks of the great Derbyshire denudation, and the others occur, both above and below the grey lime rock, which forms the floor and border of the great South-Wales coal-field (Phil. Trans. 1806), also the floor and edges of the forest of Dean coal-basin, and the western edge of the Somerset and Gloucester, or Bath coal-field, the northern edge of the Newcastle-under-line, or pottery coal-field, &c. And which fact it seems to be that Mr. Kirwan alludes to, under the name of semiprotolite in some of the cases mentioned pages 257, 293, 300, 307, 312, and 336, of his "Geological Essays:" it is plain, however, that these coarse grit-stones, under our coals, do not indicate the near approach of the fundamental rock of granite, as Mr. Kirwan would have us believe. We cannot close this article, without again adverting to the importance of accurately discriminating the alluvia found on different parts of every country, and of tracing their connection with the regular and continuous masses of strata on which they rest, and from whence they have been torn. Much information on the alluvia and strata of the midland counties of England will be found in Mr. Farey's Report on Derbyshire.

GRAVEL *Rock*, signifies a concreted or indurated mass of sandy GRAVEL, (see that article,) and is carefully to be distinguished from the coarse grit-stone strata, which it often closely resembles.

GRAVEL *Fossils*, is a term applied to such reliquia, or extraneous fossils, as are found in a rounded or worn state, or lodged among gravel, or alluvial mixtures, the ruins of

abraded and worn strata. See our article COAL, where the distinctions between this and other classes of extraneous fossils are explained.

GRAVEL, in *Medicine*, the popular term for the disorder occasioned by the formation of small calculous, or sand-like concretions in the kidneys and bladder. It is the *Nephralgia arvensis* of Sauvage; (see his Nosol. Method. Class VII. Genus XXV spec. 2.) and to be distinguished from the nephralgia *calculosa* of the same nosologist, in which larger calculi, or *stones*, are formed and impacted in the kidneys, ureters, or bladder.

The symptoms which indicate the presence of gravel in the kidneys, or in the passages from the kidneys to the bladder, called the ureters, are chiefly a severe pain in the loins, which is often accompanied by a sense of numbness, extending down the thighs of the side affected, with a retraction of the testicle in the male, and with a sickness of the stomach, often amounting to vomiting. During the passage of the small calculus through the canal of the ureter, the distension and irritation occasioned by the calculus, especially if its surface should be rugged and uneven, excites those symptoms in a more or less severe degree, or for a longer or shorter duration, according to its size and form; and they suddenly cease when it has entered the bladder. Pain is again excited in the urinary organs, when the calculus either lies over the aperture, or enters the canal of the urethra, and a pain and difficulty of passing the urine is excited. These symptoms, attending the transit of a small stone from the kidney, or its expulsion from the bladder, constitute what is usually called a fit of the gravel. The more common forms of the disease, however, consist in the formation of a sort of sandy matter, of a red colour, which impedes the free passage of the urine, and occasions considerable pain in the attempt, as well as an aching pain in the loins, through the sympathy of the kidneys with the bladder. A whitish mucous matter is sometimes discharged with the urine, under both these forms of the disorder, probably from the irritation excited in the secreting vessels, that open on the internal surface of the bladder: the passage of the small calculi occasionally causes a laceration of the small blood-vessels, and bloody urine is therefore discharged.

The little calculi, excited in those cases, are sometimes of a bright red colour, and consist, as well as the red sand which passes with the urine, or is deposited from it, of the uric or lithic acid in a concrete state.

The gravel is a disease chiefly of advanced life. It is common in gouty habits, in which it often alternates with the paroxysms of gout. It has been observed, too, that it descends by hereditary transmission, like that disease; and that of the children of gouty parents some have been attacked with the gravel, while others have had the gout. It is a curious fact, also, that the concretions, called chalk-stones, which are deposited in the joints in the gout, consist of the same substance as these gravelly concretions, viz. the uric acid. It is to be distinguished from the rheumatic affection of the loins, called lumbago, by the sickness which attends the more severe cases, the numbness of the thigh and retraction of the testicle, as well as by the mucous or bloody urine, the pain and difficulty of passing it, and the appearance of the sandy sediment in it.

Chemistry has enabled the physician to administer great relief to the sufferings occasioned by gravel. The discovery, by chemical experiments, that the substance of these calculous and fabulous concretions is an acid, and therefore capable of solution in or combination with alkaline substances, led to the administration of the alkalies internally, as remedies for the disease: and, although it has not been found,

that the larger stones of the bladder are dissolved or diminished by the action of alkaline medicines, yet the smaller concretions appear to be prevented from forming, and great relief from the pain and irritation, under all the varieties of concretion, is produced by the use of them. Perry's solvent, Mrs. Stephens' medicines, and Chittick's Receipt for the stone, are all of the alkaline class. It is probable that these alkaline medicines operate principally on the fluids in the first passages, by neutralizing the acids occasioned by indigestion, rather than by passing in the circulation, and combining with the uric acid in the kidneys or bladder. This would appear, partly from the fact, that the carbonated alkalis are equally or even more beneficial than the pure or caustic alkalis, in relieving the symptoms of stone or gravel; but it is principally proved by a circumstance, recently ascertained by the experiments of Mr. Home and Mr. Brande, that the absorbent earths, especially magnesia, are considerably more efficacious in relieving those symptoms, and in diminishing the quantity of uric acid in the urine, than the alkalis themselves. The magnesia is to be given in moderately large doses, two or three times a day; and if it proves purgative to the bowels, a few drops of the tincture of opium may be added to it. (See *Philosoph. Transact.* part i. for 1810.)

Of the alkalis, it would appear that the potash is, on the whole, more beneficial in these complaints than the soda: the pure or caustic potash may be given freely, beginning with doses of fifteen or twenty drops, and gradually increasing it, well diluted with any thin drink; and it may be continued for a considerable time with perfect safety. But the carbonate of potash is not less useful, and, especially when dissolved in water saturated with carbonic acid gas, it is more agreeable, and probably more efficacious. The efficacy of these acidulous alkaline waters was at first indeed attributed to the carbonic acid which they contain, and not to the alkali. (See a Medical Commentary on Fixed Air, by Dr Dobson.) The soda water acidulated by the same gas operates in a similar way, and is another agreeable mode of taking the medicine. Lime-water is likewise possessed of some remedial powers, but is less efficacious than the alkaline water.

All these aqueous liquors operate in some measure, perhaps, upon another principle; that of increasing the quantity of fluids which pass through the urinary organs, and thus of diluting the irritating uric salts, and consequently diminishing the distress which they occasion: and they may likewise operate negatively, by rendering the patient unable to drink the usual quantity of wine or other strong liquors. Other matters, which tend to increase the flow of urine, seem to relieve the symptoms of gravel, upon the principle of dilution; especially small doses of the nitrous æther, or spiritus ætheris nitrosi, of the pharmacopœias.

When extreme pain is excited, either by the passing of a small concretion along the canal of the ureter or of the urethra, opiates will afford a temporary relief to the sufferings of the patient, and will perhaps aid in relaxing any spasmodic contraction that may take place in these passages, and thus expedite the passage of the calculus. The same object may be promoted by the use of the warm bath, by fomentations to the loins and pubes, and by warm glysters.

For the modes of relieving the symptoms, connected with the presence of the larger calculi of the bladder, and of extracting these concretions by surgical means, see *STONE*:—see also *NEPHRALGIA* and *NEPHRITIS*.

GRAVELAINAS, in *Geography*, a town on the S.W. coast of the island of Negroponte, on the site of the ancient Eretria; 10 miles S. E. of Negroponte.

GRAVELINES, a sea-port town of France, in the department of the North, and chief place of a canton in the district of Bergues, situated in the English channel, at the mouth of the river Aa. Although it is not large, it is well fortified with battions, half-moons, and horn-work, and the adjacent country is intersected by canals, one passing to Dunkirk by Bourbourg, and another directly to Bergues. It was built in 1160, and ceded to France by the peace of the Pyrenées; 9 miles W.S.W. of Dunkirk. N. lat. 50° 59'. E. long. 2°.

GRAVELLANO, a town of Italy, in the department of the Gogna; 30 miles N. of Novara.

GRAVELLING, among *Farriers*, a disorder incident to travelling horses, occasioned by little gravel-stones getting in between the hoof and the shoe, which, settling to the quick, fret and fester the part.

It is cured by pulling off the shoe, drawing the place to the quick, picking out all the gravel, and poulticing the foot, rather than stopping it, according to the old practice, with horse-grease and turpentine poured in hot.

GRAVELLY LAND, a term applied to such land as rests upon a sub-stratum of the gravel kind, or which is much intermixed with that sort of material. This sort of land is generally light and dry when under the plough, but apt to burn in the summer season, when in the condition of grass.

The manures should be adapted to the particular nature of these lands; but where they are of the more light descriptions, they may be greatly improved by the use of marle, loamy clay, chalk, mud, and other similar matters, as well as different sorts of earthy composts. See *SOIL*.

GRAVELLY Soil, a term signifying that sort of soil, which is chiefly constituted of gravelly matters. See *SOIL*.

GRAVEN, in *Geography*, a town of Norway, in the diocese of Bergen; 42 miles S.S.W. of Bergen.

GRAVENAU, a town of Bavaria; 20 miles N. of Passau. N. lat. 48° 48'. E. long. 13° 22'.

GRAVENWERT, a town of Bavaria; 15 miles N. of Amberg.

GRAVER, a steel instrument, serving to engrave on metals. The graver consists of four sides or faces, and the point usually terminates in a lozenge: in some it is round, and in others square. The round point is best for scoring lines, the square for cutting broad and deep, and the lozenge for more delicate and fine strokes and scratches. Le Bossé recommends those of a form betwixt the square and lozenge. See *ENGRAVING*.

The gravers should be made of the best steel, which must be drawn out into small rods with a charcoal fire. These rods, after having been cut into the proper lengths for gravers, should be softened, by heating them in a charcoal fire, and suffering them to cool very slowly: let them next be filed into the desired form, and brought back to a hard temper by heating them red-hot, and in this state dipping their ends into soft soap. This should be done in a perpendicular direction; for, if they be turned in the least degree obliquely, the graver will warp and be crooked. If the temper of the graver be too hard after this treatment, and prevent the whetting it properly to an edge, it may be softened, by laying its end on a large burning piece of charcoal till it begins to grow yellow, and then thrusting it into a lump of tallow, or dipping it in water; but if water be used, the graver must not be too hot. It may be known whether the graver be tempered to a proper hardness by touching the edge of it with a file, which, if any effect attends it, proves the temper to be too soft. The best proof of too great hardness is the breaking of the point

point in engraving; after which, if a new edge be made by whetting the graver, it will be frequently found very good without any other alteration. Handmaid to the Arts, vol. ii. p. 56.

The other end is fitted into a wooden handle.

Besides engravers, the seal-cutters, lock-smiths, gun-smiths, gold-smiths, armourers, spurriers, &c. likewise make use of gravers.

GRAVEROL, FRANCIS, in *Biography*, was born at Nismes in 1635. He was educated for the profession of the law, and practised, as an advocate, in the parliament of Touloufe, and in the presidial chamber of Nismes, and as director and secretary of the academy in the latter place. He was not only well versed in the studies connected with his profession, but deeply read in subjects of general literature, and particularly distinguished for his knowledge of medals and inscriptions. In religion he adhered strictly to Calvinistic principles, which impeded his advancement in life, and at length involved him in persecution. To avoid the lash of cruel laws he retired to Orange, but, not thinking himself safe there, he attempted to pass into Switzerland. In his journey he was apprehended by the officers of the civil power, and thrown into prison in the citadel of Montpellier. He was, after a long confinement, liberated, and died in the year 1694. His works consist of several dissertations on particular medals, and other monuments of antiquity. His "Observations on the Arrests of the Parliament of Touloufe," in 4to. were much esteemed. He was well known to all the learned in Europe, and was admitted a member of the Ricovrati at Padua. At his death he had in hand some other literary works. Moreti.

S'GRAVESAND, WILLIAM JAMES LE, in *Biography*, was born at Bois-le-Duc in the year 1688. Having received the elements of learning at a common school, he was sent to Leyden to study the civil law, but he soon exhibited a decided taste for philosophical and mathematical studies, which he determined to pursue in preference to the learning of the courts. He produced, when he was only eighteen years old, an excellent "Essay on Perspective," which gave him a considerable reputation among the mathematicians of the age in which he flourished. In 1707 he took his doctor's degree, quitted the university, and settled at the Hague, where he practised at the bar, and cultivated an acquaintance with learned men. He joined some other persons in conducting a periodical work, entitled "Le Journal Litteraire," which was continued without interruption from the year 1713 to 1722. S'Gravesand contributed to it the original dissertations relating chiefly to geometry and physics. Among the discourses most worthy of notice, and which were original pieces of his own composition, were the following, "Remarks on the Construction of Pneumatical Engines;" and "An Essay on the Collision of Bodies," which was attacked by Dr. Clarke and other learned men, on account of its opposing the principles of the Newtonian philosophy. In 1715 the States General sent an embassy to England, to congratulate king George I. on his accession to the throne of Great Britain. S'Gravesand was on this occasion appointed secretary to the persons composing this body, and during his stay in London, he became intimately acquainted with sir Isaac Newton, and was, upon the recommendation of that great man, admitted a member of the Royal Society. Upon his return to Holland, he was appointed professor of mathematics and astronomy at the university at Leyden. He immediately undertook to teach and illustrate the Newtonian philosophy to the students of the university, and in 1734 he had the additional professorship of philosophy conferred upon him.

Vol. XVI.

So great were his exertions in the several duties of his office, and in preparing for publication his several works on the sciences, that he injured his constitution, and finally sunk under his labours in 1742, when he was only fifty-four years of age. His principal publications were: (1) "Physicæ Elementa Mathematica, Experimentis confirmata, sive Introductio ad Philosophiam Newtonianam," which consists of the author's lectures: (2) "Matheseos Universalis Elementa," containing a system of algebra for the use of students, with a commentary on Newton's Universal Arithmetica: (3) "Philosophiæ Newtonianæ Institutiones," which is an abridgment of his Elements of Physics: (4) "Introductio ad Philosophiam, Metaphysicam, et Logicam continens." His mathematical and philosophical works, excepting the first article, were collected and published at Amsterdam, in 2 vols. 4to., with an account of the life and writings of the author. The private character of S'Gravesand was highly respectable and amiable: his morals were exemplary, and he was beloved for his generosity, benevolence, and obliging manners. He was consulted by the ministers of the republic on all matters of finance, and he was of great service to them in deciphering and detecting the secret correspondence of their enemies.

GRAVESANDE, in *Geography*, a town of Holland, distant about four miles from the sea, six miles W.S.W. of Delft.

GRAVESEND, a town in the hundred of Toitington, in the county of Kent, England, consists of several streets, built on a declivity leading to the Thames; and is partly situated in the parish of Milton, which adjoins to that of Gravesend on the east side. The early prosperity of this town received a considerable check in the reign of Richard II., when the French and Spaniards failed up the Thames in galleys, plundered and burned many of the houses, and took a great number of the inhabitants prisoners. To alleviate the loss, the king was induced to give the townspeople a legal claim to the water-passage to London, by a grant to the abbey of St. Mary le Grace. In the tenth of queen Elizabeth the parishes of Gravesend and Milton were incorporated by her letters patent: but the principal charter was granted by Charles I. in the year 1632. The chief officer, who had before this time been called the portreeve, was by this charter constituted mayor; and in him, twelve jurats, twenty-four common councilmen, a seneschall or high steward, and other inferior officers, the government of the town is now vested. The liberty of holding two additional weekly markets on Wednesdays and Saturdays, and an annual fair of four days, was also granted at the same time, together with a full confirmation of the exclusive privilege, conferred by king Richard, of conveying passengers and goods by water to the metropolis. In August 1727 the greater part of the town was destroyed by a fire, which commenced in a barn-yard adjoining to the church, and consumed that fabric, with about 120 houses, besides out-buildings, stables, &c. The present church, which is dedicated to St. George, was erected on the old site in the year 1732, under an act of the fourth of George II. which appropriated 5000*l*. for that purpose, from the duties on coals and culm, levied under the acts of the ninth and tenth of queen Anne, for building fifty new churches in or near London.

Gravesend has been greatly improved since the year 1764, when a new town-hall, having an area beneath where the poultry market is kept, was erected by the corporation. In 1767 a new wharf, crane, and causeway, were made, the expence of keeping which in repair is defrayed by small tolls for cranage and wharfage. The increase of the trade,

population, and buildings has been particularly rapid since the middle of the last century. Under the late act, the number of inhabitants was returned at 2483, and that of houses at 412; yet these numbers are very incorrect, and the population can scarcely amount to less than 4000, nor the number of houses be fewer than 700. Most of the inhabitants are engaged in maritime pursuits or employments. A small manufactory for cables and ropes is carried on here; and about the year 1780, a yard for ship-building, which had long been disused, was hired by a quaker, named Cleverly, and several men of war and frigates, besides smaller vessels, have been built here. About eighteen or twenty smacks find employment in the cod and haddock fishery; and most of the Dutch turbot vessels lie off this town, and send their cargoes to the London markets in small boats. Most of the East and West India trade, and, indeed, of the outward-bound ships in general, are supplied with live and dead stock at Gravesend; and also with vegetables; about eighty acres of ground in the two parishes being cultivated for that purpose, and for supplying the London markets with asparagus, which is remarkable for its size and fine flavour. Gravesend is situated 22 miles E. from London. Hasted's History of Kent, vol. i. 8vo. Beauties of England and Wales, vol. vii.

GRAVESEND, a township and village of America, in Long island, New York, seven miles from the city, containing 489 inhabitants.

GRAVIMETER. See HYDROMETER.

GRAVINA, DOMENICO DA, in *Biography*, who flourished in the fourteenth century, was a native of Gravina, in the kingdom of Naples. He was by profession a notary, but in literature an historian. He seems to have taken an active part in the civil wars which agitated his country at that period, and on account of the side which he espoused, he was stripped of all his property, and driven into exile with his wife and children. He wrote a history of Naples in the Latin language, and likewise a history of the transactions in that part of Italy during his own times, from 1330 to 1350. A fragment of this work only is in existence, the beginning and end being lost; it is, however, reckoned a valuable document for the fidelity of the narration, and is to be found in Muratori's collection of Italian historians.

GRAVINA, JOHN VINCENT, was born in 1664 at Rogiana, a castle in Calabria. He enjoyed all the advantages of a very liberal education, and became well versed in the learned languages; geometry, physics, history, and antiquities. He also made himself acquainted with the principles of theology. Having thus attained to a general knowledge of the learning of the times, he went to Naples to study the civil and canon law. After this he passed to Rome, and lived with Paul Coardo of Turin. He was one of the original founders of the academy of Arcadi, and had the charge of drawing up their laws in the style of the Roman tables. He arrogated to himself the merit of having devised these laws, a circumstance which involved him in a quarrel with the other members, particularly with Crescimbeni, the founder of the society, so that these two learned men were for several years at the head of two factions which divided the body. In 1698, he was nominated professor of civil law at the college of Sapienza, and, in five years after, he succeeded to the chair of the canon-law. His method of instruction was excellent; he avoided trifling verbal disputes, and mere scholastic speculations, and entered into the spirit of the laws, illustrating their theory by observations drawn from ancient writers, and by a criticism founded on his extensive erudition. This mode of

instruction excited much public attention, but the haughtiness of his temper prevented him from being popular. By the public at large, his manners could be no obstacle to the celebrity of his writings, and his reputation daily increased. His works were numerous, and the subjects on which he treated very various. His "Origines Juris Civilis," has been ever esteemed a classical performance, lucid in its arrangements, and replete with solid and very important learning. This was first published at Leipzig in 1708, and afterwards there was a more correct edition of it in 1713; to the latter impression was subjoined a treatise "De imperio Romano," esteemed a master-piece, though not free from error. Gravina undertook to establish a poetical code, for which purpose he wrote two books, entitled "De la Region Poetica;" one entitled "Della Tragedia," and a treatise "De Institutione Poetarum." Another work was printed contrary to his inclination; this was his "Institutes of Civil and Canon Law," which he intended to have revised and given in a corrected and augmented form. In 1714, Gravina re-visited his native country, where he staid about two years and then returned to Rome. He was preparing to depart for Turin, whither he had been invited by the duke of Savoy, in order that he might take the general direction of the learned institutions, when he was seized with an illness which carried him off in 1718, in the arms of his beloved pupil Metastasio, whose poetical talents he first discovered and cherished, and whom he left heir of all his property out of Calabria. Gravina was of a contentious disposition, excessive in his praise of persons whom he esteemed, and also in his censure of those who offended him; he was arrogant, from a high opinion of his own superiority. This created him many enemies, with whom he was perpetually at war. Of his great learning there can be no doubt; but with respect to his poetical talents, it has been remarked, that he was more successful as a legislator than as a practiser in the art; for his five tragedies written on the model of the ancients were not favourably received by the public, and the author's angry expostulation, proving that they ought to have been applauded as usual, was totally inefficacious. Moreri.

GRAVINA, in *Geography*, a town of Naples, in the province of Bari, the see of a bishop, suffragan of Acerenza, 24 miles S. of Trani.

GRAVINA'S *Islands*, a range of islands in the N. Pacific ocean, each from 20 to 50 miles in circumference, interspersed with some islets, stretching N. W. to S. E. about 40 miles, between the duke of Clarence's strait and the canal of Revilla Gigedo. N. lat. 54° 52' to 55° 27'. E. long. 228° 24' to 229° 5'.

GRAVING, the act or art of cutting lines, figures, and other designs, on metals; more properly called *engraving*; which see.

GRAVING, in the *Sea Language*, is the bringing a ship a-ground, and then burning off with furze, reed, or broom, all the filth and foulness that stick to her bottom without board, in order to pay her anew. See BROOMING and CARENING.

GRAVING-dock, or *Dry Dock*, is a place from which the water can be let out or pumped, after ships and boats are floated into it to be cleaned or repaired; sometimes, graving-docks are above the level of the water, and boats are dragged upon inclined planes into the same. By the sides of tidal rivers or harbours these are constructed with strong close gates meeting in an angle to shut out the tide; which gates are furnished with a small sluice or valve for emptying or filling the dock, when a vessel has entered at high water,

or is about to leave the dock at such time. See DOCKS, and CANAL.

GRAVISKOL, in *Geography*, a fortress of Russia, in the government of Kolivan, on the Irtysh; 240 miles S. S. W. of Kolivan. N. lat. $50^{\circ} 15'$. E. long. $75^{\circ} 14'$.

GRAVITAS, Βαρύτης, in the *Ancient Music*, was used to signify a sound produced by the remission or falling of the voice. Gravitas differs from remission, as the effect from the cause.

GRAVITAS is also used to denote the state of a woman going with child. See PREGNANCY.

GRAVITATION, the exercise of gravity, or the action which a body exerts on another body by the power of gravity. It is sometimes distinguished from gravity. Thus, Maupertuis takes gravity for that force by which a body would fall to the earth supposed at rest; and gravitation for the same but diminished by the centrifugal force. See figure of the earth determ. p. 206 of Mr. Murdoch's translation.

It is only gravitation, or gravity thus blended with the centrifugal force, that we can measure by our experiments. However, methods have been found to distinguish what remains of primitive gravity, and what has been destroyed by the centrifugal force.

It is one of the laws of nature, discovered by sir Isaac Newton, and now received by most philosophers, that every particle of matter in nature gravitates towards every other particle; which law is the hinge on which the whole Newtonian philosophy turns. See NEWTONIAN *Philosophy*.

What we call *gravitation*, with respect to the gravitating body, is properly called *attraction* with respect to the body towards which the other gravitates.

The planets, both primary and secondary, and also the comets, do all gravitate towards the sun, and towards each other; and the sun towards them: and that in proportion to the quantity of matter in each.

The Peripatetics, &c. hold, that bodies only gravitate when out of their natural places, and that gravitation ceases when they are restored to the same, the intention of nature being then fulfilled. The final cause of this faculty, as they maintain, is only to bring elementary bodies to their proper place, where they may rest. But the moderns shew, that bodies exercise gravity even when at rest and in their proper places.

This is particularly shewn of fluids; and it is one of the laws of hydrostatics demonstrated by Mr. Boyle and others, that fluids gravitate *in proprio loco*, the upper parts pressing on the lower, &c.

For the laws of gravitation of bodies in fluids specifically lighter, or heavier than themselves, see *Specific GRAVITY, FLUID, &c.*

GRAVITATION, *Theory of Universal*. Newton is very justly considered as the author of this great hypothesis, though several preceding and cotemporary writers seem to have formed conjectures on this subject that did not differ very widely from the truth. From the time of Kepler it had every day become more and more evident, that some mechanical cause had a very material influence on the laws of the planetary motions. The problems which the discoveries of that great astronomer had left for future ages to solve were these: Why do the planets and satellites describe *elliptic* orbits, the former round the sun, the latter round their primary planet? Why is the centre of motion in the focus rather than in the centre of the ellipse? Why are equal areas described in equal times about the centre; and what can be the cause of that remarkable law that is found

constantly to subsist between the distances of the planets from the sun and the times of their revolution?

Des Cartes first attempted a solution of these difficulties, by suggesting a simple mechanical cause. He supposed the existence of a subtle fluid, which, though imperceptible to the senses, was in constant motion round the sun, and that it involved the planets in its powerful agency. This theory, on its first enunciation, does not seem deficient in plausibility, but upon more careful examination, it is found incapable of explaining any one astronomical phenomenon correctly, and indeed the action of such a fluid would produce effects in many cases exactly the reverse of what it was intended to explain. The spirit of rational enquiry that now began to be exerted on all philosophical subjects, rendered this theory of short duration.

Kepler at a much earlier period had formed more correct opinions on this subject than Des Cartes: indeed he seems to have had a very distinct idea of the existence of gravitation, though he never could have been aware of its agency being so extensive, or that it would ever explain in so satisfactory a manner as it has done his own great discoveries. Gravity, he says, in his "Commentary on Mars," is only a mutual and corporeal affection between similar bodies. Heavy bodies do not tend to the centre of the world, but to that of the round body of which they form a part; and if the earth were not spherical, heavy bodies would not fall towards its centre, but towards different points. This conjecture has been fully verified by theory and observation; the earth appears not to be a perfect sphere, and accordingly a plumb-line does not tend to the exact centre of gravity of the whole earth, but to a point considerably remote from it, as has been explained under DEGREE, EARTH, *figure of*, &c. &c.

Kepler likewise strongly suspected that the attraction of the moon was the cause of the tides, and that the lunar irregularities arose from the action of the earth and sun. Perhaps, from the earliest times, some indistinct conceptions are to be occasionally traced in different authors concerning the existence of this universal principle.

Fermat, who preceded Kepler, affirmed, that the weight of a body was the sum of the tendencies of all its particles to all the particles of the earth; and Kepler was of opinion that two bodies left alone in free space would approach each other with velocities inversely proportional to their masses or quantities of matter.

A short time previous to the great discovery of Newton, Dr. Hooke made a still nearer approach to the truth. At a meeting of the Royal Society, May 3, 1668, he expressed himself in the following manner: "I will explain a system of the world very different from any yet received, and it is founded on the three following positions:

1. That all the heavenly bodies have not only a gravitation of their parts to their own proper centres, but that they also mutually attract each other within their spheres of action.

2. That all bodies having a simple motion will continue to move in a straight line, unless continually deflected from it by some extraneous force, causing them to describe a circle, an ellipse, or some other curve.

3. That this attraction is so much the greater as the bodies are nearer. As to the proportion in which those forces diminish by an increase of distance, I own I have not yet discovered it, although I have made some experiments to this purpose. I leave this to others who have time and knowledge sufficient for the task."

This is a very precise enunciation of a proper philosophical theory. The phenomenon, the change of motion, is con-

sidered as the mark and measure of a change of force, and his audience is referred to experience for the nature of this force. He had before exhibited to the society a very pretty experiment contrived to shew the nature of this force. A ball, suspended by a long thread from the ceiling, was made to swing round another ball, laid on a table immediately below the point of suspension. When the impulse given to the pendulum was nicely adjusted to its deviation from the perpendicular, it described a perfect circle round the ball on the table; but when the impulse was very great, or very small, it described an ellipse, having the other ball in its centre.

Hooke shewed that this was the operation of a deflecting force proportioned to the distance from the other ball. He added, that although this illustrated the planetary motions in some degree, yet it was not suitable to their case: for the planets describe ellipses, having the sun not in their centre but in their focus. Therefore they are not retained by a force proportional to the distance from the sun.

The exalted genius of Newton can suffer no diminution by the enumeration of the above opinions, for though the idea of such a principle as gravitation was not suggested first by Newton, yet so very obscure were the notions of even the most enlightened philosophers on this subject, that it had never been successfully applied to the explanation of a single astronomical phenomenon.

So intimately connected is this great discovery with the history of the human mind, that every known circumstance relating to it has been recorded with the greatest care. Dr. Pemberton relates that Newton, in the year 1666, having retired from Cambridge to the country on account of the plague, was there led to meditate on the probable cause of the planetary motions, and upon the nature of that central force that retained them in their orbits. It then occurred to him that possibly the same force, or some modification of the same force which caused with us a heavy body to descend with a certain velocity to the earth, might likewise retain the moon in her orbit by causing a constant deflection from a rectilinear path. Before, however, this conjecture could be put to the test of calculation, it was necessary that Newton should have formed some conditional hypothesis relative to the modification of the force with respect to the distance. That any agency emanating from a central point should decrease as the square of the distance from that point increases, is an hypothesis so natural, that we cannot be surprized that Newton should have selected it; but whether or not he had previously tried any other, or whether he had even at this time deduced it from the nature of the planetary orbits, does not now appear. The calculation which it was necessary to institute, we shall give with great minuteness in its proper place; it is therefore only necessary to remark at present, that it requires that the proportion between the radius of the earth and the lunar orbit should be exactly known. When Newton first attempted to verify this hypothesis, these requisite data had not been exactly determined, and a slight discordance between the result of the calculation and the supposed fact, induced him for a time to abandon his hypothesis. This circumstance has, with great propriety, been recorded as a striking instance of the cool and dispassionate frame of mind which this great philosopher preserved, at a moment when he had flattered himself with the hope of having discovered one of the most important secrets of nature.

Some few years afterwards he was again tempted to renew these calculations, as in this interval a degree of the meridian had been measured in France by Picard. This second attempt succeeded. It is related, that towards the

end of the calculation he became so much agitated, as to be obliged to request a friend to assist him in finishing it; and certainly a moment of greater importance in philology will never be recorded in the annals of science.

The computation which was made by Newton to determine the identity of the force of terrestrial gravity, with that which retains the moon in her orbit, is still a subject of great interest to astronomers, as they now reverse the process; and taking the theory of gravitation as admitted, they deduce from the same computation the distance of the moon from the earth. We shall give it in the words of La Place.

The force which at every instant deflects the moon from the tangent of her orbit, causes it to describe, in one second, a space equal to the versed sine of the arc which it describes in that time; since this sine is the quantity that the moon at the end of a second deviates from the direction it had at the beginning. This quantity may be determined by the distance of the earth, inferred from the lunar parallax in parts of the terrestrial radius; but to obtain a result independent of the inequalities of the moon, we must take for the mean parallax that part of it which is independent of these inequalities. This part is, according to observation, $50' 54''.9$, relatively to the radius drawn from the centre of gravity of the earth, to the parallel, of which the square of the sine of the latitude is equal to $\frac{1}{3}$. We select this parallel because the attraction of the earth, on the points corresponding to its surface, is at the distance of the moon, very nearly equal to the mass of the earth divided by the square of the distance from its centre of gravity. The radius drawn from a point of this parallel to the centre of gravity of the earth is 6369374 metres, from whence it may be computed the force which solicits the moon towards the earth causes it to fall $0''.00101727$ in one second of time. It will be shewn hereafter, that the action of the sun diminishes the lunar gravity $\frac{1}{33}$ th part. The preceding height must therefore be augmented $\frac{1}{33}$ th part, to render it independent of the action of the sun; it then becomes $0''.00102011$. But in its relative motion round the earth, the moon is solicited by a force equal to the masses of the earth and moon divided by the square of their mutual distance; therefore to obtain the height which the moon would fall through in one second, by the action of the earth alone, the preceding space must be diminished in the ratio of the mass of the earth to the sun, and of the masses of the earth and moon: but by the phenomena of the tides, it appears that the mass of the moon is equal to $\frac{1}{81}$ of that of the earth, multiplying therefore this space by $\frac{81}{7}$, we have $6''.00100300$ for the height which the moon falls through in one second by the action of the earth.

Let us now compare this height with that which results from observations made on the pendulum. Under the parallel above-mentioned the length of the pendulum vibrating seconds is equal to $3''.65706$: but on this parallel the attraction of the earth is less than the force of gravity by $\frac{2}{3}$ of the centrifugal force due to the motion or rotation of the earth at the equator; and this force is $\frac{1}{3}$ th part of that of gravity; the preceding space must therefore be augmented $\frac{1}{3}$ d part, to get the space due to the action of terrestrial gravity alone, which on this parallel is equal to the mass divided by the square of the terrestrial radius: we shall therefore have $3''.66553$ for this space. At the distance of the moon it should be diminished in the ratio of the square of the radius of the terrestrial spheroid to the square of the distance of the moon: for this purpose it is sufficient to multiply it by the square of the tangent of the lunar parallax, or $56' 55''.2$, this will give $0''.00100483$ for

GRAVITATION.

for the height which the moon should fall through in one second by the attraction of the earth. This quantity, derived from experiments on the pendulum, differs very little from that which results from direct observation of the lunar parallax; to make them coincide, it is sufficient to diminish the parallax $2'$, and to reduce it to $56' 53'' 3$. This is the parallax resulting from the theory of gravity, differing only $\frac{1}{100000}$ part from that derived from actual observation, to which La Place thinks it preferable, considering the exactness of the elements from which it is computed. It would be sufficient to diminish a little the mass of the moon to obtain, by this theory of gravity, the same parallax that is given by observation: but all the phenomena of the tides concur in giving this satellite a mass more considerable, and very nearly such as has been used in the above computation. But however that may be, the small difference between the two parallaxes is within the limits of the errors of observation, and of the elements employed in the calculation. It is then certain that the force which retains the moon in its orbit, is the terrestrial gravity diminished in proportion to the square of the distance.

Having thus shewn how the nature of the force which retains the moon in its orbit is investigated, it next remains to inquire if the same force of gravity pervades the rest of the solar system. The same great mathematician, above quoted, observes, that "of all the phenomena of the solar system, the elliptic motion of the planets, and of the comets, seems the most proper to conduct us to the general law of the forces by which they are animated.

Observation has shewn, that the areas described by the radii vectores of the planets and comets about the sun are proportional to the times. Now we see, in the article *CENTRAL FORCES*, that, for this to take place, the force which deflects the path of these bodies from a right line must constantly be directed towards the origin of their radii vectores. The tendency of the planets and comets to the sun is therefore a necessary consequence of the proportionality of these areas to the times in which they are described. To determine the law of this tendency, let us suppose that the planets move in circular orbits, which supposition does not greatly differ from the truth. The squares of their real velocities will then be proportional to the squares of the radii of these orbits, divided by the squares of the times of their revolutions. But, by the law of Kepler, the squares of these times are to each other as the cubes of their radii; the squares of the velocities are therefore as these radii. It has been shewn, that the central forces of bodies, moving in circular orbits, are as the squares of the velocities, divided by the radii of the circumferences described; the tendency, therefore, of the planets to the sun, is reciprocally as the squares of the radii of their orbits, supposed circular. This hypothesis, it is true, is not rigorously exact; but the constant relation of the squares of the times to the cubes of the greater axes of their orbits being independent of their eccentricities, it is natural to think it would subsist also in the case of the orbits being circular. Thus, the law of gravity towards the sun, varying reciprocally as the square of the distance, is clearly indicated by this relation: analogy would lead us to suppose that this law, which extends from one planet to another, should subsist equally for the same planet at its different distances from the sun; and its elliptic motion confirms this beyond a doubt. To comprehend this, let us attend to this motion, beginning at the departure from its perihelion. Its velocity is then at its maximum, and its tendency to recede from the sun surpassing its gravity towards it, its radius vector augments, and forms an obtuse angle

with the direction of its motion. The force of gravity towards the sun, decomposed according to this direction, continually diminishes the velocity till it arrives at the aphelion; at this point the radius vector becoming perpendicular to the curve, its velocity is a minimum; and its tendency to recede from the sun being less than its gravity towards it; the planet will approach it while describing the second part of its ellipse. In this part, the gravity towards the sun increases its velocity in the same manner as it before decreased it; and the planet will arrive at its perihelion with its primitive velocity, and recommences a new revolution, similar to the first. Now the curvature of the ellipse at the aphelion and perihelion being the same, the radii of curvature are the same, and, consequently, the centrifugal forces of these two points are as the squares of the velocities. The sectors described in the same time being equal, the aphelion and perihelion velocities are reciprocally as the corresponding distances of the planet from the sun; the squares of these velocities are therefore reciprocally as the squares of these distances; but at the perihelion and aphelion distance, the centrifugal forces in the osculatory circumferences are evidently equal to the gravity of the planet towards the sun, which is therefore in the inverse proportion to the squares of these distances. Thus the theorems of Huygens on the centrifugal force were sufficient to demonstrate the tendency of the planets towards the sun: for it is highly probable that this law, which extends from one planet to another, and which is verified in the same planet, at its aphelion and perihelion, extends also to every part of the planetary orbit, and at the same time to every distance from the sun. But to establish it in an incontestible manner, it was requisite to determine the general expression of the force which, directed towards the focus of an ellipse, would oblige the projectile to describe that curve. And it was Newton who demonstrated that this force was reciprocally as the square of the radius vector. It was essential also to demonstrate rigorously that the force of gravity towards the sun only varies in one planet from the same force in another, according to their different distances from it.

This great geometrician shewed, that this followed necessarily from the law of the squares of the periodic times being reciprocally as the cubes of the distances; supposing therefore all the planets at rest at the same distance from the sun, and abandoned to their gravity towards its centre, they would descend from the same height in equal times: this result should also extend to the comets, notwithstanding the greater axes of their orbits are unknown; for we have seen in the second book, that the magnitude of the areas described by their radii vectores, supposes the law of the squares of the periodic times proportional to the cubes of their axes.

A general analysis, which embraces every possible result from a given law, shews us that not only an ellipse, but any other conic section, may be described by virtue of the force which retains the planets in their orbits; a comet may therefore move in an hyperbola, but then it would be only once visible, and after its apparition would recede from the limits of the solar system, to approach other suns, which it would again abandon, thus visiting the different systems that are scattered in the immensity of the heavens. It is probable, considering the infinite variety of nature, that such bodies exist. Their apparition should be a very rare occurrence; the comets, we usually observe, are those which, having closed orbits, return, at the end of intervals more or less considerable, into the regions of space that are in the vicinity of the sun. The satellites tend also perpetually to the sun. If the moon was not subject to its action, instead of describing an orbit almost circular round the earth, it would soon abandon

GRAVITATION.

don it; and if this fatellite, and those of Jupiter, were not solicited towards the sun, according to the same law as the planets, perceptible inequalities would result in their motions which have not been recognized by observation.

The planets, comets, and fatellites are therefore subject to the same law of gravity towards the sun. At the same time that the fatellites move round their planet, the whole system of the planet and its fatellites is carried by a common motion, and retained by the same force, round the sun. Thus the relative motion of the planet and its fatellites is nearly the same as if the planet was at rest, and not acted upon by any external force.

We are thus conducted, without the aid of hypothesis, by a necessary consequence of the laws of the celestial motions, to consider the sun as the centre of a force, which, extending infinitely into space, diminishes as the square of the distance increases, and which attracts all bodies that are within the sphere of its activity. Every one of the laws of Kepler discovers a property of this attractive force. The law of the proportionality of the areas to the times shews us, that it is constantly directed towards the centre of the sun. The elliptic orbits of the planets shew that this force diminishes as the distance increases; finally, the law of the proportionality of the squares of the periodic times to the cubes of the distances demonstrates, that the gravity of all the planets towards the sun is the same at equal distances. This gravity may be called the solar attraction when it is considered as relative to the centre of the sun, towards which it is directed; for without knowing the cause, we may by one of those suppositions, common among geometers, imagine an attractive power residing in the centre of the sun.

The errors to which observations are liable, and the small alterations in the elliptic motions of the planets, leave a little uncertainty in the results deduced from the laws of motion; and it may be doubted if the solar attraction diminishes exactly in the inverse ratio of the square of the distance. But a very small variation in this law would produce a very perceptible difference in the motions of the planetary orbits. The perihelion of the terrestrial orbit would have an annual motion of $1^{\circ} 5'$ if we only increased by one ten thousandth part the power of the distance to which the solar orbit is reciprocally proportional; this motion is only $11''.6$ according to observation, and of this we shall hereafter see the cause. The law of the square of the distance is then, at least, extremely near, and its extreme simplicity should induce us to adopt it, as long as observations do not compel us to abandon it. At the same time we must not measure the simplicity of the laws of nature by our facility of conception, but when those which appear to us the most simple accord perfectly with observations of the phenomena, we are justified in supposing them rigorously exact.

The gravity of the fatellites towards the centre of their planet, is the necessary consequence of the proportionality of the areas described by their radii vectores to the times, and the law of the diminution of this force, according to the square of the distance, is indicated by the ellipticity of their orbits. But this ellipticity is hardly to be perceived in the orbits of the fatellites of Jupiter, Saturn, and Uranus, which renders the law of the diminution of the force difficult to ascertain by the motion of any one single fatellite; but the constant ratio of the squares of the times of their revolutions to the cubes of their distances, indicates it beyond a doubt, by demonstrating, that from one fatellite to another, the gravity towards the planet is reciprocally as the square of the distance from its centre.

This proof is wanting for the earth, it having but one fa-

tellite, but it may be supplied from the following considerations:

The force of gravity extends to the summits of the highest mountains, and the small diminution which it there experiences, leaves no doubt but that this force would be perceptible at much greater altitudes. Is it not natural to extend this to the moon, and to suppose that the force which retains it in its orbit, is its gravity towards the earth, in the same manner as the solar gravity retains the planets in their orbits round the sun? for, in fact, these two forces seem to be of the same nature; they both of them penetrate the most intimate parts of matter, animating them with the same velocities; for we have seen that the solar gravity solicits equally all bodies placed at equal distances from the sun, and that the terrestrial gravity also causes all bodies to fall through the same height in equal times.

A heavy body, projected with force horizontally from a great height, falls on the earth at a considerable distance, describing a curve, which is apparently parabolic; it will fall still further, if the force is greater, and supposing it about seven thousand metres in a second, it would not fall to the earth, but would circulate round it like a fatellite, setting aside the resistance of the air: for it has been fully shewn above, that, to form a moon of this projectile, it must be taken to the height of that body, and there receive the same motion of projection; and the identity of the moon's tendency to the earth, has been already demonstrated, by shewing that to obtain this tendency, it is sufficient to diminish the terrestrial gravity according to the general law of the variation of the attractive force of the celestial bodies: and we have seen, that the law of the diminution of gravity, which in planets, accompanied by several fatellites, is proved by a comparison of their periodic times, with their distances, is demonstrated for the moon, by comparing its motion with that of projectiles, at the surface of the earth.

The observations of the pendulum made at the summits of mountains, had already indicated this diminution of the terrestrial gravity; but they were insufficient to discover the law, because of the small height of the most elevated mountains, compared with the radius of the earth: it was requisite to find a body very remote from us, as the moon, to render the law perceptible, and to convince us, that the force of gravity on the earth is only a particular case of a law that pervades the whole universe.

Every phenomenon throws new light on, and confirms the laws of nature. Thus the comparison of experiments on gravity with the lunar motion shews us, that the origin of the distances of the sun and planets, in the calculation of their attractive forces, should be placed in their centres of gravity; for it is evident, that this takes place on the earth, whose attractive force is of the same nature as that of the sun and planets.

The sun, and those planets which are accompanied by fatellites, being thus proved to be endowed with an attractive force, varying inversely as the square of the distance, a strong analogy leads us to attribute the same property to the other planets. The spherical figure common to all these bodies, indicates that their particles are united round their centres of gravity by a force which, at equal distances, equally solicits them towards these points; but the following considerations leave no doubt upon this subject.

We have seen, that if the planets and comets were placed at the same distance from the sun, their gravity towards it would be in proportion to their masses: now, it is a general law in nature, that action and re-action are equal and contrary; all these bodies, therefore, re-act on the sun, and attract in proportion to their masses: they are therefore endow-

GRAVITATION.

dowed with an attractive force proportional to their masses, and varying inversely as the square of the distance. By the same principle, the satellites attract the planets and the sun according to the same law. This attractive property, then, is common to all the celestial bodies: it does not disturb the elliptic motion round the sun, when we consider only their mutual action; for the relative motion of the bodies of a system are not changed by giving them a common velocity: by impressing, therefore, in a contrary direction to the sun and to the planet, the motion of the first of these two bodies, and the action which it experiences on the part of the second, the sun may be considered as immovable, but the planet will be solicited towards it with a force varying reciprocally as the square of the distance, and proportional to the sum of the masses; its motion round the sun will therefore be elliptic. And we see by the same reasoning, that it would be so if the planet and sun were carried through space with a motion common to each of them. It is equally evident that the elliptic motion of a satellite is not disturbed by the motion of translation of its planet, nor would it be by the action of the sun, if it was always exactly the same on the satellite and the planet.

Nevertheless, the action of the planet on the sun influences the length of its revolution, which is diminished as the mass of the planet is more considerable; so that the relation of the square of its periodic time, to the cube of the major axis of its orbit, depends on its mass. But since this relation is nearly the same for all the planets, their masses must evidently be very small compared with that of the sun, which is equally free for the satellites with respect to their principal planets.

This we may readily suppose from their smallness.

The attractive property of the heavenly bodies not only belongs to them in a mass, but to each of their particles. If the sun only acted on the centre of the earth without attracting particularly every one of its particles, oscillations would arise in the ocean, infinitely more considerable and very different from those which we observe. The gravity of the earth to the sun, therefore, is the result of the gravity of all its particles, which consequently attract the sun in proportion to their respective masses; besides, each body on the earth tends towards its centre proportionally to its mass, it reacts therefore on it, and attracts it in the same ratio. If that was not the case, and if any part of the earth, however small, attracted another part without being attracted by it, the centre of gravity would move in space, in virtue of the force of gravity, which is impossible.

The celestial phenomena, compared with the laws of motion, conduct us therefore to this great principle of nature, namely, that all the particles of matter attract each other in proportion to their masses, and inversely as the squares of their distance.

Already we may perceive in this universal gravitation, the cause of the perturbations to which the heavenly bodies are subject; for the planets and comets being subject to the action of each other, they must deviate a little from the laws of the elliptic motion, which they would otherwise exactly follow, if they only obeyed the action of the sun. The satellites also, deranged in their motions round their planets by their mutual action, and that of the sun, deviate a little from these laws.

We perceive then that the particles of the heavenly bodies, united by their attraction, should form a mass nearly spherical; and that the result of their action at the surface of the body should produce all the phenomena of gravitation.

We see moreover that the motion of rotation of the celestial bodies should slightly alter their spherical figure,

and flatten them at the poles; and then the resulting force of all their mutual actions not passing through their centres of gravity, should produce in their axes of rotation similar motions to those discovered by observation. Finally, we may perceive why the particles of the ocean, unequally acted on by the sun and moon, should have oscillations similar to the ebbing and flowing of the tides. But these different effects of the principle of gravitation must be particularly developed, to give it all the certainty of which physical truth is susceptible.

It is in the universal application of this theory to all the known celestial phenomena, that the modern science of physical astronomy consists, a science which owes its origin to Newton, and which has been cultivated by every eminent mathematician, from the time of that great philosopher to the present day. It is to La Place that the merit must be given of having completed this theory, by shewing that there remains not a single phenomenon that it is not capable of explaining: he justly observes, that there is no question here of vague causes, which cannot be submitted to analysis, and which the imagination modifies at pleasure, to accommodate them to the phenomena. The law of universal gravitation has this inestimable advantage, that it may be reduced to calculation, and by a comparison of its results with observation, it presents the most certain method of verifying its excellence; and so far are we from having to fear that new observations will disprove this theory, we may be assured before hand that they will only confirm it more and more, and that its consequences are equally certain as if they had actually been observed.

The astronomical phenomena produced by the mutual gravitation of the heavenly bodies, will be found in the different parts of this work. As each subject will be particularly treated under its appropriate article, see *Figure of the Earth*; *Precession of the Equinoxes*; *NOTATION of the Earth's axis*; *PERTURBATION of the Planets, Moon, and Satellites*; *TIDES, LIBRATION of the Moon, &c.*

But as the investigation of laws by which particles of matter gravitate to spheres and other solids cannot with propriety be referred to any other article, and as it forms so very essential a part of physical astronomy, we shall enter on the subject very fully. The more simple and easy investigations of astronomy suppose the action to be confined to simple gravitating points; now as no such points exist in nature, it becomes requisite to consider the effect which an assemblage of these points will produce when arranged in different forms. Newton, who first entered upon these speculations, investigated almost all the cases which seem applicable to physical astronomy, but professor Playfair has lately extended these researches, and has presented a paper on the subject to the Philosophical Society of Edinburgh, which would reflect honour on the first mathematicians of Europe. A few of the leading propositions of this excellent memoir, will follow the investigation of the law of gravitation to a sphere.

Of the gravitation of particles of matter to spheres, and other mathematical figures.

1. *A particle of matter placed within a sphere of uniform density, remains in equilibrio.*

Let $A L B M$, $a l b m$, (*Plate XV. Astronomy. fig. 124.*) be two spherical surfaces, of which C is the common centre, and let the space between them be filled with gravitating matter, uniformly dense. Let p be a particle placed any where within this spherical shell, to every particle of which it gravitates with a force inversely as the square of its distance from it. This particle will have no tendency to move in any direction, because

its gravitation in any one direction is exactly balanced by an equal gravitation in the opposite direction.

Draw through p the two straight lines $dp\epsilon$, $ep\delta$, making a very small angle at p . This may represent the section of a very slender double cone $dpe\delta p\epsilon$, having p for the common vertex, and $de\delta\epsilon$ for the diameter of the circular bases. The gravitation of p to the matter in the base de is equal to its gravitation to the matter in the base $\delta\epsilon$. For the number of particles in de is to the number in $\delta\epsilon$, as the surface of the base de to that of the base $\delta\epsilon$, that is, as de^2 to $\delta\epsilon^2$, that is, as pd^2 to $p\delta^2$, that is, as the gravitation to a particle in $\delta\epsilon$ to the gravitation to a particle in de . Therefore the whole gravitation to the matter in de , is the same with the whole gravitation to the matter in $\delta\epsilon$: since it is also in the opposite direction, the particle p is in equilibrio. The same thing may be demonstrated of the gravitation to the matter in qr and st , and in a similar manner, of the gravitation to the matter in the sections of the cones dpe , $\delta p\epsilon$, by any other concentric surface. Consequently, the gravitation to the whole matter contained in the solid $dqre$, is equal to the gravitation to the whole matter in the solid $\delta ts\epsilon$, and the particle p is still in equilibrio.

Now since the lines $dp\epsilon$, $ep\delta$, may be drawn in any direction, and thus be made to occupy the whole sphere, it is evident that the gravitation of p is balanced in every direction, and therefore it has no tendency to move in any direction, in consequence of this gravitation to the spherical shell of matter comprehended between the surfaces $ALBM$ and $albm$.

It is also evident, that this holds true with respect to all the matter comprehended between $ALBM$, and the concentric surface pnv passing through p ; in short p is in equilibrio in its gravitation, to all the matter more remote than itself from the centre of the sphere, and appears as if it did not gravitate at all to any matter more remote from the centre.

We have supposed the spherical shell to be uniformly dense. But p will still be in equilibrio, although the shell be made up of concentric strata of different densities, provided that each stratum be uniformly dense.

For should we suppose, that in the space comprehended between $ALBM$ and pnv , there occurs a surface $albm$ of a different density from all the rest, the gravitation to the intercepted portions qr and st are equal, because those portions are of equal density, and are proportioned to $p q^2$ and $p s^2$ inversely. The proposition may therefore be expressed in the following very general terms, "a particle placed any where within a spherical shell of gravitating matter, of equal density, at all equal distances from the centre, will be in equilibrio, and will have no tendency to move in any direction."

The equality of the gravitation to the surface ed , and to the surface $\epsilon\delta$ is affirmed, because the numbers of particles in the two surfaces are inversely as the gravitations towards one in each.

For the very same reason, the gravitations towards the surfaces ed and qr and ts are all equal. Hence may be derived an elementary proposition; which is of great use in all enquiries of this kind, namely,

If a cone, or pyramid dpe , of uniform gravitating matter, be divided by parallel sections de , qr , &c. the gravitation of a particle p in the vertex, to each of those sections, is the same, and the gravitations to the solids pqr , pde , $qder$, &c. are proportional to their lengths pq , pd , qd , &c. the first part of this proposition is already demonstrated. Now, conceive the cone to be thus divided into innumerable slices of equal thickness: it is plain that the gravitation to each

of these is the same; and, therefore, the gravitation to the solid pqr , is to the gravitation to the solid $qder$, as the number of slices in the first, to the number of slices in the second, that is, as pq , the length of the first, to qd , the length of the second. The cone dpe was supposed extremely slender. This was not necessary for the demonstration of the particular case where all the sections were parallel; but in this elementary proposition, the angle at p is supposed smaller than any assigned angle, that the cone or pyramid may be considered as one of the elements into which we may resolve a body of any form. In this resolution, the bases are supposed, if not otherwise expressly stated, to be parallel, and perpendicular to the axes; indeed, they are supposed to be portions xr , ye , $z\epsilon$, of spherical surfaces, having their centres in p : the small portions xrq , yed , $z\epsilon\delta$, &c. are held as insignificant, vanishing in the ultimate ratios of the whole solids.

It is easy, also, to see that the equilibrium of p is not limited to the case of a spherical shell, but will hold true of any body composed of parallel strata, or strata so formed, that the lines pd , $p\delta$, are cut in the same proportion by the sections de , qr , &c. In a spheroidal shell, for instance, whose inner and outer surfaces are similar, and similarly posited spheroids, the particle p will be in equilibrio any where within it; because, in this case, the lines $p\delta$ and ne are equal; so are the lines pe and nd , the lines $i\delta$ and re , the lines $s\epsilon$ and qd , &c.: in most cases, however, there is but one situation of the particle p that insures this equilibrium. But we may at the same time infer this very useful proposition,

2. *If there be two solids, perfectly similar, and of the same uniform density, the gravitation to each of these solids, by a particle similarly placed on or in each, is proportional to any homologous lines of the solids.*

For, the solids being similar, they may be resolved into the same number of similar pyramids similarly placed in the solids. The gravitations to each of any corresponding pair of pyramids are proportional to the lengths of those pyramids. These lengths have the same proportion in every corresponding pair. Therefore, the absolute gravitations to the whole pyramids of one solid have the same ratio to the absolute gravitation to the whole pyramids of the other solid. And since the solids are similar, and the particles are at the similarly placed vertices of all the similar and similarly placed pyramids, the gravitation compounded of the absolute gravitations to the pyramids of one solid, has the same ratio to the gravitation similarly compounded of the absolute gravitations to the pyramids of the other.

3. *The gravitation of an external particle to a spherical surface, shell, or entire sphere, which is equally dense at all equal distances from the centre, is the same as if the whole matter were collected in its centre.*

Let $ALBM$ (fig. 124.) represent such a sphere, and let P be the external particle. Draw $PACB$ through C , the centre of the sphere, and cross it by LCM at right angles. Draw two right lines PD , PE , containing a very small angle at P , and cutting the great circle $ALBM$, in D , E , D' , E' . About P , as a centre with the distance PC , describe the arc Cdm , cutting DP in d , and EP in e . About the same centre describe the arc DO . Draw dF , eG , parallel to AB , and cutting LC in f and g . Draw CK perpendicular to PD , and dH , $D\delta$, and $IF\phi$, perpendicular to AB . Join CD and CF .

Now, let the figure be supposed to turn round the axis PB . The semi-circumference ALB will generate a complete spherical surface; the arc Cdm will generate another spherical surface, having P for the centre; the small

arcs DE, *de*, FG, will generate rings, or zones, of those spherical surfaces; DO will also generate a zone of a surface having P for its centre; *fg* and FI will generate zones of flat circular surfaces.

It is evident that the zones generated by DE and DO, (which we may call the zones DE, DO,) having the same radius $D\frac{1}{2}$, are to each other as their respective breadths DE, DO. In like manner, the zones generated by *de*, *fg*, FI, FG, being all at the same distance from the axis AB, are also as their respective breadths *de*, *fg*, FI, FG. But the zone DO is to the zone *de*, as PD to P*d*: for DO is to *de*, as PD to P*d*, and the radius of rotation D*δ* is to the radius dH, also as PD to P*d*. The circumferences, described by DO and *de*, are, therefore, in the same proportion as PD to P*d*; therefore the zones being as their breadths, and as their circumferences jointly, are as PD² and P*d*².

CK and dH, being the sines of the same arc C*d*, are equal; therefore KD and fE, the halves of chords equally distant from the centre, are also equal; therefore the triangles CDK and CFf are equal and similar. But CDK is similar to EDO, for the right angles PDO and CDE are equal. Taking away the common angle CDO, the remainders CDK and EDO are equal. In like manner, CFf and GFI are similar; and, therefore, (since CDK and CFf are similar,) the elementary triangles EDO and GFI are similar, and DO : DE = FI : GF. The absolute gravitation, or tendency of P, to the zone DO, is equal to its absolute gravitation to the zone *de*, because the number of particles in the first, is to the particles in the last, as PD² to P*d*², that is, inversely as the gravitation to a particle in the first, to the gravitation to a particle in the last; therefore let *c* represent the circumference of a circle, whose radius is 1. The surface of the zone generated by DO, will be DO × *c* × D*δ*, and the gravitation to it will be $\frac{DO \times c \times D\delta}{PD^2}$, to which $\frac{de \times c \times dH}{P d^2}$, or

$\frac{de \times c \times dH}{PC^2}$, is equal. This expresses the absolute gravitation to the zone generated by DO, this gravitation being exerted in the direction PD.

But it is evident that the tendency of P, arising from its gravitation to every particle in the zone, must be in the direction PC. The oblique gravitation must, therefore, be estimated in the direction PC, and must be reduced in the proportion of Pd to PH. It is plain that Pd : PH = *de* : *fg*, because *de* and *fg* are perpendicular to Pd and PH; therefore the reduced, or central gravitation of P, to the zone generated by DO, will be expressed by $\frac{fg \times c \times dH}{PC^2}$.

But the gravitation to the zone generated by DO, is to the gravitation to the zone generated by DE, as DO to DE, that is, as FI (or *fg*) to FG. Therefore the central gravitation to the zone generated by DE, will be expressed by $\frac{FG \times c \times dH}{PC^2}$. Now, FG × *c* × dH is the value of the surface of the zone generated by FG; and if all this matter were collected in C, the gravitation of P to it would be exactly $\frac{FG \times c \times dH}{PC^2}$, and it would be in the direction PC. Hence it follows, that the central gravitation of P to the zone generated by DE, is the same as its gravitation to all the matter in the zone generated by FG, if that matter were placed in C.

What has been demonstrated respecting the arc DE, is true of every portion of the circumference. Each has a substitute FG, which being placed in the centre *c*, the gravitation of P is the same. If P*T* touch the sphere in T, every portion of the arc TLB will have its substitute in the quadrant LB, and every part of the arc AT has its substitute in the quadrant ATL, as is easily seen. And hence it follows, that the gravitation of a particle, P, to a spherical surface, ALBM, is the same as if all the matter of that surface were collected in its centre.

We see also that the gravitation to the surface generated by the rotation of AT round AB is equal to the gravitation to the surface generated by TLB, which is much larger but more remote.

What we have now demonstrated with respect to the surface generated by the semicircle ALB, is equally true with regard to the surface generated by any concentric semicircle, such as *alb*. It is true, therefore, with regard to the shell comprehended between those two surfaces; for this shell may be resolved into innumerable concentric strata, and the proposition may be affirmed with respect to each of them, and therefore with respect to the whole. And this will be still true if the whole sphere be thus occupied.

Lastly, it follows that the proposition is still true, although these strata should differ in density, provided that each stratum is uniformly dense in every part.

It may, therefore, be affirmed in the most general terms, that a particle, P, placed without a spherical surface, shell, or entire sphere, equally dense at equal distances from the centre, tends to the centre with the same force, as if the whole matter of the surface, shell, or sphere were collected there.

This will be found to be a very important proposition.

4. *The gravitation of an external particle to a spherical surface, shell, or entire sphere, of uniform density at equal distances from the centre, is as the quantity of matter in that body directly; and as the square of the distance from its centre inversely.*

For, if all the matter were collected in its centre, the gravitation would be the same, and it would then vary in the inverse duplicate ratio of the distance.

Cor. 1.—Particles placed on the surfaces of spheres of equal density, gravitate to the centres of those spheres with forces proportional to the radii of the spheres.

For the quantities of matter are as the cubes of the radii.

Therefore the gravitation *g* is as $\frac{r^3}{d^2}$, that is, as *d*.

Cor. 2.—The same thing holds true if the distance of the external particles from the centres of the spheres are as the diameters or radii of the spheres.

Cor. 3.—If a particle be placed within the surface of a sphere of uniform density, its gravitation at different distances from the centre will be as those distances. For, it will not be affected by any matter of the sphere that is more remote from the centre, and its gravitation to what is left remote, is as its distance from the centre by the last Cor.

5. *The mutual gravitation of two spheres of uniform density in their concentric strata, is in the inverse duplicate ratio of the distance between their centres.*

For the gravitation of each particle in the sphere A, is to the sphere B, the same as if all the matter in B were collected at its centre. Suppose it so placed:

The gravitation of B to A will be the same as if all the matter in A were collected at its centre. Therefore it will be as *d*² inversely. But the gravitation of A to B is equal to that of B to A. Therefore, &c.

The absolute gravitation of two spheres whose quantities

of matter are A and B, and d the distance of their centres, is $\frac{A \times B}{d^2}$. For the tendency of one particle of A to B, being the aggregate of its tendencies to every particle of B, is $\frac{B}{d}$. Therefore, the tendency of the whole of A to B must be $\frac{A \times B}{d}$. And the tendency of B to A is equal to that of A to B.

6. But if the centripetal forces which tend to the different points of spheres are proportional to the simple distances from the attracted bodies, then the compounded force with which two spheres attract each other mutually, is as the distance between the centres of the spheres.

Case 1.—Let A E B F (fig. 125.) be a sphere; S its centre; P a particle attracted; P A S B the axis of the sphere passing through the centre of the particle; E F, ef , two planes cutting the sphere and perpendicular to the axis, and equidistant one on one side, the other on the other, from the centre of the sphere; G and g the interfections of the planes and the axis; and H any point in the plane E F. The centripetal force of the point H on the particle P, exerted in the direction of the line P H, is as the distance P H; and the same exerted in the direction of the line P G, or towards the centre S, is as the length P G. Therefore, the force of all the points in the plane E F, (that is, of the whole plane) by which the particle P is attracted towards the centre S, is as the distance P G multiplied by the number of those points, that is, as the solid contained under that plane E F, and the distance P G. And, in like manner, the force of the plane ef , by which the particle P is attracted towards the centre S, is as that plane multiplied into its distance P g ; or as the equal plane E F multiplied into that distance P g ; and the sum of the forces of both planes is as the plane E F, multiplied into the sum of the distances P G + P g , that is, as that plane multiplied into twice the distance P S of the centre and the particle; that is, as twice the plane E F, multiplied into the distance P S, or as the sum of the equal planes E F + ef multiplied into the same distance. And by a similar train of reasoning, the forces of all the planes in the whole sphere, equidistant on each side from the centre of the sphere, are as the sum of those planes, multiplied into the distance P S, that is, as the whole sphere, and the distance P S jointly.

Case 2.—Let the particle P now attract the sphere A E B F, and, by the same reasoning, it will appear that the force with which the sphere is attracted is as the distance P S.

Case 3.—If another sphere be now composed of innumerable particles P, and because the force with which every particle is attracted is as the distance of the particle from the centre of the first sphere, and as the same sphere conjointly, and is therefore the same as if the whole proceeded from a single particle situated in the centre of the sphere; the entire force with which all the particles in the second sphere are attracted, that is, with which the whole sphere is attracted, will be the same as if that sphere were attracted by a force proceeding from a single particle in the centre of the first sphere, and is therefore proportional to the distance between the centres of the spheres.

Case 4.—Let the spheres attract each other mutually, and the force will be doubled, but the proportion will remain the same.

Case 5.—Let the particle P be placed within the sphere A E B F, (fig. 126.) and because the force of the plane ef , upon the particle, is as the solid contained under that plane

and the distance $p g$; and the contrary force of the plane E F, is as the solid contained under that plane and the distance $p G$; the force compounded of both will be as the difference of the solids, that is, as the sum of the equal planes multiplied into half the difference of the distances; that is, as that sum multiplied into $p S$, the distance of the particle from the centre of the sphere. And, by a similar train of reasoning, the attraction of all the planes E F, ef , throughout the sphere, that is, the attraction of the whole sphere is conjointly as the sum of all the planes or as the whole sphere, and as $p S$ the distance of the particle from the centre of the sphere.

Case 6.—And if a new sphere be now composed of innumerable particles, such as p , situated within the first sphere A E B F, it may be proved, as before, that the attraction, whether single of one sphere towards the other, or mutual of both towards each other, will be as the distance $p S$ of the centres.

7. If the structure of the spheres be dissimilar and unequal, proceeding directly from the centre towards the circumference, but similar and equal throughout every circumference, at equal distances from the centre, and if the attractive force be as the distance of the attracted body, then the entire force with which two spheres of this kind attract each other mutually is proportional to the distance between the centres of the spheres.—This is demonstrated from the preceding proposition.

The above investigations relate to the principal cases of attraction, namely, when the centripetal forces decrease in a duplicate ratio, or increase in the simple ratio of the distance. And it is remarkable that both these suppositions cause bodies to revolve in conic sections, and compose spherical bodies, whose centripetal forces observe the same law of increase or decrease, in the recess from the centre, as the forces of the particles themselves do.

8. If a circle A E B (fig. 127.) be described round the centre S, and two circles E F, ef , be also described round the centre P, intersecting the former in E and e, and the line P S in F and f ; and if E D, ed , be drawn perpendicular to P S; then if the distance of the arcs E F, ef , be supposed to be infinitely diminished, the limiting ratio of the evanescent line D d to the evanescent line F f is the same as that of the line P E to the line P S.

For if the line P e intersect the arc E F in q , and the right line E e, which coincides with the evanescent arc E e, be produced and meet the right line P S in T; and the perpendicular S G be drawn from S to P E, because the triangles D T E, $d T e$, D E S, are similar, D d will be to E e as D T to T E, or D S to E S; and because the triangles E e q, E S G, are similar, E e will be to e q or F f as E S to S G; and ex æquo D d is to F f as D E to S G; that is, (because the triangles P D E, P G S, are similar,) as P E to P S.

9. If a superficies, as E F f e (fig. 128.) be supposed to have its breadth infinitely diminished, and that by its revolution round the axis P S it describes a spherical concavo-convex solid to the several equal particles of which equal centripetal forces tend: then the force with which that solid attracts a particle placed at P is in a ratio compounded of the ratio of the solid D E² × F f, and the ratio of the force with which the given particle in the place F f would attract the same particle.

For if the force be first considered of the spherical superficies F E, which is generated by the revolution of the arc F E, and is intersected any where, as in r, by the line d e, the annular part of the superficies generated by the revolution

GRAVITATION.

revolution of the arc rE will be as the small line Dd , the radius of the sphere remaining the same; as Archimedes has demonstrated in his book on the sphere and cylinder. And the force of these superficies exerted in the direction of the lines PE or $P'F$ situated all round in the conical superficies, will be as this annular superficies itself; that is, as the line Dd , or, which is the same, as the rectangle under the given radius PE of the sphere, and the line Dd ; but that force, exerted in the direction of the line PS , tending to the centre S , will be less in the ratio of PD to PE , and therefore will be as $PD \times Dd$. If the line DF be now considered as divided into innumerable equal particles, each of which may be called Dd , then the superficies FE will be divided into so many equal annuli, whose forces will be as the sum of all the rectangles $PD \times Dd$; that is, as $\frac{1}{2} PF^2 - \frac{1}{2} PD^2$ and therefore as DE^2 . Let now the superficies FE be multiplied into the altitude Ff , and the force of the solid $EFfe$ exerted upon the particle P will be as $DE^2 \times Ff$; that is, if the force be given which any given particle, as Ff , exerts upon the particle P at the distance PF . But if that force be not given, the force of the solid $EFfe$ will be as the solid $DE^2 \times Ff$, and that force not given conjointly.

10. *If to the several equal parts of a sphere ABE fig. 129.) described about the centre S , there tend equal centripetal forces; and if from the several points D , perpendiculars D, E , be drawn to the axis of the sphere AB , in which a particle P is placed, meeting the sphere in E ; and if in these perpendiculars the lengths D, N , be taken as the quantity $\frac{DE^2 \times PS}{PE}$, and as the force which a particle of the sphere situated in the axis exerts at the distance PE upon the particle P conjointly; then the whole force with which the particle P is attracted towards the sphere is as the area ANB , comprehended under the axis of the sphere AB , and the curve line ANB , the locus of the point N .*

For supposing the construction in the last lemma and theorem to remain, let the axis of the sphere AB be supposed to be divided into innumerable equal particles D, d , and the whole sphere to be divided into so many spherical concavo-convex laminæ $EFfe$, and let the perpendicular dn be drawn. By the last theorem the force with which the laminæ $EFfe$, attracts the particle P , is as $DE^2 \times Ff$, and the force of one particle exerted at the distance PE or PF conjointly. But (by the last lemma) Dd is to Ff as PE to $P'S$, and therefore Ff is equal to $\frac{PS \times Dd}{PE}$; and $DE^2 \times Ff$ is equal to $Dd \times \frac{DE^2 \times PS}{PE}$; and therefore the force of the laminæ $EFfe$, is as $Dd \times \frac{DE^2 \times PS}{PE}$, and the force of a particle exerted at the distance PF conjointly; that is, by the supposition, as $DN \times Dd$, or as the evanescent area $DNnd$. Therefore the forces of all the laminæ exerted upon the particle P are as the areas $DNnd$, that is, the sphere will be as the whole area ANB .

Cor. 1.—Hence if the centripetal force tending to the several particles remain always the same at all distances, and DN be made as $\frac{DE^2 \times PS}{PE}$, the whole force with which the particle is attracted by the sphere is as the area ANB .

Cor. 2.—If the centripetal force of the particles vary reciprocally as the distance of the particle attracted by it, and

DN be made as $\frac{DE^2 \times PS}{PE^2}$, the force with which the particle P is attracted by the whole sphere will be as the area ANB .

Cor. 3.—If the centripetal force of the particles vary reciprocally as the cube of the distance of the particle attracted by it, and DN be made as $\frac{DE^2 \times PS}{PE^3}$, the force with which the particle is attracted by the whole sphere will be as the area ANB .

Cor. 4.—And universally of the centripetal force tending to the several particles of the sphere be supposed to be reciprocally as the quantity V ; and DN be made as $\frac{DE^2 \times PS}{PE \times V}$, the force with which a particle is attracted by the whole sphere will be as the area ANB .

11. *Supposing every thing to remain as above, it is required to measure the area ANB , fig. 130*

From the point P let the right line PH be drawn touching the sphere in H ; and having drawn HI perpendicular to the axis PAB , bisect PI in L , and PE' will be equal to $PS^2 \times SE^2 \times 2PSD$. But because the triangles SPH, SHI , are similar, SE' or SH^2 is equal to the rectangle PSI . Therefore PE' is equal to the rectangle contained under PS and $PS \times SI \times 2SD$; that is, under PS and $2LS \times 2SD$; that is, under PS and $2LD$. Moreover DE' is equal to $SE^2 - SD^2$, or $SE^2 - LS^2 + 2SLD - LD^2$, that is, $2SLD - LD^2 - ALB$. For $LS^2 - SE^2$, or $LS^2 - SA^2$, is equal to the rectangle ALB . Therefore if instead of DE' we write $2SLD - LD^2 - ALB$, the quantity $\frac{DE^2 \times PS}{PE \times V}$, which is as the length of the ordinate DN ,

will now resolve itself into three parts, $\frac{2SLD \times PS}{PE \times V} - \frac{LD^2 \times PS}{PE \times V} - \frac{ALB \times PS}{PE \times V}$; where, if instead of V

we write the inverse ratio of the centripetal force, and instead of PE , the mean proportional between PS and $2LD$, those parts will become the ordinates of so many curve lines, whose areas may be found by the common methods.

Ex. 1.—If the centripetal force tending to the several particles of the sphere be reciprocally as the distance, instead of V write PE the distance, then $2PS \times LD$ for PE^2 ; and DN will become as $SL - \frac{1}{2}LD - \frac{ALD}{2LD}$.

Suppose DN equal to the double $2SL - LD - \frac{ALB}{LD}$

and $2SL$ the given part of the ordinate drawn into the length AB will describe the rectangular area $2SL \times AB$; and the indefinite part LD drawn perpendicularly into the same length with a continued motion, according to such a law that its motion in either direction may, by increasing or decreasing, remain always equal to the length LD , will describe

the area $\frac{LB^2 - LA^2}{2}$, that is the area $SL \times AB$;

which taken from the former area $2SL \times AB$, leaves the area $SL \times AB$. But the third part $\frac{ALB}{LD}$, drawn in

a similar manner with a continued motion perpendicularly into the same length, will describe the area of an hyperbola, which subtracted from the area $SL \times AB$ will leave ANB the area sought. Whence this construction of the problem arises. At the points L, A, B . (fig. 131.) erect

GRAVITATION.

the perpendiculars Ll , Aa , Bb ; making Aa equal to Ll , and Bb equal to Ll . Making Ll and Lb asymptotes, describe through the points a , b , the hyperbolic curve ab ; and the chord ba being drawn, will enclose the area aba equal to the area required ANB .

Example 2.—If the centripetal force tending to the several particles of the sphere be reciprocally as the cube of the distance, or, (which is the same thing,) as that cube applied to any given plane; substitute $\frac{PE^3}{2AS^2}$ for V , and $2PS \times LD$ for PE^2 ; and DN will become as $\frac{SL \times AS^2}{PS \times LD} - \frac{AS^2}{2PS} - \frac{ALB \times AS^2}{2PS \times LD^2}$; that is, (because PS , AS , SI , are continually proportional,) as $\frac{LSI}{LD} - \frac{1}{2}SI - \frac{ALB \times SI}{2LD^2}$. If these three parts be then drawn into the length AB , the first, $\frac{LSI}{LD}$, will generate the area of an hyperbola; the second, $\frac{1}{2}SI$, the area $\frac{1}{2}AB \times SI$; the third, $\frac{ALB \times SI}{2LD^2}$, the area $\frac{ALB \times SI}{2LA} - \frac{ALB \times SI}{2LB}$, that is, $\frac{1}{2}AB \times SI$: from the first subtract the sum of the second and third, and there will remain ANB , the area sought. Whence arises this construction of the problem. At the points L , A , S , B , (*fig. 132.*) erect the perpendiculars Ll , Aa , Ss , Bb , of which suppose Ss equal SI ; and through the point s , to the asymptotes Ll , Lb , describe the hyperbola asb , meeting the perpendiculars Aa , Bb , in a and b , and the rectangle $2ASI$, subtracted from the hyperbolic area $AasbB$, will leave ANB , the area required.

Example 3.—If the centripetal force, tending to the several particles of the sphere, decrease in a quadruplicate ratio of the distance from the particles, substitute $\frac{PE^4}{2AS^3}$ for V , then $\sqrt{2PS + LD}$ for PE , and DN will become as $\frac{SI^2 \times SL}{\sqrt{2SI}} \times \frac{1}{\sqrt{LD^3}} - \frac{SI^2}{2\sqrt{2SI}} \times \frac{1}{\sqrt{LD}} - \frac{SI^2 \times ALB}{2\sqrt{2SI}} \times \frac{1}{\sqrt{LD^3}}$. These three parts, drawn into the length AB , produce as many areas, namely, $\frac{2SI \times SL}{\sqrt{2SI}}$ into $\frac{1}{\sqrt{LA}} - \frac{1}{\sqrt{LB}}$, $\frac{SI^2}{\sqrt{2SI}}$ into $\sqrt{LB} - \sqrt{LA}$, and $\frac{SI^2 \times ALB}{3\sqrt{2SI}}$ into $\frac{1}{\sqrt{LA^3}} - \frac{1}{\sqrt{LB^3}}$; and these, after the proper reduction, become $\frac{2SI^2 \times SL}{LI}$, SI^2 , and $SI^2 + \frac{2SI^3}{3LI}$: and these, by subtracting the latter terms from the former, become $\frac{4SI^3}{3LI}$; therefore the entire force with which the particle P is attracted towards the centre of the sphere, is as $\frac{SI^3}{PI}$, that is, reciprocally as $PS^3 \times PL$.

The attraction of a particle, situated within the sphere,

may be determined by the same method; but more expeditiously by the following theorem.

12. If SI , SA , SP , (*fig. 133.*) be taken continually proportional, in a sphere described round the centre S , with the radius SA ; then the attraction of a particle within the sphere, in any place I , is to its attraction, without the sphere, in a place P , in a ratio compounded of the sub-duplicate ratio of IS , PS , the distances from the centre, and the sub-duplicate ratio of the centripetal forces tending to the centre in those places, P and I .

As, if the centripetal forces of the particles of the sphere be reciprocally as the distances of the particle attracted by them, the force with which the particle situated at I is attracted by the entire sphere, will be to the force with which it is attracted at P , in a ratio compounded of the sub-duplicate ratio of the distance SI to the distance SP , and the sub-duplicate ratio of the centripetal force in the place I , arising from any particle in the centre to the centripetal force in the place P , arising from the same particle in the centre; that is, in the sub-duplicate ratio of the distances SI , SP , to each other reciprocally. These two sub-duplicate ratios compose the ratio of equality; and, therefore, the attractions in I and P , produced by the whole sphere, are equal. By a similar calculation, if the forces of the particles of the sphere are reciprocally in a duplicate ratio of the distance, it will be found that the attraction in I is to the attraction in P , as the distance SP to the semi-diameter SA of the sphere. If those forces are reciprocally in a triplicate ratio of the distances, the attractions in I and P will be to each other as SP^2 to SA^2 ; if in a quadruplicate ratio, as SP^3 to SA^3 . Therefore, since the attraction in P , in this last case, was found to be reciprocally as $PS^2 \times PI$, the attraction in I will be reciprocally as SA^3 into PI ; that is, because SA^3 is given reciprocally as PI ; and the progression is the same indefinitely. The demonstration of this theorem is as follows:

Retaining the same construction as above, and a particle being in any place P , the ordinate DN was found to be as $\frac{DE^4 \times PS}{PE \times V}$; therefore, if IE be drawn, that ordinate for any other place of the particle, as I , will become (substituting PS and PE for IS and IE) as $\frac{DE^4 \times IS}{IE \times V}$.

Suppose the centripetal forces proceeding from any point of the sphere, as E , to be to each other at the distances IE and PE , as PE^n to IE^n (where the number n denotes the index of the powers of PE and IE), and those ordinates will become as $\frac{PE^2 \times PS}{PE \times PE^n}$, and $\frac{PE^2 \times IS}{IE \times IE^n}$, whose ratio to each other is as $PS \times IE \times IE^n$ to $IS \times PE \times PE^n$. Because SI , SE , SP , are continually proportional, the triangles SPE , SEI , are alike; and thence IE is to PE , as IS to SE , or SA . Substitute the ratio of IS to SA for the ratio of IE to PE , and the ratio of the ordinates becomes that of $PS \times IE^n$ to $SA \times PE^n$. But the ratio of PS to SA is sub-duplicate of that of the distances PS , SI ; and the ratio of IE^n to PE^n , (because IE is to PE as IS to SA) is sub-duplicate of that of the forces at the distances PS , IS ; therefore the ordinates, and consequently the areas which the ordinates describe, and the attractions proportional to them, are in a ratio compounded of those sub-duplicate ratios.

13. To find the force with which a particle, placed in the centre

GRAVITATION.

centre of a sphere, is attracted towards any segment of that sphere.

Let P (fig. 134.) be a particle in the centre of a sphere, and R B S D a segment thereof contained between the plane R D S, and spherical superficies R B S. Let D B be intersected in F by a spherical superficies E F G, described from the centre P, and let the segment be divided into the parts B R E F G S, F E D G: let that surface be supposed not purely mathematical, but physical, having some but a very inconsiderable thickness: let that thickness be called O, and (by what Archimedes has demonstrated) that superficies will be as $P F \times D F \times O$: let us suppose besides, the attractive forces of the particles of the sphere, to be reciprocally as that power of the distances of which n is the index; and the force with which the surface

E F G attracts the body P will be as $\frac{D E^2 \times O}{P F^n}$; that is, as $\frac{2 D E \times O}{P F^{n-1}} - \frac{D F^2 \times O}{P F^n}$. Let the perpendicular F N,

drawn into O, be proportional to this quantity, and the curvilinear area D B I, which the ordinate F N, drawn through the length D B, with a continued motion describes, will be as the whole force with which the whole segment R B S D attracts the body P.

14. To find the force with which a particle, placed without the centre of a sphere, in the axis of any segment, is attracted by that segment.

Let the body P, placed in the axis A D B, of the segment E B K (fig. 135.) be attracted by that segment: round the centre P, with the radius P E, let the spherical surface E F K be described; and let it divide the segment into two parts E B K F E and E F K D E. Let the force of the former part be found by Prop. 11. and the force of the latter part by Prop. 13. and the sum of the forces will be the force of the whole segment E B K D E.

These are the principal propositions by which Newton has investigated the nature of the attraction exercised by spherical bodies. In the thirteenth section of the Principia, the author shews the manner in which the law of attraction is investigated for other bodies; the most interesting results are contained in the following propositions.

Of the attractive forces of bodies which are not of a spherical figure.

15. If a body be attracted by another, and its attraction be considerably stronger when it is contiguous to the attracting body, than when they are separated from one another by a very small interval; the forces of the particles of the attracting body decrease, as the attracted body recedes, in more than a duplicate ratio of the particles attracted.

16. If the forces of the particles, of which an attractive body is composed, decrease as the attracted body recedes, in a triplicate, or more than triplicate ratio of the distance from the particles, the attraction will be considerably stronger in the place of contact, than when the attracting and attracted bodies are separated from each, though by the most minute interval.

17. If two bodies, similar to each other, and consisting of matter equally attractive, attract separately two particles, proportional to those bodies, and in a similar situation to them; the accelerative attractions of the particles towards the entire bodies will be as the accelerative attractions of the particles towards particles of the bodies proportional to the whole, and similarly situated in them.

18. If the attractive forces of the equal particles of any body be as the distance of the places from the particles, the force of the whole body will tend to its centre of gravity; and will be

the same with the force of a globe, consisting of similar and equal matter, and having its centre in the centre of gravity.

19. If there be several bodies, consisting of equal particles, whose forces are as the distances of the places from each, the force compounded of all the forces by which any particle is attracted, will tend to the common centre of gravity of the attracting bodies; and will be the same as if these attracting bodies, preserving their common centre of gravity, should unite there, and be formed into a globe.

20. If a solid be plane on one side, and infinitely extended on all other sides, and consist of equal particles equally attractive, whose forces decrease, as they recede from the solid in the ratio of any power greater than the square of the distances; and a particle placed towards either part of the plane is attracted by the force of the whole solid; then the attractive force of the whole solid, as it recedes from its plane superficies, will decrease in the ratio of a power whose side is the distance of a particle from the plane, and is indeed less by three than the index of the power of the distances.

Though the above propositions are sufficient for all astronomical investigations, yet there are many questions in natural philosophy, particularly those which relate to the attraction of mountains, which require that these enquiries should be extended to a greater variety of cases; and the following propositions form a part of the interesting investigations of professor Playfair, as he has communicated them to the public, in the sixth volume of the Edinburgh Transactions, as above-mentioned: they were suggested to the learned author by the experiments which have been made of late years, concerning the gravitation of terrestrial bodies, particularly by Dr. Maskelyne on the attraction of mountains, and by Mr. Cavendish, on the attraction of leaden balls, as has been described at length under the article DENSITY, to which the reader is referred.

I. To find the solid into which a mass of homogeneous matter must be formed, to attract a particle given in position with the greatest force possible in a given direction.

Let A (fig. 136.) be the particle given in position, A B the direction in which it is to be attracted; and A C B H a section of the solid required, by a plane passing through A B.

Since the attraction of the solid is a maximum by hypothesis, any small variation in the figure of the solid, provided the quantity of matter remain the same, will not change the attraction in the direction A B. If, therefore, a small portion of matter be taken from any point C in the superficies of the solid, and placed at D, another point in the same superficies, there will be no variation in the force which the solid exerts on the particle A in the direction A B.

The curve A C B, therefore, is the locus of all the points, in which a body, being placed, will attract the particle A in the direction A B, with the same force. This condition is sufficient to determine the nature of the curve A B C. From C any point in that curve, draw C E perpendicular to A B;

then if a mass of matter, placed at C be called m^1 , $\frac{m^1}{A C^1}$ will be the attraction of that mass on A, in the direction A C, and $\frac{m^1 \times A E}{A C^1}$ will be its attraction in the direction A B: as this is constant, it will be equal to $\frac{m^1}{A B^2}$, and, therefore, $A B^2 \times A E = A C^1$.

All the sections of the required solid, therefore, by planes passing through A B, have this property, that $A C^1 = A$

$= \Lambda B^2 \times A E$; and as this equation is sufficient to determine the nature of the curve to which it belongs, therefore all the sections of the solid, by planes that pass through ΛB , are similar and equal curves; and the solid, in consequence, may be conceived to be generated by the revolution of $\Lambda C B$, any one of those curves, about ΛB as an axis.

The solid so generated may be called the *solid of greatest attraction*, and the line $\Lambda C B$ the *curve of equal attraction*.

II. To find the equation between the co-ordinates of $\Lambda C B$, the curve of equal attraction.

From C (fig. 136.) draw $C E$ perpendicular to ΛB ; let $\Lambda B = a$, $\Lambda E = x$, $E C = y$.

It has been found that $\Lambda B^2 \times A E = A C^3$, that is $a^2 x = (x^2 + y^2)^{3/2}$, or $a^2 x^2 = (x^2 + y^2)^3$, which is an equation to a line of the sixth order.

To obtain y in terms of x , $x^2 + y^2 = a^2 x^2$, $y^2 = a^2 x^2 - x^2$ and $y = x \sqrt{a^2 - 1}$.

Hence $y = 0$, both when $x = 0$, and when $x = a$. Also, if x be supposed greater than a , y is impossible. No part of the curve, therefore, lies beyond B .

The parts of the curve on opposite sides of the line ΛB are similar and equal, because the positive and negative values of y are equal. There is also another part of the curve on the side of Λ , opposite to B , similar and equal to $\Lambda C B$; for the values of y are the same, whether x be positive or negative.

III. The curve may be easily constructed without having recourse to the value of y just obtained.

Let $\Lambda B = a$ (fig. 136.) $\Lambda C = z$, and the angle $B \Lambda C = \phi$. Then $\Lambda E = \Lambda C \times \cos \phi = z \cos \phi$, and so $z^2 \cos \phi = z^3$, or $a^2 \cos \phi = z^2$; hence $z = a \sqrt{\cos \phi}$.

From this formula a value of ΛC or z may be found, if ϕ or the angle $B \Lambda C$ be given; and if it be required to find z in numbers, it may be conveniently calculated from this expression. A geometrical construction may also be easily derived from it. For if with the radius ΛB , a circle $B F H$ be described from the centre Λ ; if ΛC be produced to meet the circumference in F , and if $F G$ be drawn at right angles to ΛB , then $\frac{\Lambda G}{\Lambda B} = \cos \phi$, and so $z = a \times$

$$\sqrt{\frac{\Lambda G}{\Lambda B}} = \sqrt{\Lambda B \times \Lambda G} = \Lambda C.$$

Therefore, if from the centre Λ , with the distance ΛB , a circle $B F H$ be described; and if a circle be also described on the diameter ΛB as $\Lambda K B$, then drawing any line ΛF from Λ , meeting the circle $B F H$ in F , and from F letting fall $F G$ the perpendicular on ΛB , intersecting the semicircle $\Lambda K B$ in K ; and if ΛK be joined, and ΛC made equal to ΛK , the point C is in the curve.

For $\Lambda K = \sqrt{\Lambda B \times \Lambda G}$, from the nature of the semi-circle, and therefore $\Lambda C = \sqrt{\Lambda B \times \Lambda G}$, which has been shewn to be a property of the curve. In this way a number of points of the curve may be determined; and the *solid of greatest attraction* will be described, as already explained, by the revolution of this curve about the axis ΛB .

IV. To find the area of the curve $\Lambda C B$.

1. Let $\Lambda C E$, $\Lambda F G$ (fig. 137.) be two radii indefinitely near to one another, meeting the curve $\Lambda C B$ in C and F , and the circle described with the radius ΛB in E and G . Let $\Lambda C = z$ as before, the angle $B \Lambda C = \phi$, and $\Lambda B = a$. Then $G E = a \phi$, and the area $\Lambda G E = \frac{1}{2}$

$a^2 \phi$, and since $\Lambda E^2 : \Lambda C^2 :: \text{sect. } \Lambda E G : \text{sect. } \Lambda C F$, the sector $\Lambda C F = \frac{1}{2} z^2 \phi$. But $z^2 = a^2 \cos \phi$, whence the sector $\Lambda C F = \frac{1}{2} z^2 \phi$. But $z^2 = a^2 \cos \phi$, (III.) whence the sector $\Lambda C F$, or the fluxion of the area $\Lambda B C = \frac{1}{2} a^2 \phi \cos \phi$, and consequently the area $\Lambda B C = \frac{1}{2} a^2 \sin \phi$, to which no constant quantity need be added, because it vanishes when $\phi = 0$, or when the area $\Lambda B C$ vanishes.

The whole area of the curve therefore is $\frac{1}{2} a^2$, or $\frac{1}{2} \Lambda B^2$; for when ϕ is a right angle $\sin \phi = 1$. Hence the area of the curve on both sides of ΛB is equal to the square of ΛB .

2. The value of x , when y is a maximum, is easily found. For when y , and therefore y^2 , is a maximum, $\frac{2}{3} a^2 - x^2 = 2 x$,

$$\text{or } 3 x^2 = a^2, \text{ that is, } x = \frac{a}{\sqrt{3}} = \frac{a}{\sqrt{27}}$$

Hence calling b the value of y when a is a maximum, $b^2 = a^2 \times \frac{a^2}{27} - \frac{a^2}{27} = a^2 \left(\frac{27^2 - 1}{27^2} \right) = \frac{2 a^2}{\sqrt{27}}$, and so $b =$

$a \sqrt{\frac{2}{\sqrt{27}}}$, and therefore $a : b :: \sqrt[4]{27} : \sqrt{2}$, or as 11 : 7 nearly.

3. It is material to observe, that the radius of curvature Λ is infinite: for since $y^2 = a^2 x^2 - x^2$, $\frac{y^2}{x} = \frac{a^2}{x} - x$.

But when x is very small, or y indefinitely near to Λ , $\frac{y^2}{x}$ becomes the diameter of the circle, having the same curvature with $\Lambda C B$ at Λ ; and when x vanishes, this value of $\frac{y^2}{x}$, or $\frac{a^2}{x} - x$ becomes infinite, because of the divisor x being in that

case $= 0$. The diameter, therefore, and the radius of curvature at Λ , are infinite. In other words, no circle, having its centre in ΛB produced, and passing through Λ , can be described with so great a radius, but that at the point Λ it will be within the curve of equal attraction.

The solid of greatest attraction then, at the extremity of its axis, where the attracted particle is placed, is exceedingly flat, approaching more nearly to a plane than the superficies of any sphere can do, however great its radius.

4. To find the radius of curvature at B , the other extremity of the axis, since $y^2 = a^2 x^2 - x^2$, if we divide by $a - x$, we have $\frac{y^2}{a - x} = \frac{a^2 x^2 - x^2}{a - x}$.

But at B , when $a - x$, or the abscissa reckoned from B vanishes, $\frac{y^2}{a - x}$ is the diameter of the circle, having the same curvature with $\Lambda C B$ in B . But when $a - x = 0$, or $a = x$ both the numerator and denominator of the fraction $\frac{a^2 x^2 - x^2}{a - x}$ vanishes, so that its ultimate value does not ap-

pear. To remove this difficulty, let $a - x = z$, or $x = a - z$, then we have $y^2 = (a - z)^2 - (a - z)^2$.

But when z is extremely small, its powers higher than the first may be rejected; and therefore $(a - z)^2 = a^2 \left(1 - \frac{z}{a} \right)^2$

$= a^2 \left(1 - \frac{2z}{a} \&c. \right)$ Therefore the equation to the curve becomes in this case, $y^2 = a^2 \times a^2 \left(1 - \frac{2z}{3a} \right) - a^2 + 2 a z = a^2 - \frac{2}{3} a z - a^2 + 2 a z = \frac{4}{3} a z$.

Hence

Hence $\frac{y^3}{2a}$, or the radius of curvature at B = $\frac{2}{3}a$. The curve therefore at B falls wholly without the circle BKA, described on the diameter AB, as its radius of curvature is greater. This is also evident from the construction.

V. To find the force with which the solid above defined attracts the particle A in the direction AB.

Let B (fig. 137), be a point indefinitely near to B, and let the curve Acb be described similar to ACB; through C draw CcD perpendicular to AB, and suppose the figure thus constructed to revolve about AB; then each of the curves ACB, Acb, will generate a solid of greatest attraction; and the excess of the one of these solids above the other, will be an indefinitely thin shell, the attraction of which is the variation of the attraction of the solid ACB when it changes into Acb.

Again, by the line DC, when it revolves along with the rest of the figure about AB, a circle will be described; and by the part Cc, a circular ring, on which, if we suppose a solid of indefinitely small altitude to be constituted, it will make the element of the solid shell ACc. Now the attraction exerted by this circular ring upon A will be the same as if all the matter of it were united in the point C, and the same, therefore, as if it were all united in B.

But the circular ring generated by Cc is $\pi(DC^2 - DC'^2) = 2\pi DC \times Cc$. Now, $2DC \times Cc$ is the variation of y^2 , or DC^2 , while DC passes into Dc, and the curve BCA into the curve bca; that is, $2DC \times Cc$ is the fluxion of y^2 , or of $a^2x^2 - x^3$, taken on the supposition that x is constant and a variable, namely $\frac{4}{3}a^2x^2 \dot{a}$. Therefore the space generated by Cc = $\frac{4}{3}\pi a^2x^2 \dot{a}$.

If this expression be multiplied by \dot{x} , we have the element of the shell = $\frac{4}{3}\pi a^2x^2 \dot{a} \dot{x}$.

In order to have the solidity of the shell ACBbc, the above expression must be integrated relatively to x , that is, supposing only x variable, and it is then $\frac{2}{3}\pi a^2x^3 \dot{a} + C$.

But $C = 0$, because the fluent vanishes when x vanishes, therefore the portion of the shell ACc = $\frac{2}{3}\pi a^2x^3 \dot{a}$, and when $x = a$ the whole shell = $\frac{4}{5}\pi a^2 \dot{a}$.

Now, if the whole quantity of matter in the shell were united at B, its attractive force exerted on A would be the same with that of the shell, therefore the whole force of the shell = $\frac{4}{5}\pi \dot{a}$. The same is true for every other indefinitely thin shell, into which the solid may be supposed to be divided; and, therefore, the whole attraction of the solid is equal to $\int \frac{4}{5}\pi \dot{a}$, supposing a variable, that is, = $\frac{4}{5}\pi a$.

Hence we may compare the attraction of this solid with that of a sphere of which the axis is AB, for the attraction of that sphere = $\frac{\pi}{6}a^3 \times \frac{4}{a^2} = \frac{2}{3}\pi \times a$: the attraction of the solid ADBH (fig. 136), is, therefore, to that of the sphere on the same axis as $\frac{4}{5}\pi a$ to $\frac{2}{3}\pi a$, or as 6 to 5.

VI. To find the content of the solid ADBH, we need only integrate the fluxionary expression for the content of the shell, namely, $\frac{4}{5}\pi a^2 \dot{a}$. We have then $\frac{4}{15}\pi a^3 =$ the content of the solid ADBH. Since the solidity of the

sphere on the axis A is = $\frac{\pi}{6}a^3$, the content of the solid

ADBH is to that of the sphere on the same axis as $\frac{4}{15}\pi a^3$ to $\frac{\pi}{6}a^3$; that is, as $\frac{4}{15}$ to $\frac{1}{6}$, or as 8 to 5.

VII. Lastly, to compare the attraction of this solid with the attraction of a sphere of equal bulk.—Let m = any given mass of matter formed into the solid ADBH; then for determining AB, we have this equation $\frac{4}{15}\pi a^3 = m^3$, and $a =$

$$m^3 \sqrt[3]{\frac{15}{4\pi}}; \text{ and, therefore, also, the attraction of the solid,}$$

$$\left(\text{which is } \frac{4}{5}\pi a \right) = \frac{4}{5}\pi m^3 \sqrt[3]{\frac{15}{4\pi}} = m \left(\frac{4 \cdot 5 \cdot 3 \cdot \pi}{4 \cdot 5} \right)$$

$$= m \left(\frac{4 \cdot 3 \cdot \pi^{\frac{2}{3}}}{5^{\frac{2}{3}}} \right) = m^{\frac{2}{3}} \sqrt[3]{48\pi}.$$

Again, if m^3 be formed into a sphere, the radius of that sphere = $m^3 \sqrt[3]{\frac{3}{4\pi}}$, and the attraction of it on a particle at its surface $\frac{m^3}{\left(\frac{3}{4\pi}\right)^{\frac{3}{2}}} = m \frac{(16\pi)^{\frac{1}{2}}}{9}$.

Hence the attraction of the solid ADBH, is to that of a sphere equal to it, as $m \left(\frac{48}{25}\pi^{\frac{2}{3}}\right)^{\frac{1}{2}}$ to $m \left(\frac{16}{9}\pi^2\right)^{\frac{1}{2}}$; that is, as $(27)^{\frac{1}{2}}$ to $(25)^{\frac{1}{2}}$, or as 3 to the cube root of 25.

The ratio of 3 to $\sqrt[3]{25}$, is nearly that of 3 to $3 - \frac{2}{27}$, or of 81 to 79; and this is therefore also nearly equal to the ratio of the attraction of the solid ADBH, to that of a sphere of equal magnitude.

VIII.—It has been supposed in the preceding investigation, that the particle on which the solid of greatest attraction exerts its force, is in contact with that solid. Let it now be supposed, that the distance between the solid and the particle is given; the solid being on one side of the plane and the particle at a given distance from the same plane on the opposite side. The mass of matter which is to compose the solid being given, it is required to construct the solid.

Let the particle to be attracted be at A (fig. 137), from A draw AA' perpendicular to the given plane, and let EF be any straight line in that plane drawn through the point A', it is evident that the axis of the solid required must be in AA' produced. Let B be the vertex of the solid, then it will be demonstrated as has been done above, that this solid is generated by the revolution of the curve of equal attraction, that of which the equation is $(y = a^2x - a)$ about the axis of which one extremity is at A, and of which the length must be found from the quantity of matter in the solid.

The solid required then, is a segment of the solid of greatest attraction, having B for its vertex, and a circle of which A'E or A'F is the radius, for its base.

To find the solid content of such a segment, CD being = y , and AC = x , we have $y = a^2x - a$, and $\pi y^2 \dot{x} = \pi a^2 x^2 \dot{x} - \pi a^2 \dot{x} =$ the cylinder, which is the element of the solid segment.

Therefore $\int \pi y^2 \dot{x}$, or the solid segment intercepted between B and D, must be $\frac{2}{3}\pi a^2 x^3 - \frac{1}{2}\pi a^2 x + C$. This must vanish when $x = a$, or when C comes to B, and therefore

fore $C = \frac{4\pi}{15} a^3$. The segment therefore intercepted between B and C, the line AC being x , is $\frac{4\pi}{15} a^3 - \frac{3\pi}{5} a^2 x + \frac{\pi}{3} x^3$.

This also gives $\frac{4\pi}{15} a^3$, for the content of the whole solid, when $x = 0$, the same value that was found by another method at VI.

Now, if we suppose x to be $= A A'$, and to be given $= b$, the solid content of the segment becomes $\frac{4\pi}{15} a^3 - \frac{3\pi}{5} a^2 b + \frac{\pi}{3} b^3$ which must be made equal to the given solidity, which we shall suppose m^3 , and from this equation a , which is yet unknown, is to be determined. If then for a , we put u , we have $\pi (\frac{4}{15} u^3 - \frac{3}{5} b u^2 + \frac{1}{3} b^2 u) = m^3$, or $\frac{4}{15} u^3 - \frac{3}{5} b u^2 + \frac{1}{3} b^2 u = \frac{m^3}{\pi}$, and $u^3 - \frac{9}{4} b u^2 + \frac{15 m^3}{4\pi} = \frac{1}{3} b^3$.

The simplest way of solving this equation would be by the rule of false position. In some particular cases it may be resolved more easily; thus, if $\frac{15 m^3}{\pi} - \frac{1}{3} b^3 = 0$, $u^3 - \frac{9}{4} b u^2 = 0$, and $u = \frac{3}{4} b$; that is $a = \frac{3}{4} b$, or $a = b \times (\frac{3}{4})^{\frac{1}{3}} = b \sqrt[3]{\frac{729}{64}}$.

IX.—1. If it be required to find the equation to the superficies of the solid of greatest attraction, and also to the sections of its parallel to any plane passing through the axis; this can readily be done by help of what has been demonstrated above.

Let AHB (fig. 138), be a section of the solid, by a plane passing through AB its axis. Let G be any point in the superficies of the solid, GF a perpendicular from G on the plane AHB, and FE a perpendicular from F on the axis. Let AE = x , EF = z , FG = v , then x , z , and v are the three co-ordinates by which the superficies is to be defined. Let AB = a , EH = y , then from the nature of the curve AHB, $y^2 = a^2 x^2 - v^2$. But, because the plane GEH is at right angles to AB, G and H are in the circumference of a circle of which E is the centre; so that GE = EH = y . Therefore $EF^2 + FG^2 = EH^2$, that is $z^2 + v^2 = y^2$, and by substitution for y^2 in the former equation, $z^2 + v^2 = a^2 x^2 - v^2$, or $(z^2 + z^2 + v^2) = a^2 x^2$ which is the equation to the superficies of the solid of greatest attraction.

2. If we suppose EF, that is z , to be given $= b$, and the solid to be cut by a plane through FG and CD (CD being parallel to AB) making on the surface of the solid the section DGC; and if AK be drawn at right angles to AB, meeting DC in K, then we have, by writing b for z in either of the preceding equations, $b^2 + v^2 = a^2 x^2 - v^2$, and $v^2 = a^2 x^2 - x^2 - b^2$ for the equation to the curve DGC, the co-ordinates being GF and FK, because FK is equal to AE or x .

This equation also belongs to a curve of equal attraction; the plane in which that curve is being parallel to AB, the line in which the attraction is estimated, and distant from it by the space b .

Instead of reckoning the abscissa from K, it may be made to begin at C. If AE or CK = b , then the value of b is

determined from the equation $b^2 = a^2 x^2 - b^2$, and if $x = b + u$, u being put for CF, $v^2 = a^2 (b + u)^2 - (b + u)^2 - a^2 b^2 + b^2$, or $v^2 + (b + u)^2 + b^2 = a^2 (b + u)^2$, or $(v^2 + b + u)^2 + b^2 = a^2 (b + u)^2$.

When b is equal to the maximum value of the ordinate EH (IV. 2) the curve CDG goes away into a point; and if b be supposed greater than this, the equation to the curve is impossible.

X.—The solid of greatest attraction may be found, and its properties investigated, in the way that has now been exemplified, whatever be the law of the attractive force. It will be sufficient in any case to find the equation of the generating curve, or the curve of equal attraction.

Thus, if the attraction, which the particle C (fig. 136.) exerts on the given particle at A, be inversely as the m power of the distance, or as $\frac{1}{AC^m}$, then the attraction in the direction AE will be $\frac{AE}{AC^{m+1}}$, and if we make this $= \frac{1}{AB^m}$, we have $\frac{AE}{AC^{m+1}} = \frac{1}{AB^m}$, or making

$$AE = x, EC = y, \text{ and } AB = a, \text{ as before } \frac{x}{(x^2 + y^2)^{\frac{m+1}{2}}} = \frac{1}{a^m}, \text{ or } a^m \cdot x = (x^2 + y^2)^{\frac{m+1}{2}} \text{ and } x^2 + y^2 = \frac{2m}{a^{m+1}} \frac{x}{y^{m+1}}$$

$$\text{or } y^2 = \frac{2m}{a^{m+1}} \frac{x}{y^{m+1}} - x^2.$$

If $m = 1$, or $m + 1 = 2$, this equation becomes $y^2 = a - x^2$, being that of a circle of which the diameter is AB. If, therefore, the attracting force were inversely as the distance, the solid of greatest attraction would be a sphere.

If the force be inversely as the cube of the distance, or $m = 3$, and $m + 1 = 4$, the equation is $y^2 = a^2 x^2 - x^4$ which belongs to a line of the fourth order.

If $m = 4$, and $m + 1 = 5$, the equation is $y^2 = a^5 x^2 - x^5$, which belongs to a line of the tenth order.

In general, if m be an even number, the order of the curve is $m + 1 \times 2$; but if m be an odd number, it is $m + 1$ simply.

In the same manner that the solid of greatest attraction has been found, may a great class of similar problems be resolved. Whenever the property that is to exist in the greatest or least degree belongs to all the points of a plane figure, or to all the points of a solid, given in magnitude, the question is reduced to the determination of the locus of a certain equation, as in the preceding example.

Let it, for instance, be required to find a solid given in magnitude, such, that from all the points in it, straight lines being drawn to any number of given points, the sum of the squares of the lines so drawn shall be a minimum. It will be found, by reasoning, as in the case of the solid of greatest attraction, that the superficies bounding the required solid must be such, that the sum of the squares of the lines drawn from any point in it, to all the given points, must be always of the same magnitude. Now, the sum of the squares of the lines drawn from any point, to all the given points, may be shewn by plane geometry, to be equal to the square of the line drawn to the centre of gravity of these given points, multiplied by the number of points together with a given space. The line, therefore, drawn from any point in the required superficies, to the centre of gravity of the given points, is given in magnitude, and therefore the superficies is that of a sphere,

sphere, having for its centre the centre of gravity of the given points.

The magnitude of the sphere is next determined from the condition that its solidity is given.

In general, if x , y and z are three rectangular co-ordinates, that determine the position of any point of a solid given in magnitude, and if the value of a certain function ϕ of x , y , and z be computed for each point of the solid, and if the sum of all these values of ϕ added together be a maximum or a minimum, the solid is bounded by a superficies, in which the function ϕ is every where of the same magnitude. That is, if the triple integral $\int x \int y \int z \phi$ be the greatest or least possible, the superficies bounding the solid is such, that $\phi = A$, a constant quantity.

The same holds of plane figures. The proposition is then more simple, as there are only two co-ordinates, so that $\int x \int y \phi$ is the quantity that is to be a maximum or minimum, and the line bounding the figure is defined by the equation $\phi = A$.

All the questions therefore that come under this description, though they belong to an order of problems, which requires in general the application of one of the most refined inventions of new geometry, the *calculus variationum*, form a particular division, admitting of solution by much more simple means, and directly reducible to the construction of loci.

In these problems also, the synthetical demonstration will be found extremely simple. In the instance of the solid of greatest attraction, this holds remarkably. Thus it is obvious, that (fig. 136) any particle of matter placed within the curve $A C B H$, will attract the particle at A in the direction $A B$, less than any of the particles in that curve, and that any particle of matter within the curve will attract the particle at A more than any particle in the curve, and more, *a fortiori*, than any particle without the curve. The same is true of the whole superficies of the solid. Now if the figure of the solid be any how changed while its quantity of matter remains the same, as much matter must be expelled from within the surface, at some one place C , as is accumulated without the surface, at some other point H . But the action of any quantity of matter within the superficies $A C B H$ on A is greater than the action of the same without the superficies $A C B H$. The solid $A C B H$ therefore by any change of its figure must lose more attraction than it gains. Thus is its attraction not distinguished by every such change, and therefore it is itself the solid of greatest attraction.

Among a number of propositions which the limits of our work do not permit us to notice, it is proposed, "to determine the oblate spheroid of a given solidity, which shall attract a particle at its pole with the greatest force." And it appears that the gravitation at the pole of an oblate spheroid is not a maximum, until the excentricity of the generating ellipse vanish, and the spheroid pass into a sphere. When a sphere passes into an oblate spheroid its attraction varies at first exceeding slowly, and continues to do so till its oblateness, or excentricity, becomes very great.

The cone of greatest attraction has the radius of its base nearly double that of its altitude, and the attraction of the cone, when a maximum, is about $\frac{2}{3}$ the attraction of a sphere of equal solidity.

Of all the cylinders given in mass or quantity of matter, that which attracts a particle at the extremity of its axis with the greatest force is when the radius of the base of the cylinder is to the altitude as five to eight nearly, and it appears that the attraction of the cylinder, even when its form is the most advantageous, does not exceed that of a sphere of

the same solid content, by more than a hundred and eighty-third part.

A semi-cylinder given in magnitude, attracts a particle situated in the centre of its base, with the greatest force possible, in the direction of a line bisecting the base, when the altitude of the semi-cylinder is to the radius of its base as 125 to 216.

GRAVITATION, *Centre of*. See CENTER.

GRAVITATION, *Line of*. See LINE.

GRAVITATION, *Plane of*. See PLANE.

GRAVITY, TERRESTRIAL, is that force by which all bodies are continually urged towards the centre of the earth.

It is in consequence of this force that a body cannot remain at rest on the surface of the earth, without exercising a pressure either on some intermediate body, or on that portion of the surface of the earth which sustains it; and the intensity of this force is measured by the degree of pressure, produced by a given mass. The tension of a string, by which a weight is suspended, arises from the force of gravity. The spring steel-yard, an instrument sold at the shops for weighing, is extremely well adapted to illustrate the effect of the force of gravity; the suspended substance draws out a scale by overcoming the resistance of the spring. These machines are not capable of great exactness, but if an instrument of this kind could be made with sufficient accuracy, the alteration of the scale, (the weight remaining the same,) would shew any change in the force of gravity; and we might, by taking this apparatus to the summit of a high mountain, observe whether any change took place in the force of gravity by such an operation. We measure likewise the force of gravity by the time which a body, suffered to descend freely from a state of rest, employs to fall through a given space, or (as has been explained under DYNAMICS) by the velocity which a body, thus falling, acquires at the end of a given time. Thus a body, falling freely, during the interval of one second, acquires a velocity of 32, that is, it would strike an obstacle with the same force as another body would of the same mass, which was moving uniformly with the velocity of 32 per second.

The density of the earth being about 2.5 that of water, we infer that the force of gravity of a sphere, 8000 miles in diameter, and whose specific gravity is twice and a half that of water, would attract a particle of matter placed just without its surface, in such a manner as to cause it to move towards its centre, 16 $\frac{1}{7}$ feet in one second.

It is, however, to be observed, that it is only at the pole that the *whole* force of the earth's gravity is actually exerted on a particle of matter: at every other part of the earth's surface, the force of gravity is diminished by the motion of rotation, which producing a centrifugal force, opposite in its tendency to that of the force of gravity, diminishes the effect of the latter as we recede from the pole and approach the equator. But, besides this, there is another cause which contributes in a very remarkable manner to modify the force of gravity at different points of the earth's surface, which is the elliptic figure of the earth.

The equatorial regions being more elevated than the polar, are more removed from the influence of the central attraction. Both these circumstances, and their effects, must be attended to when we propose to make any very accurate computation of the force of terrestrial gravity.

The diminution of gravity arising from the elliptic figure is nearly equal to the product of the $\frac{1}{17}$ th part of the force of gravity, by the square of the cosine of the latitude. The centrifugal force diminishes the force of gravity in the same proportion: thus by the combination of these two causes, the diminution of gravity from the pole to the

equator is equal 0.00694 multiplied by the square of the cosine of the latitude, the force of gravity at the equator being taken as unity.

The most exact instrument we possess, for measuring the intensity of the force, is the pendulum, whose oscillations are immediately accelerated or retarded by the slightest alteration in the force of gravity, and it is only by means of this instrument that we are enabled to infer with precision, the exact space that a heavy body falls through in one second of time.

GRAVITY, *The Nature of.*—Of the nature of gravitation, or the force of gravity, nothing more is known, than that it is apparently an essential property of matter, or, at least, of all matter that hitherto has become the object of human investigation, for Newton was not disposed to believe but that matter might exist which was not endowed with this property, and suggests the supposition that it is caused by the agency of an elastic medium pervading all space. This medium, he supposes, to be much rarer within the dense bodies of the sun, the stars, the planets, and the comets, than in the empty celestial spaces between them, and to grow more and more dense at greater distances from them, so that all these bodies are naturally forced towards each other by the excess of pressure. Upon this supposition, Dr. Young remarks, in his Lectures, that the effects of gravitation might be produced by a medium thus constituted, if its particles were repelled by all material substances with a force decreasing like other repulsive forces, simply as the distances increase; its density would then be every where such as to produce the appearance of an attraction, varying like that of gravitation. Such an ethereal medium would, therefore, have the advantage of simplicity, in the original law of its action, since the repulsive force, which is known to belong to all matter, would be sufficient, when thus modified, to account for the principal phenomena of attraction.

It may be questioned whether a medium, capable of producing the effects of gravitation in this manner, would also be equally susceptible of those modifications which have been supposed necessary to the transmission of light. In either case, it must be supposed to pass through the apparent substance of all material bodies with the most perfect freedom, and there would, therefore, be no occasion to apprehend any difficulty from a retardation of the celestial motion; the ultimate impenetrable particles of matter being, perhaps, scattered as thinly through its external form as stars are scattered in a nebula, which has still the distant appearance of a uniform light; and there seems no reason to doubt the possibility of the propagation of an undulation through the Newtonian medium, with the actual velocity of light. It must be remembered, that the difference of its pressure is not to be estimated from the actual bulk of the earth, or any other planet alone, but from the effect of the sphere of repulsion of which that planet is the centre; and we may thus deduce the force of gravitation from a medium of no very enormous elasticity.

Dr. Young observes, that a similar combination of a simple pressure with a variable repulsion is also observable in the force of cohesion, and supposes that if two particles of matter, floating in such an elastic medium, capable of producing gravitation, were to approach each other, their mutual attraction would at once be changed from gravitation to cohesion, upon the exclusion of the portion of the medium intervening between them. The well known experiment of the two exhausted hemispheres of Magdeburg affords an illustration of this hypothesis, where we see apparent cohesion derived from atmospherical pressure, and if we place between them a thick ring of elastic gum,

we may represent the natural equilibrium between the forces of cohesion and repulsion, for the ring would resist any small additional pressure with the same force as would be required for separating the hemispheres so far as to allow it to expand in an equal degree; and at a certain point the ring would expand no more; the air would be admitted and the cohesion destroyed, as when a solid of any kind is torn asunder. These suppositions, however, are directly opposite to the hypothesis which assigns to the elastic medium the power of passing freely through all the interstices of the ultimate atoms of matter, since it could never pass between two atoms cohering in this manner; we cannot, therefore, at present assert the identity of the forces gravitation and cohesion so strongly as theory would allow us to do if established. In short, the whole of our enquiries respecting the intimate nature of forces must be considered as merely speculative amusements, which are of no farther utility than as they make our views more general, and assist our experimental investigations.

La Place, after having shewn how the law of gravitation is deduced from the phenomena of the solar system, concludes his reflections on this subject by enquiring whether the principle of gravitation is a primordial law of nature, or if it may not be the general effect of some unknown cause? Here, he observes, we are stopped by our ignorance of the nature of the intimate properties of matter, and deprived of every hope of answering this question in a satisfactory manner. Instead, says this great author, of forming hypotheses on this subject, let us content ourselves with examining more particularly the manner in which this principle has been employed by philosophers.

They have admitted the five following suppositions:

1. That gravitation takes place between the most minute particles of bodies.
2. That it is proportional to the masses.
3. That it varies inversely as the square of the distance.
4. That it is transmitted instantaneously from one body to another.
5. And that it equally acts on bodies in a state of repose, and on those which by their motion in the direction of its action should seem likely to avoid a part of its influence.

The first of these propositions is, as we have seen, a necessary result of the equality which exists between action and re-action, every particle of the earth attracting it as the particle itself is attracted; this supposition is confirmed by the measures of the degrees of the meridian, and by experiments on pendulums; for amidst all the irregularities of the measured degrees, we may perceive the traces of a regular figure, which is conformable to the theory. The great influence that the compression of Jupiter has upon the nodes and perigees of the orbits of its satellites, proves to us that the attraction of this planet is composed of the attractions of all its particles. The proportionality of the attractive force to the masses is demonstrated in the earth by experiments on pendulums, the oscillations of which are of the same length of whatever substance they are composed. It is proved in the celestial regions by the constant relation which exists between the squares of the periodic times of bodies revolving about a common focus, to the cubes of the greater axes of their orbits.

We have seen with what precision the almost absolute state of repose of the perihelia of the planetary orbits indicate that the force of gravity varies according to the inverse square of the distance: and now that we know the cause of the motions of these perihelia, we may regard this law as rigorously exact. It is the same with all emanations which proceed from a centre, such as light;

GRAVITY.

light; it seems as if all forces whose action could be perceived at sensible distances obeyed this law. It has lately been observed, that the attractions and repulsions of electricity and magnetism decrease in proportion to the squares of the distances. A remarkable property of this law is, that if the dimensions of all the bodies of the universe, their mutual distances and velocities were to be augmented or diminished proportionally, they would describe curves entirely similar to those described at present, and their appearances would be entirely the same. For the forces which animate them being entirely the result of attractions proportional to the masses divided by the squares of the distances, they would be augmented and diminished proportionally to the dimensions of this imaginary universe. It may be remarked at the same time that this property can only belong to the law of nature. Thus the apparent motions are independent of its absolute dimensions, as they are likewise of the motions it may have in space, and we can only observe and recognize relative phenomena.

It is this law which gives to spheres the property of attracting each other mutually, as if their whole masses were united at their respective centres. It terminates also the orbits and the figures of the celestial bodies by lines and surfaces of the second order, at least if we neglect their perturbations and suppose them fluid.

We have no method of measuring the length of time in which gravity is propagated, because the action of the sun having once reached the planets, it continues to act on them as if the attractive force was communicated instantaneously to the extremities of the system. We cannot, therefore, ascertain in how long a time it is transmitted to the earth, no more than we could measure the velocity of light, were it not for the aberration, and the eclipses of Jupiter's satellites. But it is not the same with the small difference that may exist in the action of gravity upon bodies according to the direction of their velocity.

M. de la Place has found by analysis, that an acceleration should result in the mean motions of the planets round the sun, and in the mean motions of the satellites about their planets.

M. de la Place had assumed this method of explaining the secular equation of the moon, when he believed, with other geometricians, that it was inexplicable on the principle of universal gravitation. He found that if it arose from this cause, a velocity must be supposed to exist in the centre of the moon, in order to release it entirely from its gravity towards the earth, at least six million times greater than that of light: the true cause of this equation being now known, we are certain that the action of gravity is much greater than this. This force, therefore, acts with a velocity which we may consider as infinite; and we may conclude, that the action of the sun is transmitted in an indivisible instant to the extremities of the planetary system.

Do any other forces act on the heavenly bodies besides their mutual attractions?

We are unacquainted with any, and we may affirm that their effect is totally insensible. We may likewise be certain that these bodies experience no sensible resistance from the fluids through which they pass, as light, the tails of comets, or the zodiacal light.

The attractive force disappears between bodies of an inconsiderable magnitude, and re-appears in their elements under a variety of forms. The solidity of bodies, their crystallization, the refraction of light, the elevation and depression of fluids in capillary tubes, and all chemical combinations, generally are the results of attractive forces, the

knowledge of which forms the principal object of natural philosophy.

Are these forces the same as that of the gravity observed in the celestial regions, and modified on the earth by the figures of the integrant particles? To admit this hypothesis we must suppose much more space empty than full in all bodies, so that the density of their particles must be incomparably greater than the mean density of their whole volume. A spherical particle of one hundred thousandth of a foot in diameter should have a density at least ten thousand million of times greater than the mean density of the earth, to exert at its surface an attraction equal to the terrestrial gravity. But the attractive forces of bodies greatly surpass this gravity, since they deflect light, whose direction is not changed by the attraction of the earth. The density of these particles should, therefore, be to that of substances in a ratio which the imagination would fear to admit, if their affinities depended on the law of universal gravitation. The ratio of the intervals which separate the particles of bodies to their respective dimensions, would be of the same order as in stars which form a nebula, which in this point of view may be considered as a great luminous body. There is no reason, however, which absolutely forbids us to consider all bodies in this manner. Many phenomena are favourable to the supposition, particularly the extreme facility with which light penetrates diaphanous substances in all directions. The affinities would then depend on the integrant particles, and we might, by the variety of these forms, explain all the variety of attractive forces, and reduce to one general law all the phenomena of astronomy and natural philosophy. But the impossibility of ascertaining these figures, renders this investigation useless to the advancement of science.

Some geometricians, to account for these affinities, have added to the laws of attraction, inversely as the squares of the distances, new terms which are insensible at small distances; but these terms would be the expressions of as many different forces, and besides being complicated with the different figures of the particles, they would only complicate the explanation of the phenomena.

Amidst these uncertainties the wisest plan seems to be, to endeavour to determine by numerous experiments the laws of affinities; and to effect this, the most simple method appears to be, by comparing these forces with the repulsive force of heat, which may be itself compared with that of gravity. Some experiments already made with this view, afford us reason to hope, that one day these laws will be perfectly known, and that then, by the application of analysis, the philosophy of terrestrial bodies may be brought to the same degree of perfection, which the discovery of universal gravitation has procured for astronomy.

GRAVITY, in Hydrostatics. The laws of bodies gravitating in fluids, make the business of hydrostatics.

Gravity is here divided into *absolute* and *specific*.

GRAVITY, absolute or true, is the whole force wherewith the body tends downward.

GRAVITY, Specific, called also *relative, comparative,* and *apparent gravity,* is the excess of gravity in any body, above that of an equal quantity or bulk of another; and denotes that gravity, or weight, peculiar to each species, or kind of natural body; and whereby it is distinguished from all other kinds.

In this sense, a body is said to be *specifically heavier* than another, when under the same bulk it contains a greater weight than that other; and that other is said to be *specifically lighter* than the first. Thus, if there be two equal spheres, each a foot in diameter; the one wood, the other lead, since the leaden one is found heavier than the wooden

one, it is said to be *specifically*, or in *specie*, heavier: and the wooden one *specifically lighter*.

This kind of gravity some call *relative*; in opposition to *absolute gravity*, which increases in proportion to the quantity or mass of the body.

GRAVITY, *laws of the specific, and levity of bodies*.—I. If two bodies be equal in bulk, their specific gravities are to each other as their absolute gravities. Thus a body is said to be twice as heavy, *specifically*, as another, if it have twice its gravity under the same bulk.

Hence, the specific gravities of equal bodies are as their densities.

II. If two bodies, compared together, be of the same specific gravity, their absolute weights will be as their magnitudes or bulks.

III. The specific gravities of bodies of the same weight are in the reciprocal ratio of their bulks. Hence the masses of two bodies of the same weight are in a reciprocal ratio of their bulks.

IV. The specific gravities of two bodies are in a ratio compounded of the direct ratio of the absolute gravities, and the reciprocal one of their bulks. Hence, again, the specific gravities are as the densities.

V. The absolute gravities of two bodies will be in a compound ratio of their specific gravities and their bulks.

VI. The bulks of two bodies will be in a compound ratio of their absolute gravities directly, and their specific gravities inversely.

VII. A body specifically heavier than a fluid, loses so much of its weight therein as is equal to the weight of a quantity of the fluid of the same bulk.

For, suppose a cubic inch of lead immersed in water; a cubic inch of water will, thereby, be expelled from its place: but the weight of this water was sustained by the resistance of the ambient water. Therefore, such a part of the weight of the leaden cube must be sustained by the resistance of the ambient water, as is equal to the weight of the water expelled. The gravity of the body immersed, therefore, must be diminished by so much.

Hence, 1. Since a fluid, specifically heavier, has a greater weight, in the same bulk, than a lighter; the same body will lose a greater part of its weight in a fluid, specifically heavier, than in a lighter: and therefore it weighs more in a lighter than a heavier.

2. Equal homogeneous bodies weighing equally in air, lose their equilibrium if one of them be immersed in a heavier fluid; the other in a lighter.

3. Since the specific gravities are as the absolute gravities under the same bulk; the specific gravity of the fluid will be to the gravity of the body immersed, as part of the weight lost by the solid, to the whole weight.

4. Two solids, equal in bulk, lose the same weight in the same fluid: but the weight of the specifically heavier body is greater than that of the specifically lighter; therefore, the specifically lighter loses a greater part of its weight than the specifically heavier.

5. Since the bulks of bodies, equal in weight, are reciprocally as the specific gravities; the specifically lighter loses more weight in the same fluid than the heavier; wherefore, if they be in equilibrio in one fluid, they will not be so in another; but the specifically heavier will preponderate, and that the more, as the fluid is denser.

6. The specific gravities of fluids are as the weights lost by the same solid immersed in the same.

VIII. *To find the specific gravity of a fluid*.—On one arm of a balance suspend a leaden globe; and to the other, fasten a weight, which is in equilibrium therewith in the air. Im-

merge the globe successively in the several fluids, whose specific gravities are to be determined, and observe the weight which balances it in each. These several weights, subtracted, severally, from the first weight, the remainders are the parts of the weight lost in each fluid. Whence the ratio of the specific gravity of the fluids is seen.

Hence, as the densities are as the specific gravities, we find the ratio of the densities of the fluids at the same time.

This problem is of the utmost use: as by it the degree of purity or goodness of fluids is easily found; a thing not only of service in natural philosophy, but also in common life, and in the practice of physic. See HYDROMETER.

That the specific gravity may be found the more accurately, the weight of the thread not immersed in the fluid is to be subtracted from the weight of the solid in air; and the force necessary to make the thread subside (if it be specifically lighter) is to be added to the weight lost. But if the thread that sustains the solid be heavier than the fluid, the weight of the thread in the air is to be subtracted from the weight of the solid in air; and the weight the thread loses from the weight lost in the fluid. Indeed, this precaution may be spared, if, in examining the specific gravity of several fluids, care be taken that the same thread be immersed to the same depth in each.

IX. To determine the ratio which the specific gravity of a fluid has to the specific gravity of a solid that is specifically heavier than the fluid,

Weigh any mass of the solid in a fluid, and note the just weight therein: the specific gravity of the fluid will be to that of the solid, as the part of the weight lost by the solid to its whole weight.

X. The specific gravities of equally heavy bodies are reciprocally as the quantities of weight lost in the same fluid. Hence we find the ratio of the specific gravities of solids, by weighing masses thereof, that are equal in air, in the same fluid; and noting the weights lost by each.

XI. A body, specifically heavier, descends in a fluid specifically lighter, with a force equal to the excess of its weight, above that of an equal quantity of the fluid.

Hence, 1. The force which sustains a specifically heavier body in a fluid, is equal to the excess of the absolute gravity of the body, above that of the fluid, under the same bulk: *e. gr.* $47\frac{1}{2}$ pound of copper loses $5\frac{1}{2}$ pounds of its weight in water; therefore a power of 42 pounds is able to sustain it.

2. Since the excess of the weight of a solid over the weight of a fluid specifically heavier, is less than that over the weight of a specifically lighter fluid under the same bulk; it will descend with less force in a specifically heavier fluid than in a lighter; and, consequently, it will descend more slowly in the former than in the latter.

XII. A specifically lighter body sinks in a heavier fluid, till the weight of a quantity of the fluid, equal in bulk to the part immersed, be equal to the weight of the whole body.

Hence, 1. Since the specific gravities of bodies of the same weight are reciprocally as their bulks; and the bulks of fluids equal in weight, are as the parts of the same solid immersed therein; the specific gravities of fluids are reciprocally as the parts of the same body immersed therein.

2. A solid, therefore, immerses deeper in a lighter fluid than in a heavier, and deeper, as the proportion of the specific gravity of the solid to that of the fluid is greater.

3. If a body be of the same specific gravity with a fluid,

the

GRAVITY.

the whole body will be immersed; and it will remain in any given place of the fluid.

4. If a specifically lighter body be wholly immersed in a fluid, it will be urged, by the collateral columns of the fluid, to ascend with a force equal to the excess of the weight of the fluid, bulk for bulk, over the weight of the solid.

5. A body, therefore, specifically lighter, lying on the bottom of a vessel, will not be raised up, unless the heavier fluid rise above such a part as is equal in bulk to a quantity of the fluid of the same weight with the whole solid.

XIII. The specific gravity of a solid is to the specific gravity of a lighter fluid, wherein it is immersed, as the bulk of the part immersed is to the whole bulk.

XIV. The specific gravities of equal solids are as their parts immersed in the same fluid.

XV. The weight and bulk of a specifically lighter body, and the weight of the specifically heavier fluid, being given, to find the force required, to keep the solid wholly immersed under the fluid.

As this force is equal to the excess of the weight of the fluid beyond that of an equal bulk of the solid; from the given bulk of the solid, and the weight of a cubic foot of water, find, by the rule of three, the weight of a bulk of water equal to that of the body. From this subtract the weight of the solid; the remainder is the force required. *E. gr.* Suppose the force necessary to detain a solid eight feet in bulk, and 100 pounds in weight, under water, required: since a cubic foot of water is found to weigh 70 pound, the weight of water under the bulk of eight feet, is 560; whence, 100 pound, the weight of the solid, being subtracted; the remainder 460 pound is the force necessary to detain the solid under water.

Hence, since a specifically lighter body ascends in a heavier fluid, with the same force that would prevent its ascent: by the present problem, we can likewise find the force wherewith a specifically lighter body ascends in a heavier.

XVI. The weight of a vessel, to be made of a specifically heavier matter; and that of a specifically lighter fluid, being given: to determine the cavity the vessel must have to swim on the fluid.

The weight of a cubic foot of the fluid being given, the bulk of the fluid equal to the weight of the vessel is found by the rule of three. If, then, the cavity be made a little bigger than this, the vessel will have less weight under the same bulk than the fluid, and will therefore be specifically lighter than the same, and consequently it will swim.

XVII. The force employed to retain a specifically lighter solid, under a heavier fluid; and the weight lost by a heavier solid in a lighter fluid, are each added to the weight of the fluid, and weigh together with it.

The several theorems here delivered, are not only all demonstrable from the principles of mechanics, but are conformable to experiment. In effect, experience is here found to answer exactly to calculation, as is abundantly evident from the courses of philosophical experiments, now frequently exhibited; where the laws of specific gravitation are well illustrated. See *HYDROSTATICAL balance*.

The specific gravity of any substance is the relative weight of a given volume of it, compared with the same volume of some other substance taken as a standard, and which is usually distilled water at some given temperature. The absolute gravity of a body is its entire weight, its specific gravity is the weight of a given portion, as a

cubic foot or cubic inch. As it would be very difficult, and in many cases impossible, to measure the exact volume required to be weighed, a method of determining the specific gravity of solids has been devised, founded on a principle of *Hydrostatics*. It appears to have been known to Archimedes, that when a solid body, heavier than water, is plunged into that fluid, it loses as much of its weight as is equal to the weight of the fluid it has displaced.

By the application of this principle we are enabled, in a very easy manner, to determine the specific gravity of a body by first weighing it in air and afterwards in water. Then if the weight in air be divided by the weight lost, or the difference of the weights in water and air, the quotient will express the specific gravity of that body, or the relative weight of an equal volume of that substance, and of the water in which the experiment was made.

The specific gravity of two fluids may be determined by the same principle; for if we weigh a solid of any magnitude, as a ball of glass, first in water and then in any other fluid, the quantities of weight lost in each experiment will be in the same proportion as the specific gravity of the two fluids.

The specific gravities of any substances, and in particular of such as are lighter than water, may also be very conveniently determined by means of a common balance, employing a phial with a conical ground stopple filling it first with water and then either with a given fluid, or with a portion of the solid of which the weight has been ascertained, together with as much water as is sufficient to exclude the air.

It is necessary to attend to a great number of minute circumstances when we wish to determine the specific gravities of substances to a great degree of accuracy: these will be particularly noticed when describing the particular instruments that have been invented for the purpose. See *HYDROSTATIC Balance*, *HYDROMETER*, &c.

One mode of ascertaining the specific gravities of fluids, differing but little from each other in density, is to have a series of globules of glass so loaded, as to correspond to the specific gravities indicated by as many numbers, which are marked on them, and throwing several of them together into the fluid, and to observe which of them remains nearly stationary, without either rising to the surface or sinking. This method, though not expeditious, appears to be very secure from error, and is well adapted to determine the strength of spirituous liquors. But in all these experiments it is necessary to be aware that a considerable change of the joint bulk of two substances is often produced by their mixture, and that in general their dimensions are considerably contracted. Thus, 18 gallons of water and 18 gallons of alcohol, instead of 36 gallons, make only 35, consequently the specific gravity of the compound is one 35th greater than the mean of the specific gravities of the ingredients. And in some cases the whole dimension of a single substance may even be contracted by the addition of another substance; thus iron, by the addition of one-eighth of its bulk of platina, becomes contracted one-fortieth of that bulk.

For measuring the specific gravity of gases, Mr. Leslie has devised a new method, which consists in observing the time employed in emptying a vessel through a small orifice, by means of the pressure of an equal column of water.

A Table of Specific Gravities.

Principally from Davies and Lavoisier. Davies's table is compiled with great diligence from many different authors; Lavoisier's is chiefly extracted from Brisson; it is carried

GRAVITY.

to four places of decimals, but little dependence can be placed on the last.

GRAVITY, in *Mechanics*, denotes the conatus or tendency of bodies towards the centre of the earth.

That part of mechanics which considers the motion of bodies arising from gravity, is peculiarly called *statics*.

Gravity, in this view, is distinguished into *absolute*, and *relative*.

The former is that with which a body descends freely through an unresisting medium: the laws of which see under DESCENT of bodies, ACCELERATION, MOTION, *Inclined PLANE*, &c.

The latter is that with which a body descends after having spent part of its weight in overcoming some resistance. Such is that with which a body descends along an inclined plane, where some part is employed in overcoming the resistance, or friction of the plane. The laws of relative gravity, see under *inclined PLANE*, DESCENT, FLUID, RESISTANCE, &c.

GRAVITY, *Centre of*. See CENTER of gravity.

GRAVITY, *Diameter of*. See DIAMETER of gravity.

GRAVITY, *Paracentric solicitation of*. See PARACENTRIC.

GRAVITY, *Plane of*. See PLANE of gravity.

GRAVITY, *Retardation from*. See RETARDATION.

GRAVITY of the air. See WEIGHT of the Air, AIR and ATMOSPHERE.

GRAVITY, in *Music*, is an affection of sound by which it becomes denominated *grave*, low, or flat.

Gravity stands in opposition to *acuteness*, which is that affection of sound by which it is denominated *acute*, *sharp*, or *high*.

The relation of gravity and acuteness, is the principal property on which music depends; and it is the distinct, fixed, and determinate quality of this relation which entitles sound to the denomination of *melodious*, *harmonical*, or *musical*.

Gravity is, therefore, that modification of sound by which it is considered as *grave* or low, with respect to, or compared with, other sounds, that are acute or high. See ACUTE.

The degrees of gravity, &c. depend on the nature of the sonorous body itself, and the particular figure and quantity thereof: though, in some cases, they likewise depend on the part of the body where it is struck. Thus, *e. gr.* the sounds of two bells of different metals, and the same shape and dimensions, being struck in the same place, will differ as to acuteness and gravity; and two bells of the same metal will differ in acuteness, if they differ in shape or magnitude, or be struck in different parts.

So in chords, all other things being equal, if they differ either in matter, or dimension, or tension, they will also differ in gravity.

Thus again, the sound of a piece of gold is much graver than that of a piece of silver of the same shape and dimensions; and in this case the tones are, *ceteris paribus*, proportional to the specific gravities: so a solid sphere of brass, two feet in diameter, will sound graver than another of one foot diameter; and here the tones are proportional to the quantities of matter, or the absolute weights.

But it must be observed, that acuteness and gravity, as also loudness and lowness, are but relative things. We commonly call a sound *acute* and loud, in respect to another which is *grave*, or low with respect to the former; so that the same sound may be both *grave* and *acute*, and also loud and low, in different comparisons.

The degrees of acuteness and gravity make the different tones or tunes, of voice, or sound; so we say one sound is in tune with another, when they are in the same degree of gravity.

The immediate cause or means of this diversity of tones lies very deep. Mathematicians express the proportion of sound to sound, by the ratio of numbers. The moderns fix it on the different velocity of the vibrations of the sonorous body: in which sense gravity may be defined, a relative property of sound, which, with respect to some other, is the effect of a lesser number of vibrations accomplished in the same time, or of vibrations of a longer duration. In which sense also, acuteness is the effect of a greater number of vibrations, or vibrations of a shorter duration.

If the vibrations be isochronous, the sound is called musical, and is said to continue at the same pitch. See CHORD and STRING, in *Music*.

If two or more sounds be compared in the relation of gravity, &c. they are either *equal*, or *unequal*, in the degree of tune. Such as are *equal*, or produced by isochronous vibrations, are called *unisons*.

The *unequal* including, as it were, a distance between each other, constitute that we call an interval in music; which is properly the difference, in point of gravity, between two sounds.

Upon this inequality, or difference, does the whole effect depend; and in respect of this it is, that these intervals are divided into *conords* and *discord*s. See HARMONICS and RATIO.

As the gravity of sounds depends on the thickness, length, and tension, of the strings, or on the length and diameter of the pipes, and, in general, on the volume or mass of the sonorous bodies; the increase of any of these qualities (except tension) augments the gravity of sound. But there is no absolute point of gravity in nature, and no sound is *grave* or acute, but by comparison.

GRAULKET, in *Geography*, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavaur; nine miles N. E. of Lavaur. The place contains 3419, and the canton 7159 inhabitants, on a territory of 135 kilometres, in six communes.

GRAUN, CHARLES HENRY, in *Biography*, chapel-master to Frederic II. the late king of Prussia, was the favourite composer of that prince, from 1732 to the time of his decease, in 1759. On the accession of the prince of Prussia to the throne in 1740, his majesty, having determined to have an Italian lyric theatre in his capital, sent Graun to Italy to study the Italian language and taste in music, and to engage vocal performers. Graun remained two years in Italy, during which time the king, his royal master, had constructed, in spite of the Silesian war, one of the most magnificent, complete, and convenient theatres in Europe, for which Graun was the composer to the end of his life; and even after his decease little music but of his composition was ever performed in it for a long time.

The works of this master are very numerous; before his arrival at Berlin, he set three or four operas in the German language at Brunswick, but the words were bad, and it is not fair to judge of his genius by those early productions.

He composed for the Berlin theatre, in the space of fourteen years, from 1742 to 1756, twenty-seven Italian operas;

and for the church, a *Te Deum*, and a *Passione*, besides miscellaneous productions of less importance, as odes and cantatas, with the overture and recitatives of the pastoral opera of Galatea, of which his majesty, Quantz, and Nibelman, set the fongs.

On the decease of this excellent composer, innumerable poems and panegyrics were written to his memory. Among the "Critical Letters concerning Music," published by M. Marpurg, there is an address to M. Fried. Wilhelm Zachariä, the celebrated poet and musician of Brunfwick, recommending the death of Graun to his muse. No great strefs can be laid on panegyrics; however, there are few of Graun's admirers, who are not ready to burn with fire and faggot all those who dare to doubt of this author's veracity.

"Graun, the brightest ornament of the German muse, the noble master of sweet melody, is now no more! creator of his own taste, he spoke not, but to our hearts; tender, soft, compassionate, elevated, pompous, and terrible, by turns;—he could force tears of admiration from us, at his pleasure; an artist, who made no other use of art, than to imitate nature, in the most pleasing and expressive manner; each stroke of his pencil was equally perfect, full of invention, and of new ideas, his genius was inexhaustible. The model of sacred music, and in the theatre inimitable! a man who commanded our affections, not only by his talents, but by his virtues, of friendship, probity, and patriotism; no man was ever so universally lamented by the whole nation, from the king, to the lowest of his subjects." *Britische Briefe über die Tonkunst*. I. Band. Berlin 1760.

Now, to reverse the medal; it is denied, by the other party, that Graun was the creator of his own taste, which is the taste of Vinci; they deny, that he is ever pompous or terrible, but say, that an even tenor runs through all his works, which never reach the sublime, though the tender and graceful are frequently found in them; they are equally unwilling to subscribe to his great invention, or the originality of his ideas; and think that still more perfect models of sacred music may be found in the chorusses of Handel, and the airs and duos of Pergolesi and Jomelli: nor can they well comprehend, how that composer can be called *inimitable*, who is himself an *imitator*.

We have recently examined the scores of Graun's operas, and see no reason for changing the opinion which we formed 30 years ago. He was certainly a great master, elegant in his melodies, and correct and regular in his harmony; but if any one of his operas were now to be revived, it would be thought in want of variety and fire.

During the life of his great and illustrious patron, he was revered as much at Berlin as Handel in England; both great men, most assuredly; but much discrimination is necessary in drawing a parallel between them. Handel formed his style on the best models of the old school, at the time of its greatest perfection; such as Carissimi, Colonna, Aless. Scarlatti, Steffani and Corelli; Graun on that of the inventor of the new style, Vinci; who, though extremely and justly admired for the grace and elegance of his melodies, the simplicity of his accompaniment, and the facility and clearness of his style in general, has been far surpassed by Pergolesi, Jomelli, Piccini, Sacchini, and Pacchiello. Germany is perhaps more obliged to Graun for smoothing, simplifying, and polishing the rough, laboured, and inelegant style of their old masters, than to any Italians that have been employed at the imperial court or at Dresden, to set the dramas of Apollolo Zeno and Metastasio. Handel had more spirit and invention, and Graun more polish and refinement. Handel was wholly unrivalled in the country where

he spent the greatest part of his life; but Graun had a rival in the Roman Catholic courts, in the celebrated Haffe, his countryman, whose compositions were as much in circulation and favour all over Europe, as those of Vinci and Pergolesi. Those of Graun seem wholly confined to Germany, and almost to the court of Berlin; nor do we ever remember to have heard Mara sing one of his airs in England, though during many years she performed the principal female parts in his operas at Berlin. His *Te Deum* was first appointed to be performed at the concert of ancient music in 1786, by the late duke of Leeds, then marquis of Caermarthen, and it has continued a stock piece ever since. Many of his duets, and his *Tod Jesu* are admirable compositions, and he certainly deserves to be ranked very high among the great masters of the last century.

GRAUN, JOHN GOTTLIB, brother of the above composer, and concert-master to his late Prussian majesty, Frederick II. his admirers at Berlin, say that "he was one of the greatest performers on the violin of his time, and most assuredly, a composer of the first rank; his overtures and symphonies are majestic, and his concertos are master-pieces, particularly those for two violins, in which he has united the most agreeable melody with all the learning that the art of counterpoint can boast; he has likewise frequently set the *Sa'ez Regina*, and composed masses, which are rendered grand and noble by simplicity and good melody, even in the most laboured parts."

But less quarter is granted to this master, by the admirers of more modern music, than to his brother; they often find his overtures and symphonies too like those of Lulli, and too full of notes to produce any other effect, when played at Berlin, than that of stunning the hearers: and in his concertos and church music, when that is not the case, the length of each movement is more immoderate, than Christian patience can endure.

Perhaps the truth may lie between these two opinions; and with respect to the chapel-master Graun, it should be remembered, that he was seldom allowed to follow the bent of his own genius.

GRAUNT, JOHN, born April 24, 1620, was brought up to the trade of a haberdasher, but by his good sense and integrity in business he acquired the esteem of his fellow citizens, so as to be elected into the common council of the city of London. The bills of mortality, which were annually laid before this body, led Mr. Graunt to turn his attention to the science of political arithmetic. From very small beginnings he collected a large body of materials, from which he composed a work entitled "Natural and Political Observations made upon the Bills of Mortality." This work was well received by the public, and passed through several editions: it obtained likewise for the author an admission into the Royal Society, upon the particular recommendation of the king, who gave it in particular charge to those concerned, that if they found any more such tradesmen, they should be sure to admit them all. It is generally supposed that Mr. Graunt received valuable assistance from Sir W. Petty; but the style is such as might be expected from a plain citizen, and the tabular form, presenting at one view the general results of a number of important facts, was a thought essentially leading to all the conclusions which have since been established relative to these subjects. After he retired from business, he was admitted a trustee for Sir William Baeckhouse, into the management of the New River Company, which, with the unlucky circumstance of his being a convert to popery, gave occasion to the groundless calumny of his having had a hand in the great fire of London.

The

The story, though given by Burnet, is abundantly refuted by the writers of the *Biographia Britannica*. Mr. Graunt continued his application to his studies, and made large additions to his "Observations" but two years before his death, which happened on the 18th of April, 1674. He was buried at St. Dunstan's Well, and many of the most eminent and ingenious persons of that time, among whom was Sir William Petty, paid their last respects to his memory. He left behind him a discourse upon the advance of the excise, and some papers on religious topics, which have not been published. It must be mentioned to his honour, that immediately after the publication of his book, *Lewis XIV.* or his ministers, enacted a law to enforce the most exact register of births and burials that was to be found any where in Europe. *Biog. Brit.*

GRAUPEN, a term used by the German miners to express the residuum of any ore after the regulus, or metalline part, is run from it. Thus the ores of bismuth leave behind them, after the regulus is melted off, an earthy substance, called bismuth graupen, with which, mixed with flints and an alkali, they make a kind of smalt, not distinguishable from the true smalt made from cobalt. *Phil. Trans. N. 390.*

GRAUSTONE. See *GREYSTONE*.

GRAY, THOMAS, in *Biography*, a distinguished English poet, descended from very respectable citizens of London, was born in Cornhill, December the 26th, 1716. His grandfather was a considerable merchant; but his father, Mr. Philip Gray, was of an indolent and reserved temper; and therefore diminished rather than increased his paternal fortune. He had many children, of whom Thomas, the subject of these memoirs, was the fifth: all of them except himself died in their infancy, and he is said to have narrowly escaped suffocation, owing to a too great fullness of blood, which destroyed the rest, and he would certainly have been cut off as early, had not his mother, with a courage remarkable for one of her sex, ventured to open a vein with her own hand, which instantly removed the paroxysm. He was probably destined for a profession, and accordingly sent to Eton school to acquire the fundamental stock of classical literature. Here he was placed under the immediate care of Mr. Antrobus, his mother's brother, at that time one of the assistant masters, and likewise a fellow of St Peter's college, Cambridge, to which place Mr. Gray removed, and was admitted a pensioner in the year 1734. Of his residence at Cambridge few memorials are recorded; he seems rather to have cultivated a literary taste in silence, than to have had any aim at public distinction. He nevertheless appeared as a poet among the university congratulators of the prince of Wales's marriage, and his verses were admitted to be the best of the academical collection. His letters, during this period, to Mr. West, which are printed by Mr. Mason, shew that he had little reverence for the graver studies, or for the dignified personages of the place, and that he had acquired that classic fastidiousness which was the permanent feature in his character. He quitted college in 1738, and occupied a set of chambers in the Inner Temple, with the avowed intention of studying the law. A Latin ode, addressed upon this occasion to Mr. West, who had the same purpose in view, exhibits in a striking manner the ascendancy which the poet possessed in his mind over the ideal lawyer; and on the invitation which Mr. Walpole gave him to be the companion of his travels, he laid aside this intention, and never after resumed it. They set out in the spring, and his letters from the different stages of his progress, are a proof of the intelligent curiosity with which he viewed all the striking objects of art and nature, and the manners and habits of mankind. Thus, in his letter from

Amiens, he describes every thing that he saw on the road, paints in vivid colours what was remarkable in the several towns through which he passed; and he adds, that "on every hillock is a windmill, a crucifix, or a Virgin Mary dressed in flowers, and a siren's robe; one sees not many people or carriages on the road; now and then a strolling friar, a countryman with a great muff, or a woman riding allride on a little ass, with short petticoats, and a great head-dress of blue wool." They travelled through France, crossed the Alps, visited the principal towns of Italy as far as Naples, returned to Florence, and in the spring of 1741 proceeded for Venice. Upon their way thither the two companions fell into a disagreement, which occasioned their separation. Of this unfortunate incident the biographer says, "Mr. Walpole enjoins me to charge himself with the chief blame in their quarrel; confessing that mere attention and complaisance, more deference to a warm friendship, superior judgment and prudence, might have prevented a rupture that gave much uneasiness to them both, and a lasting concern to the survivor; though, in the year 1744, a reconciliation was effected between them." Mr. Gray, with his own very moderate resources, finished the rest of the tour, and arrived in England in September 1741, two months previously to the death of his father. He now returned to academic retirement at Cambridge. In the following year he had the misfortune to lose his friend Mr. West, the confident of his sentiments and partner of his studies. The death of this hopeful young man left a vacancy in Mr. Gray's heart, which was never after supplied. He had an ambition to excel in Latin poetry, but was convinced that lasting fame could only be acquired by works accordant to the general taste of his countrymen. He made many noble beginnings of poems, which, if he had possessed perseverance enough to have completed them, would have redounded to his immortal honour. In the year 1742, he took the degree of bachelor of civil law, a circumstance which gave him every necessary privilege for improving an university residence, and he sat down to a course of reading, which he pursued with the diligence of an exact critic. For several years his exquisite learning and high poetic talents were known to but a very few of his most intimate friends. In 1747 he published his "Ode on the distant Prospect of Eton College;" and in 1751 his "Elegy written in a Country Church-yard," was sent into the world without the author's name. Few poems were ever so popular; it has passed through an almost indefinite number of editions, and is at this moment one of the most favourite productions of the British muse. It has been translated into Latin and Greek verse. In 1753 Gray buried his mother, to whom he had always behaved with true filial duty and affection, and on her tomb he wrote, "the tender mother of many children, one of whom alone had the misfortune to survive her." At college he was, on account of some peculiarity in his manners, subject to the boisterous tricks of a few riotous young men of fortune, who took a pleasure in disturbing and alarming him; he made remonstrances on the subject to the head of the house, which not producing the effect which he anticipated, he removed his residence to Pembroke Hall in 1756, and in the succeeding year he was, on the death of Cibber, offered the post of poet laureat, which he declined. His motive for refusing this office could not have been through any doubt of his being adequate to its duties, for in the same year he shewed what he was capable of doing as a lyric poet by the publication of his two principal odes, entitled "On the Progress of Poetry;" and "The Bard." It would indeed have been most lamentable that a man of his genius and independent mind should have been fettered by the obli-

gation of producing periodical oblations of court incense. The odes just mentioned were much less popular than the elegy: many could not understand them, some ridiculed them, and in general they were more the objects of astonishment than of rapturous feeling; nevertheless, among persons of real literary taste, they raised the author's poetical character to a level with that of the first poets of his country. In the year 1759, Mr. Gray varied the uniformity of his life by a residence, which continued three years, in lodgings near the British Museum, chiefly for the purpose of consulting curious books and manuscripts in that great national repository. In 1765 he took a journey into Scotland for his health, was introduced to the most eminent literati in that country, and fed his imagination with those scenes of natural sublimity and beauty which no man was better qualified to taste, and to improve. He had, previously to this, sought for the professorship of modern history at Cambridge, but either his application was too late, or the patron, lord Bute, had other interests to serve; it was given to another candidate. A second vacancy occurred in 1768, when it was conferred upon him, unsolicited and unexpected, in the most handsome way possible, by the duke of Grafton, who, notwithstanding some defects in the former part of his life, has always been capable of doing noble things in a noble manner. The place was worth 400*l. per ann.* and Gray made a voluntary return for the favour by an "Ode to Music," for the installation of that nobleman, as chancellor of the university in 1769. His new office laid him under an obligation to some exertions: he might indeed have sheltered himself by the example of his predecessors, and received the emoluments without paying any regard to its duties, but the idea of retaining a perfect sinecure did not accord with his temper; he immediately set about preparing for active service, he sketched an admirable plan for his inauguration speech, in which, after enumerating the preparatory and auxiliary studies requisite, as ancient history, geography, chronology, &c. he descended to the authentic sources of the science, such as public treaties; state records, private correspondence of ambassadors, &c. He also drew up and laid before the duke of Grafton, three different schemes for regulating the method of choosing pupils privately to be instructed by him, which were highly approved, and if he had been accustomed, by general habits, to those exercises which he felt would have been beneficial to the improvement of his pupils, much might have been expected from his lectures, but with a mind replete with the stores of knowledge, ancient and modern, he was totally unable, through the baneful effects of habitual literary indolence, to bring his vast acquisitions to use on demand; and after many uneasy struggles, he proceeded no farther than to sketch out a plan. His health was indeed rapidly on the decline; low spirits, "the indolent scholar's familiar malady," seized him; an irregular hereditary gout made more frequent attacks than usual on his feeble constitution: at length a sudden nausea, with which he was affected while dining in the College Hall, indicated that the disease had left the extremities and established itself in the stomach. He died July 30th 1771, in the fifty-fifth year of his age. He was sensible to the last, and aware, through the whole of the disease, of his great danger, but expressed no visible concern at the thoughts of his approaching dissolution. With a warm imagination, Mr. Gray had cool affections, and a calm sedate disposition. He was attentive from economy, yet wholly void of avarice: he was generous, even when his circumstances were the most narrow. He was careful of himself, and so timorous, that it is asserted, some of the finest views in a tour to the Lakes escaped him, because he did not choose to venture to those

spots whence they were to be seen. This want of personal courage is a singular contrast with the manly and martial strains of his poetry. In morals he was temperate, upright, and a constant friend to virtue. His religious opinions were not known, but he always abhorred the dissemination of scepticism and infidelity. Few men of his reputation have had less vanity, and he bore with good-humour and easy negligence all the criticisms upon his compositions. The learning of our poet was general and deep: it comprised almost every topic of human enquiry, excepting what belonged to the sciences properly so called. As a poet his name must descend to the latest posterity, at least, as long as there is taste enough left to feel and enjoy elegant writing. No one appears to have possessed more of that faculty of poetical perception which distinguishes among all the objects of art and nature what are fittest for the poet's use, together with the power of displaying them in their richest colours. According to a critic, Mr. Gray "did not excel in pure invention, neither is he highly pathetic or sublime, but he is splendid, lofty, and energetic; generally correct, and richly harmonious. Though lyric poetry is that in which he has chiefly exercised himself, he was capable of varying his manner to suit any species of composition. Perhaps he was best of all qualified for the moral and didactic, if we may judge from his noble fragment of "An Essay on the Alliance of Education and Government." As a writer of Latin verse he is perhaps surpassed by few in classic propriety. His letters are entertaining and instructive; free from all parade; they possess a fund of pleasantries, which will ever render them popular among those of his countrymen, who are at all imbued with the principles of literary taste. By a friend who has described his character it is said that "perhaps he was the most learned man in Europe; he was equally acquainted with the elegant and profound parts of science, and that not superficially but thoroughly. He knew every branch of history both natural and civil, and had read all the original historians of England, France, and Italy; and was a great antiquarian. Criticism, metaphysics, morals, and politics, made a principal part of his plan of study; voyages and travels of all sorts were his favourite amusement, and he had a fine taste in painting, prints, architecture, and gardening: with such a fund of knowledge, his conversation must have been equally instructive and entertaining; but he was also a good man, a well bred man, a man of virtue and humanity. There is no character without some speck, some imperfection; and I think the greatest defect in his, was an affectation in delicacy, or rather effeminacy, and a visible fastidiousness or contempt and disdain of his inferiors in science. He also had in some degree that weakness which disgusted Voltaire so much in Mr. Congreve: though he seemed to value others chiefly according to the progress they had made in knowledge, yet he could not bear to be considered himself merely as a man of letters; and though without birth, or fortune, or station, his desire was to be looked upon as a private independent gentleman." *Mason's Life and Letters of Gray*, four vols. 8vo. 1778.

GRAY, or *Grey*, a mixed colour, partaking of the two extremes, black and white. In dyeing, many of the varieties of grey, iron-grey, slate colour, &c. are given by processes, in general, similar to those for black, but with smaller quantities of the ingredients, and especially a shorter time of immersion. They are often finished with a weak bath of weld, cochineal, Brazil-wood, and other livelier colours to give some particular tints.

In the *Manege* they make several sorts of grays: as the *branded* or *blackened* gray, which has spots quite black, dispersed here and there. The *dappled* gray, which has spots

of a darker colour than the rest of the body. The *light* or *silver* gray, wherein there is but a small mixture of black hairs. The *fad* or *iron* gray, which has but a small mixture of white. And the *brownish* or *sandy-coloured* gray, where there are bay-coloured hairs mixed with the black.

GRAY, in *Zoology*, a name given in some counties of England to the badger.

GRAY is also used in some places for a species of wild-duck, more commonly known by the name of the *gadwall*. See DUCK.

GRAY, in *Geography*, a town of France, and principal place of a district, in the department of the Upper Saône, seated on the Saône, which is navigable by boats to Lyons, whither the inhabitants send grain and iron, the chief articles of their commerce. The place contains 5009, and the canton 13,825 inhabitants, on a territory of 215 kilometres, in 26 communes. N. lat. 47° 27'. E. long. 53° 40'.

GRAY, a post-town of America, in Cumberland county and state of Maine; 15 miles N.W. from Portland. The township was incorporated in 1778, and contains 987 inhabitants.

GRAY'S Bay, a bay on the N. side of the river Columbia, in New Georgia. N. lat. 46° 19'. W. long. 236° 22'.

GRAY'S Creek, a river of Virginia, which runs into James river. N. lat. 37° 8'. W. long. 76° 56'.

GRAY'S Harbour, a port or bay on the W. coast of North America, examined and described by Mr. Whitbey. The surrounding shores are low and apparently swampy, with salt-marshes; the soil is a thin mixture of red and white sand over a bed of stones and pebbles. At a small distance from the water side, the country is covered with wood, chiefly pines of an inferior stunted growth. The number of Indians inhabiting this place were estimated at about 100; they spoke the Nootka language, though it did not seem to be their native tongue, and they appeared to vary in little or no respect from those people occasionally seen. N. lat. 47° E. long. 236° 7'.

GRAYLING, or UMBER, the English name for the fish called by authors *thymallus*, and *thymus*, and by Artedi made a species of *corregonus*, and the *SALMO thymallus* of Linnæus, which see.

It is caught in the fresh rivers and clear rapid streams, chiefly in the mountainous counties of England, and in the like situations in Germany, and other kingdoms, and is one of the finest tasted of all the fresh-water fish. It is common in Lapland, where the guts of it are used instead of rennet to make cheese, which they get from the milk of the reindeer. It is a voracious fish, rises freely to the fly, and will very eagerly take a bait. It feeds on worms, and spawns in May.

GRAYSON, in *Geography*, a county of Virginia in the upper waters of the Great Kanhawa. It contains 3742 free inhabitants, and 170 slaves. Its form is triangular; the longest line being about 50 miles, and its greatest breadth 15 miles. It is mountainous, abounding with timber and iron ore; and two sets of iron-works are erected in it: about a fifth part is arable. The court house is in N. lat. 36° 35', 250 miles S.W. of Richmond.

GRAZALEMA, a town of Spain, about 1½ mile from the borders of the province of Granada, built partly on the side, and partly on the top of a mountain. Most of the inhabitants are employed in the manufacture of woollen and coarse cloths, and also of crucibles. Their number is about 5000.

GRAZIANI, ANTON-MARIA, in *Biography*, a bishop and elegant writer, was born of a distinguished family at

Borgo-san-Sepolero, in Tuscany, about the year 1527. Having obtained a good knowledge of grammatical learning at Friuli under the celebrated Abilemio, he was sent to Padua to study the law. In 1560 he visited Rome, and was kindly patronized by Commendone, afterwards cardinal. He accompanied this friend, between whom and himself there was an unalterable attachment, in all his journeys into Germany and Poland, and refused to quit him, though solicited with great promises by Henry of Valois, at that time king of the latter country. After the death of Commendone in 1584, he was made secretary to pope Sixtus V, and took a considerable share in the election of Clement VIII. who, in 1592, in gratitude for his services, created him bishop of Amelia, and sent him as his nuncio to the Italian princes and states, in order to unite them in a league against the Turks. When at Venice, he prevented that republic from declaring in favour of Cesar d'Este after the demise of Alphonso II. duke of Ferrara. In 1598 he retired to his see, where he remained, till his death in 1611, most assiduously employed in the duties of his high office. As an author Graziani is known by the following works. "De Bello Cyprio," lib. v. 4to. 1624; "A History of the War of Cyprus;" "De Vita Commendonii, Cardinali," which was intended as a tribute of gratitude and affection to his deceased friend and patron: "De Casibus adversis Virorum illustrium," and a collection of synodical ordinances. In 1745 the public were presented with a curious posthumous work of this author, entitled "De Scriptis Invita Minerva, ad Aloysium Fratrem," lib. xx. in which he not only gives an account of his own life and writings, but that of his native town and family; of his brother's travels, and of the public affairs in which he was engaged. Moreri.

GRAZIANI, D. BONIFACIO DA MARINO, maestro di capella of the Jesuits' chapel and seminary at Rome, was a very voluminous composer of sacred music and cantatas, who flourished from the year 1650 to 1678. Padre Martini has given the following list of his ecclesiastical publications; three books of psalms for five voices, *a due cori*, or for two choirs; published at Rome 1652 and 1670. Masses à 5 Rome, 1671. Six books of motets, for 1, 2, 3, 4, 5 and 6 voices; Rome, from 1651 to 1671; antiphons, for the blessed virgin Mary, for 4, 5 and 6 voices, Rome, 1665. *Responf. della Settim. santa*, Rome, 1663. *Litanie* for 3, 4, 5, and 8 voices, Rome 1675. Sacred and moral compositions, for 1, 2, 3 and 4 voices, 1678. Of his cantatas, though none are mentioned in this list, yet the number of them, that have been preserved in MS. collections of old music, is equal to those of Carissimi, Celli, and Luigi Rossi, particularly in the British Museum; Dr. Aldridge's collection of music in the library of Christ-church, Oxford; Dr. Burney's Collect. &c.

GRAZIER, in *Agriculture*, a term commonly applied to such farmers as are engaged in the art and business of fattening various sorts of live stock on pasture and other grass-lands. That this sort of business may be managed to the best possible advantage, the grazier should have a perfect knowledge of the nature, properties, and value of all sorts of cattle and sheep stock, as well as of the quality of the ground on which they are to be fed, and of the most proper methods of fattening them to each other. And he should also be well informed concerning the nature and states of markets in general. It is obvious that upon these being well understood and properly regarded, much of the success of this sort of farming business must depend, as thereby proper advantage may be taken, not only of fairs and markets, but a variety of other necessary circumstances.

The markets for the sale of fat stock, especially those of the neat cattle and sheep kinds, are generally as high about the end of April as at any other period of the year, in consequence of the supply, at that season of the year, being only had from cake or corn-fed animals, not one farmer in a thousand having then any sort of winter green food remaining. On this account such beasts or sheep as are really fat at that time are sure to fetch a good price in the markets, and particularly at Smithfield. With the latter animals, however, the case is, in some instances, rather different as to those farmers who are good providers: spring food is now beginning to be ready, though seldom in such plenty, from the number of bad managers, as to reduce the markets in any great degree.

The inexperienced grazier should consequently fully weigh and consider the different modes in which he may be able to dispose of his fat stock to the greatest advantage. The first and principal place to which his attention will be directed, will probably be Smithfield market, especially for the more southern graziers. If he be situated in a district that is divided into small or middling sized farms, and in which the farmers are commonly in the regular practice of employing district drovers, in whom proper confidence can be placed, he will of necessity be as safe as his neighbours, and may not have reason for any particular caution. This mode is very common in the eastern part of the county of Norfolk. Where he occupies a very large farm, whatever the nature of it may be, whether an arable grazing one, as is customary in West Norfolk, or a grass grazing one, as in the county of Lincoln, on a scale that enables him to send many droves in a pretty regular manner to his saleman, he may safely trust to him; as the usual confidence and integrity of trade mostly take place in such cases. But it must be observed, that it is seldom the case that the grazier who sends occasionally or accidentally a lot of fat beasts or sheep to Smithfield market, gets as fair a price for them as his great neighbour, who is in constant dealing, gets the same day, or his little one, whose stock took the same chance through the means of a confidential drover. The person who thus drops in a lot, out of the regular course of his business, is scarcely ever satisfied with the treatment he meets. And there is, without doubt, much truth in the remark, in consequence of the frequency of its being made by persons from different places.

On this account the inexperienced grazier should consider the circumstance well, and try the country butchers, in order to feel his way through the difficulty as well as he can, provided his farm be of such a size, and in such a situation, as to lay him open to its influence and effects.

In the business of grazing, great advantage may be derived, by those who have not had much experience, from the frequent weighing of the animals while alive; as by a comparison of the living with the dead weight, in such cases, as when they are killed in their own neighbourhoods, they may soon become able to judge, with a tolerable degree of correctness, of the dead weight of any common sized beast, of which they have ascertained the weight while in the living state. And where the living weight has been taken from tables of admeasurement, such as those composed by Bantor, they may compare the result in a pretty exact way.

The work of ascertaining the living weight in sheep, calves, hogs, and other similar kinds of animals, may be effected in a simple and easy manner, merely by the contrivance of a sort of cage or large covered basket, with a door at each end for their reception and discharges, to which is attached a pair of large steelyards, so as to shew the weight.

The frequent weighing of the fattening stock shews the grazier the different degrees of progress which the animals have made in different periods and situations, as well as what the effects of different sorts of food are upon them; what changes may be necessary in it, and when it may be the most proper to sell, provided the markets should be suitable. In short, a sort of confidence is in this way gained by the grazier, that could not be readily acquired in any other manner.

But assistance of this nature is not by any means necessary for such graziers as have been long accustomed to the handling and judging of the weights of animals, as they can in general form tolerably correct opinions by the eye and the feel, in consequence of such long experience; though it not unfrequently happens that they are deceived, the beasts turning much better and heavier than they had imagined. It has, indeed, been remarked that, let the grazier be as experienced as he may in buying and selling, as well as in judging by the hand and the eye, the butcher will beat him, from having been able to bring the live to the test of the dead weight, in such a variety of different instances, as must render his judgment perfect. The grazier, though he cannot therefore equal him, may, in a great measure, approximate to him by means of frequent careful weighing of the living animals.

It must of course appear evident that it is a matter of great consequence for the stock farmer, to make himself, as soon as possible, perfectly conversant with this part of his business, as without it he must be liable to be greatly deceived in his dealings.

GRAZING, the practice of feeding and pasturing down grass-lands with different sorts of live stock, with the intention of improving and rendering them fit for the market. It is a sort of management that cannot be carried on to much advantage, except in those districts where the quantity of pasture land is considerable, and of a suitable quality for the purpose, or where the value of the produce of such sward land is but small in comparison with the stock which is fed upon it.

There are particular districts in different parts of the kingdom that are much more in this system of farming than others, as is exemplified by those of the counties of Lincoln and Leicester, in the middle part of the island, Somerset, Gloucester, &c. in the west, and Romney marsh, &c. in the south.

But there are tracts of grazing ground of more or less extent in most of the counties of the kingdom.

It is well remarked that there are certain situations as well as descriptions of pasture ground on which this method of farming may be had recourse to with better profits, and more success than that of any branch of the dairying system: This must be the case in all those districts where the proportion of land in the state of tillage is very small in comparison to that of the pasture kind, consequently the price of produce of the grass sort trifling in comparison to that of the fat stock. In all such districts of the kingdom where the grass-lands are of so fine and rich a quality, as to be capable of fattening large bullocks or other cattle, this system may be had recourse to with much success and profit, and is perhaps the best application to which the lands can be applied, as is fully shewn by such districts being mostly under some management or other of this nature.

It may be observed that the art of grazing to advantage depends upon a variety of circumstances, such as those of the nature and quality of the grounds, the propriety of the management of them in respect to feeding down, changing, and shutting them up; the properly adapting the stock to

GRAZING.

them in quantity, size, and quality; the judgment of the grazier not only in selecting such as are most suitable for the purpose and most disposed to fatten, but in obtaining them, where they are to be purchased, at such prices as that they may pay well for keeping; and disposing of them, when fattened, at their full value and advantage.

It has been stated, by Mr. Kent, that the stocking of land with proper cattle is one of the nicest parts of the science of farming. Where nature is left to herself, she always produces animals suitable to her vegetation, from the smallest sheep on the Welsh mountains to the largest sort in the Lincolnshire marshes; from the little hardy bullock in the northern highlands to the noble ox in the richest pastures in Somersethire. But good husbandry admits of our increasing the value of the one in proportion to that of the other. Land improved enables us to keep a better sort of stock, which shews the double return the earth makes for any judicious attention or labour we bestow upon it. The true wisdom of the occupier is best shewn in preserving a due equilibrium between this improvement of his land and stock. They go hand in hand, and if he neglect the one, he cannot avail himself of the other. It should, therefore, be first considered what kind of cattle, or other sorts of stock, will answer the purpose best, on the particular description of land upon which they are to be grazed; and next, what sorts may pay the most in the consumption of the produce.

“In general, it will probably be found, that upon strong florid pastures of the driest kinds, the large sorts of cattle, with some of the larger breeds of sheep, will be the most suitable stock; but that where the grass-lands are neither so luxuriant nor so dry, and upon turnip-lands, the small English, Welsh, or Scotch cattle, with some of the small breeds of sheep, will be most profitable. Thus, as different sorts of grass-land and different kinds of produce seem in point of profit to require different descriptions of animals to feed upon and consume their produce, it is of much importance to be at some pains to make the best and most suitable application.” And in cases where the grazier breeds his own stock, he will have little difficulty in selecting such of the different kinds as are the most adapted to his views; but where the animals are to be purchased in, which must most frequently be the case, more care and circumspection will be necessary. It will be proper, though a difficult task, to make a choice of such as have been well kept and are in a thriving condition; as when they have been stinted in their food, and have the contrary appearance, they seldom do so well for the uses of the grazier. It will likewise be of advantage to have them from situations in which the lands are inferior in point of richness. It is noticed by some, that many farmers have found great advantage in buying sheep from the poorest spots, as they generally thrive most when they come into a richer pasture, like trees which endure transplanting the better for coming from a poor nursery. They likewise think that they endure folding and penning better than sheep which are bred on a more luxuriant soil. And they are certainly right, in these observations. But, with respect to the notion which farmers are apt to entertain, that all kinds of sheep will not endure penning, they labour under an error. It is believed that all lean or store-sheep are the better for being folded. They are generally more healthy; and, above all other advantages, this one is certainly obtained by it; when such sheep are put to fatten they thrive much better and faster, as oxen do that have been moderately worked. But where the grazing-lands are very moist, sheep are not by any means a sort of stock to be depended upon, as they are extremely liable to become diseased.

In addition to these points, it is necessary to have consider-

able regard to the qualities or properties of the kinds of animals, whatever they may be, in the intention of grazing them with profit; those kinds, whether of cattle or sheep, which have the property of keeping themselves fat, or in tolerably full condition, by the least consumption or expenditure of food, being constantly preferred, whatever the size or breed may be, as that is evidently a quality of much greater importance to the grazier than that of mere size, considered in an abstract manner. It is stated, that where there are fine and rich pastures, the grazier may “choose his beasts as large as he can find them, provided they are of the right breed and shape; but let him always prefer shape to size; for it will assuredly pay him better;” and, that “those who are upon indifferent grass must take care to proportion the size of their beasts to the goodness of their pastures: their cattle had much better be too small than too large; as there are vast tracts of land that will answer in grazing, which are not good enough to support large breeds.” And it is not improbable, but that the same thing may hold good in a great degree in regard to sheep. But in all such cases, as where the stock is reared upon the land of the farm, which is often a good practice, there can be little difficulty, as has been seen, in fixing upon such animals as are the most proper in these different intentions; but as it must often be necessary for the grazing farmer to purchase his live-stock at fairs and markets, and in other circumstances, much care and attention, as well as knowledge, will be required for him to accomplish it in the most advantageous manner.

In a system of Practical Agriculture, lately published, it is noticed to be “of great importance in this business to provide such as have been kept in a proper manner, and are in a healthy, improving state; as, where the contrary is the case, they are difficult, and require a much greater length of time to be brought into the state proper for sale than would otherwise have been necessary. It is, perhaps, experience alone that can qualify the grazier to form a correct judgment in these respects; in general, however, he is led to the choice of stock by no fixed or scientific principles, but by the impression the appearance of the animals have upon him.” And, it is stated on the authority of Mr. Marshall, “that the experienced grazier, who has been accustomed to attend fairs and markets, knows at sight, or by the assistance of the slightest touch, whether the animals he is about to purchase will suit him. Their general form and looks please him. They are every where clean; have little ossal about them; their eyes are full and vivid; their countenances brisk; their skins alive, and their flesh mellow. On the whole, they have the resemblance of those which have been grazed before with success. Others are rejected, from the grazier not having found any such as they resemble to have done well, but many to have turned out in an unprofitable manner.” And the writer of the above work conceives, that there are certain “principles in this branch of the farmer’s business which may be attended to with great advantage, as the animals have certain points or parts, the proper or improper forms of which denote them to be valuable, or the contrary, for this purpose. These are, that the legs should be short in proportion to the size of the animal; the back very straight, broad, and flat; the loins wide; the carcass deep round, or rather barrel-shaped below; the fore-quarters round, full, and spreading; the bones small; the flesh affording an elastic feel; the skin thin, and a disposition to fatten well, and on the best parts. Where these marks are predominant, the stock is mostly suitable for the purposes of the graziers.” And, “that where the hair of the hide, in fattening cattle, is inclined to curl instead of

being straight, they are most disposed to thrive. This has been found to be the case in practice in different parts of the kingdom," as has been shewn in various publications on agriculture.

"In lean beasts also, when the hair of the hides is curled, they commonly keep themselves in better condition than where the contrary is the case. In all cases a disposition in the animals, of whatever sort they may be, to wildness, and not remaining quietly in their pastures, forms an insurmountable objection in this system of management; as no animal ever fattens well that has a tendency to ramble: it is quietness, feeding quickly, and lying much, that has the greatest tendency to make them become fat in a short time;" a fact which is fully confirmed by what happens in the new Leicester or Dishley breed of sheep, which are so tame and quiet as scarcely to move over a common gutter in the pasture. And, "from the result of actual experiment with four different beasts, in which the least possible difference could not be discovered on the most minute examination, it has been shewn that too much attention cannot be bestowed in the choice of the breed of fattening stock, as, though they were in every respect the same in appearance, two, from their superior disposition to fatten, were found to afford a profit in the proportion of fifteen shillings the week, while the other two did not yield more than about five shillings and ten-pence." This fact is recorded in the Annals of Agriculture, and clearly shews that too much attention cannot be paid by the grazing farmer to the discovery of this propensity in the stocking of his pasture, or other grafs-lands.

Notwithstanding it must often happen that the grazier cannot fully avail himself of this, from the impossibility or vast difficulty of procuring such animals, and is consequently under the necessity of buying in such as are more at hand, and ready for his use.

It is the usual custom in Leicestershire, and the neighbouring districts, to have commonly recourse to the improved long-horned breed of cattle, from the animals being found to fatten in a ready manner, and to afford good beef. And, in the adjoining county of Lincolnshire, a mixture of the large sorts, of both the long and short-horned breed, are had recourse to as grazing stock, besides those bred in the county, and such as are brought into it by the Scotch drovers.

On the contrary, in Somersetshire, the dark-red sort, or Devonshire breed, has been long much in esteem by the graziers, and have lately spread themselves much into the midland districts, as Leicestershire, Oxfordshire, and Warwickshire, from the grazing farmers in these districts finding them to answer upon their pastures more perfectly. And in Suffex, the same breed is also held in considerable estimation by the farmers, as well as their own variety of it, as they are both found to fatten kindly, and with considerable expedition, upon their lands, and to have a ready sale in their markets and fairs.

However, in the more arable or tillage districts of Norfolk and Suffolk, where turnips and artificial grasses are more in use, the Kiloe, Galloway, and other small Scotch breeds, as well as those of the Welsh runt kind, are in preferable demand, from their answering better on these sorts of food, their more kindly disposition to fatten, and the excellent quality of their flesh, which never fails to have a ready sale in the London market, where the greatest part of their fat stock is sold. But the grazing farmers in the northern counties have mostly recourse to their own long-horned breed, raised on the farms, with the different Scotch breeds brought into the districts, their home sort being in their experience the

least disposed to take on fat and become saleable. And the large Hereford sort, as well as that kind of Welsh cattle termed the Glamorgan, are also very advantageous grazing stock in situations where the pastures are good, and they can be finished with other sorts of food. Great numbers of the former of these sorts are purchased by the graziers round the metropolis for being fattened or brought considerably forward on the rich grafs lands, which have been mown for hay, and finished with other sorts of food. Yet the small breeds of the Scotch, Welsh, or other similar kinds, may, in many cases of the inferior sorts of grazing lands, often be the most beneficial in affording profit to the farmer, as he can suit them more to the nature and state of such lands, and they have more chance of becoming fat upon them. Indeed it has been stated in the tenth volume of the Bath Papers, on the experience of fifteen years, that the small animal has generally "a more natural disposition to fatten, and requires (proportionably to the large animal) less food to make it fat; consequently the greater quantity of meat for consumption can be made per acre." If this point was satisfactorily proved, there could be no doubt of small animals being preferable both on this description of grazing land, and that of a better quality; but, as an able and accurate observer has upon much experience been induced to think differently on this subject, the grazier should be cautious how he has recourse to small breeds upon lands that are capable of fattening large ones, until the question has been fully decided.

In respect to what relates to the sort of cattle that may be employed to the greatest advantage under this system, oxen, and such heifers as have been spayed, are in general considered, by the best informed graziers, as the best sort of stock; as besides being more quiet, the latter have not only the property of fattening in a more expeditious manner, but with a less consumption of food. They are not, however, so readily provided by the grazier. The ox is of course the most commonly, as well as most extensively, employed for the purpose of the grazier, as having the advantage of being capable of being fattened, and of affording good beef, after he has been beneficially wrought in the team of the farmer. Cows, under different circumstances, are likewise often bought in by the grazing farmer for the purpose of being made fat, such as those that have become dry, have slipped the calf at an early period, or are becoming aged; but much caution is necessary in the purchase of this sort of grazing stock, as they frequently turn out less favourably than bullocks or heifers, though in some cases they leave a good profit. When old, they rarely thrive well or get fat with any degree of expedition. Indeed it is, perhaps, the best way, in all cases, for the grazier to have such stock as is not too far advanced in age, as young animals are invariably more disposed to get flesh, and become fat, than such as are old. In the grazing of both heifers and cows, they should be suffered to take the bull as soon as they have an inclination, and be ready for being sold off fat several months before the time they would have calved. Such cow or heifer stock as are in calf, may sometimes be purchased in at a cheap rate in the fairs in the autumnal season, and be fattened off in the early spring with a good profit. There is likewise another description of this sort of stock sometimes grazed, which is what are termed *free martins*, or cows that are barren; but they are said to seldom answer in this intention in any very advantageous manner.

In relation to the most proper sheep stock for the grazier, when the pastures are rich, and afford full keep, the improved, large long-woolled breeds, as the new Leicesters, may yield the

the best profit; but where the lands are less rich, and the feed of course less plentiful, the small, improved, short-wooled breeds, as the South Downs, may leave a more ample profit to the farmer. Where wethers of the former kind can be procured, they mostly turn out well for the purpose. And in the contrary circumstances, perhaps the South Downs cannot be excelled by any of the short, or middle-wooled breeds. But in particular situations and circumstances of grafs-lands, many other breeds may, however, be more profitable to the grazing farmer. It is stated, in the Agricultural Survey of Somersetshire, that the Dorsets, formerly so prevalent in that district, have lately given way to the polled, native breed of the lower part of the county; from the circumstances of their giving a larger proportion of wool, and their fattening more expeditiously, and at the same time more fully, especially on the internal parts. However, in the rich marshes in the southern parts of the island, the grazing farmers, who are mostly in extensive business, have constantly recourse to the polled, white-faced breed, and that of the South Down, which they find the most profitable sorts on their lands that can be employed.

In the northern parts of the kingdom, the graziers have principally recourse to the native breeds, the heath and Cheviot sorts, and find the former the quickest in getting fat, and the most hardy in their nature. The Cheviot sort seems, however, lately to have gained ground in the more elevated and hilly situations.

Whatever the breeds of the animals may be that are made use of as grazing stock, it has been found, from long experience, that it is a matter of much importance to procure them from districts, where the quality of the land is inferior to that on which they are to be fattened, as by such means they not only get fat in a more expeditious manner, but without suffering any check upon being first turned upon the pastures.

It is a matter of much consequence in sheep grazing that they have a fine close pasture; and that they be prevented from going upon such grafs-lands as have been covered by water, and become sandy, as under such circumstances, they are liable to become diseased. And, besides this, it may be beneficial in many cases for the farmer to be careful that horses are not turned upon the pastures along with them, as it has been found that the tufts of long, rank grafs that rise about the dung-heaps, are apt to render them in a state of disease, except where frost has taken place, when the danger is for the most part removed; and it is supposed, that it is also dangerous to suffer sheep to browse upon the grain, especially that of barley, which shoots up among the stubble, after the harvest is completed; and fallows that are wet and unfound are equally detrimental, whether the soil be *light* or *strong*. In the former situations, they frequently pull up the herbs by the roots, which they eat with the dirt adhering to them, which will inevitably give them the rot; and, if the fallows be strong land, and should not afford a sufficient supply of food, they are liable to the hunger-rot, from being compelled to eat the rank, unwholesome vegetables produced on such grounds, especially the lesser spear-wort, and the marsh-penny-wort, both of which plants flourish in wet situations, and ought carefully to be eradicated wherever they are found. It is further advised, that in turning sheep into pastures, particularly water-meadows, and also into those places that are subject to rot, to pursue the same precaution as with neat-cattle; which is previously to satisfy the craving of appetite, by giving them hay or cut straw, and after the dew has been evaporated by the rays of the sun, to drive them gently round the field for two or three hours before they are suffered to eat. But, whenever any sort of dry

food is given, they ought to be supplied with *pure water*, particularly during the intense heat that usually prevails in the summer months, and which often renders the grafs as dry as a stubble. "For this purpose, clear, limbit-running water is always to be preferred, when it can be obtained; though, in general, whatever presents itself is made use of. But where this necessary of life is found only in a tainted state, or over-charged with the juice of dung, it will be advisable to give them well-water in troughs or shallow tubs. This must be particularly attended to in the folds, so long as the sheep are confined there by the severity of the weather." It has been noticed, that "the watering of sheep is, on the Continent, regarded as a circumstance of the greatest moment, and accordingly receives that attention which it requires. Thus, in Sweden, and at the national farm at Rambouillet in France, they are daily watered with running-water, or with that obtained from lakes or springs, *stagnant water* being most properly and rigorously prohibited. In some of the Saxon sheep-farms, the sheep are watered in the cots or folds during the winter, instead of taking them to watering-places. Spring or well-water is conducted by means of pipes into troughs, out of which the sheep drink at pleasure; they in consequence drink oftener, and each time take less water, which is favourable to their health. The ordinary mode of watering sheep in that, and we may add in many parts of our own country, is attended with many inconveniences. The animals refuse to drink water in the winter, if it be too cold; they hurry while drinking, and do not take enough when the weather is very windy, or hail, rain or snow falls.

"Besides which, they often disturb the water with their feet; this disgusts them, and at length one part of the flock completely prevents the other from approaching the watering-place." And it has been advised to fold them before the dew falls in summer and winter, and not remove them till it exhales, letting them have hay or other dry food of some sort.

It is stated, that all grazing-land of rich quality ought to be stocked with sheep, cattle, and horses, so that the grafs may be eaten clean off; for, unless it is regularly depastured, much damage ensues. Each of the above three kinds of animals prefers, as most palatable food, some grasses which the others reject; and none of them will lie near their own dung, though they may near that of others; and thus they conjointly contribute to keep the pasture level without much expence. Pastures or grazing-lands should be kept as level as a bowling-green, both for ornament and use; for, by one part being left higher than another, the long grafs keeps increasing in patches; and land where it grows may be considered as taken away from the pasture, as the cattle will almost sooner starve than eat it. By leaving the sort of grasses the animals refuse from year to year, the land increases in useless plants, and diminishes in useful ones; as the seed of such plants continually drops, and the useful ones are prevented feeding by the cattle eating them. If such pastures were mown in those places, it would give the useful plants room to grow. There are in this kingdom an infinite number of acres of rich and excellent land, which, from bad management, and from want of judgment in stocking, become of no more value than a barren soil. But such grazing land as is intended for the purpose of feeding cattle, a few sheep are conceived absolutely necessary to eat up the weeds. If any part of the pasture be getting into bents, or higher grafs than it ought to be, and the animals begin to neglect it, you must mow it immediately, and as near the ground as possible; for the closer you cut down such coarse parts, the sweeter and the quicker will the grafs spring up in the place. Could animals, by hunger, be

driven to eat the long grafs, they would not fatten upon it ; for, as the nearer the bone the sweeter the flefh, fo the nearer the ground the sweeter the grafs ; it is not, he fuppofes, fo much the quantity as the quality of the food that muft be attended to. And in further proof of the advantage of hard flocking, it is ftated, that it is a common complaint, that the land is good in fpring, but it goes off. Is this to be wondered at, when one-third, or perhaps one-half of the field is become fo rank, that no one animal in the pature will bite a mouthful of it ? Suffer the very beft piece of grafs-land, entirely free from weeds, to lie without either eating off the grafs, or mowing it, and in a few years it will be over-run with weeds, have very little ufeul grafs in it, and in fact be little better than rubbifh. Confequently, there can be little doubt of the beneficial confequences of hard or clofe flocking on the older forts of grazing-land ; but on the new leys it fhould probably be feldom attempted, as injury may be done to fuch lands without the flock being thereby adequately improved.

But in grazing farms, there are feveral different fyftems of management purfued, in refpect to cattle as well as fheep. The practice with fome graziers is, “ to purchafe their cattle in the fairs in the autumn-feafon, about October, or in the following month, fupporting them through the winter, principally with flraw, or fometimes, which is a much better practice, with a little hay mixed with it, till towards the beginning of March, continuing their fattening through that and the fucceeding month with fome fort of fucculent food, fuch as turnips, potatoes, or other fimilar kinds, until the grafs be in a ftate fit to be turned upon in May, on which they may be carried forward and completed, according to circumftances, about Auguft, or in the following month.”

And another practice “ is to purchafe their bealts lean, as foonas the grafs-lands are in a ftate fit to be turned upon in May, wholly completing their fattening on the grafs about the latter end of October, or later in the autumn, according to their quicknefs in feeding. In this fyftem of management, the fmaller kinds of cattle flock may be found in general the moft advantageous, efpecially where the lands are of the lefs fertile and luxuriant defcriptions.”

Another practice, fometimes had recourfe to by grazing farmers, but which is, in general, perhaps lefs profitable than either of the above modes, is that of buying in flock at fuch periods, according to the difference in their fizes, as that they may be ready to be fold off about April, or in the fucceeding month, a period at which they ufually fetch high prices in the markets. It has been obferved, that “ in this fyftem, with large oxen or other forts of bealts, it is fometimes the practice to keep them through two winters, giving them only one fummer’s grafs ; being in the firft winter not fully fed, but kept in good grafs in the fummer-feafon, and forced on with the beft feeding in the fecond ; but with the fmaller forts of flock, one fummer’s grafs and a winter’s ftalling is the ufual mode ; the cattle being bought in as foon in the fpring as the grafs is rifen to a good bite.” It is in very few inftances that the animals can pay for this length of keeping. And, “ in fome diftricts, heifers are preferred to oxen ; in which cafe, they buy them in about March or April, and, after keeping them through the fummer, fell in October and November. This method is thought, by fome, a profitable fyftem of management.” By the author of the Modern Syftem of Practical Agriculture, on thefe different fyftems, it is noticed that they may all “ probably be practifed with advantage under different circumftances ; but it is obvious that the firft can only be had recourfe to with propriety, where green winter food is raifed in fufficient abundance, and the grazier has a ftore of litter

for being converted into manure. Under other circumftances, the fecond mode of management will be much more profitable. The two laft methods are the leaft convenient, and, probably, on the whole, except in very favourable circumftances, the leaft profitable, efpecially the former of them, as, from the great length of time which they are kept, much management and attention to food becomes neceffary to render them advantageous ; which, with common fervants, is feldom fufficiently regarded.”

But in addition to thefe feveral modes or plans of fattening neat-cattle, there is a practice followed in fome rich hay-diftricts near large towns, and particularly by the hay-farmers in Middlefex, which is, that “ of buying in fmall cattle in tolerable condition in the autumn, as foon as the after-grafs is ready, in order to their being fattened out on the rouens, and difpofed of towards the latter end of October, or beginning of the following month.”

And, regarding fheep flock, the fame difference of fyftem takes place ; as, in fome cafes, where the lands are in a ftate of inclofure, it is the “ practice to buy ewes in lamb in the latter end of fummer or beginning of autumn, keeping them on the inferior forts of grafs-lands, stubbles, or fallows, till the beginning of January ; and then, by giving them turnips or cabbages, to keep them in good condition through the period of their lambing, and afterwards in the beft manner that can be contrived, in order that the lambs may become fit for the butcher fufficiently early to admit of the ewes being afterwards fattened, and difpofed of in the beginning of the autumn.” This, in many cafes, is found a profitable fyftem of management, but which requires much care and attention in directing it.

Another practice in this bufinefs is, to purchafe wether flock about the beginning of May, at the age of two or three years, keeping them fparingly till fome weeks after the grounds have been cleared from hay ; then bringing them to good keep in the rouen, afterwards fattening them by means of turnips or cabbages, fo as not to have them ready fooner than the beginning of March, which is commonly the feafon in which they fetch the higheft prices. In this fyftem of grazing management, a good profit is moftly afforded by farmers who purfue it in a judicious and fteady manner.

And a further practice in fattening fheep is purfued in fome cafes with great profit and fuccefs, which is that of buying in lambs of the wether, or other kinds, about the beginning of September, which are kept in different methods by different graziers, being by fome brought forward with the greateft poffible expedition by the beft keep, fo as to be ready to be fold off as foon as poffible. But others have recourfe to the contrary method, keeping them only in a middling way during the winter, till about the beginning of April, and then forcing them forward by good keep, fo as to have them ready for the butcher in Auguft, or continuing them in the following month ; and then clearing the whole of the flock from the land. In this practice, large profits are often made by judicious graziers, efpecially when fituated near large towns where the population is great.

Another fyftem of fattening, which can only be purfued to advantage in fituations near large populous towns, is that of providing grafs-lambs for the markets as early as poffible in the fpring months, which pays the grazier well in many cafes. With this view, it is the practice to procure the more forward ewes, fuch as thofe of the Dorfet breed, which drop their lambs in the beginning of January, if not before. In Middlefex, where this management is much attended to, in confequence of the great demand, it is the cuftom

GRAZING.

tom to purchase this sort of ewes at Kingston, Weyhill, and other fairs in the neighbourhood. The ewes, in order that they may have a plentiful supply of milk, are extremely well kept on turnips, brewers' grains, and fine green sweet rouen hay, and the lambs thereby forced forward in such a rapid manner, as to be ready for the markets in the beginning of March or April. And the ewes, from their becoming dry so early, are capable of being fattened and disposed of towards Michaelmas, usually fetching the prices at which they were purchased in at: as the whole of the flock is in this system cleared within the year, the farmer has the opportunity of fully ascertaining its advantage or disadvantage. The statement of which is thus given in the able Survey of the Agriculture of the County of Middlesex:

Statement.	£. s. d.
Lamb, sold at - - - - -	1 10 0
Ewe, do. do. - - - - -	1 10 0
Wool, 2s. 6d. or - - - - -	0 2 0
Together - - - - -	3 2 0
Deduct prime cost - - - - -	1 12 0
Remains the increase of an ewe in one year - - - - -	1 10 0

It is hinted, that "in this management very much depends upon keeping the ewes perfectly well fed, and in dry warm inclosed pastures, as without such attention the ewes are apt to become thin and lean, in consequence of the greatness of the evacuation, and afterward to require a much longer time in being made fat," by which much loss must be sustained. In the Economy of the Midland Counties, a practice in respect to fattening grafs-lambs, is suggested, which in particular cases may be beneficial; which is that of removing the lambs from the ewes when they decline much in milk, before they are perfectly fattened, in order to complete them on young clover, or other sorts of "prime keep." The chief object in this case is, that of the ewes becoming sooner ready for the butcher. Some, also, conceive, that after the first flush of milk is gone, and it begins to be scanty, the lambs thrive better "on grafs alone, away from the ewes," than when kept along with them, as the hankering after the little milk that is afforded prevents their feeding freely on the grafs. Hence it is supposed, that "where this method is followed, which can probably be with advantage only where the milk of the ewes is greatly deficient in supporting and bringing the lambs forward, much attention must be paid to having the keep early and in abundance. In this view, rye-grafs and white clover for early use, and broad clover at a later period, may be the most proper and useful crops. In this management the ewes should be carefully examined occasionally; and, where much deficiency in the milk is found, the lambs be immediately removed to the pastures."

In respect to the stocking of grafs-lands in the most advantageous manner for the grazier, it must depend materially on the richness of the lands, and the nature of the stock in respect to size, and other circumstances. But, according to Mr. Billingsley, the Somersethire graziers, in stocking the rich and middling sorts of grafs-land, allow, to an ox, from one acre to an acre and a half; and some add one sheep to each ox. But, in Lincolnshire, they stock in much larger proportions; as is shewn in the Agricultural Survey of that district, where they are brought into a tabular form as below, for the more rich pasture land.

Table of Stocking rich Pastures.

Names of places.	Sleep in summer per acre.	Acres per bullock in summer, with the sheep.	Sleep in winter per acre.	Rent.
Long Sutton - - - - -	5 $\frac{1}{2}$	2 $\frac{1}{2}$		
Mr. Scroop - - - - -	11	No bullocks		
Bollon, &c. - - - - -	4	1 $\frac{1}{2}$	2

Average - - - - -	3 $\frac{1}{2}$	1 $\frac{1}{2}$	2	

Upon this it is observed, that "considering the size of the sheep, which cannot be estimated at less than 24lb. a quarter, on an average; and that the bullocks rise from 50 to 100 stone (14lb.), this rate of flocking is very great indeed. There are, on every acre, 360lb. of mutton, and reckoning the bullocks at 42 stone, dead weight, there is also 336lb. of beef; in all, 696lb. of meat per acre in summer, besides the winter produce, which is immense."

But, in the rich grazing counties in the more southern parts of the island, a large proportion of both sheep and cattle stock is admitted per acre: the exact proportion, however, differs with different graziers very greatly.

But the great and leading principle in this business is, however, never to stock in such a manner as to restrict the animals in the leas; as it is by their being enabled to fill themselves quickly, and to lie down much, that the greatest progress and advancement in fattening are made, whether in stock of the cattle, sheep, or any other sort, when at grafs. But, on the inferior or weaker grafs-lands, a much smaller proportion of stock than on those of the rich and fertile kind only can be employed. It can frequently not be more than an ox and a sheep or two, to two acres, or two acres and a half. However, in stocking with neat-cattle, for the purpose of fattening, it should constantly be such as that the animals may have a full bite; but with sheep, such as to keep the pasture in a rather close state of feeding. Another circumstance is necessary to be attended to, in order to bring the grazing-stock properly forward in pastures, which is that of changing them more frequently than has generally been the case with grazing farmers. And it is, perhaps, on this principle, as well as those of their affording greater

degrees of warmth and shelter, and thereby promoting the growth of the herbage more abundantly, that small inclosures are more advantageous in this practice than those of a size larger. See PASTURE.

But the practice of different districts, where the grazing system is much in use, will, however, afford a more clear idea of this sort of management. In the Agricultural Survey of Lincolnshire, it is stated, that in the low-land in Barton on the Humber, there was a horse-pasture and a sheep one contiguous, and upon the inclosure it was remarkable to observe the great difference between them; that which had been under sheep so greatly superior. And in the tract of marsh-land on the sea-coast they observe, that, where most grafs is left in autumn, there the herbage is the coarsest and worst next year. The remark was, it is observed, made in answer to recommending eddish for spring-feeding sheep, which they thought would not do on rich marsh, though it might on uplands. This likewise shews that the Romney Marsh system of close feeding is right, and would answer as well in Lincolnshire. And in the hundred of Skirbeck, they like, it is added, to have a tolerable head of grafs in the spring, before turning in; and afterwards so to stock as to prevent its getting coarse by *running away*, so as to prevent the necessity of *bobbing*, which, however, must be done in a wet growing season. Mr. Parkinson observes, that the less sheep are changed the better. This remark, which he takes to be very just, demands, he says, attention: it bears on the question of folding. Beasts are changed while *bobbing* is done; and the sooner it is hobbled the better, as, if cut while young, cattle will eat it. But in Somersetshire, according to Mr. Billingsley, in summer feeding, attentive farmers have the dung which falls from the animal scraped up and wheeled into heaps, and the thistles and rough spots frequently mown. Besides they make a point of excluding horses and sheep from their cow-pastures. And when their mown ground is fit to be stocked, they hayn their summer leaze, so as to have a good supply of rough grafs or roun in the winter. They also mow and feed alternately, by which means the best sorts of grasses are preserved and encouraged; and in the Synopsis of Husbandry, it is stated, that, "when the summer turns out moist and growing, the herbage often shoots faster than the stock can eat it down. In this case it is common in Kent, to brush over the marshes at the mowing season, though they had not been originally laid in for that purpose; by which economy the farmer becomes possessed of a much larger portion of hay than he had before formed an expectation of, and which, in countries where this commodity fetches a good price, is an advantage whereof he is right to avail himself; for these casual brushings may probably furnish him with a quantity of winter provender sufficient to his own use; whilst those marshes which were primarily intended to be mown, and having been designedly laid in with that view, will produce a commodity of a better quality and more saleable; that may be disposed of at market. On the removal of this old grafs, the ground is left at liberty to send forth a more vigorous shoot in the autumn, so that these roun do at that time produce a sweet and wholesome pasturage, which would otherwise have been choked up with the rotten tore of the last year; yet there are cases where it may be necessary to suffer this old grafs to remain on the ground, as where a portion of food is required for the cows or other horned beasts in the winter. Then this old tore, having been sweetened by the frosts, will be found exceedingly useful, and the cattle will at that time greedily devour what in the summer months they turned from with disgust."

The same writer also adds, that "the manner of stocking a grazing farm in the marshes differs according to the nature of the land. In Romney Marsh, the views of the grazier are chiefly directed to the breeding and management of sheep: and in the Isle of Sheepee, both bullocks and sheep claim his attention, whilst in some parts the marsh land is wholly appropriated to the breeding of horned cattle and colts. Those grazing farms are most eligible, which admit of breeding and fattening on the same pasture. This is the case with Romney Marsh, a tract of land so eminently distinguished for a valuable breed of polled sheep, that it furnishes the graziers of Sheepee, and other places in this county, with an annual supply of lean-stock over and above what is reserved for feeding; so that it is evident the grazier here enjoys a double profit from his farm, though it is believed, since the increased value of lean-sheep, that the graziers in the Isle of Sheepee have many of them adopted the method of breeding their own stock." This is probably the most beneficial practice.

In the county of Westmoreland, the cattle bought in in September are wintered on the coarse pastures and in the straw-yard. In May following the young ones are sent to the commons; and those of an older description turned upon the best pastures as soon as possible, according to the earliness of the situation. But in the Agricultural Report of the North Riding of Yorkshire, it is said that "there the usual time of breaking the pastures is the 12th May, from which time they continue regularly stocked until about October, when, if the stock consists of milch-cows, or feeding cattle and sheep, they are removed to fog (after-grafs); the pastures, with the addition of the stubbles, remain stocked during the winter with store sheep or lean cattle; but the latter are, by many farmers, taken into the straw-yard for the night. The herbage of the pastures is, however, it is thought, thus completely destroyed before winter, and the land thus left naked is starved, and the growth of moss greatly encouraged, to the almost certain ruin of the grafs-land. An instance has not occurred in the course of the survey, of the practice of preserving a considerable part of the summer growth of grafs upon the land, for spring feed, a practice well worthy of attention. This winter clothing, it is supposed, enriches the swards, destroys the moss, and, by keeping the roots of the grafs warm, causes an early vegetation in spring, when the scarcity of the herbage so much enhances the value of it. On farms, the soil of which is not adapted to turnips, this practice would, it is said, be peculiarly beneficial."

"In March, the land intended to be pastured the ensuing summer, is, or ought to be freed, and the flock put into the land intended to be mown, where they remain, until those pastures are broken up in the beginning of May.

"In the dales of the Moorlands, the lower lands only are adapted to meadow; consequently, the land cannot be changed alternately from meadow to pasture, as may be practised in many other parts of the Riding; though there, as before noticed, the practice is not sufficiently attended to. There are many instances of cow-pasture, which have been invariably summer-fed during several generations." See PASTURE-Lands.

"The best farmers usually pasture their new laid ground the first two years, and that chiefly with sheep, as sheep improve grafs more than any other kind of stock, both by their treading more lightly and uniformly, and by the dung and urine being more regularly dispersed over the land. But the practice of eating them very bare during the first autumn and winter after sowing, and also mowing them the first summer, is too prevalent; such practices are, it is observed,

GRAZING.

served, the ruin of feeds. Some, however, think that pasturing new laid ground is most excellent management; the several grasses, by being frequently cropped, become not only firmer in nature, but much more numerous. Stock, when pasturing new lands, ought to be often changed; if ever you over-eat, they will require some time to recover their usual vigour. New laid-grounds sometimes give sheep the rot, particularly three or four years laid, on indifferent soil."

And the practice of shifting the flock from one pasture to another, of mixing different kinds of stock together in a due proportion in the same pasture, and under stocking with sheep, pastures destined for feeding larger cattle, should always be particularly attended to.

It is stated in the Survey of Lincolnshire, that "the rich grazing lands are the glory of that county, and demand a singular attention. The soil is a rich loamy clay, some very stiff, but of uncommon fertility, as may be seen by various instances. Some of the grazing lands in Long Sutton that were common, will carry five or six sheep an acre, and four bullocks to ten acres. Mr. Scrope has there four acres, which carry 45 sheep in summer, and must be *hobbed* often to keep it down. And on the grass-lands in Deeping Fen, improved by paring and burning, Mr. Graves keeps five sheep an acre from Lady-day to Michaelmas, and one and a half in winter, and a bullock of 60 stone to two acres besides in summer."

And from some trials which were made by T. Fyde, esq. in the grazing of neat cattle on the best sort of ground in Lincolnshire, and which are given below, Mr. Young is led to conclude, that 3*l.* an acre is the highest rent he has heard of in that county, and much higher than common, even for the best lands. This seems to confirm the idea he has entertained, that the rich grazing lands of this district are lower rented than such or nearly such lands in other parts of the kingdom. And further, that "the average weight of the beasts was 70 stone, being of the York or Lincoln breed; the sheep all Lincolns. The former bought in April or May, and all gone by the 11th of December; the sheep are bought in May; they are clipped twice, and fold fat in April or in May following; that there is little difference in seasons, except that, after a bad winter, the sheep are not ready for market so soon by a month as they are after good winters. The loss in weight in driving to Smithfield is very little; the expence, beasts 15*s.* 9*d.* sheep 1*s.* 9*d.* each. Mr. Fyde held for several years a piece of land in Skirbeck parish, which measured 21 acres, and kept, *communibus annis*, from Lady-day to Michaelmas, 19 heavy beasts, and a 100 sheep, and wintered fifty sheep. And he now holds a pasture adjoining his garden, at Boston, of eight acres, which keeps in summer ten oxen and forty sheep, and winters thirty sheep. But the finest grazing lands are at Boston, Alderchurch, Fofdyke, Sutherland, Kirton, Frampton, Wibberton, and Skirbeck: these will carry, in summer, a bullock to an acre and a half, besides four sheep an acre; and two sheep an acre in the winter season."

It is stated that "the Rev. Mr. Berridge, of Alderchurch, has near his house forty acres of the rich grass, upon which the flock is upon an average 300 sheep, sixteen fattening bullocks, three cows, four horses, and carries through the winter three sheep an acre. This land is valued at 40*s.* an acre. It is a vast flock. He favoured him with these particulars in the presence of a dozen neighbours, and called in his manager to confirm it; it wanted, therefore, no after-corrections." And "in the grazing lands at Swineshead, a

beast an acre of 40 to 70 stone, and two or three sheep; also two sheep an acre in winter. Mr. Tindal, at Ewerby, which is on high-land, compared with Holland Fen, stocks a bullock to two and a half acres, and three sheep per acre in summer, and two sheep an acre in winter. And in the lordships of Horbling, Billingborough, Berthorp, Sempringham, Pointon, Dowsby, Dunby, and Hackonby, there are extensive tracts of rich grazing land applied to fattening bullocks and sheep, carrying a bullock to two acres, and three sheep per acre in summer; and two sheep an acre in winter, which lands are generally rented at 30*s.* per acre. Mr. Elkington, of Howel, keeps one bullock and nine sheep to three acres, and in the winter two sheep an acre." But "Hanworth, north of Lincoln, is chiefly grass which is fed by cows, calves, and young cattle. On the Lawn at Norton Place, which is heath-land, two couples per acre in summer; but the soil not adapted to permanent grass without great exertion." And "there is a tract of pasture-land, which is of considerable extent north and south, but very narrow east and west, which lies in the vale between the heath and the Wolds. He viewed it from Norton Place in going to Owersby, which is in it; the quality is good, but of the second rate." And further, that "the grass-land close to Gainborough lets at 4*l.* and 5*l.* an acre. The marsh grass on the Trent and Knaith, &c. 20*s.* to 30*s.* and produces one and a half or two tons of hay an acre. The marshes on the river are stocked from the 12th of April to the 12th of May; this of late has, however, been omitted, as they found the grass hurt by it. Clear the hay by Lammas, one to one and a half ton an acre. Then turn in milk-cows, and afterwards other stock, till November. Rent 20*s.* but measure short. And at Garthorpe, in marsh-lands, some rich grazing lands, which will carry a good bullock an acre, but no sheep fed. This land is now let to break up at 3*l.* 15*s.* an acre for 14 years." But that "Mr. Hefelden, at Barton, has four acres near the town; levelled and manured it after the allotment, and this year it feeds four cows: three of them joisted at 3*s.* a week, a produce of 12 guineas. At Immingham and Stallenborough, there are some marsh-lands that will carry nine bullocks of 80 stone upon 12 acres, and 12 sheep, and two sheep per acre in winter; some has only one. But the same lordships have, it is remarked, clay pastures that will not do any thing like this. And, at Thornton college, Mr. Uppley has a few closes of extraordinary fine grazing-land, which will carry the largest bullocks, and it is worth, he thinks, 50*s.* an acre rent.

"The marsh on the coast of Grainthorpe, Saltfleetby, and Theddlethorpe, &c. is very good: it will keep three sheep an acre, and an ox to three acres; and one sheep and an half to an acre in winter. The hilly wold good pastures on marl and chalk at Gayton, near Louth, will carry three ewes and three lambs *per* acre, and a sprinkling of young cattle, &c. besides; some only two ewes and lambs, besides cattle, such land as is worth 15*s.* to 20*s.* an acre. In the marshes that are in the vicinity of Saltfleet and Sutton, there is some distinction, which it will be proper to note by parishes. In Northcotes, the quality rather inferior, being chiefly for breeding. Mars Chapel, better, but still weak; and for breeding also. In Grainthorpe, a great deal very good grazing land. Conisholm, low, swampy, and but little good. Skidbrook, a great deal, and very good. South Somercotes, the same; but 1000 acres of *ingrass*, or common meadow. The three Saltfleetby's 5000 acres, and a great deal very strong and good for feeding beasts. Some of the late Mr. Chaplin's marshes here said so high as 77*l.* the statute

GRAZING.

statute acre. In general, the measure short from Saltfleet to Sutton, there statute. In the Theddlethorpes, much very good; but some low, and not well drained. Marblethorpe, very good. Sutton, remarkable good and strong feeding land.

"In these marsh parishes, the rich grazing ground of the first quality lets at about 40s. an acre, and the rest about 30s. Such as will not feed, but only breed, at 20s. to 25s.; and this distinction of feeding and breeding is here also expressed by saying, that one sort of marsh will feed sheep; but the other, keep them in holding order, will make them hold the flesh they have got, but not fatten profitably. If the best of these lands are compared with the grazing districts of Boston and its vicinity, it was remarked to him, that these are more naturally good, and much better watered: they have at all times plenty of fresh water here, which is a great object; but for artificial fertility, locality to fairs and markets, &c. the Boston lands are much superior. The measure at Boston, &c. is here said to be more than an acre; here less, not more than three roods, and the *ing* land still less. On ten acres, at Skidbrook, eight beasts and sixteen sheep have been summered, and the sheep wintered also. And, in general, the marsh that lets from 30s. to 40s. will carry a beast to two acres, and two sheep an acre; but, perhaps, he says, more generally one and a half sheep."

With respect to the profit of grazing the best land, it is stated in this manner:

Statement.

A beast bought at 20 <i>l.</i> to two acres, at the profits of 5 <i>l.</i>	£. s. d.
-	2 10 0
Two sheep per acre, bought in at 45 <i>s.</i> and sold at 55 <i>s.</i>	- 1 0 0
Four fleeces at 9½ <i>lb.</i> 38 <i>lb.</i> at 8 <i>d.</i>	- 1 5 4
	4 15 4

Capital employed.

Beasts	£. 20 0 0	£. s. d.
Sheep	4 10 6	1 6 6
	24 10 6	
A year's rent	2 0 0	
	26 10 6	3 13 9
At 5 <i>l.</i> per cent.		Profit - 1 1 7

Here the total interest made is about 9*l.* per cent. on the capital of 26*l.*, and this seems to be rather inadequate, for there is nothing for losses, which, in a course of time, must be something considerable. The interest made ought to be, at least, 10*l.* per cent. after a proper deduction for losses.

Either, therefore, the land carries more stock, or it is too highly rented. Grazing is accounted a profitable profession; but when it is considered that this 26*l.* capital would stock five acres of good arable land, and that they could not be reckoned to pay a less profit than from 12*s.* to 15*s.* an acre, from 3*l.* to 4*l.* 5*s.* it will appear that the plough is much more beneficial than such grazing calculated in this way.

Mr. Kershaw, of Driby, and Mr. Bourne, of Haugh, agree in the following marsh account for land there at 35*s.* the acre.

The gross interest rather better than 10*l.* per cent.

Mr. Parkinson, of Reevesby, observed, that the rich marshes were better managed, and in better order, twenty years ago, than they are at present; the wold farmers had not then got such possession of them, and they were in the hands of resident graziers, who attend much more to *holbing*, which kept them fine; for nothing hurts marsh land so much as letting it run coarse, from permitting the grafs to get a head. And he calculates an acre of rich marsh in Wrangle, &c. thus,

In the hundred of Skirbeck, the pasture consists of three sorts in point of rent, &c. the highest at about 45s. being from 32s. to 50s. The second from 26s. to 32s. average 28s. The third, average 1l. 1s. Besides this a small quantity of open meadow, called *ings*, average about 18s. The best kind of pasture is chiefly stocked with shearling wethers, bought at the spring market at Boston, which, having yielded two fleeces of wool, are sold off easily in the next year; and by beasts in the summer, sold in autumn; some kept on farther in eddish, but all gone in the winter. The second best is chiefly fed by young beasts and hogs, kept on to shearlings: these are well kept, as their value materially depends on it; there are also some few breeding sheep on this division of the pasture. The third class is chiefly mown. But it is to be noted that all these particulars relate to an acre larger than statute measure, about $\frac{3}{4}$ roods."

"The first division is stocked at the rate of three sheep per acre, winter and summer, with the overplus of some bought in the spring, and not cleared from the land till some months later than the time at which they are bought. The beasts are in proportion, on an average of seven to ten acres, from 54 to 100 stone. The second class winters about five sheep to two acres, with not less than four per acre in summer, with a few cows and young beasts; and on both these there will be some few horses, too uncertain to average. On the best land, they are chiefly horses making up for sale; and, on the second quality, horses employed in work, or young ones; it is not usual to keep any horses in summer except on the pastures. The produce of hay on the third may be about 35s. an acre; the eddish eaten by cattle from the other grounds; or by lambs or hogs, before they go to their winter keeping."

The writer hints that the profit upon this first class of land is greater than upon the rest; and that the third sort yields very little profit by grazing, and would pay much better in tillage. There are many graziers there, who have no other land than what is upon these flats, and some who are supposed to have made by their business enough to have realized

GRAZING.

realized a comfortable subsistence. The grazing accounts of certain fields in the occupation of Mr. Loft, of Mafh Chapel, are stated in this way :

It is however stated, that very few fields will yield any thing like this: he has but one clofe; and there are some expences omitted. And “ Mr. Tennison, of Lincoln, has 13 acres of marsh at Grimsby, that summer-feeds 14 bullocks; and carries 35 sheep the year through.” But that “ in the tract of marsh-land on the sea-coast, they observe, that where most grafs is left in autumn, there the herbage is the coarsest and worst next year; the remark was made in answer to recommending eddish for spring-feeding sheep, which would not do on rich marsh, though it might on uplands.” It also shews, that the system of clofe feeding is proper, and would answer well in many districts where it is not the practice.” And “ in the hundred of Skirbeck, they like to have a tolerable head of grafs in the spring, before turning in; and afterwards so to stock as to prevent its getting coarse by running away, so as to prevent the necessity of hobbing, which, however, must be done in a wet growing season.”

But after the flock has been brought into a proper state for the market, there is in many situations much difficulty in disposing of it to the best advantage. Mr. Marshall has

remarked, that though it be attended with less difficulty than that of buying in the flock, it requires much knowledge, as well as experience, to execute it in the best manner, or with the least possible loss. A due consideration of the progress of the stock while feeding, and of the length of time they have been upon the land, may afford some sort of guide in the business; but the most correct judgment may be formed by the young grazier, by the practice of frequent weighing, and the accurate comparison of the living with the dead weight of such stock as are killed in his neighbourhood, as it is a much more certain method than the use of the eye and hand, as has been shewn under the head GRAZIER. Having recourse to frequent weighing has also the advantage of shewing the progress that is made by animals under different sorts of keep or food. But besides this, the grazing farmer must be regulated in the sale of his stock by the nature of his situation. In most of the midland and southern parts of the kingdom, Smithfield is the place where the fat stock of the farmers are disposed of: while in other parts, they are frequently sold in the neighbourhood, or to the large towns which are at no great distance. In the former cases, especially on the less extensive farms, the fat stock are brought up by persons, who make it a business, being employed by various graziers in the same vicinity, who have an entire confidence in them. With the more extensive graziers, who send up frequent lots, the business is done by a salesman, in whom they have confidence. With little grazing farms, the custom is often to sell them to the butchers in the neighbourhood, which is frequently the best method. And the advantages of these different modes must depend greatly upon circumstances. Some, however, suppose that the London market is the best calculated only for those who give a weekly attendance, on account of the uncertainty of the supplies. The expences being materially different, as with the salesman's commission, they frequently amount to twelve shillings a head there, while in the country they are not more than from three to five. Consequently, that fat stock may in many cases, where only a few, or what are termed small lots, are to be disposed of, be sold at home with less expence than having them sent to distant markets; but that with large lots, the latter mode must be had recourse to, as more certain, expeditious, and convenient. Upon the whole, the facts which have been stated fully shew that the advantages of the grazing system must be materially different under different circumstances, and be greatly influenced by those of a local kind. It has indeed been remarked by a Kentish grazier, that the profits of no two grazing farmers are exactly “ alike on the same given quantity of land,” nor even on the same land, as years, prices, as well as the exertions and talents of each individual, are different. In all cases, the superiority of the success must in a great measure depend upon the knowledge, exertion, and excellence of the method which is adopted by the particular farmer. Statements can of course only shew what are the general profits of the system. With neat-cattle, in the western and midland districts, they are given by Mr. Billingsley, and Mr. Young, in the Surveys under the direction of the Board of Agriculture. In this way, the former says, that a grazing farmer who has 200 acres of land, may fatten annually one hundred head of cattle, as oxen, with seventy sheep and ten colts, which together may afford a comfortable but not exorbitant profit to him.

G R A Z I N G.

And on the rich grazing lands in Lincolnshire, according to the latter writer, the practice seems to afford a much greater advantage to the farmer; as the account, given by T. Fyde, esq. M. P. for twenty acres, in 1796, stands thus:

Statement.

<i>Dr.</i>	£.	s.	d.

And that "the difference between the buying and selling price, loss deducted, 20*8l.* 8*s.*, is the produce of the land, or 10*l.* 8*s.* per acre, which is very great indeed, and shows that this land would let at 5*l.* 4*s.* an acre, supposing this year to be an average one.

"This difference of rent would deduct 4*l.* from the profit of 87*l.* and leave 43*l.* which, with 2*l.* charged, make 64*l.*; interest on the year's advance of 546, or 11½ per cent."

But in the system of grazing pursued in some of the southern rich marshy districts with sheep, as stated some time ago, the amount stands as below, according to Mr. Price; but at present the profit must be much higher, from the improved management of the Romney Marsh graziers in general.

Account of Stock bought in for Fifty Acres of Pasture Land, for the Year 1778.

	£.	s.	d.
310 barren ewes, at 1 <i>l.</i> 1 <i>s.</i> each	325	10	0

It is remarked, "on the first of these statements, that the year was favourable for vegetation; and that such profits could not probably be made seven years together, which is the most accurate method of calculating profits on land. There being no assesses on the land, also, makes it more profitable." And further, that two modes in respect "to the profits on fattening land are stated; the first used by the best graziers; the other, the most common: some take bullocks in to keep, others buy runts; the profits of which must depend on their judgment; but 3*l.* is the medium profit between the whole: 10*s.* each sheep is generally allowed as the gained profit by fattening." It is added that "it cannot be supposed that this profit will always amount to so much as the years differ; therefore dry seasons will abate it, and a large tract of land cannot have the supply of stock to make it so great. There are losses to be taken out; but, upon the whole, it is very profitable, as the expences are so moderate, that one servant-man can manage a thousand acres of pasture-land. The value or rent of land is put too low, except for long leases unexpired, or where a large quantity of land is taken. The average price of rent is from 40*s.* to 3*l.* for fattening land, unless four or five hundred acres of breeding and fattening,

perhaps about 30*s.*; and some old leases 1*l.* breeding land."

It is stated that where sheep, in order to fatten them in a more expeditious manner, or to finish them in cases where the grafs is insufficient for the purpose, have the addition of turnips or other sorts of luxuriant green food, great care should be taken, by the grazier, that a due proportion of some sort of dry material be had recourse to at the same time; as without such precaution, not only loss may be sustained by the death of some of the sheep in particular instances, but by their making less progress in becoming fat than would otherwise be the case. Hay, cut chaff, bran, or a few oats, answer the purpose very well. See SOILING.

It is necessary, in order that the consumption of these sorts of food may be conducted in the most economical manner, that proper troughs, racks, cribs, or baskets, should be provided, and fixed in such a way, as that they cannot be overturned. The graziers, in some parts of Lincolnshire, have a large sort of crib or wicker-work basket, being eight or ten feet in circumference, and wattled to the height of one foot or a foot and a half, in a close manner, and then left open for about a foot and a half; after which it is closely wattled again for nearly a foot, being drawn in, in a narrowing manner at the top, so as to have only proper room for introducing the food. The studs or staves are placed about eight or ten inches apart, which admit of the sheep feeding in a distinct manner. It is described in the fourth volume of the first series of the Repertory of Arts, &c. and denominated a *tumbril*. It may be seen at *fig. 8.* in the *Plate on Granaries*. This contrivance affords much advantage, both in the saving of food from being wasted, and in affording the less strong sheep an opportunity of feeding without being disturbed or driven away by the strong ones, and consequently much injured.

In the Rural Economy of the Midland Counties, it is noticed in respect to the practice of grazing in such seasons as are very wet, that an incident of this sort that occurred to the writer in the very wet autumn of 1789 is interesting. "The general complaint is, that grazing stock, though they have this year rolled in grafs, have not done well; Mr. Henton, of Hoby in Leicestershire, being singular in saying, that his feeders had done tolerably. Indeed his stock corroborates his assertion. He had a lot of cows at Loughborough, the 12th of August, the fattest in the show.

"But his management is more remarkable than his success." He "foddered them with hay all the wet weather; that is, he mowed the broken grafs for them, beginning under the hedges, and continuing to mow the coarsest patches throughout the piece.

"The first day (the day it was mown), the cattle seldom touched it; but the second or third day they fell to it freely, eating it "between whites," in preference to grafs. In the morning, it was always the first thing they filled their bellies with.

"The cattle having eaten up the more palatable parts of the herbage, the thistles, and other offal, were raked up, and carried off the ground: most excellent management!

"This stock consisted of about sixty head. At first one man only was employed in mowing, &c. But, before the rainy weather ceased, he set on another man.

"What an admirable thought! that which other men suffered to stand waste in itself, an encumbrance to the ground, and a nursery of weeds, was converted to food, more nutritious, in a wet season, than the best of the standing herbage."

Mr. Parkinson, of Lincolnshire, had made a practical observation,

ervation, which is, that "the less sheep are changed, the better." It demands the farmer's attention, as shewing the injury of folding in many cases. And it is noticed, that the grazing cattle are changed while the business of *bobbing* the fields is performed, and that the sooner this is executed the better; as when the grass tufts are cut while young, the cattle will eat the produce well.

Upon the subject of flocking grazing land, Mr. Marshall remarks, that "the fairs at Birmingham are among the worst in the country for fat stock, the butchers giving the graziers no encouragement to drive their stock to them, preferring the toil of riding twenty, thirty, or perhaps forty, miles from home to pick up their "fat!" spending a principal part of their time and their profits in an employment truly ridiculous. How convenient it would be to the grazier, as well as to the butcher, to have a weekly market, a Smithfield at or near Birmingham! to the grazier, in thereby having a constant and certain market whenever he wanted either keep or money; and, to the butcher, in saving time and travelling expences. Yet the few animals which are taken there at present, are frequently drove out unfold. But Thursday, which is the ordinary market-day, is improper. Monday or Tuesday would be a more suitable day; and Sutton, perhaps, the most suitable place. In performing the business of purchasing in stock, the nearest fairs are always to be preferred, if it can be done there with propriety; as much injury and loss is frequently sustained by driving from a considerable distance.

And the business of grazing other sorts of animals may, in some cases, be a profitable concern, but must always be regulated by the nature of the land and circumstances of the farmer. Where he has a considerable extent of the more coarse sort of pasture-land, he may often find it advantageous to graze young horses, especially where he has the convenience of breeding them likewise. But though it is a practice sometimes followed by grazing farmers, to admit horses in the same pastures with the other stock, it should constantly be avoided as much as possible, as they are very injurious by teasing and driving the fattening cattle about, and preventing their resting so much as is otherwise the case. It is a better method to let them follow this sort of stock. When horses are admitted upon the grazing lands in Somersetshire, it is seldom done in a larger proportion than that of one to twenty acres. But there is another animal which it has long been a practice in particular situations to graze. This is the hog, which, where the farmer has a piece of rich grass, either of the artificial or natural kind, he may turn upon it with much advantage. With clover, and some other artificial grasses, the animals are found to succeed perfectly well in this sort of management; but it is objectionable as losing a vast source of manure of an excellent kind. When the field is so situated as that the hogs can return in the evenings to the well littered sties, it may, however, be a highly beneficial system of practice. There can be no doubt but that this sort of management might be much more extensively employed with this animal, and that thereby much of the food of store pigs might be saved. See Hog.

GRAZIOSO, *Ital. Graciously, Fr. graceful*, are terms in *Musie*, addressed to the performer; but if the composition is devoid of *grace*, the term can convey no instruction to the performer. It is in vain for the composer to fit down with a resolution to compose a *graceful* movement; it must come unsought, and insensibly.

Marmontel has defined grace in poetry, grace in attitudes, grace in motion, grace in the arrangement of words in prose, of figures in painting, as a polish, a lacquer, a varnish,

a gilding to every human action; without which we may be surprised and entertained, but never perfectly pleased.

No poet, perhaps, abounds in grace and facility so much as Metastasio; for examples, see his cantatas.

Among musical composers, perhaps, none have been more gifted with this charm than Pergolesi, Sacchini, and Cimarosa.

The time of a grazioso movement is nearly the same as *andante*; smooth, gentle, and inclined to *piano*; no coarse strokes of the bow on the violin, or dry *cups de langue* on the G flute, except, to vary the expression and effect, the composer indicates the contrary.

GRAZZANO, in *Geography*, a town of Italy; 13 miles S.S.W. of Verona.

GRAZZINI, GIO. PAOLO, of Ferrara, in *Biography*, left the profession of goldsmith to become a painter at an advanced period of his life; his chief instructions he owed to the friendship of Carlo Bononi. The first specimen of his capacity was a picture of St. Eligio placed in the goldsmith's hall of Ferrara. Eight years which he had employed to finish the work were amply redeemed by the display of a master-hand, and a tone of colour that placed him near in rank to Pordecone, and astonished all Ferrara, who had known Grazzini for half a century. He continued to produce works of less compass, but of equal taste, which are met with in private collections. He died in 1632. Fuseli's Pilkington.

GRAZZINI, ANTHONY-FRANCIS, surnamed *Il Lasca*, an Italian writer, was born at Florence in 1503, and is known to posterity as a considerable writer in prose and verse. He is particularly remembered for his light and jocose poems, among which are many of the *Canti Carnascialeschi*, or Carnival Songs. These, it is said, were first invented by Lorenzo de Medici, and a collection of them was published by Grazzini at Florence in 1559. His other works are as follow: "La Guerra de Mothi, poema giocoso," 1584. "Stanze," &c. "Comedie VII;" "Il Lasca, Dialogo," &c.; "Lettere," "Orazione," "Rime," *Novelle XI*. The last was an extremely popular work, and as a novelist Grazzini was thought to be a worthy rival of Boccace in the elegance of his narration and purity of his style. He was one of the founders of the academy Della Crusca Moreri.

GREASE, among *Farriers*, &c. an inflammation and swelling of the heels about the fetlocks, and sometimes of the legs of a horse, as high as the knee or hock, with the secretion of an oily matter, to which the disease owes its name. The matter discharged from the heels has a peculiar offensive smell, and the heels themselves are sometimes ulcerated. Heavy horses, with round fleshy legs, are the most subject to this disorder, and the white legs more than the rest. It is almost always found in the posterior extremities. Grease is occasioned by sudden changes from a cold to a hot temperature, such as the removing of horses from grass into hot stables; from the too sudden change of a generous to an impoverishing diet; from neglect on the part of grooms in leaving the heels wet and full of sand; and from constitutional debility. On the approach of this disease, and for several days before any very considerable appearances of swelling and inflammation, the animal seems to feel much pain in the affected heel, which is indicated by his raising it frequently from the ground, and his not being able to rest upon it without uneasiness. At this early period, the disorder may in general be removed by a poultice of boiled bran and linseed powder constantly applied to the part, and kept moist with warm water; giving every night, or every second night, a mild diuretic. When the inflammation and swelling are consider-

able, the fore-mentioned poultice may be used, and a strong diuretic, or a purgative may be administered as long as the case seems to require it. When the swelling and inflammation have abated, which will commonly happen in three or four days, the poultice may be discontinued, and the following astrigent lotion may be applied five or six times a day. Forms of astrigent lotion, *viz.* No. 1. Alum powdered, 1 oz., vitriolic acid, 1 dr. and water, 1 pint. No. 2. Alum powdered, 4 oz., vitriolated copper, $\frac{1}{2}$ oz., and water, $1\frac{1}{2}$ pint. No. 3. Sugar of lead, 4 oz., vinegar, 6 oz., water, 1 quart. In each of these recipes mix the ingredients. Some alteration may be necessary, according to circumstances, in the strength of these lotions. Where the inflammation and irritability of the part are considerable, they must be diluted with an equal quantity of water; but if the inflammation be subdued, and a swelling and ulceration remain, the alum solution cannot be made too strong. If the heels be ulcerated, and especially if they appear foul and have an offensive smell, one or other of the following astrigent ointments should be applied to the ulcers, *viz.* No. 1. Hog's lard, 4 oz., oil of turpentine, 2 dr., and water of acetated litharge, $\frac{1}{2}$ oz. No. 2. Venice turpentine, 1 oz., hog's lard 4 oz., and alum finely powdered, 1 oz. Mix the respective ingredients. If the ulcers be deep, and do not readily heal, they should be washed with the detergent lotion previously to each dressing. Regular exercise on clean and dry ground is of the highest importance. In slight cases of grease, the astrigent lotion and a few diuretic balls will generally effect a cure; but if the disease is of long standing, and more especially if the horse has had it before, it will be more difficult to remove it. In such cases an alterative powder, composed of powdered resin and nitre of each 4 ounces, mixed and divided into 8 doses, should be given in the corn every day, until it produces a considerable diuretic effect. In very obstinate cases, rows in the thigh have been found useful. Digitalis, or fox-glove, has been recommended in those swellings of the legs which are the consequences of grease; but as this is a violent medicine, and apt to injure the stomach, it should be cautiously administered; the dose is from half a dram to one dram. When a horse has suffered much from this disease, and appears to be weak and out of condition, a liberal allowance of corn will tend to recover him, especially if it be assisted by the astrigent lotion, and careful grooming. In cases of this kind exercise is indispensable. When the disease depends upon debility it is obvious that a dose of physic would be improper; but considerable benefit has sometimes attended the exhibition every morning, till the bowels are moderately opened, of the following alterative; *viz.* soccotrine aloes, 1 oz., castile soap, $1\frac{1}{2}$ oz. powdered ginger and myrrh, of each $\frac{1}{2}$ oz. Form these into a mass with syrup, and divide it into six balls. This medicine, though of an opening quality, will improve the horse's strength, and at the same time promote absorption. Or the following preparation may be administered: *viz.* antimony, finely powdered, and flowers of sulphur, of each 6 oz.; linseed powder, 2 oz.; and honey sufficient to form a mass for 12 balls; one of which may be given once or twice a-day.

Nothing tends so much to prevent grease and swelling of the legs as frequent hand-rubbing, and cleaning the heels carefully, as soon as a horse comes in from exercise. In inveterate cases of grease, where the disease appears to be in some degree habitual, a run at grass is the only remedy. If a dry paddock can be procured where the horse may be sheltered in bad weather, it will be found very convenient; for thus circumstanced the horse may perform his usual labour, and be kept free from the complaint. In the earlier stages of the disease, the practice of turning the horse into a salt-

marsh is serviceable: and a few months' run on a salt-marsh has frequently eradicated the disorder, when other remedies have failed. Obstinate cases of grease may very frequently be cured by withholding the horse's allowance of water for two days, or even a longer time, and then riding him into the sea or salt water, when his thirst will induce him to drink freely; and the salt water will act as an useful laxative and alterative. This process must be frequently repeated, whenever it does not appear to be injurious in any material respect. In a few obstinate cases, Mr. White says, (Treatise on Veterinary Medicine,) that he has seen the mercurial alterative of service, giving one ball every morning, until the bowels are opened: it is formed of calomel, $\frac{1}{2}$ dr., aloes, 1 dr., Castile soap, 2 dr., and oil of Juniper, 30 drops, made into a ball with syrup for one dose. In the treatment of those ulcers, or "cracks," as they are often termed, which particularly occur in the back part of the pastern, and which are of difficult cure, cleanliness is of great importance; and when they appear inflamed and painful, it will be useful to apply a soft poultice, in which a little Goulard has been mixed, for two or three days. The following ointment, *viz.* fresh hog's lard, 4 oz. and white lead finely powdered, 1 oz. mixed, may then be applied, spread on tow, and secured with a light thin bandage. If cracks or ulcers appear in the heels, without that general swelling of the legs and discharge of matter, which constitute the disease named grease, they may be soon cured by applying the astrigent ointment, and giving a few doses of diuretic alterative: but when these are accompanied by the grease, laxatives or purgatives are proper, according to the condition of the animal. The astrigent ointment is made of hog's lard, 4 oz. palm oil, 2 oz. and fine olive oil, 1 oz. melted by placing the pot which contains it in boiling water, and, when melted, stirring in $1\frac{1}{2}$ oz. of the water of acetated litharge, and continuing to stir it till the mixture is nearly cold. If the ulcers are deep, the horse should be kept in the stable till they are nearly healed, with a cooling opening diet; and his legs should be frequently and briskly rubbed with the hand; and a few of the diuretic alterative powders should be given. When proud flesh, as it is called, appears in the ulcers, it must be destroyed by caustics, such as blue vitriol powdered, or dissolved in warm water, or lunar caustic. When this is neglected, they sometimes increase to a large size, and become almost of a horny consistence, in which state they are commonly named "grapes."

In recent cases of grease, in which the heels are inflamed and swollen, and discharge a whitish-coloured matter, much benefit has resulted from fomenting them for a considerable time with warm water, in which a small quantity of Goulard has been mixed, and immediately applying the Goulard poultice. In obstinate cases of grease, where the matter discharged is very solid, the fomenting poultice is useful, that is, a poultice of linseed meal, warm water, and yeast, which soon removes the offensive smell, and causes a less acrid matter to be formed. Powdered charcoal has also been recommended for the same purpose. In recent cases the Goulard poultice and mild purgatives will soon reduce the inflammation considerably; and then the cure is easily accomplished by astrigent lotions. For preventing a return of the complaint, exercise and good grooming are indispensably necessary; frequent hand rubbing of the legs, and a diuretic powder occasionally, are also useful. Horses with white hinder legs, or such as are much disposed to swelling of the legs, should be bandaged for some time, particularly after hard work, keeping the bandage constantly moist with a solution of alum and water. In some cases of grease the inflammation seems to extend to the cellular membrane under the skin, the consequence of

which is a more severe pain and lameness than when it is superficial. The inflammation generally terminates in an abscess of the heel, which bursts and leaves a deep ill-looking ulcer. Although the general swelling of the legs subsides, the ulcer is extremely irritable, and healed with difficulty, particularly if the horse be exercised. By applying poultices and warm digestive ointment, and by keeping the horse at rest, the ulcer gradually heals. When ulcers of the heel do not appear disposed to heal, the astringent ointment above-mentioned should be changed for the following, which is more stimulant, and, previously to its application, the sore should be washed with a solution of blue vitriol. The stimulating ointment is prepared by mixing ointment of yellow resin, 4 oz. olive oil $\frac{1}{2}$ oz. and red nitrated quicksilver in fine powder $\frac{1}{2}$ oz. See White's Treatise of Veterinary Medicine, vol. i.

If the greafe be an attendant of some other disease, it will be in vain to attempt the cure before the disease be removed, that is the original cause of it; and therefore, if it be a hectic, the yellows, or the farcin, &c. the directions given for those diseases are to be followed, and in the mean time proper applications are to be used outwardly for the greafe.

GREASE, Molten, a disease of the intestines, incident to horses, and generally dependent on some constitutional affection. Horses that have been well fed, without much exercise, are peculiarly subject to this complaint: although they appear sleek and fat, they are not fit for violent or long-continued exertion, unless they have been brought to it gradually: and therefore when they are put to work in this state, and violently exercised, a fever often ensues; and this fever commonly depends upon general inflammation or increased action of the whole arterial system. In this disease, nature makes an effort to remove it by a violent purging; and the mucus, formed on the inner surface of the bowels for the purpose of lubricating and protecting them from the action of any acrimonious matter that may happen to be passing through them, being now more abundant, appears somewhat like fat mixed with the dung. When blood is drawn from a horse in this state, a large quantity of inflammatory crust, coagulable lymph, or buff-coloured jelly, appears on its surface. Such is the account which Mr. White gives of this disease, and he explains the account of those veterinary writers who represent molten greafe as consisting in a coagulation or general melting of the fat of the body, great part of which is absorbed, and thrown upon the blood and upon the intestines, whence it is voided with the excrement. Nor does he approve of the description of this disease, given by Mr. Blaine, in his Treatise on Veterinary Medicine, who considers it to be the same with the human dysentery. In the course of a ten years' extensive practice, he says that he has never met with a single case that resembled the dysentery described by medical authors. "I have often observed," says this writer, "during the progress of symptomatic fever, internal inflammation, mucus mixed with the dung, which had sometimes the appearance of part of one of those long white worms so often found in the horse's bowels; at others it resembled a membrane. I have observed the same thing in horses apparently healthy, or after the operation of very strong physic. I have also seen many cases where there was tenesmus or considerable irritation in the rectum; the horse frequently voiding a small quantity of dung, and appearing in pain. But this was always a symptom of some more important complaint, and easily removed, or the effect of physic, and very unlike dysentery." Molten greafe, according to Mr. White, is not to be considered as a distinct disease, but merely as a symptom, sometimes appearing in general inflammation, but more frequently in fevers. In either of these cases some of the internal organs are more

affected than others. When a difficulty of breathing occurs, indicated by an unusually quick motion of the flanks and expansion of the nostrils, it is a sign of an affection of the lungs. When molten greafe appears, it shews that the mucous membrane of the bowels is more particularly affected; sometimes both these parts are affected at the same time. The principal remedy in this disease is copious bleeding, according to age, strength, and other circumstances of the case. It is often necessary to repeat the operation of bleeding; and if the disease appears to be principally seated in the lungs, only laxatives should be administered and rowels inserted in the chest and belly; the sides also may be blistered, or the mustard embrocation rubbed on the sides and belly. In molten greafe, or when the bowels are affected, if a copious purging occurs, it should not be suppressed, but encouraged, by giving frequent decoctions of linseed, gum arabic dissolved in water, starch, or the powder of arrow root, and boiled in water. When the dung is voided sparingly, but frequently, and particularly when any knobs are mixed with it, let a pint of castor oil be given, which may be repeated, if necessary, about two days. In this case it will be proper to rub the mustard embrocation on the belly. If the disease continue, and especially if there be considerable irritation about the anus; the horse frequently ejecting a small quantity of excrement, and appearing to be in great pain, the following opiate clyster may be given, *viz.* opium ʒi dram, warm water 8 oz. mixed, to which add about a quart of starch water, *i. e.* starch boiled in water, of a proper consistence for a clyster. If the exhibition of a clyster seems rather to increase than alleviate the pain and irritation, the dose of castor oil must be repeated, and a clyster thrown up only of water gruel or a little oil. As the gut in this case is very tender and irritable, the clyster pipe should not be rough, and it should be introduced with caution; it should therefore be perfectly smooth, covered with oil or lard, and not protruded with violence. It is probable, says Mr. White, that a small, short tube of bone, about three times the bulk and length of the pipe used in human subjects, would be preferable on this occasion to that which is commonly employed. White's Treatise of Veterinary Medicine, vol. i.

GREASE, among Hunters, denotes the fat of a boar or hare.

GREASY, in *Agriculture*, a term provincially made use of to imply any thing foul, whether in animals or land. It is frequently used to signify such tillage lands as are much over-run with grass when in the state of fallow.

GREASY-Blues, or *Creechy-blues*, in *Mineralogy*, are terms by which kind shale or slate clay, or that which has a greasy appearance, and works or digs easily, is distinguished. See **SHALE**.

GREAT, a term of comparison, denoting a thing to have more extension than some other to which it is referred. Thus we say, a great space; a great distance; a great figure, a great body, &c. See **COMPARISON**.

GREAT is likewise used figuratively, in matters of morality, &c. to signify ample, noble, elevated, extraordinary, important, &c. Thus we say, Shakspeare was a great genius; queen Elizabeth had a great soul; Cromwell was a man of great designs; Da Vinci, a great painter; Galileo, a great philosopher; Bossuet, a great orator, &c.

GREAT is also a title or quality appropriated to certain princes, and other illustrious personages. Thus we say, the great Turk; the great Mogul; the great Khan of Tartary; the great duke of Florence, &c.

GREAT is also a surname bestowed on several kings and emperors. Thus we say, Alexander the great, Cyrus the great; Charles the great, or Charlemagne; Henry the great

of France, &c. So the English frequently say, Edward the great, or the great Edward; William the great, meaning king William III. or the great William. The French say Louis the great, *le grand*, speaking of Louis XIV. Giles of Paris says, Charlemagne first got the surname great from the tallness and eminence of his stature. Helgaud adds, that Hugh the great of France was thus denominated on account of his great piety, goodness, &c.

GREAT is also applied to several officers who have pre-eminence over others. Thus we say, the lord great chamberlain; the great marshal of Poland, &c.

GREAT *Circles of the sphere.* See GREAT CIRCLE.

GREAT *Circle sailing.* See SAILING.

GREAT *Apparatus.* See APPARATUS.

GREAT *Artery.* See ARTERY.

GREAT *Bairam.* See BAIRAM.

GREAT *Bank of Newfoundland,* in *Geography.* See BANK. It lies between 41° and $50^{\circ} 24'$ N. lat., and between $49^{\circ} 45'$, and $54^{\circ} 45'$ W. long.

GREAT *Barrington.* See BARRINGTON. The number of inhabitants by a late estimate is 1754.

GREAT *Bay,* a bay of North America, at the mouth of the Piscataqua river, between Portsmouth and Exeter, in the state of New Hampshire.

GREAT *Bear lake.* See BEAR lake.

GREAT *Bear.* See URSA major.

GREAT *Cape,* in *Geography,* a Cape of Upper Canada, where lake Superior descends into the narrows of the fall St. Mary.

GREAT *Diachylon.* See DIACHYLON.

GREAT *Egg harbour,* &c. in *Geography.* See EGG harbour river.

GREAT *Famine,* a river of America, in New York, which rises in the mountains near the source of the river Oneida, and runs N. W. by W. to lake Ontario.

GREAT *Gun.* See CANNON and GUN.

GREAT *Intervals,* in *Music,* signify the same, with Holden and some other writers, as greater and major do with the generality of musicians, and is applied to the intervals marked with Roman capitals, as II, III, V, VI, VII, &c. See GREATER.

GREAT *Island,* in *Geography,* a small island in the East Indian sea, near the N. coast of the island of Flores. S. lat. $7^{\circ} 59'$. E. long. $120^{\circ} 54'$.—Also, an island in the river Niagara, between lake Erie and lake Ontario. N. lat. 53° . W. long. $78^{\circ} 59'$.—Also, an island of Ireland, in the county of Cork, being the largest of the islands formed by the river Lee in Cork harbour; on it is the flourishing town of Cove.—Also, an island in Piscataqua harbour, New Hampshire, in the United States.

GREAT *Kanaway.* See KANAWAY.

GREAT *Letters.* See CAPITALS.

GREAT *Mafs.* See MASS.

GREAT *Mecatina.* See MECATINA.

GREAT *Octave,* in *Music,* is applied by the Germans, according to their tablature, or notation of musical notes, to the octave, or rather septave, beginning with C on the second leger line below the bass staff, and ending with B on the second line, or *ni* of Guido, and to which they exclusively apply the Roman capitals C, D, E, F, G, A, B. See Dr. Callcott's *Musical Grammar*, art. 34. See also SMALL OCTAVE, ONCE-MARKED *Octave*, and TWICE-MARKED *Octave*.

The object of this tablature is, to enable musical notes to be written or printed without clefs or lines and spaces in a staff.

GREAT *Officers.* See OFFICER.

GREAT *Pelican Island.* See PELICAN.

GREAT *Repeat.* See REPEAT.

GREAT *Ridge,* in *Geography,* one of the ridges of the Alleghany mountains, which separates the waters of the Savannah and Alatomaha. At the S.E. promontory of this ridge is that extraordinary place called Buffalo lick, distant about 80 miles from Augusta. It occupies several acres of ground. A large cane swamp and meadows, forming an immense plain, lie S.E. of it, and in this swamp Mr. Bartram apprehends that the branches of the great Ogechee take their rise. The lick is nearly level, and lies between the head of the cane swamp and the ascent of the ridge.

GREAT *River,* a river of Virginia, which runs into the Staunton river. N. lat. $36^{\circ} 46'$. W. long. $79^{\circ} 12'$.—Also, a river of Canada, which runs into the river St. Lawrence, 20 miles below Quebec.

GREAT *River.* See RIO GRANDE.

GREAT *Scale,* in *Music.* The late sir Marmaduke Overend, after a life almost spent in researches into the nature and proportion of musical intervals, succeeded, to the satisfaction of Dr. Boyce, his intimate friend, to whom his labours were submitted, in unravelling the mysteries of the Greek scales of music, as he says, in a paper on the great scale, in his quarto manuscripts, vol. ii. page 113 to 133, now in the library of the Royal Institution, which is thus entitled, *viz.* "All the Greek scales of music combined, with the diatonic intense, extended in the acumen and gravitas, with their remissions and intensions to double flats and double sharps in each; first restored, elucidated, and calculated, by Marmaduke Overend, Isleworth 1779." In pages 143 to 149 of the same volume of MS. we find also the several ratios of this scale in their least terms, and the indices of the component primes, of one octave of the acumen and the gravitas with the synemmenons, the remissions, &c. This scale, which contains 86 notes within the octave, is a great musical curiosity, which we are sorry that our limits will not admit of inserting: by the notice here taken of it, the curious may resort to the manuscripts themselves for further satisfaction. See GREEK SCALE.

GREAT *Seal.* See SEAL.

GREAT *Sixth, Redundant,* in *Music,* or redundant great sixth, according to Holden, is the inversion of the deficient less third of his scales ($\frac{2}{3}$), and has a ratio of $\frac{7}{5}$, = $475.94799 \div + 9f + 41m$ in Farey's notation, its common logarithm being $.7659167.9396$, its Euler's log. or decimal of the octave = $.7776075$, and it contains 43.38868 major commas. This interval does not belong to the received or diatonic system, having the number 7 in its ratio.

GREAT *Sodus.* See SODUS.

GREAT *Third,* in *Music,* probable, according to Holden's new and fanciful system, is the ratio which the mind "probably" conceives (page 371 of his "Essay") as pertaining to the major third in the common chord minor, and to which he assigns the numbers $\frac{13}{8}$, = $206.270982 \div + 4f + 18m$ in the new notation; its common logarithm is $.8985423 5924$ and that of Euler, $.3370350$, it also contains 18.80576 major commas; it is far removed from the received or diatonic system of intervals, as involving the prime number 19, and yet it is one of those which result from earl Stanhope's directions for tuning; it is the lesser equal-beating biequal third of his lordship, see EQUAL BEATING. Mr. Holden, at page 384 of his essay, relates an experiment in which this third proved an "intolerable discord," which is more than might be expected, from the temperament of rather more than $\frac{9}{8}$ ths of a comma, which it has.

GREAT *Tithes.* See TITHES.

GREAT *Wardrobe.* See WARDROBE.

GREAT Wheel, in *Clock* or *Watch-work*, is that wheel which the weight, spring, or fusee, first moves.

GREAT Work, in *Chemistry*, is the alchemical process whereby gold is made, or pretended to be made.

GREAT Year. See *PLATONIC year*.

GREATER Barons. See *BARON*.

GREATER Enharmonic diefis. See *DIEFIS*.

GREATER Excommunication. See *EXCOMMUNICATION*.

GREATER Fasti. See *FASTI*.

GREATER Hexachord. See *HEXACHORD*.

GREATER, in *Music*, is applied to distinguish several intervals, whereof there are two of the same name, as greater second, lesser second; greater third, lesser third; &c. Major interval is as often applied to these, and by some few writers they are called great intervals. The semitone or difference between the *greater* and the *lesser* intervals of the same names, are not all equal, but of two different magnitudes, viz. the semitone minor ($\frac{2}{3} \Sigma = 36 \Sigma + f + 3 m$), which occurs between the thirds and the sixths major and minor, and the semitone medius ($\frac{1}{2} \Sigma = 47 \Sigma + f + 4 m$), which occurs between the seconds, fourths, fifths, and sevenths, major and minor: the difference of these semitones being the major comma $\frac{2}{3} \Sigma = 11 \Sigma + m$.

GREATHAM FLEET, in *Geography*, a river of England, which rises in the county of Durham, and runs into the German sea, 5 miles S. of Hartlepool. N. lat. $54^{\circ} 43'$.

GREATMAN'S BAY, a bay of Ireland, on the N. coast of Galway bay; six miles N. from S. Arran isles.

GREAVES, JOHN, in *Biography*, was born at Colmore, near Alresford, in Hampshire, in the year 1602. He was educated in the classics, and in the other elementary parts of learning by his father, who was rector of the place, and the most celebrated school-master in that country. When he was fifteen he was sent to Baliol college, Oxford, where he applied himself with great assiduity to the studies of the place, and took his first degree in the year 1621. Three years after this he stood candidate for a fellowship of Merton college, when he was the first on the list of five who were then elected. In 1628 he took the degree of M.A., and more particularly directed his attention to the study of the mathematics and oriental learning, and became the friend of the most eminent scholars in the university, among whom were Mr. Briggs, Savilian professor of astronomy, and Mr. Peter Turner, professor of geometry in Gresham college, London. Had he wanted any motive to induce him to pursue his studies with vigour, the example of his contemporaries would have furnished that motive. Mr. Greaves read over all the writings of the most celebrated mathematicians of that and the preceding age, and he made himself familiar with the ancient Greek, Arabian, and Persian authors. In the year 1630, upon the resignation of Mr. Turner, he was elected professor of geometry at Gresham college, in consequence of the high reputation which he sustained in the university. At this period he was introduced to archbishop Laud, the chancellor of the university of Oxford, from whom he received several marks of favour. Soon after this, Mr. Greaves resolved to travel for improvement, and in 1635 we find him in Holland, attending the lectures of James Golius, professor of Arabic at Leyden; from thence he proceeded to Paris; afterwards to Rome, Florence, and Padua, making exact observations upon everything deserving of notice. Upon his return he determined to take a voyage to Egypt, a design which met with the decided approbation of the archbishop. His object in this was not only to make himself acquainted with such remains of antiquity which that far-famed country possessed as might serve to illustrate ancient literature, but also to make

astronomical and geographical observations; he therefore furnished himself with instruments of every kind for the purpose, and such printed Greek and Arabic books as he thought might be advantageously exchanged for MSS. and other objects worthy of collection. He embarked in the river Thames for Leghorn in the year 1637, accompanied by his friend Mr. Edward Pococke, and proceeded first to Italy, and thence to Constantinople, where they arrived about Michaelmas. Here he was received with great attention by sir Peter Wyche, to whom he brought out letters of recommendation from archbishop Laud. He was immediately introduced to Cyril Lucar, the Greek patriarch, who afforded him much valuable assistance in purchasing Greek MSS. The venerable patriarch promised to recommend him to the monks of mount Athos, in Macedonia, where, he said, "he would have had the liberty of entering all the libraries in that place, to have collected a catalogue of such books, as either were not printed, or else, by the help of some, these might have been more correctly set out." These, by dispensing with the anathemas which former patriarchs had laid upon all Greek libraries to preserve the books from the Latins, the patriarch proposed to have presented to the archbishop of Canterbury, for the better prosecution of his grace's designs in the edition of Greek authors, but the death of that patriarch frustrated Mr. Greaves' intention of visiting the celebrated mount, and occasioned his being a sufferer in another respect; for having procured from a Greek monastery some MSS. of the fathers, he was under the necessity of restoring them, and losing his money to avoid a greater inconvenience. Mr. Greaves, having lost his friend, determined to proceed to Egypt, but before his departure he had an opportunity of shewing his great attention to astronomical science: knowing that there would be an eclipse of the moon in the course of a few months, he furnished proper persons with convenient instruments for observing it at Constantinople, Bagdad, Smyrna, and Alexandria, and gave them necessary instructions for the purpose. For his conduct in this respect Dr. Halley paid him the highest compliment by saying that a greater service could not be rendered to the science of astronomy than by taking the phases of the moon's eclipses at those places, in order to determine their longitudes, since in and near them were made all the observations by which the mean motions of the sun are limited. Mr. Greaves having finished his arrangements for this business, went by Rhodes to Egypt, and arrived there in the month of September 1638. This was the boundary of his intended journey, and here an immense field for the exercise of his inquisitive genius opened upon his view. He omitted no opportunity of examining whatever the heavens, the earth, or subterraneous parts offered him, that might be deserving of notice; but complains of having his astronomical observations frequently interrupted by the clouds and rain, which he found to be frequent, especially in the middle of winter. But what particularly engaged his attention, and employed his care, were the pyramids, of which, at that time, there was no satisfactory account before the public. This talk he undertook, and towards the close of the year 1638 he took a careful survey and mensuration of them. Having gratified his curiosity, furnished his mind with a large stock of useful knowledge, and collected some Greek, Arabic, and Persian MSS., as well as ancient coins, and other varieties, he embarked at Alexandria in the month of April 1639, and arrived at Leghorn in June. He now made a second tour of Italy, which occupied him nine months. At Florence he was received with particular marks of respect by the grand-duke of Tuscany, Ferdinand II., to whom he addressed a Latin poem sent from Alexandria; and he also was permitted to

have

have free access to the Medicean library, which had been refused to him as a stranger when on his former tour. From Florence he went to Rome, whence he returned to Leghorn, and embarked on board a vessel for London, with a rich cargo of MSS., gems, coins, and other valuable antiquities. Upon his arrival in England he found his native country distracted by the contests between the king and parliament: he was, from principle, a friend to the royal party, and involved himself in much trouble by the zeal which he displayed in the cause of monarchy, and in his attachment to archbishop Laud. Having made a short stay at Gresham college, he went to Oxford to digest and prepare his papers for publication, in which he was assisted by archbishop Uther, who had long known and esteemed him; and he now drew a map of the Lesser Asia, at his grace's request, who was writing his dissertation on that country, which was printed in 1641. In this year archbishop Laud having presented to the university a second collection of medals, the task of arranging them was confided to Mr. Greaves, which he performed to the entire satisfaction of that learned prelate. By continuing to reside so long at Oxford, Mr. Greaves lost his professorship at Gresham college, but he was almost at the same time chosen the Savilian professor of astronomy at Oxford, and obtained likewise a royal dispensation to hold his fellowship at Merton college, on account of the diminution in his stipend as professor, arising from the circumstances of the civil war. The labours of the professorship being suspended, he proceeded with his literary avocations, and in the year 1644 translated into Latin the "Lemmata of Archimedes," correcting the diagrams, and supplying what was frequently found defective in the demonstration itself. This piece was published by Mr. Samuel Foster in his Miscellanies, or "Mathematical Lucubrations," 1659. Mr. Greaves, about the same time, compiled "A Persian Lexicon," out of such words as could be met with in the evangelists, the psalms, and two or three Arabian and Persian nomenclators. In 1645 he drew up a scheme for gradually introducing the new or Gregorian style, by omitting the intercalary day of the leap-year for forty years, which scheme was highly approved by the king and council, and would probably have been carried into execution, had the times been favourable to the innovation. In 1646 he published his work entitled "Pyramidographia," or a description of the pyramids of Egypt, and soon after a "Discourse on the Roman Foot and Denarius," from whence, as from a common standard, the measures and weights used by the ancients may be deduced. About the year 1648 Mr. Greaves found that he should be under the necessity of resigning his professorship, he accordingly, before his interest was entirely gone, introduced a successor, viz. Mr. Seth Ward, afterwards bishop of Salisbury. He then went to London, where he married, and living upon his patrimony, devoted his time to literary labours. He published many learned works, among which was "Elementa Linguæ Persicæ," 4to. to which the author subjoined "Anonymus Perse Sighis Arabum et Perfarum Astronomicis." In 1652 he published an astronomical work, to which he prefixed "A short History of the Rise and Progress of Astronomy among the Arabians," and subjoined his Binæ Tabulæ. Besides these, he published many other works, and had prepared many more for the press, when he was attacked by a disorder that proved fatal to him. He died in the fiftieth year of his age. Of his learning, ingenuity, diligence, and wonderful perseverance, there is abundant evidence. He was highly esteemed by many of his most eminent contemporaries both at home and abroad; steady in his principles and in his friendships, and his death was lamented as a real loss to science and literature. *Biog. Brit.*

GREBANISH HEAD, in *Geography*, a cape of Scotland, on the E. coast of the peninsula of Harris. N. lat. 57° 48'. W. long 6° 43'.

GREBE, in *Ornithology*, is classed by Linnæus under the genus of *Colymbus*, which see.

GREBENAU, in *Geography*, a town of Germany, in the principality of Hesse Darmstadt; 35 miles S. of Cassel. N. lat. 50° 43'. E. long. 9° 31'.

GREBENSKOI. See **COSSACKS**.

GREBENSTEIN, a town of Hesse-Cassel, 12 miles N.W. of Cassel. N. lat. 51° 26'. E. long. 9° 22'.

GREBER, **GIACOMO**, in *Biography*, a German musician, who had been some time in Italy, and who brought hither a female singer, his scholar, la signiora Margarita de P'essine. He set to music a pastoral entertainment, entitled "The Loves of Ergasto," after the manner of the Italian opera, that is, in recitative, with airs intermixed. This was the first performance in Sir John Vanburgh's new theatre in the Haymarket, afterwards called the Opera House. Greber's scholar, Margarita, sung in most of the early attempts at operas in England, and from the name of her master, Greber, was long called "Greber's Peg;" which occasioned his name to be better known, and longer remembered than his works. See **MARGARITA**.

GRECI, in *Geography*, a town of Naples, in the province of Principato Ultra, founded by a colony of Albanians, who left their country after their prince George Castriot, near Ariano.

GRECOURT, **JOHN-BAPTIST-JOSEPH VILLART DE**, in *Biography*, was born at Tours, in France, in 1683. He was devoted by his friends to the church at a very early period, and was in possession of a canonry when he was only fourteen years of age. He became celebrated as a preacher, but his discourses were satirical rather than moral, and did not redound much to his credit as a preacher of the gospel. Quitting his profession he became a man of the world, and made his way to the fashionable circles by his convivial talents, and his faculties of writing and reciting licentious and burlesque verses. He was patronized by the marshal duke d'Etrees, who frequently carried him to his seat, which the poet called his earthly paradise. The life which he led would not bear reflection; and though he apparently spent a joyous course, yet there was a small portion of respectability attached to his character. He died in 1743. His printed works were tales, epigrams, songs, fables, and other light pieces. Few of them rise above mediocrity, but they are lively, pleasant, and popular. His poem, entitled "Philotamus," which was a satirical history of the bull Unigenitus, had prodigious success. The verses are burlesque, some of them extremely humorous, though their general texture is mean and vulgar. *Moreri*.

GREDDING, in *Geography*, a town of Germany, in the principality of Aichtatt, on the Schwarzach; 13 miles N.E. of Aichtatt.

GREE, a town of Persia, in Segestan; 20 miles S.W. of Meimend.

GREE, in our *Law Books*, signifies agreement, contentment, or good liking. Thus, to make gree to the parties, is to satisfy them for offence done. "Judgment shall be put in suspense, till gree be made to the king of his debt." Stat. 25 Edward III.

The word is formed from the French *gré*, good will, good liking, or allowance.

GREECE, in *Geography*, a country of Europe, subject to the Turks, and more generally known under the name of *Turkey in Europe*, which see.

GREECE, in *Ancient Geography*. See **GRÆCIA**.

GREEK Accents. See ACCENT.

GREEK Church. See CHURCH

GREEK Church, *Music of the*. The schism between the Greek and Roman churches, which happened in the ninth century, prevented such changes as were made in the Roman ritual, after that period, from being adopted by the Greeks; and the notation used before seems long to have continued in the East. In Russia, however, all the rituals were called in at the beginning of the last century; and a uniform liturgy was established, in which the modern method of writing music was received. But in the Greek isles a notation peculiar to its inhabitants is still in use, which is not only as different from our's as their alphabet, but totally unlike that in the ancient missals.

In examining the most ancient of these in the Vatican library, which were written in capitals, the first notation which we could discover, consisted chiefly of accents; and when small letters were afterwards used, these accents were only somewhat lengthened. In the tenth and eleventh centuries, they very much resemble the characters to be found in contemporary Latin missals. However, the melodies in the lower ages became more elaborate, and the notes more numerous than in those of higher antiquity.

St. John Damascenus, who lived in the eighth century, is celebrated by the writers of his life, and by ecclesiastical historians, as the compiler and reformer of chants in the Greek church, in the same manner as St. Gregory in the Roman. And Leo Allatius (*De Libris Eccl. Græcorum*) under the title "Ὀκτώηχος" (ὀκτώηχος; eight tones), tells us they were composed by J. Damascenus. Zarlino goes still farther, and informs us (*Instit. Harm. 4to. parte. cap. viii.*) that in the first ages of Christianity the ancient Greek notation by letters having been thrown aside, John Damascenus invented new characters, which he accommodated to the Greek ecclesiastical tones; and that these characters did not, like our's, merely express single sounds, but all the intervals used in melody; as a semitone, tone, third minor, third major, &c. ascending and descending, with their different duration. This resembles, in many particulars, the notation in the ecclesiastical books of the Romish church, before the time-table, and characters in present use were invented, or, at least, generally received.

The abate Martini of Venice (see "Present State of Music in France and Italy") having visited the Greek isles in hopes of acquiring such a knowledge of the music practised there at present, as would enable him to judge whether any of the miraculous powers attributed to it by their ancestors still remained, as well as to compare its excellence with that of his own country; and as this learned and sagacious enquirer confided to us his papers on that subject, we shall communicate to our readers a sketch of their contents.

The system of modern Greek notation seems much more complicated and obscure than the ancient. The characters convey nothing to the mind either by their form or names, the greatest part of which cannot be construed; and the rest are construed to no purpose. Their signification, as words, does not point out their meaning as musical characters; and all that we can discover is, that some of them seem descriptive of gesticulations; such as ἀναίστημα, which, perhaps, directed the priest to look up, or stretch his hands towards heaven. Οὐρανός, which might direct him to make the sign of the cross, or to carry the cross. Ἀναίστημα, *flexio, contortio*. Indeed, it is said in the papers, that some of these characters are for the *Neigobouma*, or *legerdmain*, and not

for the voice. This is the more likely, as the Greek service abounds in gesticulations and manual dexterity.

The abate was informed, that though the oriental Greeks have signs for musical sounds equivalent to our's, they sing more by tradition than science. However, the distinctions for the duration of sounds, such as our time-table furnishes, are still wanting. The abate procured an extract from a tract upon the music of the modern Greeks, written by Lampadarius; but who he was, or when he lived, no one could inform him. In this it appears, that the characters amount to more than fifty; among which most of the names of those musical terms, given by Du Cange, from a MS. treatise on the ecclesiastical music of the Greeks, are to be found. (*Gloss. Med. et Inf. Græcitat.*) Du Cange, who has so amply collected and explained the characters used by the modern Greeks in chemistry, botany, astronomy, and other arts and sciences, is silent as to their musical notation; nor have we been able to acquire any information on that subject, except that with which the abate Martini has supplied us. The title of the treatise by Lampadarius is the following: Τεχνολογία τῆς μουσικῆς ἡμετέρας. The extract from it, which is in our possession, is too long for insertion here; nor would it be of much use could we allow it room, as no equivalents to the Greek characters are to be found in our own notation. But with respect to the author, we find among the memoranda which we made in the king of Sardinia's library at Turin, an account of a Greek MS. of the fifteenth century, N. 353. b. 1. 24, in which Lampadarius is often mentioned as author of the music to the hymns and prayers it contains. Fabricius likewise, *Hibl. Græc. vol. ii. p. 269, 564,* and 586 speaks of a MS. in the Selden collection at Oxford, and another in the Jesuits library at Louvain, in which there are explanations of the notes used by the modern Greeks, and musical compositions by several authors, particularly Lampadarius. In the patriarchal church of Constantinople there are four singers, who are placed on the right and left sides of the choir; the first on the right is called ἡγουσὸς ἀλάρας, the principal singer; the first on the left ἄκτιπαιος, Lampadarius; the two others who assist the principals are called *domestici*. It is probable that Lampadarius, who flourished about the year 1300, either took his name from the office he filled; or, on account of his eminence in music, that his name was given to the office.

To insert here the musical characters still used in the rituals of the Greek church out of Russia, and endeavour to explain them, will perhaps be conferring but a small favour on our readers; for from the scarcity of music written in such characters, so few will be their opportunities of making use of any knowledge they may acquire by the study of them, that it would be like learning a dead language in which there are no books, or a living language without the hopes of either reading or conversing in it.

Those readers who may be desirous of gratifying themselves in matters of curiosity, may consult Dr. Burney's *History of Music, vol. ii. p. 50.* where they will find the fourteen musical characters that occur in the Greek MSS. of the Evangelists, written in capitals during the seventh, eighth, and ninth centuries, though at present they are wholly unintelligible, even to the Greeks themselves. It is observable that the more ancient the MSS. the fewer and more simple are the notes; the "Codex Alexandrinus," in the British Museum has none; and the *Evangelistæ MSS. in the Harleian collection, 5785, 5598,* both of the tenth century, have only such as these, which were copied in Greece by the abate Martini.

The "Codex Ephrem," in the king's library at Paris, of the fifth century, has likewise the same kind of musical notes, and it is assigned as a reason for the "Codex Alexandrinus" not having them, that it was written for private use, not for the service of the church.

Kircher undertakes to give his reader an idea of modern Greek music and its characters; and has indeed collected a great number of notes and their names, but pretends not to furnish equivalents in the music of the western world. And to insert such barbarous names, and more barbarous characters here without explanation, would no more help to initiate a student in the mysteries of Greek music, than the Hebrew or Chinese alphabet. At the first glance they very much resemble the characters used in Choregraphy, an art invented about two hundred years ago to delineate the figures and steps of dances. They are too numerous and complicated to be inserted and explained here; however, we have given the names and correspondent notes in the History of Music, vol. ii. p. 51—52, by the study of which the musical reader will be able to form some idea of the melody which they are intended to express.

There are eight ascending, and six descending characters, some for single sounds, and others for wider intervals, as thirds and fifths, such as Zarlino, in the passage mentioned above, had imagined were invented by J. Damascenus; and all these have their particular *Chironomia*, or signs for the gestures with which the priest is to accompany the inflections of voice.

The beginning, or first note of every chant, is called *Ison*, which is equivalent to the key or tone in which any melody is sung.

Kircher, to whom even Egyptian hieroglyphics are easy, has resolved the names of these Greek notes into Latin. *Mufurgia, ubi supra.*

The abate Martini heard the Greeks, in Passion Week, sing several tropes or modes, which they now term *ᾠδαι*, in four parts, in the style of Palestrina: and this kind of music they call Cretan, but why, is not easy to divine, unless they learned counterpoint while the Venetians were masters of the island.

The abate says that he often heard the common people of Greece sing in concert, and observed that they made frequent use of the *fourth*: "della consonanza che noi chiamiamo oggi quarta." By this he must mean that they used it as a concord in two parts, or if there were more than two parts, in positions where our harmony forbids the use of it; otherwise it would not have affected his ear as a singularity.

The fact is curious, and we find it confirmed by Zarlino, who observed the same practice in the Greek church at Venice. The fourth, we find, was in such favour during the time of Guido, as to be preferred in disant to every other concord, and thought to constitute the most pleasing harmony. This partiality may probably have arisen from the importance of fourths in the ancient Greek system, and the want of a temperament to render thirds and sixths more agreeable; but the improvements in harmony soon brought it into disgrace in Italy, while, from a contrary cause, it has kept its ground to the present time in Greece, at least among the populace. And, indeed, even in Italy, it seems to have retained a part of its ancient privileges long after the time of Guido, and when harmony was thought to be in great perfection: for Zarlino says, that Jusquin, and the other old Flemish masters, used it frequently in their compositions: "nella parte grave, senza agguingerle altro intervallo."

The present state of Greek music, indeed, does not confirm or favour the opinion of Dr. Brown, who asserts with

his usual courage, that, "about four hundred years after Guido, the debauched art once more passed over into Italy from Greece: certain Greeks, who escaped from the taking of Constantinople, brought a refined and enervate species of music to Rome, &c." As many travellers assert that the modern Greeks have no music in parts, we may suppose, that in those places where it was heard by the abate Martini, it had been brought thither by the Venetians, during the time that they had possessions in the Archipelago.

That the Greek music has undergone many alterations since the ancient treatises that are come down to us were written, is certain from the change and increase of its vocabulary. Bryennius has given, as names of intervals, a list of barbarous terms not to be found in any preceding writer within our knowledge; and in the Greek glossary of Du Cange, and the abate Martini's papers, a great number occur that are not to be found either in writers of high antiquity, or in Bryennius.

The technical language of the Greeks has always been copious, and in music perhaps its seeming redundancy is more conspicuous than in any other art or science. But in other arts and sciences words are representatives of things existing; whereas, in denominating the tones and inflexions of voice, which, to realize, require new creation, there can be no correspondence between the type and substance. The colours, the forms, and objects, which a painter wishes to represent, are in nature; and the poet, in all the ebullition of wild enthusiasm and fervid imagination, describes what he has seen and felt, or what is to be seen and felt, and for which common language must supply him with symbols. But it has never entered the thoughts of man to give names to all the minute shades of colour between black and white, or to the gradations by which light is propagated between the time of total darkness and the sun's meridian. And yet, in a scale of sounds, from the lowest musical note in the human voice to the highest, where octaves are not represented by similar signs and appellatives, the names and characters must be numerous. The lines and clefs of the European music have certainly freed it from many perplexities with which it was embarrassed, even in the artless times of canto fermo.

But however flowery the Greeks may have made their ecclesiastical melody, or however they have multiplied its characters, the desire of permanence in the heads of the western church, with respect to all sacred matters, long kept music in the plain and simple state in which it was left by pope Gregory the Great; for we do not find, till the invention of counterpoint, that it received any material change or improvement. Our own bible and liturgy, if they remain in their present state five or six hundred years, will, perhaps, be unintelligible to the vulgar, though written in the best language of this country when they were introduced into the church. And the Greek and Roman languages, which were so well understood by the primitive Christians, became dead and obsolete by degrees, to all but the learned in after ages. The preclusion of change or innovation in sacred concerns which has occasioned permanence, has likewise been the cause of inelegance and obscurity.

"Peter the Great, like his predecessors, had a particular partiality for the music of the church; maintained his own choir, or singers for divine service, and read publicly in the church the epistles and the hours, which, in that country, is permitted to be done by any layman, who delights in such exercise, as well as by the priests." (King's Rites of the Greek Church.)

Many of the kings of France not only sung in the choir, but composed hymns for it, and set them to music. (Laborde.)

(Laborde.) And we have heard his present majesty, at six o'clock prayers in St. George's chapel at Windsor, officiate alone as clerk; repeating the responses, and reading the psalms aloud verse for verse, with the minister, and uttering the amen in the clerical style.

Music has been very much cultivated at Petersburg in the Imperial chapel and metropolitan church during the last century, as well as in the theatre. And though no instruments are admitted in the Greek church, any more than in the Sistine or pontifical chapel at Rome, yet every vocal refinement, both in composition and performance, that can with propriety be allowed in ecclesiastical music, has been received in the church service at Petersburg, in the Imperial chapel and cathedral of which capital, near a hundred voices are daily employed; and at Moscow, in several churches, when the sovereign is there, forty or fifty.

The music of the Hymnologia of the Russian ambassador's chapel in London, is sung to figurative music in three and four parts, distinct from the intonations or canto fermo. It consists of short, elegant, and simple strains or movements, in the Italian style, in plain counterpoint, composed to Slavonian words, by Bortnianski, who was sent to Italy, early in life, by the empress Catherine, to study composition.

The taste for good music passed from the theatre to the church. The plain chant of the modern Greeks is different from that of other Christian churches. It is more varied than the Gregorian chant; and that of the hymns rather resembles the figurative music of motets, than canto fermo. The empress Elizabeth, who was well acquainted with the kind of counterpoint *à capella*, and had great pleasure in uniting her voice with the choir, would never allow the Italian *florid song* to have admission in the sacred service; but says the Gotha Almanac, in an abridged history of the music of Russia, 1772, "Italian music has invaded even the Greek church as well as the Roman." This voice of complaint borders on *croaking*. We have taken considerable pains to obtain information on the subject, and have heard the service of the Greek church performed in several parts of Europe; and we have been favoured with a score of some of the music in present use in that service, composed by Bortnianski, a native of Petersburg, and find that it is neither so bald and dry as canto fermo, nor so florid and flighty as that of the Italian theatre. It is plain counterpoint, *non fugato*, in which the words seem well accented, the parts moving all together; so that there is measure, clearness, tranquil and soothing air, pure harmony, and natural and simple modulation. Nothing vulgar occurs, nor any thing to remind us of the opera house, yet the strains are not without grace or gravity. It seems to excite attention by its sweetness and simplicity, more than by the art of fuge, or extraneous modulation.

GREEK Music, Ancient. We shall here introduce some observations on the subject, extracted from a dissertation written several years ago.

Section I.—Of the Notation or Tablature of Ancient Music, including its Scales, Intervals, Systems, and Diagrams.

The music of the ancients, according to Euclid, Alypius, and Martianus Capella, was divided into seven constituent parts: these were *sounds, intervals, systems, genera, modes, mutations, and melopœia*, or the composition of melody. To these divisions, which comprehended only what was denominated harmonics, or the science of music, strictly so called, were added five other requisites, no less essential for a musician to know, than the preceding seven: and these were, *rhythm*, or the regulation of cadences in all kinds of movement; *metre*, or the measure of verses; *organic*, or the instrumental art; *hypocritic*, or gesture; and *poetic*, or

the composition of verses. And still to these divisions, Aristides Quintilianus, and some other musical writers, add *odicum*, or the art of singing; which, indeed, seems of more importance to music, than either the *organic* or *hypocritic art*. In order to communicate to our readers all the information we are able, upon so dark and difficult a subject, we shall consider the music of the ancient Greeks under such heads only as absolutely concern music, according to our appropriation of the word; for it is plain that several of its ancient divisions more immediately belonged to poetry. Indeed these two arts were at first so intimately connected, and so dependent on each other, that rules for poetry were, in general, rules for music, and the properties and effects of both were so much confounded together, that it is extremely difficult to disentangle them.

Leaving, therefore, for the present, all other distinctions, divisions, and sub-divisions, with which ancient musical treatises abound, we shall proceed to fulfil the title of this section.

In the study of modern music, the first objects of enquiry are the names by which the several sounds in the scale are expressed; and, if we regard music as a language, the scale or gammut may be called its alphabet.

Plutarch says, that it is not sufficient for a musician to know what kind of music should be set to any particular poem; he should likewise know how to write it down in all the genera, that is to say, in the *diatonic* or natural scale, consisting of tones and semitones as at present; in the *chromatic*, in which the scale was divided into semitones and minor thirds; and in the *enharmonic* genus moving by quarter tones, and major thirds, as will be explained hereafter.

It does not appear from history, that the Egyptians, Phœnicians, Hebrews, or any ancient people, who cultivated the arts, except the Greeks and Romans, had *musical characters*; and these had no other symbols of sound than the letters of their alphabet, which likewise served them for arithmetical numbers and chronological dates.

As the notation of the Greeks was imagined in the infancy of the art of music, when the flute had but few holes, and the lyre but few strings, the simplicity of expressing the octave of any sound by the same sign, as in modern music, was not thought of; the most ancient and constant boundary of musical tones having been the *diatesseron*, or fourth, the extremes of which interval were fixed, though the intermediate sounds were mutable: and in the manner of tuning these consisted the difference of intervals in the several genera.

The Greek scale, in the time of Aristoxenus, the oldest writer upon music, whose works are come down to us, extended to two octaves, and was called *systema perfectum, maximum immutatum*; the great, the perfect, the immutable system; because its extremities formed a perfect concordance, including all the simple, double, direct, and inverted concords, with all the particular systems; and it was the opinion of the ancients that this diatessaron, or double octave, was the greatest interval which could be received in melody.

This whole system was composed of five *tetrachords*, or different series of four sounds, and one note added at the bottom of the scale to complete the double octave; whence the string which produced this sound was called *πρωτολυμναρχον*, *prōtolambanomenos*, or note subjoined to the scale; for though this was constantly the lowest sound in all the modes, it was not included in the tetrachords.

All these sounds had different denominations in the system, like our gammut, *A re, B mi, C fa ut*, &c. besides two different characters, one vocal, and the other instrumental, appropriated to each sound in the several modes and genera, for the purpose of writing down melodies.

That the fourth was a favourite and important interval in

the music of the ancients, is plain from the great system of two octaves having been composed of five of these tetrachords, in the same manner as the scale of Guido is of different hexachords.

The first tetrachord is called by the Greek musicians *hypaton*, or principal; the sounds of which are denominated:

1. *Hypate hypaton*, principal of principals;
2. *Parypate hypaton*, next the principal;
3. *Lichanos hypaton*, or index of principals; from its having been played with the index or fore-finger. This third found of the first tetrachord in the diatonic genus was likewise called *hypaton diatonos*.

4. *Hypate meson*, or principal of the middle or mean tetrachord; for this found not only served as the last or highest note of the first tetrachord, but as the first or lowest of the second: whence these two tetrachords were called conjoint, or connected. These four denominations of the sounds in the first tetrachord may be compared with the terms B *mi*, C *fa ut*, D *sol re*, and E *la mi*, in the Guido scale; or with the sounds

The sounds of the *meson*, or middle tetrachord, were placed in the following order:

- Hypate meson*, or principal of the mean tetrachord;
- Parypate meson*, next to the middle principal;
- Lichanos meson*;

Mese, or middle, as this found completes the second tetrachord, and is the centre of the whole system. The sounds of this tetrachord correspond with those which in the base of the scale of Guido are called E *la mi*, F *fa ut*, G *sol re ut*, and A *la mi re*, which are equivalent to

Durum Hexachord.

Natural Hexachord.

Molle Hexachord.

It appears from the Greek tetrachords, as well as from this example, that neither the ancients nor the early moderns admitted the *sharp seventh* of a key into their scales.

The fourth tetrachord, ascending, is called *diezeugmenon*, disjunct, or separated, as it begins at B natural, which is not a note in common with any one in the other tetrachords. But though this system of four sounds is only an octave higher than that of the first tetrachord, and though the next is but a replicate of the second, we shall present them to the reader, as the several sounds of which they are composed have in the Greek music different denominations.

The first sound of the second octave, or series of eight sounds in the ancient great system, is *mese*, and the first of the fourth tetrachord begins with the note

Paramese, near the *mese*, or middle found; the next is called

Trite diezeugmenon, or third string of this tetrachord from the top: then follows the *paranete diezeugmenon*; and lastly, the

Nete diezeugmenon, or final found of this tetrachord;

The *mese* in ancient music was of equal importance with the key note in modern music: being an octave above the *proslambanomenos*, which was the lowest found of the ancient modes, and a kind of key note to them all.

Euclid calls *mese* the found by which all other sounds are regulated. And Aristotle, in his XXXVth Problem, sect. 19. says that all the tones of a scale are accommodated, or tuned, to the *mese*. The same author likewise tells us, Problem XX. that all melody, whether it moves above or below the *mese*, has a natural tendency to that found.

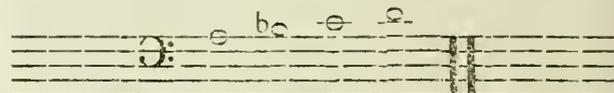

The third tetrachord, beginning by the last note of the second, was thence called *synemmenon*, the united, or conjoint tetrachord; the sounds of which proceed in the following order:

Mese;

Trite synemmenon, or third string of this tetrachord from the top;

Paranete synemmenon, penultima of this tetrachord;

Nete synemmenon, last of the *synemmenon* tetrachord; the four sounds of which correspond with those in the centre of our gammut, that are called A *la mi re*, B *fa*, C *sol fa ut*, and D *la sol re*, or

After ascending regularly thus far, up to D, by three conjoint tetrachords, the fourth tetrachord in the great system is begun by descending a minor third to B natural, the octave above the first found of the lowest tetrachord. Something of this *dodging* kind is to be found in the scale of Guido, divided into hexachords: for, after ascending six notes regularly in the *durum hexachord*, it is necessary to descend a major third, if we would begin the *natural hexachord*; and when the natural hexachord is completed, if we would begin at the *molle*, it can only be done by a leap of a third below. This will best appear by an example in notes:

which includes the sounds B *mi*, C *sol fa ut*, D *la sol re*, and E *la mi*, in the middle of the Guido scale, or

The last found of the fourth tetrachord is the first of the fifth, which is called the *hyperbolæon*, or supreme tetrachord; the sounds of which ascend in the following order:

Nete diezeugmenon, last of the *diezeugmenon* tetrachord;

Trite hyperbolæon, third string of the *hyperbolæon* tetrachord;

Paranete hyperbolæon, penultima of the supreme tetrachord;

Nete hyperbolæon, last of the supreme, or highest tetrachord, and of the great system, or diagram.

This last tetrachord, being added to the scale long after its first formation, was called *hyperbolæon*, from its sounds being more acute than the rest, and beyond the common bounds

bounds of the scale ; in the same manner, as, with us, the notes above D in the treble are said to be *in alt*. This tetrachord includes the sounds E *la mi*, F *fa ut*, G *sol re ut*, and A *la mi re*, or

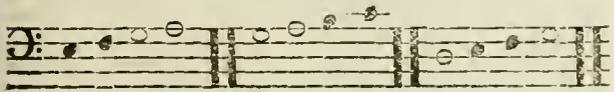

The ancients used likewise four different monosyllables ending with different vowels, by way of *solmisation*, for the exercise of the voice in singing ; like our *mi, fa, sol, la*. These were, for the first note of each tetrachord, $\alpha\bar{\alpha}$, for the second $\beta\bar{\beta}$, for the third $\gamma\bar{\gamma}$, and for the fourth, if it did not serve as the first of the adjoining and relative tetrachord, $\delta\bar{\delta}$; but if it began a new tetrachord, it was called by the first name, $\alpha\bar{\alpha}$.

The repetition of these monosyllables is a further proof that the fourth in the ancient music served as a boundary to a system of four sounds, in the same manner as a hexachord did in the Guido scale, and as an octave does for eight sounds in the more modern practice.

Any interval between the terms of which one or more sounds intervened, was by the ancients called a *system* : EG, for example, constituted a system of a third minor ; EA, of a fourth ; EB, of a fifth, &c.

These smaller systems were of different species ; thus there were three kinds of tetrachords, that differed in melody by the position of the semitone, which was sometimes at the beginning, sometimes at the end, and sometimes in the middle ; as in the following example, where the black notes are semitones, and the white, tones.

As the Greeks used all the four and twenty letters of their alphabet for musical characters, or symbols of sound ; and as their most extensive system or scale did not exceed two octaves, or fifteen sounds, it should seem as if their simple alphabet was more than sufficient to express them ; for their music being at first only a notation of their poetry, the rhythm, or air, must have been determined by the metre of the verses, without the assistance of signs of proportion peculiar to music. But supposing it was necessary for them to have different characters to express the different feet of the verse, it is certain that vocal music was in no want of them ; and instrumental being chiefly vocal music played by instruments, had likewise no need of them, when the words were written, or the player knew them by heart.

However, in order to multiply these characters, the letters of their alphabet were sometimes written in capitals, and sometimes small ; some were entire, some mutilated, some doubled, and some lengthened ; and besides these distinctions in the form of the letters, they had others of situation, sometimes turning them to the right, sometimes to the left ; sometimes inverting, and sometimes placing them horizontally ; for instance, the letter *gamma*, by these expedients, served to express seven different sounds : Γ Υ P P P P P . Some of the letters were also barred, or accented, in order to change their symbolical import ; and these still not sufficing, they made the common grave and acute accents serve as specific musical notes.

It is a matter that has been long disputed among the learned, whether accents were originally *musical characters*,

or marks of *prosody*. It is in vain to set about determining a question concerning which the proofs on both sides are so numerous. (See Gally and Spelman *against accents*, and Primatt and Forster in defence of them.) Mr. West is firmly of opinion "that accents were originally *musical notes*, set over words to direct the several tones and inflexions of the voice, requisite to give the whole sentence its proper harmony and cadence." (Pind. vol. ii.) And the abbé du Bos, who frequently by a peremptory decision cuts the knot of such difficulties as he is unable to untie, asserts, without sufficient proof, that as poets originally set their own verse, they placed for this purpose a figure, or accent, over each syllable. So that, according to this writer, we are at present not only in possession of the *poetry* of Homer, Pindar, Anacreon, and Sappho, but their *music*. Why then do we complain of the total loss of Greek music? (See Reflex. Critique, c. iii. p. 85.) But as music had characters different from accents so early as the time of Terpander, to whom the invention is given by the Oxford Marbles, which place this event about six hundred and seventy years before Christ ; and as accents for prosody are likewise proved to be of high antiquity, it seems as if there could have been no necessity for the ancients to use one for the other.

But it has already been remarked that the letters of the alphabet, though turned, distorted, and mutilated, so many different ways, were insufficient to express the sounds of all the modes in the three genera ; so that recourse was had to accents, as the scale became more extended, in order to augment the number of characters. And Alypius, in the enumeration of the notes in the enharmonic genus, tells us, that *trite synemmenon* is represented by *beta* and the *acute accent* ; and *paranete synemmenon enarmonics* by *alpha*, and the *grave accent*.

This is a proof that the accents were known at the time of Alypius, and were then used chiefly for prosody, not music, for which they were only called in occasionally. Indeed they are mentioned as accentual marks by writers of much higher antiquity than Alypius ; for not only Cicero and Plutarch, but Aristotle and Plato, speak of them as merely regarding the elevation and depression of the voice in speech. However, in the early Greek and Roman missals, as will be shewn hereafter, the musical characters used in *canto fermo*, seem to have been only *lengthened accents*.

These various modifications of letters and accents in the Greek notation composed in all one hundred and twenty different characters, which were still considerably multiplied in practice ; for each of these characters serving many purposes in the vocal as well as instrumental tablature or gammut, and being changed and varied according to the different modes and genera, as the names of our notes are changed by different cleffs and keys, the one hundred and twenty Greek characters produced one thousand six hundred and twenty notes !

Two rows of these characters were usually placed over the words of a lyric poem ; the upper row serving for the voice, and the lower for instruments.

If we had not the testimony of all the Greek writers who have mentioned these characters, for their use and destination, it would be natural to suppose that the double row of different letters placed over each other, and above the words of a poem, were intended to express *different parts*, with respect to *harmony* ; as with us, in modern music, the treble notes are written over the base, and the first treble over the second ; but Alypius, who is extremely minute in his instructions concerning the use of these characters, in all these modes, tells us, in express terms, that the upper line of the notes is for the words, and the lower for the lyre. ($\Sigma\text{p}\mu\ \alpha\bar{\alpha}\ \tau\bar{\alpha}$

μεν αυω, της λειξως τα δε κατω της κρησιως. *Introductio Musice*, edit. Meibom. p. 2.) We are told, not only by Alypius, but by Gaudentius, p. 23, that of the two rows of letters used for musical characters, the upper is for the words, that is, *to be sung*, and the under *to be played*. And he afterwards proves them to have been unisons to each other, both by his definitions and by placing them opposite to the same found in all the scales.

In this author, the notes of the great system of the Lydian mode in the diatonic genus are arranged in the following order:

Z. T R Φ C P M I Θ Γ Ω Z E Ω Φ Δ M' I
 Γ Γ L F C Ω Π < V N Z Γ Δ Z η ε. π' <'

And these he defines in such a manner as leaves no room to doubt of the identity of their signification.

It is somewhat strange that the notes for the voice in ancient music should be placed *above* those for the lyre, and consequently further from the words. Meibomius, in his preface, has, however, given a curious reason for this custom, from a fragment of Bacchius, senior: "The upper line of notes is for the poem, the lower for the lyre; because the mouth, which alone gives utterance to the words, is placed by nature above the hands, which produce tones from the instrument."

Z Γ *Proslambanomenos*, an imperfect Zeta, and Tau placed horizontally.

Γ Γ *Hypate hypaton*, an avèrted Gamma, and a Gamma direct.

R L *Parypate hypaton*, an imperfect Beta, and a Gamma inverted.

Φ F *Hypate diatonos*, a Phi, and a Digamma.

C C *Hypate meson*, Sigma and Sigma.

Π C *Parypate meson*, Rho, and Sigma inverted

M Π *Meson diatonos*, Mu, and a lengthened Pi.

I < *Mese*, Iota, and a horizontal Lambda.

Θ V *Trite synemmenon*, Theta, and an inverted Lambda.

Γ N *Synemmenon diatonos*, Gamma and Nu.

Ω Z *Nete synemmenon*, an inverted Omega and a Zeta.

Z Γ *Paramese*, Zeta, and Pi placed horizontally.

E Δ *Trite diezeugmenon*, Epsilon, and an inverted Pi.

Ω Z *Diezeugmenon diatonos*, as *Nete synemmenon*, which was the same string in the lyre.

ε η *Nete diezeugmenon*, horizontal Phi, and a small Eta lengthened.

Δ ε *Trite hyperboleon*, an inverted Upsilon, and an imperfect Alpha.

M' π' *Hyperboleon diatonos*, Mu, and a lengthened Pi, accented.

I <' *Nete hyperboleon*, Iota, and an accented Lambda, placed horizontally.

It is from the indefatigable labour of the learned Meibomius, in his Commentaries upon the ancient Greek musicians, particularly Alypius, that we are able to decipher these characters; which, before his time, had been so altered, corrupted, disfigured, and confounded, by the ignorance or negligence of the transcribers of ancient manuscripts, that they were rendered wholly unintelligible.

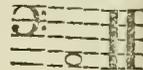

With our utmost study, reading, and contemplation, we could reduce the Greek notation to no order, nor ascertain whether it was to be read upwards or downwards. The neglect of these distinctions will introduce an universal scepticism concerning every part of ancient music.

Galilei, Zarlino, Bontempi, Tevo, M. Rousseau, Dr. Brown, and others have asserted, that the terms *high* and *low* had different acceptations among the ancients, from those in which they are understood by the moderns, without guard-

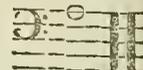

ing, as they ought to have done, against such consequences, with respect to the situation of the scale, as it was natural for the reader to draw from that assertion.

At length, an infallible rule presented itself to us in the works of the great Euclid, who has been regarded for so many ages as the legislator of mathematicians, and whose writings have been their code. In his section of the Canon, p. 37, edit Meibom. he represents *proslambanomenos* by the *whole string*: so that, if any thing concerning ancient music can be made certain, it is, that this whole string represented the *lowest sound* in the Greek scale, which, in the Hyper-

borian mode, was equivalent to the note A

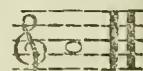

Half the string, *Mese*, its octave, a,

Third part, *Nete diezeugmenon*, fifth of the octave, e,

And the fourth part of the string, *Nete hyperboleon*, the double octave, aa,

which include all the concords that the ancients admitted. Eight ninths of the string are allotted to the sound *Hypate baria gravis*, which is B in the base, one tone higher than *proslambanomenos*, or A.

This representation of the whole string and its divisions into harmonic and aliquot parts, must put an end to every doubt concerning the order of the scale, which may have arisen from the inverted application of the words *high* and *low*, constantly occurring in all the more ancient and authentic Greek writers on music.

SECT. VIII.—Whether the Ancients had counterpoint or music in parts.

This is a subject which has given birth to many learned disquisitions and disputes; and as it long remained a mere matter of opinion, those who believed, and those who denied the point in question, consequently treated each other with all due polemic acrimony. The champions for antiquity thought themselves involved in the controversy; and whether they were possessed of musical knowledge, or were sensible to the charms of harmony, or not, they determined to regard every man as an enemy to sound literature, who did not subscribe to the articles of their faith.

A poem, called "Le Siècle de Louis le Grand," written by Charles Perrault, of the Academy of Sciences, and brother to Claude Perrault, the famous physician and architect, occasioned the long and acrimonious dispute between him and Boileau, and soon brought on a general war among the learned throughout Europe, concerning the superiority of the ancients or moderns, with respect to arts, sciences, and literature. This piece was first read by the author at the Academy of Sciences in 1687, and was soon followed by his "Parallele des Anciens et des Modernes." The notes to Boileau's translation of Longinus were intended as a reply to Perrault, and are full of bitter invectives, not only

only against him, but the moderns in general. Racine, La Bruyere, and Fontenelle, took sides in the quarrel, which in France was kept alive, with great animosity, for near thirty years.

In England, the controversy between sir William Temple and Mr. Wootton, Mr. Boyle and Dr. Bentley, and Swift's "Battle of the Books," were consequences of this quarrel.

Those who had written *ex professo* on music, had frequently differed in their opinions concerning counterpoint having been known by the ancients, previous to the learned, in general, interesting themselves in the dispute; and before we give our own opinion, as an individual, it is incumbent on us, as an historian, to inform our readers, who were the principal champions on both sides. Would it not render our article too long, the reasons assigned by each for seizing his sword, that is, his pen, in the quarrel, should likewise have a place here. But our limits will only allow us to say, that the most eminent defenders of ancient harmony in our sense of the word, are Gaffurio Zarlino, Gio. Battista Doni, Isaac Vossius, Zaccharia Tevo, the abbé Fraguier, and Mr. Stillingfleet, author of "Principles and Power of Harmony."

Their opponents are Gharianus, Salinas, the cavalier Hercules Bottrigari of Bologna, Artusi, Cerone, Kepler, Merfennus, Marilius Ficinus, Kircher, Claude Perrault, and the late elegant and learned poet Mr. Mason, who had studied modern music, and has left his decided opinion against the ancient Greeks having cultivated counterpoint. (Hist. Mus. vol. i. p. 125.) To these we may add Bontempi, the first Italian musical historian, the learned Dr. Wallis, M. Burette, who has explored the subject, and considered it in all its ramifications. Padri Martini of Bologna, a learned and diligent inquirer, has given a specimen (Stor della Mus. t. i. p. 174.) of such meagre counterpoint as was likely to have been produced without the use of imperfect concords, which the Greeks termed discords. The late shrewd and penetrating critic J. J. Rousseau is very explicit upon this subject in his "Musical Dictionary," at the article *Counterpoint*, which he terminates by saying, "It has long been disputed whether the ancients knew counterpoint; but it clearly appears from the remains of their music and writings, especially the rules of practice, in the third book of Aristoxenus, that they never had the least idea of it."

After this list of the most respectable writers on both sides of this long disputed question, it now remains to tell the reader ingenuously our own sentiments: and to confess the truth, we will venture to say, that we do not believe the ancients ever did use *simultaneous harmony*, that is, *music in different parts*; for without thirds and sixths it must have been insipid; and with them, the combination of many sounds and melodies moving by different intervals, and in different times, would have occasioned a confusion, which the respect that the Greeks had for their language and poetry would not suffer them to tolerate.

See IX.—Of the Dramatic Music of the Ancients. See DRAMATIC Music.

The Greek dramas consisted of soliloquy, dialogue, and chorus, and it has naturally been supposed, that these were sung to different kinds of music. Soliloquies full of sentiment and passion had probably a different, more elaborate, and refined melody, than the dialogues; but the chorus must necessarily be set to measured music, or the performers, if left *ad libitum*, could never have kept together.

See X.—Of the effects attributed to the music of the ancients.

Materials for this part of our dissertation are so numerous, that if we were only to present the reader with all the stories

that have been related by the most grave and respectable historians and philosophers of Greece and Rome, concerning the moral, medicinal, and supernatural powers of ancient music, this section would be as full of the miracles of musician, as the "Golden Legend" is of those operated by the saints. The credulous and exclusive admirers of antiquity have, however, so long read and revered all these narrations, that they are impressed by them with an extravagant idea of the excellence of ancient music, which they are very unwilling to relinquish; and yet, after a most careful investigation of the subject, and a minute analysis of this music, by examining its constituent parts, we have not been able to discover that it was superior to the modern in any other respects than its simplicity, and strict adherence to metrical feet, when applied to poetry. For, as *music*, considered abstractedly, it appears to have been much inferior to the modern, in the two great and essential parts of the art, *melody* and *harmony*.

We have considered the marvellous effects ascribed to ancient music, under three several heads:

First, in softening the manners, promoting civilization, and humanizing men, naturally savage and barbarous:

Secondly, its effects in exciting, or repressing the passions:

And thirdly, its medicinal power, in curing diseases.

And we think, that the whole may be construed into poetical fables, allegories, and vulgar errors. Many strange stories of the power of music over man and beast have gained admission into books, even in this philosophical and unbelieving age, at which posterity will doubtless stare!

GREEK *Grammar*. See GRAMMAR.

GREEK *Language*, the language of the Greeks. Whether we consider the high antiquity of this tongue, its varied excellencies, the unrivalled models of composition which it contains, or the extensive influence which the study of it has produced on the more modern dialects of Europe, it claims, in an eminent degree, the attention of learned men, as a subject no less curious than useful. The advantages to be derived from the study of those authors who have written in this tongue, are too notorious to need description, and are recommended to us by the united testimony of the learned in every age and country. The Greeks have left the most durable monuments of human wisdom, fortitude, magnificence, and ingenuity, in their improvement of every art and science, and in the finest writings upon every subject necessary, profitable, elegant, or entertaining. They have furnished the brightest examples of every virtue and accomplishment, natural or acquired, political, moral, or military; they excelled in mathematics and philosophy; in all the forms of governments, in architecture, navigation, commerce, war; as orators, poets, and historians, they stand as yet unrivalled, and are likely to continue unrivalled for ever; nor are they less to be admired for the exercises and amusements they invented and brought to perfection, in the institution of their public games. Nor can we become sensible of these admired excellencies in any of the best translations from the Greek. They may indeed communicate some knowledge of what the originals contain: they may present us with propositions, characters, and events; but allowing them to be more faithful, more accurate than they really are, or can well be, still they are no better than copies in which the spirit and lustre of the originals are in a great degree necessarily lost. The powers of the Greek are vastly beyond those of any other tongue. Whatever the Greek writers describe is always felt, and almost seen; motion and music

music are in every tone, and enthusiasm and enchantment possess the mind when we peruse them with taste and judgment.

The Greek tongue, as it was spoken in different provinces, was divided into different *dialects*, called the *Attic*, the *Ionic*, the *Doric*, and the *Æolic*. The Attic is that which was used at Athens, and in the adjacent country; those who have particularly distinguished themselves in this dialect, are Thucydides, Aristophanes, Plato, Hocrates, Xenophon, and Demosthenes. The Ionic differed very little from the ancient Attic; but having afterwards made its way into some towns of Asia Minor, and into the adjacent islands which were colonies of the Athenians and Achæians, (among which are reckoned Samos, Miletus, Ephesus, Smyrna, and some others,) it imbibed a new tincture, and fell very far short of that delicacy to which the Athenians afterwards attained. The principal writers in this dialect were Hippocrates and Herodotus. The Doric first prevailed among the Lacedæmonians and the inhabitants of Argos. It travelled afterwards into Epirus, Sicily, Rhodes, and Crete. This dialect has been used by Archimedes and Theocritus, (both of Syracuse,) and Pindar. The Æolic was spoken at first among the Bœotians and their neighbours, and afterwards it passed into Æolia, a province of Asia Minor, between Ionia and Mysia, which included ten cities, all Greek colonies. The chief writers in this dialect were Sappho and Alceus, of whose writings little has survived the loss of ancient learning; but this idiom is occasionally blended with the use of the other dialects in the compositions of Homer, Theocritus, Pindar, and others. It may be remarked farther that the lapse of time which occasioned the difference of these dialects, as they arose from a common stem, has moreover caused them to differ from themselves. For instance, in the Attic there is a wide distinction between the style of Demosthenes, and that of Thucydides. Nor has the Ionic dialect invariably continued the same, the people of Asia speaking it differently from the old Ionians of Greece, who followed the ancient language of Athens, and the same observation holds in regard to the Dorians and Æolians.

The ramification of the Greek tongue into its several dialects, while it forms one leading cause of its copiousness, occasions one of the most serious difficulties in the acquisition of it by learners. This difficulty, however, will be much diminished, if the dialects be reduced to those unavoidable changes, which are founded in the nature of language, and in the organs of speech. The changes we mean are such as flow from the fluctuation of the vowel sounds, from the different manner of combining, or of resolving any two concurrent vowels, and lastly, from the substitution or interchange of the homogeneous consonants, *i. e.* the consonants of the same organs.

Oriental grammarians, with much propriety, have divided the consonants into three classes, corresponding with the organs employed in founding them. Thus π, β, φ, being founded by the lips, are hence called *labials*. On the other hand, τ, θ, λ, ς, λ, ς, ς, enunciated by a contact of the tongue with the extremities of the upper teeth, are, for a similar reason, styled *dentals*; while κ, γ, χ, uttered by a contraction of the *larynx*, receive the name of *gutturals*. This distribution of the consonants, though here confined to the Greek alphabet, necessarily extends to any other system of letters, and well deserves the attention of him who would acquire a philosophical acquaintance with the origin and derivation of words. To the interchange of the homogeneous consonants, it is chiefly owing that the primæval language of men, at first rude and barren, became copious and

refined (the same original term hence splitting into many), was afterwards diversified into distinct dialects, and at length lost in distinct languages. Nor is it, we conceive, beyond the reach of philological enquiries to prove that the simple terms of any one language have their kindred terms in all other languages, disguised indeed by the differences of character, termination, and meaning; and that they may be traced back through the several stages of social life, till they meet, like so many shoots, in one common root.

The Greek language is a very copious subject, and a full account of it would carry us beyond the limits necessarily prescribed by our plan; we shall therefore content ourselves with some remarks calculated to ascertain its origin, and to unfold those analogies by which it grew from a few simple roots to the copiousness and refinement which distinguish it beyond most other tongues.

In enquiring into the origin of the Greek tongue, or in referring it to a higher dialect, we of course mean its roots or primæval words, which were simple, few in number, and consisting of two, three, or at most four letters; while its compound terms, which are exceedingly numerous and diversified, must have been indigenous, the products of time, and of improvement in knowledge and the arts of life, long after the introduction of its more elementary parts into Greece. With this limitation we have no hesitation in saying, that the simple words of the Greek language are all derived from the Hebrew, Arabic, and Persian, and principally from the first of these tongues. And for the affirmation that the Greek is derived from the Hebrew, or that the Greek primitives are Hebrew radicals, we offer the following observations. Moses, in the tenth chapter of Genesis, the fountain head of universal history and geography, enumerates those heads of separate families by whom the earth was divided after the flood. He describes them by those names which the nations that sprung from them, or the countries they severally occupied, retained in his time. By those parts of the earth, which he calls אֲרָצוֹת הַגּוֹיִם, or *the isles of the nations*, it is understood that he means *Europe*, and its adjacent islands. These were divided by the sons and grandsons of *Japheth*, or rather by *Gomer* and *Javan*, and their sons,—“In their lands every one after his tongue, after their families in their nations.” This division must have been regularly conducted. It must have taken place in the time of the patriarchs here mentioned; for the act was *theirs*, and the nations retained their names to the time of Moses; nay many of them long afterwards, for we find them recognized by history and geography. *Javan* is well known as the parent of the *Greeks*, the name *Ionians* being anciently applied from him to the several branches of that nation. Τοὶ Ἑσσηαί, καὶ Ἀχαιοὶ, καὶ Βοιωτοὶ Ἴωνες ἑκαλοῦν. *Hesychius*. Παντοὶ Ἑλλήνων Ἴωνες ἐν Βαβυλῶνι ἑκαλοῦν. But it appears from the sacred history that Javan spoke the Hebrew tongue; and he, with the colony under him, must have introduced it with them, and made it the first language of Greece. The letters of the Greek tongue refer its origin to the same oriental source; for they are nearly the same with the *Samaritan* when inverted, or written after the European manner, from left to right; and with little variation they have ever retained the names of the Samaritan or Hebrew alphabet. This is confirmed by Diodorus the Sicilian, lib. v. who gives it as the opinion of persons in his days, that letters were invented by the *Syrians*, from whom the Phœnicians first learnt their use, and then communicated them to the Greeks. These Assyrians, Herodotus describes (l. iii.) as the inhabitants of Jerusalem, to which he gives the name of *Cadysius*, the name it had of old, and still continues to have in the East. The authority of Herodotus and Diodorus, Pliny, it

GREEK LANGUAGE.

These examples are sufficient to shew how the Greek has been derived from Hebrew roots. Some thousands of Greek primitives owe their origin to the same source; and it is not too much to say that, if the Hebrew language had been preserved in the full extent in which it once flourished, not a Greek term could be named, which might not be traced to some one of its roots. But as its records are comparatively so scanty, many of the parent terms of Greece may more immediately be found in the kindred tongues of Syria, Chaldea, Arabia, and even Persia, which last, though different in structure from the Greek, contains a multitude of its radical terms. The conclusion that Greek originally flowed from the Hebrew tongue, serves to explain many of the properties which distinguishes this celebrated language, and to correct many errors into which learned men have fallen in treating this subject.

"The eastern tongues, says Dr. Gillies, (History of Greece, vol. i. p. 15.) are in general extremely deficient in vowels. It is, or rather was, much disputed, whether the ancient orientals used any characters to express them. Their languages, therefore, must have had an inflexible thickness of sound, extremely different from the vocal harmony of the Greek, which abounds not only in vowels, but in diphthongs. This circumstance denotes, in the Greeks, organs of perception more acute, elegant, and discerning. They felt such faint variations of liquid sounds as escaped the dulness of Asiatic ears, and invented marks to express them. They distinguished in this manner, not only their articulation, but their quantity, and afterwards their musical intonation." We do not think this observation altogether just, but think it rather founded in a misconception of the oriental languages. In these every consonant included in itself the vowel necessary to its enunciation; and while they thus presented a series of consonants to the eye, each in pronunciation is accompanied with its appropriate vocal sound, which rendered every word just as many syllables as it had of consonants, and gave to the language an exact mixture of vowels and consonants. When the Hebrew tongue ceased to be a living language, its true pronunciation was of course lost; and with it was lost the found and even the existence of the included vowel; and to supply this loss were invented the vowel points in Hebrew, Arabic, and the accents in Greek, which appear to be of kindred or rather of the same invention with the diacritical marks in the Asiatic tongues. The early Greeks, being sensible of the included vowel in the parent tongue, gave it a separate existence, by annexing it to the consonant: and as this vowel, though originally the same and always short, was liable to fluctuation, and to perceptible difference of sound, it naturally gave birth to the several short vowels. In Homer the digamma, which was a labial consonant, interposed between two vowels, which otherwise would have formed a diphthong. And this circumstance might lead us to conclude that the early Greeks conformed to the Asiatic tongues in rejecting the use of diphthongs, and that the use of diphthongs prevailed only as the digamma was laid aside. In the more ancient languages of Asia, all the included vowels were short, and every vowel that had an independent form was probably long: but short as well as long vowels came in time to have a separate existence; and the Shanferit, so far from being deficient in vowels, can boast of sixteen, a number more than the double of those in Greek.

We remark, in the second place, that the derivation of the Greek primitives from the oriental tongues will, in general, set aside as nugatory and erroneous the derivations of the ancient *scholiasts*, and of those modern lexi-

cographers who have adopted their explanations. These scholiasts and grammarians are valuable as expounders of the Greek text; but as they were apparently ignorant of the oriental tongues, the account which they give of the words thence derived are often frivolous in the extreme. It is necessary to justify this assertion by a few examples. *Αἴμασις*, a hedge or fence, occurs in Theocritus, Idyl. i. 47, and the scholiast derives it from *αἷμα*, blood; because those who pass through such a fence are made to bleed. This derivation, nugatory as it appears, is adopted by Hederic in his lexicon: whereas its origin is the Hebrew *אָמַץ*, *amez*, to strengthen, to secure, and thence applied to a hedge, which by surrounding defends a place. On the same principle *κῆπος*, a garden, the origin of which neither Hederic nor any of the ancient scholiasts, we believe, have attempted to unfold, is borrowed from *קָפַף*, *koph*, to surround: hence the term denoted a place furrounded or secured as a garden is. Lennep indeed derives it from *καπῶς*, *breath*, a word quite foreign to the purpose. The word *βουρεια*, which occurs in Theocritus Idyl. vii. 10, is thus explained by the scholiast; *πηγή ἐν Κῶ, ἀπὸ τοῦ βῶν μωρεῖαι, καὶ τοῦ βῶν ἢ ὅτι βοὸς ἴνι παρὰ πλοῦσις*, i. e. a fountain in Cos, from the particle *βου* (large), and *βῶν*, to flow, or because it resembles the nostrils of an ox; whereas *βουρεια* is evidently the Hebrew *בַּאֵר*, *baar*, or *בֹּר*, *bur*, a fountain. The Greek scholia, annexed to every author, abound with such puerilities as the above; nor is the "Etymologicum Magnum" to be excepted, though the Greek lexicographers have fought for no better or more rational guides in their enquiries after the origin of the words which they explain.

Hemsteruse, Valckenaer, Ruhnken, Villoison, Lennep, Scheid, are indeed justly celebrated among modern critics for their researches into the origin and meaning of the Greek tongue. Their theories contain many valuable observations on the analogy by which that language grew from comparatively few radicals to its present complicated form; but their system of etymologies appear to us, for the most part, fanciful and erroneous; because in no instance, or at least in very few instances, have they sought the Greek terms in the languages of the East, whence assuredly they had been derived. Hemsteruse derives *θεός*, *Dens*, from the verb *θεω*, to run, to dispose; while its real origin, in our opinion, is the Hebrew and Arabic *נָאָה*, *nae*, pronounced in the latter language *dhao*, to shine. The Chaldeans represented the Supreme Good under the figure of light; and to this representation the sacred writer seems to allude, when he says that God is light. The same writer deduces *στρῶμα*, *strong*, from *βῆβυς*; while its source is *אָבִיר*, *abur*, to be strong. From the same origin he supposes *πῆν* or *πεῖ*, *before*, to have flowed, though it seems to point to the Hebrew *פְּרָע*, *phra*, which in Arabic means the head or root of a family, and hence it came to signify origin or priority in the form of *πεῖ*: hence *prior* or *prius* in Latin.

Scheid derives *τετρας*, an omen, from *τερον*, *tero*, to wear, because omens, says he, obterant, quasi, sine stupore percillant, enecent que mortales. But the word is the Hebrew *טֵר*, *teer*, a bird, divination, which was taken from birds. The same writer will have *τῆδε*, or *τῆδω*, *to eat*, to have come from *τῆα*, or *τῆα*, to stretch, though far more naturally it points to the Persian *دند*, *dend*, *dens*, a tooth; and hence *τῆδω* primarily meant, to cut with the teeth. The Hebrew *זָרַח*, *zer*, to shine, to scorch, gave birth to *ξηρός*, aridus; but Villoison foolishly derives it from *ξίω*, *radere*. The same critic as wisely traces *ξίλον* to the same root, because, says he, lignum sit ad radendum aptum. But its origin is evidently *גֵּרְעָה*, a grove, hence *αξύλοσ*, wood, and by dropping the first vowel *ξύλοσ*, and by transposition *αλόσοσ*, *nemus*.

nemus. *Οπταί, affo*, ab, *οπτος*, affus, says Scheid, quod ab *οπτα*, quod idem atque *οκω*, et *ακω*, *pungo pungendo figo*. But the parent word is *ἵψα*, to roast; and *οπταί*, to fry, *ἄπτα*, to kindle, *ἴψα*, to boil, are, with all their compounds, but the common offspring of this term. We shall only add one instance more from the Etymologicum of Lennep. *Ορχομαι* falto ab *ορα*. Dicitur videtur a motu in altum. Compendium quoque est cum *ερχομαι* (venire.) Ab *ορα* factum ex *ορεω*, hinc *ορεγω*, cum contentione moveo, pec. in altum: unde facillima via ad *ορχω*; *ορχω*, *ορχεω*. Rectissime igitur Etymol. c. 634, 52, *παρά το ορεγειν, και εκτενειν τας χειρας—και ορχησθης Αρης, ο ενκινητος κατά πολεμοις*. Unum tamen addidisse liceat, secundum analogiæ leges, ab *ορχος*; (derivata voce verbi *ορχω*) pp. repetendum fuisse *ορχεω*, cujus Media forma est *ορχομαι*.

This paragraph is a fair specimen of the manner in which these etymologists have, by certain analogies, founded on their own fancies rather than on the real structure of the Greek tongue, yoked together under one common root words the most foreign to each other.

The verb *ορχω* did not come from *ορα*, or *ορεω*, but from *ארכ*, *areg*, to desire, or to stretch to an object, when desired. From the same origin are derived *ορχηνημι*, *ορχηθω*, *ορχηθω*, *ορχητω*, *ορχησμαι*, *ορχησμαι*, *ορχω*, and *αρχω*, all of which are but different modifications of the same primitive words by different people who used the same tongue. On the other hand, *ερχομαι*, to come or go, originated in *ארח*, *arukh*, or *ארח*, *arek*, to travail, prolong, extend. On the other hand *ορχος*, which means a row of plants, or the order in which any thing is done, is from the Hebrew *ארכ*, *arek*, to arrange or place in order. From *ορχος*, arrangement, measure, rhythm, came the verb *ορχεω*, or *ορχομαι*, to move to the sounds of music in a dance or to battle. The movements in a dance and in war appear to have been regulated by the same measures; and hence dancers and warriors had the same names applied to them. *Mars* being called *ορχησθης*, as the author of the Etymologicum writes, *ως προς πολεμοις ενυητος*. Hence, too, a leader, i. e. one who put the men in order of battle, was called *ορχημος*; and, moreover, *περλι*, which denoted a species of dance, came in Latin to signify prælium. Such learning, acuteness, and diligence as were possessed by Hemsteruse, and the celebrated men above-mentioned of his school, however perverse, could not altogether have been misapplied. Their labours, therefore, must present some instances of just etymology, but their system, upon the whole, appears to us both fanciful and erroneous, and calculated more to perplex their readers than to furnish them with solid information.

Etymology, as it may serve to ascertain the primary sense of a word, to unfold a general principle in the formation of language, to exemplify the manner in which philosophical notions, political occurrences, and religious institutions influence the mind and give birth to new modes of speech, is a subject of rational and useful enquiry. In this enlightened view it blends itself with the history of philosophy, of politics, and of religion, with the structure of the human frame, and even with the theory of the human mind. Connected with any or with all of these purposes, none but the uninformed will neglect or decry this branch of philology as vain and useless; and without such connection none but pedants will pursue or extol it as worthy of attention. As the Greek originated in the Asiatic languages, a knowledge of these languages to a certain extent is absolutely necessary, to form a rational and competent etymologist in the dialects of Greece: and many passages must exist in the Greek writers, especially the more ancient poets, which can be understood only by light reflected from the East. It will not be foreign to our purpose to illustrate this position by

a few examples. The first we select occurs in Homer's Iliad, ii. 815:—

Εἰ δὲ τις προπαροῖδε πόλει: αἰτήια κολώνη
 Ἐν πιδίῃ ἀπανηυῖ, περιόρομος ἔθα και εἶδα,
 Τοῦ ποῖ ἀνδρῶν Βατιῖα κληθσκούση,
 Ἀθανάτοῖ δὲ τὶ στήμα πολυσακχέθροῖ Μυρῖνης.

Of this passage the following is a literal version: *There exists apart in the plain, in the front of the city, (namely Τροί) a lofty mount, accessible by a circular ascent. This men call ΒΑΤΙΕΙΑ; but the Immortals the tomb of far-bounding Myrmine.*

The language of the Trojans, though a dialect of the Greek, was, we may well suppose, from their situation, mixed by an influx of Asiatic terms. Of this class is *Βατιῖα*, which in Hebrew is *בֵּית*, *beit*, and means an *abode*. In Isaiah, xiv. 18, and Job, iii. 15, it signifies the last home of man. The term here occurs in the Syriac form *בֵּיתֵי*, *battea*, and has the sense which it bears in the Jewish scriptures. Hence we discover the meaning of the passage, which has escaped the knowledge of the critics, ancient and modern. *Βατιῖα* means the same thing with *στήμα*, and the clause, *πολυσακχέθροῖ Μυρῖνης*, is to be connected with the former as well as with the latter; and the import of the phrase is, *Men call it (Βατιῖα) the grave, and the Immortals the tomb, of Myrmines*. By *men* Homer meant the vulgar people of Troy; by the *Immortals* he intended the polished Greeks. Here we see the partiality or rather the pride of the poet respecting his language and countrymen. The phrase is purely oriental. The elegant Shاعرit is styled *Daeb Nagoree*, writings of the Immortals. Conformably to the same lofty figure, Homer calls Greek, from its superior polish, *the language of the immortal gods*, while he characterizes the dialect of Troy, from its barbarity and rudeness, *the language of men*.

The explanation which the critics have given of *Βατιῖα* is various, each rendering it more uncertain and improbable. Hesychius explains it to be *πόλις Τροίικη*. Others derive the term from *βαῖω*, or *βανω*, to go; and others again from *βατος*, *bramble*, because, as Heyne says, *collis fentibus obductus esse potuit*. As the commentators did not know the origin or meaning of the word, it is not to be expected that they should understand the singular phraseology grounded upon the use of it. Eustathius's account of it is, *το μὲν ἕως κρείττον των ονοματων θεοῖ: δὶδασιν ἢ ποιηται; the poet ascribes the best name to the gods*. The scholiast says, *τοῖ μὲν προγενεστοτερον ονομα εἰς θεοῖ: αναφερει ὁ ποιητης, το δε μετα: εἰς ἑσεν εἰς ἀνθρωπους; the poet refers the more ancient name to the gods; the more recent name to men; which cannot be true: for Βατιῖα is at least equally ancient with στήμα*. Clarke comes nearer the truth, who supposes the language of the *Immortals* to mean the language of the learned; and this great critic would have seen that Homer intended to contrast not the language of the learned with the vulgar Greek, but the polished language of the Greeks with the barbarous dialect of the Trojans, if he had been aware that *βατιῖα*, in this dialect, meant a *tomb*, or the same thing with *στήμα*. We shall only observe that this word exists in Celtic, and bears the same signification—*bedd*, a *grave*.

The next passage in which the use of the Oriental tongues serves to illustrate obscurities in Greek authors, we shall select from the Agamemnon of Æschylus. On this paragraph much has been written, and written in vain by the critics. *Clytemnestra*, the lady Macbeth of ancient days, boasts in it of her fidelity, during the absence of her lord, and the joy with which she would receive him on his return.

Οὐδὲ οἶδα τρεῖς ἡ, αἰδὲ οὐ μὲν ἔστιν,
 Ἄλλου προς ἀνδρῶν μάλλον ἢ χαλκοῦ βατῖα.

GREEK LANGUAGE.

The lines are thus rendered in the elegant and poetical version of Mr. Potter:

—————Never knew I pleasure
In the blamed converse of another man,
More than the virgin metal in the mines
Knows an adulterate and debasing mixture.

On this passage the author has the following note: Pausanias says, "aliquid subest quod non intelligo." Mr. Heath disapproves the allusion, though he thinks it a proverbial expression, the grace of which is lost on our ignorance, and says, "quod nos non videmus alius olim forsitan videbit."—In the old Persian called the *Pehlevi*, the first principle of things was called 𐬨𐬀𐬎𐬎: and though supposed to be fire by the disciples of Zoroaster, the term is a modification of 𐬨𐬀, *ab*, water, which the Arabians maintained to be the original element. With the notion that water is the primary matter, the early Greek philosophers appear to have borrowed the term. Hence βεπτειν, *to plunge*, (which Lennep absurdly deduces from βασι): hence too βεβησις, *immersion*; and the phrase χαλκον βεβησεν is a metaphor for a *stab* or *swound*, it being produced by a weapon plunged into the body as into water. The sentiment which the words convey to the herald, whom Clytemnestra addressed, is to this effect, *I know no pleasure with any man, and feel no more the sting of calumny, than the point of steel*. But the language is studiously equivocal; and in this peculiarity consisted at once the skill and the obscurity of it. While the queen appeared to express the above meaning, she in reality expressed quite the reverse. I know no greater pleasure, though no report more disgraceful, than a steel plunged in him, (namely Agamemnon,) by another husband. This artful equivocation arises from the manner in which the clause αλλου προς αυτου is connected. If taken with τερπειν the lines convey the *first* sense; but with χαλκον βεβησεν, they convey the *last*.

For this interpretation we have the best authority, namely that of the *Chorus*, who were present: who, perceiving that the herald was misled by the artful ambiguity of the words, hints at their true signification as soon as the queen withdrew from the stage.

Αυτη μιν ετυνησ επει μακρονοει σοι
Τοροισιν ερμηνεισιν ευπειπως λογον.

Which may be thus rendered: *This woman hath told thee learning (thee who hast yet to learn) what she is, a tale which discerning interpreters perceive to be very becoming,—well to become her character and views.* Here τοροισιν ερμηνεισιν depend on ευπειπως; and the *Chorus* intimate, that her words, understood, as they seem to have been by the herald, were false and unbecoming, but strictly true and appropriate in the sense in which *they*, who knew the woman better, had reason to regard them. Taken in the first sense, the metaphor χαλκον βεβησεν is too violent for the simplicity of the sentiment; and the falsehood, moreover, is so glaring as to class the queen with the basest of deceivers, without a trait of that masculine intrepidity and elevated ardour with which she pressed to the object of her desire. In the latter it exactly suits the dark ambiguity of prophetic language: and the boldness of it is in unison with that vehemence and glow of pleasure, with which she anticipated the plunging of the weapon in the bosom of her husband. For these reasons the *Chorus* justly pronounce her language ευπειπως, as at once expressive of her true feelings, her artifice, and her intrepidity.

Lycophron, who flourished under Ptolemy Philadelphus, is known to have studiously affected the use of hard and ob-

scure terms, which, from their antiquity, must demand the attention of Asiatic scholars. In his *Cassandra*, the only remains of his voluminous productions, occur these lines:

Τραπηλις σ' σχιζει; και Φερεκλειου ποδες
Δισσας σιλαμβασι; κ' απε Γυβου πλακας
Εν υψισι προς κινουσα, καμπυλας σχασσας
Πλευης οδους; εκουσα; κλημμενυδου.

They contain a prophetic address to Paris, now commencing his expedition for the rape of Helen, and may thus be literally rendered:—*The ship and feet of Pherecleus will bear thee to the two ports and coasts of Gythium, having in these fixed to the rocks the crooked teeth of the pine, Helors (i.e. sustainers,) of the flood.* Pherecleus as an artist constructed the ship, and as a soothsayer, consulted the gods, and endeavoured to conciliate them to the projected expedition. As such, he was naturally led to give the vessel the name of τραπηλις, which with the Greek termination is the Chaldean and Phœnician term for the tutelary gods, 𐤏𐤍𐤕𐤍, *torpim*, or *trapim*. The scholiast says, it is the name of a *foreign ship*; and in this he is followed by Hesychius. It was certainly usual to carve the images of the gods on the ship, which they were supposed to protect; and to them the sailors fled in seasons of danger. (See Hor. i. 14.) The figures, which at this day are often framed in the forepart of the ship, are but the remains of the same custom. The practice, no doubt, originated with the Phœnicians: and it was natural for them to call their ship by the name of those gods which were supposed to preserve them. The rudders, the oars, the sails, by which the vessel was moved, are here affectedly called the *feet* of Pherecleus, he being the author of them. Of the derivation of the term the scholiast and Hesychius appear equally ignorant, and the whole of this passage is a striking instance how incompetent the ancient commentators were to explain in many places the terms of the Greek tongue.

The ancients had statues of their gods erected before their doors, and in the entrance of their harbours. These received the salutations of strangers and passengers. Lucretius mentions this custom in his first book. Hence the doors and ports received the name of σιλαμβασι, as being places where the gods were *saluted*, from the Arabic 𐤏𐤍𐤕𐤍, *salaam*, salutation. The account which the scholiast gives of this term is ridiculous: σιλαμβασι δε σι βουσι λεγομεναι, ποσα το ν σιλα βανου. The explanation of Hesychius is more rational, though not the true one; σιλαμβη η σπηλις το σιλας εανου. This is a fair specimen of the manner in which the Greek words, derived from the East, are explained in the old glossaries. But farther, πλακας, *coasts*, is the Hebrew 𐤏𐤍𐤕𐤍, *flag*, or *plag*, (the vowels being arbitrary, and not existing but as included in the consonants of the original,) and signifies to divide, and thence as a noun any thing divided, such as portions of the land and sea. From the same original is derived πελαγος, as serving to divide the earth into distinct territories: hence too, the Latin *plaga*, a clime or region. Finally, the unusual term κινουσα originated in the Persian *kinuar*, an extremity or limit which, as the limits of a river came hence to signify its *banks*; as the limits of the sea its *shores*, or the *rocks* lining them. The limits of a door are its *posts*; and hence the Celtic word *lynnor*, the door posts; and probably from the same source, on account of their remoteness, has been derived the appellation assigned to the Canary Islands.

The attempts of Paris, under the auspices of Pherecleus, to appease or conciliate the gods, are alluded to by Horace, lib. i. 15. who appears to have had the passage of Lycophron in his view. Pherecleus, the first adviser, perhaps,

GREEK LANGUAGE.

of the expedition, is represented by Homer as properly punished; for he received an ignominious death from the hand of Merion. The poet adds, *Il. v. 65.* $\epsilon\pi\iota\ \sigma\omega\tau\iota\ \beta\iota\alpha\upsilon\ \epsilon\kappa\beta\sigma\ \delta\alpha\tau\alpha\ \nu\acute{\alpha}\rho$, since he did not at all know the decrees of the gods. To say that Pherecleus did not possess this knowledge, appears not only a profane, but an unnecessary saying: for who is the man that is acquainted with the divine decrees, while yet unfulfilled? But when it is considered that Pherecleus had *pretended* to be so knowing, and probably predicted ultimate success, while the event turned out very different from his predictions, there is much propriety and even point in the remark; since it holds forth the *diviner* as a *deceiver*, who by his impostures brought ruin upon himself and his country. From this we may conclude, that the beauties of Homer, who confines himself beyond any other poet to general nature, yet in many instances depend upon circumstances unknown to, or unobserved by modern readers.

The prevailing taste for oriental literature promises to contribute much to the improvement of philology. And when classic scholars shall engage with due attention in this pursuit, the more ancient Greek writings will share in the general benefit, by the light reflected upon them from the East. The derivation of the Greek from the oriental tongues, the frequent use of terms which Homer, Hesiod, Lycophron, and others have adopted in their primary significations, have occasioned difficulties which a critic, however able, but versed only in Greek and Roman authors, is hardly able to solve. These difficulties, instead of being explained, have been glossed over by the futile etymologies of the ancient scholiasts and lexicographers: and they can be properly felt and successfully removed only by those who have extended their study from the elegant language of the Greeks, to the no less polished languages of Persia, Arabia, and Judea. Of this position the examples above cited afford sufficient illustration: and they are, it is hoped, too curious, new, and solid, not to be undeserving of a place in a dictionary of science.

In the last place, the derivation of the Greek from the ancient languages of the East, will account for the origin of the much disputed *digamma*. In these tongues gutturals abounded, which, like other consonants, contained in themselves the vowel necessary to their pronunciation. But it is the tendency of every guttural, when become habitual, to soften down, in the rapidity of utterance, into a mere aspirate, till it at length vanishes. Thus *cornu* has degenerated into *horn*; $\chi\epsilon\upsilon\mu\omicron\varsigma$, into *humus*, earth, and into *homo*, a creature of earth, man. Thus also the Hebrew $\chi\lambda\iota$ ($\chi\lambda\iota$), which signifies *life, soul, self*, appeared in Greek in the form of $\chi\lambda\iota$, $\chi\lambda\iota$. Moreover $\kappa\beta\beta\epsilon\tau$, *kabed*, a liver, gave birth to $\kappa\beta\beta\epsilon\tau$. This word retains an unquestionable mark of its derivation, for it has the form $\kappa\beta\beta\epsilon\tau$, *kabed*, or, $\kappa\beta\beta\epsilon\tau$, *kabar*: and this variation has been transfused into the Greek $\kappa\beta\beta\epsilon\tau$ and $\kappa\beta\beta\epsilon\tau$. Hence we obtain the origin of the aspirate placed over a vowel. It was originally a guttural, which losing its power as a consonant left the included vowel behind, with an inverted comma above, to perpetuate that part of the letter which fell into disuse.

The guttural, when softened into an aspirate, is apt to be dilated into a long vowel. Hence the reason why η , in the ancient Greek, seems to have been accompanied by an aspirate, as in $\eta\tau\alpha\varsigma$. On the same principle that a guttural softens into an aspirate, the aspirate often melts into a gentle breathing, or becomes in pronunciation quite quiescent, as the Latin *honor* and *honestus* become in English *honour* and *honest*, the *h* being mute. On the same principle *toogh* became silent in our tongue, as in *taught*, *fought*. So in the Greek

$\kappa\beta\beta\epsilon\tau$, *kbaan*, a king, has degenerated into $\kappa\beta\beta\epsilon\tau$, which Homer pronounced $\kappa\beta\beta\epsilon\tau$. This leads us to remark, that the aspirate, instead of vanishing, was changed into a labial letter *w, v, b, f, or z*. Thus laugh, cough, which are still strong guttural sounds among our northern neighbours, are sounded *luff, coff*, among us. Thus also in Greek, what was at first written $\chi\epsilon\upsilon\mu\omicron\varsigma$, was pronounced $\kappa\beta\beta\epsilon\tau$; and the words $\beta\iota$, $\beta\iota$, $\beta\iota$, were sounded $\epsilon\omega\upsilon$, $\epsilon\omega\upsilon$, $\epsilon\omega\upsilon$, or *foi, foi, fe*.

But the digamma did not always originate in a guttural, but sometimes in consonants allied to our *w* or *y*. Thus from $\gamma\eta$, *yido*, is derived the Greek $\epsilon\iota\delta\omicron$, which in Homer is sounded *aido*, because the original is *yido*, hence the Latin *video*. So again from $\gamma\iota\upsilon$, *gin*, is taken $\epsilon\omega\upsilon$, *winos*, sounded *winos*: hence *vinum*, and *vine*.

We have already observed, that in Hebrew every consonant contained in itself the vowel necessary to its pronunciation. This vowel the Greeks detached and gave it a separate excellence, by subjoining it to the concomitant consonant. And as the Hebrews seem at first to have sounded every consonant, thus dividing each word into as many syllables as it had of consonants; and as they farther seem to have used vowel only in conjunction with consonants, and to have considered them as unfit to be employed alone and independent, so the Greeks, in imitation of them, used at first only short vowels: they next adopted the long or compound vowels η and ω ; but still avoided the diphthongs, and when any two vowels concurred, they converted the first of them into a labial consonant. Thus, $\lambda\alpha\mu\pi\epsilon\tau\omicron\omega\upsilon\tau\iota$, was sounded not *lampetoonti*, but *lampetowonti*, or *lampetovonti*; and $\mu\omicron\upsilon\sigma\sigma\alpha\upsilon\upsilon\upsilon$, pronounced *monfawon*, or *monfawon*; $\tau\epsilon\tau\alpha$, *teifo*.

This letter is called *digamma*, because it has the form of two *gammas*, one upon another like our capital *F*, and also called *Æolic*, as supposed to belong exclusively to the *Æolic* dialect. But this account of it proves, that it did not belong, as Dr. Bentley and others have supposed, to the *Æolic* dialect only, but to all the dialects of Greece, in their more ancient mode of pronunciation. It follows also that the universal opinion of the learned, who say that the *digamma* at first prevailed, and was afterwards succeeded by the *aspirate*, is the reverse of the truth. For the true state of the case is, that gutturals at first prevailed; these softened into mere aspirates; and these again were changed for a more easy and agreeable letter, which being simply a labial was diversified by different people into *y, w, v, z, b, or f*. But the digamma, it will be said, is to be found only in Homer, by far the most ancient writer of Greece, while the aspirate is in all the more recent authors. The answer is this: the use of the aspirate obtained in the written language, and was, therefore, less susceptible of corruption. On the other hand, that of the digamma prevailed in pronunciation, which was more liable to change, and to deviate from the original terms. Homer, we may naturally suppose, adopted the first in composing and reciting his poems, and the last in reciting them to the people. The written form, we may presume, was at first used but little, but prevailed by degrees; while the peculiarities of pronunciation in their turn began to decline. The language, as written by Homer, at length became fashionable in the conversation of polished people, and the aspirate, being thus triumphant in the daily converse of learned men, would of course, in their writings, triumph over oral and temporal corruptions.

The change of a guttural into an aspirate, or into a long vowel, or into a labial letter called the *digamma*, is not peculiar to any one language, but is founded on the structure of the organs of speech; and instances of it prevail in all languages, both ancient and modern.

The preservation of the aspirate in the written language of Homer,

GREEK LANGUAGE.

Homer, while the *digamma* was used in reciting them, is a proof (if a proof be wanting) that Homer did actually use a *written* language, and that his works were preserved by a written language: otherwise the aspirate would have been lost, and the *digamma* alone would have prevailed in all the Greek authors who succeeded that celebrated bard. If an editor of Homer in modern days would insert the *digamma*, he would corrupt the original orthography of Homer, and substitute in the room of the original characters the corruptions of pronunciation.

We shall now make some observations on the leading parts of speech, which may serve to unfold the peculiar nature and amazing extent of this language. As gender is the distinction of sex, there cannot in strictness be in any language more than *two* genders, masculine and feminine; nouns expressing inanimate objects, or things without life, being in a philosophical sense *neuter* or *neither* gender. But neuter nouns had by analogy assigned them the terminations of masculine and feminine nouns; and unfortunately for Greek, and the other European languages affected by it, the termination became soon regarded as an index of the gender, without any reference to the meaning. Thus nouns designating females ended in *α* or *η*; and for this reason the names of inanimate things, and also adjectives, having the same ending, are said to be *feminine*. For the same reason nouns in *ο* or *η*, though meaning things without life, are generally masculine, because these happened to be the predominant terminations of the names of males. There are, therefore, in this language two principles which regulate the gender of nouns, the signification and the termination: the former ascertaining the gender of living things, or things whose sex it is of importance to distinguish, the latter that of inanimate objects. There is, however, a third principle, on which is founded the distinction of gender, we mean the analogy which inanimate objects sometimes have to living creatures. There are some terminations common to males and females, and these afford such analogy an opportunity to operate. Thus *λογος*, reason, though expressive of what is neither male nor female, is made masculine, as signifying the commanding and the most excellent faculty of the human mind; whereas *ἔδος*, away, from its affinity to *γη*, the earth, or from the passive nature of its signification, a characteristic more of the female than of the male, is made feminine. That this analogy is not fanciful might be proved by many instances. In Aristophanes *βουτο*, is masculine; but Theocritus (Idyl. i. 132.) in representing it as producing *violet*, makes it feminine. This affinity to the female sex is the reason why *arbor*, with the specific names of trees in *us*, are always feminine, though the termination is decidedly masculine. In cases where the termination absolutely belongs to the names of males or females, this principle of *analogy* necessarily gives way to the termination. Thus, because *η* final is invariably appropriated to feminine nouns, *θαλασσα*, the sea, is feminine: on the other hand, *χρονος*, time, is masculine, from its termination as well as from analogy.

Nouns and verbs in Greek have a *dual number* to express two things, or such things as are in pairs, as hands, eyes, feet. The use of the dual occurs frequently in the poets, though not peculiar to them, nor always observed by them, when speaking of two objects. The dual number is by no means necessary in language, though it may enable the Greek to express the number two or pairs with more emphasis and precision. It was, therefore, rejected by the Æolians and by the Latins, who derived their tongue from the Æolic dialect. The seventy translators, moreover, have rejected the use of the dual number, and in this they

have been followed by the writers of the New Testament and the Greek fathers.

Cases have been defined by all modern grammarians to be *changes* in the termination of nouns; but the name *πτωσις*, in Greek expressive of cases, clearly shews that this is not the primary meaning of a case. For *πτωσις* means a *fall*, and, from signifying a *fall*, it came to signify the place in which a noun falls in a sentence. The idea, then, which a case at first expressed is the *position* of a noun in a sentence, and by that position expressing the relation of one word to another. Thus, if a noun denoted the *direct* subject of a proposition or discourse, it is said to be in the *right case*, *πτωσις ορθη*, i. e. the direct or straight position; but if a noun expresses an object or quality *indirectly*, it is said to be in an *oblique position*, *πτωσις πλαγια*, and this deviation from a direct to an indirect position, as the subject of discourse, is in the language of grammarians farther called *κλισις*, declension. Farther, cases express the relation of things in motion or action, and the relations necessary for the purposes of language are chiefly the following: the relation of *cause*, the relation of *effect*, the relation of *beginning*, the relation of *medium* or *instrument*, and the relation of *end*. A noun denoting the relation of cause, i. e. denoting the agent of an active or the subject of a neuter or connecting verb, is in the *nominative*; that of effect in the *accusative*; that of beginning in the *genitive*; that of medium or instrument in the *ablative*; and that of end in the *dative*. The nominative alone is called the *right* or *direct* case, the rest are all deemed *oblique* cases; though the accusative, as expressing a direct part of a proposition, might more properly be called a *right*, than an oblique case.

Moreover, the relations of bodies in motion or action were at first expressed by *prepositions*: and as our ideas of relation arise from the things related, and which succeeded them in their formation, prepositions should, and probably did, in the early use of language come after, instead of going before the nouns which they governed. In consequence of this arrangement, they combined into one word with the final syllables of the connected noun, and thus served to give it a diversity of terminations. Hence the origin of cases in the sense in which cases have hitherto been understood by modern grammarians. It is worthy of remark, before we quit this subject, that the nominative, as expressing *cause*, has a close affinity to the genitive, which means beginning. But the former fixes the attention on the noun, as an *agent* or a *cause* in action: while the latter holds forth its noun as the *source* or *beginning* of motion. The beginning of a thing is often the author and owner of that thing: hence the genitive has the secondary sense of *possession*. On the other hand, the accusative is nearly allied in sense to the dative; but the former is not used in its strict and original signification, unless it denotes an *effect*, or the thing in which *action* terminates; while the latter, in strict propriety, marks the end to which *motion* points, and in which it terminates. The genitive stands opposed to the dative, as beginning to the end, like the opposite points of a right line; while the ablative expresses the medium or instrumentality of the motion by which that line is generated. The ablative case therefore denotes one of the most important and distinct relations in language, and yet the Greek, with all its boasted copiousness and precision, has not a distinct termination to express this case, but denotes it sometimes by the genitive, and at others by the dative, with or without a preposition. Finally inanimate things only move after they are put in motion, or act as they are acted upon. This is probably the reason why neuter nouns in Greek have no termination to express cause, distinct from

that which marks effect, that is, why the nominative and the accusative of Greek neuter nouns are always the same.

A multitude of nouns in all languages express the abstract ideas of action, and consequently are derived from verbs, as subsequent to verbs in their formation. Our ideas moreover of the persons, the characters, the offices of men, are derived from the same sources; and from verbs are derived the nouns which express those persons, characters, and offices.

The name of the *actor* is derived from the corresponding verb by adding τος, ρος, υος, εις; as μαθεω, to learn, μαθητης, the person that learns, a learner; ιχθυω, to seek, ιχθυητης; μαρτυρω, to enquire, μαρτυρος, the person who enquires; σπαιρω, to sow; σπαιρων, a sower.

Nouns expressing the action of the verb abstractedly considered, or the effect of that action, are derived from the corresponding verbs by adding σι; in the room of the final ω; as τερπειω, to delight, τερπεισι; τερπεις, delight, the act of delighting; τευω, to produce; τευσι, τευς, the act of producing, production; κρινω, to judge, κρισι, κρισις, judgment. Hence it is evident that verbs in πω or πτω, βω, φω, must have their corresponding nouns in Δις: those in κω, γω, χω, and those in σω (for γω) in Ξις; and those in ζω and σσω (for ζω) in Σις. The penultimate vowels α and ι are changed into η, and ο into ω; as μαθεω, to learn; μαθησις, instruction; ορθωω, to rectify; ορθωσις, rectitude.

Other verbs are changed into abstract nouns by changing the last syllable into μω or μος, or simply into ρ, the penultimate ε being changed into ο after the analogy of the perfect middle; as βλεπω, to see; βλεπωμα, βλεμμα, a sight; κρινω, κριμα, κριμα, judgment; τραχω for τρανω, to pierce; τρανωμα, a wound; αγραπτεω, to plunder; αγραπτεωμα, plunder; ιδριω, to define; ιδριωμα, definition; φθειρω, to corrupt; φθειρωμα, corruption; σπειρω, to sow; σπειρωμα, seed.

Adjectives are converted into abstract nouns by changing the last syllable into τη, or into νη, or into α, or into ια; ποιω, qualis, such; ποιωτη, quality; κειρω, base; κειρωτη, baseness; μονω, alone, or one; μονωτη, the number one, monad; δυω, two; δυωτη, the number two; αληθεω, true; αληθεωτη, truth; δοκιμω, approved; δοκιμωτη, approbation.

Adjectives, being the names of qualities, are taken from the names of the objects to which those qualities in a prominent manner belong; as ανοι, an ass; ανοστοι, contemptible; ανεμος, wind; ανεμοιοι, windy; ανωμωλοιοι, empty, like the wind. But adjectives are derived from nouns by annexing to them the verbs expressive of similitude, ιμοι, like; υμοι, resemblance; ιμοι, such, like; as ανδρωποιοι, a man; ανδρωποιοι, man-like, manly; ανθρωποιοι, for ανθρωποιοι, man-like; also ανθρωποιοι, for ανθρωποιοι, having the form of a man, manly. This composition is the origin of that class of nouns called *patronymics*. Πελευιοι, Πελευιοι, one having the form of Peleus, i. e. the son of Peleus.

There are in Greek but two personal pronouns, that is, substitutes for nouns, or, as we have explained them in the article GRAMMAR, numeral adjectives, assuming the character of nouns by association with the verb. These are εγω, I; συ or τυ, thou; and they are evidently derived from the Hebrew יָנֹכֶךְ, *ankee*, I, which in Greek is written in the various forms of εγω, εγω, εγω, εγω, εγω; ατα, and by dropping κ, η, ται, or the Æolic τυ: ου always expresses the subject or agent in one of the oblique cases, and therefore, as not wanting, has not a nominative case. Its origin is the Hebrew יָנֹכֶךְ, *kbi*, life, soul, self, which latter is the sense of ου. Pronouns of the third person are only definitives or restrictive adjectives agreeing with the noun defined, expressed, or implied. The chief of these is ι, *the, he*, which very improperly

has been called an *article*; whereas it is a *definitive* derived from the Hebrew יָנֹכֶךְ, *ba*, which, as an abbreviation of יָנֹכֶךְ, *en*, serves to direct the attention to an object, and thus to distinguish that object from all other things. Ο, *who, αυτοι*, *the same, αυτοι*, *this*, are but different modifications of ι. In speaking briefly of the verb, we shall do little more than copy Mr. Jones's system, as explained in that part of his Greek grammar where he treats of the origin of verbs. This system is founded on the Hebrew tongue, in which all the varieties of mood, tense, number, and person arise from the combination of the personal pronouns with a radical noun or verb. Though a multitude of abstract nouns are borrowed from verbs, yet all or most of the Greek verbs are nouns converted into verbs, by annexing to them the personal pronouns. His own words are: We acquire the ideas of action by reflecting on ourselves, or observing others in certain circumstances; and the most simple way which nature could at first suggest of expressing these ideas was to combine the name of the person or thing which acts with the person or thing acted upon. Thus εγω; and εγω joined, and abbreviated, is εγω; and this term would be sufficient to express *I drink wine*, though it originally meant only *wine I*: association supplying to the speaker, and to the person addressed, the intermediate notion of *drinking*. From tl's account of the origin of verbs, he deduces three conclusions of importance to be observed. *First*, verbs were originally the names of things; and thus received their characters as verbs from association. *Secondly*, that every verb consists of a pronoun expressing an agent, and of a noun or the substitute of a noun expressing an object. *Thirdly*, that the terminations, α, ει, η, ετοι, ομοι, εις, ουσι, were originally the personal pronouns, and from these, with the changes which they underwent, have proceeded all the variations of mood, tense, number, person and voice.

The first person, ε, is a fragment of εγω; and by the same analogy that εγω becomes εμε, verbs in ω are changed into verbs in εμι; as ισταω, ισταμι, to place, στα, or τιστω, τιστεμι, to fix; δαω, or διδωω, διδωμι, to give; αλωω, or αλωω, αλωμι, or κλυωω, κλυωμι, to bear. The personal terminations of verbs in εμι are therefore but a modification of those in ε, and consequently a modification of the personal pronouns εμι, ετι, ετοι, ετον, εμιν, ετι, ετοι. On this principle the verbs in μι, which grammarians have hitherto divided into four distinct classes, are, according to Mr. Jones's theory, but one class, having each the same personal termination, and differing only by different modes of contraction; as ισταμι, ιστημι; τιστεμι, τιστεμι; διδωμι, διδωμι; κλυωμι, κλυωμι. This complex species of verbs is hence reduced into great simplicity, and the acquisition of them rendered very easy. The first person optative, even of verbs in α, conforms to the analogy of verbs in μι, τυπτοιμι, which originated in τυπτεμι, though obsolete. From this source the Latins have derived the final *m*, amabam.

The second person in Hebrew is תָּ, *tha*, or *ta*, a fragment of אָתָּה, *ata*. Hence the Ionians formed this person in θα—γνωσθα, *thou knowest*; σθηθα, *thou wast*. The above fragment, consisting of *th* or *t* only, has been corrupted into *s*. Hence the second person in every tense of the active voice terminates in *s*, with ε or α short preceding. The subjunctives ι, ε, form no part of the original pronouns, but were inserted, as is often the case, to lengthen the preceding vowel. The third pronoun in Hebrew is הוּא, *hoc*, which is the parent of *he* in English, and in Greek of ι. This, with the subjunctive ι, forms the third person, τυπτοι. To the original ι the Ionians added σι. Thus in verbs in μι, τιστεσι,

ἐπι, for τῆ, and in the subjunctive of verbs in α, we meet with ἐλθῆσι for ελθῆ. In Sanskrit, a language which has a great similitude to the Greek, *su* or *sub* means *be*.

In Arabic the ordinal of *two* is *tan*. Hence the Greek dual τῶ or τῷ, τῆς τῆσσι, or τῶν τῶνσσι, they *two* beat. The personal termination in the plural are all formed from the singular. Thus εἶμι, by the analogy of the third declension, is ἐμεῖ, and in this form it was used by the Doric, the most ancient dialect of Greece, τυπτομεῖ, εὐφραμεῖ. In the common tongue the final ι became corrupted into υ. The second plural is the same in its origin with that of the singular *ta* or *tu*, τυπτεῖ, and the third plural is the same with the third singular differently contracted, τίθεισι τίθησι, *he* places, τίθησι, *they* place. The third of verbs in α is formed from the third of those in μι, with the subjunctive υ annexed, τυπτεῖσι, τυπτοῦσι, which is the Æolic form, and hence in the common tongue, τυπτοῦσι. The vowel ε, not only in single instances, but in whole classes of words, is changed into ο. Thus in the formation of nouns from verbs τρυφή, *to eat*, τροφή, *a feeding*; in forming the perfect middle, πείθε, *to persuade*, πειθοῖς, and sometimes the perfect active βρέχει, *to rain*, βεβροχη; in forming circumflex from other verbs, ἔριμος, *to tremble*, τριμέν; by corruption in single words ὀδοῦτες, ἔδοῦτες, *teeth*, γονῆ, *genu*. On the same principle the Æolic εἶσι became οῦσι.

The personal terminations of the imperfect or past tense in μι, are ἐ, εἶ, εῖ, εῖ, εῖον, εῖον, ἐμεῖ, εἶε, εῖον; as τρέψομαι ἐπιῖ-εν, διδόνομαι ἐδίδο-εν, ἰσχυρομαι ἰσχυ-εν, κλυθῆναι ἐκλυθ-εν. These are also formed, according to Mr. Jones's theory, without the reduplication, ἔεμε ἐπι-εν, ῥο-εμε ἐδο-εν, φα-εμι ἰσχυ-εν, κλυ-εμι ἐκλυ-εν. These are hence contracted either with or without the reduplication; ἐπιθεῖν ἐπιθῆναι, εἶεν εἶην, ἐδόον ἐδίδον, ἐδοῦν ἐδῶν, ἐκκλυθῆναι ἐκκλυθῆναι, ἐκλυθῆναι ἐκλυθῆναι. By the conversion of ε into ο, on the principle above illustrated, the personal terminations of the verbs in μι, it was that ἐ, εἶ, &c. became οἶ, εἶ, εῖ, εῖον, εἶον, οἶμεν, εἶε, οἶον. The first person singular in Hebrew is עָנִי, *eni*, *I*. Hence the personal termination υ or ον. The third plural εἶμι or εῖον, is the Persian عَسَان, *esfan*. Hence we read ἐλθῶσιν in verbs in α, and τίθησιν in verbs in μι; but εῖον is contracted in the common tongue into οἶ; as εὐπτοῦσιν, εὐπτοῖν.

The second aorist is the same tense with the imperfect, and verbs of the imperfect differ from verbs of the second aorist, not because they express different modifications of past time, but because they came from different roots. Thus, from τυπτεῖ and σπυρεῖ are derived the imperfect εὐπτεον and σπυρεον; while εὐπτεον and σπυρεῖ, in the second aorist, have been deduced from the obsolete τυπτε and σπυρεω; as is the signification, so are the terminations the same in both. The pluperfect has its personal terminations from the imperfect, by annexing the subjunctive ι in each person—εἶ, εἶ, εἶ, &c. εἶμι, εἶ, εἶ, &c. The characteristic of the first future is σ inserted before the final ω of the present—τυπτεω or τυπτε, τυπσω τυπῶ, λέγω, λέγσω, λέξω. And what grammarians call the second future, is no other than the first future, where, after a very general analogy, σ is dropped. Thus, βεβήξα, 1 fut. βεβήσα, βεβήω; ἐχχῶ, 1 fut. ἐχχῶσα, ἐχχῶ, *I will pour*; ἐξέλαω, *to exhort*, ἐξέλασα, contracted ἐξέλα. So τυπῆ, said to be the second future, is a contraction of τυπτεσα, from the root τυπτεῖν. And this observation holds in regard to all other verbs supposed to be the second future, while, in fact, no such tense exists.

The subjunctive mood is derived from the indicative, by changing ε into τ, ο and εἰ into υ, and subscribing ι where it occurs. It is thus formed, in every tense, through the active, the passive, and the middle voice. Thus, τυπτεῖ, τυπτεῖσσι, &c. have given birth to τυπτεῖαι, τυπτεῖσσι, &c.: so, in the first future, τυφῶ, τυφῆσσι, τυφῆσσι, originated τυφῶ, τυφῆσσι, τυφῆσσι,

which is not the first aorist, as is supposed by grammarians, but the first future, which is, indeed, proved by its signification, as well as by analogy: for, in all instances this tense expresses a future time, not absolutely so, but time future in regard to another verb connected with it in the sentence. The optative has its tenses, in general, derived from the corresponding tenses in the indicative, by changing ε into ο: but the first person, as has been observed, is derived from verbs in μι; as, if τυπτεῖμι, τυπτεῖσσι, τυπτοῖμαι, τυπτοῖσσι. The third plural, like the third singular, follows the analogy of verbs in μι—τυπτοῖσσι, contracted τυπτοῖσσι; in the same manner as δοῖσσι becomes δοῖσσι.

The imperative mood, originally in the first person, retained ε of the imperfect tense; as λαβε, *let me receive*. Thence, dropping the final ι, it has, in the common tongue, the first person in ι—λαβε. The pronoun τυ, which, in Persian, is *to* added in the form of τα, conlittutes the second or third person—τυπτε. And εσα, contracted into σαν, forms the third plural—τυπτεσαν, which, by dropping σα, is again abridged into τυπτεσαν, erroneously supposed to be the dual number. When a command is given, it is necessarily given in the present time, and it can be executed, not in the past, but in the future. It is impossible, therefore, in reason, that the imperative mood can have a past tense. Thus, τυπτε is the present imperative, or that of the second future; and τυφῶ the first future, not the first aorist. In some of the dialects υ is substituted for the subjunctive vowel. On the other hand, the Ionians change υ, with or without its concomitant vowel, into α. Thus, in the imperfect, for κ, or εἶν, they used εἶα, *I was*: for the pluperfect εἶετοφῆναι or εἶετοφῆναι, εἶετοφῆσσι, which the Attics contracted into εἶετοφῆναι; and in the third person plural, of the passive form, for τυπτοῖσσι, they write τυπτοῖσσι, and for κενταῖ, κενταῖ. In the same manner τυφῶ, which is said to be the first aorist, but which, in reality, is the first future, becomes, when τω is added, not τυφῶντα, but τυφῶτα. From the imperative thus principally ending in ον, we obtain the attic third person plural in ονται—τυπτοῖσσι, ποιουῖσσι, which are contractions of ποιουῖσσι, τυπτοῖσσι, the first being ποιῶν or ποιῶναι, and τῶντων for τυπτεῖν. By the above Ionic analogy, we also obtain what is called the Æolic first aorist, τυφῆα, which has the personal terminations of the first aorist indicative. It is thus changed from τυφῆων or τυφῶναι, used for τυφῶμαι, in the same manner as φῶσιν is for φῶμαι.

The infinitive is formed by adopting ε, or, as it is in Hebrew, εἰ—τυπτεῖν, and by adjoining ι, τυπτεῖν. In the perfect it has ἐναι, τετυφῆναι; but in the first aorist υ is dropped—τυφῆαι, probably for τυφῆσαι, which, after the analogy of the perfect, would be τυφῆσαι. In the Ionic and Attic dialects, the infinitive, however, is formed from verbs in μι, though obsolete, τυπτεῖμι, τυπτεῖσσι; δεῖμι, or δεῖμι, δεῖσσι; δεῖμι, δεῖσσι, δεῖσσι, δεῖσσι, δεῖσσι, δεῖσσι. To these, after the analogy of the perfect, is added αι—τυπτεμεναι, δεῖμεναι, δεῖμεναι, εἰμεναι.

The passive voice is formed by combining the subject of discourse with the personal pronoun in the dative case—μοι, σοι, τῷ. Thus οἰκοῖμοι, *house for me*; οἰκοῖσοι, *house for thee*; οἰκοῖται, *house for him*. These combinations, which by a slight change become οἰκοῖσοι, οἰκοῖσοι, οἰκοῖσοι, came to convey the idea, *I have a house, thou hast a house, or I am housed, thou art housed*. And this is the reason why the passive form in all authors have either an active or a passive signification, the context alone serving to ascertain the sense of the verb. The dual τῶν is made passive by changing τ into σθ—τυπτεσθαι, τυπτεσθῶν and not τυπτεσθῶν; and it is worthy of remark, that in the first person plural θ takes σ before it very frequently, as τυπομεσθα for τυπτομεσθα, and in the imperative εἶσθι for εἶθι.

As the personal pronoun, combined with the radical word

word to form the passive voice, was *μοι*, the primary form of the verb must have been *τυπτομαι*, and not *τυπτομαι*; and in the imperfect *ετυπτομαι*, and not *ετυπτομαι*: but afterwards *ε* was changed into *ο*, as in other numerous instances. Hence the passive form of verbs in *α* was originally the same with that of verbs in *μ*: and this form had only two senses, *μ* for the present, and *μην* for the past. The second person singular is formed in the common tongue by dropping *σ*, and contracting the two succeeding vowels in every mood and tense. Thus *τυπτισαι*, *τυπτισαι*, *τυπτη*; imperfect *ετυπτισο*, *ετυπτισο*, *ετυπτισο*; first aorist middle *ετυπασο*, *ετυπασο*, *ετυπασο*; optative *ετυπτοιτο*, *ετυπτοιτο*; *θυσω*, *θυσω*. The first future middle is derived from the first future active, by changing *ο* into *ομαι*, *ετιθυσαι*. The second future middle is derived from *ετυπτισο*, (which is from the obsolete *τυπτισαι*), *ετυπτισομαι*. This drops *σ*, and is contracted—*ετυπτισομαι*, *ετυπτισομαι*. Hence what is called the second future is no other than the first future. The same obsolete radical has given rise to the second future passive, which is no other than the first future—*ετυπτισομαι*, *ετυπτισομαι*, *ετυπτισομαι*; while the first future is from the obsolete in *θω* *ετυπτισομαι*, *ετιθυσαι*, *ετιθυσαι*, *ετιθυσαι*; *λεγειν*, *λεξειν*, *λεξειν*, *λεξειν*.

The termination *ων* of the two aorists passive is borrowed from verbs in *μ*; and from this form, though obsolete, verbs in these tenses are in reality derived. Thus *ετυπτην*, which is erroneously supposed the second aorist passive, is only the part of verbs in *μ*; as *επαγγαμει*, (the obsolete of *επαγγαμω*) is *επαγγαμω*; *ετυπτην*. What grammarians call the first aorist passive is from verbs in *θω*; as *ετιθυσαι*, *ετιθυσαι*, *ετιθυσαι*; *λεξειν*, *λεξειν*, *λεξειν*. In the third plural *σ* is dropped—*ετιθυσαν*, *ετιθυσαν*, *ετιθυσαν*. So in the active voice, *ετυπτισομαι* for *ετυπτισομαι*; *ετιθυσαι* for *ετιθυσαι*; *ετυπασαι* for *ετυπασαι*; and *ετυπτισομαι* for *ετυπτισομαι*. In the infancy of language, while words were yet scanty, the most natural way whereby a writer or speaker might give an additional weight to his meaning, was to repeat such terms as he wished to render *emphatic*. The more ancient any language is, the more numerous appear the traces of such repetition; and, next to the Hebrew, they form a remarkable feature in the Greek tongue. Thus, *μωω*, *μωω*, *I desire, desire*, blended into one word, become *μωωωω*, and means *I greatly desire*; *βωω*, *βωω*, *I walk, walk*; *βωωωω*, *I stride*: and such words are numerous in this tongue; from which we may draw the following inferences.

First, that the augment is only the remains of a verb doubled, in order to augment the sense. Secondly, this augment takes place in the present tense as well as in the imperfect; as *παινω*, *παινω*: *παινω*, *παινω*: *παινω*, *παινω*. Thirdly, that the augment of the imperfect, and of the aorists, is but a corruption, still more remote of the reduplication; and that the dialect, which prefixes a consonant to the vowel like the perfect, such as *παινωωω*, for *παινωωω* is the most ancient usage, and comes nearest to the primitive simplicity of the language. Fourthly, the augment is applied to the first and second futures; and the effect of it is to increase the signification of the verb; *ετυπασαι*, *ετυπασαι*; *ετυπασαι*, *ετυπασαι*; *ετυπασαι*, *ετυπασαι*. Fifthly, that the form called by grammarians *paulo post futurum*, is not a distinct tense, but the first future middle augmented; *ετυπτισομαι*, *ετυπτισομαι*; *ετυπτισομαι*, *ετυπτισομαι*. Sixthly, that the augment of the perfect comes nearest to the original reduplication than that of any other tense, which is preserved still more distinctly in the augment of verbs beginning with vowels *οι-αδω*, *οι-αδω*, and the like.

The Ionians, we have observed, changed *ο* into *α*; and this analogy, perhaps, converted the imperfect form *ετυπτο*,

or *ετυπτο*, into *ετυπτο*, or *ετυπτο*. The third person plural would be then *ετυπτοσαν*. Hence the Boeotians used *ετυπτοσαν*. The Dorians write *ετυπτοσαν*, which, in the common tongue, is softened into *ετυπτοσαν*. The simple and natural way of forming the perfect was to give it the characteristic of the present which it always implies, as an action, though past, still continuing in its effect; *ετυπτο*, *ετυπτο*; *λεγειν*, *λεγειν*. But from the facility by which letters of the same organs are changed for one another, *ετυπτο* became *ετυπτο*, and *λεγειν*, or *λεγειν*, became *λεγειν*. Hence *ετυπτο*, and *λεγειν*, which are improperly called the perfect middle, seem to have been the original perfect active, accidentally corrupted. And as there is no foundation for the distinction of perfect active and perfect middle, in fact there is none in signification. When, from whatever cause, *α* in some verbs became the characteristic of the perfect, it prevailed in other verbs, which still retained the characteristic of the present—*παινω*, *παινω*, *παινω*. The distinction, therefore, of perfect active and perfect middle is a fiction of grammarians, founded on the interchange of similar consonants, or the blind impulse of analogy.

Prepositions form the most difficult part of the Greek tongue, not only because they, for the most part, govern different cases, but because each has a great variety of significations. Yet the author of the Greek grammar, above mentioned, has laid down two observations, which tend greatly to simplify this branch of the Greek language. The primary meaning of a preposition, says he, is to be sought in the root from whence it is derived, and the meaning so obtained, or one obviously connected with it, and flowing from it by analogy, it preserves in all cases whatever. A preposition combines with its own signification the meaning of the case in which the dependant noun is used; and it governs the genitive, the dative, or the accusative, as the writer wishes to fix the attention of his readers on the *origin*, the *instrumentality*, or the *object* of the governed noun.

We cannot forbear transcribing one instance (which is the first that occurs) of his manner of explaining the prepositions—*επο* (from the Hebrew *עץ*, *ab, a stem or root*; and as the root is underneath, the plant or tree springing from it, the primary sense of *επο* is) *under, επο* *απο*, *under a shield*. Farther, the root of a tree is the *cause* of its growth; hence *επο* denotes the cause or *agent* of the action specified in connection with it. "And they were baptized by him, *επο* *απο*"; he being the cause of their baptism." Finally, as a root shoots upwards, so as to appear above the ground, *επο* is sometimes to be rendered *from under*—*επο* *ζυγου* *from under the yoke*—*επο*, (from the same Hebrew origin with *επο*; and as the root is the origin of a thing, it denotes *beginning, cause, motion*, and is rendered) *from*. As by the use of *απο*, the attention is directed backward to the beginning of motion, its governed noun is always in the genitive. "He was not able to see Jesus, *απο* *οχλου*, *from the crowd*," the crowd being the cause of his inability. From signifying beginning, *απο* came to express the exact point of time at which motion begins. "They went from supper, *απο* *δευτερας*, i. e. *immediately after supper*. It expresses also the distance to which a thing has advanced, in consequence of moving. *απο* *της γης*, *far from the land*. The consequence of distance in most cases is *separation*, or *privation*, *απο* *των οπλων*, *from their arms*, i. e. *without them*. Taken in this sense, *απο*, abbreviated into *α*, as in Latin *ab*, becomes *a*, and compounded with nouns, adjectives, and verbs, imparts to them a contrary signification; *αποστασις*, *cear*, *αποστασις*, *unwarlike*. On the contrary, the effect of distance in some cases is *increase*, as a *Pyram* grows larger the farther

it flows from its source, or as a tree becomes greater with its gradual expansion from the root. For this reason *απο* abbreviated, sometimes increases the signification of its compound.

The Greek surpasses almost all other languages in the number and variety of its terms; and the causes of its superior copiousness are, *first*, the many dialects which it comprehends, and which served to divide by accidental corruption the same primitive into many words; *secondly*, the facility with which nouns combined with the personal pronouns in the formation of verbs, and the great variety of ways the same noun may be converted into verbs, so as to form distinct verbs, yet allied in sense and found to each other; *thirdly*, the various ways in which verbs, adjectives, and participles have been changed into abstract nouns; and *lastly*, the great multitude of compound terms, formed by the union of verbs or adjectives with nouns, and of prepositions with verbs. The combination indeed of prepositions with simple verbs is the most fertile cause of the extent and comprehension of the language. The simple verb *παλλω*, thus combined, has given birth to no less than *fifty-two* compound verbs. This single instance sufficiently shews the genius of the language, and proves that, however few its simple primitive words may have been, its derived and compound words are in a high degree voluminous and varied, yet connected by an obvious and uniform analogy, both in regard to the formation and the meaning of each term.

But this language is not less remarkable for the harmony of its structure, than for the comprehension and variety of its terms. The perfection of language, as well as of music, depends on the melody of its sounds; their measure or rhythm, their variety, and their suitableness to the subject, which they are meant to describe or express. The circumstances of the Greeks in the earliest periods of their society, rendered them peculiarly attentive to all these objects. They lived continually in crowds; all matters of consequence were decided by the voice of the assembly, and, next to the force of his arms, every warrior felt himself indebted to the persuasive accents of his tongue. The perpetual necessity of employing the power of eloquence, during the infancy of their political state, made them retain the original tones and cadences, by which men, as yet unpractised in the use of arbitrary signs, had made known their affections and their wants. These tones and cadences, imitating the language of action. (the first and most natural language of savages.) possessed a degree of energy and of warmth which can never be attained by the mere artifice of articulate sounds. By uniting them to these sounds, the Greeks gave all the force of a natural to an arbitrary sign. Music and action were incorporated in the substance of their speech; and the descriptive power of words was extended to all those objects which can be characterized by sound and motion, or which the various modifications of those qualities can suggest to the mind of man. Gillies' Hist. of Greece, vol. i. p. 238.

GREEK, *modern or vulgar*, is the language now spoken in Greece, and called *Ῥωμαϊκή γλώσσα*, from Constantinople being called *Roma Nova*.

There have been few books written in this language, from the taking of Constantinople by the Turks: scarcely any thing but some catechisms, and the like pieces, composed or translated into the vulgar Greek, by the Latin missionaries.

The native Greeks are contented to speak the language without cultivating it; the Turkish politics not allowing any of the subjects of their estates to apply themselves to the arts and sciences.

It is not easy to assign the precise difference between the *vulgar* and the *ancient* Greek: it consists of the terminations of nouns, pronouns, verbs, and other parts of speech, which make a difference between those two languages much like that observed between some of the dialects of the Italian or Spanish: we instance in those languages as being the most known; but we might have said the same thing of the Hebrew, Slavonic, &c. dialects. The *modern* Greek, also curtails words, runs them into one another, and adds a sort of enclitic particles to the end of them: it confounds the vowels *ε*, *ι*, *υ*, and the diphthongs *ει* and *οι*, which they pronounce and often write only *iota*. They likewise often confound cases, moods, tenses, and particles. See Breerewood's Inquiry concerning the Diversity of Languages, &c. chap. 2.

Besides, the modern Greek has divers new words not in the ancient; particularly several participles which appear as expletives, and which are introduced to characterize certain tenses of verbs, and other expressions, which would have had the same meaning without such particles, had custom dispensed with them; divers names of dignities and offices unknown to the ancient Greeks; and abundance of words borrowed from the vulgar tongues of the neighbouring nations.

Accordingly one may distinguish three ages of the Greek tongue: the first ends at the time when Constantinople became the capital of the Roman empire; not but there were several books, especially of the fathers of the church, written with great purity after that time; but as religion, law, and policy both civil and military, began then to introduce new words into the language, it seems necessary to begin the second age of the Greek tongue from that epocha, which lasted to the taking of Constantinople by the Turks, where the last age commences.

GREEN, in *Biography*, an organ-builder, on the model of Snetzler, whom he succeeded, and has left behind him monuments of his skill and ingenuity in many of our churches and mansions of the nobility and gentry.

To this modest and ingenious man, ever ready to adopt any hint tending to the perfection of his art, we are indebted for the improvement of the mechanism of the most noble and comprehensive of all instruments, having eased the touch, voiced the pipes, and contrived a swell of the whole instrument, in a manner superior to any of his predecessors. He died when scarcely arrived at the midway of the period of mortal life.

GREEN, MATTHEW, was born, probably in London, about the year 1696. He was educated among the dissenters, and his learning extended to the knowledge of a little Latin. At this period, those who dissented from the established church were rigid in their principles and gloomy in their manners. He appears to have been, on this account, dis-

gusted

gusted with those who were the associates of his youth, and to have completely abandoned the party. He speculated freely on religious subjects, and at length adopted the system of outward compliance with established forms. At one time he appeared to be ready to join the quakers, but something occurred which prevented him from making an outward profession of their principles. His circumstances were very narrow, but he was fortunate enough to obtain a place of some trust in the Custom house. He died at the age of forty-one, in the year 1735. His disposition was remarkably mild, and his conversation abounded with wit. He was subject to low spirits: as a cure for this, he composed the work by which, as an author, he is principally known, "The Spleen." This poem presents a picture of his mind and manners, which implies a practical philosophy of the sober and rational Epicurean cast. The other works of Mr. Green consist of "The Grotto;" "Verses on Barclay's Apology;" "The Seeker;" and some smaller pieces. "In manner and subject," says the critic, "they are some of the most original pieces in the language: they rank among the easy and familiar, but are replete with uncommon thoughts, new and striking images of remote ideas by some unexpected similitude, in which wit principally consists. Few poems will bear more repeated perusals; and with those who can fully enter into them, they do not fail to become favourites." Gen. Biog.

GREEN, one of the original colours of the rays of light. Grass and herbs, and even all vegetables in places exposed to the open air, are green; and those in subterraneous places, or places inaccessible to the air, white and yellow. Thus when wheat or the like germinates under-ground it is white or yellow; and when it is in the open air, green; though this too is yellow before it be green.

GREENS, *Artificial*, are very rarely simple colours, but produced by mixture of yellow and blue.

Two powders, the one blue, and the other yellow, well mixed, appear perfectly green; though, when viewed with a microscope, we observe a chequer of blue and yellow.

The tincture of red roses with oil of tartar per deliquium, or with spirit of sal ammoniac, produces green. The tincture of many red flowers is changed into green by an alkali. The tincture of red roses, and the yellow tincture of crocus, or the blue tincture of cyanus, and the white spirit of sal ammoniac, produce green. The solution of verdigris becomes colourless by the affusion of the spirit of nitre, and by the affusion of the oil of tartar it becomes green again.

As no vegetable has yet been discovered, which is capable of giving to cloth of any kind a permanent green colour, the dye for this purpose is a compound colour, formed in dye-vats either by putting a yellow on a blue ground, or a blue on the yellow ground, or by mixing the blue and yellow materials, and dyeing with them as with a simple colour. The common and most permanent green is given to woollen cloth in the following manner. The cloth, being first dyed blue in the indigo vat (see INDIGO), is then well scoured, and afterwards dyed in a bath of weld or any other yellow dye with alun and tartar, as in the mode of dyeing of simple yellows, except that the yellow materials are used in greater quantity than the yellow alone of equal body would require. Very deep greens are made to acquire a slight brown or kind of burnish by adding to the bath small quantities of log-wood and sulphat of iron. As for silks, they are first strongly alumed, then dyed yellow with weld, and afterwards finished in the indigo vat. Silk, cotton, and linen are dyed green in the same general mode, but with considerable

variations in the different processes. The most beautiful green hitherto known, and which perfectly well resists the action of light and air, is given by the combination of Prussian blue and yellow, but this colour is destroyed by soap and alkalies. To cotton this colour is given, by first dyeing it olive with weld, or any other yellow dye, and a compound mordant of alun and iron, and then raising the green by prussiat of potash. (See PRUSSIAN blue.) Berthollet observes, that in the process for this purpose there seems to be a mutual distribution of the mordants and colours, the Prussian colour taking the iron and becoming blue, whilst the alun and weld remaining in the olive form a fast yellow, and unite with the blue into a fine green. The only simple green in common use is that of the carbonated oxyd of copper precipitated from verdigris by an alkali. A solution of verdigris is made in vinegar, and a few hours before dyeing a solution of as much pearlsh as verdigris is added to it, the mixture is heated, and the cotton, previously alumed, is passed through this bath. The colour then given is a soft apple-green. Aikin's Dict.

The dyers make divers shades, or casts of green, as *light green*, *yellow green*, *grass green*, *laurel green*, *sea green*, *dark green*, *parrot green*, and *celaden green*.

GREEN, *Brunswick*, is a pigment used by some of the German artists, which they prepare by adding to the saturated solution of one part of muriated ammonia in cold water, three parts of copper clippings; and by covering the glass vessel that contains it with gauze so as to keep out the dust, and placing it in a warm situation, so that the moisture may evaporate, which purpose will be effected in a few days. The muriat of ammonia soon begins to be decomposed by the copper, which is corroded and converted into a green oxyd. When the whole is evaporated to dryness, let it be digested in two or three successive portions of spirit of wine, as long as any green oxyd is taken up; then add the solutions together and expel the liquor by a gentle heat, the residue is a pure dark green sub-muriat of copper, known in the shops by the name of refined Brunswick green.

GREEN, *Mountain*, or *Hungary green*, is a sort of greenish powder found in little grains, like sand, among the mountains of Kernaufent in Hungary, and those of Moldavia. Though some hold, that this mountain green is facitious, and the same with that the ancients called *jos aris*, prepared by casting water, or rather wine, on copper red-hot from the furnace, and catching the fumes thereof on copper plates laid over for that purpose: or by dissolving copper-plates in wine, much as in making verdigris. The painters make use of this colour for *grass green*. It is sometimes counterfeited by grinding verdigris with cerufs.

GREEN, *Calced*, and *distilled green*. See VERDIGRIS.

GREEN, *Prussian*. See the process for making PRUSSIAN blue.

GREEN, *Sap*. See colours from FRUITS, BUCKTHORN, and SAG-gran.

GREEN, *Saxon*, an extremely beautiful green colour, so called because the blue part is given by the Saxon blue or sulphat of indigo; the process of dyeing which is this; the cloth or silk is first to be dyed a Saxon blue, in the following manner. Having ground nine parts of indigo with twenty of red arsenic into a fine powder, add forty-eight parts of strong spirit of vitriol; which mixture swells, grows hot, and emits a sulphureous smell. After standing in a moderate warmth of twenty-four hours, pour off the liquid part, which will be of an extremely deep blue. A small quantity of this liquor, drop'd into hot water, instantly spreads, tinges it of a fine light blue, and fits it for dyeing

the prepared wool, cloth, or silk: and by increasing or diminishing the proportion of the blue composition, the colour may be rendered deeper or lighter. This, Dr. Lewis says, is the method used for preparing the blue composition by the dyers of Norwich, who purchased this secret from Saxony.

The cloth or silk, thus dyed blue, is next alamed, and then dipped in the yellow decoction of weld or fustic, and the desired colour will be obtained.

Fustic is commonly preferred as the yellow material, because it is less liable to be altered by the adhering acid of the sulphat of indigo than weld or the other yellows. To correct this effect of the acid, and enable quercitron to equal the fustic in this respect, (whilst its natural colour much exceeds it,) Dr. Bancroft advises, after the cloth has received the blue, to mix chalk with the alum mordant, in order to neutralize the adhering acid, before the yellow is given.

Or the subject may be dyed green at one operation, by boiling it for a little time in a mixture of the blue and yellow liquors. For this purpose the cloth is first alamed and well rinsed; and the cloth is then dyed in a strong decoction of fustic, to which, when cooled to a blood heat, is added sulphat of indigo. Dr. Bancroft recommends for dyeing a beautiful Saxon green, the following expeditious process, by using the compound alum and tin mordant; put into the boiler six or eight pounds of quercitron bark to every one hundred pounds of cloth; boil with a sufficient quantity of water; then add six pounds of the nitro-sulphat of tin, (in preference to the nitro-muriat,) and four pounds of alum: when these have boiled five or six minutes, lower the heat with cold water to blood-warm, after which, add as much sulphat of indigo as may be thought necessary for the intended depth of colour, and then dye the cloth in this bath with proper care. Aikin's Dict.

By combining any blue and yellow dyes, in different proportions, all the shades of green may be produced, from the bluish green of the cabbage-leaf to the greenish-yellow of the olive.

GREEN, in *Agriculture*, a term provincially signifying grass-land, or such as is in the state of turf.

GREEN, in *Geography*, a county of America, in New York, taken from Ulster and Albany counties, bounded on the N. by Albany and Schoharie, E. by the river Hudson, S. by the county of Ulster, and W. by the county of Delaware; 30 miles in length from E. to W., and from 12 to 20 in breadth. The number of its inhabitants is 15,870, and its chief town is Kaatskill.—Also, a county of Pennsylvania, bounded N. by Washington, S. and W. by Virginia, E. by Monongahela river; 33 miles long, and 18 broad. The number of its inhabitants is 8605.—Also, a county of Kentucky, extending from Ohio river on the N., to Tennessee state on the S., and bordering W. on the Mississippi river, and E. upon Hardin and Jefferson counties. The number of its inhabitants is 6025, of whom 816 are slaves.—Also, a county of N. Carolina, in the district of Newbern, containing 4218 inhabitants, of whom 1496 are slaves.—Also, a post-town in Kennebeck county, and state of Maine, situated on the E. side of Androscoggin river, 164 miles N. E. from Boston; containing 933 inhabitants.—Also, a post-town in Franklin county, Pennsylvania, situated near the Conegocheague creek; 156 miles W. by S. from Philadelphia; containing about 80 houses, 2 German churches, and a Presbyterian church, and 884 inhabitants.—Also, a township in Franklin county, and also a township in Washington county, in the same state.—Also, a navigable river of Kentucky, which rises in Mercer county, has a gentle current, generally in a W. direction, and is navigable nearly

150 miles: at its confluence with the Ohio it is upwards of 200 yards wide.—Also, a small river which rises in the town of Marlborough, in Vermont, and falls into Connecticut river, above Deerfield, in Massachusetts.—Also, a river of New Brunswick, which runs into the St. John. N. lat. 47° 20'. W. long. 67° 58'.—Also, a river of Canada, which runs into the river St. Lawrence, 106 miles below Quebec.

GREEN Bank, one of the banks near the island of Newfoundland; 129 miles long, and 48 wide. N. lat. 45° 30' to 46° 50'. W. long. 53° 30' to 53° 50'.

GREEN Bay, a bay on the W. side of lake Michigan, about 90 miles long, and 15, 20, or 30 broad in different parts, lying nearly from N. E. to S. W. At its entrance is a string of islands extending N. to S., called the "Grand Traverse;" these are about 30 miles in length, and serve to facilitate the passage of canoes, as they afford them a shelter from the winds. The communication between lake Michigan and the Green bay is sufficiently deep for a vessel of 60 tons, with a proportionable breadth; the land adjoining to the bottom of the bay is very fertile, the country generally level, and the views of it agreeable and extensive. The inhabitants of its coasts call this bay the Menomie bay. N. lat. 45°. W. long. 87° 58'.—Also, a bay on the E. coast of the island of Antigua, S. from Green island.

GREEN Briar, a large and fertile county of Virginia, surrounded by Bath, Randolph, Harrison, Kanaway, Botetourt, and Montgomery counties; about one hundred miles long and 45 broad: containing 3894 free inhabitants, and 271 slaves. The chief town is Lewisburg; 103 miles W. of Staunton.—Also, a river of Virginia, which pursuing a S. W. course, runs into the eastern side of the great Kanaway. N. lat. 37° 57'. W. long. 80° 58'.

GREEN Bug, in *Agriculture*, the name of a small insect, which is often found destructive to different plants in both fields and gardens. It also frequently proves destructive to hop crops. It is very difficult to destroy it in many cases.

GREEN Cheese, in *Rural Economy*, the name of that sort of cheese which is prepared with some kind of green vegetable juice, as that of sage and other similar plants.

GREEN Copperas, See **COPPERAS**, and **Sulphat of IRON**.

GREEN Creek, in *Geography*, a river of Pennsylvania, which runs into the Susquehanna. N. lat. 40° 58'. W. long. 76° 30'.

GREEN Crop, in *Agriculture*, that sort which is formed of some kind of green vegetable; such as that of some sort of artificial grass, the turnip, cabbage, tare, rape, &c. which are so termed in contradistinction to those of the grain description. The introduction of crops of this nature between those of the grain kind, has constituted one of the most important improvements in modern agriculture. By this means, land has not only been prevented from being exhausted and worn out, but brought into the most proper condition for the growth of grain, without undergoing the injurious process of naked or summer fallowing. It has likewise had the effect of greatly increasing the number, and improving the quantity of all sorts of live stock, in consequence of their having more abundant supplies of food, and these at the same time of better qualities. There can therefore be no doubt of the great advantage of these crops, which should of course be grown as extensively as possible by the farmer, as by them he may be enabled to support much larger stocks of cattle and sheep than could otherwise be the case, and at the same time raise much larger quantities of good manure. See **MANURE**. Besides this, great advantage might, in different instances of cattle-farms of the breeding kind, be de-

rived from the more extensive cultivation of such green crops as the winter support of the stock.

And crops of this nature have likewise been found of extensive utility in the feeding of milch-cows in winter dairying, as is fully shewn in the various trials made by J. C. Curwen, esq. in a northern district of the kingdom, in the view of supplying the poor of a large town with milk. The value of which crops in this sort of application, on the supposition of their being fold to the cow-keeper, and the expenses of their cultivation, are stated in the following manner.

<i>Green Crops.</i>		
	£. s. d.	
Twenty-two acres of green crop, at 10 <i>l.</i> } per acre - - - - - }	220 0 0	
<i>Expences of raising and cleaning.</i>		
Four acres of cabbages, } at 12 <i>l.</i> per acre	48 0 0	
Two acres of Swedish tur- } nips, at 5 <i>l.</i> per acre	10 0 0	
Six acres of common red } turnips, at 4 <i>l.</i> per acre	24 0 0	
One acre of Kahlrabi - - - }	5 0 0	
Nine acres of rape or cole, } at 3 <i>l.</i> 10 <i>s.</i> per acre	31 10 0	
	118 10 0	
Gain on crops	£. 101 10 0	

It is considered that the improvement of the land, and the value of the succeeding crops, are fully adequate to the rent and taxes.

This statement shews in the most clear point of view the vast benefit of this kind of crops even in this sort of application, and that they should not be disregarded by those engaged in the business of husbandry. But in some other modes of application they will be found far more important and beneficial.

By some they have also been considered as of great utility when turned into the soil by way of a manure, though others are wholly of a different opinion; probably in consequence of the trials having been made in very opposite descriptions of soils, and under very different circumstances of them. It is extremely probable, likewise, that the advantage of this practice will be much greater where the crops are turned in during the summer months than in other cases, in consequence of their running more quickly into the putrefactive state. It has been advised, that whatever may be the nature of the crops, they should be ploughed under by means of a skim-coulter plough, as constituting the only means of turning them in, in so complete a manner as wholly to conceal them. And that, in case of sowing the land with broad cast turnips, the work should be performed at least three weeks before the seed is put into the soil, and that it should be afterwards only very slightly harrowed in. See *Turning in Green Crops.*

Green Earth, in *Mineralogy*, Baldoege, Sauss. ; *Chlorite baldogée*, Brong. ; *Argilla veronesis*, Wern. ; *Grünerde*, Wern. ; *Tale chlorite zoographique*, Haüy ; *Verde di Verona*, *Verde di Brentonico*, Ital. ; Veronese earth, an earthy substance belonging to the argillaceous genus. Its colour is indicated by its name, but there are several shades of it, the principal of which are verdigris, and celadon green, passing sometimes into leek and mountain green, frequently with an admixture of grey ; it has also been observed of a more or less pure olive green.

It occurs massive and disseminated, in rounded and angular fragments, and in globular concretions ; likewise in grains mixed with sand, and as coating on agate balls, in the hollows of amygdaloid, (toad-stone,) &c. Internally it is dull, but on the rifts a fat-like lustre is sometimes observable.

Fracture fine-earthly, or more or less flat conchoidal, approaching to stony. Divisible into indeterminate angular, blunt-edged, opaque fragments.

It feels rather greasy, is always more or less soft, mild, and easily frangible ; streak rather shining ; adhesion to the tongue inconsiderable. Specific gravity about 2½.

The chemical characters of green-earth, derived from Klapproth's analysis of three varieties, viz. those from Monte Baldo, in the Veronese, from Cyprus, and from East Prussia, are the following :

The green-earth from Monte Baldo, when heated to redness, loses six per cent. of its weight, while its hardness is considerably increased. The fragments thus subjected to the fire become externally of a yellowish-brown colour, internally greyish-black and glistening. That of Cyprus, after ignition, loses eight parts of its weight ; and its colour is converted into dirty brownish-yellow. Exposed to the fire of the porcelain furnace in the charcoal crucible, it fuses to a somewhat porous greenish glass, externally of a dirty-green colour, internally of that of emerald ; in the clay crucible it is converted into a greenish-grey slag. The green-earth of New East Prussia, when freed from the admixed sand by elutriation, and ignited, changes its green colour into light leather-brown ; the conglomerated particles are converted into a hard mass, and thus lose nine per cent. of their weight. The acids do not act upon green-earth, and they leave its colour unaltered.

The results of the analyses of the above three varieties were :

Green-earth of Monte Baldo, in the Veronese.	Green-earth of Cyprus.
Silica - - - 53	51.50
Oxyd of iron - - 28	20.50
Magnesia - - - 2	1.50
Kali - - - 10	18.
Water - - - 6	8.
Loss - - - 1	.50
Klapr. Beitr. vol. 4. 100	ibid. 100
Green-earth of New East Prussia.	
Silica - - - - -	51.
Alumina - - - - -	12.
Magnesia - - - - -	3.50
Lime - - - - -	2.50
Oxyd of iron - - - - -	17.
Natron, with a trace of kali - - - - -	4.50
Water - - - - -	9.
Loss - - - - -	50
	ibid. 100

The Prussian green-earth, by thus differing from the two others, particularly with regard to the alumina as a constituent part, appears to approach the nature of chlorite.

Green-earth occurs principally in amygdaloid, also as incrustation on the nodules of zeolite, &c. contained in the vacancies ; sometimes as coating the sides of these vacancies, which are often partly filled with the earth. It is also, though less frequently, found in porphyry and basalt, as nodules in the newer sandstone, and even in the rocks belonging to the new fletz-trap-formation, such as at Aichau in

in Bohemia, where calcareous tuff is seen alternating with narrow layers of a conglomerate, made up of grains of calcareous spar, and blunt-edged fragments of the tuff to which the green earth serves as the cementing substance. But in the same place green-earth forms a stratum of about a foot in thickness, whose base consists of wacke-like clay and calcareous tuff; the roof of indurated marl. The green-earth of New East Prussia, consisting of earthy particles mixed with a coarse sand, forms a considerable bed in the neighbourhood of the river Memel, between Lossowia and Salloweje.

Among the *localities*, besides those of Monte Baldo in the Veronese, Cyprus, Prussia, and Bohemia, already pointed out, the following may be mentioned: Altenburg and Planitz, in Saxony; Oberstein, in the Palatinate; Kovacs, in Hungary; Pontaudemer, in Normandy; Scotland, Iceland, the Ferroe-islands, and wherever true amygdaloid occurs.

This earth is used as a pigment, particularly for water-colour painting; and, being very durable, and not too expensive, also for house painting, &c.

The green-earth of Cyprus, according to Mariti, is sold at $4\frac{1}{2}$ piasters for a measure of 100 cakes. It is carried from the pit in large baskets made of the palm-tree; three of these baskets generally contain the above mentioned quantity. A great deal was exported to Holland; often by way of ballast.

That of Bohemia, above mentioned, is sold, according as its colour is deeper and its grain finer, from two to four florins the cwt. Part of it is also burnt there in small kilns, and sold as a red pigment.

By the Italians green earth is called Verde di Brentonico, from the vicinity of Monte Bolca to a place of that name.

GREEN Fallow, in *Agriculture*, a term often applied to such arable land as is rendered clean and free from weeds, by means of green crops, without having recourse to the process of naked or summer fallowing. This constitutes one of the numerous improvements in modern husbandry. See FALLOWING of Land.

GREEN Finch, in *Ornithology*. See LOXIA Chloris. See also TANAGRA Gyrola, and FRINGILLA butyracea.

GREEN Fish. See COD-FISHERY.

GREEN Food, in *Agriculture*, that sort of food which is employed in its green or succulent condition, in the feeding, foddering, and supporting of various kinds of live stock. This is a sort of food that has, within these late years, been much more extensively employed than was formerly the case; yet its advantages are probably in general not so fully understood as they ought to be. Its importance and utility will, however, soon appear by the making of a few experiments in a proper manner.

GREEN Glass. See GLASS.

GREEN Hew, or green-hue, in our *Old Writers*, the same with vert in forests, &c.

GREEN Hides, are those not yet tanned, or dressed, but such as are taken off from the carcasses. See HIDE and CURRYING.

GREEN Iron Earth. See IRON.

GREEN Island, in *Geography*, a small island among the Philippines, near the S. coast of the island of St. Lucan. N. lat. 13° 30'. E. long. 121° 2'.—Also, a small island in the East Indian sea. S. lat. 6° 5'. E. long. 123° 30'. Also, one of the smaller Bahama islands. N. lat. 21° 38'. W. long. 57'.—Also, one of the lesser Virgin islands, called likewise "Serpent island," situated near the E. end of Porto Rico.—Also, a low woody island near the N. E. coast of New Holland; 12 miles E. N. E. of Cape Grafton. S. lat. 16° 48'. W. long. 214° 5'.—Also, an island in Hud-

son's bay. N. lat. 61° 2'. W. long. 72° 40'.—Also, an island in the Atlantic, near the coast of Main. N. lat. 44° 41'. W. long. 67° 23'.—Also, a small island near the E. coast of Antigua. N. lat. 17° 13'. W. long. 61° 21'.—Also, a small island in the West Indies, about a mile N. E. from the island of St. Thomas.

GREEN Islands, a cluster of small islands in the Pacific ocean, discovered by Schouten and Le Maire. N. lat. 4° 53'. E. long. 154° 50'.—Also, a range of small islands in that part of the East Indian sea, called the "sea of Mindero," near the E. coast of Palawan. N. lat. 9° 33'. E. long. 119° 6'.—Also, a group of low islands in Prince William's sound, situated within the S. W. channel, between Montagu's island and Knight's island. Capt. Cook, in his third voyage, 1778, observed that they were entirely free from snow, and covered with wood and verdure, and therefore called them by this name. The channel between Montagu island and the Green islands is between two and three leagues broad, and from 34 to 17 fathoms deep.

GREEN Island Harbour, a bay on the W. coast of the island of Jamaica. N. lat. 18° 24'. W. long. 78° 17'.

GREEN Key, or PNERCO, a small island among the Bahamas. N. lat. 23° 56'. W. long. 77° 50'.

GREEN Lead Ore. See LEAD.

GREEN Mountains, in *Geography*, a range of mountains in America, extending N. N. E. to S. S. W. and dividing the waters which run easterly into Connecticut river from those which fall westerly into lake Champlain, lake George, and Hudson's river. The ascent from the east to the top of the Green mountain in Vermont is much more easy than that from the west, till you get to Onion river, where the mountain terminates. The vegetables that naturally grow on this mountain are hemlock, pine, spruce, and other evergreens, which always exhibit a green appearance; and hence its name. The chain of mountains extends through Massachusetts and Connecticut, and terminates in New Haven. Kellington peak, the highest of these mountains, is about 3454 feet above the level of the ocean. Morse.

GREEN Point, a cape on the W. coast of Africa. S. lat. 11° 53'.—Also, a cape on the coast of West Florida, in Pensacola bay. N. lat. 30° 31'. W. long. 87° 4'.

GREEN Sauce, in *Agriculture*, a term sometimes provincially applied to the common sorrel.

GREEN Scouring, a disease to which sheep, calves, and cattle are frequently exposed, and which is with difficulty removed. See SCOUR.

GREEN-Shank, in *Ornithology*, the SCOLOPAX glottis of Linnæus; which see.

GREEN Sickness. See CHLOROSIS.

GREEN Side, in *Agriculture*, a term often provincially applied to grass-land, turf, or sward.

GREEN Silver, the name of an ancient custom within the manor of Writtle, in the county of Essex; which is, that every tenant, whose fore-door opens to Greenbury, shall pay a half-penny yearly to the lord, by the name of green silver. Blount.

GREEN Sod, in *Agriculture*, a term provincially applied to grass-ground, turf, or sward.

GREEN-Stone, in *Mineralogy*, according to the more general acceptation of the word, is a rock composed of hornblende and feldspar, and belonging to what is termed by Werner the trap formation. (See TRAP.) Mica and quartz are likewise seen to constitute ingredients of this rock, but they are not considered as essentially belonging to it. The Groensten of Cronsted is, upon the whole, the same as our green-stone; but in some cases too great latitude has been given to that name.

GREEN-STONE.

This rock, with a view to the periods of its formation, is divided into primitive, transition, and fletz green-stone.

The *primitive green-stone* is generally distinguishable from the others by its highly crystalline structure. The hornblende, in which a tendency to crystallization is almost always observable, generally constitutes the predominant ingredient; but sometimes this is only apparently so, the feldspar being not seldom stained by it in such a manner, that it bears the greatest resemblance to small laminae of hornblende. In this case the blow-pipe discovers the illusion by melting the hornblende; when the feldspar recovers its usual whitish colour, and is converted into a white glass.

Werner subdivides primitive green-stone into four varieties:

1. *Common green-stone*, in which the two ingredients, mixed in different proportions, form a granular mass. 2. *Porphyritic green-stone*, being the common variety, including large crystals of feldspar. 3. *Green-stone porphyry*, in which "the granular basis, which is with difficulty distinguishable, includes crystals of feldspar;" and 4. *Green porphyry*, in which "the granular nature of the basis is no longer visible to the naked eye; it appears uniform and simple; has a blackish green or pistachio green colour, and includes crystals of compact feldspar." (Jameson.) To these are to be referred the porfido nero, and porfido verde antico of Italian antiquaries, of which we shall say more hereafter. The third and fourth of these varieties might, we think, be safely united; at least the definition given of them does not indicate any difference, except in the shade of green.

This old green-stone appears sometimes stratified. Gneiss is the rock in which the different varieties first appear; the next rock in which they occur is mica-slate, but the beds of green-stone in either of them are scanty and inconsiderable; they are observed more numerous and of greater extent in clay slate in Scotland. According to Mr. Jameson, the clay-slate and mica-slate, that form a great portion of the country extending from Loch Lomond, by Callander, Comrie, and Dunkeld, contain numerous beds of green-stone; and there, we are informed by this geognostian, as in all other countries, the clay slate contains more numerous and larger beds than the mica slate.

There is a vast number of varieties of primitive green-stone in Bohemia; thus it is found in the Saatz district of that country, where it rests chiefly on gneiss. It occurs there also with quartz as a constituent part. The varieties mentioned by Reuss, as being found there within a narrow compass, are, 1. A small grained mixture of velvet black hornblende, which exhibits a tendency to a prismatic crystalline form, with yellowish white feldspar, and greyish-white and smoke grey quartz. The hornblende is the predominant part; the quartz is here and there entirely wanting; the mixture pretty uniformly granular. 2. A variety in which the hornblende is seen in groups, distinct from those of the feldspar and quartz; so that the whole forms an assemblage of black and yellowish-white spots. 3. A variety in which the hornblende is so prevalent, that feldspar and quartz can with difficulty be distinguished by the magnifying glass, which discovers these ingredients collected into small spots and stripes: it contains also here and there some scales of mica. 4. Var. in which the hornblende is seen partly massive, in spots, stripes uniformly blebbed with the feldspar and quartz; partly in small circular crystals that are divergingly aggregated, or cross each other in all directions; feldspar tile and brownish-red; quartz only here and there in smoke grey grains. 5. Var. in which the hornblende shows a strong tendency to crystallization, and is much accumulated in some places; though, generally speaking, its proportion to the mixture of yellowish-white and reddish-grey feldspar and greyish-

white quartz, is but small: it contains larger and more numerous scales of silvery and yellowish-white mica. 6. Var. in which the texture becomes more thick-flaky; the smoke-grey quartz becomes predominant, the yellowish-white feldspar disappears almost entirely, and the hornblende is only thickly disseminated. 7. Var. in which the yellowish-white and reddish-grey feldspar predominates over the hornblende, which is seen partly massive and in fine granular concretions, partly in insulated and dispersed minute six-sided prisms, imbedded in the feldspar; while the quartz is entirely wanting. It is remarkable that in this district the primitive green-stone is seen, by slow gradation, to pass over into perfect gneiss. The more it approaches the latter, the more the granular texture becomes indistinct; the rock adopts a thick slaty texture, the hornblende is seen more and more to diminish, while the mica increases both in quantity and size, until perfect gneiss stands confessed as the constituent rock.

This rock is common also in many other parts of Europe; but the accounts we possess of the green-stone of several countries is too imperfect to enable us to determine how much of it may be considered as primitive.

The *transition green-stone* is not easily discriminated in hand-specimens. It is characterized by Mr. Jameson as being "a fine granular mixture of hornblende and feldspar; and sometimes the mixture is so intimate, that the constituent parts are not to be distinguished. Quartz sometimes traverses it in the form of veins, or is disseminated through it; a character which distinguishes it from fletz green-stone, which rarely contains quartz. Sometimes it occurs in globular distinct concretions, and these again consist of curved lamellar concretions, forming the globular rock (Kugelfels) of Voigtland. Sometimes it is penetrated with reddish-brown oxyd of iron, which, combined with the dark-brown hornblende, gives the rock a liver-brown colour; hence it is denominated in Voigtland, where it occurs, leber-fels, or liver rock. Beds of it occur in the upper part of Dumfriesshire, in the Hartz, Bohemia, &c."

Fletz-green-stone. Prof. Jameson, in his "Mineralogical Description of Dumfriesshire," has given a short account of the occurrence of green-stone in the independent coal-formation; and Mr. Flürl has discovered beds of amygdaloid in the first or oldest fletz-lime-stone; whence the former author considers himself entitled to introduce what he terms the *fletz-trap*, which is distinct from the still newer formation called the *newest fletz-trap* by Werner. In the independent coal formation it occurs in beds from one foot to many fathoms in thickness; it contains imbedded olivine and augite, and is traversed by numerous veins of calc-spar; it often also contains drusy cavities, which are lined with calc-spar, quartz, barytes, cubicite and prehnite; and the cavities are sometimes filled with water.

The green-stone of Werner's *newest fletz-trap formation* is, upon the whole, distinguishable from the older formation, by its structure being of a less crystalline appearance, and by its distinct concretions approaching more to the coarse granular. "Its colour usually inclines more or less to green. Certain varieties are reddish, and these are denominated *stonitic green-stone*. When fresh and rather large granular, it usually exhibits a simple structure; when, on the contrary, it is disintegrated, and smaller granular, it occurs in globular, and these again in curved lamellar distinct concretions. Certain varieties approach to wacke, and these are usually vesicular, and form a kind of amygdaloid. It is sometimes very distinctly stratified, and frequently occurs in veins." Jameson.

The *uses* to which the common green-stone is applied are

not manifold. As it frequently contains a considerable portion of iron, and is sufficiently fusible, it serves for a flux in the iron work in Smoland. Of the porphyritic varieties of the primitive green-stone used for ornament, the following deserve to be mentioned :

Antique black porphyries (porfido nero antico). There are two or three varieties differing, with regard to the intensity of the colour, from greenish-black to velvet-black; and likewise with regard to the size of the whitish feldspar-crystals: in one of them the crystals are very small, and this is more frequently seen among the remains of antiquity than the other.

Mr. Grassinauer, in his mineralogy of Alsace, mentions a black porphyry as occurring at Framont; and also as rounded blocks in the river Ill.

In the black *Corfican* porphyry, the feldspar-crystals have a slight tint of green, like those of the antique green porphyry. Ferber makes mention of a *Sardinian* black porphyry, and Sauffure of one found in the neighbourhood of *Geneva*, which, besides small prismatic crystals of feldspar, includes rounded grains of transparent colourless quartz. The latter addition is likewise observed in a variety of a blackish *Siberian* porphyry, which is sometimes wrought for ornamental purposes.

Antique green porphyry (porfido verde antico). This is the *ophites* of the ancients; a name derived from some supposed resemblance of this rock, when polished, to the skin of a serpent; whence, in modern times, antiquaries have referred the porphyry in question to the magnesian stone called serpentine, a mixture of which, with primitive limestone, constitutes the rock called *verde antico*. When once considered as the same with the real serpentine, the name *verde antico*, of course, also was equally applied to the green porphyry; a circumstance which has been productive of great confusion. There are now but few monuments of ancient art executed in this porphyry to be met with.

There are some varieties of green porphyry, much resembling the antique, still found in several parts of Europe. There is a quarry of it on Monte Viso, in Piedmont; which, besides the feldspar, contains reddish grains, supposed to be garnets.

The *green Corfican porphyry*, found in the district of Niotto, in Corsica, has a deep bottle-green base, and fine white feldspar crystals; another, which contains some dark red garnets, occurs in the district of Golo in the same island.

Sauffure describes the *green porphyry of Geneva*, resembling the black porphyry above-mentioned, in the figure and colour of the feldspar and quartz, but differing in its base, which is light green and, in fragments, translucent at the edges. Both this and the black take an excellent polish.

The *green porphyry of the Vosges* has a dark green base, and contains numerous middle-sized feldspar-crystals of a pale green colour. It is found at La Chevetrey, on the heights of Fresse en Comté, and made use of for ornamental purposes. In another variety, found not far from this quarry, the feldspar-crystals are so pressed against each other, that they are ill-formed, and conceal almost the whole of the base. They are manufactured into slabs for tables, chimney-pieces, &c. and sometimes pass by the improper name of green granite.

There is abundance of the green porphyry in the Pyrenees, where it is known by the old appellation of *ophite*.

Green-stone slate, a compound rock, which may be considered as a variety of the preceding, from which it differs in having a distinct slaty structure; the feldspar, moreover, being generally more abundant than the hornblende. It

ranks with the primitive trap, but, not occurring in rocks older than clay-slate, is considered as the newest of the first class of the trap formation. It occurs in considerable beds, and in Sweden whole mountains are said to consist of it. Several mining districts are situated in this rock, such as those of Gerfsdorf, in Saxony, of Radolstadt, in Silesia, and of Adelfors, in Sweden.

Green Sward, in *Agriculture*, a name applied to the grass, turf, or sward, by which land is covered while in the state of pasture or under the scythe. Such land as has been long in this state, is mostly covered with a close compact sward; while in the contrary case, it is mostly light, open, and thin. See *SWARD*.

Green Turtle Bay, in *Geography*, a small island among the Bahamas. N. lat. 26° 40'. W. long. 77° 59'.

Green Wax is used where estreats are delivered to the sheriffs out of the exchequer, under the seal of that court, made in green wax, to be levied in the several counties.

Green Weed. See *BROOM*.

Green Winter. See *WINTER Gr.cn*.

GREENÆ, in *Geography*, a town of Denmark, in North Jutland; 28 miles N. E. of Aarhuus.

GREENBURGH, a township of West Chester, in the state of New York, containing 1581 inhabitants.

GREENBUSH, a township of Rensselaer county, New York, containing 3472 inhabitants.

GREENCLOTH, a board, or court of justice, held in the compting-house of the king's household, for the taking cognizance of all matters of government and justice within the king's court royal; and for correcting all the servants therein, that shall any way offend.

To this court also belonged the authority of maintaining the peace for twelve miles round the king's court, wherever it shall be, excepting at London.

The judge of this court was the lord steward, assisted by the treasurer, comptroller, cosserer, clerks of the greencloth, &c. It took its name, *greencloth*, from a greencloth spread over the board where they sat, whereon were the arms of the compting-house. The clerks of this court were officers who attended there, and had business assigned them by the board. All bills of comptrolments, relating to the office, were summed up, and allowed by the clerks comptrollers, and audited by the clerks of the greencloth. They also appointed the king's, queen's and household's diet, and kept all records, ledgers, and papers, relating thereto; made up bills, parcels, and debentures for salaries, &c. and provisions and necessaries for the officers of the pantry, buttery, cellar, &c. They also waited upon foreign princes, when entertained by his majesty. This court has been abolished.

GREENE, MAURICE, Dr. in *Biography*, was the son of the Rev. Thomas Greene, vicar of St. Olave Jewry, in London, and nephew of John Greene, serjeant at law. He was brought up in the choir of St. Paul, and when his voice broke was bound apprentice to Brind, the organist of that cathedral. He was early noticed as an elegant organ player and composer for the church, and obtained the place of organist of St. Dunstan in the Well, before he was twenty years of age. In 1717, on the death of Daniel Purcell, he was likewise elected organist of St. Andrew's, Holborn; but the next year, his master Brind dying, Greene was appointed his successor by the dean and chapter of St. Paul's; upon which event, he quitted both the places he had previously obtained. In 1726, on the death of Dr. Crofts, he was appointed organist and composer to the Chapel Royal; and on the death of Eccles, 1735, master of his majesty's band. In 1739, he obtained

GREENE.

the degree of doctor in music at Cambridge, and was appointed public music professor in the same university, in the room of Dr. Tudway. Greene was an intelligent man, a constant attendant at the opera, and an acute observer of the improvements in composition and performance, which Handel and the Italian singers employed in his dramas, had introduced into this country. His melody is therefore more elegant, and harmony more pure, than those of his predecessors, though less nervous and original. Greene had the misfortune to live in the age and neighbourhood of a musical giant, with whom he was utterly unable to contend, but by cabal and alliance with his enemies. Handel was but too prone to treat inferior artists with contempt; what provocation he had received from Greene, after their first acquaintance, when our countryman had a due sense of his great powers, we know not; but for many years of his life, he never spoke of him without some injurious epithet. Greene's figure was below the common size, and he had the misfortune to be very much deformed; yet his address and exterior manners were those of a man of the world, mild, attentive, and well-bred. History has little to do with the infirmities of artists; who being *men*, in spite of uncommon gifts and inspirations, are subject to human frailties, which enthusiasm, praise, and the love of fame, more frequently augment than diminish.

Greene had the honour, early in life, to teach the duchess of Newcastle, which, joined to his professional merit, and the propriety of his conduct, was the foundation of his favour with the prime minister, and the notice of the first people about the court. In 1730, when the duke of Newcastle was installed chancellor of the university of Cambridge, he was appointed to set the ode, and then not only obtained his doctor's degree, but, on the death of Dr. Tudway, he was honoured with the title of professor of music in that university. As an exercise for his degree, he set Pope's ode for St. Cecilia's day; having first had interest sufficient to prevail on the author to make new arrangements in the poem to render it more fit for music, and even to add an entire new stanza, between the second and third, which had never appeared in any of the printed editions.

Greene had sense and knowledge sufficient, in his younger days, to admire and respect the abilities of the two great musical champions, Handel and Bononcini, whose disputed talents occasioned as much discord in the capital as the factions of Whig and Tory. At the same time as he was impressed with the highest reverence for Handel's great style of playing the organ, and the force of his genius for composition, he could not help listening with pleasure to Bononcini's performance on the violoncello, and to the grace and good taste of some of his opera songs; at which, perhaps, Handel took umbrage—for during these feuds, he broke off his acquaintance, and ever afterwards, regarding him as an enemy, never mentioned his name but with contempt. This treatment naturally rendered Greene a partizan on the side of Bononcini, and in 1728 he defended him, as long as he was able, from the charge of plagiarism, with respect to a cantata which had been introduced at the academy of ancient music as Bononcini's, and which was afterwards discovered to be the composition of Lotti, at Venice. See BONONCINI.

Greene's merit and connections were such, that he soon arrived at the most honourable appointments in his profession: for besides being organist of St. Paul's, in 1727, on the death of Dr. Croft, he was appointed organist and composer of the Chapel Royal; and in 1735 he succeeded Eccles

as composer to his majesty, and master of his band, in which station he set all the odes of the laureate, Colley Cibber, as long as he lived.

The compositions of Dr. Greene were very numerous, particularly for the church. Early in his career he set a *Te Deum*, and part of the *Song of Deborah*, which were never printed; but the anthems and services which he produced for St. Paul's and the King's Chapel, he collected and published in two vols. folio; and of these the merit is so various as to leave them open to much discrimination and fair criticism. Among the faults to be ascribed to this composer, none are so flagrant as the light divisions in which his solo anthems abound, and the repetition of passages a note higher or a note lower in what the Italians call *rosalia*, which are always dull, tiresome, and indications of a sterile fancy. The opening of his second solo anthem, vol. i. p. 26, is very solemn and pathetic, and the organ-part judicious and pleasing; but, page 45, *Santa Rosalia* tells her beads six times, while one very short passage is singing. "Lord how long wilt thou be angry," *alla Palestrina*, for five voices, though none of the subjects are new, seems to us the best full anthem of his composition. The style is clear, the answers are regular, and the modulation such as discovers a familiar acquaintance with the best ancient writers for the church. Of the full anthem: "O sing unto the Lord," for five voices, the fugue in the first movement is well worked, and has a good effect in performance; but the rest of the anthem is not equal in its subjects, or their treatment. "Lord how are they increased that trouble me," seems one of the most pleasing of Dr. Greene's solo anthems. The last anthem in the first volume, for two voices, has many pleasing passages, and rather more variety of subject than most of the others.

The first movement in the second volume seems calculated to display, in the performers, the power of making a shake upon short notice! A shake, judiciously applied, is a brilliant embellishment in a singer; but when lavished, improperly, is pert and unmeaning; nor is it ever more so than upon the first note of a movement. There are no fewer than seventeen or eighteen shakes distributed among the performers in the course of one page, which are more than a modern opera singer of judgment, taste, and expression, would use in a month, were his shake ever so good; the rest of the anthem is on common subjects, which are commonly treated.

The two-part anthem, "Thou, O God, art praised," has repeatedly a passage on the word *praised*, which has to our ear the disagreeable effect of two fifths; and there is a point at "unto thee shall my vow be performed," for which he was manifestly obliged to the second movement of Handel's fourth organ concerto. The rest of the anthem consists of agreeable passages of the times, but nothing like originality appears in any one idea.

"The King shall rejoice," for three voices, is agreeable common-place. Perhaps that is hardly enough to say of the second movement: "O Lord grant me a long life."

"Let my complaint," a full anthem, à 5, is very solemn and solid composition.

The anthem for Christmas day has an air of cheerfulness, suitable to the occasion, which runs through the whole composition. "Hear my prayer, O God," has more merit of gravity and expression than most of the anthems in this volume. "O sing unto God," is agreeable music, but too secular in its melody, and return to the subject. "Have mercy upon me;" the two first movements of this anthem

are sober and affecting; but the second and third have too many vulgar and worn-out divisions; the last chorus, however, is more ecclesiastical, and less common in melody and modulation. The solo anthem: "Hear, O Lord," for a bass voice, is grave and pathetic, on the model of Handel's best oratorio songs. The same may be said of the next, for two voices: "I will seek unto God." "O God of my righteousness," is superior in the duet movement, solo verse, and chorus, to any thing in the preceding part of this volume; this anthem rises somewhat above mediocrity. "O give thanks," is wholly built with Corelli's and Handel's materials, though somewhat differently disposed; particularly page 86, where the whole harmony moves together, one note lower, three times, after a crotchet rest, to this base: E, B \times 3d, E; D, A \times 3d, D; C, G, C. "The Lord is my shepherd," has too many light song-passages in it, notwithstanding the white and square notes which give it a venerable look on paper. "O how amiable are thy dwellings," is a very agreeable anthem, though the passages were not new at the time it was composed. The movement with an organ accompaniment, in the anthem: "My soul truly waiteth," is well conducted, and not common; the rest of the anthem has merit, particularly the chorus of the last movement. "The Lord, even the most mighty God," for a bass voice, is set with great gravity and propriety; few anthems, indeed, for that species of voice, are more agreeable; the points, however, in the chorus, are very common. The anthem in eight parts, *à due cori*: "How long wilt thou forget me," is very well written, *à capella*, and good music. Indeed, the first movement of this anthem manifests greater abilities than any of his productions that we have seen, who is in general very correct in his harmony; but as to invention and design, he seldom soars above mediocrity. "O Lord give thine ear unto my prayer," for two voices, is very pleasing music, particularly the first movement. The last anthem of this volume is made up of common play-house passages; the first movement is heavy and monotonous; the andante tiresome, by the repetitions of an old harpsichord-lesson passage in the bass; the chorus justifies Mr. Mason's censure of the author, (collect. of the words of anthems) for his too long and frequent divisions; these are too vulgar and riotous for the church, and, indeed, would have no merit of novelty any where. The *vivace*, page 151, upon which the last chorus is built, has more of the dancing minuet, or Vauxhall song, in it, than belong to that species of gravity and dignity which befits devotion. We think we could neither play nor hear this movement in a church, without feeling ashamed of its impropriety.

There is considerable merit of various kinds in the Collection of Catches, Canons, and two-part Songs, published by Dr. Greene; the composition is clear, correct, and masterly; the melodies, for the times when they were produced, are elegant, and designs intelligent and ingenious. It was sarcastically said, during the life of this composer, that his secular music smelt of the church, and his anthems of the theatre. The truth is, he produced but little secular music. His song of "Go rose," was long in general favour, and some of his easy ballads, as "Busy, curious, thirsty fly;" "Dear Chloe while thus beyond measure," &c. were the delight of ballad-mongers fifty years ago. The collection of harpsichord lessons, which he published late in his life, though they discovered no great powers of invention, or hand, had its day of favour, as a boarding-school book; for being neither so elaborate as those of Handel, nor so difficult as the lessons of Scarlatti, or the sonatas of Alberti, they gave but little trouble, either to

the master or scholar. Indeed, as all the passages are so familiar and temporary, they seem to have been occasionally produced for idle pupils at different times, with whom facility was the first recommendation.

Dr. Greene, during the last years of his life, began to collect the services and anthems of our old church composers, from the single parts used in the several cathedrals of the kingdom, in order to correct and publish them in score; a plan which he did not live to accomplish; but bequeathing his papers to Dr. Boyce, it was afterwards executed in a very splendid and ample manner. Dr. Greene died in 1755, and was succeeded, as composer to the Chapel Royal and master of his majesty's band, by his worthy pupil Dr. Boyce.

GREENE, in *Geography*, a county of Washington district in Tennessee, containing 7610 inhabitants, of whom 471 are slaves. Greenville college has been established by law in this county. (See GREENVILLE.)—Also, a county in the upper district of Georgia, bounded W. by the upper part of Oconee river, E. by Wilkes county, and S. by that of Washington, containing 10761 inhabitants, including 3657 slaves. The chief town is Greensborough.—Also, a county in the state of Ohio, bounded N. on the Indian ocean, S. on Ross and Warren, E. on Ross and Franklin, and W. on Montgomery county. Its extent from N. to S. is 58, and from E. to W. 21 miles. By the census of 1803 it contains 446 white males of 21 years and upwards.—Also, a township in Chenango county, New York, on the E. side of Chenango river, containing 655 inhabitants.

GREENFIELD, a handsome flourishing post-town in Hampshire county, Massachusetts, about 104 miles W. by N. from Boston. This township lies on the W. banks of the Connecticut river; it was incorporated in 1753, and contains 1254 inhabitants.—Also, a post-town in Saratoga county, New York, containing 3073 inhabitants.—Also, a town in Hillsborough county, New Hampshire, containing 934 inhabitants.

GREENHILL, JOHN, in *Biography*, a painter of much promise, but whose dissolute morals cut short his thread of life, at the early age of 20. He was born at Salisbury in 1649, and became a pupil of Lely, whose manner of course he imitated, and with much success.

GREENHOUSE, in *Gardening*, a house of shelter in a garden; contrived for preserving the more tender and curious exotic plants, which will not bear the winter's cold abroad in our climate.

Greenhouses, as they are now built, serve not only as conservatories, but likewise as ornaments of gardens; being usually large and beautiful structures, in form of galleries, wherein the plants are handsomely ranged in cases for the purpose.

The greenhouse is a sort of building, fronted and covered with glazed frames, destined for the purpose of preserving various sorts of exotic shrubs, &c. through the winter season: the aid of artificial heat is not here necessary, except in very intense cold weather. It is advisable, in constructing such houses, to erect flues to use occasionally, which may prove serviceable, not only in severe frosts, but also in moist foggy weather, where a moderate fire will now and then dry up the damps, which would otherwise prove pernicious to many of the tender kinds of plants.

It differs from the conservatory chiefly in this circumstance, that the plants, trees, or shrubs, are in pots or tubs, and placed upon stands, frames, or stages, during the winter, to be removed to proper situations in the open air, in the hot summer season; while in that there are beds, borders,

GREEN-HOUSE PLANTS.

ders, and clumps, laid out in the ground plan, and made up with the best earthy materials, to the depth of three or four feet, in which the shrubs, trees, &c. are regularly planted; the whole of the roof being removed during the summer to admit fresh air, and replaced on the approach of the autumn, to remain until the following summer renders it unnecessary.

The green-houses are at present mostly contrived to stand in the pleasure-ground, near to the house, if possible. They should be upon a somewhat elevated spot, full to the south, and where the sun has access from its rising to its setting: these buildings are commonly of brick or stone, having the fronts and tops almost wholly of glass-work; and ranging lengthways east and west. They are generally constructed upon some ornamental plan. As to the general dimensions in respect to length, width, and height, they may be from ten to fifty feet, or more in length, according to the number of plants to be contained; and in width, from ten or fifteen to twenty feet; but for middling-houses, fifteen or eighteen feet is a sufficient width; and in height in the clear, nearly in proportion to the width.

The walls on the backs and ends, particularly the former, should be carried up two bricks thick; and if more than fifteen feet high, two bricks and a half thick; at one end of the back wall on the outside, it is eligible to erect a furnace, for burning fires occasionally, communicating with flues within, ranging in two or three returns along the back wall, having one flue running along the front and end walls, raised wholly above the floor of the house.

The fronts of the buildings should have as much glass as possible, and wide glass doors should be made in the middle, both for ornament and entrance, and for moving in and out the plants. It would also be convenient to have a smaller entrance door at one end: the width of the windows for the glass sashes may be five or six feet; and the piers between the sashes may be either of timber, six, eight, or ten inches wide, according to their height, or if of brick or stone-work, two feet wide at least, sloping both sides of each pier inward, that by taking off the angles, a free admission may be given to the rays of the sun. For the same reason, the bottoms of the sashes should reach within a foot of the floor of the house, and their tops almost as high as the roof; and if brick or stone piers two feet wide, shutters may be hung on the inside to fall back against each pier. The roof may be either wholly or only half glass-work, next the front; the other half slated, especially if the upright or front piers are of timber; and the shutters to cover the top glasses may be so contrived as to slide under the slated roof: where the piers are of brick or stone, it is common to have the roof entirely slated or tiled; but slating is the most ornamental for a half or whole roof; and the ceiling within should be white; which, as well as the whole inside wall, must be well plastered and white-washed, so as to render it clean and neat.

But in green-houses of modern construction, in order to have as much glass as possible in front, the piers between the sashes are commonly of timber only, from six to eight or ten inches thick, according to the height, so as to admit as great a portion of light and heat of the sun as possible, and the roofs wholly of glazed frame-work.

The green-houses for large collections of plants have sometimes two wings of smaller dimensions, added to the main buildings, at each end, in a right line, separated sometimes from it by a glass partition, with sliding sashes for communication, and the front almost wholly of glass-work, and half or whole glass roofs. Thus, by these additional wings, the houses consist of three divisions, whereby the different

qualities and temperatures of the various plants can be more eligibly suited. The middle, or main division, may be for all the principal and more hardy, woody, or shrubby kinds, which require protection only from frost; one of the wings appropriated for the succulent tribe, and the other to the more tender kinds that require occasional heat in winter, but which can live without the heat of a stove or hot-house.

On whatever plans green-houses are constructed, the whole of the inside walls should be neatly finished off with plaster and white-wash, and the wood-work painted white, the bottom being painted with large square paving tiles, or some other similar material.

In the green-house there should be stands, frames, or trellises, which may be moved in and out, upon which rows of planks may be fixed, so as to place the pots or tubs of plants, in regular rows, one above another; by which their heads may be so situated as not to interfere with each other: the lowest rows of plants next the windows being placed above four feet from them, that there may be convenient breadth left to walk in front; and the rows of plants should rise gradually from the first, in such a manner, that the heads of the second row be entirely advanced above the first, the stems only being hid; and at the back of the house a space allowed of at least five feet, for the conveniency of watering the plants, and to admit a current of air round them, that the damps occasioned by their perspiration, may be the better dissipated; which by being pent in too closely often occasion a mouldiness upon the tender shoots and leaves, and, when the house is close shut up, this stagnating, rancid vapour is often very destructive; for which reason they should never be crowded too close to each other, nor should succulent plants ever be placed among them.

In *Plate Gardening*, (*Green-houses*) there is a ground plan and elevation of an improved green-house in which *fig. 1.* shows the front elevation, *fig. 2.* the ground plan, and *fig. 3.* a section of the same.

And at *fig. 4.* is another house of this kind upon another plan.

GREEN-HOUSE Plants, in *Gardening*, are such as require the protection of this sort of building during the winter or other season; the following are the principal of the different sorts that demand this kind of treatment.

Succulent Kind.

Agave, agave or American aloe; comprising common great American agave, with entire green leaves, and a branching flower-stalk;—common agave with striped leaves;—Virginian agave, with narrower pale-green leaves.

Aloe, African aloe; containing mitre-shaped aloe-tree, or sword aloe;—aloe ferox;—fan aloe;—saccharine aloe;—foam aloe;—partridge-breast aloe;—tongue aloe;—warted-tongue aloe;—pearl-tongue aloe;—cobweb-aloe;—hedge-hog aloe;—cushion aloe;—spiral aloe;—pentagonal spiral aloe;—triangular spiral aloe;—iris uvaria aloe.

Anthericum, spider-wort; containing shrubby stalked, onion-leaved anthericum;—aloe-leaved anthericum;—mock asphodel anthericum.

Cacalia, foreign colt's-foot; comprising *cacalia ficoides*;—Kleinia or Indian cacalia;—anteuphorbium cacalia;—papillary cacalia.

Cactus, melon-thistle; containing cactus opuntia, or common Indian fig.

Costyledon, navel-wort; containing round-leaved, long-leaved, hemispherical-leaved navel-wort.

Craffula, lesser orpine; containing several species.

GREEN-HOUSE PLANTS.

Euphorbia, euphorbium; containing most of the sorts.
Mesembryanthemum, fig marigold; containing many curious species.
Sempervivum, live-ever, or house-leek; containing tree-house-leek;—variegated tree-house-leek;—lesser canary tree-house-leek.

Herbaceous Kind.

Antholyza, Ethiopian corn-flag; containing ringent scarlet antholyza;—Ethiopian crimson antholyza;—cunonia, or large spathed scarlet-flowered.
Antirrhinum, snap-dragon; containing variegated snap-dragon;—Gibraltar spotted flowered linaria;—Dalmatian toad flax.
Aristolochia, birth-wort; containing evergreen aristolochia;—pittolochia, or small birth-wort.
Bryonia, bryony; containing African tuberous-rooted bryony.
Calla, calla; containing sweet calla, or Ethiopian arum.
Campanula, bell-flower; containing American bell-flower.
Canarina, canarina; containing canary bell-flower.
Canna, Indian flowering reed; containing common Indian flowering reed, and varieties;—glaucous Indian reed.
Crinum, asphodel lily; containing African asphodel lily;—broad-leaved asphodel lily.
Cyclamen, cyclamen; containing Persian cyclamen, and several varieties.
Erodium, erodium; containing pentandrous geranium or crane's bill;—thick-leaved erodium;—upright dwarf erodium.
Erythrina, coral-tree; containing herbaceous erythrina.
Ixia, ixia; containing African woolly-headed ixia;—bulbiferous ixia;—flexuous ixia;—corymbose spotted-flowered ixia.
Leonurus, lion's-tail; containing African scarlet leonurus;—striped-leaved leonurus.
Ornithogalum, star of Bethlehem; containing Cape ornithogalum.
Tropæolum, Indian cress; containing double Indian cress, or nasturtium.

Shrubby Kind.

Andromeda, andromeda; containing tree andromeda, or Carolina forrel.
Anthospermum, amber-tree; containing Ethiopian smooth amber-tree;—ciliated amber-tree.
Anthyllis, Jupiter's beard, or barba Jovis;—common barba jovis, or silver bush;—Spanish ternate-leaved barba jovis;—dwarf Portugal barba jovis;—erinacea, or prickly anthyllis.
Arctotis, arctotis; containing rough-leaved arctotis;—narrow-leaved arctotis;—sea rag-wort leaved arctotis;—plantain-leaved arctotis.
Artemisia, mug-wort; containing tree wormwood.
Asclepias, swallow-wort; containing shrub asclepias.
Asparagus; comprising white prickly asparagus;—declivated bristly-leaved asparagus;—acute-leaved asparagus;—retrofracted great prickly asparagus.
Aster, star-wort; containing shrubby African aster.
Astragalus, milk-witch, &c.; comprising the tragacanth, or goat's-thorn, and several varieties.
Azopla, deadly nightshade; containing shrubby deadly nightshade of Spain.
Baccharis, ploughman's spikenard; containing ivy-leaved baccharis;—oleander-leaved baccharis;—halimus-leaved baccharis.

Bosca, yerva-mora; or shrubby golden-rod tree.
Brunia, brunia; containing knob-flowered, or imbricated-leaved, woolly-leaved abrotenoides, or thyme-leaved radiated brunia.
Bubon, Macedonian parsley; containing shrubby galbaniferous bubon;—shrubby gummiferous bubon.
Buddleia, buddlea; comprising American long-spiked, occidental American, globular-headed buddlea.
Buphthalmum, ox-eye; containing shrubby Jamaica ox-eye;—maritime, or sea ox-eye.
Bupleurum, hare's ear; containing shrubby Ethiopian hare's ear;—shrubby difforme-leaved Cape hare's-ear.
Calendula, marigold; containing shrubby Cape marigold;—shrubby grafs-leaved Ethiopian marigold.
Capparis, caper-bush; containing spinous capparis, or true caper shrub.
Cassia, cassia; containing Cape phillyrea;—Mauweema, or Hottentot cherry.
Ceanothus, ceanothus; containing African ceanothus.
Celastrus, staff-tree; containing pyracantha-leaved celastrus;—box-leaved;—myrtle-leaved celastrus.
Ceratonia, carob-tree; comprising common carob-tree, or St. John's beard.
Chamærops, chamærops; containing dwarf palm.
Chrysanthemum, chrysanthemum; containing shrubby canary chrysanthemum;—shrubby floccular chrysanthemum.
Chrysocoma, goldy-locks; containing shrubby coma aurea, or greater African goldy-locks;—shrubby nodding goldy-locks.
Cistus, cistus; containing bay-leaved cistus;—sea purslane-leaved cistus;—and several other species.
Citrus, citron-tree; containing lemon-tree, and orange, with all the varieties of each.
Cliffortia, cliffortia; containing sea-leaved cliffortia.
Cluytia, alaternoides cluytia; containing purslane-leaved cluytia;—elateria or Indian cluytia.
Colutea, colutea; containing shrubby Ethiopian scarlet colutea.
Convolvulus, convolvulus; comprising evergreen canary convolvulus;—silvery convolvulus.
Coronilla, coronilla; containing valentine coronilla;—glaucous coronilla;—silvery coronilla.
Dais, dais; containing catinus-leaved dais.
Digitalis, fox glove; containing shrubby canary fox-glove.
Diosma, African spiræa; containing opposite-leaved, hairy-leaved, red diosma, &c.
Elenus, ebony; containing ebony of Crete.
Genista, broom; containing shrubby canary broom.
Geranium, geranium; containing all the shrubby kinds.
Gordonia, gordonia; containing loblolly bay.
Gorteria, gorteria; containing shrubby prickly-leaved gorteria.
Grewia, grewia; containing occidental grewia.
Halleria, halleria; containing African-fly honeyfuckle.
Heliotropium, turn-sole; containing shrubby Peruvian heliotropium.
Hermania, hermania; containing althæa-leaved, alder-leaved, lavender-leaved, gooseberry-leaved hermania.
Hypericum, St. John's wort; containing warted-leaved Minorca St. John's wort;—Carolina St. John's wort;—China monogynous St. John's wort.
Jasminum, jasmiae; containing Catalonian jasmine;—Azorian jasmine;—yellow Indian jasmine.
Jteris, candy-tuft;—evergreen tree candy-tuft;—ever-green striped-leaved candy-tuft;—ever-flowering tree candy-tuft.
Justicia, Malabar nut-tree.

GREEN-HOUSE PLANTS.

- Lantana, American viburnum*; containing African lantana, or flax-leaved jasmine;—sage-leaved lantana.
- Laurus, bay-tree*; containing Carolina blue-berried bay;—red-berried bay-tree;—Indian bay-tree;—cinnamon-tree;—camphire-tree;—deciduous bay-tree.
- Lobelia, lobelia*; containing shrubby, pine-leaved, blue lobelia.
- Lycium, box-thorn*; containing African box-thorn;—Barbary box-thorn.
- Malva, mallow*; containing African shrub-mallow medicago; containing shrubby hoary medicago, or moon trefoil.
- Melia, melia*; containing the bead-tree.
- Mentha, mint*; containing tree-mint.
- Moria, moria*; containing canaliculated-leaved moria;—rush-leaved moria.
- Myrica, gule, sweet-willozo, and candle-berry myrtle*; containing oak-leaved myrica;—Æthiopian heart-leaved myrica.
- Myrtus, myrtle-tree*; containing common myrtle, which comprehends many varieties.
- Nerium, oleander, or rose-bay*; comprising common oleander, with red flowers, scarlet flowers, white flowers, double flowers, striped-leaved.
- Olea, olive tree*; containing European olive tree;—Cape or African olive tree.
- Ononis, rest harrow*; shrubby Spanish ononis.
- Osteospermum, osteospermum*; containing hard-seeded chrysanthemum.
- Othonna, ragwort*; containing pectinated-leaved othonna;—southernwood-leaved othonna.
- Passerina, sparrow-wort*; shrubby African passerina.
- Pelargonium, African geranium*; containing many shrubby species.
- Phlomis, Jerusalem sage*; containing yellow phlomis, and varieties;—purple phlomis.
- Physalis, physalis*; containing alkekengi, or winter cherry;—forniferous winter cherry;—flexuous winter cherry.
- Pistacia, Pistachia nut, and myrtle tree*; two or three varieties.
- Polygala, milk-wort*; containing shrubby myrtle-leaved polygala.
- Portulaca, purslane*; containing shrubby Cape purslane tree.
- Poterium, burnet*; containing shrubby prickly burnet.
- Prasium, shrubby hedge nettle.*
- Protea, silver-tree*; containing common silvery protea, or changing tree;—coniferous protea.
- Punica, pomegranate tree*; containing dwarf pomegranate.
- Rhus, sumach*; containing African hoary sumach, and varieties;—African narrow-leaved sumach, and varieties;—shining-leaved African sumach.
- Royena, royena*; containing African bladder-nut.
- Rumex, dock*; containing sorrel tree.
- Ruscus, knee-bolby*; containing Alexandrian laurel;—tongue-upon-tongue laurel.
- Salvia, sage*; containing shrubby African golden-flowered sage;—shrubby African blue flowered sage;—Canary sage;—Mexican sage, or shrubby Mexican clary.
- Scabiosa, scabious*; containing shrubby scabious.
- Senecio, groundsel*; containing shrubby African groundsel.
- Sideritis, iron-wort*; containing Canary iron-wort;—Cretan iron-wort.
- Solanum, night-shade*; containing amomum Plinii;—bastard capscum, or winter cherry;—African jagged-leaved solanum, or pomum amoris;—American twin-fruited solanum;—thorny, downy night-shade.
- Tanacetum, tansey*; containing shrubby Æthiopian tansey;—under-shrubby samphire-leaved tansey;—tree tansey.
- Turchonanthus, tarchonanthus*; containing shrubby African fleabane.
- Tetragonia, tetragonia*; containing shrubby tetragonia.
- Teucrium, germander*; comprising Spanish tree-germander;—broad-leaved tree-germander.
- Vitex, chaste-tree*; containing evergreen chaste-tree.
- Ulex, furze or whin*; containing African berry-bearing furze.
- Xeranthemum, xeranthemum*; containing broad-leaved xeranthemum;—narrow-leaved xeranthemum;—trailing xeranthemum.
- Yucca, Adam's needle*; containing common Adam's needle;—thready-leaved Adam's needle;—aloe-leaved yucca;—dragon tree-leaved yucca.
- Zygophyllum, bean caper*; containing fissile-leaved bean caper;—purflane-leaved bean caper.

Under-shrubby Kind.

- Dracocephalum, dracocephalum*; containing Canary dracocephalum, or balm of Gilcad.
- Gnaphalium, gnaphalium*; containing oriental gnaphalium, and varieties;—sweet-scented gnaphalium.
- Inula, inula.*
- Keggelaria, keggelaria*; containing African keggelaria.
- Lavateria, lavateria*; containing Cape lavateria.
- Lavendula, lavender*; containing cat-leaved Canary lavender.
- Lotus, bird's-foot trefoil*; containing Cretan silvery lotus;—lotus Jacobæus;—upright lotus.
- Mediola, mediola*; containing climbing African mediola.
- Origanum, origany*; containing dittany of Crete;—dittany of mount Sipylus;—Cretan marjoram;—origany of Smyrna.
- Periploca, Virginian silk*; containing African hoary-climbing periploca, and varieties.
- Phylica, bastard alaternus*; containing box-leaved phylica;—heath-leaved phylica.
- Phyllis, bastard hare's ear*; or simpla nobla.
- Polium, or mountain poly*; containing inarum, or Syrian mastich.

- Rhamnus, buckthorn*; containing broad-leaved Indian rhamnus;—zizyphus, or jujube.
- Sclago, felago*; containing corymb felago.
- Smilax, rough bind-weed*; containing Chinese rough bind-weed, or China-root;—laurel-leaved rough bind-weed, and several varieties of each.
- Stabe, stabe*; containing bastard elichrysum.

It may be observed, that these sorts of plants must constantly be kept in pots, and some large kinds in tubs, for moving into shelter in winter, and into the open air in summer; as, being all exotics from various warm parts of the world, they are of tender growth in this climate, and consequently not able to live in the open air in the winter months.

And the pots and tubs for containing them must be of different sizes, according to the size and nature of the plants, which, as they advance in growth, should have large pots, &c. provided for them accordingly; and when they become wholly too large for the pots, they must be shifted into tubs hooped with iron, with two iron handles to each at the top-part.

It is necessary in potting or planting the different sorts, care should be taken that the pots or tubs have holes at bottom for the discharge of redundant moisture, each hole being

GREEN-HOUSE PLANTS.

being covered with a piece of tile or oyster-shell before the mould is put in, to prevent their being flopped up, and the earth from being washed out below.

The best modes of propagating the different sorts, the nature of the earth in which they succeed best, and the season most proper for raising them, are fully explained under the culture of the respective kinds, and may be seen under their proper heads.

General Method of Management of Green-house Plants.—As most plants of this sort are capable of bearing the open air from the latter end of May till October; but the rest of the year demand the protection of the green-house, they, of course, require to be set out into it as soon as the weather begins to be suitable, in the spring and summer months; especially for such as all the several varieties of myrtles, geraniums, oleanders, cistuses, phlomis, shrubby aloe, tree-wormwood, tree-candy-tuft, yellow Indian and Spanish jasmynes, Indian bay, &c. &c. And this should be done in the last week in May, or first in June, according as the season proves more or less favourable for all the other sorts: but it should not be attempted till the season is become perfectly settled, and there is a fair prospect of summer being arrived, as there are often very cold nights and frequently frosty mornings in May, and even in the beginning of June, which, if the plants were fully exposed, would pinch the ends of their young shoots and leaves, and greatly injure them. A mild warm day should be chosen for this work; and if a warm rain, it will be of much advantage, as it washes the leaves and branches from the dust they have contracted, and greatly refreshes the plants that are thus exposed to it.

Method of Setting out the Plants.—This is done in the more hardy sorts in thin pots about the middle of May.

When first brought out, it is proper to place them in some sheltered sunny place, for a fortnight, till they are inured to the open air; then to set them in any open exposure, where they are to remain for the summer. And as soon as they are brought out, they should be cleared from all dead leaves, and all dead wood; and the earth on the surface of the pots be stirred, taking a little of the old out, and adding some fresh mould in its stead, which will prove very beneficial; then give moderate watering, not only to the mould, but also over the heads of the plants, to clear them effectually from all dirt and filth which they have contracted in the green-house during the winter.

In putting them out, they may be placed according to the fancy of the proprietor; some of the handsomest plants being occasionally placed to adorn spacious fore-courts, or arranged on each side of large walks contiguous to the main habitation; and others near ornamental garden-buildings; they are also sometimes disposed in groups, or small clumps in the most conspicuous places, in different parts of the pleasure-ground; exhibiting different sorts in each group, in order to cause the greater variety and effect in such situations.

As soon as they have been thus placed out, their chief culture is, to supply them plentifully with water during the summer season, in hot dry weather: all the woody or shrubby kinds in particular; likewise the herbaceous kinds that are not very succulent, require it three times a week at least; and in a very hot dry time once every day. The succulent kinds must also have a moderate supply of water two or three times a week in dry weather; the proper time for watering all the sorts at this season is, either in a morning before nine o'clock, or in the afternoon about four or five; for, if performed in the middle of the day in summer weather, the sun would exhale a great part of the moisture before it effected its intended operation on the fibres of the plants: this busi-

ness should be duly attended to in dry weather. As the mould roots, and fibres of the plants are circumscribed within the narrow limits of a pot or tub, the earth, as well as the fibres, dries very fast in summer, and necessarily requires frequent refreshments of water, to preserve that due and constant degree of moisture which is requisite for the support of healthy vegetation in the different plants.

Even moderate rains should not prevent watering occasionally, especially such plants as have spreading heads, which prevent the rains, unless very heavy or constant, from falling in sufficient quantities on the earth of the pots, to moisten it properly. And in hot weather, if some mowings of short grass are spread on the surface of the orange-tree tubs and others, it will greatly preserve the moisture. During this season, it will also be a good practice to loosen the surface of the earth now and then in such pots and tubs as have a tendency to bind or become stiff by time.

Manner of taking in the plants.—About the beginning of the autumn, as towards the latter end of September, the more tender kinds of these exotic plants must be removed into the house; the succulent tribe, in particular, should be removed to shelter at the first approach of excessive wet and cold nights. The oranges, lemons, and all the other species should be moved into shelter in due time, either in the end of September or early in October; for, if they are permitted to remain in the open air till attacked by sharp weather, it changes the beautiful verdure of their leaves to a rusty yellow hue, which they do not recover during winter; therefore, about the latter end of September, or beginning of October at latest, the principal plants should be brought in; the succulent and others of a more tender temperature, as early in the former month as the cold weather begins to come on; and continue moving in all the others as the cold increases; and by the middle of October have the whole collection in the house. As the time approaches for moving in the different sorts, clear them perfectly well from decayed leaves, &c. all the pots being well cleaned, loosening the surface of the earth in each pot, and adding a little fresh mould. As the different sorts are brought occasionally into the green-house, they may be placed promiscuously till the whole are in, and then be arranged regularly, as they are to remain for the winter; leaving all the windows quite open till that time. When the whole is brought in, they should be disposed in regular order, so as to appear to the best advantage, both in respect to their general arrangement and variety, and so as each may have an equal portion of sun and air; the tallest plants being arranged in the back, the others in their several ranks, according to their degrees of height, gradually down to the lowest in front; and as there is a vast variety both in size, shape, and colour, of the foliage, they should be disposed so as to set off each other and give a pleasing variety to the whole; and if possible, they should stand clear of one another; by which each plant will be separately conspicuous, and the whole exhibit a greater air of freedom and variety, as well as admit an equal portion of sun, and a more free circulation of air among them.

When the plants have been thus collected in, their principal culture is the supplying them with fresh air at all opportunities in mild weather, and giving moderate waterings occasionally, picking off decayed leaves, cutting out casual decayed shoots, and making occasional moderate fires in severe weather, also, sometimes to dispel great damps and noxious fogs from them.

With respect to giving air, it should be admitted every mild, calm day, by opening the windows more or less, according to the temperature of the weather. When the plants
are

GREEN-HOUSE PLANTS.

are first housed, they should have as much free air as the nature of the season will admit, by opening the windows every mild day to their full extent; and if the air is quite temperate, they may remain open in the nights for the first week; but in cold nights they should be constantly shut; this work of admitting air must be constantly attended to all the winter; for, without a due portion of this essential article in mild weather, the plants soon lose their fine verdure and assume a sickly yellowish colour, become diseased, and the young shoots, in many sorts, grow mouldy and rot off, and the leaves of the plants drop; therefore, never omit every mild day, when not very damp or foggy, to open some or all of the windows little or much, according as the air is more or less temperate; the proper time during winter for this, is from about eight, nine, or ten in a morning, till three, four, or five in the evening, according to the mildness of the day; but as the days lengthen and the warm weather increases, give more air in proportion, earlier and later in the day as may be judged proper, being careful always to shut all close in due time every evening, as soon as the sharp air approaches. In foggy weather, it is advisable to keep the windows quite close; for the great damps occasioned by fogs are very pernicious to these plants whilst they are confined in the house; also, when boisterous or cold cutting winds blow towards the front of the green-house, the whole should be kept shut; or only, if thought necessary, some of the upper sashes drawn down a little way at top, above the reach of the wind rushing immediately upon the plants: likewise, in all froly weather, the house should be kept close, except the frost is moderate, and the middle of the day sunny and warm, when some of the windows may be opened a little, but shut close again if the sun is clouded, and at any rate before the air changes cold: in severe weather, the shutters, &c. should be shut every night, also, occasionally when the frost is extremely rigorous and no sun; and likewise, in such weather, the assistance of fire-heat as hereafter directed may be necessary. As the spring approaches, and the weather grows warmer, enlarge the portion of air accordingly, admitting it also both earlier in a morning and later in the evening as the days lengthen; for then the plants will assume a growing state, and a considerable portion of air is requisite every mild day, both to strengthen the new shoots and inure the plants by degrees to the air against the time for removing them fully into it again for the summer season.

And watering will also be necessary to most of the sorts, but must be afforded them as sparingly as possible during the winter months, and scarcely any should be given when the house is obliged to be shut close through the severity of the weather: there are no certain rules to be given for the application of this; some plants require only a little water once a week, or ten or twelve days in mild weather, such as the orange and lemon trees, myrtles, oleanders, shrubby-geraniums, and other woody kinds; all that is necessary being just to preserve the earth very moderately moist; the pots and tubs must therefore be examined with proper attention, and water given to such only as are in want. The herbaceous kinds should be rather more sparingly watered than the shrubby sorts; and all the succulent tribe have water but seldom, some not oftener than once a fortnight or three weeks, and that always but very sparingly at each time; and some that are very succulent require but very little from November till March; indeed all the succulents should only have it now and then at this season, when the earth in the pots becomes very dry and hard.

In executing the business of watering in general, care should be particularly taken to do it with great moderation

at the time the plants are in the green-house, as when you once over-wet the earth at this season, it will continue in that state for a long time, and by chilling the tender fibres of the roots of the plants, often cause the loss of the leaves of many of them, and even the death of some kinds. In a sunny day, from about eleven o'clock to two, is the most proper time for having this sort of work done.

Soft water, if possible, should be used, or at least such as had been exposed to the air two or three days, as fresh spring water is much too cold: and during frosty weather great attention is requisite to keep all the windows close, night and day, unless when very moderate, as just observed, and the middle of the day is sunny and warm; when some part of the house may be opened a little for two or three hours, having particular regard to shutting all close in due time in the afternoon, before the air changes to become sharply cold: but in very severe frosts it must be kept close night and day, and the shutters or other covers of canvass or mats be also used every night; also, occasionally in the day time, when the weather is intensely severe, and no sun appears, and there are no flues for fires to keep out the frost. The shutters, or other shelters, besides the glasses, should however be used as little as possible in the day-time, except in cases of particular necessity, as every opportunity ought to be taken for the admission of light and fresh air, as much as the temperature of the weather will possibly admit, as most of the plants only want protection from frost and the common shelter of the house, which, with shutting the sashes close every night, will be sufficient for the purpose.

In cases where there are flues for fires, it will be advisable to make moderate ones at such times as the frost cannot be otherwise kept out, especially on nights; but this must by no means be continued longer than is necessary to guard against very severe frosts and the danger of the plants.

In very cold, foggy, damp weather, a moderate fire now and then in the flues also proves very beneficial in expelling the damp unwholesome vapours, so pernicious to all plants of this nature. Whilst the plants are in the house, all decayed leaves, &c. should likewise be constantly picked off, being necessary both to preserve the beauty and health of the plants. The decayed leaves of the succulent kinds should be cut off close with a sharp knife; the plants in general should likewise be occasionally cleaned from any filth they may contract in the house, such as dust, cobwebs, &c.

General Method of Culture of the Plants.—These sorts of plants generally want shifting into larger pots and fresh earth as they advance in growth; such as are fast growers, as some of the shrubby geraniums, &c. annually, or every other year; and some plants in large pots, &c. once in two or three years, and others not so often, especially some large grown American aloes, orange and lemon-trees, and those in large tubs, having a considerable substance of earth about the roots. Sometimes these and other similar kinds, when not convenient to shift them, have the top earth, and a little down round the sides, loosened to some moderate depth in the spring, removing the loosened soil, and filling the space up with fresh compost. But as the plants in general increase considerably in proportion to their nature of growth, shifting into larger pots or tubs, with some fresh earth, should not be omitted occasionally as it may seem necessary, as it proves beneficial to most of the sorts. They may most of them be shifted with the ball of earth about their roots entire; but others, that are weak and sickly, require shifting into entire fresh earth prepared for the purpose.

The most proper time for shifting all the sorts is in April,

or before they are removed into the open air for the summer; but it may be occasionally done in autumn, as in August or the beginning of September, in time to strike fresh root before winter. In the work of shifting, each plant should be drawn out of its pot or tub with the ball of earth about its roots entire, then all the dry matted fibres round the outside of the ball pared off and cleared away, also, some of the old earth at the sides, bottoms, and tops: then having the new pots and fresh earth ready, the holes at the bottoms of the pots should be covered with pieces of tiles or oyster-shells, and some of the fresh earth put in; placing the plant in the pot, and filling up the vacancy all round with more fresh compost, bringing it an inch over the top of the ball, giving a good watering to settle the earth close in every part: after this, it is necessary to place the plants to have shade from the mid-day sun for a week or fortnight, and sometimes longer.

All such plants as are become of a weak sickly nature should, at shifting, have all the earth taken clean from about their roots, having them washed, and then planted into entire fresh earth properly prepared for them.

And the larger sorts of plants, such as the orange-trees, lemons, citrons, American aloes, and others of similar growth, should be shifted, when large, from pots into tubs hooped with iron, having two iron handles at top, as observed above, for the convenience of lifting them in and out of the green-house, as they sometimes grow to so large a size as to require two and sometimes three or four men to move them.

But all such plants as are not shifted annually should, in spring, have the earth in the tops of the pots or tubs loosened to a little depth, also, a little way down round the sides, taking the loosened earth out; and in its stead adding a quantity of fresh mould, giving it directly a little water to settle it close. This should never be omitted when necessary. At any time when the surface of the earth is observed to be stiff, whether in the shifted or unshifted plants, it is of much service to stir it an inch in depth occasionally, and add a little fresh compost when necessary to the plants.

And the mould or compost into which the plants are to be shifted is of considerable importance. The best is obtained from commons where sheep and cattle pasture, particularly in low places, where the finest grass grows and the soil is deepest. A foot of the top soil with the turf should be taken off, and, if a sandy or hazel loam, it will do alone; but if a strong loam, some sand and black peaty, boggy, or moorish soil should be added. Such soils should be laid in a heap six winter months or more, and frequently turned over. Some plants, as aloes, mesembryanthemums, ixias, and exotic liliaceous plants in general, require a soil which is a degree lighter, and which does not retain the water, but lets it pass readily. A little coal-ashes at the bottom of each pot is useful in this view as well as others.

Most of the ericas, or heaths, and other beautiful plants from the Cape of Good Hope, from America, and Botany Bay, delight and flourish in this sort of earth, which comes nearest to their native soil: thus, the heaths like a black peat or moorish soil; and the others, that which is made a degree stronger, with loamy earth intermixed with it.

It is necessary to keep the heads and every part clean from dust and other filth, by occasionally washing with water all the sorts, which in most is done by waterings over their heads; but in others, when very foul, by washing their leaves with a sponge and water, especially in winter.

This is often necessary to the oranges and lemons, and other large-leaved kinds of plants that have been mentioned.

Where the heads of any of the shrubby kinds are become very irregular or shabby, the branches may be pruned shorter or longer, as necessary, in the early spring months.

And where any of the principal exotics assume a declining state, such as oranges, lemons, &c. or have thin, straggling, weakly heads, or are apt to drop their leaves, it is proper either to shift them wholly, or apply some fresh earth to their roots, and then prune the heads moderately close in the early spring, plunging them in a bark-pit under glasses. The heat of the bark-bed so greatly revives their growth, that they break forth into many strong new shoots, and form handsome renewed full heads in the summer season.

While in the green-house, some plants drop all their leaves, either by the effects of cold or over-watering, or sometimes by being kept too long in too dry a state, as frequently occurs in myrtles and geraniums, and sometimes oranges, lemons, and others; in which case it is proper in the spring to prune the heads, shortening the long strong shoots and branches, and to shift them with balls into fresh earth, or, if not shifted, to loosen the earth in the tops and sides of the pots, drawing out the loosened mould, and supplying the place with fresh. They afterwards soon push forth into young shoots and leaves, and renew their heads with verdure. Sometimes myrtles, geraniums, &c. in this state, when headed, may, on being brought forth in the summer, be drawn out of the pots, and plunged in the ground in a sheltered situation, and watered in dry weather; when they will send their roots into the full earth and break forth strongly at top into young wood and foliage, and form full heads, being then re-potted with balls of earth to the roots.

But the heads of green-house plants should never be clipped with garden-shears, nor, by any mode of pruning, trimmed into any formal figure, as sometimes practised; but every sort be let assume its own natural growth, only just using the knife to regulate any very irregular or rambling shoot or branch, or to thin out some where too much crowded, and to cut out the dead wood they may contain in any part of them.

GREENLAND, in *Geography*, comprehends a peninsula generally allowed to be attached to North America, and a number of detached islands, situated in high northern latitudes; the former is called *West* or *Old* Greenland, and the latter *East* or *New* Greenland, and more commonly Spitzbergen.

West or *Old* Greenland, is now generally believed to be a peninsula, connected in its north-western parts, hitherto unexplored, with America. The reasons alleged for supposing that the N. W. side is contiguous to America, and actually attached to it are the following: Davis's strait, or Baffin's bay, it is said, becomes narrower and narrower towards 78° N. lat.; the coast also, which in other places is very high towards the sea, gradually lowers northward; and the tide, which at Statenhook, and even as far as Cockin's sound, in the 65th degree, rises 18 feet at the new and full moon, decreases so much in the north above Disko, that in the 70th degree it does not rise much above eight feet, and probably loses itself entirely at last. Hence captain Baffin gave up all hopes of finding a passage into the South seas through Davis's straits, and consequently concluded, that Greenland joined with America. The Greenlanders report, though much dependance cannot be laid upon their information, that the strait at last becomes so narrow, that they can approach the other side so nearly, as to be able to call to the inhabitants, and strike a fish from

GREENLAND.

from both sides at once: but they affirm, that a strong current runs from the north into the strait, which prevents their coming to one another.

The name Greenland was given to the east side of this territory many hundred years ago by the Norwegians and Icelanders, who are said to have first discovered it, because its appearance was *greener* than that of Iceland. But this east side, sometimes called *Old* or *Loft* Greenland, is now almost totally unknown, because ships cannot navigate this coast, on account of the great quantities of floating ice. West Greenland lies between the straits of Davis and Frobisher, and Iceland, and is bounded on the W. by Baffin's bay, on the S. by Davis's strait, and on the E. by the northern part of the Atlantic ocean; but its northern boundaries are unknown. It reaches from the southernmost point of Cape Farewell, and Statenhook, in the 59th degree, on the right side north-eastward, towards Spitzbergen, to the 80th degree; and on the left side opposite to North America, N. W. and N. till about the 78th degree; the coasts having been so far discovered. Most of the Greenlanders live from Statenhook to the 62d degree, or, as the inhabitants say, in the south; but as no Europeans live there, these parts are imperfectly known. The interior of this dreary country is extremely mountainous, and some of the mountains are so high that they may be discerned at the distance of 40 or 60 leagues. This is particularly the case with that which is the highest mountain in the country, called "Hiorte-tak," or *flag's-horn*. It has three branches or points, the most lofty of which serves as a sea-mark to navigators, and also as a weather-gage, for when a storm is approaching from the south, the summit of this mountain is enveloped in a small misty cloud. The hills and rocks of this country are covered with perpetual snow; though the low lands on the sea-coast are clothed with verdure in the summer season. The ice and snow, like the glaciers of Switzerland, fill the elevated plains, and even many vallies. The coast is indented with many bays and creeks that enter far into the land: and it is encompassed with innumerable large and small islands, and both visible and imperceptible rocks. The shore, however, is in many places inaccessible on account of the floating mountains of ice. This country is said to have been discovered by some emigrants from Iceland: the distance, according to the best maps, being about 8^d of longitude, in lat. 66°, or nearly 200 geographical miles, though some maps reduce it to 5°, or not more than 130 geographical miles. The discovery was accidentally made by Eric Raude, or the red-headed, who being exiled from Iceland on account of the murder of one of its chiefs, found this country; and, coasting along the S. W. border, wintered at an agreeable island near a sound, which he called Eric's sound. Having in the following year examined the main land, he returned in the third year to Iceland: and in order to induce the inhabitants of Iceland to accompany him he called it Greenland, expressing its verdant appearance, and represented it as abounding with pasture, wood, and fish. The effect of his representation was such, that in the succeeding year he was followed by twenty-five ships full of colonists, who had furnished themselves richly with household goods and cattle of all sorts: however, only fourteen of these ships arrived safe: but in process of time more colonies flocked to Greenland, both on the east and west side, from Norway as well as Iceland. Torfæus, a native of Iceland, in his "*Greenlandia Antiqua*," dates the discovery of Greenland in the year 982. But it has been inferred from a bull issued by pope Gregory IV. in 835, and which commits the conversion of the northern nations, and in express words, of the Icelanders and Greenlanders, to the first northern apostle Ansgarius, (if this bull be indeed authentic,)

that Greenland must have been discovered and planted about the year 830, by the Icelanders and Norwegians. Leif, the son of Eric Raude, is said to have made a voyage to Norway, A. D. 999, to give the king, Olaus Tryggveson, an account of the new colony in Greenland; and this king, having just renounced heathenism, converted Leif, and persuaded him to be baptized, and to take with him to Greenland a priest, for the conversion of the inhabitants. Upon his return his father was induced to embrace Christianity, and the rest of the colony followed his example. In the year 1122 they chose Arnold, a Norwegian, for their bishop; and he fixed his episcopal residence at Gardar. In the year 1261, they, and the Icelanders, subjected themselves voluntarily under the Norwegian sceptre; and from that time they were governed by a king's deputy from Norway, according to the laws of Iceland; and when an archbishopric was erected at Drontheim in Norway, the Greenland bishops became suffragans to this metropolitan. The intercourse between this colony in Greenland and Norway continued, with little interruption, till the beginning of the 15th century; the last of 17 bishops being appointed in the year 1406. During this period the Greenland trade is said to have been very considerable; and it is very probable that they exported a large quantity of flesh, butter, cheese, fish, train, and pelts, chiefly by means of foreign ships; for though the Norwegian settlers in Greenland, upon their first establishment, sailed in their own vessels from Iceland and Norway to this country, they afterwards very much neglected navigation. After the period above-mentioned Greenland seems to have been little regarded, and its intercourse with other countries almost wholly ceased. In order to account for this sudden change of condition, it should be considered, that the first settlers were very much harassed by the natives, who were a barbarous and savage people, and who resembled, in their customs, garb, and appearance, the Esquimaux found about Hudson's bay. These people were denominated "Skrallings," or "Korralit," an appellation assumed by the Esquimaux. The Danish Chronicle, a work written in verse, and, indeed, of doubtful authority, though cited by Torfæus, informs us, that certain Armenians were first driven hither by a storm, and that from hence they peopled Norway and America, and that many tribes were found in Greenland, who were governed by different chiefs. The Skrallings, it is supposed, and not without some degree of probability, first came to Greenland in the 14th century, not from the east out of Europe, but from the west out of North America. But their origin is traced to the N. E. regions of Great Tartary, between the Ice-sea (*mare glaciale*) and Mungolia. They first came into Tartary, after the great dispersion of the nations, and were driven on further and further by imperious or more potent nations that followed them, till at last they were compelled to withdraw into the remotest corner of Tartary near Kamskatka, and from hence they migrated to America; extending themselves round the S. E. part of Hudson's bay, or through Canada as far as the North sea: and here, it is supposed, they were first found by the Norwegians in the 11th century. Dreading and wishing to avoid the molestation which they suffered from the other Indians, these fugitives retreated northwards, till, probably, in the 14th century, they either crossed Davis's straits in their boats, from Cape Walsingham, in the 66th degree, to the South-bay in Greenland, which can be scarcely 60 leagues wide; or else they went higher up by Baffin's bay, and so came down on the parts where the Norwegians formerly had their habitations, first on the west side, and then by degrees round to the east. These Skrallings are supposed to have exterminated the Ice-

land and Norwegian settlers who inhabited the western district, in the 14th century; after they had been previously diminished in number, or very much enfeebled by a pestilence, which raged about the year 1350. On this occasion the Norwegians were driven from the west to the east side, so that the western parts of Greenland were wholly occupied by these Skrellings. Some of them blended themselves with their conquerors, and others of them receded farther northwards into the inlets between the mountains. The ancient settlement contained several churches and monasteries, from which it would seem that the colony extended over about 200 miles in the south-eastern extremity. On the west some ruins of churches have been also discovered. In the eastern district, as we have reason to imagine, there are some remains of the ancient colony, though no intercourse can be maintained between the inhabitants of both sides of the country, on account of high mountains, perpetually covered with snow, which separate the two parts of Greenland; and the navigation from one to the other is impeded by the mountains of ice, that are driven southward from Spitzbergen, or East Greenland. From authentic records we can derive little information that is satisfactory, or upon which we can rely. From some of the most credible we learn, that Greenland was divided into two districts, called "West Bygd," and "East Bygd;" the former contained four parishes, and 100 villages; but the latter was more flourishing, as it is nearer to Iceland, and was sooner settled, and also more frequented by Norwegian navigators. The colony that first settled in the east, of which we have already given an account, is said to have comprehended, in ancient times, 12 extensive parishes, 120 villages, a bishop's see, and two monasteries. The present inhabitants of the western district are separated from those of the east by impassable deserts and mountains, so that they know little of one another; excepting that the eastern Greenlanders are thought by those of the west to be a cruel and barbarous nation, that destroy and eat all strangers that fall into their hands. For about a century after the cessation of intercourse between the Greenlanders and other nations, they were very much neglected; all the attempts made by the kings of Denmark to explore the eastern district having miscarried. At length, in the year 1578, Frederic II. sent the famous navigator, Magnus Henningsen, who, having encountered much danger from storms and ice, and gained sight of land, was obliged to return, probably on account of some unfounded apprehensions which deterred him from proceeding farther. About two years before this event, viz. in 1576, queen Elizabeth sent out Martin Frobisher to find a N. W. passage to China; he discovered land, which he named "meta incognita," and particularly the straits which bear his name; and traded with the Indians. On his return he brought with him a black stone, from which gold was extracted. In the year 1578 he was sent out again with a view of establishing a colony in Greenland, but he returned, after a stormy passage and several disasters, with as much of the mineral earth or ore as he could procure, and the design was never prosecuted. Frobisher was followed, in the year 1585, by John Davis, who sailed as high as N. lat. 64 15', *i. e.* to Ball's river, where he landed and traded with the natives. Then, and in the two following years, he discovered the coasts of America as high as the 70th degree, and gave the straits his own name. In the year 1605, Christian IV, king of Denmark, sent the Danish admiral Godske Lindenow, accompanied by John Knight, an English mariner, to reconnoitre the coasts of Greenland: the inhabitants on the west side were found to be much wilder than those on the east side, nor did they at all resemble one another in their language, dress, and manners. Voyages

of a similar nature were repeated, but no permanent advantage resulted from them.

At length, in the year 1721, a pious clergyman of Norway, Hans Egede, having long lamented the wretched condition of the Greenlanders, through the want of religious instruction, as well as a variety of worldly comforts, and having projected, from the year 1708, schemes for their relief, without effect, determined to relinquish his church preferment, and to make a voyage to Greenland, with a view of accomplishing his benevolent intentions. After having collected a capital of about 2000*l.*, by various subscriptions, and obtained from the king an appointment of missionary, with the yearly salary of 60*l.*, besides a present of 40*l.* towards his equipment, Mr. Egede placed himself at the head of a colony of 40 persons, and sailed for Greenland. These adventurers, having passed Statenhook, encountered many dangers from storms and ice, happily landed at Ball's river, N. lat. 64, on an island near Kangek, which they called after the name of the ship in which they had sailed, "Haabats-Oe," *i. e.* Hope island. They were hospitably received by the natives, and Mr. Egede took great pains, by his condescending attention, and by the assiduity with which he communicated to them religious instruction, to conciliate their friendly attachment. He also took great pains to acquaint himself with the language of the country, and to discover the best places for hunting and fishing, so as most effectually to serve the convenience of the colony. He made repeated attempts for exploring the eastern side of the country, and for discovering Frobisher's straits, but the wind and ice rendered his efforts unsuccessful. As a missionary, he discharged the trust which he had undertaken with singular fidelity, diligence, and zeal, and having continued in this inhospitable region till the year 1736, he returned to Denmark with a debilitated constitution. He was soon after appointed superintendent of the mission in Greenland, with a salary of 100*l.* per annum, and was ordered to found a seminary of students and orphans, whom he was to instruct in the Greenland language, and who were to supply a succession of missionaries and catechists. He spent his latter years in a recess with his daughter, on the island of Falster, and there closed his life of service and honour, November 5th, 1758, in the 73d year of his age. To him and to his son, Paul Egede, we are indebted for the most ample and authentic account of modern Greenland. The example of Mr. Egede has been since followed by several missionaries, particularly from among the Moravians, whose principal settlements were at Kangek, New Herrnhuth, and Lichtenfels. From Mr. Egede we learn that the most practicable method of reaching the eastern part of Greenland will be to coast north about in small vessels, between the great flakes of ice and the shore; the Greenlanders having always declared, that the currents, which rush from the bays and inlets, and run south-westward along the shore, hinder the ice from adhering to the land, so that there is always a channel open, through which vessels of small burden may pass, especially if lodges were built at convenient distances on the shore, for the accommodation and direction of the adventurers. The part of the country that is now visited by the Danes and Norwegians, lies between the 64th and 68th degrees of N. latitude, and so far the climate is found to be temperate. We are told, however, that the country is inhabited as far as 76; but the Danish and Moravian settlements are chiefly in the south-west, though at one time there appears to have been a factory as far north as 73°.

In the summer, from the end of May to the middle of September, the weather is warm and comfortable, when the wind blows from the east: though violent storms then occur,

GREENLAND.

and the fogs on the sea-coast are insalubrious. The land near the shore exhibits a pleasing verdure, but the inland mountains are perpetually covered with ice and snow. Beyond the 68th degree of latitude the cold is very intense, so that the rocks often burst by the frost; and towards the end of August, the whole coast is covered with ice, which never thaws till April or May, and sometimes not till the latter end of June. The prodigious masses of ice that surround the whole coast exhibit an appearance, in calm weather, no less dazzling than dreadful, by the reflection of the sunbeams in its variety of colours; but when the wind blows and the waves are lifted up in mountain billows, these masses of ice dashing against one another occasion shocks that make the observer tremble. Thunder and lightning seldom occur in Greenland, but the Aurora Borealis has frequent and brilliant appearances. At the time of new and full moon, the tide rises and falls upon this coast about three fathoms, and the springs and fountains on shore rise and fall with the flux and reflux of the ocean.

The soil of Greenland resembles that of other mountainous countries, the hills being barren, and the vallies and low grounds, especially near the sea, rich and fruitful. It is, for the most part, unfertile clay or sand. But whatever is said of the fertility of Greenland is applicable only to that part which lies between the 60th and 65th degrees of latitude. The most northern parts are totally destitute of herbs and plants. This country is said to have formerly produced a great number of cattle, and to have exported considerable quantities of butter and cheese to Norway. Some parts of the country yielded excellent wheat, and the oaks that grew in it were so large as to furnish acorns as big as apples. In its present state, however, though some oaks remain, and the traces of ploughed land are perceivable, Greenland is destitute both of corn and cattle; but its pasture is good, and if the soil were properly cultivated, it would probably yield grain. It produces excellent turnips and coleworts. The sides of the mountains near the bays are clothed with wild thyme, of powerful fragrance. The country abounds also with many other plants, and among its fruits we may reckon juniper-berries, blueberries, bilberries, and bramble-berries.

The animals which are most abundant, are rein-deer, dogs resembling wolves, (see *DOG*,) arctic foxes, and white or polar bears. Hares of different colours are common, but they are smaller than those of Denmark and Norway. The walrus, and five kinds of seals, frequent the shores. Here are found also ravens in great numbers, eagles of a very large size, falcons, and other birds of prey, and likewise a linnæus, which warbles very melodiously. Whales, sword-fish, porpoises, &c., abound on the coasts; and also halibut, turbot, cod, haddock, &c. The species of insects exceed 90. The more dubious animals, which are said to inhabit these seas, are the mermaids, sea-serpents, and krakens. The polar bears, seals, and manati, says Pennant, (*Arctic Zoology*,) were originally natives of these countries. The other quadrupeds found their way here from either Hudson's bay or Labrador, on the islands of ice. The arctic fox found the same kind of conveyance from Greenland to Iceland as it did with the rein-deer to Spitzbergen. To the last was wasted, probably from Labrador, the common weasel, the red or common fox, and the mouse, which missed Greenland, but stocked Iceland; and the common bat, which was originally tempest driven to the latter from Norway; the wolverene and varying hare never reached farther than Greenland. This, says Pennant, seems the progress of quadrupeds in the frigid zone, as high as land is found.

Greenland is thought to contain many mines of metal. To the southward of the Danish colony are some appear-

ances of a mine of copper; Mr. Egede once received a lump of ore from one of the natives, and here he found calamine of a yellow colour. Crantz observes, that the highest mountains of this country are on the west side, and the rocks are full of clefts, commonly perpendicular, and seldom wider than half a yard, filled with spar, quartz, talc, and garnets. The rocks are generally rather vertical or somewhat inclined, consisting of granite, with some sand-stone and lapis olariz. Crantz also mentions micaceous schistus, coarse marble, and serpentine; with asbestos and amianthus, crystals, and black schorl. It is said that fluete of argill, a new substance, has been recently found in Greenland; and this is perhaps the soft transparent stone of Crantz. The lapis olariz is of singular utility in Greenland, and the north of America, as it is used for lamps and culinary utensils.

The present inhabitants of the western coast of Greenland, and who are the descendants of the ancient Skrællings, whom we have already mentioned, and who exterminated the Iceland colony, very much resemble the American Samoieds and Laplanders in their persons, complexions, and way of life. They are without doubt a branch of the Esquimaux of Labrador, who fled that country, and peopled Greenland. They are short, brawny, and inclined to corpulency; with broad faces, flat noses, thick lips, black hair and eyes, and a yellowish tawny complexion. They are for the most part vigorous and healthy, but very short-lived, few reaching the grand climacteric, and many dying in their infancy, and in the prime of their youth. The sharpness of the wind, and the glare of the snow, render them subject to a disorder of the eyes. They are also afflicted with the leprosy; and those who inhabit the northern parts are miserably tormented with dysenteries, rheums and pulmonary disorders, boils, and epilepsy. The small-pox in 1734 made dreadful havoc among these people, who have no aid from medicine, and who depend merely on their "Angekoks," or conjurers. The Greenlanders, with regard to their constitutional temperament and disposition, are cold, phlegmatic, indolent, and dull of apprehension; but quiet, orderly, and good-humoured. They live peaceably together; and have every thing in common, without strife and animosity; and to strangers they are civil and hospitable. They never wash themselves with water, but lick their paws like the cat, and then rub their faces with them. They eat after their dogs without washing their dishes; devour the lice which devour them; and even lick the sweat, which they scrape off from their faces with their knives. The women wash themselves with their own urine, under a notion that it makes their hair to grow; and in the winter-time immediately expose themselves to the air, that the liquor may freeze upon their skin.

In their general habit and manner they are intolerably filthy. In times of scarcity they subsist on pieces of old skin, reeds, sea-weed, and a root called "tugloronet," dressed with train oil and fat. The dung of rein-deer taken from the intestines, the entrails of partridges, and all sorts of offals, are counted dainties among these savages; and of the scrapings of seal-skins they make delicate pancakes. The Danish provisions were at first tasted by them with disgust and abhorrence; but they are now become fond of bread and butter, though they still retain an aversion to tobacco and spirituous liquors. The Greenlanders in common content themselves with one wife, who is condemned to drudgery, and liable to be divorced at the pleasure of the husband. Persons of superior rank and qualities are, however, indulged with a plurality of wives. Their young women are generally chaste and bashful; nevertheless, at some of their feasts the men retire with the wives of their neighbours for licentious amours. Their superstitious customs are innumerable; e. g. when

GREENLAND.

a woman is in labour, the gossips hold a chamber-pot over her head, as a charm to hasten the delivery; and when a child is a year old, the mother licks and flabbers it all over, to render it, as she imagines, more strong and hardy. Their cloaths are made of the skins of rein-deer, seals, and birds. The men wear their hair short, commonly hanging down from the crown of their head on every side, and squared off at their foreheads. Some cut it off as high as their poll. But it would be a reproach to a woman to cut off her hair, which is never done except in cases of the deepest mourning, or if they resolve never to marry. All the Greenlanders speak the same language, though different dialects prevail in different parts of the country. Some few words are probably the relics of the old Norwegian; but these excepted, their language seems to have no affinity in etymology, declension, or signification, with any of the Northern, Tartarian, or Indian languages, as far as they are known to us; but we must except the language of the Esquimaux in Labrador, who seem, as we have already said, to be one people with the Greenlanders. Their great number of polysyllables, and of repeatedly combined words, make their language very intricate. Nevertheless, it abounds so much with words, that the Greenlanders, like the Chinese Tartars, have a proper word for every object or art that requires the least distinction. Besides, their words are varied and declined with such different modifications, yet according to a fixed rule with few exceptions, and are attended with prefixes and suffixes, far more than the Hebrew, that the language is not only graceful, but plain and unequivocal. Moreover, they join many words together, as we have already said, like the North Americans, so that they can express themselves very concisely and yet significantly. Some of our letters are wanting in their language, and they never begin a word with B, D, F, G, L, R, or Z. They seldom join many consonants together, and never at the beginning of a syllable. The accent, upon which much depends, must be laid upon the proper syllable, commonly the last; and the Greenlanders, especially the women, accompany many words, not only with a particular accent, but with a certain significant respect, which is necessary to be regarded in order to ascertain their meaning. They have but few adjectives, and these are mostly participles; they are placed after the substantive, which always begins the sentence. Substantives, as well as verbs, have singular, dual, and plural numbers, but no genders, and they want no article. The dual and plural are formed according to the different termination of the word, with few exceptions. The declensions are easy; the genitive has at the end a *h*, or if a vowel follows, an *m*, either by addition or change; and the rest of the cases have a preposition affixed to them. The pronouns are not placed before the word, but one or two of its letters are attached to it at the end, and in different ways according to the different numbers. They have only five prepositions, which are not set before the nouns, as in other languages, but at the end, and again are varied in declining. The verbs have been divided into five conjugations, according to their terminations. They have three tenses, the present, preterperfect, and future; and they have six moods, the indicative, imperative, permissive, conjunctive, and infinitive. The Greenlanders have no verbs deponent nor passive, but the latter are formed from the active by some adjunction. They have several classes of adverbs, like other nations; but their numerals are few, so that they can scarcely count five; but in order to arrive at 20, they count the fingers of both hands and the toes of both feet. If they want to proceed farther, they begin again with their fingers and toes. They tack their conjunctions to the end of a word, as the Latins do their

que; and they do not want interjections. Their syntax is simple and natural; the capital word stands in the front, and the rest follow in order according to their importance. Their style or mode of speaking is not at all hyperbolic, pompous, or bombast, like that of the orientals, but simple and natural; yet they are fond of similitudes and metaphors. Their poetry has neither rhyme nor measure; but it consists of short periods; which, however, are sung to a certain time and cadence.

The Greenlanders have no traditions of the most memorable events of their ancestors in heroic songs, as other nations have, who possess no written records. All they can say of their progenitors is, that they were brave seal-catchers, and that they killed the old Norwegians. Yet in their satirical songs, to which they are much addicted, they are more acute. They are well versed in genealogy, and can often trace their pedigree as far back as ten of their progenitors, together with all the collateral branches. Their imperfect arithmetic we have already noticed. Of writing they have no conception. On their first acquaintance with Europeans, they were frightened by speaking paper. In chronology, they reckon their years by winters, and their days by nights. They are not learned enough to fix the equinoxes, but they can guess at the winter solstice, within a few days by the sun-beams upon the rocks; and then they celebrate their new year by a sun-feast. From hence they reckon three full moons to the spring, and then they move from their winter houses into tents. In the fourth moon, *i. e.* in April, they know that the small birds make their appearance, and the ravens lay eggs. In the fifth their angmarfet, and the seals with their young ones give joy to their coasts by their revolutionary visit. In the sixth the eider-fowls breed. When they lose the moon in the bright summer nights, they carry on their calendar partly by the growth of eider-fowls, and size and shape of the seals, and partly by the shining of the sun on the dial of the rocks and mountains; so that they exactly tell when the seals, fishes, and birds will arrive in flocks and shoals here and there, and when it is time to repair to the winter-houses, in which they generally shelter themselves soon after Michaelmas. They divide the day according to the ebb and flood, and the night by the rising and setting of certain stars. They think the globe of the earth stands upon posts, which are so rotten with age, that they often crack; and that they would have sunk long ago, if they had not been kept in constant repair by the Angkoks, who sometimes bring back a piece of rotten wood as an evidence of their important service. Their astronomy makes the firmament to rest on a lofty pointed hill in the north, and on that centre it performs its revolutions. But this specimen is sufficient. When it thunders, two women are stretching and flapping a dried seal-skin, and the thunder is occasioned by that rattle. The mystery of the Aurora Borealis is unravelled by the souls of the dead frisking at a dance or a foot-ball. The rains are the overflowings of the celestial reservoirs; and if the banks should break, the sky would fall down. Such is their meteorology! In medicine and surgery they are no less ignorant than in the other sciences.

When a Greenlander is in the conflicts of death, they array him in his best cloaths and boots, and bend his legs up to his hips, probably that his grave may be the shorter. After death, they silently bewail him for a short hour, and next prepare for his burial. The corpse, being wrapped and sewed up in the man's best seal or deer-skin, is laid in the burying place, covered with a skin, and also with some green fods, and finally with heaps of great broad stones to keep off the birds and foxes. Near the burying spot they deposit the

the kajak and darts of the departed, and the tools he daily used; or if the deceased was a woman, her knife and sewing implements, that they might not be defiled by them, or sorrow too much on their account, or because they should want them in another world. After the interment, those who attended the procession, betake themselves to the house of mourning: then the men sit silent for some time with their elbows leaning upon their knees, and their heads between their hands; while the women lie prostrate upon their faces on the ground, and softly weep and sob. Then the nearest relation pronounces an eulogy, reciting the good qualities of the deceased, and at every period deploring his loss with loud crying and weeping. After this mournful ditty, the women continue their lamentations in a tremendous howl. This kind of mourning is continued for a week or a fortnight. The howling is after intervals renewed, and prolonged for some weeks, and in some cases for a whole year.

As for the religion, or rather the superstition of the ancient Greenlanders, they are reported to be such gross idolaters as to worship the sun, and sacrifice to the devil, that he might forward, or at least not hinder, their hunting and fishing. The first missionaries, however, conceived that the Greenlanders had no kind of religion or idolatrous worship; and that there was not any observable trace of their entertaining any conception of a Divine Being. Others, however, have thought, with greater reason, that a faint idea of the Divine Being lay concealed in the minds of these people, because they directly assented without any objection to the doctrine of God and his attributes. Among the Greenlanders, different opinions are entertained concerning the soul of man; some supposing that it is material or corporeal, and others that it is a spiritual essence, different from the body, and all material substances, and capable of surviving after death. They seem to have some confused and indistinct notions of a future state; of the place which is to be the final abode of good men; and of the nature of their reward. The most stupid Greenlanders, it is said, conceive a horror at the thoughts of the entire annihilation of the soul. They place their hell in the subterraneous regions, which are devoid of light and heat, and filled with perpetual terror and anxiety. The Greenlanders speak of other superior and inferior spirits, besides the soul of man, which bear some resemblance to the major and minor gods of the ancient heathens. Of the first rank there are only two; a good spirit and a bad one. Besides the great spirits to an audience with whom an *Angekok* only can be admitted, there are other lesser spirits in all the elements.

The Greenlanders believe in apparitions, of the ghosts of the deceased. The "*Angekoks*," are their forcerers or diviners, to whom peculiar privileges and honours belong. Although the Greenlanders have neither religion nor government, they are free from many of the grosser vices, which may be found among persons much more enlightened than themselves.

The traffic of the Greenlanders is very simple and concise, and is carried on altogether by barter. They very rarely cheat, or take the advantage of one another, much less steal, which they reckon infamous; but they glory in over-reaching, or robbing an European, because they think it is a proof of their superior wit and ingenuity. Their traffic is carried on partly among themselves, and partly with factors and seamen. Wherever there is a great assembly, or rendezvous of Greenlanders, as at a dancing match, or the sun-feast in winter, there are always some that expose their wares to view, and announce publicly what goods they want in exchange. As those in the south have no whales, and those

in the north no wood, many boats of the Greenlanders coast every summer out of the south, and even from the east side of the land, and proceed from two to four hundred leagues, as far as *Disko*, with their kajaks and women's boats, and the tackle and implements belonging to them, and barter wood for the horns of the unicorn fish, teeth, bones, whale-bones, and whale's sinews, and part of these they truck on their return home. In these voyages they take with them their whole family and substance; and sometimes form a new settlement in the course of their voyage. The Greenlanders vend their fox and seal-skins, and especially their blubber, to agents or factors, and receive in return iron points for their darts, knives, lock-saws, gimblets, chisels, and sewing needles; also, striped linen and cotton, kerseys, woollen stockings and caps, handkerchiefs, chests or boxes, wooden dishes, pewter plates, copper kettles, looking-glasses, combs, ribbons, and all sorts of toys for children. They are fondest of buying snuff, also guns, powder, and shot; tobacco, which they use only as snuff, serves instead of small money with them. Indeed, they expect a little tobacco for every service they perform.

The assembly for dancing, and the sun-feast above-mentioned, are not religious acts or ceremonies, but mere sports and amusements. The sun-feast is kept at the winter solstice, to rejoice at the return of the sun, and the renewal of good hunting and fishing weather. For this purpose they assemble all over the country in large parties, and treat one another in the best manner they are able. When they have gorged themselves with food, they rise up to play and to dance. The means of intoxication they do not possess, and drink only water. Their only musical instrument is the drum, which is beaten to common musical time. The music and dancing are accompanied with a song in honour of seal-catching, and such kinds of exploits; the performer extols the noble deeds of his ancestors, and expresses his joy at the return of the sun in the hemisphere. Every stanza of his ode is accompanied by the auditory. The following is a specimen of a complete cantata; the second and fourth lines expressing the chorus:

"The welcome sun returns again,
Amna ajah, ajah, ah-hu!
And brings us weather fine and fair,
Amna ajah, ajah, ah-hu!"

Such dancing meetings are appointed at other seasons of the year, when they have leisure to attend them. It is somewhat singular, and deserves mention, that they decide their quarrels by singing and dancing, and they call this a "*Singing Combat*." A Greenlander, who conceives himself injured, composes a satirical poem, and repeats it so often with singing and dancing, till his domestics, and particularly the women, are able to remember it. He then publishes a challenge that he will fight a duel with his antagonist, not with a sword but with a song.

The respondent appears in the appointed place; when the accuser begins to pronounce his satire to the beat of the drum, and his party join with repeating "*Amna ajah*," which occasions laughter among the attendants.

The defendant then retorts in the same manner, and the laugh changes sides; the plaintiff again renews the same kind of assault. The whole body of attendants constitute the jury, and confer the laurel on the victor, and afterwards the two contending parties are the best friends.

The Greenlanders are employed through the whole year in fishing or hunting. At sea they pursue whales, morse, seals, fish for food, and sea-fowl. On shore they hunt the rein-deer in different parts of the country. And they have

GREENLAND.

methods peculiar to themselves, and corresponding imple-
ments, for accomplishing their objects both by sea and land;
which we shall not here describe. The Greenland canoe, or
"kaiak," like that in Nova Zembla and Hudson's bay, is
about three fathoms in length, pointed at both ends, and
 $\frac{1}{2}$ of a yard in breadth. It is constructed of thin rafts
fastened together with the sinews of animals, and covered
with dressed seal-skin, both above and below, so that only a
circular hole is left in the middle, large enough to admit the
body of one man. Into this the Greenlander thrusts himself
up to the waist, and fastens the skin so tight about him that
no water can enter. Thus secured, and armed with a paddle
broad at both ends, he ventures out to sea in the most
stormy weather to catch seals and sea-fowl; and if he is
overfet, he can easily raise himself by means of his paddle.
The "kone-boat" is made of the same materials, but more
durable; and so large, that it will contain 50 persons with
all their tackle, baggage, and provisions. It is fitted with
a mast, which carries a triangular sail made of the mem-
branes and entrails of seals, and is managed without the help
of braces and bowlines. These kones are flat-bottomed,
and sometimes 60 feet in length. They are left to the con-
duct of the women, who are obliged to do all the drudgery,
including even the building and repairing of their houses,
while the men are wholly employed in preparing their hunt-
ing implements and fishing-tackle.

Greenland is a country very thinly inhabited. In winter
they live in houses and in summer in tents. The houses are
constructed of stones, on a sleep rock, with layers of earth
and sods between them. On these walls they rest the beam,
or connected beams, for the length of the house, being from
4 to 12 fathom; and over these they lay the rafters, with
small wood between them; the whole is covered with bil-
berry-bushes, and then with turf, with fine earth on the top.
Their houses have neither door nor chimney; the use of both
being supplied by a vaulted passage made of stone and earth,
entering through the middle of the house. The walls are
hung on the inside with old worn tent and boat skins,
fastened with nails made of the ribs of seals; and the roof
is covered with them on the outside. In these huts, so con-
structed, they are guarded from wind, damp, and cold.
The floor is divided into several apartments, separated by
skins, according to the number of families for which it is
designed. On these floors they sleep on pelts; and they
commonly sit in them all day long, the women cooking and
sewing, and the men carving their tackle and tools. On
the front wall of the house are several square windows, about
two feet in size, made of seal's guts and halibut's maws, and
sewed so neat and tight, that the wind and snow are kept
out, and the light let in. These huts are well warmed with
fires, and lighted by means of lamps filled with train oil,
and furnished with moss instead of a wick, which burns so
bright that the house is both lighted and warmed by it.
Over the lamp is suspended a bastard-marble kettle, in which
they boil all their meat; and over this again is a wooden
rack, on which they lay their wet cloaths and boots to dry.
On the outside of their dwelling-house they have their little
store-houses, in which they lay up their little stock of fish,
fish, train oil, and dried herrings; and close by their store-
houses they lay their boats, with their bottoms upwards,
under which they hang their hunting and fishing tackle and
their skins. Their summer tents are made with poles, put
together in a conical form, covered on the inside with rein-
deer skins, and on the outsides with seal-skins, doubled, or
so dressed that the rain cannot penetrate them. Crantz's
History of Greenland, vol. i.

GREENLAND, *East*, or *Spitsbergen*, was formerly con-

sidered as part of the continent of West Greenland; but it
is now known to be a collection or group of islands, varying
in their extent, and lying between $76^{\circ} 46'$ N. lat. the lati-
tude of the South Cape, and $80^{\circ} 30'$, the northernmost
point of the Seven islands, and between 9° and 23° E. long.
Sir Hugh Willoughby, who first discovered land in this
high northern latitude, A. D. 1553, called it *Greenland*;
conceiving it to be part of the western continent. It was
afterwards visited, A. D. 1595, by William Barentz and
John Cornelius, two Dutchmen, who claimed the honour
of the first discovery, and called the country "Spitsbergen,"
or sharp mountains from the numerous sharp pointed and
rocky mountains which they observed in it; and in order
to ascertain their own claims, they pretended that this was
not the country discovered by Sir Hugh Willoughby, which
in the maps and charts delineated by the Hollanders was
denominated "Willoughby land," though no such land
ever existed. It is moreover said, that before the voyage
of these Dutchmen, an English navigator, whose name was
Stephen Burrows, had coasted along a desolate country
from 78° to $80^{\circ} 11'$ N. lat. which must have been Spitsber-
gen. This country was also visited at different times by
navigators, who were employed in exploring a passage to
the East Indies by the north-pole; a project which was
suggested and strongly recommended by Robert Thorne,
a merchant of Bristol, as early as the year 1527. Bourne,
in his "Regiment of the Sea," written about the year 1577,
mentions this as one of the five ways to Cathay, and seems
to admit the practicability of it from a mistaken notion of the
mildness of the climate near the pole, owing to the constant
presence of the sun during the summer. In 1607, a voyage
was proposed by some London merchants, for the discovery
of a passage by the north pole to Japan and China, and it
was undertaken by Henry Hudson, who fell in with land to
the westward in 73° N. lat.; and soon after he fell in with
Spitsbergen, where he met with much ice; and this navi-
gator advanced to the latitude of $80^{\circ} 23'$; but he was pre-
vented from proceeding farther by the ice. In 1609, Jonas
Poole was appointed by the Muscovy company on the same
service; and he with much difficulty made the south part of
Spitsbergen, afterwards sailing along and sounding the coast,
giving names to several places, and making many very ac-
curate observations. Having twice attempted in vain to
get beyond $79^{\circ} 50'$, he was obliged to relinquish his object
and to return home. A second attempt in the following
year was equally unsuccessful. In the year 1614, another
voyage was undertaken, in which Baffin and Fotherby were
employed; and Fotherby made a second attempt in the
following year; but their progress was obstructed by the
ice. This country and the adjoining seas have since been
frequently resorted to by ships employed in the whale
fishery; but its situation was never accurately ascertained
till Captain Phipps (now Lord Malgrave) undertook a voyage
by order of his majesty George III. in the year 1773. He
found that the land, which was formerly supposed to extend
as far as 82° N. lat., terminated with the "Seven islands,"
the most northerly point of which does not exceed $80^{\circ} 30'$
N. lat. He observed other lands lying eastward at a con-
siderable distance; but Spitsbergen was found to be encom-
passed by water and in no part of it to be contiguous to the
continent of Asia. He explored, with a degree of resolu-
tion and perseverance that did honour to himself and his
associates in this expedition, the northern and western coasts,
though he was prevented by the ice from advancing so far
northwards as he wished; and he ascertained by accurate
observation the longitudes and latitudes of several points,
capes, and bays, which he visited. On his approach to the
land

land he picked up a piece of drift wood, which was found to be fir, and not worm-eaten; and upon standing close in with the land, the coast appeared to be neither habitable nor accessible; it was formed by high, barren, black rocks, without the least marks of vegetation; in many places bare and pointed, in other parts covered with snow, appearing even above the clouds; the vallies between the high hills were filled with snow or ice. "This prospect," he says, in his "Journal," printed in 1774, "would have suggested the idea of perpetual winter, had not the mildness of the weather, the smooth water, bright sun-shine, and constant day-light, given a cheerfulness and novelty to the whole of this striking and romantic scene." The current on this coast was found, both by the common and Bouguer's log, to run north half a knot an hour. The height of one mountain, above the level of the sea, was found by measurement with the megameter, to be 15,035 feet, but by M. de Luc's calculation from observations with the barometer it was found to be 1588.

Among the harbours in which captain Phipps anchored, we may mention a small bay to the southward of Magdalena Hook and Hamburgher's bay; the former in N. lat. $79^{\circ} 34'$, the same as Fotherby observed it to be in 1614: the high-water in this bay full and change at half an hour past one, or with a S.S.W. moon, which agrees exactly with Bassin's observation in 1613, the flood coming from the southward. Another anchoring place was Vogel Sang, N. lat. $79^{\circ} 50'$. E. long. $10^{\circ} 2' 30''$; the north easternmost point being the Cloven cliff, $79^{\circ} 53'$. E. long. $9^{\circ} 59' 30''$, a bare rock so called from the resemblance of its top to a cloven hoof, which appearance it has always exhibited, having been so named by some of the first Dutch navigators who frequented these seas. It is also nearly perpendicular, so that it is never disguised by snow, and on these accounts it is one of the most remarkable points on the coast. The southernmost land is a high bluff point, called by the Dutch Vogel Sang. This sound, though open to the northward, is not liable to any inconvenience from that circumstance, the main body of ice lying so near as to prevent any great sea; nor are ships in any danger from the loose ice setting in, as this road communicates with several others formed by different islands, between all which there are safe passages. To all the sounds and harbours formed by this knot of islands the old English navigators had given the general name of Fair Haven, of which Fotherby took a *plat* in 1614. In this situation Hackluyt's Head-land was found to be in N. lat. $79^{\circ} 47'$. E. long. $9^{\circ} 11' 30''$. The tide rose about four feet, and flowed at half an hour after one, full and change. The harbour of Smeerenberg, distant about 11 miles, N. lat. $79^{\circ} 44'$. E. long. $9^{\circ} 50' 45''$, has good anchorage in 13 fathom, sandy bottom, not far from the shore; and it is well sheltered from all winds. The island close to the place where our navigators lay is called Amsterdam island, the westernmost point of which is Hackluyt's Head-land; here the Dutch formerly used to boil their whale-oil, and the remains of some conveniences erected by them for that purpose are still visible. They once attempted to make an establishment, and left some people to winter here, who all perished. Nevertheless, as they seem to have died not through the intensity of the cold, but in consequence of being attacked by the scurvy, and as others, both English and Russian sailors, have wintered here, a colony might be settled in this country, if such an establishment were likely to answer any good purpose. The Dutch ships still resort to this place for the latter season of the whale fishery. The stone found in this country was chiefly a kind of marble, which dissolved easily in the marine acid. But our navigators perceived no marks

of minerals of any kind, nor the least appearance of present, or remains of former volcanos. Neither did they meet with insects or any species of reptiles; not even the common earth-worm. They saw no springs, or rivers; the water, which was found in great plenty, being altogether produced by the melting of the snow from the mountains. During their stay in these latitudes, they had no thunder or lightning. The sky was in general loaded with hard white clouds; so that neither the sun nor the horizon was wholly free from them even in the clearest weather. They could always perceive when they approached the ice, long before they saw it, by a light appearance near the horizon, which the pilots called the "blink of the ice." (See BLINK.) One of the most remarkable phenomena which this country exhibited was the "iceberg." (See ICEBERG.) Of the animals and plants of Spitzbergen, captain Phipps has given an account in the appendix to his Journal. The animals are the arctic walrus, the common seal, the arctic fox, the polar bear, the reindeer, the common whale, the fin fish; and the birds the eider-duck, the puffin, the alca alle, the fulmar, the colymbus grylle and troile, the northern diver, the larus rissa, arctic gull, and larus eburneus, the greater tern, the greater brambling, the sea-snail, the coal-fish, the prawn, the cancer-boreas, or singular species of crab, and cancer nujax, not before described, and also cancer ampulla, and cancer pilex; several species of vermes, and shell-fish. Among the plants are a small species of agrostis, several species of saxifraga, of bryum, of cochlearia, and of lichen.

GREENLAND, a town of America, in Rockingham county, New Hampshire, near the sea, five miles southerly from Portsmouth, incorporated in 1713, and containing 548 inhabitants.

GREENLAND Fishery. See WHALE FISHERY.

GREENLAND Company. A joint stock of 40,000*l.* was by statute to be raised by subscribers, who were incorporated for fourteen years from the first of October 1693, and the company to use the trade of catching whales, &c. into and from Greenland, and the Greenland seas; they may make bye-laws for government, and of the persons employed in their ships, &c. (Stat. 4 and 5 W. III. cap. 17.) This company was farther encouraged by parliament in 1696; but partly by unskilful management, and partly by real losses, it was under a necessity of entirely breaking up, before the expiration of the term assigned to it, ending in 1707. But any person who will adventure to Greenland for whale-fishing, shall have all privileges granted to the Greenland company, by 1 Anne, cap. 16 and thus the trade was again laid open. Any subjects may import whale-fins, oil, &c. of fish caught in the Greenland seas, without paying any customs, &c. stat. 10 Geo. I. cap. 16. And ships employed in the Greenland fishery are to be of such burden, provided with boats, so many men, fishing-lines, harping-irons, &c. and be licensed to proceed; and on their return shall be paid 20*s.* per ton bounty, for whale-fins, &c. imported. 6 Geo. II. cap. 33. See WHALE FISHERY.

GREENLAW, in Geography, a town of Scotland, which, though the county-town of Berwickshire, is an inconsiderable place, pleasantly situated in a plain, bathed by the Blackader or Blackadder. The acclivities of the neighbouring eminences are tolerably cultivated. In its vicinity, about midway between Greenlaw and Kelso, on a rising ground, is Herne castle, which commands a view of the greatest part of the Merse and Roxburghshire, and was celebrated during the contentions on the border. It was a noted place of defence, often besieged by the English, and demolished

GREENOCK.

lished by Cromwell. It is distant 37 miles S.E. from Edinburgh, and contains 1270 inhabitants.

GREENOCK, the principal sea-port town on the firth of Clyde, situated on the south bank of the river, about 24 miles below the city of Glasgow. The town of Greenock is pretty well situated for commercial purposes, but in other respects it is neither pleasant nor so circumstanced as to afford the prospect of any great increase either of extent or population. Indeed the great number of young men, who, from habits of imitation as in other sea port towns, early attach themselves to a seafaring life, must prevent of itself a great obstacle to the latter. The town of Greenock is held under and is entirely surrounded by the lands of sir John Stewart of Blackhall, bart., who is feudal superior, and no purchase or acquisition of ground, either for the purposes of extension or improvement, can be had from any other person. This must of itself render extension a matter of more difficulty than where there are many landed proprietors, the lands of some of whom, from the common casualties and vicissitudes of human affairs, must be occasionally in the market.

The harbour of Greenock is divided into two compartments, and is entirely surrounded by well-built and commodious quays of freestone. The entrance is narrow, and in the centre opposite to the end of the mid quay, which serves as the division of the harbours. The eastern harbour is shallow, and is therefore mostly frequented by coasting vessels, herring buxses, fishing boats, and other small craft. The west harbour, being considerably deeper, is the general resort of West Indian, American traders, and other vessels of greater burthen. In the west harbour is a very capital dry or graving dock, with flood gates to exclude the water, and capable of containing two large ships at the same time. It has been long in contemplation to improve the harbour of Greenock by the erection of wet docks, similar to those of London, Liverpool, Hull, and Leith, but probably from the difficulty of engaging the joint consent of the numerous interests concerned, and other causes, no steps have been hitherto taken for carrying this scheme into effect. The principal deficiency of the harbour of Greenock, exclusive of the ships bottoms taking the ground every ebb tide, arises from want of water, there being never more than seventeen or eighteen feet in the harbour, even at spring tides. Hence large vessels are obliged to discharge part of their cargoes into lighters in the roads before they can come into the harbour at all. This is of less consequence where the cargo is to be brought to Glasgow, if the weather be mild, but it is very inconvenient and expensive when the cargo is to be landed, and when the weather is boisterous. The whole rise of the tide at Greenock is only about twelve feet, whereas at Liverpool it is thirty-six and at Bristol forty-two. This also forms an additional disadvantage to the harbour of Greenock, and presents a very great obstacle to every plan of artificial improvement. With all these disadvantages, however, it has many advantages over the neighbouring harbour of port Glasgow, situated about three miles farther up the river. The chief obstacle to vessels of great burthen making any of these ports, is an immense bank of sand, accumulated for many ages in this *embouchure* of the Clyde by the current of the river, and which is sensibly though slowly increasing. Indeed nearly opposite to port Glasgow, this bank is entirely uncovered for miles at low water. Notwithstanding these natural disadvantages, the favourable situation of the Clyde for maritime intercourse with every part of the western hemisphere and the south of Europe, the great coasting trade with the western parts of England and Wales,

and with Ireland, and the extensive herring fishery, has raised Greenock to a high rank among the commercial ports of Britain, and has been productive of the acquisition of splendid fortunes to many of the principal inhabitants. As Greenock is not the seat of any staple manufactory, this carrying trade is her chief, and indeed may be fairly called her only support. During the American war, when the carrying trade was entirely suspended in some channels, and greatly impeded in all the others, a number of ship-owners fitted out their vessels as privateers, but in general these speculations were not productive of gain to the adventurers, and in some instances with serious loss. In the recent wars no attempts at privateering have been made.

The town of Greenock is governed by two magistrates, elected annually, and a council; besides whom, the baron baillie, nominated by the superior, also possesses a jurisdiction. The sheriff court of the county of Renfrew is held at Paisley, to which the inhabitants of Greenock are amenable, the same as the rest of the county.

In the external appearance of Greenock there is little elegance or splendour to be seen. In the centre of the town there is a small square, immediately fronting the mid-quay, which divides the harbour. In this square is a very handsome church of modern architecture. The other buildings are the inns, of which the chief, recently built upon a tonne scheme, like that of Glasgow, is a very spacious, and even splendid house. There is also a small neat theatre, the private property of Mr. Stephen Kemble, the manager, and some dancing-halls for the occasional recreation of the inhabitants and strangers, of whom, from the maritime situation, there is, at certain seasons, particularly at the arrivals of the West India fleets, a considerable influx.

The scenery of the Clyde around Greenock is picturesque and sublime. The river is about seven miles broad to the opposite shore, where the village of Helensburg is erected upon the property of sir James Colquhoun of Lufs, bart. This village is built in a very pleasant situation, upon a fine bay, formed by two projecting promontories, *viz.* by the hill of Ardmore, on the east, and by Roseneath, the property, and one of the splendid residences of the duke of Argyle, on the west. Beyond this, to the westward, appear the lowering mountains of Argyleshire, between which is the vast arm of the sea, Lochlong, which is twenty-four miles in length, and in some places said to be unfathomably deep. About two miles to the west is a small village, called Gourock, situated on a very fine deep bay, well sheltered by projecting head-lands, with a very good bottom for anchorage. It is the opinion of most professional men, whether engineers or seamen, that this situation affords by far the greatest number of natural advantages for a large and commodious sea-port upon the Clyde; and it is almost singular that Greenock should have risen to its present commercial importance, whilst Gourock, situated within less than two miles, and possessing every superiority of physical advantage, should have remained an insignificant village. However this may have originated, too much capital has now been expended upon Greenock and Port Glasgow, to leave the smallest room to suppose that they will be in any respect rivalled by a village which possesses nothing but natural situation to recommend it. On the road from Greenock to Gourock are many very fine villas, belonging to the opulent merchants of Greenock. At both Greenock and Gourock are extensive rope-works, belonging to the same company of proprietors. A little below Gourock is the Clough light-house, a very high and well-built tower, lighted by reflectors, for the safety of vessels coming up, or going down the channel during the night. Some miles below

this

this is the island of Bute, belonging chiefly to the nobleman to whom it gives the title of marquis. Bute is about seven miles long, and generally level and fertile. Mount-Stewart-castle, the residence of the noble proprietor, is situated near the middle of the island, on the south side, and is a superb and delightful place. Of the other proprietors, lord Bannatine, one of the Scottish judges, is the most conspicuous. The chief, and, indeed, almost only town on the island, is Rothsay, from which his royal highness the prince of Wales derives one of his Scottish titles, is a handsome, clean, small town, and has a considerable cotton mill and manufactory by it, belonging to a company of manufacturers in Glasgow. There are also the ruins of an old castle, which appears to have been of great extent, and once belonged to the royal family of Scotland. The inhabitants of Rothsay are chiefly sea-faring people, and employ themselves much in the herring fishery during the season. Large quantities of fine cod-fish are also caught off the coasts of Bute, Arran, and Argyshire, with which the markets of the west of Scotland are supplied, generally at a rate not exceeding two-pence *per* pound of 22½ ounces. Contiguous to Bute is a small island, called Inch Marnock, which is level and cultivated. It is the residence only of those employed in its cultivation. The island of Arran is nearly thirty miles in length, and is very mountainous. The highest hill, called Goatfield, is seen from a great distance. The island of Arran is the property of the duke of Hamilton, who is earl of Arran, who has a fine house, called Brodiek castle, on the island, where his family sometimes reside, especially during the season for shooting grouse or black game. Arran used to be much noted for a smuggling trade, both in contraband articles brought by the seamen employed in the vessels trading to the Clyde, and also in the distillation of whisky. The vigilance of the revenue cruisers in the Clyde has, in a great measure, checked the former, and that of the excise officers the latter. On Arran are found a number of fine stones, and it is sometimes visited by lapidaries, during the summer, for the purpose of searching for them, or of purchasing those occasionally picked up by the natives. On the island are only two small towns or villages, *viz.* Brodiek and Lamalisk, the latter of which, being defended from the south winds by an island in the mouth of the bay, is resorted to as a shelter in stormy weather by the ships and vessels navigating the frith of Clyde.

Besides those already mentioned, there are a few smaller islands in the frith, *viz.* the Cumbræes, which are two small islands lying pretty close to the southern shore, near the Renfrewshire coast, opposite to the village of Largs, about 16 miles below Greenock. The larger island is about two miles long, and on it is a very neat village, called Milport, chiefly inhabited by fishermen and seamen's families. The lesser island is a mere rock, where a few persons reside, who take charge of the light-house, and sometimes persons in a state of insanity are boarded here by their relatives, on account of the purity of the air, and the retirement of the situation. Farther down, and near the Ayrshire coast, is the stupendous rock, or crag of Ailfa, from which the proprietor, the earl of Cassius, derives his British title. Ailfa is a high abrupt and barren rock, totally uninhabited, and covered by myriads of sea-fowl, in search of which it is sometimes visited. Of the general trade of the Clyde notice has already been taken under the article GLASGOW.

GREENORE POINT, a cape of Ireland, in the county of Wexford, in the Irish sea. N. lat. 52° 16'. W. long. 6° 18' from Greenwich.

GREENSBORO, a post-town of America, in West Chester county, New York; 264 miles from Washington.

GREENSBOROUGH, a post-town and chief town of Greene county in Georgia, 30 miles from Lexington; containing 25 houses, a court-house, gaol, and Presbyterian meeting-house. Lands are appropriated for the establishment of an academy in this town.—Also, a neat township in Orleans county, in Vermont, containing 280 inhabitants.

GREENSBURG, a post-town and capital of Westmoreland county, in Pennsylvania, situated on a branch of Sewickly creek, which empties into Youghiogony river. It contains 100 dwelling houses, a German Calvinist church, a brick court house, a stone gaol, 270 miles W. by N. from Philadelphia.—Also, a post-town in Green county, Kentucky; 875 miles W. by S. from Washington.

GREENSVILLE, a county of Virginia, encompassed by Brunswick, Southampton, and Sussex counties, on the N. W. and E. and by N. Carolina on the S. It is about 24 miles long, and 20 broad, and contains 2611 free inhabitants, and 4116 slaves.

GREENVILLE, Sir RICHARD, in *Biography*, a gallant naval officer, son of Sir Roger, of an ancient family, in the west of England, was born about 1540. At the age of sixteen he obtained leave from queen Elizabeth, with others of his young countrymen, to serve in the imperial army in Hungary, against the Turks. Upon his return, he engaged with the troops employed for the reduction of Ireland, where he displayed so much courage and prudence, as to obtain the appointment of sheriff of the city of Cork. He sat in parliament in 1571, as knight of the shire for the county of Cornwall. He was afterwards high sheriff of the county, and received the honour of knighthood. Notwithstanding his civil employments, his attention was chiefly fixed upon plans of foreign discovery and settlement, proposed by his relation Sir Walter Raleigh. When the patents were made out for the purpose, Sir Richard obtained the command of a Squadron fitted out for the purpose, consisting of seven small vessels. With these he sailed in the spring of 1585, and reaching the coast of Florida in June, he left there a colony of one hundred men, and then sailed homewards. He made other voyages, but when the nation was threatened with the dangers of a Spanish invasion, he was appointed one of a council of war, to concert means of defence, and received the queen's commands not to quit the county of Cornwall, which prevented him from executing his intentions of making another voyage to the American coast. In 1591 he was appointed vice-admiral of a Squadron, fitted out for the purpose of intercepting a rich Spanish fleet from the West Indies. This fleet, when it appeared, was convoyed by a very superior force, and Greenville was urged to tack about, but he preferred, and no doubt his sailors agreed with him, taking chance of breaking through the enemy's fleet, which almost immediately surrounded him. The Spanish admiral, with four other ships, began a close attack at three in the afternoon; the engagement lasted till break of day next morning, during which the Spaniards, notwithstanding their vast superiority, were driven off fifteen times. At length the greater part of the English crew being either killed or wounded, and the ship reduced to a wreck, no hope of escape remained. The brave commander had been wounded at the beginning of the action, but he caused his wounds to be dressed on deck, and refused to go down into the hold, and in that state he was shot through the body. He was now taken to the cabin, and while in the act of being dressed, the surgeon was killed by his side. The admiral still determined to hold out, wishing rather to sink the ship than surrender, but the offers of quarter from the Spaniards induced the men to yield. Sir Richard was taken on board the Spanish ship, and honourably

ably treated, but he died of his wounds in less than three days. His last words shew the temper of the hero, better than any eulogium that could be formed for him; they were spoken in the Spanish language, "Here die I, Richard Greenville, with a joyful and quiet mind; for that I have ended my life as a true soldier ought to do, fighting for his country, queen, religion, and honour; my soul departing from this body, leaving behind the lasting fame, of having behaved as every valiant soldier is in duty bound to do." This noble minded man has been blamed for rashness; but excess of bravery, if such it may be denominated, in a British seaman meets with a ready pardon, and such examples as Greenville and a Nelson, though not always to be justified on the score of prudence, have effected more advantages for this sea-girt island, than can be well described. *Biog. Brit.*

GREENVILLE, *Sir BEVIL*, grandson of the preceding, was born in the year 1596. He was educated at Exeter college, Oxford, under the celebrated D. Prideaux, where he acquired a large stock of knowledge, and an ardent attachment to the established religion of his country. When he came to his estate he distinguished himself as a most respectable country gentleman, and sat, very often, in parliament, as knight of the shire for the county of Cornwall, and burgess of Launceston. In 1638, he attended the king with a troop of horse, raised at his own expence, in an expedition to Scotland. For this service he received at the hands of his sovereign the honour of knighthood. He distinguished himself during the civil wars, and had a command in the battle of Stratton, gained by Hopton against the earl of Stamford, in May 1643. He was present, and made a considerable stand in other engagements, particularly in that which was fought at Lansdown, near Bath, in which the parliament forces were commanded by sir William Waller. In this action sir Bevil, at the head of his Cornishmen, received a fatal blow with a pole-ax. His body was afterwards found, surrounded by those of his officers; and it was observed, to the honour of the gentlemen of England, that there were more officers and gentry, than common men, slain on the king's side. Sir Bevil was extremely lamented: his character was drawn by lord Clarendon: "That which would have clouded any victory, was the death of sir Bevil Greenville. He was, indeed, an excellent person, whose activity, interest, and reputation was the foundation of what had been done in Cornwall, and his temper and affection for public, that no accident which happened could make any impression on him; and his example kept others from taking any thing ill, or at least seeming to do so: in a word, a brighter courage and gentler disposition were never married together, to make the most cheerful and innocent conversation." A monument was erected to his memory on the spot on which he fell. *Biog. Brit.*

GREENVILLE, in *Geography*, a county in Washington district, South Carolina; situated in the N.W. corner of the state; containing 11,504 inhabitants, of whom 1,439 are slaves. This county is mountainous and hilly; but it is well watered, and the climate is pleasant and healthy.—Also, a post-town of South Carolina, and chief town of Cheraws district; situated on the W. side of Great Pedee river, in Darlington county. It contains about 30 houses, a court-house, gaol, and academy; 55 miles E.N.E. from Camden.—Also, a post-town and capital of Pitt county, North Carolina, on the S. bank of Tar river, distant 23 miles from Washington, and containing about 50 houses, a court-house, a gaol, and a seminary, called the Pitt academy.—Also, a post-town of Mecklenburg county, Kentucky; 766 miles W. by S. from Washington.—Also, a post-town in Jefferson county, Missi-

ssippi territory; 1217 miles from Washington.—Also, a small post-town in Green county, in the state of Tennessee, situated on the W. side of the north-easternmost branch of Nolachucky river, about six miles N. by E. of Greenville college; 653 miles S.W. of Philadelphia.—Also, a fort and settlement in the state of Ohio, on the S. side of a north-western branch of the Great Miami, six miles N.W. of fort Jefferson, on the same branch, about 23 miles S.E. of fort Recovery. It has bastions at each angle, and is capable of accommodating 2000 men.

GREENVILLE Bay, or *La Bay*, a town and port of entry on the E. or windward side of the island of Grenada. It has about 60 dwelling-houses, a church, and several rich stores of Indian and European goods, and plantation utensils. Its situation is low and rather unhealthy.

GREENVILLE College, a college in Green county, in Tennessee, founded in 1794, by the first act of the first assembly of the south-western territory. It is situated between two small northern branches of Nolachucky river, not far from Greenville, (which see) the county town. Its local situation conduces very much to its utility, as it is retired, healthy, cheap, and near public roads in every direction. It is under the management of 14 trustees, and possesses a library of between one and two thousand volumes, and philosophical apparatus, and a convenient building.

GREENWICH, a market-town and parish in the hundred of Blackheath, and county of Kent, England, is situated on the banks of the Thames, adjoining to Deptford, and 5½ miles distant from London. There are traces of a royal residence at Greenwich so early as the reign of Edward I., A.D. 1300. Henry IV. dated his will in 1408 from this manor, which was granted by Henry V. to Thomas duke of Exeter, after whose death it was conferred on Humphrey duke of Gloucester, uncle to Henry VI., who, in 1433, gave the duke licence to fortify and embattle his manor-house, and to make a park of 200 acres; under this grant the duke rebuilt the palace, and inclosed the park, in which he erected a moated tower. On the duke's death in 1447, the manor reverted to the crown; and was a favourite residence of Edward IV., who enlarged and finished the palace. Henry VII. spent much of his time at Greenwich, where his two sons, Henry and Edmund, were born. Henry VIII. made considerable additions to the buildings, and during his reign Greenwich became one of the principal scenes of that festivity for which his court was celebrated. Tournaments and revels were frequently held; and in 1513 the first masquerade ever seen in England was here introduced. Edward VI. kept his Christmas here in 1552, and died in this palace in July following. The queens, Mary and Elizabeth, were both born here, and the latter chrillened with peculiar state. She was particularly partial to this mansion, and made it her summer residence, passing the festive hours of that romantic period in various diversions and splendid exhibitions. This palace was frequently visited by James I. and Charles I.; was afterwards assigned by parliament to the Protector; and, after the restoration, again devolved, with the park and appendages, to the crown: when the king, finding the whole building in a ruinous state, ordered it to be pulled down, and commenced a magnificent palace of free-stone on its site, under the direction of Webb, the son-in-law of Inigo Jones, from whose papers the designs are said to have been made. One wing, however, was all that was completed, at the expence of 36,000*l.*, in which the king occasionally resided; but no further progress was made in the building either in that or the succeeding reign. Soon after the accession of William and Mary, a project was formed for providing an asylum for aged and disabled seamen;

GREENWICH.

men; and their majesties having resolved to carry it into execution, sir Christopher Wren recommended that the unfinished palace at Greenwich should be completed and enlarged for this purpose. His advice being adopted, he contributed his time and abilities in the superintendance of the works for several years without any emolument. Such was the origin of Greenwich hospital, of which the foundation was laid June 3, 1696, and which has been gradually enlarged and improved, till it arrived at its present height of magnificence. The hospital is a splendid and extensive structure, principally built with Portland stone, and consists of four distinct quadrangular piles of buildings, distinguished by the names of the respective sovereigns, in whose reigns they were founded or built. The grand front opens on a terrace, skirting the southern bank of the Thames, and extends 865 feet in length, in the centre of which is a descent to the river, by a double flight of steps. The ground plan of the whole edifice forms nearly a square; of which king Charles's building occupies the north-west angle; queen Anne's, the north-east; king William's, the south-west; and queen Mary's, the south-east. The interval between the two former buildings forms a square 270 feet wide, in the middle of which is a statue of George II., sculptured by Rybrach, out of a single block of white marble, which weighed eleven tons, and was taken from the French by admiral sir George Rooke: this statue was given to the hospital by sir John Jennings, who was governor from 1720 to 1744. The space between the two latter buildings which include the hall and chapel, with their elegant domes, and the two colonnades, forms a lesser square, apparently terminated by the ranger's lodge in the park. The two squares are intersected by a spacious avenue, leading from the town through the hospital. The buildings which immediately front the Thames have a general correspondence in style and arrangement. The north and south fronts of each exhibit the appearance of a double pavilion, conjoined above by the continuation of an Attic order, with a balustrade, which surmounts the whole, but is separated below by an open portal: the centre of each pavilion displays an elegant pediment, supported by four Corinthian columns, and the sides a double pilaster of the same order. King Charles's building contains the apartments of the governor and lieutenant-governor, the council-room, and anti-chamber; with fourteen wards, wherein 300 pensioners may be accommodated. In the council-room are several portraits: in the anti-chamber two large sea-pieces, given to the hospital by Philip Harman, esq., representing the exploits of his ancestor captain Thomas Harman of the Tyger frigate, in the reign of Charles II.; and a series of six small pieces, descriptive of the loss of the Luxemburgh galley, in the year 1727. Queen Anne's building contains several apartments for inferior officers, with twenty-four wards, for four hundred and thirty-seven pensioners. King William's building stands to the south-west of the great square, and comprises the great hall, vestibule, and dome, designed and erected by sir Christopher Wren, between the years 1698 and 1703. To the east of these adjoins a colonnade, three hundred and forty-seven feet in length, supported by Doric columns, and pilasters twenty feet in height. The great hall is one hundred and six feet in length, fifty-six in width, and fifty high: the ceiling and sides are covered with portraits and emblematical figures, executed by sir James Thornhill, for which he was paid at the rate of 3*l.* per square yard for the ceiling, and 1*l.* for the sides, amounting in the whole to 6685*l.* The west front of King William's building, which is of brick, was finished about 1725 by sir John Vanbrugh: the building contains eleven wards, wherein are five hundred and fifty-one beds. The foundation of

the eastern colonnade, which is similar to that on the west side, was laid in 1699; but the chapel, and the other parts of queen Mary's building which adjoin to it, were not finished till 1752. It corresponds with king William's, and is furnished with one thousand and ninety-two beds, in thirteen wards. The present chapel, one of the most elegant specimens of Grecian architecture in this kingdom, was erected from the classical designs of the late James Stuart, esq., better known, perhaps, by the appellation of "Athenian Stuart," which he acquired from the Attic elegance of his buildings, and his interesting publication on the antiquities of Athens. The chapel is one hundred and eleven feet in length, and fifty-two in width, and is capable of accommodating one thousand pensioners, nurses, and boys, exclusive of the seats for the directors and other officers. The portal consists of an architrave, frieze, and cornice, of statuary marble: the folding-doors are of mahogany, highly enriched by carving. The interior is finished in an elegant style; and is adorned with many appropriate paintings; the most distinguished of which is the altar-piece, executed by West, and representing the preservation of St. Paul, on the island of Melita; a subject peculiarly adapted to this establishment. Without the walls of the hospital stands the Infirmary, erected in 1763, after a design by Stuart: it forms an oblong quadrangle, one hundred and ninety-eight feet long, and one hundred and seventy-five broad; and consists of two stories for the reception respectively of those whose cases require surgical aid, and of those who are in need only of medical assistance. It contains sixty-four rooms, each is fitted up for the accommodation of four patients. It also includes a chapel, hall, kitchen, and apartments for the physician, surgeon, and apothecary; with hot and cold baths, and other necessary offices. The pensioners, who are the objects of this noble charity, must be seamen disabled by age, or maimed, either in the king's service, or in the merchant service, if the wounds were received in defending or taking any ship, or in fight against a pirate; foreigners who have served two years in the British navy, become entitled to the benefits of this institution in the same manner as natives. The widows of seamen are provided for, having the exclusive privilege of being nurses in the hospital. The number of pensioners is upwards of 2400, who are furnished with clothes, diet, and lodging, with a small allowance of pocket-money. The nurses are 144, each of whom receives eight pounds per annum as wages, with every necessary of life. The governors of the hospital are about 100, and consist of all the great officers of state, the archbishops, the lord chancellor, the judges, the master and five senior brethren of Trinity-house, the lord mayor, and three senior aldermen of London, with some of the principal officers of the hospital. The annual average expence of each pensioner, according to the report of the commissioners of naval enquiry, was estimated at 27*l.* 10*s.* 9*d.* per man; and of the nurses, 29*l.* 15*s.* 0*d.* each; the total annual expence being 69,206*l.* 5*s.* The funds of the establishment are principally derived from a duty of sixpence per month, paid by every mariner, either in the king's or merchant's service; the forfeited estates of the earl of Derwentwater; and various benefactions from different sovereigns, from parliament, and from private persons.

The old tower at Greenwich, built by duke Humphrey, temp. Henry VI. was pulled down in 1675, by order of Charles II., who founded on its site the present Royal Observatory, for the purpose of ascertaining the motions of the moon, and the places of the fixed stars, in order to facilitate the attempts to discover the longitude at sea.

Mr. Flamsteed, the first astronomer royal, began his observations

servations in September 1676, and did ample justice to his appointment, though walking in an almost untrodden path, and not having, till 1689, the advantage of a mural quadrant, and even then not such as is now in use, but one contrived by himself. He died in December 1719, and was succeeded by Dr. Halley, who fixed a transit instrument, and had a new mural quadrant of eight feet radius, constructed by Graham. On the death of Dr. Halley, in 1742, Dr. Bradley was appointed: in his time very valuable additions were made to the instruments at the observatory. Dr. Bradley, dying in 1762, was succeeded by Mr. Bliss, whose decease, in 1764, made room for the advancement of Dr. Maskelyne, the present astronomer royal, who has displayed eminent ability in his situation. Since his appointment, the observatory has been furnished with an excellent achromatic telescope, of forty-six inches, focal length, with a treble object glass, &c. by Dollond; and the whole astronomical apparatus has been greatly improved by Dollond, Nairne, and Arnold. The observations made by the astronomer royal have been, since 1767, published annually under the inspection of the Royal Society, who have the power of visiting the observatory every year, to see that the instruments are kept in proper order.

The church at Greenwich is dedicated to St. Alphage, archbishop of Canterbury, who is said to have been killed by the Danes on its site: it is one of the fifty new churches erected in the reign of queen Anne; the old church having become so ruinous by lapse of time, that the roof fell in about midnight, November 28, 1710. At the end of the town is the duke of Norfolk's college, for the maintenance of 20 decayed housekeepers. Here is also an hospital for 20 poor persons, founded by Mr. Lambarde, author of the "Perambulation of Kent," and called queen Elizabeth's college. There was a convent of friars at Greenwich, founded about the time of Edward IV. For many years here was a considerable powder magazine, which, after repeated application to parliament by the inhabitants, was removed to Purfleet in Essex, in 1760.

The population of Greenwich, as returned under the late act, was 14,339; the number of houses 2,121; many of these are handsome buildings; the streets are irregular, and the whole town is intersected by the hospital and its precincts. Fairs for three days are held at Easter and Whitsuntide; and well supplied markets every Wednesday and Saturday. *Joyson's Environs of London*, vol. iv. *Beauties of England and Wales*, vol. vii.

GREENWICH, a township of America, in Hampshire county, Massachusetts, incorporated in 1754, and containing 1,460 inhabitants; 20 miles E from Northampton.—Also, a township in Gloucester county, New Jersey, on the E. bank of Delaware river, opposite to Fort Mifflin; 6 miles S. E. of Philadelphia.—Also, a township in Sussex county, New Jersey, on the E. side of Delaware river, in a mountainous country, 31 miles S. W. of Newton; it contained, in 1790, 2,035 inhabitants.—Also, a town in Cumberland county, New Jersey, on the N. W. bank of Cobanzy creek, about 3 miles from its mouth, in Delaware bay, containing about 80 houses and a Friends' meeting-house; 66 miles S. by W. from Philadelphia.—Also, a maritime and post-town in Fairfield county, Connecticut, 40 miles E. of New York, and containing 3,147 inhabitants.—Also, a town in Washington county, New York, on the E. bank of Hudson's river. At the saw-mills of this town much business is done.

GREENWICH, *East*, a post-town, and the chief township in Kent county, Rhode island, distant 16 miles S. from Providence, and containing 1,775 inhabitants. It includes

a meeting-house and a handsome court-house; and though its commerce is much reduced, it derives advantage from its fisheries, and sends some vessels to the West Indies. It is situated on the N. W. part of Narraganset bay. It is noted for its good cyder, and formerly raised tobacco for exportation.

GREENWOOD, a township in Cumberland county, Pennsylvania, having 724 inhabitants.—Also, a township in Missin county, in the same state, containing 969 inhabitants.

GREEN WOODS, a large forest of stately pines in Litchfield county, Connecticut, covering part of that county, and clothed in a green bearded moss, which gives to the whole a gloomy, wild, and whimsical appearance.

GREES, a river of Ireland, in the county of Kildare, which flows by the pretty town of Ballitore, and joins the Barrow; 6 miles S. from Athy.

GREESA, a town in Algiers; 30 miles E. S. E. of Tiffesh.

GREGARIOUS BIRDS, are such as do not live solitarily, but associate in flights or coveys, a great many together in company.

GREGARIOUS, in *Geology*, is applied to such reliquia or extraneous fossils, found imbedded in the strata, as are congregated a great number of the same species together, which very commonly is the case, particularly in calcareous rocks.

GREGGIA, in *Botany*, so named by the late Dr. Solander, in compliment to Mr. John Greg, a gentleman long resident in Dominica, the correspondent of Ellis, Garden, and other naturalists of his day. He sent many plants to Kew and other collections, and returned to England about the year 1784, dying some years afterwards, at his seat near Hampton Court.—*Gærtn. t. 33.* (*Myrtus Gregii*; *Swartz. Ind. Occ. 896.* *Ait. Hort. Kew. vol. ii. 159.* *Mart. Mill. Dict. v. iii.*) See **MYRTUS**.

GREGOIE, or **GREBOU**, in *Geography*, a small island of Africa, in the river Jacquin, about a league from the sea, on the Gold Coast, where the European nations have factories.

GREGORIAN CALENDAR. See **CALENDAR**.

GREGORIAN Chant. See **CHANT**.

GREGORIAN Code. See **CODE**.

GREGORIAN Epocha, is the epocha, or time, whence the Gregorian calendar or computation took place. The year 1810 is the 228th year of the Gregorian epocha.

GREGORIAN Notes, in *Ecclesiastical Music*. In the Romish missals, breviaries, antiphonaries, and graduals, only four lines are used in the notation of the chants; with two clefs, the base and tenor, or those of F and C, which are removable; and two kinds of notes, the square and the lozenge; the first for long syllables, and the second for short. In some modern French missals a third species of note is used, generally at a close; this is square with a tail added to it, and is of longer duration than either of the other two. However, the Italians seldom use any other than square notes in their canto fermo, nor did the French, in their more ancient books.

These characters are not supposed to have been invented by St. Gregory, nor were they in use till many ages after his time; but since their invention, having been appropriated chiefly to the purpose of writing ecclesiastical chants in the antiphonary of that pontiff, they obtained the appellation of Gregorian notes.

GREGORIAN Year. See **YEAR**.

GREGORIO de Puerto Viejo, in *Geography*, a district and

and town of South America, in the audience of Quito, and jurisdiction of Guayaquil.

GREGORIO, *St.* a town of Naples, in Principato Citra; 8 miles N. W. of Cangiano.

ST. GREGORIO *de Abo*, a town of New Mexico; 110 miles S. of Santa Fé.

GREGORIUS, in *Ichthyology*. See SALMO *lavaretus*.

GREGORY I. in *Biography*, pope, furnished the Great, and also dignified with the title of Saint, was a native of Rome, and born about 544 or 5. He was descended from one of the most illustrious families in that city, and was educated in a manner suitable to his rank. His proficiency in literary pursuits answered the most sanguine expectations of his friends; it was said that none in Rome excelled him in grammar, rhetoric, and logic. Having left the usual routine of school learning, in the course of which he had imbibed sentiments of deep piety, as well as the elementary principles of knowledge, he paid particular attention to the study of jurisprudence, which was necessary to persons who filled those stations, to which he was entitled by his birth. When he came under public notice, he discovered such abilities, integrity, and prudence, in the exercise of the different senatorial employments, that the younger Justin, who was emperor, appointed him to the honourable post of governor of Rome. In this office he acquitted himself to the satisfaction of the emperor, of the senate, and of the people. At the death of his father, he became possessed of immense wealth, and being, probably from some disappointments, disgusted with the world, he determined to embrace the religious life. He devoted the greater part of his property to the foundation of religious houses, and to charitable purposes. He founded six monasteries in Sicily, and one at Rome in his father's house, dedicated to St. Andrew, over which he constituted Valentius abbot, whom he had selected for that post from a country monastery, and to whose discipline he submitted himself. From the time of his taking the vows, he abandoned himself to meditation, devotion, and the most rigorous abstinence. He was, however, in the year 579 taken from his retreat, ordained deacon, and sent nuncio from the pope to the imperial court: the object of this mission was to apply for relief in behalf of the inhabitants of Italy, against the ravages of the Lombards. So ably did he conduct the business, that the emperor was entirely satisfied, and Gregory became one of his principal favourites: he was equally beloved by the principal courtiers, and even by the bishops, notwithstanding the jealousy which they usually entertained of a pope's nuncio. While he was at Constantinople, he had a dispute with the patriarch Eutychius, on the question, Whether, after the resurrection, the bodies of the righteous would or would not be palpable. The argument was carried on in the presence of the emperor Tiberius; Gregory maintained the affirmative side of the question, to which the emperor gave his decided sanction, at the same time, he ordered the patriarch to acquiesce in the judgment, and condemned to the flames a treatise of that prelate in support of the negative side of the question. In 583 Gregory was recalled to Rome, and appointed secretary to pope Pelagius, until he obtained permission to retire to his monastery. He was chosen abbot; and in that office exacted of his monks as strict an observance of rigorous abstinence and discipline, as he practised himself. After a short exercise of the monastic virtues, he was dragged from the cloister to the papal throne, by the unanimous voice of the clergy, the senate, and the people. He alone resisted his own elevation: and his humble petition, that the emperor would be pleased to reject the choice of the Romans, could only serve to exalt his character in

the eyes of the emperor and the public, and he not only confirmed the wishes of the people, but congratulated the Romans on the choice which they had made. When the mandate was proclaimed, Gregory solicited the aid of some friendly merchants to convey him in a basket beyond the gates of Rome, and he concealed himself a few days in the mountains, and among the woods, where he believed, or affected to believe, that he should be safe from discovery. Notwithstanding this precaution, he was in a few days found in a cave, and brought back in triumph by the people, who would not abandon their charge, till they had taken him to the church of St. Peter, where he was instantly ordained. The pontificate of Gregory the Great, which lasted rather more than six years and a half, is reckoned one of the most flourishing periods of the church; his virtues, and even his failings, were happily suited to his station, and to the temper of the times. His first step was to satisfy the bishops of the chief sees, as to the orthodoxy of his faith. For this purpose, he wrote to the patriarchs of Constantinople, Alexandria, Antioch, and Jerusalem, declaring that he received the first four councils as the four books of the holy gospel; that he revered the fifth, and that he condemned the three chapters. In his rival, the patriarch of Constantinople, he condemned the Anti-christian title of universal bishop, which the successor of St. Peter was too laughty to concede, and too feeble to assume; and the ecclesiastical jurisdiction of Gregory was confined to the triple character of bishop of Rome, primate of Italy, and apostle of the West. He frequently ascended the pulpit, and kindled by his eloquence the congenial passions of his audience: the language of the prophecies of the Old Testament he interpreted and applied, and he took the opportunity of improving the present calamities of the people, by directing their hopes and anxieties to the invisible world. His precepts and example defined the model of the Roman liturgy; the distribution of the parishes, the calendar of festivals, the order of procession, the service of the priests and deacons, the variety and change of sacerdotal garments. Till almost the last period of his life, he officiated in the canon of the mass, which continued above three hours at a time. Gregory was no friend to heretics: he spared no pains to arm the civil and ecclesiastical power against the Donatists in Africa, and all who favoured them. At first, he was defeated in his wishes to destroy the harmony that subsisted between the Catholic and Donatist parties in that country: he contrived to introduce invidious distinctions, which by degrees renewed the animosities by which they had been formerly distracted, and terminated in the ultimate triumph of the Catholic, which was the strongest party. Notwithstanding the zeal of pope Gregory against the heretics, he was favourable to the Jews, and protected them against some violent Christians. In certain letters, which he wrote to the bishops who were for forcing them to embrace Christianity, he condemned persecution of all kinds in the strongest terms, though he enforced it in the instance of Christians, who ventured to differ from the Catholic creed. On his accession to the papal throne, a general relaxation of discipline, as well as of piety and morals, prevailed in the clerical orders: he immediately set about the correction of these evils with the utmost diligence and perseverance. While Gregory was enforcing reformation on the clergy, he set before them an example of the conduct which he prescribed. He was strictly attentive to the duties of piety: he was humble, mild, compassionate, hospitable, and disinterested, an enemy to all pomp, grandeur, and show, frequently abridging himself of the necessaries of life to relieve the indigent, and was most indefatigable in instructing his flock, both by preaching and writing. With

all his humility, however, Gregory was a most zealous assertor of the power and prerogatives which his predecessors had exercised, or at any time claimed. He would declare, and no one seemed to doubt the sincerity of his assertion, that he would rather lose his life, than suffer the see of St. Peter to forfeit any of the privileges which it had ever enjoyed, or the prime apostle to be any ways injured, or robbed of his rights. In the year 593, the emperor issued an edict, forbidding any soldiers to quit the army, under the pretence of embracing a monastic life, till the time of their service was expired. The pope determined to remonstrate against the decree, being persuaded that the ecclesiastical road was more safe than any other to the attainment of a heavenly crown. For this and some other acts of interference, the emperor expressed his dissatisfaction with the steps taken by the pope, in strong and even abusive terms, and they proved the means of frustrating his application for a redress of grievances occasioned by the cruelty and avarice of the imperial officers. The king of the Lombards threatened to lay siege to Rome, in order that he might avenge himself of some circumstance that had happened contrary to his dignity, but Gregory made friends with his favourites, who had themselves embraced the Catholic faith, and by their intercessions the prince was induced to draw off his troops. About this time the patriarch of Constantinople assumed the title of "Universal Patriarch," a measure which alarmed Gregory, who made every exertion to prevent him from making good his claims. All his entreaties were vain, the patriarch established his title, and entailed it on his successors. When Gregory was informed of this he renounced the patriarch's communion, and condemned his conduct on the occasion as vain, ambitious, profane, impious, execrable, anti-christian, blasphemous, infernal, and diabolical. In the year 596, Agilulph, king of the Lombards, broke into the imperial territories, laying waste the Roman dukedom of Campania, and carrying away the inhabitants into captivity. On this occasion Gregory exercised the most unbounded charity, in relieving the poor, and redeeming great numbers of prisoners, not only applying the revenues of his see to those benevolent purposes, but large sums which he obtained by his application to the bishops, and the great men who were his friends, both in the East and West. Under his reign the Arians of Italy and Spain were reconciled to the Catholic church, and the conquest of Britain reflects less glory on the name of Cæsar than on that of Gregory I. Instead of six legions, forty monks were embarked for that distant island, and the postiff lamented the austere duties which forbade him to partake the perils of their spiritual warfare. In less than two years he could announce to the archbishop of Alexandria, that they had baptized the king of Kent with ten thousand of his Anglo-Saxons, and the Roman missionaries, like those of the primitive church, were armed only with spiritual and supernatural powers. The credulity or the prudence of Gregory was always disposed to confirm the truths of religion by visions and pretended miracles, and he accordingly acquired a high reputation with his own and succeeding ages. The patriarch of Constantinople dying, he was succeeded by Cyriacus, whose faith was deemed orthodox by the pope, but who persisted in claiming the title "Universal Patriarch." Gregory still resisted, and in the course of the correspondence which he maintained with the patriarchs of Antioch and Alexandria to interest them on his side of the dispute; the last mentioned prelate gave him the title of "Universal Pope," in hopes thereby of terminating the difference between the contending parties. Gregory, however, rejected the title with great indignation, and by way

of contrast to the patriarch's conduct, he adopted the appellation of "Servant of Servants," which his successors have retained to this day, and affected to use it even when distinguished by the most scandalous exercise of pride and despotism. In the year 1601, at the request of Augustin; the pope sent a fresh colony of monks into Britain, and with such directions to that apostle of the Anglo-Saxons, as he has been denominated, as have proved the means of introducing the grossest corruptions and superstitions into the system of Christianity established through his mission. During this same year Serenus, bishop of Marzeilles, ordered all the images throughout his diocese to be cast out of the churches and destroyed: his conduct was not quite approved by Gregory, though he pretended to applaud Serenus's zeal, in not suffering any thing to be worshipped that is made with hands. Nevertheless, he condemned his casting them out of the churches and dashing them to pieces, as the effect of an inconsiderate and indiscreet zeal, observing, that "though images were not set up in the churches to be worshipped, yet they serve to instruct the ignorant: and it is one thing to adore an image, and another to learn from an image what is to be adored." During the year 602 a revolution took place at Constantinople, in consequence of the revolt of the army, at the instigation of Phocas, a centurion, who was proclaimed emperor, and obtained possession of the imperial city and throne. The first object of the new sovereign was to destroy the abdicated prince, with his six sons and a number of his relations and friends, and then he got himself acknowledged lawful emperor in all parts of the empire. On this occasion, Gregory expressed his utmost satisfaction and joy at the change that had taken place, without hinting that he felt any sorrow at the means by which it had been accomplished. He immediately wrote letters to the new emperor, congratulating him on his accession to the imperial crown, which he said was effected by a particular providence, to deliver the people from the oppressions under which they had so long groaned, and he even commended, flattered, and extolled the tyrant, for his justice, clemency, and piety, in the most fulsome terms. His object in this subject behaviour was that he might, by means of the influence of the emperor, defeat the attempt of the patriarch to assume the title of "Universal Bishop." This he plainly told to Leontia, the new empress, representing to her what blessings they might expect from St. Peter in heaven, provided they obliged the patriarch to relinquish the title, which the pope considered derogatory to the honour, dignity, and interests of his see. In this object he succeeded, for Phocas enacted a law, by which he prohibited the bishop of Constantinople from styling himself oecumenical or general patriarch, declaring that this title belonged to none but the bishop of ancient Rome. This was not the only instance in which Gregory condescended to flatter base and infamous characters: he shewed equal or even greater complaisance to Brunehaut, queen of France, who is described by Bayle as the most wicked woman upon earth, but as capable of winning over the clergy to her interest, because at the same time that she committed the most enormous crimes, she was excessively liberal to ecclesiastics, and founded temples and convents, not forgetting to sue very devoutly for relics to the holy father. In all the letters which the pope wrote to her, he treated her with the most abject flattery, declaring that no nation in the world was so happy as the French, since it merited such a queen, endowed with virtues and fine qualities of every kind. In the year 604, Gregory was attacked with a severe fit of the gout, a disorder to which he had been accustomed, and which rendered him incapable

of performing the duties of his high office. Ambassadors were sent to him from the queen of the Lombards, announcing the birth and baptism of her son: he was unable to write an answer to her majesty, with regard to some difficulties which she wished to have solved, but he returned by her ambassador, a complimentary note, containing commendations of her zeal for the Catholic faith, and with presents to the new-born prince, of a cross to wear at his neck, in which was enclosed a piece of the true cross, as he was pleased to affirm, together with the gospel, in a Persian box. This was one of the last acts of the pope. He died in the month of March 604. Such were the transactions of Gregory I. who has, for his talents and merits, been surnamed the Great. There was, however, a strange mixture of inconsistencies in his character. In some respects he discovered a sound and penetrating judgment, but in others the most shameful and superstitious weaknesses. He was no friend to secular and polite learning: he has even been accused of having destroyed the noble monuments of the ancient magnificence of the Romans, lest travellers and foreigners, who came to visit Rome on religious motives, by paying undue attention to them, should neglect the holy places. This accusation does not stand on undeniable evidence. It is doubted by Gibbon and other well-informed historians. "The writings of Gregory," says Mr. Gibbon, "reveal the implacable aversion to the monuments of classic genius; and he points his severest censure against the profane learning of a bishop, who taught the art of grammar, studied the Latin poets, and pronounced with the same voice the praises of Jupiter and those of Christ. But the evidence of his destructive rage is doubtful and recent; the temple of peace, and the theatre of Marcellus, have been demolished by the slow operation of ages, and a formal proscription would have multiplied the copies of Virgil and Livy in the countries which were subject to the ecclesiastical dictator." Gregory invented new offices for the services of the church, and the sacraments, in which he prescribed a vast number of rites and ceremonies that were unknown before his time. He took great pains in reforming the psalmody of the church, instituting an academy of choiristers, whom he taught to chant, and for whose use he composed that music which goes by his name. He left more writings behind him than any other pope from the foundation of the see of Rome to the present period. These consist of twelve books of "Letters," amounting to upwards of eight hundred in number. "A comment on the book of Job," generally known by the name of "Gregory's Morals on Job." "A Pastoral," or a treatise on the duties of a pastor. This work was held in such veneration by the Gallican church, that all the bishops were obliged, by the canons of that church, to be thoroughly acquainted with it, and punctually to observe the rules contained in it. He was author also of "Homilies" on the prophet Ezekiel; and on the gospels, and of four books of "Dialogues." His works have been printed over and over again, in almost all forms, and at a number of different places on the continent, as Lyons, Paris, Rouen, Basil, Antwerp, Venice, and Rome. The best edition is that of Paris, in 1705, in four vols. folio. The charity and wealth of this pontiff have already been referred to: in the use of his abundant riches, he acted like a faithful steward of the church and poor. The voluminous accounts of his receipts and disbursements were kept above three hundred years in the Lateran as the model of Christian economy. On the four great festivals, he divided their quarterly allowance to the clergy, to his domesticities, to the monasteries, to the churches, the places of burial, the alms-houses, and the hospitals of Rome, and the rest of the diocese. On the first day of every month he distributed

to the poor, according to the season, their stated portion of corn, &c.; and his treasurers were continually summoned to satisfy in his name the extraordinary demands of indigence and merit. The distress of the sick and helpless, of strangers and pilgrims, was relieved by the bounty of each day and of every hour, nor would the pontiff indulge himself in a frugal repast till he had sent the dishes from his own table to some objects deserving of his compassion. The misery of the times had reduced the nobles and matrons of Rome to accept, without a blush, the benevolence of the church. Three thousand virgins received their food and raiment from the hand of their benefactor, and many bishops of Italy escaped from the barbarians to the hospitable abode of the Vatican. Gregory might justly be styled the father of his country, and such was the extreme sensibility of his conscience, that, for the death of a beggar, who had perished in the streets, he interdicted himself during several days from the exercise of sacerdotal functions. Moreri Gibbon. Lardner.

Ecclesiastical writers seem unanimous in allowing that it was the learned and active pope Gregory the Great, who collected the musical fragments of such ancient hymns and psalms as the first fathers of the church had approved, and recommended to the primitive Christians; and that he selected, methodized, and arranged them in the order which was long continued at Rome, and soon adopted by the chief part of the western church.

The anonymous author of his life, published by Canisius, speaks of this transaction in the following words: "This pontiff composed, arranged, and constituted the *Antiphonarium* and chants used in the morning and evening service." Fleury, in his *Hist. Eccl.* tom. vii. p. 150, gives a circumstantial account of the *Scola Cantorum*, instituted by St. Gregory. It subsisted 300 years after the death of that pontiff, which happened in 604, as we are informed by John Diaconus, author of his life. The original Antiphonarium of this pope was then subsisting; and the whip with which he used to threaten to scourge the boys; as well as the bed on which he reclined in the latter part of his life, when he visited the school in order to hear them practise. Two colleges were appropriated to these studies; one near the church of St. Peter, and one near that of St. John Lateran; both of which were endowed with lands.

It has been imagined that St. Gregory was rather a compiler than a composer of ecclesiastical chants, as music had been established in the church long before his pontificate; and John Diaconus, in his life, (lib. i. cap. 6.) calls his collection "Antiphonarium Centonem," the ground-work of which was the ancient Greek chant, upon the principles of which it was formed. This is the opinion of the Abbé Lebœuf, (*Traité Historique et Pratique sur le Chant Ecclésiastique*, chap. iii.) and of many others. The derivation is respectable; but if the Romans in the time of St. Ambrose had any music, it must have been composed upon the Greek system: all the arts at Rome, during the time of the emperors, were Greek, and chiefly cultivated by Greek artists; and we hear of no musical system in use among the Romans, or at least none is mentioned by their writers on the art, but that of the Greeks.

GREGORY II., pope, was a native of Rome, and educated from childhood, in the Lateran palace, under pope Sergius, who appointed him his sub-deacon, almoner, and librarian. He was afterwards raised to higher posts in the church, and was selected by pope Constantine, as the most learned man of his time, to accompany him when he went to Constantinople, in the year 710. In that city Gregory distinguished himself by answering certain difficulties proposed to him by the emperor Justinian, and solving his doubts with regard to some questions

in which, it should seem, he was much interested, though what those difficulties were we are not informed. Upon the death of Constantine, in 715, he was raised to the papal dignity, and almost immediately upon this event, the Lombards made an irruption into the imperial territories, and took by surprize the city of Cumæ. Gregory, in his quality of Holy Father, endeavoured to prevail on them to restore it, first by threatenings of the vengeance of heaven if they should prove so wicked as to retain it, and afterwards by the offer of a large sum of money, and the particular protection of St. Peter, provided they withdrew their troops, and abstained from all farther hostilities. Finding that they were equally deaf to the threatenings and promises of the pope, he applied for the assistance of the king of Naples, who, for a stipulated sum, undertook to recover the place, and succeeded in the enterprize. In the year 717, the emperor Theodosius, having resigned the imperial dignity, and retired to a monastery, Leo, the Isaurian, was, by the senate and army, raised to the throne, on which occasion he wrote a letter to the pope, accompanied with a confession of faith, and also with promises to maintain the Catholic doctrine, as defined by the six general councils and the fathers. Gregory, in return, congratulated the emperor, in warm expressions of respect and loyalty, upon his accession, and assured him, that he would not only receive him for his sovereign, but would use his influence to preserve peace and amity between him and all the Christian princes of the West. In 721, Gregory held a council at Rome, in which several important canons were enacted on the subject of unlawful marriages and other points relating to ecclesiastical discipline. While this council was sitting, Winifrid, afterwards archbishop of Mentz, and known by the name of Boniface, arrived on a pilgrimage at Rome, where he was received with extraordinary marks of respect. A few years after this, Ina, king of the West Saxons, arrived at Rome, on a pilgrimage to the tomb of the Apostles, having resolved to renounce the world, and embrace the monastic life. During his stay in the city, he built a college for the education of youth, and the reception of such of his subjects as should undertake pilgrimages; for the support of which he imposed a tax on every house or family, known by the name of Rome-foot or Peter-pence. This tax, which, about the middle of the ninth century, was laid on the whole kingdom of England, was originally destined solely to the charitable uses above-mentioned, but it was afterwards converted, by the popes, to their own use, and levied under the denomination of a tribute to St. Peter, till Henry delivered the country of the burden. About the year 726, Leo, determined to restore the Christian worship to its primitive state, forbade all kinds of image-worship, and caused the edict to be promulgated through the empire. He gave notice of the same to the pope, requesting his assistance in carrying the resolution into effect, but Gregory made no scruple of avowing his decided opposition to the measure, and threatened the emperor with the indignation of St. Peter, should he persist in his projected reform. The emperor was not to be intimidated: he published his edict in Italy, but the populace was seriously against the innovation, and insurrections were immediately excited, which the soldiery could not suppress without much mischief and bloodshed. Luitrand, king of the Lombards, joined the popular cry, and taking advantage of the disturbances, made a rapid progress in Italy. Every where he declared his readiness to protect image-worship, and every where he was received by the people as one sent from heaven to defend the Catholic faith. These events went beyond the wishes of the pope, he was filled with the utmost consternation, well knowing that if the Lombards were suffered

to make head in the Italian territories, he should feel the weight of their yoke. He applied for assistance to Ursus, the doge of Venice, which was readily granted, and which was effectual in rescuing the emperor's dominions from the power of the Lombards. Gregory pursued his design, and urged Leo, by all the eloquence in his power, to abandon his plan with regard to image worship; but the determination of the emperor was unalterable, and he took measures to get possession of the person of Gregory, to prevent him from fomenting divisions, and even rebellion among the people. Gregory obtained timely notice of his intention, and frustrated the design: he immediately thundered out a sentence of excommunication against the emperor's exarch, for endeavouring to obey his master; and the people instantly took up arms, overpowered the garrison, pulled down the statues of the emperor, broke them in pieces, and openly declared that they renounced their allegiance to him as sovereign: not satisfied with this, they some time afterwards murdered all those who were adherents to the emperor's cause, and among others the exarch himself. Notwithstanding this opposition, the emperor in 730 held a council of the senate, the great officers of the state, and the bishops who were at Constantinople, in which it was determined, that as it was found by experience that images could not be suffered to remain in churches, and idolatry prevented, they should all be pulled down and destroyed. This being effected, he made a new effort with regard to the churches in the West: he again solicited the pope, but Gregory's answer breathed a determined spirit of hostility, and was written in a style of arrogance and abuse which was unexampled. He went still farther, he assembled a council at Rome, consisting of all the neighbouring bishops, which issued a decree, not only declarative of the lawfulness of worshipping images, but commanding them to be worshipped, and condemning, as heretics, all who did not worship them, or who should presume to teach that they were not to be worshipped. The emperor, indignant at this assumption of power, seized on the rich patrimonies of the Roman church in Sicily and Calabria, tore from the Roman see the provinces of East Illyrium, and subjected the whole to the patriarch of Constantinople. By this conduct he inflicted the most severe wound in the heart of the pope, but before he had time to ripen any schemes of revenge, he died in 731, after he had sat in the papal chair near seventeen years. From the details of his actions already given, it appears that Gregory had a zeal for exalting the power and dignity of his see; he was, besides arrogant and superstitious. As an author there are fifteen of his "Letters," and a "Memoir," transmitted to his legates in Bavaria, containing instructions for their guidance in managing the ecclesiastical affairs of that country. These are inserted in the sixth volume of the "Collectio Conciliorum:" he was author also of a liturgy, which was printed, with a Greek version, at Paris in 1595. Moreri.

GREGORY III., pope, was a Syrian by birth, became a presbyter of the Roman church, and was much celebrated for his learning and talents as an eloquent and impressive preacher. Upon the death of Gregory II. he was unanimously chosen his successor by the Roman people and clergy. He seemed determined to follow the steps of his predecessor, and declared himself a determined supporter of the worship of images, and he had no sooner taken possession of his see, than he wrote a letter to the emperor Leo and his son Constantine, whom he had taken as a partner in the empire, exhorting them to renounce their error, and to return, like dutiful children, into the bosom of the church. This letter he sent by Gregory, a presbyter of the Roman church, on whose zeal and firmness he thought he could depend, but

when

G R E G O R Y .

when the presbyter arrived, he understood that the emperors not only maintained their ground, but were determined to extirpate image worship, and those who presumed to justify it: he therefore thought it most prudent to return to Rome without acquainting them with the object of his mission. On his arrival, the pope was so exasperated at the pusillanimity which he had shewn, that he called a council to determine upon some exemplary punishment, but, upon his promise of going back and executing his mission, he was pardoned. He immediately set out, but as soon as he had landed in Sicily, in his way to the imperial court, he was arrested, his letter taken from him, and he himself sent into exile. In the year 732, Gregory held a council at Rome to revenge himself upon the emperor for sending his legate into banishment, and he procured a decree to be passed, establishing the worship of images, and denounced excommunication against all who should presume to pull down, destroy, profane, or blaspheme them: he even expended immense sums on the purchase of pictures and statues with which he filled the churches at Rome, and encouraged the people in the daily worship of them: he likewise caused relics to be brought from all parts to Rome, where he erected a magnificent building for their reception and worship, appointing them an appropriate service, and monks to perform it. He made another unsuccessful effort towards the conversion of the emperor, who, weary of his applications, prepared to reduce the pontiff, and the Romans who supported him, to obedience by force. Upon this event, the people of Rome, at the instigation of the pope, withdrew from all subjection to the emperor, and formed themselves into a kind of republic, in which they were governed by magistrates appointed by their own authority, under the pope, not as prince, but only as their head. After this they were involved in hostilities with Luitrand, king of the Lombards, who ravaged their whole country, and even laid siege to the city. In this extremity, Gregory applied for assistance to Charles Martel, who refused to interfere till proposals were made that the pope and Roman people should solemnly renounce their allegiance to the emperor, as an avowed heretic, and persecutor of the church, and that they should acknowledge Charles for their protector, and confer on him the consular dignity; and, on the other hand, Charles was to engage to protect and defend the pope, the Roman church, and the people of Rome, against the Lombards, and likewise against the emperor, should they either be attacked or molested. To these terms Charles readily acceded, and as soon as Luitrand heard of the treaty he abandoned the siege of Rome, and retired to his own dominions. Gregory did not live long to enjoy the fruits of this policy, which contributed materially to the separation of the Italian provinces from the Grecian empire. He died in 741, after a pontificate of between ten and eleven years. The only literary remains of this pope are "Seven Letters," which are to be found in the fourth vol. of the "Collect. Concil." Moreri.

GREGORY IV., pope, a native of Rome, succeeded to the high office on the death of Valentine, in the year 827. He is commended for his extraordinary piety, of which some of the strongest testimonies are repairing and adorning churches and monasteries, and instituting the festival of "All Souls" day. When the quarrel took place between the emperor Lewis le Debonnaire, and his sons, Lotharius persuaded the pope to accompany him into France, to mediate a reconciliation between him and his father. When the pope had served this purpose, he was permitted to return to Rome, where the best action performed by him that we read of, was his rebuilding and fortifying the city of Oiba, as a protection against the descents of the Saracens. This

pope died in 844, having presided over the Roman church about 16 years. Three of his "Letters" are extant in the seventh vol. of the Collect. Concil. Moreri.

GREGORY V. pope, whose original name was Bruno, was a German by birth, and a relation of the emperor Otho. He was chosen bishop of Rome when he was but twenty-four years of age; at his ordination he assumed the name of Gregory, and in a very short time after he solemnly crowned Otho emperor, who had before been only styled king. He held a council in the first year of his pontificate, at which the emperor was present, and, it has been said, the German electoral college was instituted, but it is more probable, from the evidence of history, that the origin of this college is to be referred to a later date. Upon the breaking up of the council, he returned to Germany, having first made the Romans swear allegiance to him, and obedience to the pope, but scarcely had the Germans repassed the Alps, when Crescentius, a man of considerable wealth and power, persuaded them to revolt, renounce their allegiance to the emperor, and choose himself for their head. These events obliged Gregory to fly from Rome, on which occasion Crescentius declared the see vacant, and caused a person named Philagathus to be raised to it, who took the name of John XVII. Gregory excommunicated the usurper, and also his patron, a sentence which was confirmed by all the bishops of Italy, France, and Germany. Soon after this Otho, urged by the intreaties of Gregory, returned to Italy, with a large army, and advanced with the pope towards Rome. At their approach, the anti-pope John took to flight, but, falling into the hands of some of the pope's friends, was deprived of his sight, and otherwise cruelly mutilated. Crescentius was also taken, and, with his accomplices, ignominiously executed. Gregory was now restored to his see, and one of his first acts was to convene a council to meet at Rome, in which the marriage of Robert, king of France, with Bertha, widow of Odo, count of Champagne, was declared incestuous and null. He died in the beginning of 999, having left behind him many honourable testimonies of the vigilance and fidelity which he had exhibited in his office. His reign was very short; there are four of his "Letters" extant, in the 9th vol. of the Collect. Concil. A fifth, concerning the privileges of the abbots of Mont. Major, may be found in the 4th vol. of "Baluze's Miscellanea." Moreri.

GREGORY VI. pope, whose original name was John Gratian, was descended from one of the most opulent families of Rome, and elected pope in 1044, as successor to Benedict. Upon his accession, there were no fewer than three persons who were pretenders to the honour of being successors of St. Peter. In this state, Henry III. king of Germany, resolved to go to Italy himself, and to inquire on the spot into the conduct of the pope, and the state of the church. He assembled a council at Sutri, in 1046, and sent an invitation to Gregory to preside at this council; with which he readily complied, flattering himself that the king would acknowledge him for lawful pope. But when he made his appearance there, a charge was preferred against him of having purchased the pontifical dignity with a sum of money. He confessed himself guilty of the charge, and, quitting his chair, divested himself of his pontifical ornaments before the council, and, begging forgiveness, renounced all claim to the throne of St. Peter. After this abdication, Henry carried him prisoner into Germany, where he ended his days. During the short time that he was at the head of the church, he performed some very beneficial acts. Finding the lands and revenues of the see greatly diminished by usurpations, the roads infested by robbers, and other disorders pre-

G R E G O R Y.

vailing in the government, Gregory acted with such vigour, that a powerful party was raised up against him by those who had been accustomed to live by plunder. Moreri.

GREGORY VII. pope, who, by his talents, raised the Roman see to the highest pitch of power, is said to have been the son of a carpenter, and to have been born at the small town of Soano, in Tuscany. His original name was Hildebrand, by which he is frequently known in history. He was educated at Rome, where he was highly esteemed by Benedict IX. and Gregory VI., on the latter of whom he attended, when he was sent prisoner to Germany. Upon the death of Gregory, Hildebrand embraced the monastic life in the monastery of Cluny, where he was raised to the post of prior. By Leo IX. he was created sub-deacon, and by Nicholas II., archdeacon of the Roman church; by these pontiffs, and by some others, he was successfully employed in several negotiations. Under the pontificate of Alexander II. he was made chancellor of the holy see, and had the absolute administration of all affairs, both ecclesiastical and civil, as well as the entire disposal of the revenues of the church of Rome. Upon the death of pope Alexander, Hildebrand appointed a fast to be kept, and prayers to be offered up for three days together, before they should proceed to the election of a new pope. While they were performing the obsequies of Alexander in the Lateran church, on the day after his death, the assembled people tumultuously cried out with one voice, "Hildebrand is pope, St. Peter has chosen him:" upon which he was immediately laid hold of and placed by force upon the pontifical throne. This election was confirmed on the same day by the whole body of the clergy and people. His next object was to obtain the confirmation of the king of Germany, which was a matter of no great difficulty, and immediately he took the name of Gregory, out of respect to his friend, Gregory VI. He was the last pope, the decree of whose election was transmitted to the emperor, or king, before his consecration, or who was consecrated in the presence of the imperial envoy. Gregory began his reign by engaging in the most bold and daring schemes for extending the jurisdiction of the Roman see, and enriching the patrimony of St. Peter. He conceived the design, not only of emancipating the church from all subjection to princes, but of subjecting all princes to the church, and the whole church to his see: of constituting himself supreme judge and determiner of all affairs, both ecclesiastical and civil; the disposer not only of bishoprics and archbishoprics, and other ecclesiastical benefices, but of kingdoms and states, and the revenues of individuals; and, in fact, sole and despotic monarch of the earth in temporals as well as spirituals. Gregory was soon embroiled in a dispute with Henry IV., and he omitted no measures which he thought likely to strengthen his party, and, aided as he was by the superstition of the times, as well as by the resentment of several princes, whom Henry had disoblged, or who wished to shake off his authority, he soon created a formidable body of confederates in his support. This confederacy encouraged the pope to think of raising some other person to the throne instead of Henry, and, without hesitation, he wrote a letter to the princes, bishops, and people of Germany, empowering them to chuse another king, if Henry did not, by a sincere repentance, render himself worthy of being replaced on the throne, which he had forfeited by his disobedience to the apostolic see. Upon the receipt of this letter, the confederate princes and bishops held a diet at Tribur, near Mentz, and they declared the king suspended from his royal dignity, and added, that if he did not obtain absolution before the anniversary of his excommunication, he should be exeladed for ever from the

throne. Henry submitted to the degradation of preparing to throw himself at the feet of the pontiff, to solicit absolution. He set out for Italy with his wife and infant son, and, after sustaining uncommon hardships in the passage of the Alps, amidst the rigours of an extremely severe winter, he arrived in that country. He was there speedily attended by the counts and bishops of Lombardy, who encouraged him to revenge the treatment which he had received from the pope, and offered to assist him with men and money. Gregory had, in the mean time, proceeded as far as Lombardy accompanied by the countess Mathilda, whose close intimacy with Gregory afforded too much reason for propagating many scandalous reports. Upon hearing of the king's arrival, and of the reception he had met with from his Italian subjects, the pope retired to the strong hold of Canosa, in the diocese of Reggio. While remaining in this fortress, many German bishops, and others who had been excommunicated for taking part with the king, repaired to him barefooted, clothed in hair cloth, to pray for absolution and forgiveness, which they did not obtain without submitting to severe penance and mortification. The pontiff enjoyed the malignant pleasure of seeing the king added to the number of his humiliated suppliants. It was some time before the pontiff would admit the monarch into his presence, and when the order was issued for the purpose, it was on the condition that he should enter at the outer gate of the fortress without attendants; and at the next gate he was required to divest himself of the ensigns of royalty, and put on a coarse woollen tunic, in which dress, and barefooted, he was suffered to stand for three whole days at the third gate, exposed to the severity of the weather, fasting and imploring the mercy of God and the pope. At length the persons of distinction who were with Gregory, affected at the sufferings of the king, began to complain of the severity of his holiness, which they said was more becoming a tyrant than an apostolical father or judge. These reports were carried to the pope, who on the fourth day admitted the king, and after much difficulty granted him absolution. When the Lombard lords heard of the treatment which the king had met with, and his opprobrious convention, they were highly incensed not only against the pope, but against Henry, whom they accused of cowardice and treachery, in submitting to beg absolution of a man whom they were determined no longer to acknowledge as their spiritual head. They seemed, at first, determined to depose him, and place his infant son on the throne in his stead, but to appease their resentment he broke the convention with the pope, resumed his title and other marks of royalty which he had laid down, and putting himself at the head of his forces, he prepared to check the pope's immoderate ambition. After various successes, in which the contending armies were alternately victorious, Henry summoned a council of German bishops to meet at Mentz, who adjourned their sessions to Brixen, where they were joined by many of the Italian bishops and German and Italian princes. In this council, Gregory was accused of oversetting the hierarchy, and making himself sole monarch of the church; encouraging sedition and rebellion; persecuting, excommunicating, and deposing a peaceable king, and placing a rebel on the throne. For these crimes they resolved that he should be deposed, and another chosen in his room. Notwithstanding these measures, Gregory was able to recover himself, but he was again embroiled in new difficulties, and the Romans became so incensed against the pope whom they considered as the author of the many calamities which they had endured, that apprehensions were entertained of his safety at Rome, and he thought proper to place himself under the protection

protection of duke Robert at Salerno. In that place he died in 1085, having held the see of Rome little more than 12 years, and leaving Europe involved in complicated calamities to which his ambition gave rise. "He was," as Mosheim has well described him, "a man of uncommon genius, whose ambition, in forming the most arduous projects, was equalled by his dexterity in bringing them into execution; sagacious, crafty, and intrepid, nothing could escape his penetration, defeat his stratagems, or daunt his courage; haughty and arrogant beyond all measure, obstinate, impetuous, and intractable, he looked up to the summit of universal empire with a willful eye, and laboured up the steep ascent with uninterrupted ardour and invincible perseverance, void of all principle, and destitute of every pious and virtuous feeling, he suffered little restraint in his audacious pursuits from the dictates of religion, or the remonstrances of conscience." He was the first pope who claimed the power of deposing princes and absolving subjects from their oaths of allegiance. He also laid claim to most of the kingdoms and states of Europe, and by the boldness of his pretensions, and his menaces of exercising the ecclesiastical authority, terrified many of their sovereigns and rulers into acknowledgments of their being feudatories and vassals of the apostolic see. Three hundred and fifty-nine letters of this pope have reached our time, which are divided into nine books, and are inserted in the 10th volume of the Collect. Council. He is generally supposed to have been the author of "A Commentary upon the seven penitential Psalms," which some writers have improperly ascribed to Gregory I.: and of a "Commentary upon the Gospel of St. Matthew," which is said to be preserved in MS. in the library at Lambeth. Bower. Moreri. Mosheim.

GREGORY VIII. pope, originally known by the name of Albert de Mora, was a native of Benevento, and created cardinal by pope Adrian IV. in the year 1135. He was employed in very important missions, viz. as legate to Spain, and in the year 1172 into Normandy, where he absolved Henry II. king of England, from the censures which he had incurred by being supposed in some degree accessory to the death of Thomas à Becket, but not before that monarch had submitted to a disgraceful penance. Upon the death of Urban III. in the year 1187, cardinal Albert was unanimously chosen his successor, when he took the name of Gregory VIII. A short time before his election, intelligence had arrived at Rome of the advantages gained by Saladin over the Christians in the East, and his capture of the city of Jerusalem. Gregory, as soon as he was consecrated, wrote a letter addressed to the Christians in the West, exhorting them to contribute all in their power to the relief of their distressed brethren, and for the recovery of the holy city. He enjoined a five years' fast, to appease the anger of heaven, by abstaining from meat on Wednesdays and Saturdays as well as Fridays throughout the year. The labours of this pontiff were of very short duration. He died within two months of his elevation. He has been applauded for his learning, eloquence, humane disposition, and exemplary manners. There are three of his letters extant in the tenth vol. of the Collect. Council. Moreri. Bower.

GREGORY IX. pope, whose former name was Ugolin, was created cardinal bishop of Ostia, by pope Innocent III., and was afterwards employed on different legations to Germany and elsewhere, chiefly to preach up the necessity of engaging in the crusades. He was elected pope upon the death of Honorius III. in the year 1227, when he took the name of Gregory IX. Immediately after his consecration he commanded the western bishops to exert their authority, and oblige such persons as had taken the cross, to set out

without delay for the Holy Land. He wrote also to the emperor Frederic II. exhorting him to fulfil the solemn promises which he had made to embark a sufficient army for the relief of the Christians in the East, adding the severest menaces if he should decline the undertaking, declaring that he would exert the power which heaven had put into his hands, and proceed against him as guilty of a breach of his vows. Frederic was obedient to the order, but having embarked with a large army, he returned in three days, alleging that the ill state of his health rendered him incapable of to great an exertion. His excuses were not deemed valid, the pope would hear of no apologies, and passed on him sentence of excommunication, till at length the emperor embarked for Palestine, but not having sued for absolution before his departure, he was still the object of Gregory's resentment, who took every method to render his expedition fruitless, and to excite civil wars in his Italian dominions. Even after the emperor had, by treaty, secured possession of the city and kingdom of Jerusalem, and was preparing for his coronation there, by the patriarch he found that the prelate had been terrified by the papal emissaries from taking a part in the ceremony, and had also laid the city, and the church of the sepulchre, under an interdict, that no divine service might be performed in them during Frederic's stay. The German bishops, likewise, who attended the emperor, partook so much of the patriarch's alarms, that they refused to perform any religious function, or even to be present at the coronation; so that Frederic was under the necessity of taking the crown from the altar, and placing it upon his head with his own hands. On the emperor's return in 1229, Gregory excommunicated him again; and new causes of complaint were continually occurring between Frederic and the pope, the former being desirous of acting for himself, and the latter being fully bent upon reducing him to the most abject slavery. In the year 1241, Gregory called a general council to meet at Rome, and had sent legates with letters to all the Christian princes, entreating them to oblige the prelates in their respective kingdoms to repair to it. At first Frederic consented to the holding of the council, and promised not to molest the bishops who should attend it. But afterwards, finding that the pope was resolutely bent on his ruin, and that he intended to make use of the proposed council for this purpose, and even to arm the whole Christian world against him, he revoked his promises, and published a manifesto, which was sent through the whole of Europe, declaratory of his determined opposition to the pope's project. Nevertheless, great numbers of the bishops did assemble at Genoa, in their road to Rome, who, with two cardinals and all their treasure, fell into the emperor's hands, and the holy men were sent prisoners to Naples. This disappointment, together with the approach of the emperor, and his victorious army, gave such a shock to the pope, that he was seized with an illness which put an end to his life in a few days. He had been at the head of the church nearly fifteen years, which were distinguished by the calamities in which Italy was involved, chiefly owing to his immoderate ambition, injustice, arrogance, and obstinacy. Many of his letters are to be found in the eleventh vol. of the Collect. Council: there are also extant some fragments of his "Decretal Letters." Moreri. Bower.

GREGORY X. pope, whose original name was Theobald, was first a canon in the church of Lyons; then archdeacon of Leige, and, taking the cross, he accompanied Edward prince of Wales in his expedition into Syria. After the death of Clement IV. in 1278, the Roman see was vacant for nearly three years, owing to the intrigues of the cardinals, assembled at Viterbo, who all aspired to the dignity themselves,

G R E G O R Y .

themselves, and opposed the election of any other. At length the magistrates, tired out with the delay, ordered them to be closely confined in the bishop's palace, where they were subjected to many inconveniences, and they began daily to lessen their allowance of provisions. At length they chose Theobald, who was at that time with the crusaders in the East. Friars were dispatched to announce to him the important news; they found him at Ptolemais, now called Acre, waiting for a favourable opportunity of passing to Jerusalem, but upon receiving the decree of his election, he resolved to embark for Italy. Before his departure he preached a sermon to the Christians at Ptolemais from these words, "If I forget thee, O Jerusalem, let my right hand forget her cunning, &c." And in his sermon he gave them very solemn assurances that he would render them every assistance in his power. He never forgot his promises, but both before and after his consecration, the success of the crusades was an object the nearest his heart. With this view he signified his intention of convening a general council at Lyons in 1274, and invited Michael Palaeologus to meet it, in order to complete a work so necessary for the harmony and security of Christendom. In 1273, while Gregory (a name which he assumed at his consecration) was at Orvieto, Edward, who was now king of England, arrived at the city on his return from the Holy Land, and was received by the pope with every mark of esteem and affection. On the king's complaining of the cruel murder of his cousin Henry, son of the duke of Cornwall by Guido, the pope instantly summoned Guido to appear before him within a limited time. Upon his paying no regard to this summons, he was not only excommunicated, but declared infamous, with all his descendants to the fourth generation, and all were anathematized, as equally guilty, who should receive, favour, or admit him into their houses. Finding himself driven from society like a wild beast, he embraced the opportunity of the pope's travelling from Orvieto to Florence, unexpectedly to make his appearance before him, stripped of his garments to his shirt, with a rope about his neck, begging for mercy, and submitting entirely to the clemency of his holiness. Gregory gave him his life, but delivered him up to the king of Sicily to be kept in close confinement till his death. Omitting the mere political events, which happened during the pontificate, we observe that in 1274 the general council which Gregory had summoned met at Lyons, and was by far the most numerous of any that had ever been held. The principal points which occupied its attention, were the procuring relief for the Christians in the East, the union of the Greek and Latin churches, and the restoration of ecclesiastical discipline. To the first object, Gregory persuaded the dignified ecclesiastics to devote a tenth of their income for the space of six years. While the council was deliberating, Gregory deposed the bishop of Liege, on account of his irregularities and profligacy. This council introduced the famous constitution which provides that the cardinals shall be shut up in the conclave during the vacancy of the pontificate. Gregory died soon after the termination of the council, having held the Roman see four years and four months. Several of his "Letters" are extant in the eleventh volume of the "Coll. & Concil." He is mentioned by historians on account of his extraordinary sanctity, and there seems sufficient reason to believe that he was influenced by a milder spirit than many of his predecessors. In none of them, however, is it possible to observe any conduct at all corresponding to the benevolent spirit of Christianity: in none of them do we behold any attempt, however distant, to imitate the example of Christ, whose disciples, in a superior degree, they professed themselves. Moreri. Bower.

GREGORY XI. pope, son of the count de Beaufort, and nephew of pope Clement VI. was created cardinal before he had completed his seventeenth year, and even then had accumulated upon him a number of rich benefices for the support of his new dignity. He was honoured also with other high offices in the church, while he was thus young. At this time he could have made no great progress in literary acquirements, but it is much to his credit that he afterwards applied himself so closely to study, under the instructions of the learned Baldi and other eminent tutors, as to become one of the ablest civilians, canonists, and divines of his time. Upon the death of pope Urban V. he was chosen his successor, and was consecrated at Avignon, which was then the seat of the papal residence, in the beginning of the year 1371, when he was about forty years old. Almost as soon as he was consecrated, he sent legates to mediate a peace between the kings of France and England, and wrote to those princes, pathetically exhorting them to spare the blood of their subjects, and to compose their differences in a Christian and amicable manner; but unfortunately without success. In the same year he created twelve cardinals at once, and upon the cession of Sicily to Frederic of Arragon, Gregory erected that island into a kingdom, on condition that the kings should do him and his successors homage. In 1374, the Florentines, having entered into an alliance with the Visconti of Milan, invaded the territories of the church, making themselves masters of several cities, and encouraging the people to throw off the papal yoke, and resume their liberty. Gregory's remonstrances on this occasion being fruitless, he issued out a bull of excommunication against the Florentines, which prohibited all people and nations from any communication or commerce with them; declared their estates forfeited, and the lawful property of those who should seize them. To his bull Gregory added other and still more forcible arguments to convince the Florentines of their error. He raised an army of ten thousand men which he sent under the command of the cardinal of the twelve apostles; and which was successful in stopping the ravages of the enemy. The Florentines, whose existence almost depended on their commerce, finding their traffic entirely stopped by the pope's bull, thought it prudent to make an attempt at reconciliation with the apostolic see, but the terms to effect this could not be agreed on by both sides, and hostilities were carried on with ardour, and chiefly in favour of the invaders. Gregory had hitherto resided at Avignon, though he had frequently been invited to Rome. In 1377, he arrived in that city, where he was received with great marks of joy by persons of all ranks, but the magistrates, though anxious for his presence among them, refused to give up any part of their power. Gregory having no means of establishing his authority, thought it prudent, and becoming his dignity, to withdraw to Anagni; but before he left Rome, he wrote several letters to England, against Wickliff and his doctrines, commanding the imprisonment of that worthy reformer and the suppression of his opinions. Wickliff, however, was so much respected and beloved by the English nobility, and people at large, that the bishops, to whom the pope's letters were addressed, did not dare to attempt his arrest. Towards the close of the year, Gregory, having come to some terms with the citizens of Rome, returned to that city, where he continued to receive many mortifications, which led him to the resolution of removing the papal seat to Avignon. But before he could execute his resolution he was taken off by death in 1378, after a pontificate of little more than seven years. He left behind him many letters, of which the greater part have been published by Waddingus. He is praised by his biographers

biographers for piety, benevolence, and humanity: he was a patron of men of letters, and was himself respectable for learning, particularly in civil and canon law. He was apt to be partial to his own relations, and paid more regard to their recommendation in the disposal of preferments than to the merit of the persons whom they recommended. Bower. Moreri.

GREGORY XII. pope, whose original name was Angelo Corario, was a native of Venice, and was preferred to the bishopric of that city by pope Urban VI. By Boniface IV. he was made titular patriarch of Constantinople, and by Innocent VII. he was raised to the dignity of Cardinal in 1405. He was now eighty years of age, and upon the death of Innocent in the following year, Angelo Corario was raised to the chair of St. Peter, and at his consecration took the name of Gregory XII. Peter de Luna was a rival candidate for the supreme honour, and assumed the name of Benedict XIII. Upon the consecration of Gregory he wrote to Benedict, and the rival competitors agreed to hold a congress at Savona in the year 1407, accompanied by their respective cardinals, with a view of restoring order in the church. It is probable that neither of them was desirous of this interview, but that both were secretly determined to use every means in their power to retain their dignities. Gregory refused to repair to the congress, though the meeting had been proposed by himself, which gave his enemies great advantage over him; his cardinals, disgusted at his conduct, deserted him, and withdrew to Pisa, where they published a manifesto in justification of their procedure, and an appeal to a general council, of which they sent copies to all Christian princes and states. A council was held at Pisa in March 1409, which was attended by a numerous body of ecclesiastics, and ambassadors from the kings of France, England, Sicily, &c. and after fifteen sessions it passed sentence of deposition against Benedict and Gregory, who were declared guilty of heresy, perjury, and contumacy, and unworthy of the smallest tokens of honour or respect, and cut off from the communion of the church. Alexander V. was elected in their stead. Gregory, after some fruitless resistance, formally sent in his resignation to the council of Constance, laying aside all marks of the pontifical dignity. The council were so well pleased with his submission that they decreed he should retain the dignity of cardinal so long as he lived; and that he should have the precedence among the cardinals, and the title of perpetual legate of the marche of Ancona. He died at Recanati in 1417, when he was ninety-two years of age. Some of his letters are extant in the eleventh and twelfth volumes of the "Collect. Concil." He never was a man of shining parts; but at the time of his advancement to the head of the church, he was highly esteemed on account of his probity, but before his death he had so completely lost his character, that no credit whatever was paid to his declarations, though made in the most solemn manner. Bower. Moreri.

GREGORY XIII. pope, was born of a very respectable family at Bologna, in the year 1502. He was brought up to the study of the civil and canon law, made uncommon proficiency in the pursuit, and taught the science in his native city with uncommon reputation for more than eight years. When he was about twenty-eight years of age, he took his degree of doctor, and was afterwards appointed judge of the court of commerce at Bologna, credited for the trial of mercantile causes. He removed to Rome, was employed in some important missions, admitted into the church, obtained considerable preferment, and on the death of Pius V. in 1572, he was unanimously elected his successor, and at his consecration he took the name of Gregory XIII.

The most important event in the pontificate of Gregory, was the reformation of the calendar, according to a method suggested by Lewis Lilio, a Calabrian astronomer, which after his death was presented to the pope by his brother. This method, which is fully explained under the word CALENDAR, and referred to in divers other articles in our work, was immediately adopted in all Catholic countries, but was rejected by the Protestants, and by the Greeks, who chose rather to remain in error, than be indebted to the pope for the knowledge of the truth. In 1584, Gregory incurred the suspicion of having encouraged the assassination of Elizabeth queen of England, by Parr, an English Catholic, who was detected in a conspiracy against the queen's life. There was, however, no direct proof of Gregory being at all privy to the scheme. This pope contributed greatly to correct and amend Gratian's decretals, which he enriched with learned notes. A short time before his death, he received ambassadors from the islands of Japan, where the labours of Xavier and other Jesuits were said to have been crowned with abundant success. The ambassadors had a most flattering reception given them, and great rejoicings were ordered to be made in the city, on account of the prospect which their appointment seemed to open, of triumphs to the Catholic faith in a rich and populous empire. In the midst of these rejoicings Gregory was seized with a quinsy, which carried him off in the 84th year of his age, and the 14th of his pontificate. Several of his "Letters," "Harangues," &c. are said to be in existence, and preserved in the cabinets of the curious. He was much beloved by the Romans on account of the mildness of his government, which, by degenerating into weakness, gave occasion to numerous irregularities, and an almost general corruption of manners in the ecclesiastical state. He was a zealous friend to the Jesuits, to whom he granted many privileges, and built for their use, and richly endowed, the Roman college, and nearly thirty other seminaries in different parts of the world. Moreri. Bower. Univer. Hist.

GREGORY XIV. pope, son of a senator, who, after the death of his wife, embraced the ecclesiastical life, was made bishop of Cremona, and appointed cardinal with the same title. Upon the death of Urban VII. in 1590, the conclave was divided by the pretensions of 16 candidates for the papal chair, who were all rejected, and Nicholas Sfondrati, the subject of this article, was elected and acknowledged pope, and upon his consecration took the name of Gregory XIV. He performed many humane acts as soon as he was settled in his see, and then endeavoured to signalize himself as the zealous defender of the Catholic faith. Among other public measures, he sent bulls into France, in which he declared Henry IV. excommunicated, and threatened the nobles with ecclesiastical censures if they did not desert his cause. In France these bulls were treated with the contempt which they merited: they were besides declared scandalous and seditious, and ordered to be burnt by the common hangman. The pope would probably have taken measures to avenge the insult thrown upon his decrees, but he died of the stone in the year 1592, when only in his fifty-seventh year, and in the eleventh of his pontificate. As a man, he is said to have lived a devout and abstemious life, and to have practised austerities which would rather have suited a cloister than the seat of sovereign power. He created one of his nephews cardinals, and raised six other persons to the same dignity; and he also granted the dukedom of Ferrara to duke Alphonus, who, as he had no son, endeavoured to settle the dignity on some of his relations. Bower. Moreri.

GREGORY.

GREGORY XV., pope, descended from a noble family at Bologna, and named before his election, Alexander Ludovisi, was born in the year 1554. He was educated among the Jesuits at Rome, and then returned to Bologna, where he studied the civil law, and took his degree of doctor in that faculty. Having attained this literary honour, he went back to Rome, where he acquired the friendship of three popes, *viz.* Gregory XIV., Clement VIII., and Paul V., of whom the last appointed him archbishop of Bologna, and sent him out as nuncio to adjust some differences which had taken place between the Spaniards and the duke of Savoy. For his able conduct in this difficult business he was promoted to the rank of cardinal. On his return he resided on his diocese till the death of his patron Paul, in 1621, when he went into conclave with the other cardinals, and was almost unanimously chosen pope, and assumed the name of Gregory XV. Where his own particular sentiments were not immediately concerned, he was a man of mild manners and very humane disposition, but the whole of his papacy was marked with a violent excess of zeal and bigotry against the Protestants. As the Hugonots of France had, by the violation of the edict of Nantz, been driven to take up arms in their own defence, he wrote to Lewis XIII., exhorting him, by every argument in his power, to destroy or extirpate them; and to prove the extent of his zeal, he accompanied the letter with a bull, intended to animate the Papists in their sanguinary and savage undertaking. He next published a bull, prescribing a new form in the election of a pope, by which the cardinals were allowed to give their suffrages secretly, by way of scrutiny, by which he intended to prevent the chiefs of parties from having so great an influence in future elections. As a politician, he supported, to the utmost of his power, the emperor Ferdinand II. and Maximilian, duke of Bavaria, against the elector palatine of the Rhine, son-in-law of James I. of Great-Britain: by his aid they were enabled to conquer the palatinate, an event that gratified him as well by the injury which it did to the interests of the reformed religion in Germany, as by the share which it gave him in the spoil of the valuable library of Heidelberg, a part of which was transferred to the Vatican. He also attempted the destruction of Calvinism, by endeavouring to persuade Lewis XIII. to allow the duke of Savoy to seize upon Geneva, the nursery of that system; but in this object he was disappointed. He was likewise unsuccessful in an attempt which he made to reinstate the Jesuits at Venice, from whence they had been banished during the pontificate of Paul V. In 1622 the Turks invaded Poland with a formidable army; to resist their power, Gregory sent immense supplies of money to Sigismund, by which he was enabled to withstand the barbarian power, and finally to gain a signal victory over them. About the same time the pope instituted the famous college, "De propaganda fide," and endowed it with ample revenues for the maintenance of persons to be educated for foreign missions. Gregory endeavoured to turn to his own purpose the intended marriage between the prince of Wales, son of James I. and the infanta of Spain: he refused to grant a dispensation for the marriage, but upon very severe conditions, to all which James seemed willing to submit, when the affair was suddenly suspended by the pope's death, which happened in 1623, after he had filled the papal see about two years and a half. He was the author of some literary productions, which have been lost, likewise of "Epistola ad Regem Persarum Schah Abbas, cum notis Hegalfoni;" and "The Decision of the Rota." He is highly commended for his piety and great learning, particularly in canon law, and for his charity to the sick and poor. He was, in a certain degree, the encour-

ager and patron of learning, and when his nephew, cardinal Ludovisi, had formed a kind of literary academy in his palace, he was frequently present at their meetings, and did all in his power to promote the extension of science and useful learning. He was a great friend to the Jesuits, and canonized their founder, Francis Xavier, and by him the see of Paris was withdrawn from subjection to that of Sens, and erected into an archbishopric. Moreri. Univer. Hist. Bower.

GREGORY of Neo-Cæsarea, surnamed *Thaumaturgus*, or Wonder-worker, from the miracles which he pretended to perform, was born at Neo-Cæsarea, in Pontus, and flourished in the third century; he is usually styled a saint, and was known, before his conversion to Christianity from Paganism, by the name of Theodorus. His father was a zealot for the principles in which he educated his son, but he caused him to be instructed in the elements of useful and ornamental learning. He provided for him the most able tutors, one of whom earnestly recommended to his pupil the study of the Roman law, as what might be highly advantageous to him in future life. With this advice he complied, and made himself master of the principles of the science. Having laid the foundation of learning at home, he set out upon his travels. In Phœnicia he endeavoured to improve his knowledge of law under the celebrated professors of that science who resided there. He had a sister married to a lawyer in high esteem with the governor of Palestine, and chosen by him to be one of his counsellors. This lady was sent for by her husband to Cæsarea, and as the officer who came to escort her brought with him a greater number of carriages than were sufficient for her and those who would attend her, Gregory was induced to make one of the party. At Berytus he attended a school of philosophy lately opened by the celebrated Origen. For five years Gregory and his brother were disciples of this great master, who instructed them in logic, physics, geometry, astronomy, and ethics. He encouraged them in reading all sorts of ancient authors, poets, and philosophers, whose tenets were not sceptical. He restrained them only from such as denied a deity, or a superintending providence. It was during their attendance upon Origen that they became enlightened and zealous Christians; he introduced them to a knowledge of the sacred scriptures, and explained to them the passages which to their minds might appear obscure and difficult. About the year 239, Gregory returned home: he took leave of Origen with great regret, but not before he had pronounced before a numerous auditory a panegyric oration in praise of his tutor, which is esteemed by Dupin one of the finest pieces of rhetoric in all antiquity, and which affords at once a proof of the writer's eminent abilities, and of Origen's excellent method of educating those who were placed under his tuition. The tutor was attached to his pupil, and after his return to Neo-Cæsarea, he wrote him a letter, intending, no doubt, that he should make what use he pleased of it, commending his excellent parts, which, he said, qualified him either to become a Roman lawyer of the first rank, or a philosopher of eminence among the Greeks, but he could rather wish that he would employ his great talents in the service of the Christian religion, which might be essentially benefited by his exertions. His celebrity led many to solicit him to open a school of philosophy in his native city, but a diffidence in himself led him rather to withdraw from public notice. He was next urged to undertake the office of Christian bishop, an application which he resisted a long time, though, at length, he was induced to accept the charge, and was ordained, according to Dr. Lardner, by Phœdinus, bishop of Amasea, about the year 245. He was recommended to give all his exertions to his native city, which was large and populous,

populous, but immersed in superstition and idolatry, and contained but very few Christians. By his great zeal, united to much prudence, he made numerous converts to Christianity, and established a church which is said to have been truly apostolic, both with respect to doctrine and discipline, and to have retained its purity, long after surrounding churches had admitted novelties and innovations which were a disgrace to their religion, and insensibly led the way to the grossest corruptions and abuses. This church went on flourishing and increasing under his care till the Decian persecution, in the year 250, when he thought it prudent to withdraw into retirement till the storm was blown over. He afterwards returned to his flock, among whom, during the remainder of his life, he discharged the duties of a faithful and vigilant pastor, and was instrumental in bringing not only the whole city, but the dependent district into the profession of Christianity. He was present at the first council at Antioch, in 264, when the case of Paul of Samosata was the subject of enquiry, and Gregory, with others, exerted themselves in preventing any harsh measures from being adopted against him. He is thought not to have long survived the meeting of this council, and to have died some time in the year 265. Upon the whole he was a great and good man, eminent for purity and simplicity of manners, zealous for the interests of the Christian faith and profession, and anxious to preserve them unadulterated with superstitious practices. The only works of his that are extant, which are unquestionably genuine, are his "Oration in Praise of Origen," and "A Paraphrase on the Book of Ecclesiastes." "A Canonical Epistle," consisting of eleven canons, is ascribed to him by some authors, but it is rejected by other very able and learned critics, and is considered to have been added by some modern Greek. His pieces have been frequently printed: they were collected into one volume at Paris, in 1626; and Gerard Vossius published an edition of them at Mentz, in 1604, in 4to. Dr. Lardner says there are two things to be lamented, 1st. That no more of this excellent man's writings have come down to us. It is plain that some of his writings are lost; for Jerom speaks of his epistles, whereas there is only one remaining. And Basil mentions an "Exposition of Faith," or a "Dialogue with a Gentile," which is not now in existence. 2dly. That we have no history of his life, written by some contemporary. It may be well supposed that this apostolical man was chiefly employed in increasing his church, or in building it up in knowledge and virtue, by oral instructions and works of goodness. His church continued stedfast in the faith after his death, and near the end of the fourth century the Neo-Cæsarians were all Christians, having been all along to that period blessed with pastors who were men of true worth. As Gregory, therefore, was an honour and ornament to the churches in his time, so his church continued to be an ornament to him. Lardner's *Credibility*, vol. iv. Moreri. Dupin.

GREGORY NAZIANZEN, was born near Nazianzum, in Cappadocia, about the year 324. His father was not brought up a Christian, but, by marriage, became a convert to the true faith. His learning, piety, and many virtues, pointed him out as a proper person for sustaining the episcopal character, and he was accordingly ordained, and appointed to the see of Nazianzum, where he officiated as pastor for the space of forty-five years. Gregory afforded early proofs of excellent natural abilities, and a serious turn of mind, and having made great proficiency at home, he was sent, for farther improvement, to different public seminaries of learning. He was first placed at Cæsarea, in Cappadocia, whence he removed to Cæsarea, in Palestine; thence

to Alexandria, and proceeded from that city to Athens, where he intended to finish his academical studies. At the last named city he became acquainted with Basil, celebrated in the church, and likewise with Julian, who was afterwards emperor. With the former he entered into the strictest habits of friendship. They lived together in the same house, united in the same studies, and embraced the same tenets in religion. Having been a considerable time at Athens, he felt a strong desire to visit his friends at home, and set out for Constantinople, on his journey homewards. At that city, he met his brother, Cæsarius, who had just arrived from Alexandria, and here he was strongly urged to settle, but by the influence of Gregory he declined all the flattering offers made him, and returned with him to Nazianzum. Gregory, on his return, was baptized, being about thirty years of age, and from this period he seems to have chiefly devoted himself to a studious and ascetic life, practising the austerities of monkery, and mixing no farther in the business of the world than was necessary for the management of his father's concerns. In the year 359, he visited Basil, in his retirement among the mountains of Pontus, and subjected himself to the same severe discipline which he professed. He had not long enjoyed the company of Basil, when he was sent for in haste to allay a ferment that had occurred in the church of Nazianzum. He succeeded in reconciling the differences that had occasioned the discontents; entered into orders; and was ordained presbyter. Julian, the avowed and malignant enemy of the Christians, had now ascended the throne: he published a law intended to prevent the adherents to the gospel system from being instructed in the arts and sciences, hoping to render the followers of Christ barbarians; but this effort was partly defeated by the two Apollonarii; and Gregory, who wrote a number of poems in all kinds of verse, on divers serious subjects, by which the loss of the Greek and Roman classics was in some degree compensated to Christian students, on account of their excellencies and beauties as compositions. Gregory officiated for some years as assistant to his father in the pastoral office. In this situation he was instrumental in promoting the election of his friend Basil to the see of Cæsarea, in the year 370, a circumstance, though well meant by Gregory, which had nearly occasioned a rupture between the two friends; and which determined Gregory to withdraw into retirement, where he hoped he might be allowed to spend his life in study and religious contemplation; but by his father's earnest entreaties he was induced to become his coadjutor in the episcopal office at Nazianzum, on the express condition, that after his father's death he should be perfectly free from all obligation to that charge. Accordingly when this event took place, in the year 374, he quitted Nazianzum, and retired to Seleucia, where he continued for a long time in a monastery before he returned to his native country. About the year 378 Gregory, among others, was deputed, on account of his great learning, to go to Constantinople to assist in defending the Catholic cause against the Arians, who were making head against them. When he arrived at the city he found the Catholic cause reduced to the lowest ebb, so that the Catholics themselves durst scarcely venture to avow their opinions. At first he only preached in a private manner at his lodgings, but in a short time the fame of his eloquence brought multitudes to hear him, and he converted the house in which he was into a church; to this he gave the name of Anastasia, or the Resurrection, because the Catholic faith seemed to have its resurrection in this particular spot. His success excited the jealousy of the Arian party, who instigated the populace to attack him and his hearers with clubs and stones, both in the streets and also in

his church. Gregory they dragged like a malefactor before the magistrates, accusing him of being the cause of tumult and sedition, but he was acquitted of all malice, and the perfection which he experienced served only to increase the number of his followers. His great celebrity attracted disciples from distant parts, among whom was St. Jerom, who frequently boasted of having had the honour and happiness of studying under such a master. The Catholics were now sufficiently strong in number to desire the re-establishment of the episcopal office among them, and expressed their unanimous wish that Gregory would undertake it. He met with a rival in Maximus, an Egyptian Cynic philosopher, whom he had himself baptized, and admitted to the lower orders of the church. This person contrived a scheme for supplanting him in the episcopal throne by intrigue and boldness, and engaged some of the Egyptian bishops to favour his views. Gregory, on account of ill health, was obliged to quit the city for the sake of the country air, and the confederates, unwilling to lose any time, during the first night of his absence broke into his church, and placed Maximus upon the throne. The great body of the people of all classes and parties in religion were indignant at this conduct: they assembled and with the utmost fury drove the intruders out of the church, who were now obliged to consult their safety by flight. This attempt to supplant him produced much uneasiness in the breast of Gregory, and made him very desirous of retirement, and after a time he determined to resign a charge which involved him in increasing troubles. He accordingly announced his intention to his people in a farewell discourse, in the course of which he pathetically exhorted them to persevere in the orthodox faith which he had taught them, and to be mindful of the labours and sufferings which he had undergone for that cause. No sooner had he finished his exhortations, than he was surrounded by persons of all ages, sexes, and qualities, who were so earnest in their entreaties that he would remain, that, at length, he promised not to desert them till the eastern bishops, who were expected soon to assemble at Constantinople, should release him by choosing a more worthy person to occupy his place. About this period Theodosius the Great was created a partner in the imperial throne, and avowed himself the supporter of the orthodox faith: he issued an edict, commanding all his subjects to receive the Catholic doctrine of the Trinity under the heavy penalty of being treated as heretics and infamous persons. In the year 380 he came to Constantinople, where he treated Gregory with the greatest kindness and respect, and told him that God had sent him to give him possession of the church, which he was ready to deliver up into his hands as a reward of his labours. A day was appointed for his installation, but, at Gregory's request, the ceremony was deferred for the present, and soon after having obtained the emperor's consent, he abdicated his episcopal throne, and retired to his paternal estate, near Nazianzum, with the resolution of spending the remainder of his days in studious retirement, and the exercises of devotion. In 382, however, Gregory was summoned to meet the eastern bishops at Constantinople, but he refused to attend, and told the fathers very plainly that experience had taught him how little good was to be expected from any such assemblies, in which pride and ambition chiefly predominated, and which were rather calculated to widen than to conciliate differences among Christians. Upon his return to his native country he was strongly importuned to undertake the charge of the see of Nazianzum, which had continued vacant from the time of his father's death, but he could not be prevailed upon to quit his retirement, where he died in the year 389, supposed to be about the age of

sixty-five years. He was, in many respects, a great and a good man, and an ornament to the age in which he lived. His piety was ardent and sincere, though not untinged with superstition, and his morals strict and regular, but partaking too much of the severity enjoined by monastic institutions. His benevolence and charity were boundless, and they led him to devote the whole of his income to the relief of the poor and afflicted. The works of this father consist of "Sermons," "Letters," and "Poems." They were first published at Basil in 1550 in Greek; but the best edition of them was published by Morel, in two volumes folio at Paris 1609. By Dupin he is classed with the most perfect orators of Greece, yet he admits that his style had too many antitheses, similitudes, and other rhetorical embellishments, which sometimes render his oratory effeminate. Erasmus says that he was discouraged from attempting the translation of Nazianzen's works, on account of the acumen and smartness of his style, the grandeur and sublimity of the matter, and the obscure allusions which are frequently interspersed among his writings. Moreri. Dupin.

GREGORY, surnamed *Nyssen*, a saint and father of the church in the fourth century, was a younger brother of St. Basil, and born at Cappadocia about the year 332. He was originally intended for the ecclesiastical life, though for some time he practised as a professor and pleader with great success and applause. At the persuasion of Gregory Nazianzen, he was induced to relinquish his secular pursuits, and to apply with great diligence to the study of theology, and whatever was connected with it. As soon as he had taken orders he became as eminent in the pulpit as he had formerly been at the bar. About the year 372 he was ordained bishop of Nyssa, in Cappadocia, by his brother Basil. He became distinguished for his opposition to the Arian party, and on that account was banished by the emperor Valens two years after his ordination. On the death of that emperor, he was recalled by Gratian and restored to the possession of his episcopal see. In the year 378 he was present at the synod held at Antioch, and on his return he paid a visit to Jerusalem, in the hopes of gratifying his wishes in viewing the scenes of Christ's ministry, death and resurrection, and to endeavour to allay the factions and quarrels which existed among Christians in that city. Instead, however, of finding the virtues which might have been expected from the inhabitants of the Holy Land, he found "the place to be a sink of iniquity and debauchery, the seat of envy, malice, adultery, robbery, murder, idolatry, poisoning, and bloodshed, where men assassinated each other for a trifling reward, so that in no place were murders so frequently and so easily committed." In 381 he was summoned to the council that met at Constantinople, and to him was confided the task of drawing up a creed, which was adopted, and is the same as that which has been received into the English liturgy, under the name of the *Nicene Creed*, excepting the words "and the son," in the part relating to the Holy Ghost, which were added at a later period. He was engaged in other councils, and his name appears in the lists of the prelates who were present at the synod held at Constantinople in the year 394. It is not certain how long he lived after this period. He had entered into the marriage state early in life, and continued to live with his wife after he had been advanced to the episcopal rank. His works, which consist of commentaries on different parts of the scriptures; controversial treatises; sermons and funeral orations; biographies of distinguished persons, letters, &c. are many of them more like the treatises of Plato and Aristotle, than those of other Christians. Moreri.

GREGORY, GEORGE FLORENCE, commonly known by the name of Gregory of Tours, was born about the year 544. He was educated for the ecclesiastical profession, was a proficient in the learning of the times, and acquired considerable reputation by his talents as a preacher. Being attacked by a dangerous illness, he paid a religious visit to the tomb of St. Martin at Tours, which proved the occasion of his introduction to the nobility, clergy, and other inhabitants of that city, whose good opinion he conciliated by his behaviour among them. So strong was the impression made in his favour, that on the death of Enfronius, bishop of Tours, in 573, he was unanimously elected his successor. In the year 594 he took a journey to Rome, to visit the tombs of the Apostles, and to pay his respects to pope Gregory the Great, who received him with extraordinary marks of esteem. He died soon after his return to his diocese, in 595, when he was in the fifty-second year of his age. He was author of "The History of France;" "The Lives of the Saints;" "Fragments of a Commentary on the Psalms," and other pieces. The style and language of the history are harsh and inelegant, but it supplies the historian with facts which serve to fill up the chasms in the annals of the dark ages, and which carry with them strong internal marks of authenticity. The best edition of Gregory's works is that published at Paris in 1699. Moreri. Dupin.

GREGORY of Rimini, one of the most subtle schoolmen in the 14th century, was born in the city whence he took his surname. He became a monk of the order of the Hermits of St. Augustine, and taught with great applause in the university of Paris. He was made general of his order at Montpellier in 1357, and died in the following year at Vienna. As an author, he is known by "Commentaries on the Four Books of Sentences;" "Commentaries on the Epistles of St. Paul;" and "On the Epistle of St. James;" by "A Treatise on Usury;" "Sermons," &c. Moreri. Bayle.

GREGORY ST. VINCENT, a Flemish geometrician, was born at Bruges in the year 1584. He studied mathematics under Clavius, and became a member of the society of Jesuits at Rome. He acquired a very high reputation in the sciences, was chosen to some high offices, and was selected by Philip II., king of Spain, to be mathematical tutor to his son, prince John of Austria. He died at Ghent in 1667, at the age of eighty-three. He is known as author of three learned mathematical works, of which the principal is entitled "Opus Geometricum Quadraturæ Circuli, et Sectio-nium Coni, decem Libris comprehensum," 1647, in two vols. folio. In this work he shews, that if one asymptote of an hyperbola be divided into parts, in geometrical progression, and from the points of division ordinates be drawn parallel to the other asymptote, they will divide the space between the asymptote and curve into equal portions. Moreri.

GREGORY, JOHN, a learned English divine, was born at Agmondesham, Bucks, in the year 1607. He received a good education, and was placed in the quality of servitor to Christ-church college, Oxford, in 1624, where he was under the tuition of Dr. George Morley, afterwards bishop of Winchester. In this college he took his degrees, and was appointed one of the chaplains. In the year 1634 he published a second edition in quarto, of sir Thomas Ridley's "View of the Civil and Ecclesiastical Law," with notes: by this work he acquired a high degree of reputation, on account of his deep and extensive learning, and the skill which he shewed in ancient and modern languages, Oriental as well as European. He obtained some considerable pro-

ferment in the church, particularly a prebendary in the see of Salisbury. This he did not long enjoy, owing to the civil wars, in which our author was an active partisan of the royalists. Being now much reduced in his means, he took up his abode at an obscure ale-house near Oxford, where he remained in great privacy, devoting all his time to literary pursuits. He died before he had arrived at his fortieth year: he had, however, attained to the favour and correspondence of many of the greatest men of his age. In 1646 he published "Notes and Observations on some Passages of Scripture;" which were afterwards inserted in the "Critici Sacri." In the year 1650 a collection of his learned tracts was published in quarto, under the title of "Gregorii Post-huma:" he left behind him three translations from the Greek into Latin, which were published in 1665, by Edward Bysshe, esq. in his own name. They are entitled "Palladius de Gentibus Indiæ et Brachmannibus:" "S. Ambrosius de moribus Brachmannorum:" and "Anonymus de Brachmannibus." Biog. Brit.

GREGORY, JAMES, one of the most eminent mathematicians of his age, was born at Aberdeen in the year 1648. He was educated at the grammar school of his native town, and went through the usual course of academical studies in the Marischal college, with credit and reputation. He soon discovered a great turn for mathematical pursuits, and began, at an early age, to make improvements in the science of optics. He published, in 1663, a work entitled "Optica Promota, seu abdita Radiorum Reflexorum et Refractorum Mytheria, Geometricæ enucleata," &c. quarto. This work, which gave an account of the invention of the reflecting telescope, which will be described in the article TELESCOPE, immediately attracted the notice of mathematicians in all parts. About the year 1664 or 1665, Mr. Gregory came to London in order to get his instrument executed by some able hand; but being disappointed in his object, he laid aside his telescope, and went to Italy, where he resided some years. In 1667 he published at Padua "Vera Circuli et Hyperbolæ Quadratura," &c. quarto, in which he announced another of his discoveries, that of an infinitely converging series for the areas of the circle and hyperbola, by which they may be computed to any degree of exactness. He sent home a copy of this work to Mr. John Collins, who communicated it to the Royal Society, where it met with much commendation. Another work, which he published in the following year, was entitled "Geometriæ Pars Universalis, inserviens Quantitatum Curvarum Transmutationi et Mensura," in which he shewed a method of the transmutation of curves. These works procured the author the correspondence of Newton, Huygens, Halley, Wallis, and other most eminent mathematicians. Mr. Gregory was now chosen a member of the Royal Society, and upon his return from his travels he communicated to that learned body an account of the controversy carried on in Italy concerning the motion of the earth. About the year 1668 he was appointed professor of mathematics in the university of St. Andrew's, an office which he held for six years; and in 1674 he was called to Edinburgh, to fill the mathematical chair in that university; this situation he held but little more than a year, when, in the month of October 1675, being employed in shewing the satellites of Jupiter through a telescope, he was struck with a sudden and total blindness, and died in the course of a few days at the early age of thirty-seven. Mr. Gregory possessed an acute and penetrating genius; he was unambitious, and contented with the advantages of his situation as professor, which constituted the only pecuniary reward of his eminent talents. Besides the discoveries already noticed, he invented and demonstrated geometrically, by the

help of an hyperbola, a converging series for making logarithms, which is recommended by Dr. Halley for practical purposes: he sent to Mr. Collins the solution of the famous Keplerian problem by an infinite series: he discovered a method of drawing tangents to curves geometrically, without any previous calculation, and many other things which shew that the most brilliant part of his character was that of his mathematical genius as an inventor. *Biog. Brit.*

GREGORY, DAVID, nephew of the preceding, an able mathematician, was born at Aberdeen in the year 1661. He was the eldest son of Mr. David Gregory who had the singular fortune to see three of his sons all professors of mathematics, at the same time, in three of the universities, *viz.* David at Oxford, his second son James at Edinburgh, and his third son Charles at St. Andrew's. David, the subject of this article, received the early part of his education at his native place, but completed his studies at Edinburgh, where he took his degree of A.M. and so greatly did he distinguish himself in scientific pursuits that he was elected professor of mathematics in that university, when he was only in his twenty-third year. About this period he published from his uncle's papers, with considerable additions of his own, "*Exercitatio Geometrica de Dimensione Figurarum, five Specimen Methodi generalis dimetiendi qualvis Figuræ.*" He soon perceived the excellence of the Newtonian philosophy, and was the first who had the merit of introducing it into the schools by his lectures at Edinburgh. In this city he remained as mathematical professor with distinguished honour and applause till the year 1691, when hearing of Dr. Bernard's intention to resign the Savilian professorship of astronomy at Oxford, he went to London, and was introduced to sir Isaac Newton, who, conceiving highly of his talents, recommended him to be chosen a fellow of the Royal Society. Newton introduced him to the notice of Mr. Flamsteed the astronomer royal, and with their recommendations he was elected Savilian professor, though Mr. Halley was a competitor. Their rivalry laid the foundation of a permanent friendship between these eminent men, and Halley afterwards was the colleague of Gregory, by obtaining the professorship of geometry in the same university. In 1695 he published the substance of his optical lectures which had been read at Edinburgh. This work was entitled "*Catoptrica et Dioptrica Spherica Elementa,*" 8vo. Dr. Gregory, in 1697, gave a demonstration of the Catenarian curve, or that curve which is formed by a chain fastened at each end. The paper on this curve was inserted in the "*Philosophical Transactions,*" and also in a work of much reputation, entitled "*Miscellanea Curiosa,*" as one of the noblest discoveries that had at that time been presented to the Royal Society. The most celebrated work of this learned professor appeared in the year 1701, entitled "*Astronomia Physica et Geometrica Elementa.*" This was written chiefly with the design of explaining sir Isaac Newton's geometry of the centripetal forces, as far as his discoveries in astronomy are built upon it, and to throw the astronomical part of his *Principia* into a new and more intelligible form. It was afterwards translated into English, of which the second edition was published in 1726, in two volumes octavo, entitled "*The Elements of Physical and Geometrical Astronomy, &c.*" This impression was revised and corrected by Mr. Stone. In 1703 our author published a splendid folio edition of the works of Euclid in Greek and Latin. He now began to prepare, in conjunction with Dr. Halley, a new edition of "*Apollonius's Conics,*" but he had not proceeded very far in the undertaking before he was cut off by death in 1710, when only in the forty-ninth year of his age. Besides

the works of Dr. Gregory printed in his lifetime, two others were published after his decease; one "*A short Treatise on the Nature, &c. of Logarithms,*" printed at the end of Dr. Keill's translation of Commandine's Euclid; and the other "*A Treatise of Practical Geometry,*" published by Mr. Maclaurin in 1745.

GREGORY, JAMES, brother of the preceding, rose to high eminence as a mathematician. He succeeded his brother in the professorship of mathematics at Edinburgh, which office he held thirty-three years with great reputation, and retiring in 1725, was succeeded by the celebrated Maclaurin. Charles, the other brother, was created professor of mathematics at St. Andrew's, by queen Anne in 1707. This office he held with great credit thirty-two years, when he resigned in favour of his son David, who succeeded him in 1739. He died in 1763. He published a compendium of arithmetic and algebra in Latin, entitled "*Arithmetica et Algebra Compendium, in Usum Juventutis Academicæ,*" Edin. 1736. *Biog. Brit.*

GREGORY, DR. GEORGE, was a native of Ireland, but at the death of his father, who was a clergyman, and a very elegant scholar, the subject of this article was brought to Liverpool, by his mother, who was a native of Lancashire, where he received the elements of a learned education, which he completed at Edinburgh. He took orders in the church in 1778, and was curate at Liverpool till the year 1782, when he removed to London, and obtained the curacy of Cripplegate. In 1785 he became known as the author of a volume of "*Essays,*" which had an extensive sale, and went through several editions; and in 1789 he published a translation of Lowth's lectures "*On the Sacred Poetry of the Hebrews,*" which was well received by the public. In the year 1804 he was presented, through the interest of lord Sidmouth, by his majesty, to the living of Westham, in Essex; he had previously to this obtained marks of distinction from the bishop of London, which, however, were attended with very small portions of emolument. Dr. Gregory did not live long to enjoy the ease and independence, which his noble friend intended, by the presentation of the living of Westham; he died March 12, 1808. Besides the works already mentioned, he was author of a volume of "*Sermons,*" of the "*Economy of Nature,*" in three vols.; of "*Letters on Literature,*" in two vols.; and was likewise the editor and superintendent of an "*Encyclopedia of Arts and Sciences,*" in two volumes 4to. He was author of a Church History in two vols. 8vo.; and of the life of Chatterton, for whose fate he felt the most sincere commiseration, and divers other works with and without his name. *Monthly Magazine.*

GREGORY, JOHN, an eminent physician, and professor of the practice of physic in the university of Edinburgh, was born in May, 1725. His father was professor of medicine in King's college, Aberdeen; and his grandfather was professor of mathematics, first at St. Andrew's, and afterwards at Edinburgh. Thus Dr. Gregory was the third professor of his family in a lineal descent: and it deserves to be remarked, that, from his great-grandfather, David Gregory, esq. of Kinairdy, he was the fifteenth descendant who had held a professorship in a British university: his son now fills the same chair at Edinburgh.

John Gregory began the study of medicine at Aberdeen, and afterwards prosecuted it at Edinburgh, Leyden, and Paris. In the 20th year of his age, he was elected professor of philosophy in King's college, Aberdeen, and had at the same time the degree of doctor of medicine conferred upon him. In the year 1756, upon the death of his brother, Dr. James Gregory, who had succeeded his father as

professor of medicine, he was elected to that chair. But about the year 1765, he left Aberdeen, and went to Edinburgh. Soon after this he was appointed professor of the practice of medicine in the university there, in the room of Dr. Rutherford, who resigned in his favour. The year following, upon the death of Dr. White, he was nominated first physician to his majesty for Scotland. Thus at the time of his death, which took place on the 10th of February, 1773, besides very extensive practice, he enjoyed the highest and most important professional offices, which his native country could afford him.

His first publication, entitled "A comparative view of the state and faculties of man with those of the animal world," made its appearance in 1765. This production combines many just and original reflections, with a liberality of sentiment seldom equalled. It went through four editions in two years. In the year 1770, a second work of Dr. Gregory made its appearance; but without his consent, and even contrary to his inclination. This publication was made from a short-hand manuscript taken at his introductory lectures on the practice of physic, and was entitled, "Observations on the duties and offices of a physician, and on the method of prosecuting inquiries in philosophy." Although this publication contained so much valuable matter, that, had it appeared in a much worse dress, it could have done him no discredit, yet he was dissatisfied with its form; and, therefore, he soon after published an edition of it himself, in which his former sentiments were propounded with all the advantages of a correct and elegant style. His last publication, "Elements of the Practice of Physic," was intended as a syllabus to his lectures; but he only lived to complete his account of the diseases usually termed febrile.

He was succeeded in his professorship by the celebrated Dr. Cullen. See Duncan's Med. Commentaries, vol. i. p. 210.

GREGORY Bay, in *Geography*, a bay in the straits of Magellan, on the S. coast of Patagonia.

GREGORY'S Islands, four small islands in the Mergui Archipelago. N. lat. $10^{\circ} 36'$.

GREGORY'S Sound, a passage between two of the fourth isles of Arran, on the western coast of Ireland, being one of the passages into Galway bay.

GREGOUE', a town of Africa, in the country of Whidah; four miles S. of Sabi.

GREHWEILER, a town of France, in the department of Mont Tonnerre; seven miles N. of Creutznach.

GREIFENBERG, a town of Lower Carinthia, on the Drave; 25 miles W. of Villaco.

GREIFFEN, a lake of Switzerland, in the canton of Zurich, five miles E. of Zurich. It is about six miles long and a mile broad; on one side the shores are flat or gently rising, on the other side are hills richly wooded. The village of Greiffen is agreeably situated on a small promontory, embosomed in a wood.

GREIFFENBERG, a town of Silesia, in the principality of Jauer; 32 miles W. of Jauer. N. lat. $50^{\circ} 59'$. E. long. $15^{\circ} 30'$.—Also, a town of Hinder Pomerania; 28 miles N. of Stargard. N. lat. $52^{\circ} 53'$. E. long. $15^{\circ} 12'$.

GREIFFENBURG, a town of Germany, in the Ucker Mark of Brandenburg, on the Sernitz; 45 miles N.N.E. of Berlin. N. lat. $53^{\circ} 8'$. E. long. $14^{\circ} 3'$.

GREIFFENHAGEN, a town of Hinder Pomerania; 37 miles N. of Custrin. N. lat. $53^{\circ} 20'$. E. long. $14^{\circ} 36'$.

GREIFFENSTEIN, a town of Germany, in the province of Solms Braunfels; seven miles N.N.W. of Braunfels. N. lat. $50^{\circ} 37'$. E. long. $8^{\circ} 23'$.

GREIFSWALD, or **GRISWALD**, a seaport town of

Anterior Pomerania, on the river Rik, which is navigable to the Baltic. This town has an university founded in 1456. It was formerly one of the Hanseatic towns; 15 miles S.E. of Stralsund. N. lat. $54^{\circ} 41'$. E. long. $13^{\circ} 22'$.

GREIFSWALDE OIE, a small island in the Baltic, off the mouth of the Oder, near the S.E. coast of the island of Usedom. N. lat. $54^{\circ} 13'$. E. long. $14^{\circ} 3'$.

GREIN, a town of Austria, on the N. side of the Danube; 62 miles W. of Vienna. N. lat. $48^{\circ} 16'$. E. long. $14^{\circ} 45'$.—Also, a town of the Arabian Irak, on the Euphrates; 36 miles N. of Sura.

GREITZ, or **GREWITZ**, a town of Saxony, in the Vogtland, situated on a river which runs into the Elster. In this town there are some stuff manufactures. It contains about 450 houses; 12 miles S.W. of Zwickau. N. lat. $50^{\circ} 35'$. E. long. $12^{\circ} 10'$.

GREKSAKER, a town of Sweden, in the province of Westmanland; 48 miles W. of Stromsholm.

GREMSA. See **GRAEMSAY**.

GRENADA, **LEWIS DE**, in *Biography*, a Spanish Dominican monk, in the sixteenth century, was born in the year 1504. He was probably intended for a civil life, and educated with that view, but embracing the ecclesiastical profession, he acquired a high character for sanctity and virtue, and was chosen to fill the most honourable posts of his order. He was held in much estimation by the kings of Portugal and Castile, and was made confessor to queen Catherine of Portugal, sister to the emperor Charles V. who was desirous of appointing him to the archbishopric of Braga, an honour which he resolutely declined: he uniformly refused all the offers of ecclesiastical preferment, and devoted his days to the austerities of monastic discipline, and the composition of pious and devotional treatises. He died in the year 1588. His works are theological, consisting of "A Catechism," in four volumes; "A Treatise on Prayer," in two volumes; "Sermons," in the Latin language, in six volumes; and other pious and practical pieces. The greater part of them has been translated from the Spanish and Latin into French by father Girard, and published in two volumes folio, and eight volumes 8vo.

GRENADA, in *Geography*, an island in the West Indies, about 20 miles in extent from north to south, and about 10 miles in medial breadth; the extremities gradually contracting northward and southward, and particularly towards the S.W. corner. It was discovered and named by Christopher Columbus in the year 1498; who found it inhabited by a numerous and warlike people, called Charaibes or Caribbees, among whom the Spaniards do not seem to have ever attempted to force a settlement. These original inhabitants remained happy and peaceful until the year 1650, when the avarice and ambition of a restless individual devoted them to destruction. This person was Du Parquet, the French governor of Martinico, who putting himself at the head of upwards of 200 hardy ruffians, wantonly attacked and determined to dispossess the offending natives. This atrocious act was perpetrated under the mask of religion, and with a mixture of fanaticism and knavery which no honest mind can contemplate without indignation and horror. Notwithstanding the injustice of this invasion, the commanders administered the holy sacrament, in the most solemn manner, to all the soldiers on their embarkation; and again on their landing, Du Parquet, causing a cross to be erected, compelled them to kneel down before it, and join in devout prayer to Almighty God for success to their wicked enterprise. Checked, however, in the progress of this nefarious business by some scruples of

conscience, after he had been hospitably entertained by the natives, he pretended to open a treaty with the chief of the Charaibes for the purchase of the country. Accordingly he gave the natives "some knives and hatchets, and a large quantity of glass beads, besides two bottles of brandy for the chief himself," and thus, says Du Tertre, was the island fairly ceded to the French nation by the natives themselves in lawful purchase! And their future resistance was considered as contumacy and rebellion. Du Parquet, having established a colony in Grenada, and built a fort for its protection, committed the government of the island to a kinsman, named Le Compte, who engaged in a cruel and bloody war with the Charaibes, and being reinforced with 300 men from Martinico, he proceeded to establish and maintain his authority by massacres and murders, the relation of which makes even the reader to tremble. By a series of such enormities, the whole race of Charaibes that possessed Grenada in 1650 was speedily exterminated; and the French, having destroyed all the natives, proceeded in the next place to massacre each other. Du Parquet, in the conduct and execution of those measures by which he had gained possession of Grenada, had so far impaired his fortune, that in 1656 he was under the necessity of transferring it to Count de Cerillac for the sum of 30,000 crowns. This new proprietor appointed a governor, whose tyrannical and rapacious disposition compelled the most respectable of the settlers to quit the country; and those who remained, assuming the administration of justice, brought the governor to a public trial, and ordered him for execution. Cerillac, deriving little advantage from his purchase, conveyed all his rights and interests in Grenada, &c. to the French West Indian company; whose charter being abolished in 1674, the island from that time became vested in the crown of France. The island, as we may naturally suppose, was very imperfectly cultivated during the progress of these revolutions and calamities; and even so late as the year 1700, if Raynal has been rightly informed, it contained no more than 251 whites and 525 blacks, who were employed in three plantations of sugar, and 52 of indigo. By subsequent intercourse of a fringing nature with the Dutch, the circumstances of the planters were somewhat improved, insomuch that when, in the year 1762, the fortune of war made the English masters of this and the other Charaib islands, Grenada and the Grenadines are said to have yielded annually, in clayed muscovado sugar, a quantity equal to about 11,000 hogsheds of muscovado of 15 cwt each, and about 27,000 lbs. of indigo. Grenada, having surrendered on capitulation in February 1762, was finally ceded, together with its dependencies, to Great Britain by the definitive treaty of peace at Paris on the 10th of February 1763. The chief stipulations of this treaty were as follow: 1st. That as they would become by their surrender subjects of Great Britain, they should enjoy their property and privileges, and pay taxes, in like manner as those of his majesty's subjects of the other British Leeward islands. 2dly. With respect to religion, they were put on the same footing as the inhabitants of Canada, *i.e.* liberty was given them to exercise it according to the rites of the Romish church, as far as the laws of Great Britain permitted. 3dly. Such of the inhabitants of Grenada as chose to quit the island, should have liberty so to do, and 18 months should be allowed them to dispose of their effects. The island and its dependencies being thus become a British colony, two proclamations were issued, and general Mesville was appointed governor. The crown, conceiving itself entitled by the terms of the capitulation to the duty of $4\frac{1}{2}$ per cent. upon all produce exported from the newly ceded islands, ordered such duty to

be levied in Grenada, in lieu of all customs and duties formerly paid to the French king. This order occasioned a great constitutional question, which after much agitation was referred to a solemn adjudication before the judges of the court of king's bench in England. The case was elaborately argued in Westminster hall, and lord chief justice Mansfield, in 1774, pronounced judgment against the crown: and therefore the duty in question was abolished, not only in Grenada, but also in the ceded islands of Dominica, St. Vincent, and Tobago.

The first assembly of Grenada met in 1765; and in 1768 the governor received instructions from the crown to admit two of the Roman Catholic inhabitants into the council, and to declare others to be eligible into the assembly on taking the oaths of allegiance and supremacy. These instructions, and the measures which followed them, were productive of great commotions and party divisions in the colony. The king, however, refused to revoke his instructions; upon which the most zealous of the Protestant members of the assembly declined attendance, so that it was but seldom that a house could be formed. In this state of faction and perplexity the island continued until its recapture by the French under the count D'Estaing, in 1779. By the general pacification which took place in January 1783, Grenada and the Grenadines were restored to Great Britain.

Grenada contains about 80,000 acres of land; of which the quantity actually cultivated has never exceeded 50,000 acres. The face of the country is mountainous, but not inaccessible in any part, and it abounds with springs and rivulets. To the north and the east the soil is a brick mould; on the west side it is a rich black mould on a substratum of yellow clay. To the south the land is in general poor, and of a reddish hue, which extends over a considerable part of the interior country. On the whole, however, Grenada appears to be in a high degree fertile, and by the variety, as well as excellence of its returns, seems adapted to every tropical production. The exports of the year 1776, from Grenada and its dependencies, were 14,012,157 pounds of muscovado, and 9,273,607 pounds of clayed sugar; 818,700 gallons of rum; 1,827,166 pounds of coffee; 457,719 pounds of cacao; 91,943 pounds of cotton; 27,638 pounds of indigo, and some smaller articles: the whole of which, on a moderate computation, could not be worth less, at the ports of shipping, than 600,000 sterling, excluding freight, duties, insurance, and other charges. The sugar was the produce of 106 plantations, wrought by 18,293 negroes, which is rather more than one hogshhead of muscovado sugar, of 16 cwt from the labour of each negro; a return, says Mr B. Edwards, equalled by no other British island in the West Indies, St. Christopher's excepted. The exports of 1787 were 175,548 cwt. 9 lbs. of sugar; 670,390 gallons of rum; 4,300 gallons of molasses; 8,812 cwt. 2 qrs. 4 lbs. of coffee; 2,716 cwt. 3 qrs. 18 lbs. of cacao; 2,062,427 lbs. of cotton; 2,810 lbs. of indigo, and miscellaneous articles; such as hides, dyeing wood, &c. to the amount in value of 64,545*l.* or 8*d.*; and the total value of all, according to the current prices in London, 614,908*l.* 9*s.* 3*d.*

This island is divided into six parishes, *viz.* St. George, St. David, St. Andrew, St. Patrick, St. Mark, and St. John; and its chief dependence, Carriacou, forms a seventh parish. Since the restoration of Grenada to Great Britain in 1783, an island law has been obtained for the establishment of a Protestant clergy. This act, which passed in 1784, provided stipends of 330*l.* currency, and 60*l.* for house-rent *per annum*, for five clergymen, *viz.* one for the town and

and parish of St. George, three for the other five out parishes of Grenada, and one for Carriacou. Besides these stipends, there are valuable glebe lands formerly appropriated to the Roman Catholic clergy, when that was the established religion of Grenada, which became vested in his majesty as public lands on the restoration of the island to the British government, and which, it is said, have been applied by the colonial legislature, with the consent of the crown, to the further support of the Protestant church, with some reserve for the tolerated Romish clergy. The capital of Grenada, soon after the cession of the country to Great Britain by the peace of Paris, is called *St. George*, which see. The other towns in Grenada are, properly speaking, inconsiderable villages or hamlets, which are generally situated at the bays or shipping places in the several out-parishes. The parish town of Carriacou is called Hillsborough. Grenada has two ports of entry, with separate establishments, and distinct revenue officers, independent of each other; one at St. George, and one at Grenville bay, a town and harbour on the east, or windward side of the island. The whole population of Grenada and the Grenadines has decreased considerably since these islands first came into possession of the English. In the year 1771, the number of white inhabitants was somewhat more than 1600; in 1777, they had decreased to 1300, and at a later period they were supposed not to exceed 1000, of which about two-thirds are men able to bear arms, and incorporated into five regiments of militia, including a company of free blacks or mulattoes attached to each. There are likewise about 500 regular troops from Great Britain, which are supported on the British establishment. Besides the regular troops sent from Great Britain for the protection of Grenada, there are in its garrison three companies of king's negroes, which came from America, where they served in three capacities, as pioneers, artificers, and light dragoons. In Grenada they form a company of each, and are commanded by a lieutenant of the regulars, having the rank of captain. The negro slaves have also decreased. In 1779 they were stated at 35,000, of which 5000 were in Carriacou and the smaller islands. In 1785 they amounted to no more than 23,926 in the whole. The free people of colour amounted in 1787 to 1,115. To prevent the too great increase of persons of this class, every manumission is, by an act of the island, charged with a fine of 100*l.* currency, payable into the public treasury. The evidence of these people, whether born free or manumitted, is received in the courts of this island, on producing proof of their freedom; and they are tried on criminal charges in the same manner as whites. They are also allowed to possess and enjoy lands to any amount, provided they are native-born subjects or capitulants, and not aliens. The governor is, by virtue of his office, chancellor, ordinary, and vice-admiral; and presides solely in the courts of chancery and ordinary, as in Jamaica. His salary is 3,200*l.* currency *per annum*, which is raised by a poll-tax on all slaves; but in all cases of absence beyond twelve months, the salary ceases and determines. N. B. The currency of Grenada, or rate of exchange, is commonly 6*5l.* *per cent.* worse than sterling. The council of Grenada consists of 12 members, and the assembly of 26. A free-hold, or life-estate of 50 acres, is a qualification to sit as representative for the parishes, and a free-hold, or life-estate, in 50*l.* house-rent in St. George, qualifies a representative for the town. An estate of ten acres in fee, or for life, or a rent of 10*l.* in any of the out-towns, gives a vote for the representatives of each parish respectively; and a rent of 20*l.* *per annum*, issuing out of any freehold or life-estate in the town of St. George, gives a vote for a representative of the town. The law-

courts in Grenada, besides those of chancery and ordinary are the court of grand-sessions of the peace held twice a year, *viz.* in March and September; the court of common-pleas, consisting of one chief and four assistant justices, whose commissions are during pleasure, the chief justice being usually appointed in England, with a salary of 600*l.* *per annum*, and the others being commonly appointed by the governor without any salary; the court of exchequer, lately grown into disuse; the court of admiralty for the trial of all prize-causes of capture from enemies in war, and of revenue-seizures in peace or war, having one judge of admiralty and one surrogate; and a court of error, composed of the governor and council, for trying all appeals of error from the court of common-pleas. The common and statute-laws of England are considered as extending to Grenada in all applicable cases, not provided for by the laws of the island. N. lat. 12 10'. W. long. 61 30'. GRENADA, or *Granada*. See GRANADA.

GRENADA. See GRANADO.

GRENADE, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marsan; seven miles E. of St. Séver. The place contains 1330, and the canton 7563 inhabitants, on a territory of 195 kilometres, in eleven communes.—Also, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Toulouse; 12 miles N. N. W. of Toulouse. The place contains 3500, and the canton 9142 inhabitants, on a territory of 232½ kilometres, in 13 communes.

GRENADIER. See GRANADIER.

GRENADIER, in *Ornithology*. See *LOXIA Orix*.

GRENADIN. See FRINGILLA *Granatina*.

GRENADINES, or GRENADILLAS, in *Geography*, a cluster of islands in the West Indies, amounting in number to more than 20, situated between Grenada and St. Vincent, and producing cotton, coffee, indigo, and sugar. Carriacou is the principal. These islands formerly appertained to the government of Grenada; but by an arrangement of the British administration, a line of division passes in an east and west direction, between Carriacou and Union island. The former of these, and some smaller islands south of it, are all that are now comprized in the Grenada government: Union island, with all the little islands adjoining, to the north, being annexed to the government of St. Vincent. See CARRIACOU and RONDE.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour in some of their finest china, particularly for that colour which is called *oil-red*, or *red in oil*. The china-ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no such thing as silver-coined money, but they use in commerce bars or masses of silver; these they pay and receive in large bargains; and among a nation so full of fraud as the Chinese, it is no wonder that these are often adulterated with too great an alloy of copper. They pass, however, in this state in the common payments. There are some occasions, however, such as the paying of the taxes and contributions, on which they must have their silver pure and fine; on this occasion they have recourse to certain people, whose sole business it is to refine the silver, and separate it from the copper and the lead it contains. This they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush, and dip the end of it into water; then striking the handle of the brush, they sprinkle the water by degrees

upon the melted copper; a sort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large vessel of cold water, it forms that red powder, which is called the grenaille; they repeat the operation every time they in this manner separate the copper; and this furnishes them with as much of the grenaille as they have occasion for in their china works. Observations sur les Cōtumes de l'Asie, p. 309.

GRENAHEN, in *Geography*, a town of Switzerland, in the Valais; 25 miles E. of Sion.

GRENAT, in *Ornithology*. See *TROCHILUS Auratus*.

GRENIER, in *Geography*, mountains of Hindoostan, in the country of Guzerat, near Junagur.

GRENNÄ, a town of Sweden, in the province of Smaland; 10 miles N.N.E. of Jonkioping.

GRENOBLE, an ancient, large, and well-built city of France, and capital of the department of Isere, situated in a marshy but fruitful plain, at the foot of a hill, near the conflux of the river Isere. Before the revolution it was the capital of Dauphiny, the see of a bishop, and the seat of a parliament. It was the scene of many cruelties in the religious wars, A.D. 1562. It is divided by the river Isere into two unequal parts, the largest of which is regularly built. Its manufactures are cloth, hats, gloves, &c. The number of its inhabitants is 23,500 in 3 cantons, on a territory of 265 kilometres, in 26 communes. To the north are the ruins of a citadel, on an eminence, which commands an agreeable prospect of the town, the banks of the Isere, and several fertile vallies. In a rugged valley, watered by the rapid Drac, about 5 leagues S. of Grenoble, are the mineral springs of La Motte, highly esteemed as a remedy for fluxes and all disorders of the stomach, but little used on account of the difficult access to them. Four leagues N. of Grenoble is Le Grand Chartreuse, a famous Carthusian monastery, founded A.D. 1086, consisting of an excellent library, and many apartments, on an eminence environed by rugged precipices of difficult access. N. lat. 45° 11' 59". E. long. 5° 43' 10".

GRENOUILLES, LES, a cluster of rocks in the West Indian ocean, about 36 miles S.E. from point Morand, in the island of Jamaica. N. lat. 17° 32'. E. long. 76° 32'.

GRENVILLE, a town of Nova Scotia. See *GRANVILLE*.

GRENVILLE, a county in Upper Canada, bounded on the E. by the county of Dundas, on the S. by the river St. Lawrence, and on the W. by the township of Elizabeth town, running N. 24° W. till it intersects the Ottawa or Grawl river, and thence descending that river until it meets the north and westernmost boundary of the county of Dundas. This county comprehends all the lands near to it in the river St. Lawrence.

GRENVILLE'S Canal, a channel of the N. Pacific ocean, which separates Pitt's Archipelago from the coast of New Cornwall.

GRENZHAUSEN, a town of Germany, in the county of Wied; 5 miles N.E. of Coblenz.

GREPPEN, a town of Switzerland, in the canton of Lucerne; 5 miles E. of Lucerne.

GRES, CAPE AU, a promontory on the E. side of the Mississippi, in the N.W. territory, 3 leagues above the Illinois river, and the tract of country so called extends 5 leagues up that river.

GRESHAM, Sir THOMAS, in *Biography*, an eminent London merchant, son of sir Richard Gresham, who was

raised to the high office of lord mayor of the city of London, was born in 1519. He received an academical education at Cambridge, but being designed to follow the commercial business of the family, he was bound apprentice to his uncle sir John Gresham, and thus became a member of the Mercers' company. His father was agent of the king's money concerns at Antwerp, and Thomas expected to be his successor in this business, but the preference was given to another person, by whose mismanagement they were brought into a deplorable condition. Recourse was now had to the subject of this article, who was sent over in 1532 by the regency in the minority of Edward VI., in order to retrieve them. In this affair he exerted so much talent, that in two years he was able to pay off the whole of a loan bearing enormous interest, and raised the king's credit to the most respectable rank. At the accession of Elizabeth, he was for a time deprived of his office, but it was restored to him again, and he continued in it as long as he lived. He also received at the hands of his sovereign the honour of knighthood. He transacted many important pecuniary negotiations of that long and glorious reign, and was a most spirited promoter of the infant manufactures of the kingdom, those of small wares in particular being established chiefly through his means. His own property, derived by inheritance, with that acquired by his industry and talents, made him the richest subject in the metropolis, and he made use of his wealth to noble and extensively beneficial purposes. In 1564 he had the misfortune to lose his only son, and he fell upon the means of diverting his grief on this melancholy occasion by public undertakings. The first design of building an exchange for merchants, in imitation of that of Antwerp, was entertained by his father. Sir Thomas carried the plan into effect, and completed the noble building in three years. (See *ROYAL Exchange*.) When the troubles in the Low Countries interrupted the accustomed loans to the crown from Antwerp, sir Thomas advised the minister to apply to the merchants of his own country, and this may be considered as the commencement of the immense advances since made to the crown from the same body. Sir Thomas Gresham next determined to bestow a part of his wealth in founding a college for the sciences in his native city. The principal people in the university of Cambridge endeavoured to dissuade him from thus establishing a rival institution; but his determination was fixed. He devised by will his house in Bishopsgate-street for the purpose of being converted into habitations and lecture-rooms for seven professors, or lecturers on the seven liberal sciences, who were each of them to receive a salary out of the revenues of the Royal Exchange. These lectures are still given in apartments in the Royal Exchange, whenever there are a sufficient number of auditors assembled to call for the exertions of the lecturer. The subjects of the lectures are *divinity, law, physic, astronomy, geometry, music, and rhetoric*. Sir Thomas endowed many public charities. He died suddenly in his own house in the year 1579, and was buried in a sumptuous manner in the church of St. Helens, Bishopsgate-street. He had expended large sums of money in erecting corn, oil, and paper-mills upon the stream of the Brent, near his favourite villa at Otterly-park. Biog. Brit.

GRESHAM College. See *COLLEGE*.

GRESHOLM, in *Geography*, a small island of Denmark, in the Categat; 4 miles N.E. of Leshoe.

GRESI, a town of Turkish Armenia; 28 miles S.E. of Rizeh.

GRESLEY'S CANAL, is an inland navigation in Staffordshire, near Newcastle-under-line, made in pursuance of an act of 15 Geo. III. To the account given in our article

CANAL

CANAL we have here only to add, that in 1805 the Nantwich and Newcastle rail-way was proposed, to connect with this canal, at Dale's pool.

GRESLING, in *Ichthyology*, a name given by the Germans to the *gobius fluviatilis*, or common gudgeon, which is very frequent in their smaller rivers.

GRESNICH, in *Biography*, a modern German composer of the Italian school, who has composed several successful operas in Italy, and whose capital *bravura* airs were frequently sung in England by madame Mara, for whose abilities of execution we believe they were originally composed.

GRESSEN, in *Geography*, a town of Samogitia; 20 miles N.N.E. of Miedniki.

GRESSET, JOHN BAPTIST LEWIS, in *Biography*, born at Amiens in the year 1709, was educated among the Jesuits, and from this retreat he sent forth some poems, which possessed all the ease and delicate pleasantries that could have been looked for from the pen of a man of the world. These were entitled "Ver Vert," a very pleasing tale; his epistles of "La Chartreuse;" "Les Ombres," and many others. His reputation as a poet was the cause of his quitting the society, and fixing his residence in the metropolis. He now tried his powers in dramatic composition; in tragedy he had very little success, but his comedies were better received; and that entitled "Mechant," represented in 1747, raised him to the first rank of writers in this class. It was regarded as a masterpiece in that species of comedy which paints manners with truth and force, without being highly comic. Gresset was admitted a member of the French academy in the year 1748. He grew weary of a literary life, seemed to doubt of the propriety of theatrical exhibitions, and soon after re-

nounced the stage, by a letter, in which he displayed the dangers attending public spectacles. He returned to Amiens, where he obtained a post under government, married a lady with a good fortune, and passed the remainder of his life in a manner which acquired him the esteem and respect of his fellow citizens. In 1775 he revisited the metropolis, and had the honour, as director of the French academy, to compliment Lewis XVI. and his queen on their accession to the throne. His discourse on this occasion, which was printed, was a severe satire on the vices and follies of the metropolis. He died in June 1777, having received, some time previously to this, letters of nobility, and having been likewise appointed historiographer of the order of St. Lazare. Gresset is placed between Chaulieu and Voltaire for the graces of light poetry: he is perhaps the first at the theatre for elegance of versification in comedy, and his morals were as pure as his style. Gen. Biog.

GRESSIN, in *Geography*, a town of Hindér Pomerania; 14 miles S.E. of Belgard

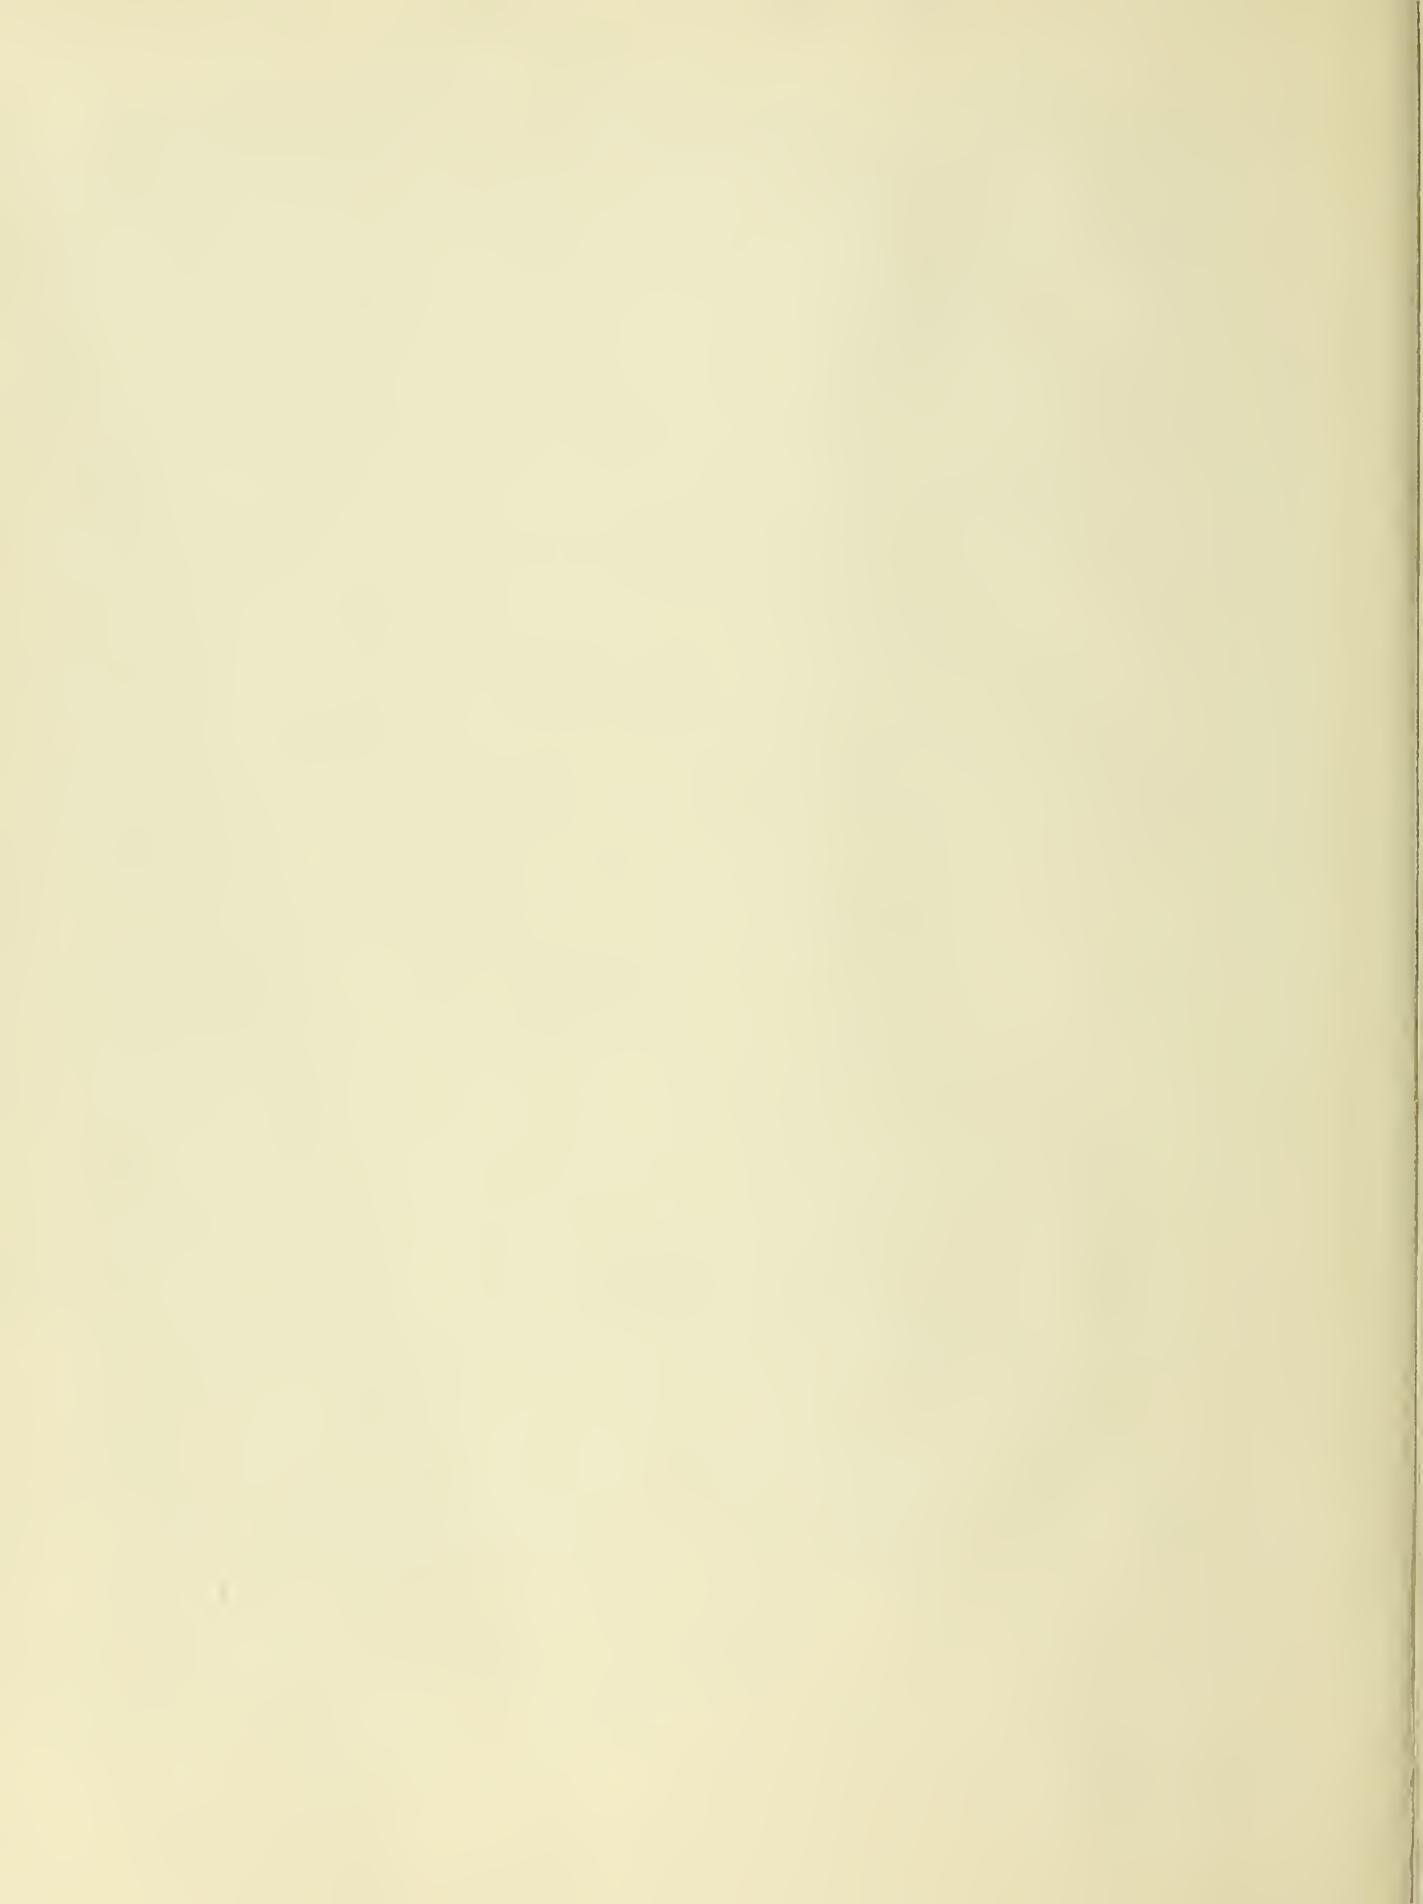

GRESTEN, a town of Austria; 9 miles N.E. of Bavaria Waidhoven.

GRETA, a river of England, which rises in the N.W. part of Yorkshire, and runs into the Tees, about 4 miles below Bernard's Castle, in Durham.

GRETNA GREEN, a mean village of Scotland, in the shire of Dumfries, 8 miles from Carlisle, and 82 from Edinburgh, at the S.E. extremity of the county, near the W. bank of the Sark, and bottom of Solway firth; famous for the clandestine marriage of parties from England, celebrated by persons who have no right to marry, or to exercise any part of the clerical function; because it is out of the jurisdiction of the marriage act.
