26. *G. byzantinus*. Mill. Dict. ed. 8. n. 3. Ic. t. 142. f. 1. Ker in Curt. Mag. t. 874. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 102. Park. Parad. 191. f. 3.—Leaves many-ribbed. Spike two-ranked. Flowers horizontal; upper segment covered laterally by the next; three lowermost equal, each with a linear-lanceolate stripe.—Supposed to be a native of Turkey, it having been for near two centuries a hardy inhabitant of our gardens, under the name of the Byzantine corn-flag, though generally confounded, as *G. communis* of Linnæus, with the two following. We readily submit to Mr. Ker's corrections of this error, in which we have, in common with most botanists, been involved, but which is now also corrected in the new edition of *Hort. Kew.*—All the three have broad, upright, acute, many-ribbed leaves, and handsome crimson flowers, projecting horizontally, in a long upright, unbranched spike, with lanceolate concave bractæas. The three segments of the lower lip are each marked with a central white or yellowish stripe, bordered with deep red, and more or less dilated in the middle. The flowers of the present species are larger than in either of the other two, their three lower segments very nearly equal in size and shape; the uppermost is embraced and covered at its sides by the lapping over of the two lateral segments, so that the flower is closed, not pervious, at that part. It blossoms in June, rather before the *communis*, but, according to Mr. Ker, never bears seeds in England, nor does it increase by root so rapidly as the other two.

27. *G. communis*. Linn. Sp. Pl. 52. Curt. Mag. t. 86. Riv. Monop. Irr. t. 110. (*G. narbonensis*; Ger. em. 104. Park. Parad. 191. f. 1.)—Leaves many-ribbed. Spike one-ranked. Flowers horizontal; upper segment covered laterally by the next; three lowermost each with a linear-lanceolate stripe; the central segment very large.—Native of fields in the south of Europe, especially in moist situations, where it is a troublesome weed. It is now less commonly kept in our gardens than the last, from which it differs in the smaller size of its blossoms, which are approximated nearly into one row, only a little spreading alternately, and whole lowermost or central lobe is as broad as both the other two, and considerably longer. This is visible even in dried specimens.

Specimens. We have this species from M. Favrod's herbarium, gathered wild in Switzerland, so that it appears to be Haller's n. 1261, the smaller variety; his larger being probably the following species. There is much difficulty in determining the synonyms of old authors, their cuts not being correct in those parts on which our characters are founded; Parkinson's *G. italicus*, for instance, Parad. 191. f. 2, has precisely the lower lip of this present species, but not the inflorescence, whilst his f. 1. does not shew the lip so well as the position of the flowers. As however he mentions but two white stripes in his description, so many only being visible, as the segments naturally stand in our *communis*, we have little doubt of his synonym. The *communis* of the Linnæan herbarium is our's, and has winged seeds, so that we trust this name will remain fixed, as belonging to the most common and general species, whatever Linnæus might comprehend under it as varieties.

28. *G. segetum*. Ker in Curt. Mag. t. 719. Dryandr. in Ait. Hort. Kew. ed. 2. v. 1. 102. (*G. communis*; Bulliard. Herb. de la France, t. 8. Sm. Fl. Græc. Sibth. v. 1. 27. t. 37, 38. Lamarck Illustr. t. 32. Tourn. t. 190. *G. italicus*; Ger. em. 104.)—Leaves many-ribbed. Spike one-ranked. Flowers horizontal; upper segment distant; three lowermost equal, each with a linear-lanceolate bordered stripe.—Native of corn-fields in the south of Europe, common in Italy, Greece, and the neighbouring countries, flowering in the spring; hardy, but not frequent in gardens. It is distinctly represented in the Hortus Eystettensis, by the name of *Viciorialis rotunda*; Ord. Eft. 4. t. 10. f. 2, though the other *Gladioli* of that huge book are less precise. This is distinguishable from the two last by the distance between the uppermost lobe of its *bloffoms* and the two next, which are peculiarly narrow; and the *seeds*, according to Mr. Ker, are round, with a somewhat pulpy coat, not flattened and winged as in the whole of the genus besides, which is a most material specific distinction, and even forms an exception to one of the generic characters. Mr. Ker suspects the existence of other European species, still confounded as varieties of these, and which may perhaps account for anomalies and incongruities in the figures of authors. Whether t. 38. of Flora Græca may be one of these, we must submit to future enquiry. Though small, it is said to be a native of fertile ground; the three upper segments seem more approximated, and the three lower ones united by a longer base, than in t. 37, our *G. segetum*; but this we learn merely from the figure, nor was the artist acquainted with the characters subsequently found out in this tribe, so as to give peculiar authority to what he has expressed in his drawing. The acquisition of living specimens at some future time can alone settle the question.—It is proper to mention that *G. spicatus* of the Linnæan herbarium, alluded to by Mr. Ker, is a Siberian specimen, with very broad lateral segments to the corolla, and as far as we can judge seems rather to be *communis*, if not, as is possible, a species hitherto undefined. It is probably different from the African plant of Van Royen, intended in Sp. Pl. ed. 1. nor has it the authentic marks of originality. What might chance to be compared with it in the Banksian herbarium, when none of the parties present had any precise ideas about these plants, we cannot answer for, but our specimen was then voted to be *communis*.

29. *G. imbricatus*. Linn. Sp. Pl. 52. Lamarck. Dict. v. 2. 723.—Leaves many-ribbed, spike of numerous, crowded, upright flowers; upper segment rather distant; three lowermost nearly equal.—Gathered by Gerber near Luban in Livonia. His own specimen in the Linnæan herbarium is the only one we have seen, nor do recent writers appear to know any thing

of this species, which appears to us very distinct, akin to the three last in *leaves* and habit; but differing widely in its curved ascending *spike*, and crowded erect *flowers*, which are smaller than those of *G. communis*, of a purple or crimson colour, pervious at the base, in consequence of a considerable distance between the claws of the upper and lateral segments, while their upper parts seem to fold over each other; but of these characters we cannot, of course, speak absolutely, from the dried flowers; the three lowermost segments seem equal and rather narrow. No white stripe is discernible in their present condition. The *leaves* rise above the spike of flowers, and have each an oblique point, but this may not be constant.

Whatever species of *Gladiolus* (exclusive of such as are now referable to the genera *Sparaxis*, *Anomatheca*, *Tritonia*, *Watsonia*, *Melassphæra* or *Babiana* of Mr. Ker), may be found here and there in authors, we decline describing without seeing living specimens. The discordance between several of the figures, above quoted for the same species, proves how variable many of them are, especially from accidental circumstances in cultivation. The Botanical Magazine is now become a faithful and valuable repository of this family, so that however botanists may differ about definitions, the memory of the plants can never be entirely lost.

GLADIOLUS, in Gardening, comprises plants of the tuberous-rooted, flowery, perennial kind; of which the species mostly cultivated are the common sword-lily, or corn-flag (*G. communis*); the imbricated flowered gladiole (*G. imbricatus*); the square-stalked gladiole (*G. tristis*); the narrow leaved gladiole (*G. angustus*); and the superb scarlet gladiole (*G. cardinalis*).

There are several varieties of the first species, as the Italian and French corn flags, with the bluish, the white, and the small purple coloured.

Method of Culture.—In the first sort and varieties the culture may be readily effected by planting the off-sets from the old roots in the beginning of the autumn in the places where they are to grow. And the other sorts may be raised in the same way as well as by seeds. These should be planted in a warm border, and be protected in the winter by glass or some other means, when there is a necessity for it, as during very severe weather, &c.

When increased by seed it should be sown towards the end of August, in pots filled with light earth, placing them in a shady situation at first, but afterwards where they may be exposed to the sun, being protected during the winter in a hot-bed frame, free air being admitted when the weather is mild. In the spring the pots should be removed to a shady situation, with only the morning sun. When the stems decay, the roots should be taken up and kept in sand in a dry place till the time of planting. In the second year's planting they should be put in separate small pots, filled with mould formed from the turf or sward.

With respect to the old roots they may be taken up every two or three years, to have the off-sets taken off from them, in order to their future increase.

All the sorts afford a fine effect and variety in the flower borders and other parts among other plants of the flowery kinds, being properly arranged in mixture with them.

GLADIUS, SWORD. *Jus Gladii*, or right of the sword, is used, in our ancient Latin authors, and in the Norman laws, for supreme jurisdiction.

Camden, in Britannia, writes "Comitatus Flint pertinent ad gladium Cestriæ:" and Selden, Tit. of Honour, p. 640. "Curiam suam liberam de omnibus placitis, &c. exceptis ad gladium ejus pertinentibus."

And it is probably from hence, that at the creation of an

earl, he is *gladio succinthus*; to signify, that he had a jurisdiction over the county.

GLADIUS piscis, in *Ichthyology*, a name used by many for the sword-fish, called also the *xiphius*, which see.

GLADKA, in *Geography*, a fort of Russia, in the government of Caucasus, on the Malva; 36 miles W. of Kishiar.

GLADWIN. See IRIS.

GLADWIN, JOHN, in *Biography*, the late organist of South Audley chapel, was the first performer on the organ at Vauxhall, after the building of the orchestra in the middle of the gardens, and the establishment of a regular band. He was a pleasing player in his day, and a worthy man, who lived to a great age, and died in 1799.

GLAIR of Eggs, is the same as the white of eggs, and is used as a varnish for preserving paintings. For this purpose it is beat to an unctuous consistence, and commonly mixed with a little brandy or spirit of wine, to make it work more freely, and with a lump of sugar to give it body and prevent its cracking; and then spread over the picture or painting with a brush.

GLAIZE, AU, in *Geography*, a S.S.W. branch of the Miami of the lake in America, which interlocks with St. Mary's river. By the treaty of Greenville, the Indians have ceded to the United States a tract of land, six miles square, at the head of its navigable waters, and six miles square at its confluence with the Miami, where port Defiance now stands.

GLAMA, in *Zoology*. See CAMELUS.

GLAMMISS, in *Geography*, a small town in the county of Forfar, Scotland, contains 385 houses, and 1931 inhabitants. Here are two small manufactories of yarn, and coarse linen cloth. The earls of Strathmore formerly possessed, and occupied a noble castle in this parish. The remains of this baronial fortress are still very considerable, and occupy a commanding site on the banks of the river Dean. In this parish are several ancient obelisks, or stone crosses; also many cairns. These are traditionally said to commemorate the murdered king Malcolm II. Glammiss is divided into two parts respectively, called the New, and the Old Town.

GLAMORGANSHIRE, the south maritime county of South Wales, is supposed to have derived its name from having afforded a temporary, though insecure, retreat to an ancient prince, at a very early period of British history. The story is briefly recapitulated by Spenser, in his *Chronicle of British kings*. (Fairy Queen, b. ii. c. 10.) Glamorgan was in succeeding ages an independent sovereign principality, distinct, as those who profess to be acquainted with the ancient history of Wales assert, from the rule and government of South Wales. The principality, or sovereign lordship of Glamorgan, as these persons say, contained the present counties of Glamorgan and Monmouth, the southern and eastern parts of Brecknockshire, and that part of Herefordshire lying to the west of the river Wye.

The lordship of Glamorgan was subdivided, at an early period, into a great many petty lordships, in every one of which their lords exercised "*jura regalia*," reserving, however, to the subject a right of appeal to the court of the chief lord, or, as he was termed, the lord paramount. There are at least 50 ancient buildings still remaining in the district, universally understood to be the halls in which the courts of legislation and of justice were held for the respective petty lordships. They are now commonly called "*Church-houses*," and belong to the parishes in which they stand. They are at present used as school-rooms, and occasionally for dancing; an amusement still common in Glamorganshire, though now beginning to decline. The ground-

floor apartments under these halls are used as alms-houses for the poor of the parish. From ancient surveys and other accounts of the lordships it appears that before the reformation a market was held in each of these halls every Sunday morning, till the tolling of the first bell, which is said to have been intended as a notice for the business of the market to cease. The second bell was a signal of preparation for church, and the third for the commencement of divine service, during which no door, but the church door, was allowed to be seen open.

This county, extending about forty-eight miles from east to west, and 27 from north to south, is bounded on the N. by Brecknockshire, on the E. by Monmouthshire, from which it is separated by the river Remny, on the S. by the Bristol channel, and on the W. by Caermarthenshire. The greatest part of the sea-coast forms a semi-circular course; the western extremity being formed into a narrow beak between the open channel on the one hand, and an arm running round to the Caermarthenshire coast on the other. (See GOWEN.) An ample account of the manner in which the lordship of Glamorgan was obtained by its conquerors, is to be found in Powell's History of Wales, written in the time of Elizabeth, or in Evans's edition of Wynn's History of Wales. The following abstract is taken from Malkin's work. Jestin ap Gurgant, a petty prince of odious character, waged war, in the year 1088, against Rees ap Tudor, and was assisted by Eneon ap Collwyn. Unable to make any impression on his enemy's dominions, Jestin commissioned Eneon to go to England, and to procure some more powerful ally. His propositions were eagerly received by Robert Fitzhauen, and twelve other Norman adventurers, who came to Glamorgan on an expedition, professedly for the purpose of retrieving the affairs of Jestin. The allies, marching against Rees ap Tudor, came up with his forces on the borders of Brecknockshire. In a battle which ensued at a place called Hirwin, Rees was entirely defeated: and in his flight was taken prisoner, and put to death. On this occasion, Jestin betrayed his characteristic treachery, by violating his agreement with Eneon, to whom he had promised his daughter in marriage, as a recompence for his services. Eneon, justly offended, was determined on revenge; and therefore, when the Normans, after having fulfilled their engagements, and having obtained satisfaction for their services, quietly returned home, Eneon represented the injuries he had sustained by the treachery of Jestin, and also the hatred of the country to its tyrant. He also stated how easy it was to obtain possession of this feeble country, with the aid of the different princes at variance with Jestin. R. Fitzhauen, and his soldiers of fortune, availing themselves of the favourable moment, turned their arms against their employer, who was unprepared for so formidable a reverse, and overran the country; whilst Jestin saved himself by flight, and died soon after, unlamented and unrevenged. Fitzhauen, upon a division of the conquered territory, took for his own share the castles of Cardiff and Kenfig, with the market town of Cowbridge, and the demesne of Llantwit; appropriating to himself the lands belonging to them, together with the sovereignty of the whole country. The other parts were distributed in various proportions among his followers. Eneon ap Collwyn, in particular, possessed Caerphilly, with Jestin's daughter in marriage, the prize which occasioned the contest. (See WALES.) With respect to the picturesque character of this county, it is distinguished by unbounded variety. It has sea, mountains, valleys and rivers; and it is said to resemble North Wales in general aspect more than any of the six counties. Its mountains are not so high as those of Brecknockshire, but they present, in a considerable degree, the appearance

GLAMORGANSHIRE.

appearance of Merionethshire, by their extreme abruptness, which imparts an air of wildness to the country, and of elevation exceeding the reality to them. They differ, however, in one material respect, that they exhibit greater traces of cultivation and occupancy. Glamorganshire lies under the imputation of want of wood; but this is only true of its level and most cultivated parts. The observation does not apply either to its eastern or western extremities. Those who know the banks of the Taff, the two Ronthas, and the Cunno, the wilds of Abudarr, and Ystradyvodwg, have seen such woods and groves as are rarely to be found. The magnificently clothed hills of Margam, Bagland, Britonferry, and the vale of Neath, unite the beauties of cultivation with the unfelled luxuriance of forest scenery. Glamorganshire produces with sufficient liberality oak, ash, beech, and all the common forest-trees, except elm, which is observed not to be indigenous. On the north and north-east sides this county is very mountainous; and in some parts presents rugged rocks, and in others a soil covered with plenty of fine wood, and concealing rich mines of coal and iron. A tract of land can scarcely any where be found more inviting to scientific cultivation than the vale of Glamorgan, between the mountains and the sea; and yet it is observed that the agriculture of this county does not keep pace with the fertility of the soil. In addition to natural fruitfulness, they have lime every where at command for manure; and this facility affords a strong temptation to that act of injustice which the farmers call "driving the land." In Glamorganshire, good land, situated near a considerable town, lets almost as high as within five miles of London; but land among the northern hills, scarcely reclaimed, and from its locality irreclaimable to any very lucrative purpose, is of course low in its rent, and occupied only by tenants, natives of the hills, and unacquainted with the superior advantages and comforts enjoyed by the farmer in the vale. Another circumstance which materially affects the value of farms, is light of mountain; where that is attached to an estate, it compensates in some degree for distance from markets or poverty of soil. These considerations are applicable to other counties as well as Glamorganshire. But what distinguishes and enriches this county above all the rest is the profusion of coal, iron, and lime-stone, with which it almost every where abounds. The earth, indeed, of which it is composed, taken externally and internally, seems to be full of every thing necessary to the use and convenience of man. Manure, metal, and the means of manufacturing that metal, are all found on the same spot; so that industry is exerted at the least possible expence, and consequently to the greatest possible advantage. The rivers, and mountain torrents, so remarkable in this district, afford an ample supply of water for all the purposes of life, as well as the means of procuring that artificial and cheap conveyance which is among the most ingenious improvements of the present age. With respect to that most extensive bed of lime-stone, of which nearly the whole of Glamorganshire forms only a part, it commences with the eastern extremity of the county, and, taking a direction due west, runs in a straight line to Swansea bay, appearing again in Gower, and, having passed under Caermarthen bay, is seen to occupy in great part the south and west of Pembrokeshire; it then takes its course through St. George's channel, and is found in Ireland in that exact bearing which unquestionably marks its continuity.

The air on the N. side of the county is sharp, occasioned by the long continuance of the snow on the hills; but on the S. side mild and temperate, occasioned by the sea-breezes. That in the vicinity of Margam is deemed peculiarly salubrious.

The antiquity of the cottages is a strongly marked feature in the appearance of this county. Many of them are probably as ancient as the castles, to which they were attached. Their architecture is particularly deserving of notice. The pointed door-ways, and pointed windows, sufficiently evince their date; and though Welch towns are universally censured by strangers, for the inelegance and inconvenience of their houses, the direct reverse is the fact with respect to the habitations of the peasantry. There is one circumstance, besides their general structure, that of many of which is the ancient Gothic, which adds to the respectable appearance of the cottages, and that is, the universal practice of lime-whitening them. This has been the custom of the county from very remote ages, and is extended even to the barns and stables, to the walls of yards and gardens. It is noticed and praised in the most ancient Welch poems, and certainly evinces a very early sensibility to the arts and decencies of life. The price of provisions in this county has of late very much increased, and is comparatively very high, on account of the increased demands of the manufacturing districts, which are numerous. The price of labour is equally enhanced from the same cause. The increase of population, owing to the influx of commerce, and the magnitude of its establishments at Swansea, Merthyr-Tydvil, Neath, Aberavon, Melin Gruffydd, near Cardiff, where are the largest tin works in the kingdom, &c. afford another reason why the cheap comforts and elegancies of life are no longer to be fought for here.

The dress in Glamorganshire is not so strongly marked as in some other counties, except that the women universally adopt the man's hat; but they wear it with a very good grace, and are remarkably neat in their attire, as well as comely in their persons, and graceful in their carriage; which may probably be attributed to the habit of dancing, which is their favourite amusement. Their modes of greeting are unusually affectionate, sometimes bordering on the ludicrous, particularly among the women, who are constantly seen saluting each other at market, and on the most ordinary occasions of business, as well as on occasions of distress. At a wedding it is the custom of all who are invited, both men and women, to ride full speed to the church porch, and the person who arrives there first has some privilege or distinction at the marriage feast. In case of death, the bed on which the corpse lies is always strewed with flowers, and the same custom is observed after it is laid in the coffin. It is an invariable practice, both by day and night, to watch a corpse; and the hospitality of the country is no less remarkable on melancholy than on joyful occasions; for the invitations to a funeral are very general and extensive; and the refreshments are not light, and taken standing, but substantial and prolonged. The grave of the deceased is constantly overspread with plucked flowers for a week or two after the funeral; the planting of graves with flowers is confined to the villages, and the poorer people. It is very common to dress the graves on Whitfriday, and other festivals, when flowers can be procured.

The Roman stations, forts, and camps, in this county, are generally understood to be at Cardiff, Caerphilly, and Caera, which lies between Wenvoe, a large handsome house built in the castellated form, and the Cardiff road. The great Roman road was over Newton Down, leaving the present road on the right, and passes through Kenfig to Margam, and as straight as the nature of the country will admit, through Aberavon parish to Neath. Glamorganshire contains one episcopal town, viz. Llandaff, and several others, as Cardiff, the capital of the county, Caerphilly, Llantrisant, Cowbridge, Bridgend, Neath, Merthyr-Tydvil,

and Swansea; which see respectively. The principal rivers are the Remney, the Taff, the Elwy, the Ronthas, great and small, the Ogmere, the Cummo, the Nedd or Neath, the Tawe or Tave, and the Lloghor. In this county are several rail-ways and canals. (See CANAL.) The canal from Merthyr-Tydvil to Cardiff was completed in the year 1798. From the tide-lock, where it enters Pennarth harbour, up to the town of Cardiff, it is navigable for ships of 400 tons; but from Cardiff to Merthyr-Tydvil, it is navigable for barges of 100 tons. The head of this canal at Merthyr-Tydvil is 568 feet five inches higher than the tide-lock two miles below Cardiff, where it falls into Pennarth harbour. This canal has upwards of 40 locks upon it in the space of 26 miles, which is its whole length; and it is crossed by more than 40 bridges. For an account of the bridge with one arch upon Taff; see BRIDGE. In a vale S. W. of Cardiff, near Duffrin house, and not far from the village of St. Nicholas, are some ancient monuments, supposed to be druidical. The most remarkable of these monuments is a grey stone, which classifies among those pieces of antiquity called Cromlechs. (See CROMLECH.) This monument is supported by five large stones, enclosed entirely on the east, west, and north sides, and open to the south, forming a considerably large, though low room, 16 feet in length, 15 wide, and, at the east end, six feet high, but only 4½ at the west end. The rubbish about it prevents the investigation of its original height. The supporting stone to the north is 16 feet long; that on the west end about nine feet in length. At the eastern extremity three stones are set closely together; the middle stone is 4½ feet wide, the northern stone of these three about three feet, and the southern nearly two feet in width. These stones, standing upright, support a large stone on the top, which forms the roof of this rude apartment. The length of this horizontal stone is 24 feet; it is 17 feet in its widest part, and of different breadths at other places; it is 10 feet at one extremity, and 12 about the middle; and from two feet to two and a half thick. The area of the top-stone, therefore, having for its mean breadth 13½ feet, and 24 feet for its length, will contain 324 square feet; whence it appears that it is nearly thrice as large as that of the famous cromlech, near Newport in Pembrokeshire. Near this cromlech are other heaps of stones called Carneu or Cairn. Of these cromlechs different opinions have been entertained. Some have supposed them to be places of shelter for the Druids, who always worshipped in the open air, and after them, for the first Christian priests, in rain and other inclemencies of the weather; others have supposed them to be oratories, from the tops of which they delivered their discourses; and others again, that they were altars on which victims were offered in the times of Druidism.

Glamorganshire is divided into ten hundreds, and 118 parishes, which, in 1801, contained 71,525 inhabitants, of whom 6903 were employed in trade and manufacture, and 18,515 in agriculture. Two members are returned for Glamorganshire to the British parliament, viz. one for the county, and one for the boroughs, Cardiff, &c. Malkin's South Wales.

GLAMOUR, or GLAMER, an old term of popular superstition in Scotland, denoting a kind of magical mist believed to be raised by forcerers, and which deluded their spectators with visions of things that had no existence, altered the appearance of things really existing, &c.

GLAN, a river of France, which runs into the Nahe, three miles E. of Sobernheim—Also, a river of Carinthia, which rises near Kofenberg, and joins the Gurek, four miles E. of Clagenfurt.

GLAND, in *Anatomy*, is a name applied to those organs of the body, which separate from the blood conveyed to them by their blood-vessels various substances, generally of a fluid nature, and discharge them through one or more tubes, called excretory ducts. The term however has been, and is employed more extensively, having been applied to various organs, which, although analogous in their structure, on superficial observation, to those already designated, do not resemble them at all in their functions. Thus, the small bodies belonging to the lymphatic system have been called lymphatic or conglobate glands; although the knowledge hitherto acquired by physiologists concerning the action of these bodies, and their anatomical relations and connections do not warrant us in ascribing to them any function similar to those exercised by the glands properly so called: the account of these will be found under the articles ABSORBENTS and ABSORPTION. The pineal, thyroid and thymus glands, the renal capsules and the spleen, have all been included in the glandular system of the body, but will not be considered in this article, as we know nothing at all of their offices, and have no reason to suppose that they secrete any fluid. Our definition will include the salivary, lacrymal, and Meibomian glands, the tonsils, the ceruminous glands of the ear, and the sebaceous glands of the face, in the head; the mammary glands in the chest; the liver, pancreas, and kidneys in the abdomen; the prostate, testicle, Cowper's glands, and glandulæ odoriferæ about the penis; and the extensive system of mucous glands about the head and trunk. These parts, although differing widely from each other in many respects, agree in a sufficient number of points to allow of their being arranged in one organic system, which has been named the glandular: the other organs just enumerated, belonging to this only in name, are excluded from the arrangement by their texture and properties, their mode of vitality and functions. The extremities contain no parts belonging to the glandular system; the fluids formed in the different organs of this apparatus belong almost entirely to the organic functions, while the limbs are particularly designed to execute the offices of the animal life.

As the physiology of these organs cannot be conveniently separated from the history of their structure, we shall consider the vital properties as well as the organization of the glandular system; and we should make a very unnatural and arbitrary division of the matter, if we did not give at the same time a view of secretion in general. We shall present the reader, in the first place, with an enumeration and arrangement of the secreted matters; we shall proceed, secondly, to give a general view of the organization of the glandular system; and shall exhibit, in the third and last place, the opinions of physiologists concerning the mode of action of the glands and the subject of secretion in general. The reader will observe that the present article is of a general nature; the structure of the particular organs will be described on other occasions, and detailed accounts of the nature and properties of the various fluids will be found under their respective titles, or in other articles of the work.

The blood, apparently an homogeneous fluid, is composed of various matters, which chemical examination can detect and separate. It contains gelatine, albumen, fibrine, acids, alkalies, earths, saline and colouring matters, which are employed for the renovation of the solids and fluids of the body. It presents these to the various organs, which, by converting them into their own substance, derive the means of supplying the waste occasioned by the natural actions of the parts, or form out of them various products, distinguished by new characters, and extraneous to their own composition.

GLAND.

tion. The former of these processes is nutrition or assimilation; the latter secretion: they resemble each other in their commencement, in which the organ, by some powers of a nature entirely unknown to us, but peculiar to living bodies, and forming part of that complicated notion, which we express by the term vitality, selects from the blood such principles as suit its nature or functions; but they differ in the employment of what is thus selected, which is retained in the body, and assimilated to the already existing organization in the former case, and applied to some other purpose in the latter. The subject of nutrition does not come under our notice at present.

The products of secretion result from an essential change in the compound conveyed to the organ, from a new combination of the principles contained in the blood, which is transformed by the specific action of the various organs into different fluids, retained in or expelled from the body, according to the qualities of each. Hence, there are organs which, after forming certain fluids, collect and retain them; while others separate and expel their secretions from the body. The object of the secretions is, to collect those which are defined to fulfil important uses in the body; while that of the excretions is, on the contrary, to expel matters which would be injurious to the frame. The two functions then of secretion and excretion resemble each other in most respects: there is in both a separation and collection of fluids. The difference consists in this, that in the former case the separated fluid remains in the body, while it is soon expelled in the second. Thus secretion always precedes excretion; and, in order to understand the latter, it is necessary to know how the former takes place.

The word secretion, derived from *secerno*, I separate, signifies simply the act of separating; and its physiological import is conveyed in that notion. It denotes, in physiology, that function of a living body, in which various fluids, differing from the blood and from each other, are prepared from the common mass of the blood, the same fluid being constantly formed in the same organ. No part of physiology is more obscure, and more difficult in its investigation, than this very function. Malpighi, who had bestowed great labour on the structure of the glands, and was considered to have unveiled, in a great measure, the mysteries of their organization, confesses his ignorance on this subject; and, as the avowal, from such a quarter, is interesting, we subjoin the passage, observing that the remarks here made, concerning the kidneys, apply equally to all other secretions. He says of the urinary secretion, "*quanam arte id contingat obscurissimum: licet enim glandularum ministerio totum hoc subsequi rationi sit consonum, quoniam tamen minima illa, simplexque meatuum in glandulis structura nos latet, ideo quædam tantum meditari possumus, ut huic quæsito probabiliter satisfaciamus. Necessè est hanc machinam interna configuratione separationis opus peragere; an vero his, quæ ad humanos usus passim usurpamus, quibus fere consimilia effingimus, consonet, dubium; licet enim occurrant analogæ spongiæ, incerniculi, fistularum cribrorumque structura, cui tamen ex his consimilibus undequaque sit reum fabrica, difficillimum est assignare, et cum naturæ operandi industria fecundissima sit, ejusdem ignotæ nobis reperientur machinæ, et quas nec mente quidem assequi licet. Illud miror tam copiosa, diversaque corpora separari per has glandulas in naturæ statu, exit enim substantia aquea cum salinis, sulphureis et consimilibus particulis, et ex morbo etiam abscessuum: reliquæ, et totius quondam corporis inquinamenta separantur deventis sanguineis particulis," &c. *De Viscerum Structura; De Renibus*, cap. 6. The whole business is carried on in the*

minute, and, as we may call them, elementary parts of the viscera and glands, the structure of which eludes the research of our senses, and can still less be developed by reasoning or reflection. Observation cannot follow the work throughout; nor does it admit of elucidation by experiment, like some other subjects which have been explained by artificial imitation of the proceedings of nature.

Unwilling to confess their ignorance and leave their systems imperfect, physiologists have attempted to raise, on hypotheses, that structure, for which anatomy afforded no foundation. Their notions, resting merely on probabilities and loose analogies, have flourished and fallen in succession; and we shall find that the list of truths and ascertained facts is much shorter than that of opinions and errors.

The composition of the secreted fluids presents various differences in the nature and proportions of their constituent parts. They possess, in common, all the general characters which belong to animal substances; but each has certain particular distinctive qualities, depending on the various simple or compound principles, the union of which determines its specific nature. Thus, setting aside the resemblance of all our fluids, considered as animal productions, fat does not resemble bile; the latter is very different from milk; which, again, has no resemblance to the salivary, gastric, pancreatic, feminal fluids, &c. which must be referred to so many different classes.

The arrangement of the animal fluids is more difficult than we should have expected at first sight. The false and imperfect notions, which were long entertained of their chemical composition, lead to classifications founded on the uses to which they seemed to be destined. Those employed in the nourishment and growth of the body were called recrementitious, such as chyle, blood, serum, lymph, &c. The excrementitious included those which are expelled from the body; as the urine, perspiration, &c. A third class was made up of such as partake of the characters of both these; of which a part is rejected as noxious, while the rest is retained, in order to answer some particular purpose. Under the head of excremento-recrementitious humours, were arranged the saliva, bile, pancreatic juice, mucus of the intestines, &c. The objections to such an arrangement are too obvious to need enumeration. This division, as well as that before alluded to, of excretions and secretions, cannot be adopted with any benefit, while the nature and objects of many secretions are so little understood, that we cannot determine whether they are expelled as noxious, or serve very useful purposes in the economy. The bile, for example, has been very commonly deemed an excrementitious fluid, but by a completely arbitrary assumption: what proof have we that perspiration separates any thing noxious from the blood? For what reason is the secretion of the pancreas placed in one rather than in the other of these divisions?

Pitcairne, who was followed by Michelotti, divided the animal secretions in a manner which has, at least, the merit of simplicity, and leads to no false notions concerning their uses; he distinguished them merely as being thick or thin.

Haller distributed the fluids into four classes, according to the chemical notions of his time, and to the degree of complication in their elements. 1. The aqueous fluids. These have a very large proportion of water in their composition; hence they are distinguished by their fluidity, and have no ropiness. Fire dissipates them almost entirely, excepting a very small proportion of earthy residue; neither alcohol nor acids coagulate them. Besides a little earth,

they

they contain some saline and oily matters. Many of our fluids belong to this division. Some are expelled from the body, and are ordinarily deemed excrementitious; such are the urine, which is not coagulable in the natural state; the insensible Sanctorian perspiration, and the pulmonary exhalation. Sweat is a mixed fluid, containing oily or sebaceous matter, together with water. Several of the fluids, which are destined to serve particular purposes in the animal economy, contain very little except water. This is the case with the secretion of the proper salivary glands, with that of the pancreas and lacrymal gland; with the perfectly pure and transparent aqueous humour of the eye, and other watery fluids in the same organ.

2. Mucous fluids. These differ from water in being less fluid; they are tenacious, so as to adhere to solid bodies, andropy. They mix with water, are insipid and inodorous, and nearly colourless. The evaporation of their aqueous parts reduces them into hard and dry crusts. Acids do not coagulate them; but alcohol has a slight effect. They yield, on distillation, a large quantity of water, volatile salt, oil, and a carbonaceous residue. To this division belong the lubricating fluids, which are poured out over the extensive surfaces of the respiratory, digestive, urinary, and genital organs, and all the parts connected with them.

3. Gelatinous fluids; which are coagulable by heat, warm water, alcohol, and acids, remain fluid below 148° Fahrenheit; and have a mild or slightly saline taste. Haller places in this order the serum of the blood, the lymph conveyed by the absorbents, the water of the amnios, the ferous exhalations of the circumscribed cavities, the lymph of the cellular substance, and the fluid of the Graafian ovula. He also places in this division the synovia of the joints, and the fluid of the tendinous thecæ; observing, at the same time, that these are partly composed of oily matters.

4. Oily fluids. These are represented by Haller as more perfectly animalized productions: they are freed from the superfluous quantity of water, and are inflammable; or at least contain much of that matter which takes fire and deflagrates. At their first production they contain much water, so as not to be capable of inflammation, nor to possess their peculiar characters, but rather to resemble mucus or gelatine: they undergo changes afterwards, which deprive them of their aqueous parts, and render them more viscid and oily. The fat and the medullary substance of the bones, are the most extensive specimens of this order: it contains also sebaceous matters of various kinds, as the greasy cutaneous matter, the Meibomian secretion of the eye-lids, that of the glans penis, and of the external organs in the female. The bile, cruor of the blood, milk, and prostatic fluid, belong to the same class.

Such are the four divisions, in which Haller has arranged the animal fluids: he observes that several, being of a mixed nature, do not belong exclusively to either class, but ought, from the diversity of their principles, to be referred to more than one: indeed there is hardly any, which can be rigorously said to consist of a single element. Then, again, many evidently contain more fluids than one, formed separately in the first instance, each in its appropriate organ, and afterwards mixed together. Thus the semen contains the secretions of the testis, prostate, and vesiculæ; the sweat is made up of the water of perspiration with the cutaneous oil; the tears are a mixture of water, mucus, and sebaceous matter; spittle contains water and mucus, &c.

The vast improvements in the science of chemistry since the time of Haller must necessarily have subverted the basis of the arrangement just described; which, when considered

by a chemist of the present day, would be found open to objection at all points. The deficiencies of the classification are too obvious to render it necessary that we should particularize them.

Blumenbach has classed the products of secretion on a somewhat different principle. "The secreted fluids," says he, "display on one hand so much variety, while on the other they seem to be joined by so many points of affinity, that their arrangement in classes must be in great measure arbitrary. They may, however, be disposed in the following order, according to the slighter or more essential changes and modifications which their elements, contained in the mass of the blood, undergo in the secretory organs. Milk may be placed in the first rank, as consisting apparently of a very simple modification of chyle, and formed from the blood by a very easy process after the influx of the chyle. The watery secretions come next, so called from their fluidity and transparency, although they differ materially from water in the nature of their constituent elements, particularly in containing a portion of albuminous coagulable matter—including the fluids of the eye; the tears, the matter of perspiration, the exhalations in the cellular substance, and in the thoracic and abdominal cavities, to which the liquor pericardii and the fluid of the ventricles seem to be analogous. The urine, ordinarily referred to the aqueous fluids, is distinguished by very remarkable peculiarities. The salivary fluids, concerned in the functions of mastication, digestion, and chylification, seem to be rather more changed. Then follow the mucous secretions, spread over the surfaces of most of the viscera belonging to the natural and generative functions, as well as the cavities of the nose, larynx, and respiratory organs. The mucus in the interior of the eye, as well as that under the epidermis, do not appear to differ essentially from the preceding. Under the title of adipous fluids may be classed, besides the common fat, the medulla of the bones, and the sebaceous matter of the skin (including also the cerumen of the ears). The greasy matter formed under the prepuce about the corona glandis of the male, and the similar production in the female pudenda, may be referred to the same class; as well as the secretion of the Meibomian palpebral glands. The liquor of the amnios, and the synovial fluids, are commonly deemed gelatinous; but their real nature is not yet understood, neither is that of the fluid, hitherto unnamed, thrown out in the uterus under the venereal stimulus, known. The fluid contained in the early months of conception between the chorion and amnios, that of the vesicula umbilicalis, and that which surrounds the vessels of the umbilical chord, is as yet little understood. The contents of the Graafian vesicles, and the prostatic fluid, seem to be truly ferous or albuminous. The male semen is quite a peculiar product, not to be compared to, or classed with, any other; and the same remark will hold good also of the bile." *Inslitut. Physiolog. sect. 32.*

The division of this able physiologist would be natural and instructive, if the animal fluids deviated from the nature of chyle by gradations which could be easily perceived and marked. But we really cannot establish among them any order corresponding to their natural composition; and the differences observable between chyle and fat, between the aqueous fluids and bile, constitute intervals, which we cannot appreciate or measure. Indeed there are often so many differences and so few relations between one fluid and another, that we can scarcely compare them at all.

The vast progress which chemistry has made of late years, and the valuable discoveries with which the analysis

GLAND.

of animal substances, as well as other parts of the science, has been enriched; might have led us to expect that the classification of the fluids would have been reformed according to their constituent principles, and brought into a condition corresponding to the rest of the science. Fourcroy has indeed given such a distribution of the subject in his *Elements of Chemistry*; but he does not seem to value the arrangement very highly, as he has not continued it in his last great work, the "*Système des Connoissances Chimiques*." In proportion as the various animal products are analysed with more accuracy, they are found to possess specific characters which distinguish them from each other; and therefore render it impossible to refer them without impropriety to any general heads: accordingly in the most recent and able chemical works, they are enumerated and considered separately. In this point of view, therefore, the exactness and perfection of modern analysis renders our attempts at a general arrangement of the animal fluids unavailing; and it has only served hitherto to shew the defects of such methods.

Dumas, in his "*Principes de Physiologie*," adopts a different plan, which he calls a natural physiological one, and to which he ascribes the advantage of connecting closely the knowledge of the fluids with that of their uses. "This method," he observes, "which is the most natural and useful of all, is to refer the fluids to the various organic systems in which their secretion takes place, to make a class of humours for each system, to consider each of them as inseparable from the system to which it belongs, and to conduct the study of both together. We shall therefore have as many different classes or species of fluids as there are organic systems in the body. This simple and natural method of considering the subject appears to me to be preferable to the more laboured arrangements founded on the essential nature and chemical composition of the fluids, because it is not exposed to that uncertainty, which the imperfection, the variations, and even the progress of our knowledge concerning the nature and properties of animal matters, must unavoidably occasion. It is, moreover, the most easy and instructive way to consider the secreted fluids in their relations to the solid organs, with whose functions they are concerned. The distribution of the animal fluids with regard to the seven organic systems of which the human body is composed, will be better understood by presenting it in a tabular view, where their relations, influences, and uses, will be immediately perceptible.

Fluids of the nervous or sensitive system.	}	Fluid of the ventricles of the brain, Aqueous, vitreous, and crystalline humours of the eye, Tears, Meibomian secretion, Mucus of the nose, Cerumen, Fluid of the labyrinth of the ear, Saliva.
Of the muscular or moving system.	}	Fibrine, Serosity, Fat.
Of the vascular or calorific system.	}	Mucus of the trachea and air-vefels, Fluid of the pericardium, ————— pleurae, Pulmonary exhalation, Blood.

Of the visceral system or organs of supply.	}	Mucus of the mouth, pharynx, and œsophagus, ————— stomach, ————— intestines, ————— kidney and bladder, Gastric fluid, Pancreatic fluid, Intestinal fluid, Exhalation of the abdominal cavity, Bile, Liquor of the renal capsules, Urine.
Of the lymphatic or collecting system.	}	Residue of all the fluids, and of nutrition, Lymph, Fat of the cellular tissue, Mucous fluid.
Of the sexual or reproductive system.	}	Prostatic liquor, Mucus of the urethra, ————— vagina, Seminal fluid, Exhalation of the tunica vaginalis, Contents of the ovarian vesicles, Liquor amnii, Meconium.
Of the bony or supporting system.	}	Gelatine, Medulla, Synovia.

Of the fluids just mentioned, some are secreted in certain organs belonging to their respective systems; *e. gr.* those of the conglomerate glands, of the glandular viscera, &c.; others are formed over whole organic systems, without any particular apparatus, as the exhalation in the cellular membrane, that of the circumscribed cavities, &c.; while others are not the produce of secretion, but move freely through all parts of the system in which they are concerned, as the blood and contents of the absorbing system. With the latter we have nothing to do at present; neither does the organization, from which the fluids of the middle class are produced, come under our consideration in this article, but it will be described in INTEGUMENTS, MEMBRANE, and CELLULAR SUBSTANCE.

The physiological theory of the secretions must be founded on a perfect knowledge of the nature of the animal fluids, and of the structure of the secretory organs. The solution of the interesting problems arising out of this subject, can be expected only from the union of anatomy, enlightened by just views of physical science, with chemistry, supported and directed by physiological observation. The secretory organs are of various kinds, and preserve a constant relation to the kind of secretion, and the manner in which it is effected. Those fluids, which seem to be derived from the blood, with the least change, are not produced by a complicated organic apparatus. The exhalation, which moistens the surfaces of the circumscribed cavities, the aqueous vapour of the lungs, and the cutaneous perspiration are formed by organic systems, composed chiefly of vascular ramifications, without possessing any thing that is at all analogous to glandular structure. The arrangement of the fibrous tissue of muscles, and of the bony fabric, admit of the same remark; if we suppose that these organs habitually secrete fibrine or bony matter. But these are cases, which come under the description of nutrition, and in this sense all parts of the body may be called secretory organs.

gans. The mucous fluids, which appear to differ more considerably from the materials in the blood, are generally separated by particular glands, which are called crypts or follicles, contained in the substance of the membranes or viscera. But it seems probable, that these also may be separated from the vascular ramifications of a simple membranous tissue without any express glandular structure, as in the case of several mucous membranes. It remains therefore for us at present to explain, in a general way, the anatomical structure of the various glands, by which the other animal fluids are secreted.

The glandular differs from most other systems, in the animal economy, in this circumstance, that its peculiar tissue is not exactly identical in all the organs belonging to it. The fibres of any voluntary muscle would serve equally well to compose any other of the same kind. Tendinous fibres, cartilaginous and bony structures, are the same every where. The substance of the liver, on the contrary, is widely different from that of the kidney; which again is very distinct in its character from that of the salivary glands. The glandular system, therefore, is marked in its various parts with very few general attributes, which also suffer many exceptions.

Situation, forms, division, &c. of the glandular system.—Glands have two different situations in the body. Some are subcutaneous, as the breasts and salivary glands; others deeply seated, as the liver, kidneys, pancreas, and most of the mucous glands, and consequently, not exposed to the action of the external bodies. Many of them occupy situations where there is much motion, as the salivary glands near the jaw, the mucous in close contact with a plane of muscular fibres, the liver in the vicinity of the diaphragm, &c. These facts have led to the supposition that the neighbouring motion, extraneous to their functions, determined the excretion of the secreted fluids. But, in the first place, the palatine glands, the pancreas, the testicles, and even the kidneys, are so situated, as to be out of the way of such external assistance. And we observe, further, that mucus is secreted as abundantly by the pituitary membrane, as in any other part, although there is no muscular plane here; that the lining of the bladder produces an equally copious supply, when the viscus is paralytic; and that various causes augment the secretions, without any connection with the circumstance first alluded to, as sialagogue medicines, or the sight of food in the case of salivary glands. We cannot doubt, therefore, as Bordeu has observed, that this mechanical cause has nothing to do with the matter, and that the essential cause of all excretion consists in a peculiar vital action.

Some glands are single, as the liver and pancreas; others are arranged in pairs, as the kidneys, salivary, and lacrymal glands. The latter are similar on both sides of the body; but the resemblance cannot be compared, in respect to its exactness, to that of the double organs in the animal life. One kidney is lower than the other; their arteries, veins, and nerves, are not analogous in length or size; often various notches exist in one, and not in the other: the same observations will apply to the salivary glands.

Generally the forms are not determined in a very certain manner in this system: they are subject to innumerable modifications in volume, direction, and the different proportions; and differ remarkably, in these respects, from the precise and rigorous laws which govern the conformation of the organs of animal life. Take some one organ, by way of example, from both lives. A small brain will be found to possess a corpus callosum, thalami optici, and corpora striata of corresponding size; while, on the contrary, a large liver often has a small lobulus Spigelii, and *vice versa*.

A kidney will often be larger in its upper portion only; or in the lower. These variations in the animal life affect the whole organ: while they frequently are observed in some part only in the organic. Bichat, who makes this remark, endeavours to explain the fact, by his opinion concerning the necessity of a harmony of action in the animal life. If one side of the brain were developed more than the other; if one eye, one ear, or one side of the nose exceeded the corresponding organs, the operations of the mind, the sense of sight, hearing or smelling, would be inevitably disturbed: while the secretion of bile or urine would go on equally well, although some particular part of the secreting organs were proportionally larger or smaller than the others. The glands, which are surrounded by membranes, as the liver, kidneys, and even the pancreas, are less subject to these variations of figure, than those which are contained in the cellular substance, without any membranous covering, as the salivary, lacrymal, mucous glands, &c. Those of the latter description in the mouth, and along the trachea, are never alike in two subjects. The parotid sometimes is prolonged over the masseter, and at others leaves that muscle uncovered; varies in its breadth, &c. When either of a pair of glands is so diseased, as to be incapable of continuing its function, that on the opposite side of the body either increases in bulk, as we may sometimes observe in the kidneys; or its secretion is augmented.

The surface of such glands as are not covered by membranes is uneven and tuberculated; it may be in contact with muscles, vessels, nerves, &c. even with bones, as in the salivary and lacrymal glands. In general, they are surrounded by less cellular tissue, than organs which have considerable motion. That which is in immediate contact with them is dense, like the exterior covering of arteries and veins, but it is not so firm. It does not usually contain fat; and by isolating the gland to a certain degree, it is analogous to the peritoneal covering of the liver, or to the proper membrane of the kidney or spleen. Anatomists have very commonly divided the glandular system into the conglobate and conglomerate glands. The former name denotes the gland-like bodies belonging to the lymphatic system, and was designed to shew that each formed only one mass. The latter term is most properly applied to the salivary and lacrymal glands and pancreas, which are made up of numerous smaller particles united together. It cannot well be given to the liver and kidneys, which possess nothing of a conglomerate structure; and these, accordingly, have been generally called glandular viscera.

Organization of the Glandular System.

1. *Peculiar tissue of this system.*—The glandular tissue differs from most others, in possessing no marks whatever of a fibrous disposition. Its component elements are not placed by the side of each other, according to longitudinal or oblique lines, as in the muscles, the fibrous system, the bones, nerves, &c.; but they are heaped together, by a kind of confused, and, as it were, casual approximation, and adhere together but weakly. Thus, while organs, which possess distinct fibres, have considerable powers of resistance, particularly in the direction of their fibres, glands are torn easily by slight degrees of violence. The broken surface is uneven, full of projections and depressions, which distinguish these organs from cartilage; the rupture of which is generally smooth. The prostate, tonsils, and mucous glands resist much more powerfully than the liver and kidneys, in which the phenomenon just mentioned is the most easily observable. The pancreas and salivary glands are elongated by any distending force, without tearing; but this circumstance

stance arises from the abundant cellular tissue distributed throughout their substance, and not from any peculiar property of their glandular tissue. Their lobes are separated in proportion as the intermediate cellular filaments are elongated.

The glandular tissue, which anatomists have generally called *parenchyma*, is disposed in three different ways. 1. In the salivary, lacrymal, and pancreatic glands, which are properly called conglomerate, the organ is made of distinct portions, connected together by a loose and copious cellular texture, the intervals of which transmit vessels and nerves. These are again made up of smaller lobes united in the same way; and the divisions are more easily pursued when water has penetrated into the connecting substance. Repeated divisions shew us smaller and smaller component portions, till we come at last to very small bodies, still conspicuous to the naked eye, and called glandular acini (grains glanduleux, Fr.) These component parts are firmer in proportion to their smallness, as they are surrounded and connected to the adjoining portions by shorter and firmer cellular substance. We can easily follow the 2d, 3d, and even the 4th division of these lobes with the scalpel. The acini are of a roundish figure and pale colour, and distinguishable from any thing of a muscular nature by the absence of fibres. When examined with magnifying glasses, they are seen divided into smaller portions by cellular interstices, and we can hardly come to an end of these divisions, if we employ successively greater magnifying powers. 2. There are no traces of the primary divisions just described, into the larger and succeeding lobes, in the liver and kidneys. They consist of an uniform and even tissue made up of glandular acini, closely united together into one substance. The connecting cellular structure of these particles, if there be any, is very small in quantity and short; hence the facility with which these bodies may be torn, and the kind of granulations which their rupture presents. 3. The prostate, tonsils, and all the mucous glands, have no appearance either of primary or secondary lobes or acini. The first of these consists of a dense parenchyma; the latter of a soft and almost pulpy substance. They cannot be torn, like the liver and kidneys.

Controversy concerning the structure of the glandular acini.—It is easy to proceed thus far in analysing the composition of the glands; but these researches do not at all contribute to explain the mechanism of secretion. In the hope of accomplishing that object, anatomists began, as soon as the improved condition of the science furnished the means of prosecuting such investigations, to subject the various secretory organs to a very attentive and close examination, and endeavoured to shew the nature of the acini, into which most of the glands were ultimately resolvable. The aid of magnifying glasses, and of anatomical injections, was resorted to on this occasion; but the opinions of two individuals, who had devoted much time to the subject, were completely at variance, and gave rise to a controversy, which had at least this good effect, that it occasioned a very thorough examination of the subject. Malpighi taught that the acini are hollow; that the arteries distributed on their surface deposit the secreted fluid in their cavities, and that it is conveyed thence by an excretory duct; that the union of these tubes forms larger excretory canals, &c. He deems the mucous glands of the alimentary canal, mouth, &c. to be the most simple forms of glandular structure, and considers that the larger glands differ only in consisting of an aggregation of such simple ones. "Glandula, qua palatum, œsophagus, intestina, et consimiles partes copiose ditantur, est omnium simplicissima, et idea reliquarum glandularum. Hæc

itaque folliculo membranoso seu loculo constat, qui ovali, interdum rotunda, quandoque lenticulari, vel oblonga constat forma; concavitate pollet, quæ ut plurimum in vasculum excretorium aperitur, quo separatus humor in peculiarem capacitatem, vel foras extra pellitur. Circa loculum seu folliculum vasa sanguinea et nervi diramantur, et ut conjectura affeque licet, carnee fibre circumducuntur, vel saltem sub plano extensi muscoli locantur, ut in ventriculo, et œsophago patet. Huic proximæ succedunt glandulæ, majori loculorum numero ditatæ, quales sunt in facie, in labris, in quibusdam cutis partibus, circa pudendum et palatum: excretorio namque vasculo, interdum oblongo multipliciter appenduntur loculi membranosi in ipsa hiantes, circa quos sanguinea vasa et nervi ramificantur." Epistola Reg. Soc. Londin. Dicata, in Opp. Posthum.

In the *Exercitationes de Structura Viscerum*, he endeavours to prove that the larger glandular bodies are formed on the same principles with the parts just alluded to. He examines the liver by removing the external membrane, macerating it in water, boiling, &c. and employs the microscope. "In compingendo itaque hepate talis videtur firma nature methodus: vasa in ramos hinc inde disperguntur; ad singulas autem vasorum propagines, licet etiam exiles, lobuli appenduntur, conicam ut plurimum ferventes figuram: consimiles etiam in pancreate, cæterisque conglomeratis glandulis observamus.—Glandulosi acini, quibus lobulus componitur, cum peculiarem circumscriptionem habeant, necessario propria et ipsis figura, quæ ut plurimum hexagona, vel plurimum laterum est: hinc etiam necesse est, ut ad invicem, præter vasorum ramos, peculiaribus membranosis vinculis necentur, et interstitia aliqua emergant, quæ in piscibus et imperfectioribus magis conspicua sunt, in perfectioribus autem obscurantur. Ad singulos autem, hosque minimos lobulos, multiplices vasorum rami derivantur. Tota jecoris moles ex his duobus coalescit, glandulosi scilicet acinis, et diversis vasorum propaginibus; quare, ut aliquod ex his commune opus emanet, necesse est, ut inter glandulas et vasa commercium intercedat." *Exercit. Anat. de Hepate, cap. 2.* He describes similar acini as existing in the kidneys, spleen, and cortical substance of the brain. And he defends his opinions on this subject in general, by arguments drawn from various sources, as the appearances of disease, &c. which cannot be allowed to prove much on either side.

The opinion opposed to that of Malpighi, considers all the viscera and glands to consist of vessels and cellular substance, without any membranous cavities interposed between the arteries and the excretory ducts. This doctrine was particularly supported and extended by Ruych, who, although he was not remarkable for quickness or learning, exceeded most of his contemporaries in his opportunities of dissection, which were very ample, and continued for nearly eight years, and in the art of injecting and preparing the organs of the body in various ways. His observations carried the greater weight, because he was averse to hypotheses, and taught only what he saw. In his youth he admitted, with other anatomists, the glandular acini of the viscera. But, when he found, as he proceeded in his anatomical labours, that membranes, naturally perfectly white, exhibit innumerable spots after injection, that the substance of the viscera is filled almost entirely with injected fluids, and may be resolved into a more vascular texture by maceration in pure water, he gradually changed his opinion, and began to teach that the viscera and the conglomerate glands, and even most of the simple ones, are composed entirely of vessels, from which the excretory tubes are continued without any intervening medium. Injections in the dead body seem to prove the latter circumstance, as fluids in some instances pass very readily from the

blood-vessels into the excretory ducts; *e. gr.* in the kidney and liver. As Ruysch continued his investigations, he found that the bodies considered as glandular and hollow acini by Malpighi, are mere blood-vessels. After accurately injecting the liver and kidney, and macerating them in water, he found them resolved into small clusters of blood-vessels, and proved this so clearly by his preparations, that Boerhaave, who had been a warm defender of Malpighi's doctrine, in defence of which he wrote the *Epistola de Fabrica Glandularum, ad F. Ruysch.*, was induced to renounce his opinion. The elegant preparations of Ruysch, and his appeal to the evidence of dissection, and other anatomical investigations, brought most anatomists over to his opinions, which, indeed, are generally received in the present day. Haller gives the following summary of his opinions on this subject. "Viscera nempe secretioni destinata, eorumque imprimis acinos, glandulasque conglomeratas, meris componi vasculis, cellulosa tela ope conjunctis, eo cum vinculi robore ut consistat acinus, aque sui similibus, laxioribus filis sibi annexis, totus et integer deduci possit. In quolibet præterea acino, vasorumve glomere, ex eadem sententia, ductus excretorius est, pluresve ductuli, quæ arteriola minima, tanquam ramulus minor et sanguini impervius, decedere videtur, quæ fabrica in rene certo reperitur, in aliis quidem colis magna cum veri specie ex conjectura admittitur. Secretio adeo a vulgari sanguinis circuitu hæcenus differt, quod in ista quidem arteriola minima cylindrica, in venam sibi æqualem, aut ampliolem continetur, quæ sanguinem recipere apta sit, in humorum vero separatione ductus excretorius, rubro vasculo arterioso minor, tanquam ramus ex eo vasculo prodeat." *Element. Physiolog. lib. 7. sect. 2. § 14.* The opinions and arguments of Ruysch may be collected in his answer to the letter of Boerhaave mentioned above, in some of his other epistles, and in various of his *Theauri*. He has given several figures representing the distribution of the minute vessels in various organs, and proves satisfactorily that the bodies called acini by Malpighi are merely minute vessels: he shews this concerning the spleen and brain, as well as in the glandular viscera. On the subject of this controversy, we may observe, that its importance does by no means warrant the pains bestowed on it, and the noise made by the combatants in conducting it. The nature of the investigation, which is carried on entirely in the minute elements of the body, and persecuted by means of magnifying glasses, injection, maceration, and corrosion, renders the conclusions, which we arrive at, in great measure, uncertain; and the parts, of which the structure is sought, are so exceedingly small, that neither opinions can be considered as clearly demonstrated, or satisfactorily refuted. The mode, in which secretion is effected, is equally obscure, whichever of the two suppositions we may adopt: neither of them solves the mystery. Let us admit with Ruysch that the excretory tube is continuous with the secreting artery; shall we then understand how such infinitely diversified products, all differing from each other, and from the blood, are formed from the common mass of that fluid? Shall we be able to point out the precise spot in the continuous canal where the blood ends, and the bile, urine, or milk begins? and to explain *how* the change is effected? If, on the contrary, we suppose, with Malpighi, that arteries, ramifying on small membranous cavities, deposit the new products in those receptacles, our ignorance of the points in question is neither more nor less complete than in the other case. Too much labour has been already spent on these idle disquisitions; modern anatomists have judged wisely in abandoning them, and in preferring the task of collecting facts concerning the natural and diseased structure and functions of our frame.

With such impressions, concerning the value of these pur-

suits, we were much diverted, at observing the complacency with which Ruysch, the great authority of the two last centuries on the structure of glands, contemplates his own doctrines, and the sang-froid with which he represents his own discoveries, as the immediate produce of a direct divine revelation. "Placuit bonitati divinæ hæc revelare meis laboribus jam senilibus. Invidi, et inimici mei hæc ridebant in initio, sed Deus cui soli omnis gloria et honor, hæc ita benedixit postea," &c. *Epistola Anatom. ad v. c. H. Boerhaave.*

The organization of all the glands is by no means so uniform as to admit of our referring the mode of glandular secretion to any one mechanism. The mammary gland and testis do not resemble the texture of the organs already described. In both of these, which again are widely different in all their sensible properties from each other, there is a vast congeries of secretory tubes, infinitely convoluted, with vascular ramifications copiously distributed among them. In the ultimate elementary parts of these glands, as far as our senses can pursue them, we discover nothing but minute, serpentine, and very slender tubes; which are particularly obvious in the testis, without any trace of Malpighian or Ruyschian acini. In the breast, indeed, the existence of these bodies has been a matter of dispute, and arguments, not deficient in plausibility, have been adduced on both sides of this important question, which, like many religious mysteries, is involved in just so much obscurity, as to make it a very suitable subject for polemical exercise.

The organs of the mucous secretion, in general, do not fall within the description already given of the glandular structure. These seem to exhibit, in many instances, a very simple form of gland, of which, however, the action is no more understood, than that of the more complicated kinds. They consist of small receptacles, lined by the membrane covering the part, receiving the secretion, and pouring it out by a single orifice in the centre. Very simple glands of this kind are seen at the root of the tongue: their figure is circular or elliptical; the cavity is lined by a thin membrane, surrounded by a pulpy vascular substance, which causes a superficial prominence, in the centre of which is a simple aperture, affording mucus on pressure after death.

In other instances, the membranous part is more conspicuous, and the glandular substance less considerable, or indeed hardly perceptible, so that the whole seems to be formed merely of membrane. These have been called *cryptæ*, *folliculi*, &c. Their figure is generally circular or oval, and they are lined by continuations of the membrane, to which they belong. They are placed in the cellular substance, and may possess more or less of the pulpy vascular matter. They have simple excretory tubes, commencing from the hollow of the membranous cavity, and terminating by open orifices on the surface of the part to which they belong, as the mouth, fauces, trachea, or intestines. Pressure forces the secreted mucus from the open orifice. To this class may be referred the glands of the lips, cheeks, epiglottis, pharynx, and œsophagus, those of the soft palate, trachea, stomach, and intestines.

These more simple kinds of crypts or follicles are united in different instances, so as to compose larger masses. Sometimes they are simply contiguous, connected by loose cellular substance, and possess each its proper duct: *e. g.* at the back of the tongue, and about the arytenoid cartilages. Such have been called *glandule congregatæ*. In other instances, numerous follicles, included in a common covering, deposit their mucus in one or more large cavities, into which several follicles open. The tonsils afford an example, and have been called *glandule conglutinatæ*.

GLAND.

The secretion of mucus is often performed in a species of structure, which does not seem to possess any thing of a glandular nature: in small membranous canals, which will admit bristles for about half an inch in length, ending by blind extremities in the cellular substance, and terminating by oblique apertures on the surfaces of the mucous membranes to which they belong. Neither acini nor round follicles can be discovered opening into such canals, which are technically named *sinuses* or *lacunæ*, and which, in the urethra, have a perfectly smooth surface. Some of these are simple, as in the septum narium, the urethra of both sexes, the entrance of the vagina, &c.; others are ramified, as in some instances in the male urethra; in the neck of the uterus, &c.

The glands, which produce various matters of an unctuous description, appear to be very simple in their structure, but they are mostly so small as to prevent us from entering into much detail concerning their organization. The ceruminous glands of the ear are small round bodies, dispersed in the interstices of the cellular substance, and each of which possesses a duct, penetrating the integuments of the meatus auditorius, and ending on its surface by an open mouth. They seem to consist of simple membranous cavities. The organs, which secrete sebaceous matter, in various parts of the integuments, do not seem to differ essentially from these. They are round membranous cavities, with their sides covered by numerous vascular ramifications, opening on the surface of the part to which they belong, with or without the intervention of a simple duct. Where they produce a fluid which concretes, it may be expressed from them in the form of a slender white thread. The areola of the nipple, the nymphæ, and the other external female organs, the corona glandis of the male, the nose, and particularly the cavity between its ala and the cheek, the upper lip, and the hollows of the external ear, possess numerous glands of this description. The Meibomian apparatus of the eye-lids is only a rather complicated specimen of the same structure; several simple glands open into a common duct.

The prostate possesses a peculiar structure, which can hardly be referred with propriety to any of the species first enumerated.

The glandular tissue, cut in slices and dried in the air, loses its original colour, acquires a dark hue, and even a blackish tint in the liver and kidney, on account of the large quantity of blood which they contain: if the latter viscera are repeatedly washed, before they are dried, they continue to appear greyish. The glandular tissue, in its dried state, is remarkably hard and brittle. If kept moist and exposed to the air, it becomes putrid very rapidly, and exhales in that state a highly disagreeable odour. A greater quantity of ammoniacal matter is formed. The liver is particularly distinguished for the insupportable stench caused by its putrefaction. The kidney goes less rapidly into that state. When boiled, the glandular substance produces at first a greyish substance, which troubles the water uniformly at first, and is then collected in an abundant froth at the top. This product is most abundant in the present, the muscular, mucous, and cellular systems; and least in the cartilaginous, tendinous, fibrous, &c. The froth produced by its boiling is of a deeper colour, and seems to contain more numerous principles, than that derived from the white organs.

Like all other systems, the glands grow hard at the first periods of ebullition, but instead of becoming softer afterwards, as the others do, the continued boiling makes them more and more hard; so that after five or six hours of ebullition, their firmness is triple or quadruple that which belongs to them naturally. This phenomenon is most remarkable in the liver. When removed immediately after the first corru-

gating effects of the hot water, they do not display the elasticity which the other systems possess at this time. A tendon or muscle in such a state, if drawn, restores itself immediately, while a slice of liver breaks. The absence of fibrous matter perhaps is the real cause of this difference. The sudden action of naked fire crisp and corrugates the surface, as in all the other solids, and produces a hard exterior crust.

Maceration in water produces different effects on the different glands. The liver resists longer than the kidney, which, after two months, is reduced to a reddish pulp swimming in the water, while the former still preserved its form and density, and had undergone no other change than from a red to a blueish brown colour. The salivary glands exhibit much of the whitish, unctuous and firm matter, which is seen in all cellular organs after long maceration. This does not arise from an alteration of the glandular tissue, but from the fat contained in the abundant cellular texture of these parts.

Acids act on the glandular tissue nearly as upon the others. They reduce it into a pulp, varying in its colour, and in the promptitude of its formation according to the nature of the acid employed. The sulphuric acts most quickly, and gives a black pulp, while the nitric renders it yellow. They act much more slowly on the glands after boiling than before.

Generally speaking, the glands are much less digestible than most other animal substances; particularly in their boiled state: for coction produces in them quite opposite effects to those which it exerts on the cartilages, tendons, and all the fibrous organs, which are rendered less dense, more gelatinous and viscous, and more speedily dissolvable by the gastric juice. The glands would probably be digested more easily, if eaten raw. Liver is less digestible in proportion as it is longer boiled. Bichat made a comparative trial of it in a raw and dressed state: the former was reduced into a pulp in the stomach of a dog, when the latter had undergone a very slight alteration.

Excretory tubes.—All glands have tubes for the purpose of conveying away the fluids, which they separate from the blood; and as these canals are only found in glands, their consideration belongs to that of the peculiar tissue of the gland. The excretory ducts have an uniform origin in all glands. They arise like veins, by an infinite number of capillary tubes, which appear to begin at the acini, where these exist. Each acinus is said to have an arterial and venous, as well as an excretory tube. Arising in this way from all the interior of the gland, they soon unite together, into more considerable tubes, which generally run in straight lines through the glandular tissue, unite to each other, and form at last one or more large tubes.

Glands are to be distinguished into three kinds, with respect to their excretory tubes. 1. Some transmit their secretion through several ducts, each formed by smaller ones, and opening near together, but distinctly, and without any communication. In some cases these separate apertures are found on a more or less distinct prominence, as in the breast, prostate, and sublingual glands. Sometimes the orifices are found in a depression, in a kind of *cul-de-sac*, as in the tonsils, the foramen cæcum of the tongue, &c. 2. Other and more numerous glands pour out their fluids by a single tube, and there is nothing remarkable in general in the orifice. 3. Some glands deposit the produce of their secretion in a reservoir, where it is retained, in order to be expelled at particular times. Such are the kidneys, liver, and testicles. In this case there must be two excretory tubes; one to convey the secretion from the gland to the reservoir, and the other to transmit it to its final destination. These reservoirs are therefore evidently connected with the excretory tubes.

Although the two first classes of glands have no reservoirs, we may in some degree regard the different ramifications of their excretory tubes as supplying their place. These, indeed, as well as in the glands, which have reservoirs, are habitually full of the secreted fluid. Under whatever circumstances the individual may have died, we may always produce a considerable flow of prostatic fluid by pressure on the gland. The papilla of the kidney affords urine on the pressure, sections of the liver shew bile in the hepatic ducts, and the lactiferous vessels are full of milk, for which there is no other reservoir. From variations in the quantity of fluid, in the latter instance, the greater or less size of the breast, during suckling, entirely depends.

It appears in general that the passage of the secreted fluids in the excretory ducts is much slower than that of blood in the veins, or of lymph in the absorbing vessels. Urine is constantly flowing through the ureters; but a much greater proportion of blood would pass through a vein of equal diameter, while the bladder was filling. The rate of motion however varies under different circumstances, the saliva is excreted much more quickly during a meal, and urine passes off much faster after watery drinks.

The size of the excretory tubes varies very considerably. 1. Where several are produced from one gland, they are very small, and sometimes scarcely perceptible. They run in a straight line, have no communications, and open immediately on quitting the gland. 2. Those which are single are larger; bearing a proportion however to the size of the gland, excepting the hepatic duct, which is manifestly very small in comparison to the bulk of the liver. They pass for some distance after quitting the gland, and are produced by the union of such tubes as belong to the last mentioned class; so that if their isolated excretory tubes were to be united together, a common single duct would be formed resembling those of this second kind. The pancreas is the only instance in which the common duct is concealed in the substance of the gland: and there is no other instance, but the testis, where it forms convolutions, so as to be much longer than the course through which it passes.

Whatever the arrangement of the excretory tubes may be, they all pour their fluids either on the surface of the body, as in the ceruminous and sebaceous glands, and the breast; or on the surface of mucous membranes, as the mucous, salivary, pancreatic and hepatic excretories. The skin and mucous membranes, therefore, are the only parts moistened by glandular fluids; no ducts terminate on serous or synovial surfaces. The excretories of the pretended articular glands would form an exception to this observation, if the glands existed. They never terminate in the cellular membrane; and if a communication should take place, by accident, abscesses are formed by the supervening irritation, as in urinary fistula; or inflammation occurs in the track of the extravasated fluid, producing adhesions, which preserve the cellular system from more extensive infiltration. Thus the alimentary canal may be regarded as a kind of general excretory, super-added to those of the liver and pancreas, &c., and expelling in one mass all the fluids separately poured through their respective ducts into its cavity. Indeed, all secreted fluids seem designed to be thrown out of the body. Separated from the mass of blood, they are heterogeneous to it, and do not enter the general circulation again in a state of health.

All the excretory ducts have an internal mucous membrane, which is a continuation of the cutaneous or mucous surface, on which they terminate. In addition to this they all possess an exterior substance, including the mucous canal, and differing considerably in the particular glands. It is a very thick and peculiar substance in the vas deferens: an

extremely dense and close texture, resembling that of the arteries and veins in the hepatic and salivary tubes, &c. The latter is very different from ordinary cellular substance. It does not appear that these tubes possess any membrane besides the tissue just described, and the mucous lining. Every excretory tube has its blood-vessels. The ureters receive very manifest arterial branches from the renal and spermatic arteries: the hepatic artery supplies the biliary tubes, and the Stenonian duct has its branches from the transversalis faciei. Various nerves from the ganglia accompany the blood-vessels; but they never form such intricate plexuses as round the arteries.

The excretory ducts possess chiefly the vital properties of the mucous system, which has the greatest share in their formation. Their sympathies are, therefore, nearly of the same kind.

2. Of the other Systems belonging to the formation of the Glands.

Cellular substance.—Glands differ much in the proportion of this tissue, which they contain, and may be divided accordingly into two classes. It is very abundant in the salivary organs, in the pancreas, and lacrymal gland, and in all such as have a conglomerate or granulated structure and white appearance. Every gland of this class is divided into lobes very distinctly isolated by grooves filled with this texture, and determining the tuberculated surface which characterizes the exterior of the organ. Each lobule, and every glandular acinus, down to the smallest division, is covered by cellular substance; hence the whole consists of an assemblage of small distinct bodies, connected together only by the circumstance of their excretory tubes being united to form a common duct, and which we could conceive to be perfectly capable of exercising their functions if actually separate. We see this in the parotid; where small accessory portions are often seen in the course of the duct, completely unconnected with the principal gland. The submaxillary and sublingual are sometimes continuous, sometimes isolated. The cellular tissue in these glands often contains an abundance of fat. This is particularly observable in the breast, the volume of which sometimes depends on the size of the gland, sometimes on an accumulation of the adipous substance; a difference, which is very easily recognized by the touch. Hence the quantity of milk is not always in proportion to the apparent size of the mammae. In the proper conglomerate glands, however, the adipous substance seldom amounts to a very considerable quantity. The connecting threads are very short and slender in the testis. In those glands, which have a dense parenchyma, as the liver, kidney, prostatic, and mucous organs, there is very little cellular tissue, and hence the facility with which some of them may be torn. Their substance never contains fat. The mucous state of the liver in various diseases does not invalidate this observation; for the fat then enters into its composition as an essential element of the organ, and is substituted in place of the colouring matter, which disappears; it is not contained in cells. Fat may be seen also in the interior of the kidney, but it is round the pelvis, and not in the proper parenchyma of the gland. The tonsils, prostatic, and mucous glands never contain any. Serous fluids are never thrown out in the substance of glands, which have a close parenchyma; they are not affected in cases of the most general and extensive anasarca. We cannot, however, doubt the existence of cellular tissue in such glands: maceration demonstrates it. The fungous tumours, growing from these organs, contain much of it; and it is principally seen round the vessels, as in the capsula Glissoni. This texture, indeed, is often diseased, while the proper substance of the gland remains sound:

GLAND.

found: hence the development of steatomatous tumours in the liver, of ferous cysts in the kidneys, and of hydatids in both, without the secretion being at all disturbed. The liver is sometimes increased three or four-fold by internal tumours, without its proper tissue being augmented: the latter forms a kind of septa between the swellings in which the biliary secretion goes on.

Blood-vessels—Glands, which are not surrounded by a membran., receive their arteries from all quarters. An abundance of small branches from the neighbouring trunks penetrates the surface of the salivary and lacrymal glands, the pancreas, &c. They first run between the lobes, penetrate into the smaller divisions, and are finally dispersed on the acini. The branches coming from different quarters anastomose freely in the gland.

Where the organ is surrounded by a membrane, as in the liver, kidney, testis, &c., the arteries penetrate on one side only, generally at a more or less deep notch, and in a single considerable trunk, which, however, is sometimes previously divided into a few smaller branches. The part, at which the artery enters, is always the farthest removed from the action of external bodies; a remark, which is common to all important organs, as the lungs, intestines, spleen, &c. The convex surface of these, where the vessels are the smallest, and where hæmorrhage would consequently be attended with the least danger, is always turned outwards. When it has entered the gland, the main artery quickly divides into various branches, which diverge and are subdivided as they approach the convexity. They have various branches in the body of the organ, as they proceed, and end by producing a large number of capillaries, covering the surface of the organ. Sometimes they come through, are visible on the surface, and ramify between it and the investing membrane. The most favourable method of observing the distribution of the arterial system in these organs is to inject them with hard injection, and to destroy the animal substance by means of immersion in muriatic or nitric acids: a cast of the vascular system, even to its very minute divisions, may be obtained in this way, and such preparations, on account of their elegance, are contained in all cabinets. Ruysch, who was remarkable for his dexterity in these processes, found that the small arteries were differently arranged in the different organs. In the kidney they are convoluted, so as to form, through the whole substance of the organ, small granular bodies less than a pin's head, which are the acini already alluded to. The surface of the liver is covered, after a successful injection, with innumerable capillaries arranged in a stellated form, and giving the appearance of little tufts of minute arteries, when the part is corroded, which have been compared to camel's hair pencils; and this arrangement has been termed the penicillous. A similar disposition is observable in the spleen.

Some have conceived that the large arterial trunks of glands communicate to the organs an interior motion very favourable to the execution of their functions. These bodies are placed, for the most part, in the trunk, and therefore near to the heart; and their vessels generally enter after a short course, so that the impulse has been considered, from this cause, to be more powerful. The spermatic artery is a remarkable exception to this observation, and the slowness of the seminal secretion has been explained from this cause. We own that we cannot discover any very convincing arguments in proof of these positions.

The veins accompany the arteries throughout, in their distribution to the glands; we have no distinction here of a superficial and deep-seated set. The liver is the only exam-

ple in which red blood enters on one side, and black goes out in the opposite direction.

Blood of the glands—The quantity of blood contained habitually in these organs differs remarkably in the different parts of the system. 1. The conglomerate gland contain very little. It imparts no colour to these organs, which are whitish in their appearance, and only require the water to be changed two or three times in maceration. 2. The mucous gland, prostate, and testicle contain a larger quantity. 3. The liver and kidney have such a considerable portion, that they differ widely in this respect from the rest of the glandular system. They contain a large quantity even after death from hæmorrhage, or when the glands are suddenly removed from a living animal. Hence, when we macerate these organs, it is necessary to renew the water at least twelve times before it ceases to be bloody: when we preserve them in alcohol, long previous maceration is necessary, to prevent the spirit from becoming turbid by the blood. This large quantity of blood occasions the glands now under consideration to be heavier than the other parts of the system; hence, too, arises their distinguishing red colour, which is not more essentially inherent in their tissue, than in mucous surfaces or muscles: in fact repeated washings will discharge it as effectually. The liver then exhibits a greyish appearance, which appears to be the proper colour of its tissue, as white is that of the muscular fibre. The hue of the kidney seems to be less immediately influenced by the blood. It retains a degree of redness after frequent renewals of the macerating water; and the pulp produced by leaving it in water for some months, with frequent changes, still has a red tint, although less deep than in the recent state. Does the state of the secretion influence the quantity of blood contained in glandular organs? Is there more blood sent to the kidney, when the urinary fluid is separated abundantly, than when it passes off slowly? or is there less returned by the veins in the former case?

Nerves.—Glands receive two kinds of nerves. 1. The lacrymal and salivary glands, the tonsils, &c. are supplied almost exclusively from the cerebral nerves. 2. The testicles, prostate, and liver, derive nearly an equal portion from the brain and the ganglia. 3. The kidney and most of the mucous glands, &c. are almost entirely supplied from the ganglia. These remarks apply to those nerves only, which are unconnected with the arteries; for each arterial trunk penetrating a gland, is surrounded by a nervous network belonging to the system of the ganglia, and very manifest in the larger organs, as the liver and kidney, where the plexuses come from the femilunar ganglion, in the salivary glands, where it is derived from the superior cervical, in the testis from the lumbar, &c.

The nerves are small compared to the size of the glands. We must not decide on this subject from those which enter the parotid and submaxillary; for the nerves merely traverse those organs, leaving a few branches behind them. But the liver obviously possesses as small a supply as any organ in the economy, which receives nerves at all. Nerves enter the glands, like the vessels; that is, they come in on all sides where there is no surrounding membrane; and enter at the notch in other cases. They divide and subdivide, as soon as they reach the gland, and are quickly lost. There are never any ganglia in the interior of these organs.

We know but little of the exhaling and absorbing vessels in the substance of glands, where they are merely subservient to the purposes of nutrition.

Properties of the Glandular Tissue.

1. *Properties derived from their Organization*.—These are very

very slightly marked in this system, probably from its texture not partaking at all of the fibrous nature. In order that an organ should be susceptible of elongation and subsequent contraction, without injury, its component particles must possess a certain degree of cohesion; and this attribute particularly belongs to fibre. The glandular system, too, is subject much less frequently to causes of distention and contraction, than those which are made up of fibres. Where the liver contains a large quantity of blood after death, in consequence of the venous system being overloaded, its bulk remains the same: its substance is compressed by the vessels. The enlargement of the testicle in gonorrhœa, and of the parotid glands under certain circumstances, and their speedy subsequent reduction, prove that these organs possess a certain degree of extensibility and contractility. Are the liver, kidney, and other internal glands subject to similar acute enlargements? The phenomena now alluded to may take place in the cellular tissue of the glands, and therefore suppose a less degree of extensibility in the proper substance of the gland than might at first have been supposed.

2. *Vital properties of the glands, and physiology of secretion.*—The remainder of the investigation is much more difficult than what we have already gone through. The nature and properties of the fluids, and the structure of the secreting organs, may be determined in a great measure by the evidence of our senses; but when we endeavour to explain why each particular fluid is separated by its respective organ, the determination of the question implies a knowledge of the hidden structure of the minute elements of our body, about which we must either be silent, or attempt conjectural explanation, at some risk of exposing ourselves. The object then is, to shew, why, in the healthy state of the body, saliva, and no other fluid, is constantly separated from the blood in the parotid gland, bile in the liver, and urine in the kidney; and how it happens that the nature of the secretion never changes, so that urine should be formed in a salivary gland, saliva in the kidney, bile in the mammary glands, &c. The difficulty of the undertaking is increased, and the prospect of arriving at a satisfactory conclusion diminished, by this circumstance; that in the different classes of fluids, each is not constantly separated in an organ of a particular structure. If that were the case, it would only be necessary to determine the relation which the structure of the gland bears to the nature of the secreted fluid: but the very contrary is the case. Fluids of each kind are produced by every variety of glandular apparatus: thus water is formed by the arteries of the skin, without any glandular arrangement, by conglomerate glands, in the instance of the salivary apparatus, and by a glandular viscus in the case of the kidney: mucus is secreted by membranous surfaces, and by different kinds of glands; and lastly, oily matters are poured from the arteries of the cellular membrane, from various sebaceous glands, from the vessels of the skin, from the liver, &c. Again, there are instances in the body, of organs, which we should, *à priori*, have pronounced, without hesitation, to be glandular, and which yet perform no secretion. Such are the spleen and thyroid gland, to which we may perhaps add the thymus and renal capsules. The spleen is a remarkable instance of the arrangement of the minute arteries, called the penicillous, which is seen also in the liver, and considered to have much connection with the peculiar functions of the secretory organs. In this place, too, we should mention the curious facts, concerning the formation of certain fluids, under particular circumstances. By other glands than those which ordinarily produce them.

Haller has collected, in his great work, a vast number of facts of this description; of which, if we should reject all that may seem insufficiently authenticated, there will remain quite enough to prove the point decisively. To the chapter in which these details are contained, he prefixes this sentence: "sere quilibet humor per quodcumque eorum separari potest;" and the cases which he cites, fully justify his concluding paragraph: "Quando hæc exempla repetemus, constabit, non ejusdem unice classis diversos humores sua inter se eola commutare, sed etiam per mucii organa aquam, per mucii, aquæ et adipis eola lympham et sanguinem, per aquæ, mucii et lymphæ vias adipem, bilem sanguinemque fecerari, atque adeo omnino, nullum in animato corpore separatorium organum esse, quod non omnium classium humores suis eum dotibus fecerere queat." *Element. Physiolog. lib. 7. cap. 1. §. 9.* When these circumstances are considered, it will very probably be suspected that the causes of the differences in the secreted fluids cannot be traced in the obvious structure of the glands; but that the reason why a peculiar fluid and no other is separated from each gland, in the healthy state of the body, lies much deeper, and flows from some conditions of the organs, which are inaccessible to our senses. We shall endeavour to illustrate the subject as far as well authenticated facts will assist us, and shall mention the opinions which have been most prevalent on the subject. It will be an easier task to shew how unsatisfactory most of these are, than to substitute any thing more rational in their place. We proceed to point out the vital properties of the glands.

No part of the system possesses animal contractility, or the power of voluntary motion. Different glands seem to be differently circumstanced with respect to the corresponding species of sensibility. The peculiar and oppressive sensation occasioned by compression of the testicle, is well known. Considerable and continued pressure on the parotid gland has produced great suffering; but large nerves pass through this organ. The liver may be injured in a living animal, without causing any of the usual signs of pain; and Haller makes the same observation concerning the glandular system in general, but his statement is not perfectly explicit: "Universæ glandulæ experienti minime irritabiles videntur, neque vehementer aut morbos sentiant, aut illatas a profectore injurias." *Elem. Physiol. t. 2. p. 377.* Stones in the kidneys often cause very severe pain. From these apparently contradictory circumstances, we can only conclude that animal sensibility, which is variously modified, may exist in organs, where certain agents do not excite it at all, while others develop it very readily. In fact, various morbid alterations render this property very manifest in the glands. The pain of inflammation bears, indeed, a peculiar character in the glandular system; it is generally obtuse and heavy.

Properties of the organic life.—Sensible organic contractility does not exist in the glandular system; but the two other organic powers are exhibited in their highest state of development, and are almost constantly in operation, being concerned in secretion, excretion, and nutrition. Organic sensibility enables the gland to distinguish in the mass of blood those materials which are suitable to its secretion; and by its insensible contractility, it has the power of rejecting whatever is heterogeneous. The blood contains the materials of all the secretions, of the nutrition of all organs, and of all the exhalations. From this common reservoir each gland draws what is requisite for its secretion, each organ for its nutrition, and every serous surface for its exhalation. The peculiar mode of organic sensibility enables each living part to distinguish what its functions require. The whole business of glandular action rests on the two powers just mentioned;

mentioned; and as this action is nearly constant, they are almost incessantly exerted.

It is evident that all glandular affections must imply a disorder in the powers above-mentioned; since diseases of an organ are particularly determined by alterations of the leading properties; of those which constitute the peculiar life of the part. Observation proves this: we see these properties, when augmented or diminished, producing on one side increased secretion, as in diabetes, mercurial salivation, cholera morbus, &c.; on the other, a decrease or even suspension of the function, as in acute diseases, where all the secretory tubes seem, as it were, closed for a time; for instance, in suppression of urine, dry state of the mouth, &c. On other occasions the nature of the glandular sensibility is changed, and it harmonizes with substances which are not admitted in the healthy state: hence the innumerable varieties of the secreted fluids under circumstances of disease. The cystic bile in the dead body presents numerous varieties of taste, smell, colour, and consistence. The numerous alterations of the urine are well known. The saliva is less liable to change; but how different is it in many diseases from its ordinary condition. Nothing can less resemble urine or bile than the fluids often discharged from the bladder and liver: whence then arise these differences? from the variations in the organic sensibility bringing the part into a relation with those substances, which were foreign to it in the natural state. Thus the same gland, without any change in its structure, but merely by altered modifications of its vital powers, may be the source of infinitely varying fluids. Might not this be carried so far as to allow that the kidney, by assuming a sensibility analogous to that of the liver, may actually form bile? why should it not secrete bile, since it does separate other fluids so widely different from the urine?

In the healthy state, the mode of sensibility in each gland is nearly uniform; and the secreted fluid is consequently nearly the same in its composition and properties. But the mode is changed by numerous causes in disease. An hysterical attack comes on; suddenly the kidney refuses to transmit the principles which colour the urine, and that fluid is consequently discharged limpid; as the paroxysm subsides, the natural type of the sensibility is restored, and the urine has its accustomed characters. In an epileptic fit, a thick frothy saliva is discharged from the mouth in abundance; as the attack goes off, the salivary secretion returns to its natural state.

The various changes in the organic sensibility, and the sensible contractility of the glands, do not affect the function of secretion only; but when they last for some time, they influence nutrition also. From the disturbances of this process arise those various organic affections, of which the glandular system offers the most abundant harvest to the pathological anatomist. We cannot avoid noticing, in dissecting rooms, the numerous diseases observed in this part of the body compared to others. The glands, the skin, the mucous, serous, and cellular system, hold the first rank in this respect; and in all these the two properties above-mentioned exist in the highest degree, and are called into action, not merely by nutrition, but also by various other functions, which reside in the capillary system, as exhalation, absorption, and secretion.

The preceding account of the physiology of secretion, chiefly derived from the "Anatomic Generale" of Bichat, seems to amount to little more than this, that each secretory organ produces its peculiar product, in consequence of its possessing peculiar vital properties, which, when variously modified under particular circumstances, enable the organ to separate very different fluids from the blood. And this we

believe to be a pretty correct statement of the extent of our knowledge of this subject. But anatomists and physiologists, not satisfied with this simple fact, have endeavoured to develop the exact mechanism of the process, and it will be necessary for us to recount some of their opinions. In all observations on this subject, it will be well for us to remember that secretion is not confined to the animal kingdom, but prevails also in the vegetable world. We frequently observe the sap giving origin to peculiar and different juices in the various parts of the same plant, and reasoners from analogy have gone so far as to admit the existence of a glandular system in vegetables. We shall be induced, by this circumstance, not to lay too much stress on the peculiar structure of the secretory organs in the more complicated animals, as essential to the business of secretion. Many of the facts already noticed, concerning the separation of perfectly similar, or at least very closely resembling fluids, by means of totally dissimilar organs, will tend to the same deduction. And this mode of argument may be still further supported by various examples in comparative anatomy; where we find fluids of the same class secreted in animals of different orders, in organs of very different external appearance. The kidneys of birds are really conglomerate in their structure; and a fluid, exactly resembling the pancreatic of warm-blooded animals is formed by the tubular pyloric appendages, variously constituted in different genera of fishes.

Of the different explanations, by which physiologists have successively attempted to elucidate the function of secretion, most are completely hypothetical and improbable. In most instances it has been assumed that the various animal fluids are all contained in the blood; and secretion, according to this opinion, consists simply in their separation by means of the glands. Differences in the diameter, length, and folds of the vessels, and supposed varieties in the holes with which the glandular system is supposed to be perforated, have been employed as the means of rendering the mechanism of secretion intelligible; hence the expressions of sieves, filters, and strainers, so frequently employed in physiology. We are dispensed from the necessity of commenting on the glaring absurdity of comparing a gland to a sieve or filter, and of deciding which of these mechanical explanations is the most exquisitely foolish, by the completely gratuitous nature of the fundamental proposition. The modern analytists of the blood have no longer even the shadow of an excuse for regarding this fluid as a mixture of all the animal liquors, and for supposing that it is formed of saliva, bile, gastric juice, urine, &c. since we can discover no trace of such fluids in it. Although all the elements necessary to form these products, as well indeed as those of the solids, are in fact found in the blood, they exist in it in a different state of combination. The blood is manifestly a homogeneous liquor, capable of forming all animal matters from the most transparent and pure water, as the cutaneous exhalation, to the firm fabric of the bony system; from it are formed saliva, bile, and urine; and it serves also for the nutrition of muscles, membranes, and nerves; but none of these modifications of animal substance are contained in it perfectly formed.

Their precipitation, says Fourcroy, in the tissues to which they belong, cannot be regarded as a simple separation; since it is accompanied by a modification in the properties, nature, and composition of each. Thus the cerebral pulp is not exactly the same albuminous matter as that in the serum of the blood; the gelatine is not isolated in this fluid, as in the membranous tissue; the muscular fibrine is not completely identical in its character with that which exists in the blood; and the phosphate of lime is not associated in the latter to the gelatinous substance, which unites its particles.

cles in the bony system. Hence secretion always implies some change or modification in the matter which results from its exercise. *Connoiss. Chim. sect. 8. ord. 4. art. 5.*

Another notion, as destitute of all solid foundation as the former, is, that the blood undergoes certain changes as it arrives at the glands; that it assumes a peculiar composition before it penetrates the organ. It has been asserted that the blood-vessels are so arranged as to produce particular modifications in the contained fluid, and that this is a disposition preparatory to the final process. The hepatic secretion has been considered to afford the clearest example of such previous changes. The structure and number of the vessels which surround and enter the organ, the proportion of those which carry blood or white fluids, the different temperatures supposed to depend on these proportions, in a word, all those points of organization which can possibly influence the nature of the blood, are said to be sufficiently diversified in order to produce in the chemical properties of the fluids a disposition favourable to the formation of saliva in the neighbourhood of the salivary glands, of urine in that of the kidney, &c. This disposition, depending on the vascular apparatus, has been represented to consist particularly in a retardation, acceleration, cooling or warming of the blood, or in the loss, by absorption, of some of its principles. But what sensible cause can produce these effects? Does not the blood flow through the trunks which are going to the glands just as in other vessels? In short, what is the change? The supposition in question is a complete assumption; not supported by a single fact, and contrary to observation as far as our knowledge hitherto extends. For we can detect no difference in the blood drawn from the carotid, spermatic, hepatic or renal arteries. We have been surpris'd to find this opinion adopted and supported by Fourcroy; but the whole of his remarks on the subject in the "*Système des Connoissances Chimiques*," *sect. 8. ord. 4. art. 5.* do not contain a single proof, and afford an example of vague and completely illogical statements. We do not mean to deny that there may be particular conditions of the whole mass of blood favourable to certain secretions. Thus, after drinking copiously of watery fluids, we find a much larger portion of urine secreted; and the cutaneous exhalation is often augmented from the same cause.

In our endeavours to discover the mechanism of secretion, it will be best for us to select the most simple mode of this function. Now the exhalation from serous membranes, and the mucous fluid covering the surface of many cavities in the body, are examples of this kind. We can discover nothing in these organs but vascular ramifications united by cellular substance. Injected fluids in the dead body follow the same route which the secreted liquors follow in the living state. And the same observation may be applied also to the case of secretions in some of the more complex instances. "Water," says Haller, "tinged with colouring matter, singlafs, or oil of turpentine, thrown into the arteries of a young subject, and occasionally even suet, in the experiments of Ruyfch and Albinus, have exuded in numerous small drops from the skin, after the removal of the cuticle in warm water, so as to imitate very closely the proceedings of nature. I have also repeatedly seen water, coloured with blue, and injected into the lungs through the inferior cava, run out with much froth from the trachea. In the kidney, water, air, or suet will pass through excretory tubes continuous with the arteries into the infundibula and pelvis. Oil of turpentine and quicksilver have passed into the chamber of the aqueous humour from the arteries: in

the same way injected water imitates the course of the tear, and exudes abundantly from the whole internal surface of the eye-lids." *Elem. Physiol. t. 2. p. 374.* Physiologists have indulged in considerable disputes concerning this kind of secretions. "Some," says Blumenbach, "assert that all separation of fluids from the mass of blood is accomplished merely by pores in the blood-vessels, and those, as they say, of an inorganic nature; while others deny altogether the existence of secretory pores. I suspect that this difference of opinion must be resolved into a verbal dispute. On the one hand, I must confess, unequivocally, that I know not what notion to form of inorganic pores in an organized body, since all the openings in such bodies must belong to their organic nature, and be regulated by their vital properties. On the other side I do not conceive that the orifices or pores in the coats of the vessels, the existence of which cannot be doubted, differ essentially, in regard to their functions, from the cylindrical ducts, in which secretion is performed in the conglomerate glands, and in the glandular viscera: since it is probable that the separation of fluids depends more on the vital properties than on the forms of the secretory organs." *Institut. Physiolog. sect. 32. § 469, note b.*

However simple the process of secretion may be deemed in the case just specified, and however closely the proceedings of nature may be imitated by the experiments with injections, we shall still find ourselves entirely ignorant of the essential circumstances of the process; *i. e.* we cannot explain the formation of the new product from the blood, and the formation of such totally different new combinations in organs where no difference of structure can be detected.

Those, who wish to see the various attempts at explaining the mechanism of secretion, may find ample gratification in the third section of the seventh book of Haller's great work: where he gives his usual detail of all that has been written on the subject. The reader will be very willing to spare us the task of recounting all these dreams, and the still more disgusting toil of refuting them. We shall merely mention one opinion, on which physiologists lay some stress even in the present day. This refers the difference of the secreted matters to the peculiar arrangements of the minute arteries of the glands. Ruyfch, who excelled in the art of making anatomical preparations, was led to remark, in his employment of injections, that the ultimate arterial ramifications differ in the different secretory organs, and indeed that there are characteristic differences in this respect in all the structures of the body. This explanation may possibly be true, and we cannot perhaps completely overthrow it: but this is all that we can say in its behalf. We must observe, in the first place, that a correct account of the facts, and an exact description of the different vascular networks, is yet a desideratum; for the question concerns the very smallest capillaries, from which the tubes conveying the new product commence. Now the larger ramifications, such, for instance, as will admit several globules, do not differ sufficiently from each other to account for the diversity of the fluids produced in the various organs. Indeed similar vessels often produce the most opposite products. The structure of the cortex cerebri, of the spleen, and of the placenta, is very much alike with the most dissimilar results. The veins, too, are arranged like the arteries, as we should conclude, certainly not for the purposes of secretion. Very different arrangements of blood-vessels may be seen in various membranes which produce the same kind of exhalation.

Recourse has been had to the science of chemistry, in order to explain the function of secretion, but no assistance has been hitherto

hitherto derived from this source in unfolding the mystery. That the changes, by which the new products constituting the animal fluids are produced from the blood are purely chemical, cannot be doubted, but we are equally in the dark as to the circumstances which determine or modify these alterations. We cannot doubt indeed that the whole essentially depends on a vital power of which chemistry can neither detect the nature, nor appreciate the force. If, however, we cannot be very sanguine in expecting from this science a development of the immediate agent by which secretion is effected, much light may, probably, be thrown on some parts of the subject by accurate chemical investigations. We may apply generally the observation of Dr. Thomson concerning the kidneys: "the changes operated on the blood in the kidneys are at present altogether unknown; but they must be important. Provided the method of analysing animal substances was so far perfected as to admit of accurate conclusions, considerable light might be thrown upon this subject, by analysing with care a portion of blood from the emulgent artery and vein separately, and ascertaining precisely in what particulars they differ from each other." *System of Chemistry*, vol. 5. p. 749. Fourcroy, too, in considering how far secretion admits of explanation on chemical principles, speaks rather of what may be done than of what has been effected in this way. "Hitherto chemistry can only furnish some general statements on this subject; and, if we look to this science for an explanation of the causes and products of the secretions, and for a demonstration of what passes in every kind of secretion in particular, we must wait till the experiments are much more numerous, the investigations more exact, and the animal analyses considerably multiplied. We must determine the temperature, consistence, and nature of the cerebral blood, of that in the vena portarum, and in the renal arteries, before we can understand the mechanism of the secretions performed in the brain, liver, and kidneys." *Syst. des Conn. Chim.* v. 10, p. 385.

We should always bear in mind, in our attempts at chemical explanations of the animal functions, that the effects of the vital power are more particularly observable in counteracting and preventing the exertion of those affinities, by which dead animal matters are regulated; and consequently, that if secretion be an example of chemical affinity, it is so modified by the vital powers, that we can have very little hope of imitating it by experiments out of the body.

In what manner, and to what extent, are the secretions influenced by the nerves? The fact that glands have a supply of nerves, leads us to expect *à priori* that the effects of their operation will be very obvious; but the laws, which regulate this matter, are hitherto by no means clearly ascertained, and even the kind of influence is very obscure. There is a want of direct evidence, from experiment, on this subject. "I divided," says Bichat, "the nerves of the testicle in a dog: the gland inflamed and suppurated; but the latter occurrence shews that nervous influence is not necessary for secretion, since suppuration is accomplished in a manner analogous to that of the latter functions. Physicians know very well that paralysed limbs may inflame and suppurate. Erection and expulsion of the semen may occur, when the lower half of the body is paralysed, and when the nerves of the prostate at least must have entirely lost their influence. An example was related to me of a soldier, who contracted a gonorrhœa in this state. In complete paralysis of the bladder, mucus is still secreted in sufficient abundance. The nostril of the affected side is as moist as usual in hemiplegia; and an equal quantity of cerumen is produced in the meatus auditorius of the same side. The glands of the uvula

do not cease to act where that organ is paralysed. After cutting the nerve of the eighth pair on one side in a dog, the air-vessels are equally full of mucus on that side. In the convulsed state of such parts as possess glands, where the nerves of these organs must consequently be unusually excited, there is no augmentation of the secretion." *Anatomic Generale*, tom. 4. p. 604. We may observe further, that when the influence of the brain on the organs of the animal life is completely suspended in apoplexy or compression, where sensation and voluntary motion are lost, the secretions continue undisturbed. On the other side we may adduce numerous phenomena, which can be accounted for only through the agency of the nervous system. Under this head we may mention the flow of saliva on the sight of food, the increased lacrymal secretion produced by various affections of the mind, the suppressed discharge from the skin from the same cause. The urinary secretion is often suddenly affected in hypochondriacal persons; distressing news will occasion it to be secreted in great abundance, and of a very pale colour; and many remarkable instances have been recorded, where the biliary secretion has been decidedly and suddenly affected by mental emotions. It has been asserted, but we know not on what authority, that a cow, after being milked by the same individual for a long time, will give much less milk, if the operation be performed by a stranger. These and other analogous facts have led many physiologists to admit of a nervous influence in the affair of secretion; the mode and degree of this action have been variously estimated. De Berger conceives that the tone of the secretory organs was kept up by the nervous fluid; De Natura Humana, p. 122. Quesnay referred the differences of the secreted fluids to various degrees of sensibility in the secretory vessels; *Essais sur l'Econ. Anim.* t. 3. p. 437. De Bordeu ascribed great influence to the nerves on the secreting arteries; *Recherches sur les Glandes*, p. 352. Stahl and his followers, who ascribed the power of guiding the vital motions to the soul (anima), conceived that it governed the business of secretion also; and A. F. Hoffman ascribes the difference of the fluids entirely to the anima, which regulates the secretory orifices by sphincters and valves, now closing them to prevent the entrance of particles heterogeneous to the fluid intended to be formed, and now opening them for the entrance of the suitable molecules; *Nov. Hypothes. Physiolog.* p. 13. After recounting these opinions, Haller observes that they ascribe too great an influence to the nerves, and reminds his reader that secretions of various kinds are performed in plants, without the assistance of nerves; and that balsams, resins, gums, and coloured milky fluid is formed from the common liquor taken in by the roots of the vegetable. On this subject we may observe, with Bichat, that the expression *nervous influence* has generally been used by physiologists in a very indefinite manner. When the irritation, division, or paralysis of a nerve supplying a voluntary organ interrupts, or entirely destroys its functions, we can observe and appreciate the influence of the nerves on such organs; but, with what propriety can we employ the same term to designate the power, which the nerves may possibly have over the secretory organs, when their division or paralysis does not at all disturb the functions of the part?

The secretions may be affected by the direct action of external irritants, although mechanical or chemical irritation in the living body produces no sensible motion or contraction of the organ. Thus, any acid matter will augment the flow of mucus from those surfaces which secrete it; and the slightest irritation of the conjunctiva increases the secretion

of the lacrymal gland. The presence of food in the mouth excites the salivary organs; and the act of suckling or milking produces a secretion of milk, &c. &c.

The same powers by which secretion is effected accomplish the passage of the fluid, when produced, through its excretory tubes; it is the insensible organic contractility by which this is effected. Experiments on the ducts of glands in living animals, shew that they are not affected by chemical or mechanical irritation, and hence many have concluded that they possess no power of contraction; but the phenomena render it necessary to allow them such a property, which may exist in parts, although the trials just mentioned should not render it obvious. External pressures and extraneous influence of other kinds have been referred to, in order to account for the expulsion of the fluids contained in excretory tubes, on the idea that these canals possessed no contractile powers in themselves. Such explanations are quite gratuitous assumptions in all cases; and in many instances are totally and manifestly inadequate, because the organ is exposed to no agency of the kind.

The secreted fluid in some instances is not conveyed immediately to the point of its ultimate destination; but is either retained in the excretory tubes, or kept in particular reservoirs; and it has been supposed that various changes take place in its nature and properties under these circumstances. "Frequentissime," says Haller, "hoc mechanismo natura utitur, ut humorem secretum retineat, perficiat, inspisset, ad destinatos usus contemperet, legitima occasione effundat." *Elem. Physiol.* t. ii. p. 445. The urinary and gall-bladders are the most remarkable instances of this description: we may mention also the vesiculae feminales, and the mucous ducts of the urethra and female organs of generation. That the secreted fluids in these, and in several other instances, are considerably altered after the time of their first production, cannot admit of a doubt, as mere inspection is sufficient to prove it; the particular changes produced in each case will be considered in the account of the various organs. The opinions entertained concerning the general effects of these reservoirs, are, that the fluids are inspissated by an absorption of these aqueous parts, that they are deperated, or rendered more perfect, and variously mixed together: it is added, that their retention in the heat of the living animal body in many instances renders them acrimonious, and that this change, in many cases, as in the bile and semen, promotes the views of nature. These notions are not very consistent with each other, nor very clear in themselves: the latter supposition, concerning the acrimonious tendency of the fluids, is founded on the observation of the changes occurring out of the body, and is not at all warranted by observation of the living subject, in which chemical alterations are resisted by the vital powers.

We have every reason to suppose that much of the secreted fluids is taken up and carried into the circulation by the absorbents; but our knowledge does not enable us to determine the exact extent or nature of the modification, which the function of secretion undergoes from this cause. The experiments of Bichat prove that the various animal products, even those which we should at first have regarded as the most noxious, may be introduced into the venous system without essential injury to the animal; so that the blood may be deemed a common fluid, receiving and retaining various principles, which may vary according to circumstances. "I injected," says Bichat, "into the jugular veins of several dogs, cystic bile taken from other dogs opened at the same time. During the first days they appeared weary, did not eat, were very thirsty, had a dull look about the

eyes, and were constantly lying down; in a little time, however, they gradually recovered their original vigour. I have since employed human bile in similar experiments: the results were the same, except that hicough and vomiting took place soon after the experiment. In one instance the animal died three hours after the injection; here I had used bile of an extremely deep black colour, like thick ink, such as is occasionally seen in the gall-bladder, and seems to form an essential part of the black vomitings observed in certain cases. When similar trials were made with saliva, the consequent languor was less sensible. I then tried mucus of the nose suspended in water. Lastly urine itself, not of the aqueous kind, but that of coction, was employed; the consequent illness was more severe, but one animal only died, and I suspect that this fatal event happened from the unguarded introduction of a little air at the time of the experiment." *Anatomic Generale*, t. 4. p. 587. He observes afterwards that the injection of any animal fluids into the carotid artery is immediately fatal, from the effects produced on the brain: but they may be thrown with impunity into other parts of the arterial system, as, for instance, into the crural artery.

Sympathies of the glandular system—These may be divided into the passive and active. The glandular tissue is very readily influenced by various excitements, either in the natural state, or in diseases, which constitute its passive sympathies. The cases in which the excitation of other organs augments glandular action, are particularly observable in the mucous system. Most of the excretory ducts open on surfaces of this nature; and examples of the observation occur in the flow of saliva determined by the presence of food in the mouth; in that of urine produced by catheters retained in the bladder; in the seminal excretion produced by irritation of the glans; the flow of tears from irritation of the conjunctiva or pituitary membrane; and in that of bile during the passage of the food into the small intestine.

The glandular system frequently exhibits passive sympathies in disease; the organic properties are brought into action under these circumstances, the animal sensibility being very seldom developed so as to produce pain. The innumerable varieties in the quantity or quality of fluids separated by the glands under circumstances of disease arise principally from sympathetic influence. Thus the salivary apparatus moistens the mouth, or leaves it dry; fills it with a viscid or a thin fluid, &c. The mucous organs cover the tongue with matters of most varying consistence, thickness, and colour; and this occurs from sympathy with various states of the stomach. The liver, kidney, and pancreas are influenced in very numerous ways; wherever any organ in the animal economy is affected, these are deranged; their secretion is increased, diminished, or altered, and frequently even inflammation and suppuration supervene. The affections of the liver from injuries of the head are well known; and the lacrymal secretion is variously modified in inflammatory and malignant fevers, so as to produce various appearances of the eyes. Weeping in various mental affections is another example of sympathetic influence. The testicles and prostate exhibit fewer instances of such sympathies, probably because their functions are so much more isolated. The relations which connect the breasts and uterus are remarkable, and frequently observed. In the sequel of considerable acute diseases, particularly fevers, the action of the glands is often considerably affected, and copious evacuations, called critical, the nature of which is not yet clearly explained, take place.

The active sympathies are less frequent than those of the

preceding class; but diseases exhibit instances of them. Inflammations of the liver, kidney, salivary system, &c. shew various phenomena produced sympathetically in other systems.

Bichat, in his *Anatomic Generale*, gives the following view of the characters which distinguish the vital properties of the glandular system.

1st. *Peculiar vitality (vita propria) of each gland*—The vitality of the glands, resulting from the preceding powers considered in a state of action, is not uniform in the whole system; because the structure varies in every instance, and each tissue possesses a peculiar modification of vitality. Hence result many phenomena noticed by Bordeu.

1. There are certain matters on which alone each gland can act in the natural state. Thus the salivary apparatus does not form bile, the liver does not separate urine, &c.; and on this principle the difference of the secretions is founded. In the same way cantharides act particularly on the urinary organs; mercury on the salivary glands, &c. 2. Each gland has its particular mode of sympathy. Thus the liver acts especially on the brain, the kidney influences the stomach, the uterus and breasts affect each other, &c. 3. Each glandular inflammation has a peculiar character: that of the kidney is different from that of the liver or testicle; the inflamed prostate has very different symptoms from the testis in such a condition. 4. Every gland has peculiar diseases, or some at least to which it is more exposed than others. Hydatids, which are very common in the liver, are never seen in the salivary glands or testicle. Sarcocoele is extremely common, while nothing is more infrequent than an enlarged parotid. The liver alone exhibits that peculiar alteration, which constitutes the fatty state; and is the most frequent seat of steatomatous tumours. Physicians, who have not been conversant with the inspection of morbid cases, use the vague and insignificant terms of obstruction and induration for every kind of glandular enlargement. The increase of size is the only common character of such affections, while the nature of the tumour is entirely different. 5. Every gland presents some peculiar modifications in what are called the critical evacuations, occasionally consequent on acute diseases. 6. The different vitality of the glands occasions them to re-act at very different intervals, in consequence of direct irritation, or sympathetic excitation. The lacrymal gland, for example, pours out suddenly an abundant secretion, when irritated; while the kidneys or pancreas can be excited only very slowly.

2d *Character. Inactive state of the vital powers*.—The glands are subject to habitual alternations of increase and diminished action. The animal functions are especially influenced by sleep, which completely suspends them. The action of the glands is only partially diminished at certain times, except in disease, when it is sometimes completely suspended. Bichat compares the sleep of the animal life to the intervals of intermittent fevers, where the apyrexia is complete: and the sleep of the glands to those of remittent fevers, where the symptoms are merely diminished in degree. Saliva flows into the mouth abundantly during mastication; it merely moistens the cavity at other times. The pancreas and liver pour out their secretions profusely, while the food is in the duodenum: they act much less intensely during the state of abstinence. The kidney is particularly exerted some little time after a meal. The intermissions in the action of the breasts are almost as complete as those of the organs of animal life. Every mucous gland has its particular period of secretion: it is, when the surface, on which the duct opens, is in contact with any substance either retained in the cavity, or passing through it. We must, therefore, form

this notion of the office of the glands; that they constantly separate a fluid from the blood, but that they are more active at certain periods, and consequently furnish a more abundant supply.

This remittance of the glandular action, says Bichat, depends on a cause analogous to that of sleep, which arises, in the animal life, from the fatigue experienced by the organs of sensation and locomotion, after a continuance of action. The lassitude, of which the glands are susceptible, is not generally marked by any painful feeling; yet there is in the breast, after long suckling, a kind of dragging sensation, and actual pain is felt in the testis after emission has been repeated two or three times.

3d *Character*.—The vitality of the glands is never increased at the same time in the whole system. When one is in action, the others are in a state of remission. We might conceive, says Bichat, that there is only a determinate quantity of vital powers for the whole, and that one cannot be exerted unusually without a corresponding diminution in the rest. The digestive apparatus is accommodated to this law. At first the salivary system produces an abundant secretion; then the stomach comes into action; thirdly, when the chyme enters the duodenum, the liver and pancreas are principally exerted; at the fourth period, the mucous glands of the large intestine act; and lastly, the kidney exercises its peculiar office to evacuate the residue of the fluids. All the glands cannot act at once; as, in the external movements, certain muscles are always in a condition of repose, while others are contracted. The most improper time for coition is during digestion, because the mucous, pancreatic, hepatic secretions, &c. must then be performed at the same time with that of the testicle. In diseases, the secretion of one gland is increased at the expence of others. This character of the glandular system is only an example of the general character belonging to all the vital powers, by which, when increased at one point, they are proportionally diminished in some other situation. Hence large abscesses, considerable tumours, and dropsies are always attended with debility of the glandular action. On the same principle is founded the use of blisters, setons, moxa, cauteries, &c. which do not act, as old physicians supposed, by evacuating any morbid matters, but by putting an end to the irritation in the diseased part, by means of that which they determine in some other organ.

4th *Character*.—Influence of climate and the seasons on the vitality of the glands. From the preceding character is derived another phenomenon, which may be considered peculiar to the glandular system; *viz.* that it is in general more active in winter than in summer, in cold than in warm climates. Warmth, by relaxing the integuments, increases the cutaneous discharge at the expence of that of the glands; while the action of cold is the inverse of the preceding. Hence the same fluid, introduced into the body, is expelled in summer by the skin, in winter by the kidneys.

5th *Character*.—Influence of sex on the vital properties of the glands. Is the vitality of these organs more active in the male than in the female? In those which are subservient to digestion, the lacrymal and urinary secretion, &c. the two sexes exhibit very little difference. In the generative system, the male possesses the addition of testicles and prostate, the female of mammary glands; so that here there is a compensation. But the influence of the former on the animal economy very much exceeds in its force that of the latter.

Development of the Glandular System.

1. *State of this system in the fetus*.—Although the secre-

tions possess very little activity in the fœtus, the glands in general are large. The salivary glands and pancreas are larger than in the sequel: the bulk of the liver is enormous; and the kidneys considerably exceed their adult volume. It is not yet ascertained whether the same observation applies to the mucous glands. The form and colour are different in several from what they afterwards exhibit. The texture partakes of that softness and delicacy, which are common to the whole body; and they abound with fluids. In respect of their secretions, they seem to be in a condition analogous to that of remission in the adult: indeed, they produce still less than at that time. In fact, all the reservoirs would not suffice to contain the produce of their secretion, if these were as much produced in a given time, as after birth. Is this because the black blood, which they contain, does not furnish suitable materials? or rather, because the actions concerned in the composition of the body predominate so remarkably over those of the other kind? All the matter brought to the organs remains in them, and affords the materials of the rapid growth, which is then taking place: consequently, the secretions, which are designed chiefly to get rid of the residue of nutrition, are then inactive. Moreover, digestion introduces into the blood none of those principles, which, not being required for nutrition, are expelled nearly as they enter, without having belonged to the composition of the organs; such as the greatest part of the drink.

2. *State of the glands during growth.*—This system acquires a sudden increase of energy at the time of birth. Red blood now circulates through its vessels; and the extremities of the excretories are stimulated in various ways, as, by the food in the case of those which open on the alimentary canal, by the air in the respiratory apparatus, &c. The organs are so much the more sensible to this sudden excitation, in proportion as they were before unaccustomed to it. Yet many of the secretions are carried on with less activity during the first years of life, than in the sequel, as those of the salivary glands, liver, &c. Affections of the glandular system are not the leading ones in the first years of life. The lymphatic glands, as they are called, and not the parotids, form the swellings so frequent about the neck. Hepatic affections are rare at this time. All the secretions connected with the generative process hitherto do not exist. The organs, which are particularly employed at any age, are chiefly affected by acute and chronic diseases at that time; while those, by which no important function is exercised, seem to be overlooked. All affections of the testis and chord are unfrequent before puberty, while the process of nutrition alone is carried on in these organs. The glandular tissue is for a long time soft and delicate in the child; and it has not that property of becoming hard in consequence of boiling, which we have mentioned as belonging to it in the adult.

3. *State of the system after growth.*—We have already spoken, in the article GENERATION, of the organs which come into activity at puberty, and of the influence which they exert on the frame. At this time all the system acquires a greater firmness in its texture. Towards the fortieth year the digestive glands seem to be predominant in the economy, and the liver is especially observable among those. Now bilious affections are most numerous; and the influence of those passions, to which the bilious temperament seems to dispose, is most observable.

4. *State of the glands in old age.*—At this time the organs gradually become more hard in their texture; but their colour changes less than that of most parts. The liver, kidney, &c. are nearly as full of blood as in the adult;

while the muscles, pale and colourless, contain a smaller proportion than before. It seems that this fluid first quits the skin and muscles, which are farthest from the heart, and is concentrated in the nearer organs: thus the secretions are still abundant in old persons, while the muscular and nervous powers are considerably weakened. The kidneys and liver still separate their particular secretions in large quantity. The activity of the generative system has long ceased. The active exertion of the glands which are still employed may be referred to two causes. The decomposition of the body is very marked at this time, and much matter is consequently thrown out by certain glands. The decay of the old subject is a phenomenon exactly opposite to that of growth in the fœtus. The skin, shrivelled and hardened, ceases to throw out the products of decomposition, and the glands supply its place.

Generally speaking, life ceases most gradually in the glandular system. In the bodies of old persons we see the gall and the urinary bladders still full of their respective fluids. Compression of any gland, even of the prostate, shews that it contains much fluid; even more than we observe in the young subject. It is also a remarkable phenomenon that all the chief internal organs, as the liver, kidney, heart, lungs, &c. still preserve a considerable share of vitality, while the parts subservient to sensation and locomotion are nearly exhausted, and the ties, which connect the individual to surrounding objects, are consequently nearly destroyed. Haller, *Element. Physiolog.* tom. 2. Dumas, *Principes de Physiologie*, t. 4. Bichat, *Anatomie Generale*, t. 4.

GLAND, in *Vegetable Physiology*, (*glandula*, a little kernel,) is defined by Linnæus as “a small tumour, discharging a fluid.” This fluid is always some peculiar secretion. The calyx and stalks of the Moss Rose, and of many other Roses in some degree, are covered with prominent glands, discharging a viscid aromatic liquor. Between the serratures of the leaf of *Salix pentandra*, the Bay-leaved Willow, is a series of such glands, whose exudation is a highly fragrant yellow gum-resin, to which the fine-scent of that leaf is chiefly owing, and several other Willows are provided with similar, though less perfumed, secretions. On the footstalks of the Guelder-rose, *Viburnum Opulus*, are very large and elaborate glands, whose discharge however is comparatively trifling, while various species of Passion-flower bear cup-shaped glands, on their footstalks, producing a considerable quantity of very sweet honey. These therefore bear more analogy to those glands, appropriated to some flowers, and called, from their produce, nectariferous glands, or nectaries. Such occur in *Geranium*, and in the Cruciform plants, constituting the Linnæan class *Tetradynamia*. In the latter the nectariferous glands occasionally exhale a powerful scent, especially in *Sisymbrium tenuifolium*, Engl. Bot. t. 525.

The kinds of glands above-mentioned, being of a secretory nature, certainly bear a great analogy to the glands of the animal body, but it appears that the more general and important secretions of vegetables are accomplished through membranes, whose organization and physiology are inscrutable to our powers of investigation. S.

GLANDS, *Diseased*. See BUBO, LUES VENEREA, SCROFULA, BRONCHOCELE, &c.

GLANDS of Birds and Fishes.—See *Anatomy of BIRDS*, and FISH.

GLANDEN, in *Geography*, a town of Prussia, in Nantangen; 30 miles E. of Brandenburg.

GLANDERS, in *Veterinary Science*, a filthy disease in a horse, so called, probably, from the swelling of the submaxillary glands that accompanies it; and consisting in a corrupt

GLANDERS.

corrupt slimy matter, running from the nose, of a different colour, according to the degree of the malignity, or as the infection has been of a shorter or longer continuance; being white, yellow, green, or black, sometimes tinged with blood.

Authors ascribe it to various causes: some to infection; some to a disorder of the lungs; others to the spleen; some to the liver; and others to the brain. After it has been of so long standing, that the matter is of a blackish colour, which is usually in its last stage, they suppose it to come from the spine; and hence they call it the *mourning of the chins*.

Kernels and knots are usually felt under the caul in this disorder; and as these grow bigger and more inflamed, so the glanders increase more. The progress of the disease is extremely uncertain; as some horses will endure it for many years, without any other obvious inconvenience than a slight discharge and the enlargement of the glands under the jaws; and instances have occurred in which these symptoms have disappeared for several weeks, and returned, perhaps, with no augmented virulence. In most cases, however, the course of the malady is more rapid; the bones and cartilages of the nose are speedily eroded by the malignity of the ulcers, from which an absorption commences, and conveys the poison into the circulation, gradually and fatally contaminating the whole frame. Neither the appetite nor the condition of the glandered horse suffers materially in the early or mild stage of the complaint. When, however, it has spread its dominion over the thoracic viscera, forming ulcers in the substance of the lungs and in the wind-pipe, great pain and difficulty of respiration are experienced, the discharge becomes very considerable, the appetite is injured, and the body of the unfortunate animal exhibits a picture of extreme distress; and unless the humanity of the owner does not induce him to terminate his sufferings, the disease will, by tardy steps, afford relief to the wretched animal by dissolution.

M. La Fosse, farrier to the king of France, has taken great pains, by repeated dissections, to discover the source and cause of this disorder, and to ascertain the proper and effectual method of cure. He has distinguished seven different kind of glanders, four of which are incurable. The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, appearing sometimes in lumps and grumes; the second is a wasting humour, that usually seizes horses at the decline of a disease caused by too hard labour, and proceeds from the lungs; the third is a malignant discharge, which sometimes attends the strangles, falls upon the lungs, and is discharged at the nostrils; the fourth is when an acrimonious humour in the farcy seizes these parts: the fifth arises from a horse's taking cold; the sixth is a discharge from the strangles, which sometimes vents itself at the nostrils; the seventh, or real glanders, is that above described.

M. La Fosse, after examining, by dissection, the carcases of glandered horses, and making a strict scrutiny into the state of the viscera, assisted in his enquiry by ingenious anatomists for the space of ten years, affirms this disease to be altogether local, and that the true seat of it is in the pituitary membrane which lines the partition along the inside of the nose, the maxillary sinusses or cavities of the cheek-bones on each side of the nose, and the frontal sinusses or cavities above the orbits of the eyes; that the viscera, as the liver, lungs, &c. of glandered horses are, in general, very sound; and, therefore, that the seat of the

disorder is not in those parts, as many authors have asserted.

He found these cavities more or less filled with a viscous slimy matter: the membrane, which lines both them and the nostrils, inflamed, thickened, and corroded with fordid ulcers, which, in some cases, had eat into the bones. He observes, that, when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found disordered; and if one gland only was affected the horse discharged from one nostril only: but if both were affected, the discharge was from both. It has been observed, that the glanders in horses very much resembles a disorder in men, called *ozena*.

In this disease, if the matter sticks to the inside of the nostrils, like glue or stiff paste; if the inside of the nose is raw, and appears of a livid or leaden hue, and the matter becomes bloody, fetid, and of an ash-colour; these symptoms are very unfavourable; but when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw does not much increase, and the disorder has been of no long continuance, a speedy cure may be expected. The cure of the milder kind of glanders may first be attempted by injections and fumigations. When these latter symptoms appear, the horse should first be bled, and treated as in the common disorder of cold; and then, let an emollient injection, prepared with a decoction of linseed, marsh-mallows, elder, chamomile flowers, and honey of roses, or such like, be thrown up as far as possible with a strong syringe, and repeated three times a day: if the running is not lessened or removed in a fortnight by these means, a restraining injection may be prepared with tincture of roses, lime-water, &c. and the nostrils fumigated with the powders of frankincense, mastic, amber, and cinnabar, burnt on an iron heated for that purpose, the fumes of which may easily be conveyed through a tube into the nostrils. When the disease is inveterate, recourse must be had to the operation of trepanning, which M. La Fosse performed on three horses, two of which discharged from one nostril only, and the third from both: he trepanned the two first on that side of the head which was affected, and the other on both sides, and found that the wound and perforation filled up with good flesh in twenty-six days, and the horses suffered no inconvenience from the operation. The method of performing this operation will be understood by means of *Plate XIX. Miscellany, fig. 1*, and the following explication: B, B, are two lines representing the bounds of the cerebellum, or back part of the brain, which commences from the line D. C C is a line, where the superior part of the sinus frontalis commences, together with a view of the bottom of the sinus, terminating between the lines D and E, where appears a substance in the form of a pear, which is the os ethmoides, or sieve-like bone through which the olfactory nerves pass, communicating sensibility to the pituitary membrane. E represents the beginning of the maxillary sinus, terminating at M: the shaded space between these lines represents the great cavities. F is a bony partition, separating this sinus into two parts that have no communication: of which partitions there are sometimes two, represented by F and G. Some horses have neither of these. N shews the place of the cornets or horns; O, the redoubling; P, their middle part; Q, the lower part of them: and M, the bony pipe or canal which guards the maxillary nerve: A A is the septum narium, dividing the nose from top to bottom, and separating the two nostrils; L shews the place where the trepan should be applied, when there is reason to apprehend that the glanders is spread into the frontal sinus; E is the place where it should be applied

to cleanse the maxillary sinus, though the round spot between D and E is preferable, because one orifice in this place will serve to wash all the parts, both above and below, with one injection. H shews the place where another perforation should be made, as a drain for discharging the foul matter washed away by the injection; and this hole, kept open by a hollow leaden pipe, would, in all recent cases, be sufficient. I represents the injection thrown in by the syringe, which flows out by the orifice and the nostril K; and, during this part of the operation, the nostrils should be held close. If there should be two bones in the maxillary sinus, it is absolutely necessary to pierce through both, with a flitto or sharp-pointed tuck, as in the figure. The trepan should be directed towards the interior part of the nose, to prevent its being obstructed by the roots of the teeth. R is the trepan, S the handle which turns it, and T the saw-part to be applied to the bone. The surgeon's trephine will answer the purpose for this operation; but before the instrument is applied, a circular piece of the skin, of about the size of half a crown, should be first cut off with the membrane which covers the bone. The syringe should be large enough to contain half a pint of injection. The injection first used should be of a deterfive nature, as a decoction of birth-wort, gentian, and centaury, to a quart of which may be added two ounces of Egyptianum and tincture of myrrh; and when the discharge abates, and the matter becomes of a thick consistence and white colour, this injection may be changed for barley-water, honey of roses, and tincture of myrrh; and for completing the cure, Bates's alum-water, or a solution of colcothar, vitriol, lapis medicamentosus, and such like, in lime-water, will serve to dry up the moisture, and to restore the tone of the relaxed glands. For this purpose Dr. Bracken recommends the following mixture: Take of alum and white vitriol powdered, of each four ounces; calcine them in a crucible; when cold, powder the calx, and mix it with a gallon of lime-water and a quart of vinegar, and decant the mixture clear for use. The perforations that are made in this operation should be kept open, after the use of the injection, by fitting to the upper one a piece of cork waxed over, and a hollow leaden tent to the lower, through which there will be a constant drain of matter from the sinuses; and both may be secured by a proper bandage. The growth of the flesh should be also checked by rubbing with caustic medicines, or applying the actual cautery. The cure will be expedited, by giving every day a quart or three pints of a strong decoction of guaiacum chips, by purging at proper intervals, and putting a rowel into the horse's chest; and if these fail, mercurials may be administered with the physic, and the alterative powders with lime-water may be given and continued for some time.

The following remedy is said to have succeeded, in fifty cases out of sixty, for curing the glanders, without trepanning. Keep the horse a day or two with small quantities of choice hay, and scalded bran; then blow up his nostrils as much asstarabacca, in fine powder, as will lie on a six-pence, evening and morning, giving him for drink small lime-water, during four or five days; then boil two ounces of elecampane roots in a quart of drink, till they mix, and give it once a day during three or four days more; then boil two handfuls of the white moss that grows on oaken pales, in two quarts of milk, till one is consumed; strain it and squeeze the moss, and give the milk just warm: repeat this for four or five days. About an hour after the horse has had his drink each day, take a piece of sweet butter, about the size of an egg, and about half an ounce of brimstone finely powdered, and work them well together; then take two clean goose feathers, as long as they can be procured, and make a

hole in each of the quill ends; in which fasten two long threads; then anoint the feathers well with the mixture, and roll them in dry flour of brimstone: open the horse's nostrils, and thrust the feathers up into his head, fastening the threads to the top of his head, to prevent their dropping out: ride him an hour or two morning and evening, and let him stand half an hour after he returns to the stable before the feathers are taken out: pursue this course eight or nine days, bathing his head with camphorated spirits of wine, and afterwards confining his head over a tub of hot grains, that he may breathe the steam. A rowel may prevent a relapse.

After all that has been said, it is now generally allowed, that no effectual remedy for the glanders has yet been discovered. The operation of trepanning has never been attended with permanent success; and whatever relief has been obtained from the use of various medicines, it has been merely temporary, and the disease has been pronounced incurable. But though all attempts for curing the glanders have hitherto proved ineffectual, the inquiry should be pursued, and efforts for this purpose should be renewed till the veterinarian's ingenuity and perseverance are crowned with success. The analogy subsisting between the glanders and the venereal disease has led some practitioners to recur to the use of mercury, but the success attending it has been very partial. Professor Coleman mentions a single case which occurred at the Veterinary College, in which the glanders yielded to the treatment employed, which was that of repeated and long-continued doses of calomel, carried to the extent of salivation. This solitary case led to many trials of a similar nature, but, unhappily, without the success which was hoped for by the professor, who exerted his wonted ingenuity to improve the hint which this single instance afforded. Others have made similar efforts in this way, with only a temporary abatement of the symptoms, but without ultimate success. Some years ago, great expectations were formed, from the use of the mineral acids in the venereal disease; and trials were made with these in some cases of glanders, which were ineffectual. The late professor of the Veterinary College, M. St. Bel, made a variety of experiments for ascertaining the nature of this disease, and for investigating an effectual remedy, whilst he was professor of the veterinary school at Lyons; he has recorded the cases that fell under his notice, with his method of treatment, which was very diversified and multifarious; but he concludes with observing, "notwithstanding my failures, I think that a remedy may be found for the glanders." Many circumstances convinced M. St. Bel, that the virus of the glanders has greater activity in southern than in northern countries; and that its progress is more rapid in the mule and the ass, than in the horse; but that the former are not so subject to receive it by infection or contact as the horse is. The use of verdigris having been recommended by a professor of the veterinary art, Mr Lawson, surgeon to the Oxfordshire light dragoons, gave this medicine a trial in two cases, those of a horse and mare, beginning with one drachm daily, and gradually increasing it to one ounce. But no beneficial effect was produced. Dissection of the horse after three months' trial shewed no disease in the brain, but it was altogether confined to the septum of the nose and nostrils.

As the glanders is a disease of such virulence, known to be contagious in a high degree, and hitherto found to be incurable, it is of importance to distinguish it from other diseases to which the horse is subject. A cold, which has been sometimes mistaken for the glanders, may be easily distinguished from them. In colds, there is generally a certain

certain degree of fever, the eyes appear dull or watery, the appetite is diminished, and there is almost always a cough. If the glands of the throat should swell, they are not so closely attached to the jaw-bone as in the glanders, but feel loose and moveable under the skin; they are also generally in a state of active inflammation, feeling hot, and softer than in the glanders. In colds, both nostrils are almost always affected; in the glanders it frequently happens that the discharge is only from one. In colds, the nostrils are not ulcerated; in glanders this always happens, though at different periods of the disease. The strangles have been sometimes mistaken for the glanders; but in this disease the inflamed glands very soon suppurate and burst, by which all the other symptoms are generally removed, whilst in the glanders the glands seldom or never suppurate. In order, however, to avoid all danger, it is adviseable, as soon as a horse is perceived to have a discharge from his nose, to put him into a stable, where he can have no communication with other horses. If the glands of the throat be enlarged and inflamed, apply a large poultice to them, steam the head three or four times a day, let the horse be well clothed, and give a fever powder every day, or once in 12 hours. By these means, the disease, if it arise from a cold, will soon be removed. When considerable ulceration is perceived in the nose, with the other concomitant symptoms of the glanders, the sooner the horse is destroyed, the better.

The most effectual method of purifying stables in which glandered horses have been kept, is to remove, or carefully scrape, and afterwards scour with soap, sand, and boiling water, every thing on which the horse may have deposited any matter, and afterward to cover every part of the stable with a thick coat of lime and fire. It is a common practice with the owners of horses, when they have had any one of them seized with the glanders, to bleed and purge the rest, by way of prevention; but this method will serve rather to promote than prevent the disease, as it will considerably increase the action of the absorbent vessels, by which action the glanders are conveyed into the system.

GLANDIUM, in *Surgery*, a name sometimes given to an excrescence near the anus.

GLANDORE, in *Geography*, a harbour of the south of Ireland, in the county of Cork: it is a little to the west of Ross, and has the village of Myros at the extremity of it.

GLANDORP, **MARTINUS LOUIS**, in *Biography*, a physician, was born at Cologne in 1595. He studied first at Bremen, in Lower Saxony, whence his family originated, and afterwards returned to Cologne, where he commenced his medical pursuits; but, by the advice of his father's friends, he was soon sent to Padua, in order to reap the benefits of studying under the great masters, who at that time were so distinguished in medicine. He attached himself particularly to Fabricius and Spigelius; and he made such great progress in anatomy under the latter, that he was deemed qualified to give public demonstrations. Before returning to Germany, he received the degree of doctor in 1618. He determined to fix himself at Bremen, in which city he found every thing favourable to his views; and his success in practice gained him so much reputation, that he was elevated to the most honourable offices. He was physician to the archbishop and to the republic, when he died in 1640. He left several works, adorned with plates, which contain many important observations on anatomy. These are, 1. "Speculum Chirurgorum, in quo quid in unoquoque vulnere faciendum, quidve omittendum, praeclaris partium affectuum anatomicarum explicatione, observationibus ad unumquodque vulnus pertinentibus adjectis, conspiciunt ac pertractantur,"

Bremæ, 1619, 8vo. This was republished in 4to 1628, with these two treatises, 2. "Methodus medendi paronychia, cui accedit decas observationum:" and, 3. "Tractatus de Polypo, varium affectu gravissimo."—4. "Gazophylacium polyplisium fonticulorum et setonum reseratum," ibid. 1633, 4to—London 1633, 4to.—He made frequent use of the actual cautery in the treatment of the most common disorders. The whole of Glandorp's works were collected and printed in London, in 4to. in the year 1729, under the title of "Opera omnia, nunc simul collecta, et plurimum emendata." This collection includes also some curious tracts on Roman antiquities. Eloy. Dict. Hist.

GLANDORP, **JOHN**, a learned philologist, who flourished in the middle of the 16th century, was born at Munster. He studied under Melancthon, and became very distinguished for his critical knowledge. He was elected rector of the college at Hanover, but, upon some dispute, he quitted in 1555, and retiring to Goslar, was followed by most of his scholars. In 1560, he was made professor of history at the university of Marburg. He died in 1564. His works are "Sylva Carnanum Elegiacorum;" "Descriptio Gentis Antoniz;" "Familia Juliae Gentis;" "Dillicha Sacra et Moralia;" "Annotat. in Jul. Caesaris Comment.;" "Annotat. in Ciceronis Epist. famil.;" "Onomasticon Historie Romanae."

GLANDULA, in *Anatomy*, the same as gland.

The word is a diminutive of the Latin *glans*, acorn; and is here used on account of some external resemblance between the glands of the body and the fruit of the oak.

GLANDULA Glandulis, among *Surgeons*, is a tumor resembling a gland; soft, single, moveable, with roots, and separate from the adjacent parts.

GLANDULE, in *English*, signifies a little gland. Thus the amygdale, or almonds of ears, are by some called glandules.

GLANDULOUS, or **GLANDULAR**, something composed of glands, or that abounds with glands.

The breasts are glandulous bodies. The cortical substance of the brain is commonly reputed to be glandulous; though Ruysch, from the discoveries made by his admirable injections, holds, that there is no such thing as a gland therein.

The ancients distinguished a particular kind of flesh, which they called *caro glandulosa*, or glandulous flesh.

GLANDULOUS Body, *glandulosum corpus*, more particularly denotes the prostatica.

GLANDULOUS Roots, among *Botanists*, such tuberosc roots as are fastened together in large numbers by small fibres or threads.

GLANIS, in *Ichthyology*, a species of *silurus*, which see.

GLANOVENTA, in *Ancient Geography*, a place of Britain, in the 10th Iter of Antoninus, supposed by Horsley to be Lanchester, in the county of Durham.

GLANS, **Acorn**, in *Natural History*, a fruit contained within a smooth but hard bark, including a single seed; its hind-part being covered with a kind of cup, and the fore-part bare. See **ACORN** and **OAK**.

GLANS Marianus, a name given to a genus of shell-fish, more usually called *lalanus*, and in English the centre shell.

GLANS Trochitifera, a name given by Gesner, and some other writers, to a kind of figured fossil, found usually among the trochitæ and entrochi, and evidently appearing to have in some manner belonged to them. All the writers, who have themselves examined the places where the trochitæ are found, have mentioned these under the names of glands trochitifera, others under less determinate ones. Agricola

calls them lapides informes; and Lister, after him, rude stones, having impressions of the entrochi. See farther Philof. Transf. N^o 100.

GLANS Penis, in *Anatomy*, the rounded extremity of the organ. See GENERATION, *organs of*.

GLANSHAMMAR, in *Geography*, a town of Sweden, in the province of Nericia; seven miles N. E. of Obreo.

GLANVILL, JOSEPH, in *Biography*, was born at Plymouth in the year 1636, where he probably received the early parts of his education: but he pursued his maturer studies at Exeter college, Oxford. He took his first degree in the year 1655, and removing to Lincoln college, he graduated master of arts in 1658, and was, about the same time, appointed chaplain to Francis Rous, esq. provost of Eton college. The death of his patron induced him, after a very short time, to return to Lincoln college, where he spent his time in literary and philosophical studies, till the restoration of king Charles II. He became acquainted with the writings of Richard Baxter, and was an ardent admirer of his preaching and religious principles. He is said to have been an eager republican in politics, but, whether this be the real fact, has been much doubted. Upon the re-establishment of monarchy and episcopacy, he conformed to the national church, a circumstance that did not in the least abate the esteem which Baxter had before manifested for him. He became a zealous convert to the principles of the new philosophy, in opposition to the system of Aristotle, and published a work in their justification, entitled "The Vanity of Dogmatizing or Confidence in Opinions," &c. This piece introduced him to the acquaintance of many of the persons who afterwards formed the Royal Society. About this time Mr. Glanvill entered into orders, and was presented to the rectory of Wimbold, in the county of Essex, and in 1662 he was inducted into the vicarage of Frome-Selwood, in Somersetshire. He published in the same year, but anonymously, a discourse on the fundamental doctrine of the ancient eastern philosophers, which he endeavoured to prove was not incompatible with revealed religion. It was entitled "Lux Orientalis: or an Enquiry into the opinion of the Eastern Sages concerning the Pre-existence of Souls; being a Key to unlock the grand Mysteries of Providence in relation to Men's Sin and Misery." Upon the establishment of the Royal Society, he published his former treatise, corrected and enlarged, under the title of "Sceptis Scientifica; or confessed Ignorance in the way of Science, in an Essay on the Vanity of Dogmatizing and confident Opinion." This work was dedicated to the Royal Society, and the author was almost immediately admitted one of its members. In 1666 he published his work, entitled "Some philosophical Considerations touching the being of Witches and Witchcraft." This performance, which is still regarded as a curiosity, though very little creditable to the judgment of the author, engaged Glanvill in a controversy which lasted as long as his life. He was now presented to the rectory of Bath, in which city he fixed his residence. Here he met with many opponents, who were apt to treat him but roughly, on account of his adherence to the new philosophy, which led him to draw up a small but elegant treatise, entitled "Plus Ultra: or the Progress and Advancement of Knowledge since the Days of Aristotle. In an account of some of the most remarkable late improvements of practical useful learning, to encourage philosophical endeavours, &c." The author was violently attacked on this occasion, but he defended himself with spirit and success. His reputation was now firmly fixed, and he was frequently called upon to preach on public occasions. At a visitation of the diocese, he delivered a discourse which met with general approbation, and

which was frequently re-printed: it was a defence of reason in the affairs of religion, against infidelity, scepticism, and fanaticism of all sorts. He next attempted to shew the correspondence between religion and the new philosophy, in a discourse concerning the religious temper and tendency of the experimental philosophy which is professed by the Royal Society. "While," says one of his biographers, "he was entitling himself to the particular acknowledgments of the members of that body, by defending the reasonableness and useful tendency of their pursuits, he also contributed to their collection of instructive and entertaining papers, some observations on the mines in the Mendip hills, and on the natural history and springs of Bath, which were well received, and inserted in the Philosophical Transactions." In the year 1672, Mr. Glanvill exchanged his rectory of Frome for that of Sreat, in the same county, with the chapel of Walton annexed; and about the same time was made one of the king's chaplains. In 1676, he published his "Essays on several important Subjects in Philosophy and Religion," consisting of the principal of his former pieces, revised and improved, with a treatise, entitled "Antifanatic Theology and free Philosophy." Two years after this, his "Essay concerning Preaching" came out; it was written for the purpose of dissuading the younger clergy from that affectation of wit and fine speaking, which began to be fashionable in those times, and to recommend and enforce a plain and practical method of enforcing the moral duties of the gospel, as the true eloquence of the pulpit. The last work of this worthy divine, was entitled "The zealous and impartial Protestant, shewing some great but less heeded Dangers of Popery." Mr. Glanvill died of a fever at the early age of forty-four, and Dr. Horneck published a quarto volume of Discourses, &c. after his death, to which is prefixed an account of the author. As a preacher, Mr. Glanvill was eloquent and pathetic: in private life he was truly amiable and praise-worthy. He was author of various other tracts besides those already noticed, the titles of which are given in the Biographia Britannica. To this work the reader is referred for further particulars.

GLAREANA, in *Ornithology*, the name of a bird described by Gesner from the figure, and suspected to be no way different from the spipoletta, a kind of lark, the *ALAUDA campestris*; which see.

GLAREOLA, a species of *Tringa*; which see.

GLAREOLA, in *Ornithology*, a genus of the Grallæ order, founded on the natural family called by Brisson "Perdrix de Mer," and also Glareola. The character of this genus consists in the bill being strong, short, straight, and turned down or hooked at the tip; nostrils linear, and placed in an oblique position at the base of the bill; gape of the mouth large; feet four-toed, the toes long, slender, and connected at the base by a membrane; tail furcated, and containing twelve feathers. The number of species, according to Gmelin, are three, namely, *Austriaca*, *Senegalensis*, and *Nævia*, the first of which, however, comprises several remote varieties. Linnæus described this as a species of *hirundo*, the second kind is a *tringa* of the same author, and the third, a *gallinula* of Ray.

Species.

AUSTRIACA. Above grey-brown; collar black; chin and throat white; breast and belly reddish-grey. Gmel. *Hirundo marina*, Aldr. *Hirundo riparia*, Merg. *Pratincola*, Kram. *Gallinula erythropus minor*, Geln. *Perdrix de mer*, Buff. *Sea swallow of Aldrovandus*, Will.

The length of this bird is nine inches; the bill black, with the base red; upper wing-coverts whitish, quill and tail-

tail-feathers dusky, the outer side of the first tail-feathers white; and the legs and naked part of the thighs in general red. The species inhabits chiefly the south of Europe, and the milder parts of Asia; towards the north it becomes more sparingly diffused, and is very rarely seen so remote from the southward as Britain. It abounds most in the plains of the deserts towards the Caspian sea, in the neighbourhood of the rivers, its food consisting of aquatic insects and worms.

One of the varieties of this species is called by Brisson *Glaucola torquata*, and by Buffon, "Perdrix de mer à collier." The plumage beneath is white; the front black, with a white spot on each side, and the collar brown. Its size is rather inferior to the former, and the legs blackish instead of red. This, like the other, is a noisy restless bird, and frequents the banks of rivers, aquatic insects constituting its principal food. The eggs are oblong, and usually about seven in number in each nest.

The bird called "Perdrix de mer" by Sonnerat is another variety of this species; the lower parts of the plumage, and also the rump, are white; and the chin streaked with black, and surrounded by a black curved line. This was caught in the open sea, in the latitude of the Maldivia isles, and lived a month on flies, and bread soaked in water.

Two other varieties occur in the East Indies, on the coast of Coromandel, and are likewise described by Sonnerat; the first of these is brown, the under parts, with the rump and base of the tail white; in the second, the tail-feathers are brown, having the outer ones marked with a white band.

SENEGALENSIS. Entirely fuscous. Gmel. *Glaucola Senegalensis*, Brisson. *Tringa fusca*, Linn. *Perdrix de mer brune*, Buff. *Senegal pratincole*. Scarcely exceeds the former in size, being nine inches and a half in length, and inhabits Senegal. The same variety is found also in Siberia.

NEVIA. Brown, spotted with white; lower part of the belly and vent reddish-white, with black spots; bill and legs black. Gmel. *La perdrix de mer tchétée*, Brisson. *Gallinula melanopus*, Rothmann, Ray. *Glarol*, Buff. *Spotted pratincole*.

Size of *Glaucola austriaca*. This variety is met with in Germany.

GLARIANUS, HENRICUS, LORITUS, in *Biography*, surnamed *Glarianus*, from the town of Glaris, in Switzerland, where he was born in 1488. He rendered himself famous by his knowledge of music, and belles lettres; but he may more properly be ranked among dilettanti theorists in music, than a musician by profession; and his abilities, as a scholar and critic, have been much less disputed by the learned, than his knowledge of music, by musicians.

He studied at Cologne, Basil, and Paris; his preceptor in music was John Cochleus; and in literature, Erasmus, with whom he lived in strict friendship, and by whom he was warmly recommended. In a letter still extant, to the archbishop of Paris. He is called by Walther a philosopher, mathematician, historian, geographer, theologian, and poet; indeed, he distinguished himself in most of these characters. Gerard Vossius calls him a man of great and universal learning; and for his poetry, the emperor Maximilian I. honoured him with the laurel crown.

His famous treatise on music, is entitled $\Omega\Delta\epsilon\epsilon\alpha\text{N}\Omega\text{P}\Delta\text{O}\text{N}$, which implies twelve modes; to which number he wished to augment the ecclesiastical tones, which had never before exceeded eight, from the time of St. Gregory. Zarlino, and a few more, adopted the opinion of Glarianus, but soon relinquished it, on finding that they had made no converts. Indeed, the whole twelve modes of Glarianus contain no other

intervals than those to be found in the key of C and A natural, or in the different species of octave, in these two keys; and though his augmentation extends the currents of sounds used in the modes, it offers no new arrangement of intervals, as may be seen by his title-page, when it tells us that the authentic modes are D, E, F, G, A, C, and the plagal B, C, D, E, G; where we perceive that A, C, E, G, are repeated, by being made both authentic and plagal.

If, instead of twelve modes, Glarianus had augmented the eight to twenty-four, by assigning two to each flat-tone in the octave, he would have done real service to the music of his time; but his contemporaries were not yet ready for such an innovation, being still held too fast in the trammels of the church to dare use any other means than those which time had consecrated, and authority admitted without its pale.

His book, however, contains many curious anecdotes and compositions of the greatest musicians of his time, which were excellent studies for his countrymen and contemporaries, and, if scored, would be still very instructive and useful to young contrapuntists. Glarianus died 1563, aged 75.

GLARIS, or GLARUS, in *Geography*, a canton in Switzerland, formerly subject to the abbots of the convent of Seckingen, in Suabia, but possessing a democratical form of government, under a mayor, appointed by the abbots, but chosen by the inhabitants; till towards the latter end of the thirteenth century, the emperor Rodolph I. obtained the exclusive administration of justice; and soon afterwards his son Albert purchased the mayoralty, which had become hereditary, and reunited in his own person the whole civil and judicial authority. The government of Albert, and of his descendant the dukes of Austria, was arbitrary and oppressive; and therefore, in 1250, Schweitz, assisted by Zurich, Lucerne, Uri, and Unterwalden, expelled the Austrians from the canton of Glarus, and re-established the democracy. Glarus then entered into a perpetual alliance with its deliverers, and was received into the Helvetic confederacy, with some restrictions, which were not abolished till 1457. It was then the 6th canton, but afterwards became last in rank of the eight ancient cantons, as they were called. The people of Glarus enjoyed their liberties unmolested till 1388, when the Austrians made an irruption into the canton, and pillaged the country and massacred the inhabitants. At this time 350 troops of Glarus, assisted by 30 Switzers, resisted the whole strength of the Austrian army, and compelled them to retire. In the 16th century the reformation was introduced into this canton; but the Protestants and Catholics have been accustomed to live together on terms of mutual toleration and friendship; of late the number of Protestants has very much increased, and their industry in every branch of commerce is observed to be far superior to that of the Catholics. The government of this canton, previous to the French revolution, was entirely democratical; every person at the age of 16 had a vote in the "Landsgemeind," or general assembly, which was annually held in an open plain. This assembly ratified new laws, laid contributions, entered into alliances, declared war, and made peace. The "Landman" was the chief of the republic, and was chosen alternately from the two sects; with this difference, that the Protestant remained three years in office and the Catholic two. The other great officers of state, and the bishops, were taken also by lot from a certain number of candidates proposed by the people. The executive powers were vested in the council of regency, composed of 48 Protestants and 15 Catholics; and each set had its particular court of justice. This canton comprehends 336 square miles; and its population is estimated

estimated at 16,000 persons; its contingent to the army, under the old government, was 400 men. According to the division of Switzerland into 18 departments or cantons, in 1798, the canton of Glarus, together with the bailliages of Wallenstadt, formed the canton of Linth; but according to the constitution of the 29th of May 1801, Glarus, together with the bailliages of Sergans, Werdenberg, Gullen, Uznac, and Rappenschwell, forms the eighth canton, and deputed five representatives to the diet.

This canton is entirely enclosed by the Alps, except towards the north; and there is no entrance but through this opening, which lies between the lake of Wallenstadt and the mountains separating this canton from that of Schweitz. At this entrance, the canton reaches from the banks of the Linth to the farthest extremity of its Alps, about 30 miles; forming a valley, which becomes narrower as you advance, and is scarcely more than a musket shot in breadth at the burgh of Glarus. It afterwards opens by degrees, and, about a league from this burgh, is divided by the Freyberg mountains; at the point of this division, the two rivers, Linth and Sernft, unite. The hillocks of the Peak in Derbyshire, says Mr. Coxe, are mere mole-hills to the Alps of Glarus. These stupendous chains of rocks are absolutely perpendicular, approach one another so near, and are so high, that the sun may be said to set, even in summer, at four in the afternoon. On each side are a number of waterfalls, which excite attention. The valley terminates in an amphitheatre of mountains, and the glaciers of the canton close the view. (See LINTH.) All the houses in this canton, like those of Appenzel, are built of wood; large, solid and compact, with great pent-house roofs, that hang very low, and extend beyond the area of the foundation. The police in this democratical state is well regulated; nor does liberty often degenerate into licentiousness. Cattle, cheese, and butter constitute the principal commerce of the canton. The cattle are fed in summer upon the Alps; it is computed that 10,000 head of large cattle, and 4000 sheep, are pastured during that season upon the mountains belonging to the canton. The inhabitants also manufacture linen and muslins. Among the exports, a considerable article is slate, with which the canton abounds; the principal quarry being in the valley of Sernft, where large slates are dug up that serve for tables. These quarries once furnished Great Britain with slates for writing; but this branch of trade has been superseded by the great slate quarries in Caernarvonshire. A great part of this canton consists of mountains, rocks, inaccessible forests, and barren heaths, covered with snow; and it is subject to frequent inundations, and to the devastations occasioned by tempests and falling rocks.

GLARNISH, a mountain of Switzerland; 7 miles W.S.W. of Glarus.

GLARUS, or GLARIS, the capital of the above-described canton, situated upon the Linth. The town is large and populous; and the town-house is a handsome structure; 32 miles E. of Lucerne. N. lat. 26° 58'. E. long. 9° 3'.

GLASENDORF, a town of Bohemia, in the circle of Koniggratz; 6 miles N.N.W. of Trautenau.—ALSO, a town of Silesia, in the province of Neisse; 11 miles S.W. of Patshkau.

GLASGOW, a very populous, handsome, and regularly built city, in the county of Lanark, in Scotland; situated on the north bank of the river Clyde, which is navigable for vessels of 100 tons and upwards. In ancient times, and during the prevalence of the Roman Catholic religion, Glasgow was chiefly distinguished as an archiepiscopal see,

and was of course principally under the influence of the archbishop and his inferior clergy. Their power seems in those days to have been civil as well as ecclesiastical, for the charters of the most ancient corporate bodies are held by this tenure, the civil magistrates being only noticed as of subordinate rank and authority, and the freedom fines, and other emoluments are expressly appropriated to ecclesiastical purposes. The revenue of the diocese of Glasgow, if it may be estimated by the extent of lands subject to the payment of tithes, or (as they are called in Scotland) treads, must have been very great; for those burthens extended over almost the whole of the counties of Lanark, Renfrew, Dumbarton, Ayr, Dumfries, and Galloway, comprehending the whole south-west district of Scotland, and perhaps a moiety of the most fertile land in the whole kingdom. Of this enormous revenue, since the reformation a small part, but now of great value, has been appropriated for the support of the university of Glasgow, some part for the payment of the parochial stipends, and a great part has reverted to the freeholders or their dependants, and these are constantly fluctuating as in other parts of the kingdom. The insurrections and civil wars, which devastated Scotland subsequently to the reformation, and previous to the revolution, having divested Glasgow of all that attraction which it had acquired as the archiepiscopal and occasionally as the royal residence, it appears to have been only remarkable as the occasional scene of those sanguinary and ferocious contests for which the age was conspicuous. It fell into the hands of the regent upon the defeat and flight of the unfortunate Mary Stewart at the battle of Langside, two miles south of the city. It was long afterwards battered and taken by Cromwell's army, and it was the refuge of the defeated party, after the battle of Bothwell bridge, fought between the regent (afterwards James II.) and the Covenanters. After the revolution it seems for many years to have been a place of little importance, possessing neither a sufficient degree of wealth or refinement to render it conspicuous for elegance or luxury, nor such security or strength as to make it desirable or important as a military post. At the time of the Union with England, its whole population was estimated at only 14,000, a fact stated in the house of commons by Mr. secretary Dundas, (now lord Melville,) in one of the debates when the Irish Union was in contemplation. Subsequently to the Union, the rise of Glasgow in commercial importance, even under the successive checks of the two civil wars in 1715 and 1745, of the vastly greater commercial embarrassment, occasioned by the suspension of its colonial trade during the American contests, and all the subsequent hostilities produced by the French revolution, has been perhaps unequalled by any other place in the empire, or perhaps in the world. Its population, under the act of 1794, including its numerous suburbs, was returned at 94,000, and from the concealment which was practised from the idle fears of ignorant people, many of whom foolishly imagined that *ceusus* to be the precursor of a military conscription, that number is supposed to be at least 30,000 short of the actual amount.

Different histories of Glasgow have been published. Of these, one published many years ago by Mr. M'Ure, one of the city clerks, was much esteemed, but is now considered as obsolete. Others have subsequently been written by Mr. Gibson about 1774, and recently by Mr. Denholm, about 1796.

The limits of this article necessarily preclude the possibility of entering much into detail, nor would it be either amusing or instructive to the general reader. We shall therefore insert what remains concerning the present state of

this great commercial and manufacturing city under the following general heads.

1. *Situation and general state of the adjacent country.*—Glasgow is situated on the north bank of the river Clyde, in N. lat. 55° 52', and W. long. from the meridian of Greenwich 4° 30'. The extreme length from E. to W., including two suburbs, is nearly two miles, and its breadth from the cathedral or high church to the river about one mile. The lower part of the city is nearly level, and the rest is upon the southern declivity of a hill. Perhaps no city or town in Europe is, upon the whole, more regularly planned; for all the principal streets are either parallel or at right angles to each other. The chief streets are better paved than those of London, and generally wider; all the front buildings are of fine free-stone, which is found in great abundance in the immediate neighbourhood. The granite, or *sobiu stone*, for paving the carriage ways, is also very plentiful close by the town. The houses are very large and lofty, being more generally upon the French plan, where every floor forms a separate lodging, accessible by a common staircase, than upon the English, where one person occupies the whole premises. The more wealthy inhabitants, however, have almost universally adopted the English taste in building. In the old part of the town it is indeed much to be regretted that there are too few public streets, so that an immense number of buildings are crowded together, many of which are accessible only by narrow passages, which are very ill calculated either for free circulation of air, admission of light, or domestic cleanliness. In the modern buildings these inconveniences are avoided, and whatever inconvenience may remain, must rather be attributed to the habits or negligence of the occupants, than to want of facilities on the part of the architects.

There are many very fine public buildings in Glasgow, the most prominent of which we shall very briefly enumerate.

Churches.—The cathedral or high church is perhaps the finest specimen in Scotland of that species of architecture, generally denominated Gothic. It was founded in the year 1123, and consecrated in the presence of king David I. in 1136. This building is more similar to that of Litchfield, than to any other of the English cathedrals, but it does not appear to have ever been completely finished, and certainly until lately little care has been used for its preservation. After the reformation it is said to have narrowly escaped destruction from the misguided zeal of the people, who confounded the building itself with the religious or superstitious ceremonies which they had exploded. It now contains two churches adapted to the Presbyterian form of worship, and the choir is used as a place of interment. The burying vaults, or cemetery, were formerly occupied as another place of worship for the barony or country parish of Glasgow; but lately a new church has been erected for this purpose at the opposite extremity of the church-yard. The great spire is very lofty, and in some degree resembles that of Salisbury. The church was dedicated to St. Mungo, or Kentigern, whose burying-place in one of the vaults is still shewn.

The remaining churches possess in general little claim to architectural encomium or description. They are six in number, *viz.* the college, St. Andrew's, North Well, Iron, St. Enoch's, and St. George's.

St. Andrew's church is a handsome modern building, of Corinthian architecture, and is very similar in appearance to the church of St. Martin in the Fields, Westminster.

St. Enoch's and St. George's are also handsome modern buildings. Besides the established or parochial churches, there

are many dissenting chapels and meeting houses, some of which are very handsome and commodious.

Prison.—This is a large and very strong building, situated in the centre of the city, adjoining to the Exchange. The lower part is occupied by the council-chambers, and rooms for the magistrates and the city clerks; the middle part of the building contains the close or lock-up rooms for those imprisoned upon criminal charges; and the two upper floors are allotted for the reception of civil debtors. The roofs are lofty, the apartments airy, and the building, upon the whole, commodious; but it is in contemplation to erect a new prison, with an enclosed space round it, where the prisoners may have the benefit of fresh air and exercise, from which they are at present precluded.

Bridewell.—This is a large building which serves as a place of confinement, or penitentiary house, for persons of depraved habits convicted of petty offences. It is very well regulated, and every means of encouragement afforded for reclaiming the prisoners from their vices, and promoting habits of industry. Many, at the period of their confinement, have thus acquired and received considerable sums, besides the expence of their subsistence, which is deducted from their earnings.

Town Hospital.—for the reception of poor persons unable to maintain themselves. The expence of this establishment is defrayed by a tax or assessment on the inhabitants, and by the proceeds of the labour of those admitted, who are supplied with work suited to their respective abilities. The inmates are aged and infirm persons and destitute children: the latter are well educated, and when arrived at a proper age, the boys are apprenticed to trades and the girls sent to service. The economy of the house is superintended weekly by gentlemen who act in rotation. The whole is very well managed.

Royal Infirmary.—a very fine modern building, from a plan of Messrs. Adams'. From 90 to 120 patients are generally under cure, but the house contains accommodation for a much larger number when required. It is supported by donations, legacies, and annual subscriptions; the funds at present amount to 10,000*l.* or 12,000*l.*, besides what has been annually expended; the annual disbursement is about 1800*l.* or 2000*l.*: the direction is vested in the lord provost, the dean of guild, convenor of the trades, professors of medicine and anatomy, president of the faculty of physicians, member for the city, and eighteen directors, ten of whom are elected by the contributors, and the others by various public bodies. The directors elected by public bodies are, one by the council, one by the merchants, one by the trades, one by the university, one by the ministers of Glasgow, and three by the faculty of physicians and surgeons. The medical assistance is afforded gratuitously.

Theatre Royal.—This superb house was erected a few years ago by voluntary subscriptions, upon transferable shares of 25*l.* each. The total cost was upwards of 15,000*l.* part of which still remains as a debt upon the property, the whole annual rent being appropriated for its gradual liquidation. The direction of the property is in sixteen directors, four of whom go out annually, in rotation, but may be re-elected. It is unquestionably the largest and most magnificent provincial theatre in Britain. The managers are merely lessees, and the lease is always given for a short period, seldom exceeding two or three years.

Concert and Assembly Rooms.—These rooms are also very splendid, and, like the theatre, were erected by voluntary subscription, upon transferable shares.

University.—The buildings of the university having been erected at various times, and in very different styles, cannot

be appreciated by any precise scale of architectural taste; but the whole has certainly an air of imposing grandeur, and is very well adapted in every respect to the purposes for which it is designed. It consists of four distinct courts, which communicate with each other, and is accessible from the high street by three gate-ways. Behind is a very large garden laid out in grass and shrubbery, with very fine walks; it is divided into three parts, of which one is appropriated as a botanical garden, another is open as a place of exercise and recreation for the students, and the third, in which the astronomical observatory is situated, is generally reserved as a place of retirement, for the professors, or of amusement for their families and friends.

The university of Glasgow was founded in the year 1450, by William Turnbull, bishop of the diocese, and then consisted of a chancellor, a dean of faculty, a principal, who was also professor of theology, and three professors of philosophy.

The professions and lectures are now as follow:

A lord chancellor: an office now honorary, and held for life.
 Lord rector; also honorary—elective annually.
 Dean of faculties; chosen by the professors or regents.
 Principal; by the crown—present incumbent, Rev. Dr. Taylor.

Professors.

Divinity,	appointed by the university.
Church history,	- - crown.
Oriental languages,	- - university
Natural philosophy, or physic,	- - do.
Mathematics,	- - do.
Moral philosophy, or ethics,	- - do.
Logic,	- - do.
Greek,	- - do.
Humanity, or Latin,	- - do.
Civil law,	- - crown.
Medicine,	- - do.
Anatomy and botany,	- - do.
Practical astronomy,	- - do.

Lectures.

Materia medica,	- - university.
Chemistry,	- - do.
Midwifery,	- - do.
Natural history,	- - do.
Elocution,	- - do.
Painting and drawing,	- - do.

The funds for the support of the university are in a very flourishing and prosperous state. Independently of the emoluments derived from the students, salaries and commodious houses are allotted to every professor, and these expences are defrayed from the funds at various times granted to the university; of these, the funds or tythes of the parish of Govan, form a very prominent part. The students of the five junior classes, *viz.* natural philosophy, moral philosophy, logic, Greek and Latin, are distinguished by wearing gowns of scarlet freeze; the students of the senior classes have no particular distinction of dress. The resident members of the university claim an exemption from all civil burthens and services, and generally from the jurisdiction of the city magistracy, but acknowledge that of the sheriff of the county, and of the supreme courts of Scotland.

The internal government of the university is vested in the principal and professors, who, in their juridical capacity, assume the title of regents. Their supreme court is a general assembly of the whole faculty, who, at a remote period, assumed the power even of capital punishment. The most

severe sentence, however, which has been passed for many years, is that of expulsion, and even this has been very rarely exercised. An inferior court is the "Jurisdiction ordinaria," consisting of at least three regents, who determine offences against the general order and peace of the university, and punish by a pecuniary fine. Each professor also possesses the power of levying small fines in his own class for negligence, contumacy, or irregularity.

The number of students in the university was estimated at 500 thirty years ago, and this number is now greatly increased. The professors and students, when assembled for the election of a rector or any other general purpose, are divided into four nations, according to the places of their respective births, *viz.*

Glesian—comprehending the natives of Clydesdale, and the adjacent districts of Scotland south of the Forth.

Transforthian—the natives of Scotland, on the north of the Forth.

Rothsian—the natives of the west highlands of Scotland and of Ireland.

Loudonian—those of the eastern districts of Scotland, of England, America, and the colonies. The votes of these nations are decided by a majority, and the majority of nations decides the question. In cases of parity the decision is in the regents.

The university of Glasgow has recently received a most valuable acquisition, by the bequest of the museum of the late Dr. William Hunter, of London. For the reception of this valuable legacy, a very handsome building has been erected, where it is now arranged. The museum consists of a valuable collection of paintings, chiefly original; a very fine selection of anatomical preparations; a cabinet of medals, and a fine library. The medals are accounted of such value, that the trustees of the British museum are said to have offered 25,000*l.* for them, besides furnishing such duplicates as they possessed, and defraying the expence of an application to parliament for an act, so far to dissolve the testator's will. This liberal offer, however, was declined.

The public library of the university is also a collection of uncommon value. It consists of upwards of 6000 volumes, and many very rare and valuable manuscripts. In the faculty hall are some valuable paintings, particularly one of the "Martyrdom of St Catharine."

Among the celebrated literary characters, which have belonged to this seminary, the names of Dr. Cullen, Dr. Adam Smith, and the late professor Miller, are most recently conspicuous.

There are many other public buildings in Glasgow, of which it will be necessary to confine ourselves to very brief notices.

The *Trades-hall*—is a fine modern building from a plan of Messrs. Adams'. It is used for the general meetings of the fourteen incorporated trades, and is also occasionally occupied for concerts, balls, and other public amusements.

Merchants' Hall—is an old building, remarkable for nothing but the spire, which is a very fine one. It is used by the body to which it belongs, in the same manner as the Trades-hall.

Public Markets.—These are very commodious, and consist of square-paved courts, surrounded by the stalls where the meat is exposed to sale. No cattle are slaughtered here, and they are kept very clean and regularly inspected.

Barracks.—These are situated in a large area walled round, and consist of three very large buildings, one of which is appropriated for officers, and two for non-commisioned officers and privates. Their complement is 1072 men, but they will lodge, on emergency, 4 or 500 more.

Town-House.—A fine old building adjoining to the prison. Only one hall is retained by the body corporate. The remainder contains the Tontine hotel, which was enlarged by subscription upon lives. The coffee-room is, perhaps, the largest and finest in Europe. It is supported by annual subscription, the subscribers amounting to upwards of 1000, who pay one pound five shillings each.

Bridges.—Three of these are of stone, and a fourth was actually built in the year 1795, when the river rising rapidly, in consequence of excessive rains, it was swept away in one night when very nearly finished. The arches being very flat, and the extremities not sufficiently secured, the accident was attributed, by professional persons, to the lateral pressure. Its place has since been supplied by a very handsome wooden bridge for foot passengers. The two bridges highest upon the river are plain, but very well built and paved. The lowest, or new bridge, is very finely executed, and is esteemed one of the most complete specimens of this species of architecture in Britain.

Water-works.—The city of Glasgow, until lately, was supplied with water by pit-wells, and the water of these, although abundant in quantity, was of inferior quality both for washing and culinary purposes; as, besides other impurities, it holds in solution a considerable portion of marine acid, by which it is rendered hard and brackish. To remedy this inconvenience a public company was formed, who, at the expense of upwards of 60,000*l.*, brought water filtered from the river into every part of the city and suburbs by cast iron pipes, and from these pipes into every house, upon receiving a moderate annual payment from the proprietor or lessee. The capital necessary was raised by transferable shares of 50*l.* each. The rapidity with which these shares were bought induced others to form a separate establishment, and to raise water also from the river for the supply of the city. The first supply is drawn from the Clyde by two large steam engines, into a reservoir about two miles to the eastward of the town. From this reservoir it is filtered into another, and from thence conveyed by the pipes to a third immediately contiguous to the town. The whole lower part may be supplied from this without further forcing, but to supply the higher parts, a portion is again forced by another smaller engine to a cistern on a higher elevation, which commands every part above the former level.

The western water-work company draw their supply from the river, to cisterns situated on an eminence about one mile west of the town, where it is filtered, and conveyed by pipes, without requiring to be forced a second time. The inhabitants are left to their own free choice from which company to take their supply.

River Clyde.—The Clyde takes its rise about 60 miles to the south-east of Glasgow, in the same mountain which forms the sources of the Tweed and the Ayr. Near the county town of Lanark, about 28 miles above Glasgow, it has three remarkable falls or cataracts, much visited by strangers. From Lanark to Glasgow it passes through a fine valley, richly wooded in many places, fertile and highly cultivated. From the new bridge of Glasgow, where it becomes navigable, until it terminates in St. George's, or the Irish channel, about 80 miles distant. About thirty years ago, Mr. Goldburn, an eminent engineer, was employed by the city of Glasgow to deepen the river, from the Broomilaw or harbour, to the sea-port towns of Port Glasgow and Greenock, the former situated 21, and the latter 24 miles below the city. This he effected in a very judicious, although gradual and economical manner. The beneficial effects of his plan became soon apparent, have been, every successive year, improving, and must continue

so for many years to come. He began by constructing, on either bank, projecting dykes, or jetties, into the river, at right angles, to the banks on either side, and placed at small distances from each other along the whole course of the navigation. These jetties intercept much of the earth and gravel washed down by successive floods, and thus supply the materials for ultimate contraction, without the expense of carriage. Besides this, a number of labourers are employed every summer season to drag the bottom of the river, and lodge the stuff which is withdrawn from the bottom between the projecting jetties. By the constant repetition of this simple process a great part of the river is now contracted to less than one-half of its original breadth, and has gained above four feet of additional depth. As the tonnage dues, the greater part of which is appropriated for this purpose, now exceed 6000*l.* per annum, these operations promise to be continued on a more extended scale than ever; and it is probable that in a few years vessels of large burthen may be brought up to the city. The largest hitherto brought up are about 150 tons, the depth of the channel being about nine feet at high water. The gentleman who now directs these improvements thinks, that in a few years this depth may be increased to 14 feet by the present plan.

It was lately proposed to improve the harbour by the construction of wet docks; but a difference of opinion having arisen respecting the controul under which these improvements were to be placed, the scheme has been suspended, but it is hoped not finally relinquished. The tonnage dues are one shilling *per* ton on merchandize, eight-pence on foreign produce, and four-pence on coals, brick, and other building materials. Manure, carried upon the river for the improvement of the adjacent country, is exempted from any tax.

The country stretching along the banks of the Clyde, for a number of miles, both above and below the city, is generally fertile, and, in most places, highly cultivated, and well enclosed. The parish of Govan, situated on the south bank of the river, is, perhaps, as highly improved as any district in Britain. Besides the natural fertility of the soil, this may be accounted for by the plentiful supply of coal, lime, and manure, which are supplied at cheap rates by water-carriage. It must also be greatly promoted by the circumstance of there being many landed proprietors, whose estates, although abundantly sufficient to maintain themselves and families in comfort and affluence under their personal superintendance, are not so large as to induce them to relinquish the profits and emoluments of cultivating their own property, which, of course, derives the united benefit of their personal skill, industry, and capital, besides that emulation which a laudable spirit of rivalry excites among them to surpass each other. The higher lands, both to the north and south, are considerably inferior, both in soil and cultivation, to those in the valley. In every direction round Glasgow, coal, lime, and iron-stone are found in great plenty, and give great advantages to the agricultural and manufacturing classes of the community.

The suburbs of Glasgow, which form the chief residences of the operative tradesmen, are the following:

Govan.—A very populous village, immediately adjoining to the city on the south-east, and bordering on the *Green* of Glasgow. This village contains upwards of 20,000 inhabitants, with many manufactories, distilleries, &c. The green serves both for pasture and for the purposes of washing and bleaching. There are a commodious washing-house, and fine walks for the recreation of the inhabitants. The dues of washing and pasture form part of the city revenue. The green contains upwards of 100 acres of ground.

Bridge-town.—

Bridgeton—another suburb adjoining to the former, and similar in every respect.

Gorbals—a village on the opposite bank of the Clyde, governed by a chief magistrate, appointed by the council of Glasgow, and two resident baillies.

Anderston, Brownfield, Finnieston, and Partick.—These four villages lye to the west of Glasgow, on the north bank of the Clyde; they also are residences for operative trademen, and contain several extensive manufactories, viz. three large cotton mills, an extensive punfield, and porter brewery, at Anderston; a large and flourishing glass-work at Finnieston, and the very large flour-mills belonging to the incorporation of bakers at Glasgow, at Partick, where are also the ruins of an ancient castle, formerly belonging to the archbishop.

Municipal Government of Glasgow.

This, as formerly remarked, in ancient times, was almost exclusively vested in the archbishop and chapter. Since the reformation, it underwent various changes during the successive alterations of government in Scotland at large. The last arrangement made by royal and parliamentary authority, was early in the 18th century, under William and Mary. It has since been modified by the authority of the Scottish convention of royal boroughs, who exercise this power without dispute. As at present constituted, the government of the city is vested in the lord provost, three merchants, and two trades baillies, the dean of guild, or president of the merchants, the convenor, or president of the trades, the city treasurer, and master of the public works, twelve counsellors from the merchants, and eleven from the incorporated trades, in all 33 counsellors. To this body the regulation of all the public business belongs; the lord provost being president, with the casting or deciding vote in cases of parity. The courts of justice within the city are the following:

1. The circuit court of judicary, for the cognizance of criminal actions, which is held twice a year at Glasgow, for the counties of Lanark, Renfrew, and Dunbarton, generally before two of the lords commissioners, although any one of their number is competent. This court also decides appeals in civil causes from any of the inferior courts within the district.

2. The magistrates or town court. This court is held under the authority of the magistrates, assisted by the town clerks as legal assessors. The jurisdiction of this court extends to any amount subject to an appeal to the court of session.

3. The conscience court, for the decision of petty causes under twenty shillings, where the formality of an oath is dispensed with, or any written pleading.

4. The sitting magistrate also decides daily trifling claims under five shillings. The magistrates also exercise a criminal jurisdiction in petty crimes, and punish by imprisonment, pillory, and sometimes public whipping and banishment from the city.

5. The sheriff court, for the under-ward of Lanarkshire, is also held at Glasgow, before the sheriff substitute. His jurisdiction is equal to that of the magistrates, not only within the city, but the district. The decisions of this court are subject by appeal to the sheriff depute and to the court of session.

6. The justice of peace court also decides civil causes to a limited amount, and regulates disputes between masters and servants. The appeal from this court is to the quarter sessions, and finally to the court of sessions.

7. The small debt court is held by two or more justices, for the decision of causes under 10*l*. No professional law-

yer is heard here, and the pleadings are verbal. They review their own decisions upon appeal, provided the sum decerned for be lodged with the clerk of court.

8. The commissary court is the remnant of the bishop's court. It decides for sums under 3*l*. 6*s*. 8*d*., and also in cases of defamation. Its jurisdiction extends over all the ancient bishopric.

Police Establishment.—This establishment was constituted a few years ago under the authority of a special act of parliament. The commissioners named in the act are, the lord provost and baillies, and twenty-four commissioners elected by twenty-four wards, into which number the city is divided. The qualification of a commissioner, is the occupation of a dwelling house valued at 15*l*. or upwards of yearly rent; and of a voter, that of any house at 10*l*. or upwards. The business of this establishment is the lighting, cleaning, and guarding of the streets, and suppression of quarrels, riots, and other breaches of the public peace. For this purpose a master, or intendant of police officers, and watchmen are employed. A magistrate sits every morning at the police office to decide upon those who have been apprehended during the night. Where the charge is serious, he generally remits the cognizance of it to the town court, and punishes petty delinquencies by a small fine. The expence is defrayed by a tax on the valued rents of shops, warehouses, and dwelling houses, by fines levied in the course of the year by the sale of manure, from cleaning the streets, &c. The maximum of the tax is from 6*d*. to 1*s*. 3*d*. per pound of valued rent, but much less has been generally found sufficient. This institution has been always hitherto conducted with the most vigilant attention to economy, and is very popular even among those of the citizens, who strenuously opposed its original adoption.

Commerce and Manufactures.—The commercial importance of Glasgow only began to rise subsequently to the Union, and had attained no very important extent until the colonization of North America opened a wide field for the exportation of British commodities and the importation of American produce in return. Previous to the commencement of the American war in 1775, it had, however, engaged very extensively in the tobacco trade, for it appears that of 90,000 hhds. of tobacco imported into Britain in 1772, 49,000 hhds. were brought into the Clyde alone, and, in 1775, the importation was 57,143 hhds.

The operations of the war necessarily put a stop to this intercourse, to the great loss of the merchants engaged in it; many of whom have never been able to recover their debts. Upon the restoration of peace in 1783, the trade with America revived, and continued again in a flourishing state, until again recently suspended by the American non-intercourse act. In 1783, the registered vessels of the Clyde, were 386, and their tonnage 22,896, and in 1803, the number cleared outwards and inwards was as follows.

At Greenock inwards,			
Foreign trade	406 ships,	53,546 tons,	5183 men.
Coast and fishing	730 vessels,	35,532	3147
Outwards,			
Foreign trade	352 ships,	50,366 tons,	3673 men.
Coast and fishing	1016 vessels,	43,009	3326
At port Glasgow inwards,			
Foreign trade	113 ships,	18,722 tons,	1081 men.
Coast and fishing	182 vessels,	7,226	551
Outwards,			
Foreign trade	177 ships,	25,137 tons,	1692 men.
Coast and fishing	119 vessels,	7,202	424
Total	3095	238,790	17,077

From

From this note some idea may be formed of the extent of the trade; but many of these vessels having probably made several voyages in the course of the year, it is not to be inferred that this number of vessels actually belongs or trades to the Clyde. The articles of exportation are chiefly British manufactured goods, coals, fish, &c. and the imports European, American, and colonial produce.

The city of Glasgow had also a very considerable commercial intercourse with the eastern parts of the island, and with the northern states of Europe, until this was suspended by the events of the war. This intercourse is carried on by means of the Forth and Clyde canal, which intersects Scotland, and forms a junction between the eastern and western seas, some account of which has already been given under the article CANAL.

The manufactures of Glasgow had obtained no very great extent previous to the commencement of the American war, although they had been progressively advancing during the whole course of the eighteenth century. So far back as the reign of Charles II. indeed, some attempts had been made to introduce the manufacture of soap, refining of sugar, and some other branches, all of which proved abortive, and were discontinued. The linen manufacture was the most extensive of the various attempts made, and the most successful during the time that it lasted. It commenced about the year 1725, and continued progressively advancing until it was almost entirely superseded by the cotton towards the close of the century. The cotton manufacture, which is now unquestionably the staple trade of Glasgow, was prosecuted to very small extent until after the year 1784, but when once introduced it advanced with unprecedented rapidity. It is impossible to ascertain with any precision its actual amount either in quantity or value at any given period for want of proper data. A computation in 1791 makes the number of looms employed 15,000, and the persons who earned their subsistence by various parts of the processes of spinning, weaving, bleaching, &c. 135,000. It also estimates the total value of the goods made yearly at 1,500,000*l.* The grounds of this calculation are not stated, and little reliance can be placed on it, for the value of cotton goods has fluctuated as remarkably as the quantity has extended.

Two manufactories of earthen ware are carried on in Glasgow, but neither of them extensively. Indeed a much greater quantity of Staffordshire ware is used in the city itself than of the produce of either. Two or three rope works are also carried on, but to no great extent.

The printing of calicoes and other goods is, however, a very extensive branch of the manufacture of Glasgow and its vicinity. The most extensive of these works, are those situated upon the water of Leven, in Dumbartonshire, about 18 miles distant. The extension of the cotton trade has also greatly improved and enlarged the number of dye-works, and the manufactures of chemical preparations for the various processes of bleaching, dyeing, and printing. These works are situated in the vicinity of the city, chiefly on the banks of the river.

Of the chemical works carried on in Glasgow, some are peculiar to it.

The manufacture of Cudbear was introduced by Mr. Mackintosh so long ago as the year 1777. It is prepared from *rack-moss*, and above 2000 gallons of human urine are daily consumed in the process. The cudbear gives a dark reddish colour, and is used in the dyeing of leather, woollen stuffs, &c. The process is kept profoundly secret.

The discharging of the Turkey red dye is also peculiar to Glasgow. This process is particularly described under the article *Discharging of COLOUR*.

The manufacture of the oxy-muriate of lime, is a dry form, for the purposes of bleaching, &c. is also almost peculiar to Glasgow. Its object is to decrease the expence of bleaching by the substitution of lime for potash. This article is made to great extent by Mr. Tennent the inventor.

Iron liquor, for the use of printers, is made here by various persons, and large alum works are established in the neighbourhood. Manufactures of red and white lead are also carried on.

Miscellaneous Remarks.

It will appear that the city of Glasgow has undergone three remarkable changes. Its first state was the residence of a great archiepiscopal see, and consequently it was for many ages entirely under clerical influence and controul. Its first eminence as a commercial place arose from its favourable situation for commerce with the American and West Indian colonies, and through this traffick it made rapid advances in commercial importance during the whole course of the eighteenth century. One branch of this traffick being at least for the present suspended, it now depends chiefly on the other, and upon its manufactures for support. From the facilities of acquiring a good education, the inhabitants of Glasgow have generally added a considerable taste for literary attainment even to their commercial habits, and this style prevails, perhaps, in a degree superior to any other commercial place in Britain. The system of education is, however, rapidly adapting itself to the modern pursuits of the inhabitants, and more pains are now taken to qualify the rising generation for eminence in the counting-house than the closet. However desirable a thorough knowledge of the principles of commercial economy, and the details of business may be in a commercial community, it is still to be hoped, that all the benefits arising from intellectual attainment will not be deemed altogether nugatory, and consequently neglected. In every situation of life, they are sources of rational and innocent amusement, and, in the vicissitudes to which commercial enterprise is peculiarly exposed, may often prove of real benefit and utility to the possessor.

The city of Glasgow returns a member to the British parliament, conjunctly with the neighbouring burghs of Ruthglen, Renfrew, and Dumbarton.

GLASGOW, *Port*, situated on the river Clyde, about 22 miles below the city, is a handsome small town, and was projected by the magistrates of Glasgow at the request of the merchants as a harbour for their ships and vessels. It is said that the first plan was to improve the harbour of Dumbarton for this purpose, but Dumbarton being a royal borough, the consent of its magistrates became necessary, and that when made, it was rejected by that body, who preferred the full enjoyment of their chartered privileges to the idea of sinking into the mere sea-port of Glasgow, however much their wealth, revenue, population, and general prosperity might be benefitted by such an union. If this were the case, it is one among the numberless instances where comfort and prosperity have been sacrificed to a mere empty title. The harbour of port Glasgow is good but shallow. The disadvantage of the bank, noticed in the article GREENOCK, is also much against it as a haven. At port Glasgow there is a custom-house, where the general customs of the Clyde are collected. There is here also a fine graving, or dry dock, built by the merchants of Glasgow long before that of Greenock was executed, and this circumstance alone brought many ships up to this port which now come no farther than Greenock. The situation of port Glasgow is more pleasant than that of Greenock, the country more level, and better adapted for cultivation. In other respects it is certainly
lets

els calculated for the general purposes of maritime traffick than its rival, and therefore there is little probability of its extension. Indeed the shipping belonging to Glasgow is certainly on the decrease, the foreign merchants finding it more for their advantage to freight or charter vessels for any purpose than to build or buy vessels of their own, which both consume or sink a considerable portion of their capital, and may, from the many casualties and fluctuations to which commerce in this eventful age is exposed, prove rather burthens than advantages, while the mere ship-owner, if deprived of a freight or charter-party at one port, may with greater facility seek it at another, than the person with whom freight is only a secondary and inferior consideration.

Port Glasgow is governed by magistrates, appointed by the council of Glasgow, and some resident magistrates. Its exports and imports have been already given and compared with those of Greenock under the article GLASGOW, which indeed furnishes by far the greater part of the freight to and from both ports.

There are no manufactures here of any extent, excepting those which are to be found at almost all sea-port towns, *viz.* ship building and rope spinning. Both of these are carried on to a very considerable extent. A work was erected some years ago for refining of sugar, and also a small cotton-mill, but neither have ever been prosecuted to any great extent.

A plan has been formed, and its execution is now begun, which in time may produce a great effect, both on this town and Greenock. This plan has for its object the formation of a more direct communication between Glasgow and the west sea, than the present circuitous navigation of the Clyde, by means of a navigable canal to be carried from Glasgow to Ardrossan, near Irvine, which is about thirty miles farther down the river than the present seaports. This canal was projected under the sanction and patronage of the present earl of Eglintoun, (lord Ardrassan of Great Britain,) a part of whose estates lie in that neighbourhood. Its objects are two-fold. First, to facilitate the maritime intercourse of Glasgow and Paisley with the New World, by a more direct channel and better harbour. Second, to improve the agricultural and internal state of Renfrewshire, and the northern district of Ayrshire, by affording means for the cheap conveyance of coal, lime, manure, and other heavy articles by means of the canal. Ardrossan is situated not more than thirty miles from Glasgow, by the line of the projected canal, and therefore the carriage of goods will not be more expensive or tedious than by the Clyde, for the canal being free from the constant interruptions arising from the operation of wind and tide upon the river, the time of arrival and departure may be depended upon at all seasons and in all weathers. A considerable sum has already been subscribed for the canal, and also for the harbour, and from the well-known energy and activity of his lordship's general character, there is no reason to doubt that every exertion for its speedy completion will be used.

It is natural to expect that every opposition will be given by those whose local interests will suffer by the success of this undertaking, and these comprehend many wealthy and powerful classes; but whilst some oppose, others will find it their interest to promote it, and the competition must be ultimately advantageous to the general body, however it may terminate as to those more immediately interested.

The other part of the plan is the formation of an excellent and secure harbour at Ardrossan, capable of receiving ships of large burthen, and this also is begun. The subscriptions for the two undertakings are conducted separately. The coal here is in some places reckoned dangerous during the

prevalence of strong gales from the north-west, when vessels are making the land; but it is said that the bay of Lamash, in Arran, will afford a safe and easy shelter within a few hours sail, when this may prove to be the case. The surveys, plans, and estimates for the canal and harbour of Ardrossan were made under the superintendance of Mr. Telford. It must be perfectly evident that this canal will in all events produce much benefit as it passes through the most populous and flourishing manufacturing district in Renfrewshire.

GLASGOW, a new county of America, in Newbern district, North Carolina, taken from Dobbs's county: bounded N. by Edgecomb, S. by Lenoir, E. by Pitt, and W. by Wayne — Also, a town of New York, on the E. coast of lake Cayuga; eight miles S. of Cayuga.

GLASS, in the general acceptation of this term among *Chemists*, denotes any substance or mixture, earthy, saline, or metallic, which is reduced by igneous fusion to the shape of a hard, brittle, uniform mass, which breaks with a conchoidal fracture, passing into splintery, and with a high degree of lustre. Most glasses of this kind are also transparent. See VITRIFICATION.

GLASS, *Vitrum*, in a more restricted sense, and as the term is commonly used in the *arts* and *manufactures*, signifies that transparent, solid, brittle, facitious substance, produced by the vitrification of siliceous earth with various salts and metallic oxyds, which is applicable to innumerable purposes of ornament and comfort, as well as of scientific investigation and research.

As to the antiquity of the term *glafs*, Tacitus (Germ. c. 45.) and Pliny (l. xxxvii. c. 3.) inform us, that amber was called among the ancient Gauls or Germans by the name of *glesum* or *gleffum*; and from the similarity which glass bore to amber with respect to transparency and brightness, it acquired a name, which was, in all probability, originally the same. The word *glesum* denoted, without doubt, a shining or transparent substance, as *gl. isfen* expresses at present in the German language to shine; and our English word to *glissen* is derived from it, and has nearly the same signification. Ducange says that some critics were of opinion, that the word *glesum* itself implied glass rather than amber. The ancient Greeks, as it has been observed, applied the same term (*μαργαρι*) both to glass and amber. The herb with which the Britons painted their bodies had also the name of *glaslum*, perhaps from the shining appearance it might give to their skins, or possibly because its ashes might be used in the making of glass. The Latins called the same plant by the name of *vitrum*, the word they used to signify glass. (Cæsar. Bell. Gall. l. v.)

We find frequent mention of this plant in ancient writers, particularly Cæsar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with *glaslum*, *guadam*, *virum*, &c. *i. e.* with the blue colour procured from this plant. And hence, as some have supposed, the facitious matter we are speaking of, came to be called glass, as having always somewhat of this blueness in it.

Merret (Not. in Art. N. r. de Art. Vitrar.) gives us the following characters or properties of glass, by which it is distinguished from all other bodies. *viz.* 1. That it is an artificial concrete of salt and sand, or stones. 2. Fusible by a strong fire. 3. When fused, tenacious and coherent. 4. It does not waste or consume in the fire. 5. When melted, it cleaves to iron. 6. Ductile, when red-hot, and fashioned into any form, but not malleable; and capable of being blown into a hollowness, which no mineral is. (See DUCTILITY of Glass.) 7. Frangible when thin, without annealing. 8. Friable when cold. 9. Always diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Dissoluble by cold and moisture. 12. Only capable of being graven, or cut with a diamond

diamond or other hard stones, and emery. 13. Receives any colour or dye, both externally and internally. 14. Not dissolvable by aquafortis, aqua-regia, or mercury. 15. Neither acid juices, nor any other matter, extract either colour, taste, or any other quality, from it. 16. It admits of polishing. 17. Neither loses of weight nor substance, by the longest and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open glass, filled with water in the summer-time, will gather drops of water on the outside; just so far as the water on the inside reaches; and a man's breath blown upon it will manifestly moisten it. 22. Little glass balls, filled with water, mercury, and other liquor, and thrown into the fire, as also drops of green glass broken, fly asunder, with a loud noise. 23. Neither wine, beer, nor any other liquor, will make it misty, nor change its colour, nor rust it. 24. It may be cemented as stones and metals. 25. A drinking-glass, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower, as the glass is more or less full; and this makes the liquor frisk and leap. See ARMONICA. For the electrical properties of glass, see ELECTRIC, &c.

GLASS, *origin and history of.* De Neri will have glass as ancient as Job; for that writer, chap. xxviii. ver. 17. speaking of wisdom, says, "gold and glass cannot equal it."

This, we are to observe, is the reading of the Septuagint, Vulgate Latin, St. Jerom, Pineda, &c. for in the English version, instead of glass, we read *crystal*; and the same is done in the Chaldee, Arias Montanus, and the king of Spain's edition. In other versions, &c. it is read *stone*; in others *beryl*: in the Italian, Spanish, French, High and Low Dutch, &c. *diamond*; in others, *carbuncle*; and in the Targum, *looking-glass*.

In effect, the original word is *z chubith*, (יְרִיבִית) which is derived from the root *zacac*, to purify, cleanse, shine, be white, transparent: and the same word (Exod. xxx. 34.) is applied to frankincense; and rendered in the Septuagint *pellucid*. Hence the reason of so many different renderings; for the word signifying *beautiful* and *transparent*, in the general, the translators were at liberty to apply it to whatever was valuable and transparent.

Herodotus (l. iii.) is, according to Dr. Falconer (Manchester Memoirs, vol. ii.), the most ancient writer (B. C. 440) who used the word *υαλας*, which is generally understood to signify glass. But he evidently does not mean artificial glass, nor crystal, but, most probably, somewhat of the talcky kind, or lapis specularis, which might readily be framed in such a manner, as to form a convenient transparent case, such as the ancient historian has described. Aristophanes (B. C. 400) seems to be the next writer who mentions glass: that poet, in his comedy called the Clouds, scene I. act. 2. uses the word *hyalus*, υαλας, which is now ordinarily rendered glass. He there introduces Strepsiades teaching Socrates a new way to pay old debts, *viz.* "by placing a fair transparent stone, fold by the druggists, from which the fire is struck, between the sun and the writing, and so melting away the letters thereof." This stone Socrates calls υαλας, which the Scholiast on Aristophanes derives from *εμ*, to rain, from the likeness it bears to ice, which is rain, or water congealed; though, it must be owned, the word υαλας is ambiguous, and signifies *crystal* as well as *glass*: and Gorraeus observes, that the ancients had a kind of yellow amber, transparent as glass, called by some υαλας.

Aristotle (B. C. 340) has two problems upon glass: the first, Why we see through it? The second, Why it is not malleable? If these problems be Aristotle's, which the learn-

ed doubt very much, this would properly be the earliest testimony in favour of the antiquity of glass. Theophrastus (B. C. 303) seems to have been well acquainted with glass; for he describes it as having been made of the sand of the river Belus, which was called *εσλα*, to which he adds, that the commonest kinds are made with copper. The celebrated sphere of Archimedes (B. C. 200), if it be truly described, is a remarkable instance of the perfection to which the art of making glass had been brought at that early period.

Lucian mentions large drinking glasses; and Plutarch, in his Symposiacion, says, that the fire of tamarisk wood is the fittest for making of glass.

Among the Latin writers, Lucretius is the first that takes notice of glass; "Nisi recta foramina tranant, qualia sunt vitri;" lib. vi. v. 3. Dr. Merret, however, adds, that glass could not be unknown to the ancients, but that it must needs be as ancient as pottery itself, or the art of making bricks; for scarcely can a kiln of bricks be burnt, or a batch of pottery-ware be made, but some of the bricks and ware will be at least superficially turned to glass.

Hence, Ferrant. Imperatus, lib. xxv. cap. 7. "Glass, like the common kind, is found under ground, in places where great fires have been. Other glasses are found in round clods, like fire-stone, some brittle, others firm, &c. This fossil glass is wrought by the Americans, and used instead of iron. And no doubt but vitrifications were more common in the ancient bricks than they are in ours; as they tempered their earth two years together, and burnt them better.

Virgil (B. C. 39) compares the clearness of the water of the Pucine lake to glass. *Æneid*, v. 759. Horace (B. C. 36) is more express, and mentions glass in terms that shew its clearness and brightness to have been brought to great perfection. *Carm. iii. Od. 2. Od. 13*. In the time of Strabo, (A. D. 27) the manufacture of glass was undoubtedly well understood, and had become a considerable article. Seneca (A. D. 65) was not only well acquainted with glass as a substance, but also understood its magnifying powers when formed into a convex shape. *Quæst. Natur. lib. iii. vi.*

Pliny (A. D. 77) relates the manner of the discovery of glass. It was first made of sand, according to that author, (Nat. Hist. l. xxxvi. c. 66, &c.) found in the river Belus, a small river of Galilee, running from the foot of mount Carmel, out of the lake Cendevia. The part of the shore where the sand was dug did not exceed 500 paces in extent, and had been used many ages before for the same purpose. The report of its discovery was, that a merchant ship, laden with nitre, or fossil alkali, being driven upon the coast, and the crew going ashore for provisions, and dressing their victuals upon the shore, made use of some pieces of fossil alkali to support their kettles. By these means a vitrification of the sand beneath the fire was produced, which afforded a hint for the manufacture. In process of time the calc of iron, in form of the magnetical stone, came to be used along with the fossil alkali, from an idea of its not only containing iron, but glass, in a liquid form. Clear pebbles, shells, and fossil sand, were also in many places employed for the same purpose. It is said, that in India pieces of native crystal were used for that purpose; and on that account the Indian glass was preferred to any other. Pliny adds, that light and dry woods were used for the melting of glass; to which they added copper from the island of Cyprus, and the fossil alkali, especially that which is brought from the East Indies. The furnaces are kept burning without intermission, that the copper may be melted with the glass, and out of this compound are irradiated masses of a coarse blackish colour. These lumps or masses are

again melted, and tinged of the colour required. Some of these pieces are brought to the shape required by blowing with the breath; some are ground on a lathe, and others are embossed in the same manner as silver. Sidon was formerly famous for these manufactures, as specula or looking-glasses were first invented there; "siquidem etiam specula excogitaverat." Such is the ancient method of making glass, described by Pliny. In his time, it was made with sand found at the mouth of the river Vulturnus, upon the shore, for six miles between Cumæ and the Lucrine bay. This sand was very fine, and was ground to powder with a ball or sphere and a mill. It was then mixed with three parts of the fossil alkali, either by weight or measure; and being fused, was conveyed in a liquid state into other furnaces, where it was formed into a mass, called "ammonitrum," (or sand combined with the fossil alkali,) which mass was melted, and became then pure glass, and a mass of white vitrified matter. The same method of making it prevailed in Spain and Gaul. Glass was likewise made to imitate the lapis Obsidianus, a substance found by a person of the name of Obsidius, in Egypt and Ethiopia. This substance was of a very black colour, yet obscurely transparent, and often placed among specula in the walls of rooms, to reflect the shadow of objects. It was also used for the same purpose as gems (probably for engraving upon) and even for statues. Pliny mentions, that he saw solid statues of the emperor Augustus made of this material; and the same emperor dedicated four elephants made of the same substance in the temple of Concord. It seems to have been used from great antiquity; but in the time of Pliny the artificial imitation of it by glass was used instead of the native material; and he intimates that the black colour was produced by some colouring ingredient. The Romans had likewise an opaque red kind of glass, used for plates and dishes for the table, called "hematiton," one of various colours, called "myrrhinum," a white, a clear red, a blue, and indeed most other colours. Pliny observes, that no substance was more manageable in receiving colours, or being formed into shape, than glass. The perfectly clear glass, which bore the greatest resemblance to crystal, was, however, most valued. Nero gave for two cups, with two handles to each, and of no extraordinary size, 6000 sesteritia, or nearly 50,000*l.* sterling. The inferior kinds were not uncommon, as Pliny informs us, that the use of glass cups had nearly superseded those of gold and silver. We shall here add, that Pliny knew the power of a hollow glass globe, filled with water, in concentrating the rays of light, so as to produce flame in any combustible substance upon which the focus fell; and he also mentions, that some surgeons in his time made use of it as a caustic for ulcers (*l.* xxxvii. c. 2.). He was likewise acquainted with the comparative hardness of gems and glass, as he observes, that the lapis Obsidianus would not scratch the true gems; and he also mentions (*l.* xxxvii. c. 13.), the counterfeiting of the latter, in his time, as a very lucrative art, and brought to great perfection. He also says, that glass might be cut or engraven upon by means of diamonds, which art is evidenced by the antique gems so frequently found. (See GEM.) Josephus, (*l.* ii. c. 10.) mentions the sand of the river Belus, in Galilee, as fit for making glass.

The first time we hear of glass made among the Romans was in the reign of Tiberius, when Pliny relates that an artist had his house demolished for making glass malleable, or rather flexible; though Petronius Arbitrator, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention. In the time of Martial, (*A.D.* 84) glass was not only brought to great perfection,

and in common use for drinking vessels, but was employed (as it seems) for bottles in which wine was kept, and likewise for pots to hold flowers. (*Epig.* i. l. ii. 22. 40. l. iv. 86.) Galen (*A.D.* 143) frequently mentions glass in several parts of his works, and seems to have been well acquainted with the method of making it. Apuleius (*A.D.* 161) mentions the manufacture of glass cups, in his time, as highly wrought and carved in various ways, and of great value. Alexander Aphrodisiensis (*A.D.* 214) a Greek writer, and a commentator on Aristotle, has several remarks on glass respecting both its brittleness, especially on change of temperature, and its transparency.

The manufacturers of glass formed a company at Rome, and had a street assigned them, in the first region of the city, near the Porta Capena. A tax was laid upon them by Alexander Severus (*A.D.* 220) which subsisted in the time of Aurelian, and probably long after.

Mr. Nixon, in his observations on a plate of glass found at Herculaneum, which was destroyed *A. D.* 80, on which occasion Pliny lost his life, offers several probable conjectures as to the uses to which such plates might be applied.

Such plates, he supposes, might serve for *specula*, or looking-glasses; for Pliny, in speaking of Sidon, adds, "siquidem etiam specula excogitaverat;" the reflection of images from these ancient specula being effected by befinearing them behind, or tinging them through with some dark colour. (See MIRROR.) Another use in which they might be employed, was for adorning the walls of their apartments by way of wainscot, to which Pliny is supposed to refer by his *vitrea camere* (*lib.* xxxvii. cap. 25. § 64.). Mr. Nixon farther conjectures, that these glass plates might be used for windows, as well as the laminæ of lapis specularis and phengites, which were improvements in luxury mentioned by Seneca, and introduced in his time, *Ep.* xc. However, there is no positive authority relating to the usage of glass windows earlier than the close of the third century: "Manifestius est," says Lactantius, "mentem esse, per oculos ea quæ sunt opposita, transpiciat, quasi per fenestras lucente vitro aut speculari lapide obductas." *De Opificio Dei*, cap. 5. See *Phil. Transf.* vol. i. art. 80. p. 601. vol. lii. art. 23. p. 123.

St. Jerome (*A. D.* 422) speaks of windows formed of glass, melted and cast into thin plates, as being used in his time. Paulus Silentiarius, a poet and historian of the 6th century (about *A. D.* 534), speaks of the brightness of the sun's rays, passing through the eastern windows of the church of St. Sophia, at Constantinople, which windows were covered with glass. Gregory of Tours (*A. D.* 571) laments the devastations frequently committed on the windows of the churches by the ravages of war. Johannes Philoponus, who lived about the year 630, or, as some say, a century earlier, not only speaks of glass, but of the panes being fastened in with plaster, much in the same way as at present.

If the opinion of Pennant, suggested under the article *ANGUINUM ovum*, be well founded, we have reason to believe, that, long before the conquest of Britain by the Romans, the art of manufacturing glass into such ornaments as beads and amulets was known among the Druids; and if the art was thus applied, it is not improbable to suppose, that it was employed for more important and useful purposes, as in the manufacture of glass vessels. Nor is it likely that the Britons derived this art from the Romans, who preferred silver and gold to glass for the composition of their drinking vessels. Besides, the glass that was commonly used by the Romans was of an inferior quality, and appears from some remains of it discovered at their stations

and

and houses to have consisted of a thick, sometimes white, but mostly blue-green, metal.

According to venerable Bede, artificers skilled in making glass were brought over into England, in the year 674, by abbot Benedict, who were employed in glazing the church and monastery of Weremouth. According to others, they were first brought over by Wilfrid, or Wigfrid, bishop of Worcester, about the same time, or, as others think, at a later period, A. D. 726. Till this time the art of making glass, or at least of applying it to this purpose, was unknown in Britain: though glass windows did not begin to be used before the year 1180: till this period they were very scarce in private houses, and considered as a kind of luxury, and as marks of great magnificence. Italy had them first, next France, from whence they came into England.

Leo Ostiensis (A. D. 760) speaks of the windows in his time being made with glass-plates fixed in lead, and fastened together with iron. Anastasius, an historian of Rome, who was librarian to the pope, mentions, that in the pontificate of Leo III. who became pope about the year 800, painted glass in windows was in use. The statutes of the church of Traguier, in Lower Britany, about the year 1156, speak of the windows of churches and chapels being ornamented with arms and military ensigns, painted upon the glass in them. A charter of Richard II. of England, quoted by Rymer, (A. D. 1386), contains a paragraph in which is mentioned glass, together with the manufacture of it for windows.

Venice, for many years, excelled all Europe in the fineness of its glasses; and in the thirteenth century, the Venetians were the only people who had the secret of making crystal looking-glasses, and which they performed by blowing, much in the same manner as a considerable quantity of the common mirror-glass is now manufactured. The great glass-works were at Muran, or Murano, a village near the city, which furnished all Europe with the finest and largest glasses.

The glass manufacture was first begun in England in 1557: the finer sort was made in the place called Crutched Friars, in London; the fine flint glass, little inferior to that of Venice, was first made in the Savoy-house, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with sea-coal or pit-coal, instead of wood, and a monopoly was granted to Sir Robert Mansell, who was allowed to import the fine Venetian flint glasses for drinking, the art of making which was not brought to perfection before the reign of William III. But the first glass plates, for looking-glasses and coach windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine glass into England, by means of Venetian artists, with amazing success. So that within a century past, the French and English have not only come up to, but even surpassed, the Venetians, and we are now no longer supplied from abroad.

The French made a considerable improvement in the art of glass, by the invention of a method to cast very large plates, till then unknown, and scarce practised yet by any but themselves and the English. That court applied itself with a laudable industry to cultivate and improve the glass manufacture. A company of glass-men was established by letters patent; and it was provided by an act, not only that the working in glass should not derogate any thing from nobility, but even that none but nobles should be allowed to work therein.

It was in the year 1665, under the ministry of the great Colbert, that a company for "blown-mirror-glass" was

first established near Cherbourg, in Normandy, on the plan of the Venetian manufacture; but the beautiful art of casting glass was invented in France about the year 1688; by a person of the name of Abraham Thevart; and a company was soon established for this branch of manufacture, which was first carried on at Paris, and soon after removed to St. Gobin, where it still exists in full activity, and undiminished reputation. An extensive manufactory of this kind was first established among us near Preston in Lancashire, about the year 1773, by a respectable body of proprietors, who were incorporated by an act of parliament. They struggled for a considerable time with difficulties; but being nobly relieved and encouraged by government, they have succeeded in producing plates rivalling, if not surpassing in size, quality, or brilliancy, the most celebrated continental manufactures. This company furnishes, at Albion Place, London, plates of various dimensions, from 12 to 144 inches in length, and from 10 to 72 inches in breadth; and also convex and concave mirrors, from 12 to 36 inches in diameter.

GLASS, Ingredients of. The materials used in the composition are some saline substance and some sort of siliceous earth.

1. The first ingredient we shall specify is flint or stone. The best is that which will melt, and which is white and transparent. It is this that gives consistence and firmness to the glass. This is found principally in Italy, being a sort of stony substance called *tarso*: the next is *puoceli*, or *cuogola*, a sort of pebbles found at the bottoms of rivers, and gathered for the Venetian manufacture out of the river Po, which are said not to be inferior in whiteness to alabaster.

Indeed, nothing makes finer and clearer glass than common flint, distinguished for this use by its clear transparent, black colour; this, before it is used, must be heated red-hot, and then immediately quenched in cold water. The heat whitens it, and the water causes it to split in every direction, and facilitates the grinding of it. The charge of preparing this deters the glass-men from using it. The rounded fragments of quartz, found in the beds of rivers among mountains, are sometimes used in foreign countries, being first heated and ground to powder. Indeed, the preparation necessary for stone, in general, is to calcine, powder, and searce it.

Ant. Neri observes, that all white transparent stones, which will not burn to lime, are fit to make glass; and that all stones which will strike fire with steel, are capable of being employed in making of glass. But this latter rule, Dr. Merret observes, does not hold universally. Where proper stone cannot be had, sand is used; and it is now almost the only kind of substance employed in the British manufactures of glass. The best for this purpose is that which is white, small, and shining: examined by the microscope, it appears to be small fragments of rock crystal. For green glass, that which is of a soft texture, and more gritty; it is to be well washed, which is all the preparation it needs. Our glass-houses are furnished with white sand for their crystal glasses from Lynn in Norfolk, and Maidstone in Kent, and from the western extremity of the Isle of Wight; and with the coarser, for green glass, from Woolwich.

2. The second ingredient in the manufacture of glass is an alkali, which is either soda, or pot-ash. It is always used at first in the state of carbonate, though the carbonic acid flies off in the process. For the method of preparing each, see CARBONAT. These alkalies are used in different degrees of purity according to the required quality of the glass. The finest sort of glass requires the best purification, purified by solution and evaporation, to dryness; but for inferior glasses coarser alkalies, such as barilla.

wood-ashes, and kelp, are employed. The ashes of fern will also yield a salt, which will make excellent glass; and, moreover, the ashes of the pods and stalks of beans, as also those of coleworts, bramble bush, millet-stalks, rushes, cyperuses, and many other plants, may be used for the like purpose, and after the same manner.

There are other fluxes used for different kinds of glass, and for various purposes. Lime, in the form of chalk, is employed in the manufacture of glass; but this must be used only in small proportions; for an excess would act powerfully on the sides of the glass-pots, in consequence of the escape of the carbonic acid from the chalk during the fusion, and, besides, it would render the glass opaque and milky in cooling, however clear it might be when hot. It is known by experience, that to 100 parts of siliceous matter the requisite quantity of alkali, no more than about six or seven parts of quick-lime, or chalk, can be added, without affecting the clearness of the glass. Borax is another very valuable flux; but its high price restricts the use of it to the finest kinds of glass, and to those which are required to be free from specks and bubbles. A very small quantity of borax will correct any deficiency of strength in the alkali.

Of the oxides of lead, litharge and minium are found to be of singular use in the manufacture of glass. Litharge is a powerful flux, and imparts to glass the valuable qualities of greater density and greater power of refracting the rays of light, and of bearing sudden changes from heat to cold, without being so liable to crack, and also greater tenacity when red-hot, so that it is more easily wrought. A considerable quantity of this oxide is contained in the finer glasses; such as the London flint glass, and that which is used for the table, for lustres, for artificial gems, and for most optical purposes. Glass, however, that contains much lead, is extremely soft; and liable to be injured by hard bodies that come into contact with it; and it is also very fusible. It is also liable to be corroded by very acrid liquors. Besides, the use of lead renders it difficult so to unite the siliceous matter and alkali, that a piece of glass shall be throughout of uniform density. Another ingredient occasionally used in glass is the black oxide of manganese, called "glass-soap," from its use in clearing the glass from any accidental foulness of colour, and more especially from the green tinge, owing to the presence of iron. Scheele and Bergman in their respective "Essays," have illustrated many curious circumstances that attend the use of manganese in glasses, which are particularly detailed in Aikin's Dictionary. The manganese should be chosen of a deep colour, and free from specks, of a metalline appearance, or a lighter cast; and it requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganese in destroying the colours of glass is accounted for by M. Montamy, in his "Traité des Couleurs pour la Peinture en Email," in the following manner; the manganese destroys the green, olive, and blue colours of glass, by adding to them a purple tinge, and by the mixture producing a blackish brown colour; and as blackness is caused merely by an absorption of the rays of light, the blackish tinge given to the glass by the mixture of colours, prevents the reflection of so many rays, and thus renders the glass less coloured than before. But the black produced by this substance suggests an obvious reason for using it very sparingly in those compositions of glass, which are required to be very transparent.

This purple colour may be corrected by charcoal, or in the glass-house, by thrusting a billet of wood down into the melted glass, which becomes charred by the intense heat, and

causes the purple hue to vanish, with a slight effervescence of the glass, and escape of numerous small air-bubbles. On the other hand, if a small quantity of nitre is added to glass containing manganese, the purple colour is restored, or, if present, the discolouring effect of the charcoal is prevented, till the nitre becomes alkalinized by the heat, and mixes with the other ingredients of the crucible. For the explanation of these phenomena, it is observed, that the oxide of manganese gives the purple colour only so long as it remains in its higher state of oxygenation; but when in contact with charcoal, the latter partially deoxygenates it, carbonic acid gas is formed, the cause of the bubbles observed on this occasion, and the colour is now lost. Nitre, on the other hand, is known to give out oxygen largely as soon as red-hot; and hence the manganese immediately retakes from this source the oxygen of which the charcoal had deprived it, and resumes its colouring power. The other substances which take away the colour from glass, tinged red with manganese, are all the salts with the basis of sulphuric acid, such as gypsum, sulphate of soda, &c. and also sulphur itself; likewise the oxides of tin and iron, and of some other metals. Nevertheless these substances have this power only when in contact with charcoal. The tinging power of manganese is perfectly destroyed by the addition of arsenic in any form. Thus, a mixture of oxide of cobalt and oxide of manganese, in the colouring state, is of a dark purple; but on the addition of any arseniate, or of white arsenic, the manganese is made inactive, and the proper cobalt-blue alone appears. Hence we perceive the necessity, when the red colour of manganese is wanted, to avoid any thing arsenical; and nitre is also generally added to keep the manganese always at the proper state for imparting its colour. The oxide of manganese is a very powerful flux for all earthy matters; and this, as well as lead, gives a great density to glass. The white oxide of arsenic is another powerful and cheap flux in the making of glass; but it should be very moderately used; for it takes a longer time to mix intimately with glass, and to allow it to be perfectly clear, than any other of the additions commonly employed. For want of this the glass has a milky hue, which increases with age; and when the arsenic is in excess, the glass becomes gradually soft, and is decomposed. Besides, glass of this kind is unsafe to be used in the form of drinking vessels.

Nitre is also used, in small quantities, in the manufacture of glass, and is designed to answer particular purposes, some of which we have already specified. It not only serves to destroy the strong tinge of yellow which is found in glass, prepared with lead as a flux; but in saline glass, it is requisite, in a smaller proportion, to render it sufficiently transparent, as in the case of looking-glasses, and other kinds of plates. For an account of Mr. Dollond's excellent contrivance for destroying the colours in the object-glasses of telescopes, &c. see **ABERRATION**.

With regard to the several fluxes above enumerated, we may observe, in general, that the more calx of lead, or other metallic earth, enters into the composition of any glass, so much the more fusible, soft, coloured, and dense this glass is, and reciprocally.

The colours given to glass by calces of lead are shades of yellow: on the other hand, glasses that contain only saline fluxes partake of the properties of salts; they are less heavy, less dense, harder, whiter, more brilliant, and more brittle than the former; and glasses, containing both saline and metallic fluxes, do also partake of the properties of both these substances. Glasses too saline are easily susceptible of alteration by the action of air and water; especially those in which alkalies prevail; and these are also liable to be injured

by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish, and become opaque when exposed to air. By attending to these properties of different fluxes, phlogistic or saline, the artist may know how to adjust the proportions of these to sand, or powdered flints, for the various kinds of glass.

GLASS, proportion of ingredients in. Different kinds of glass require different proportions; nor have these been precisely ascertained. We shall here, and in subsequent articles, state several of the most usual and approved mixtures that have been proposed. When siliceous is melted with twice its weight, or more, of dry carbonated alkali, either potash or soda, the result is a very soft deliquescent vitreous mass, always more or less opaque, strongly alkaline to the taste, and which, on exposure to moist air, or more speedily in water, totally dissolves into a clear liquor, which is a solution of siliceous in alkali. When the same alkali is equal to the siliceous in weight, or does not much exceed it, the glass is now transparent, but it is still soluble in water. It is not till the alkali is diminished to about one-half of the weight of the siliceous, that the glass becomes perfectly hard and insoluble in any corrosive liquors, (the fluoric acid excepted,) and, in short, acquires the character of a perfect glass. This proportion, therefore, of two parts of sand to one of alkali, is usually the datum on which the doses of the alkalies actually used are regulated. Thus, if common wood ashes (of which the alkaline part is reckoned at no more than 10 per cent.) are employed, 100lbs. of these would require no more than about 20lbs. of sand. If the best Spanish barilla, containing from 45 to 50 per cent. of carbonate of soda, be used, an equal weight of sand may be added; but if purified pearl-ash be taken, it will melt down perfectly twice its own weight of sand. But glasses composed merely of pure alkali and sand, require a very strong fire for their fusion, and are hard, harsh, and difficult to break: they are therefore never used alone. As one half the weight of the sand is reckoned an abundant allowance of alkali, it follows of course that when litharge, arsenic, borax, or any other fluxes are employed, the quantity of alkali will be proportionally diminished. The following proportions are extracted from Macquer's Chemical Dictionary. If a glass be required that is dense, fusible, and not saline, one part and a half of red lead or litharge may be mixed with one part of sand, and fused together: if equal parts of sand and of calx of lead be employed, a glass somewhat less dense and harder will be produced: if a glass be required of very little density, only saline fluxes must be employed. A glass of this kind may be composed of six parts of salt of tartar, or of potash, or of purified soda, mixed with eight parts of sand or of flints; or of four parts of any of the above-mentioned alkalies, mixed with two parts of nitre or of borax, and eight parts of vitrifiable earth. When a crystal glass is required, which shall be of an intermediate quality betwixt the metallic and saline glasses, it may be made from a mixture of one part of the above mentioned salts, one part of calx of lead, and two parts of sand or other vitrifiable earth. By varying the proportion of these ingredients, many different kinds of glasses may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionable to its vitrifying power.

GLASS, instruments for manufacturing. These are subservient to two different purposes; *viz.* the levigation and mixture of the ingredients, and the fusion or vitrification of them. To the former class belong horse or hand-mills, mortars and pestles, flat stones and mullars, and searces or sieves. The other sort of utensils are furnaces, with the

proper iron work, pots for containing the composition when put into the fire, and iron instruments for shifting the matter out of one into the other, in case of accidents; and for taking out small portions, in order to judge of the progress of the vitrification, and the qualities of the glass, &c. See the following articles. See also **GLASS-house**, **FURNACE**, and **GLASS-pots**.

GLASS, fusion of. When the ingredients are selected and duly proportioned, they are first calcined for a longer or shorter time, before they are put into the glass-pots. This operation is called "fritting," and is performed either in small furnaces adjoining to the proper glass-furnace, and heated by the same fuel after its chief force has been spent upon the glass-pots, or else in small furnaces or ovens constructed for this purpose. The uses of fritting are, to expel all moisture from the ingredients, by which the glass-pots would be endangered; to discharge part of the carbonic acid from the alkalies and chalk and thus to moderate the swelling in the glass-pots, and especially to cause an adhesion, or commencement of chemical union, between the alkali and siliceous, and metallic oxyds. This operation should be performed gradually, and carried to the point of semi-vitrification, in which the materials strongly adhere, and begin to become pasty, but are still opaque and not homogeneous. This operation serves also to destroy any carbonaceous matter. When the ingredients are sufficiently fritted, they are thrown with clean iron shovels through the side-opening of the furnace into the glass-pots, the fire having been previously raised to its greatest intensity, to prevent the furnace from being chilled and to save time. The pots are charged by two or three successive portions, the preceding one being thoroughly melted down before another portion is thrown in. When filled, the side-opening is closed up with wet clay, excepting a small hole for examining the work, which closure is pulled down when the glass is well refined and about to be worked off. As soon as the frit begins to feel the action of the fire in the glass-pots, which is immediately raised to its greatest pitch, it sinks down into a soft pasty state, increasing in tenacity till the fusion is complete. However, it is still opaque, from the rising of a white porous scum, known by the name of "sandiver," or "glass-gall." This substance appears to be a confused mass, consisting of all those salts contained in common alkalies, which readily melt at somewhat less than a glass-melting heat, and are either naturally soluble in a considerable degree, or have little, if any, affinity for siliceous, and not uniting in the composition of glass, but being lighter, rise to the top. Another heterogeneous substance, called "sandiver," is sometimes found at the bottom of the pots. This is quite different from the other, and seems to consist of a vitrified mass of arsenic and other impurities. But the scum, or proper "glass-gall," is almost entirely saline. When laded out and cooled, it forms a crumbly mass, sometimes white, at other times brown and fouled, and strongly saline, but not uniform in its composition, being sometimes merely salt, often very bitter, probably as common salt or sulphat of potash predominates. It is so volatile in a strong fire, that it is constantly dispersing from the surface of the glass in a dense vapour, which is first thick and black, afterwards whiter, and which corrodes the top of the crucible in its passage. With long continued fusion it would entirely escape in this state, if it were not scummed off with long ladles, and sold to metal refiners as a powerful flux. Abundance of this glass-gall is attended with one of the greatest inconveniences to the maker of glass, as it requires a considerable continuance of strong

strong heat to dissipate the whole of it, or otherwise the glass would be full of bubbles, unfound, and having a cloudy gelatinous appearance. It is observed, that glass from potash is more likely to suffer from glass-gall than the soda-glass is, because the potash glasses are harder, and do not run so thin as the other, and the glass-gall from them does not so easily dissipate in the fire.

During this process samples for examination are drawn out of the pots with an iron rod; and the glass gradually becomes more and more flexible, dense, and less brittle, and at last the glass-gall is entirely dissipated. Whilst the heat is continued, the glass which was full of specks and bubbles is refined, and becomes beautifully clear, transparent, and colourless; and this process, which goes on from the cessation of the vapour of the glass-gall and its entire removal to the time when the glass is altogether clear and free from bubbles, is called the "refining." After this the glass is complete; but being too thin for working, it is cooled, by stopping the draught of fire round the pot which contains it, and in cooling it thickens to a fit state for being wrought. For glass that is cast into plates, less cooling is necessary, as it is required to flow very thin and hot. On an average it takes about 48 hours for the fine flint glasses, from the time when the pots are first filled till the glass is ready for working, in which state it is of a very full red colour, and possesses a singular kind of confidence and tenacity. It is just soft enough to yield with ease to any external impression, even to the force of the breath urged pretty strongly in the centre of the glowing mass, and may be bent and shaped in every possible way; and such is its tenacity, that it extends uniformly without any cracks or fissures; but when stretched out to the utmost, it forms a solid string, the diameter of which is constantly decreasing till it separates from the mass in a thin capillary thread. It stiffens as it cools, and becomes perfectly brittle and also transparent. As melted glass adheres very feebly to polished metal, it is very easily wrought with bright iron tools.

GLASS, working or blowing round.—Every kind of glass, plate-glass excepted, is formed from a hollow globe that has been produced by blowing. For this purpose the operator takes his blowing-iron, which is a hollow tube, about four or five feet long, and dipping it in the melting-pot, turns it about there till the metal adheres to the iron like some glutinous or clammy juice; he then holds it near the ground, so that the mass is extended by its own weight, and blows strongly into the tube. With his breath thus penetrating into the centre of the red-hot mass, he enlarges it into an uniform hollow globe of the requisite thickness and bulk, keeping the force of his breath upon it for a few seconds till it stiffens by cooling, and thus preventing its sinking by the compression of the denser external air. This globe, adhering by a neck to the iron rod, is formed by the dexterity of the workman, and by a variety of ingenious manœuvres into all the common utensils. As a specimen of his art, we may instance a common tumbler. The hollow globe already mentioned is taken off the iron rod by the following simple process: An assistant dips the end of a short solid iron rod into the glass-pot, and, bringing out at its extremity some of the melted glass, thrusts it immediately against the hollow of the globe at the part directly opposite to the neck, to which it firmly unites, and thus the globe is cemented by the melted glass to the second rod. The workman then wets a small piece of iron with his mouth, and lays it on the neck of the globe, which is extremely hot, and this, in a second or two, cracks it round; so that with a slight pull it comes off and detaches the hollow rod, leaving the globe open at the neck, and transferred to the second rod at the opposite

side. The open globe is again softened by holding it a few seconds over the mouth of the glass-pot, and is cut away from the open end to the form of a cup by iron shears. The operator, when employed in fashioning the globe, usually sits upon a kind of arm-chair, with its arms sloping forwards and covered with a flat smooth iron-plate; and by laying the iron rod straight before him, resting on both the arms of his seat, and twirling it backwards and forwards, the hot glass at the end is made to revolve like clay on a potter's lathe, and thus is opened, widened, or compressed at pleasure by any simple iron instrument that is pressed against it. The globular cup is thus extended easily into a cylinder, or made into the shape of a barrel, if this form be required, and is smoothed up at the edges. In order to separate it from the iron-rod, it is wetted as before at the point of attachment, and the tumbler drops off complete. This last operation leaves that burr or roughness, with sharp fragments, which is seen at the bottom of all glass-vessels, unless it be taken off by polishing. The next operation is that of cooling the vessel very gradually, called "annealing." See *Annealing of GLASS*.

GLASS, different kinds of. The manufactured glass now in use may be divided into three general kinds; white transparent glass, coloured glass, and common green or bottle-glass. Of the first kind, there is a great variety; as the flint glass, as it is called with us, and the German crystal glass, which are applied to the same uses; the glass for plates for mirrors or looking-glasses; the glass for windows and other lights; and the glass for phials and small vessels. And these again differ in the substances employed as fluxes in forming them, as well as in the coarseness or fineness of such as are used for their body. The flint and crystal, mirror, and best window glass, not only require such purity in their fluxes, as may render it practicable to free the glass perfectly from all colour; but for the same reason likewise, either the white Lynn sand, calcined flints, or white pebbles, should be used. The others do not demand the same nicety in the choice of the materials; though the second kind of window glass, and the best kind of phial, will not be so clear as they ought, if either too brown sand, or impure salts, be suffered to enter into their composition.

Of coloured glass there is a great variety of sorts, differing in their colour, or other properties, according to the occasions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artists by whom they are manufactured.

GLASS, Crystal. Foreigners use this term for our flint glass, and for making it they give the following directions: Take of the whitest tarso, pounded small, and seared as fine as flour, two hundred pounds; of the salt of polverine, a hundred and thirty pounds: mix them together, and put them into the furnace, called the *calcar*, first heating it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake, that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which, being now sufficiently calcined, is called frit. From the *calcar* put the frit in a dry place, and cover it up from the dust for three or four months.

Now, to make the glass, or crystal: Take of this crystal frit, called also *bollito*; set it in pots in the furnace, adding to it a due quantity of manganese: when the two are fused, cast the flux into fair water, to clear it of the salt, called *sandiver*; which would otherwise make the crystal obscure and cloudy. This lotion must be repeated again and again, as often as needful, till the crystal be fully purged; or, this scum may be taken off by means of proper ladles. Then set

it to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet greenish, add more manganese, at discretion, by little and little at a time, taking care not to overdose it, because the manganese inclines it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown, or formed into vessels at pleasure.

GLASS, *Flint*, as it is called in our country, is of the same general kind with that which in other places is called crystal glass. It has this name from being originally made with calcined flints, before the use of the white sand was understood; and retains the name though no flints are now used in the composition of it. This flint glass differs from the other, in having lead for its flux, and white sand for its body; whereas the fluxes used for the crystal glass are salts or arsenic, and the body consists of calcined flints, or white river pebbles, tarso, or such stones. This glass, on account of the quantity of litharge, which enters into its composition, is the heaviest, the most brilliant, the softest and most easy to work, and also the most expensive. It is that fine glass, of which the common and most valuable articles of white glass in domestic or ornamental use are manufactured; and besides, many optical instruments are made of this substance. To the white sand and lead a proper proportion of nitre is added, for the purposes specified in a former part of this general article, and also a small quantity of manganese, and in some works they use a proportionable quantity of arsenic to aid the fluxing ingredients. The most perfect kind of flint glass may be made by fusing with a very strong fire a hundred and twenty pounds of the white sand, fifty pounds of red lead, forty pounds of the best pearl-ashes, twenty pounds of nitre, and five ounces of manganese.

From others we have the following composition for glass of this kind, said to be of the best quality, *viz.* 120 parts of fine clear white sand, 40 of pearl-ashes well purified, 35 of litharge or minium, 13 of nitre, and a small quantity of black oxyd of manganese.

The following composition for a fine crystal glass is given by Løysel; 100 pounds of white sand, 80 to 85 of red oxyd of lead, 35 to 40 of pearl-ash, 2 to 3 of nitre, and one ounce of manganese. The specific gravity of this glass, and of the common London flint-glass, is about 3.2.

Another composition of flint glass, which is said to come nearer to the kind now made, is the following: a hundred and twenty pounds of sand, fifty-four pounds of the best pearl-ashes, thirty-six pounds of red lead, twelve pounds of nitre, and six ounces of manganese. To either of these a pound or two of arsenic may be added, to increase the flux of the composition. A cheaper composition of flint glass may be made with a hundred and twenty pounds of white sand, thirty-five pounds of the best pearl-ashes, forty-pounds of red-lead, thirteen pounds of nitre, six pounds of arsenic, and four ounces of manganese; or, instead of the arsenic, may be substituted fifteen pounds of common salt; but this will be more brittle than the other. The cheapest composition for the worst kind of flint-glass, consists of a hundred and twenty pounds of white sand, thirty pounds of red-lead, twenty pounds of the best pearl-ashes, ten pounds of nitre, fifteen pounds of common salt, and six pounds of arsenic. The best German crystal glass is made of a hundred and twenty pounds of calcined flints, or white sand, seventy pounds of the best pearl-ashes, ten pounds of salt-petre, half a pound of arsenic, and five ounces of manganese. And a cheaper composition is formed of a hundred and twenty pounds of calcined flints, or white sand, forty-six pounds of pearl-ashes, seven pounds of nitre, six pounds of arsenic, and five ounces of manganese.

A glass, much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of fine sand; reduce both to a subtile powder, and melt them together in a large close crucible set in a wind-furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass, capable of cutting common glass like a diamond. This experiment, duly varied, may lead to several useful improvements in the arts of glass, enamels, and factitious gems, and shews an expeditious method of making glass, without any fixed alkali, which has been generally thought an essential ingredient in glass; and it is not yet known whether calcined crystal, or other substances, being added to this salt instead of sand, it might not make a glass approaching to the nature of a diamond. Shaw's Lectures, p. 426.

GLASS, *Crown*, is the best sort of window-glass, and differs from the flint-glass in containing no lead, nor any metallic oxyd, except manganese, and sometimes oxyd of cobalt, in minute doses, not as a flux, but for correcting the natural colour. This glass is much harder and harsher to the touch than the flint-glass; but when well made it is a very beautiful article. It is compounded of sand, alkali, either potash or soda, the vegetable ashes that contain the alkali, and generally a small portion of lime. A small dose of arsenic is often added to facilitate the fusion. Zaffre, or the oxyd of cobalt, with ground flint, is often used to correct the dingy yellow of the inferior sort of crown-glass, and by adding the blue, natural to glass coloured with this oxyd, to convert the whole into a soft light green. One ounce of zaffre is sufficient for 1000lbs. But when the sand, alkali, and lime are very fine, and no other ingredients are used, no zaffre nor corrective of bad colour is required. A very fine glass of this kind may be made by 200 parts of pretty good soda, 300 of fine sand, 33 of lime, and from 250 to 300 of the ground fragments of glass. We had formerly in London two kinds of crown glass, distinguished by the places where they were wrought; *viz.* 1. *Ratcliff crown glass*, which is the best and clearest, and was first made at the Bear-garden, on the Bank-side, Southwark, but since at Ratcliff: of this there are twenty-four tables to the case, the tables being of a circular form, about three feet six inches in diameter.

2. *Lambeth crown glass*, which is of a darker colour than the former, and more inclining to green. The following composition has been recommended for the best window or crown glass, *viz.* white sand, sixty pounds; of purified pearl-ashes, thirty pounds; of salt-petre, fifteen pounds; of borax, one pound; and of arsenic, half a pound. If the glass should prove yellow, manganese must be added. A cheaper composition for window glass consists of sixty pounds of white sand, twenty-five pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of nitre, two pounds of arsenic, and one ounce and a half of manganese. The common, or green window glass, is composed of sixty pounds of white sand, thirty pounds of unpurified pearl-ashes, ten pounds of common salt, two pounds of arsenic, and two ounces of manganese. But a cheaper composition for this purpose, consists of a hundred and twenty pounds of the cheapest white sand, thirty pounds of unpurified pearl-ashes, sixty pounds of wood-ashes well burnt and sifted, twenty pounds of common salt, and five pounds of arsenic.

The manufacture of the common window glass, though made by blowing, is conducted differently from that of the flint glass articles; as it is the object to produce a large, flat, very thin plate of glass, which is afterwards cut by the glazier's

glazier's diamond into the requisite shape. Without minutely detailing the several gradations of the process, it may be here mentioned, that the workman takes a very large mass of melted glass on his hollow iron rod, and by rolling it on an iron plate and swinging it backwards and forwards, causes it to lengthen, by its own weight, into a cylinder, which is made hollow and brought to the required thinness, by blowing with a fan of breath, which persons accustomed to the business know how to command. The hollow cylinder is then opened by holding it to the fire, which, by expanding the air confined within it, (the hole of the iron rod being stopped,) bursts it at the weakest part, and when still soft, it is ripped up through its whole length by iron shears, opened out into a flat plate, and finished by annealing as usual.

The large crown glass of Messrs. Hammond and Smith is superior in quality as well as in size to that of any other manufacture. The usual diameter of the tables in other manufactures may be taken at 47 or 48 inches, with an occasional variation in a table of one or two inches: and the largest square which can be cut from these measures about 24 inches by 20, and in some circumstances one inch wider or longer. Whereas the glass of Messrs. Hammond and Smith is 60 inches in diameter, and will admit of being cut into squares of about 33 inches by 23 inches; and a little more or less. This glass is almost free from those specks, wreaths, &c. which discolour other glass, and distort the objects seen through it. It now supplies the place of German sheet glass for prints, large sashes, and exportation to those foreign markets where that glass was formerly in use.

GLASS, *French*, as also called *Normandy glass*, and formerly *Lorraine glass*, because it was made in those provinces: though it has since been made wholly in the nine glass works; five of which were in the forest of Lyons, four in the country of Eu; the last at Beaumont, near Rouen. It is of a thinner kind than our crown glass; and, when laid on a piece of white paper, appears of a dirtyish-green colour. There are but twenty-five tables of this to the case.

GLASS, *German*, is of two kinds, the *white* and the *green*: the first is of a whitish colour, but is subject to those small curved streaks, observed in our Newcastle glass, though free from the spots and blemishes thereof. The green, besides its colour, is liable to the same streaks as the white; but both of them are straighter, and less warped, than our Newcastle glass.

GLASS, *Dutch*, is not much unlike our Newcastle glass, either in colour or price. It is frequently much warped, like that, and the tables are but small.

GLASS, *Newcastle*, is that most used in England. It is of an ash-colour, and much subject to specks, streaks, and other blemishes; and, besides, is frequently warped. Leybourn says, there are forty-five tables to the case, each containing five superficial feet: some say there are but thirty-five tables, and six feet in each table.

GLASS, *Phial*, is a kind of glass betwixt the flint glass and the common bottle, or green glass. The best kind may be prepared with a hundred and twenty pounds of white sand, fifty pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of arsenic, and five ounces of manganese. The composition for green or common phial glass, consists of a hundred and twenty pounds of the cheapest white sand, eighty pounds of wood ashes, well burnt and sifted, twenty pounds of pearl-ashes, fifteen pounds of common salt, and one pound of arsenic.

GLASS, *common green bottle*, is made almost entirely of sand, lime, and sometimes clay, alkaline ashes of any kind,

as cheapness or convenience direct, and more especially of kelp in this country, of barilla, varec, and the other varieties of soda in France, and of wood ashes in many parts of Germany, and the like. To these ingredients is sometimes added the earth remaining from saline ashes, after the alkali and salts have been extracted by lixiviation, and in England flags from the iron furnaces. Bottle-glass is a very hard well-vitrified glass, which resists the corrosive action of all liquids much better than flint glass. It is used, not only for wine-bottles, but for very large retorts, subliming vessels, and other articles of the chemical apparatus; and it has for this purpose the advantage of bearing as much as a pretty full red heat without melting or sinking down into a shapeless lump, as the lead-glasses would do. The following composition is given by Loyal as a good and cheap material for bottle-glass; viz. 100 parts of common sand, 30 of varec (a kind of coarse kelp made on the western coasts of France), 160 of the lixiviated earth of ashes, 30 of fresh wood-ash, or any other kind of ash, 80 of brick-clay, and any quantity, generally about 100, of broken glass. This composition yields no glass-gall. This kind of glass is formed of sand of any kind, fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the scoræ or clinkers of forges. When the softest sand is used, two hundred pounds of wood-ashes will suffice for a hundred pounds of sand, which are to be ground and mixed together. The composition with the clinkers consists of a hundred and seventy pounds of wood-ashes, a hundred pounds of sand, and fifty pounds of clinkers, or scoræ, which are to be ground and mixed together. If the clinkers cannot be ground, they must be broke into small pieces, and mixed with the other matter without any grinding.

A good bottle-glass, but nearly black and opaque, has been made in France of the decomposed pulverulent basaltic earth found in the vallies of all basaltic countries. In France it abounds in the Vivarais, in Languedoc and Auvergne. The first glass of this kind appears to have been made in 1780 by a M. Ducros at the suggestion of Chaptal, who simply melted some of this basalt without addition in a glass-pot, and formed of it two very light, black, or rather deep yellow, shining, perfect bottles. In subsequent trials by another artist, a mixture of equal parts of basalt and sand was employed, as preferable to the basalt alone; but notwithstanding a considerable demand for bottles of this material, the manufacture was abandoned for want of uniformity in the ingredients, which made them often fail. The colour of this glass was of a green-olive.

The green colour, transmitted by bottle-glass, when in its perfect state, is owing to the iron contained both in the vegetable ashes and in the sea-sand, which enter into its composition. This glass affords an instance of a semi-pellucid substance, which exhibits a blue colour by incident light, and a yellow or orange colour by that which is transmitted. See Delaval on the cause of the permanent colour of opaque bodies.

GLASS, *Plate*, is the most perfect and beautiful glass, of which all the kinds of mirrors and looking-glasses are composed. The materials of which this kind of glass is made are much the same as those of other works of glass, viz. an alkali salt, and sand.

To prepare the salt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine.

Pearl-ashes, properly purified, will furnish the alkali salt requisite for this purpose; but it will be necessary to add borax, or common salt, in order to facilitate the fusion, and prevent the glass from stiffening in that degree of heat, in which

which it is to be wrought into plates. For purifying the pearl-ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, always kept clean from rust. Let the solution be removed into a clean tub, and remain there twenty-four hours, or longer. Having decanted the clear part of the fluid from the dregs or sediment, put it again in the iron pot, and evaporate the water till the salts are left perfectly dry. Preserve them in stone jars, well secured from air and moisture.

Pearl-ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent glass, by pulverizing three pounds of the best pearl-ashes, with six ounces of salt-petre, in a glass or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red-hot, throw in the rest gradually; and when the whole is red-hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the salts be entirely melted; let it then stand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow; the nitre having burnt all the phlogistic matter that remained in the pearl-ashes, after their former calcination.

As to the sand, it is to be sifted and washed, till such time as the water come off very clear; and when it is well dried again, they mix it with the salt, passing the mixture through another sieve. This done, they lay them in the annealing furnace for about two hours; in which time the matter becomes very light and white; in this state they are called *frit*, or *fritta*; and are to be laid up in a dry clean place, to give them time to incorporate. They lie here for at least a year.

When they would employ this frit, they lay it for some hours in the furnace, adding to some the fragments or shards of old and ill made glasses; taking care first to calcine the shards by heating them red-hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added manganese, to promote the fusion and purification.

The best composition for looking-glass plates is said to consist of sixty pounds of white sand cleansed, twenty-five pounds of purified pearl-ashes, fifteen pounds of salt-petre, and seven pounds of borax. If a yellow tinge should affect the glass, a small proportion of manganese, mixed with an equal quantity of arsenic, should be added. An ounce of the manganese may be first tried; and if this proves insufficient, the quantity should be increased.

A cheaper composition for looking-glass plate consists of sixty pounds of the white sand, twenty pounds of pearl-ashes, ten pounds of common salt, seven pounds of nitre, two pounds of arsenic, and one pound of borax.

The materials of the finest plate glass, such as that of French manufacture, are white sand, soda, and lime, to which are added manganese and zaffre, or any other oxyd of cobalt for particular colouring purposes. The sand is of the finest and whitest kind, which should be previously passed through a wire sieve, moderately close, into water, in which it should be well stirred about and washed. The sharpest grained sand is preferred, and it is found that grains of moderate size melt with the alkali sooner, than the very fine dust or the larger fragments. The alkali is always soda, which is preferable to potash, as glasses made with soda are found to be softer and to flow thinner when hot, and yet to be equally durable when cold. Besides, the

neutral salts with the basis of soda which constitute the glass-gall in this instance, such as the muriat and sulphat of soda, appear to be dissipated more readily by the fire than the corresponding salts of potash. The soda that is used is considerably pure, or such as is separated from the rough ashes of barilla, and other soda plants by lixiviation. Lime adds to the fusibility of the other materials, supplying the use of litharge in the flint-glass; but excess of it would impair the colour and solidity of the glass. About 1-15th of the whole is as much as can properly be used; but some reduce the quantity to 1-24th. The decolouring substances are azure, or cobalt blue, and manganese. Besides these, there is always a great quantity of the fragments of glass, collected from the waste of the manufacture, which are made friable by quenching in water when hot, and used in this state together with the fresh materials. As to the quantities and proportions of the ingredients, much latitude is allowed. The following are said to produce a very fine glass; viz. 300lbs. of sand; 200lbs. of soda; 30lbs. of lime; 32 ounces of manganese; three ounces of azure; and 300lbs. of fragments of glass. In the manufactory at St. Gobin secrecy is observed with regard to the materials; but it is affirmed, and with much probability, that borax is used in small quantity.

Of the materials now enumerated the sand, soda, lime, and manganese are first mixed together with more care than for ordinary glass, and they are fritted in small furnaces built for this purpose, the heat being gradually raised to a full red-white, and then kept with frequent stirring till the materials undergo no farther change, nor yield any kind of vapour. The azure and glass fragments being already in a state of perfect vitrification are not added till just at the end of the process, which lasts about six hours. When the materials are thus prepared, they are fit for plate-glass, to be formed either by blowing or casting. The largest glasses at St. Gobin are run; the middle-sized and small ones are blown.

Blowing looking-glass plates. The work-houses, furnace, &c. used in the making of this kind of plate-glass, are the same, except that they are smaller, and that the carquoisses are disposed in a large covered gallery, over-against the furnace, as those in the following article, to which the reader is referred.

After the materials are vitrified by the heat of the fire, and the glass is sufficiently refined, the workman dips in his blowing iron, six feet long, and two inches in diameter, sharpened at the end, which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a small ball of matter, which sticks to the end of the tube by constantly turning it. He then blows into the tube, that the air may swell the annexed ball: and carrying it over a bucket of water, which is placed on a support at the height of about four feet, he sprinkles the end of the tube to which the matter adheres, with water, still turning it, that by this cooling, the matter may coalesce with the tube, and be fit for sustaining a greater weight. He dips the tube again into the same pot, and proceeds as before; and dipping it in the pot a third time, he takes it out, loaded with matter, in the shape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the same time blowing into the tube, and, with the assistance of a labourer, giving it a balancing motion, he causes the matter to lengthen; which, by repeating this operation several times, assumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The assistant is then placed on a stool three feet and a half high; and on this stool there are two

upright pieces of timber, with a cross beam of the same, for supporting the glass and tube, which are kept in an oblique position by the assistant, that the master workman may with a puncheon set in a wooden handle, and with a mallet make a hole in the mass: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the glass is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron tressel, placed on the support of the aperture of the furnace. Having exposed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad shears, extremely sharp at the end, widens the glass, by insinuating the shears into the hole made with the puncheon, whilst the assistant, mounted on the stool, turns it round, till, at last, the opening is so large as to make a perfect cylinder at bottom. When this is done, the workman lays his glass upon the tressel, at the mouth of the furnace, to heat it: he then gives it to his assistant on the stool, and with large shears cuts the mass of matter up to half its height. There is at the mouth of the furnace an iron tool, called *pontil*, which is now heating, that it may unite and coalesce with the glass just cut, and perform the office which the tube did before it was separated from the glass. This *pontil* is a piece of iron, six feet long, and in the form of a cane or tube, having at the end of it a small iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the glass, about four inches thick. This red-hot *pontil* is presented to the diameter of the glass, which coalesces immediately with the matter round the *pontil*, so as to support the glass for the following operation. When this is done, they separate the tube from the glass, by striking a few blows with a chissel upon the end of the tube, which has been cooled; so that the glass breaks directly, and makes this separation, the tube being discharged of the glass now adhering to the *pontil*. They next present to the furnace the *pontil* of the glass, laying it on the tressel to heat, and redden the end of that glass, that the workman may open it with his shears, as he has already opened one end of it, to complete the cylinder; the assistant holding it on his stool as before. For the last time, they put the *pontil* on the tressel, that the glass may become red-hot, and the workman cuts it quite open with his shears, right over-against the fore-mentioned cut; this he does as before, taking care that both cuts are in the same line. In the mean time, the man who looks after the carquailles, comes to receive the glass upon an iron shovel, two feet and a half long without the handle, and two feet wide, with a small border of an inch and a half to the right and left, and towards the handle of the shovel. Upon this the glass is laid, flattening it a little with a small stick a foot and a half long, so that the cut of the glass is turned upwards. They separate the glass from the *pontil*, by striking a few gentle blows between the two with a chissel. The glass is then removed to the mouth of the hot carquaille, where it becomes red-hot gradually; the workman, with an iron tool, six feet long, and widened at the end in form of a club at cards, four inches long, and two inches wide on each side, very flat, and not half an inch thick, gradually lifts up the cut part of the glass, to unfold it out of its form of a flattened cylinder, and render it smooth, by turning it down upon the hearth of the carquaille. The tool, already described, being insinuated within the cylinder, performs this operation, by being pushed hard against all the parts of the glass. When the glass is thus made quite smooth, it is pushed to the bottom of the carquaille, or annealing furnace, with a small iron raker, and ranged there with a little iron hook. When

the carquaille is full, it is stopped and cemented as in the case of run glasses, and the glass remains there for a fortnight to be annealed; after which time, they are taken out to be polished. A workman can make but one glass in an hour, and he works and rests for six hours alternately.

It may be observed, that looking-glasses, thus blown, should never be above forty-five, or at most fifty inches long, and of a breadth proportionable. Those exceeding these dimensions, as we frequently find among the Venice glasses, cannot have the thickness sufficient to bear the grinding; and, besides, are subject to warp, which prevents them from regularly reflecting objects. Whereas plates as large as nine feet in length and proportionally wide, have been manufactured by casting.

Casting or running large Looking-glass plates. This art, as we have observed in the *History of GLASS*, is of French invention. It is owing to the Sieur Abraham Thevart, who first proposed it to the court of France, in 1688.

It is performed much like the casting of sheet-lead among the plumbers; and by means hereof we are not only enabled to make glasses of more than double the dimensions of any made by the Venetian way of blowing; but also to cast all kinds of borders, mouldings, &c.

The furnaces for melting the materials of this manufacture are of large size, being about 18 feet long and 15 wide; and those for annealing the glasses, when formed, are much more so. Round a melting-furnace, there are at least twenty-four annealing furnaces or ovens; each from twenty to twenty-five feet long; they are called carquailles: each carquaille has two tilarts, or apertures, to put in wood, and two chimnies. Add, that beside the annealing furnaces, &c. there are others for making of frit, and calcining old pieces of glass.

All these furnaces are covered over with a large shed; under which are like wise forges, and work-houses for smiths, carpenters, &c. continually employed in repairing and keeping up the machines, furnaces, &c. as also lodges, and apartments for these, and the other workmen, employed about the glass, and keeping up a perpetual fire in the great furnace; so that the glass-house, as that in the castle of St. Gobin, in the forest of Fere, in the Soissonois, appears more like a little city, than a manufactory.

The inside of furnaces is formed of a sort of baked earth, or refractory clay, proper to sustain the action of fire; and the same earth serves also for melting-pots, cisterns, &c. The furnaces seldom last above three years; after which they are to be rebuilt, from bottom to top; and to keep them good, even for that time, the inside must be refitted every six months, at which time the fire is extinguished. The melting-pots are as big as wine hogheads, about three feet in height, and in diameter; and contain above two thousand weight of metal. They are in the form of an inverted and truncated cone. The cisterns, or pans, called "cuvettes," are much smaller, being about thirty-six inches long, eighteen inches wide, and as many deep; and serve for the conveyance of liquid glass, which is drawn out of the pots to the casting tables. They do not contain much more than a sixth, or when large plates are cast, a third of the pots.

When the furnace is in condition to receive the pots and cisterns, they heat it red-hot, which requires fifty cords, or a hundred cart-loads of wood. That kind of wood which emits the largest and brightest flame, without much resinous smoke, is preferred. This done, they fill the pots with the materials, or soda and sand, which is done at several times, to facilitate the fusion. When the matter is sufficiently vitrified, refined, and settled, which usually happens in thirty-

thirty-six hours, they fill the cisterns, which are in the same furnace, and which are left there about six hours longer, till such time as they appear all white through the excessive heat.

To get the cisterns with the metal out of the furnace, they make use of a large iron chain which opens and shuts with hooks and eyes. From the middle of this, on each side, arise two massive iron pins, by which, with the assistance of pulleys, the cisterns are raised upon a kind of carriage of a proper height; and thus conducted to the table where the glass is to be run. The cistern is then raised above the tables with an engine, in form of a crane, by means of two iron bars, so contrived as to throw the cistern into an inclined position, which discharges a torrent of matter, all on fire, with which the table prepared for this purpose is presently covered.

The table on which the glass is to be run, is of smooth thick copper-plate, about ten feet long, and six feet broad. It is supported on a wooden frame, with truckles, for the convenience of removing from one carquaisse, or annealing furnace, to another, in proportion as they are filled.

Or, when each pot has a casting table, it is strongly supported by masonry, and contiguous to each table on the same level are the annealing ovens, upon which, being flat, the glass, when cast and sufficiently cooled, may be slid from off the copper-table without much difficulty. The tops of the flat ovens and the tables are on a level with the corresponding opening of the furnace, whence the cuvettes or cisterns are withdrawn. When the glass is melted and fined in the manner already stated under the article *Flint Glass*, the cuvette or cistern, previously made hot in the furnace, is filled out of the pot with a copper ladle, about ten inches in diameter, fixed to an iron handle seven feet long, properly supported on an iron stay by two workmen; and after remaining in the furnace for some hours, till the samples taken out for trial appear to be quite clear and limpid, the door of the furnace is opened, and the cuvette is pulled out and removed to the side of the copper table. It is then scummed with an instrument consisting of a copper blade set in iron, and hoisted for the discharge of its contents on the table, in the manner already mentioned.

To form the thickness of a glass, and to make the surface smooth and even, there are two iron rulers or rims, placed round the edge of the table; and on these rest the two extremes of a kind of roller, or hollow heavy cylinder of copper, turned after being cast, and about 500 pounds in weight, which serves to drive the liquid matter before it to the end of the table, or mould. The iron rulers being moveable, and capable of being set closer, or farther apart, at pleasure, determine the width of the glasses, and retain the matter, that it does not run off at the edges. The waste glass, if any, falls into a vessel of water, and is reserved for the next melting.

As soon as the matter is arrived at the end of the table, and the glass is come to a consistence, examined by the directors of the manufacture, and approved, they shove it off into the annealing furnace, with an iron raker, as wide as the table, that has a handle two fathoms long; being assisted by workmen on the other side of the carquaisse, who, with iron hooks, pull the glass to them, and range it in the carquaisse, which holds six large glasses.

What is most surprising throughout the whole of this operation, is the quickness and address wherewith such massy cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured on it, the glass spread, &c. The whole is inconceivable to such as

have not been eye-witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. This they continue to do, so long as there are any full cisterns; laying as many plates in each carquaisse as it will hold, and stopping them up with doors of baked earth, or clay, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about fourteen days.

The first running being dispatched, they prepare another, by filling the cisterns anew, from the matter in the pots; and after the second, a third, and even a fourth time, till the melting pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting table is to be carried to another. It need not here be observed, that the carquaisse, or annealing furnaces, must first have been heated to the degree proper for them. It may be observed, that the oven full, or the quantity of matter commonly prepared, supplies the running of eighteen glasses, which is performed in eighteen hours, being an hour for each glass. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what glass remains, which otherwise would grow green by continuance of fire, and spoil the glasses. They are not filled again in less than thirty-six hours, so that they put the matter into the furnace, and begin to run it every fifty-four hours.

The manner of heating the large furnaces is singular enough; the two tilers, or persons employed for that purpose, in their shirts, run round the furnace without making the least stop, with a speed scarce inferior to that of the lightest courier: as they go along, they take two billets, or pieces of wood, which are cut for the purpose; these they throw into the first tistart; and continuing their course do the same for the second. This they hold without interruption for six hours successively; after which they are relieved by others, &c. It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in less than half a minute.

It is computed, that a furnace, before it be fit to run glass, costs above three thousand five hundred pounds; that at least six months are required for the building it anew, and three months for the refitting it; and that when a pot of matter bursts in the furnace, the loss of matter and time amounts to above two hundred and fifty pounds.

The glass, when taken out of the melting-furnace, needs nothing farther but to be ground, polished, and soliated. But before these operations are performed, they cut and square the edges of the plates: which is performed with a rough diamond, passed along the surface of the glass, upon a square ruler, like that of the glaziers, and made to cut into the substance of the glass to a certain depth. This cut is then opened by gently knocking with a small hammer on the under side of the glass, just under it; by which means the piece comes off, and the roughness of the edges are removed by pincers. The plates are then laid by for grinding, *polishing.*

polishing, and silvering; which see respectively. See also **LOOKING-GLASS.**

GLASS, Annealing or Nealing of. The operation of annealing of glass is performed in a peculiar furnace called the *leer*, which consists of two parts, the *tower* and *leer*. The vessels, as soon as made, are placed by the workmen on the floor of the former to anneal: which done, they are drawn slowly in a sort of pan, called *fraches*, by an operator called the *farele-man*, all along the latter, the space of five or six yards, to give them time to cool gradually; so that when they reach the mouth of it, they are found quite cold. Merret, Not. to Neri, p. 243, seq.

This annealing is generally performed in a hot chamber, built for the purpose, at the top of the glass-house, above the crucibles, and a little below the chimney. Without this precaution, the glass would be liable to fly and break, by the least change of heat and cold, by the smallest scratch, and sometimes without any apparent external cause. The hard glasses, and those especially that are made with alkali and earths, require much more annealing than the softer and more fusible glasses, containing in their composition much litharge.

The particles of glass by annealing are supposed to lose part of their springiness, and their brittleness at the same time. A gradual heating or cooling of glass, according to Dr. Hook, anneals or reduces its parts to a texture more loose, and easy to be broke; but withal more flexible than before. And hence in some measure the phenomena of glass-drops.

Some of the phenomena depending on the fragility of unannealed glass deserve the attention of the curious. Those of the lachrymæ, or glass-drops, were among the first taken notice of; and it has also been observed, that hollow bells made of unannealed glass, with a small hole in them, will fly to pieces by the heat of the hand only, if the hole by which the internal and external air communicate be stopped with a finger. Phil. Transf. N^o 477. § 3. See **RUPERT'S Drops.**

But lately some vessels made of such unannealed glass have been discovered, which have the remarkable property of resisting very hard strokes given from without, though they shiver to pieces by the shocks received from the fall of very light and minute bodies dropped into their cavities. Of this kind is the "Bologna phial." These glasses may be made of any shape; all that needs be observed in making them, is to take care that their bottoms may be thicker than their sides. The thicker the bottom is, the easier do the glasses break. One whose bottom is three fingers breadth in thickness, flies with as much ease at least as the thinnest glass. Some of these vessels have been tried with strokes of a mallet sufficient to drive a nail into wood tolerably hard, and have resisted fracture. They also resist the shock of several heavy bodies let fall into their cavities, from the height of two or three feet. For instance, musket-balls, pieces of iron, or other metal; pyrites, jasper, wood, bone, &c. but this is not surprising, as other glasses of the same size do the same. But the wonder is, that taking a shiver of flint of the size of a small pea, and letting it fall into the glass only from the height of three inches, in about two seconds the glass flies, and sometimes in the very moment of the shock; nay, a bit of flint, no larger than a grain, dropt into several glasses successively, though it did not immediately break them, yet they all flew, being set by, in less than three quarters of an hour. Phil. Transf. *ibid.* p. 509.

Some other bodies produce a like effect with flint: for instance, sapphire, porcelain, diamonds, hard tempered steel,

as also marbles, such as boys play with; to which add pearls from the animal kingdom.

The experiment succeeded also when the glasses were held in the hand, rested on a pillow, put in water, or filled with water. It is also remarkable, that the glasses broke upon their bottoms being slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing.

If the glasses be every where extremely thin, they do not break in these circumstances.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into these vessels cause a concussion, that is stronger than the cohesion of the parts of the glass, and that consequently a rupture of the same must ensue. But why does not a ball of gold, silver, iron, copper, or several other bodies, even a thousand times heavier than a shiver of flint, equally cause this concussion, and break the glasses?

Mr. Euler has endeavoured to account for these appearances from his Principles of Percussion. He thinks this experiment entirely overthrows the opinion of those who measure the force of percussion by the *vis viva*; and he thinks the principles he has established give a clear solution of this phenomenon. According to these principles, the extreme hardness of the flint, and also its angular figure, which makes the space of contact with the glass vessel extremely small, ought to cause an impression on the glass vastly greater than lead or any other metal; and this may account for the flint's breaking the vessel, though the bullet, even falling from a considerable height, does no damage. Mem. Acad. Berlin, 1745, p. 47.

Hollow cups, made of the green bottle-glass, some of them three inches thick at bottom, were instantly broken, by a shiver of flint weighing about two grains, though they had resisted the shock of a musket ball from the height of three feet. Phil. Transf. *ibid.* p. 515.

"The precise mechanical cause of this disposition to crack in unannealed glass, is very difficult to explain," says Aikin (Dict.), "but generally speaking, it is supposed to be the forcible contraction of the outer part by sudden cooling, whilst the inner portion is still soft and half-fluid, so that the whole fixes with a permanent strain or inequality of pressure of one part upon the other; and as glass is extremely elastic, though brittle, any force which tears asunder a portion, however small, of the tense part, communicates a strong and sudden impulse over the whole mass." "This most singular phenomenon," (of the Rupert's drop) says the same ingenious chemist, in consequence of his own experiments, "is obviously owing to some permanent and very strong inequality of pressure, for when they are heated so red, as to be soft and merely let to cool of themselves, this property of bursting is entirely lost, and, at the same time, the specific gravity of the drop is increased. The peculiar brittleness of the Bologna phial is also removed by again heating and cooling slowly." The common window-glass, when badly annealed, is cut by the diamond with difficulty, and the cut often flies in a direction different from what was intended, or the glass entirely breaks.

Among other more common defects of glass, we may mention its liability to be acted upon by corrosive liquors, as is the case when too much saline flux has been used. As impenetrable as glass is to the common menstrua, we find it eaten by the air in length of time, when exposed in old windows; but the effects of its being kept in a subterraneous place are much more strange. Borrichius tells us, that at

the time when he was at Rome, there was dug up a whole house from under the kitchen garden of a citizen. The house had been buried there ten ages, and there were found in it several glass urns, or lacrymatories. The glass of these had no holes made in it, as our old glass in chamber-windows has, but still retained its smooth surface and transparency; but it was split into a vast number of thin laminæ, which were as pellucid and fine as Muscovy glass; and in some places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the ancient way of working their glass; but it is not probable there could be any thing particular in the formation of the vessel, to determine it to split thus into flakes; but that glass of the same kind, in any form, would have done the same. Borrich. de Ortu Chemicæ.

There are other visible imperfections in glass, materially injuring its soundness and beauty, and enumerated by Aikin (Dict. art. *Glass*) under the denominations of *striae*, *threads*, *tears*, and *knots*. The former are undulating waves in the glass, arising from the imperfect mixture of the materials, and their different specific gravities. Accordingly, we may observe, that the most transparent glass is subject to bubbles and veins, the methods of preventing which are yet little known; and this is an inconvenience by which Mr. Dollond's excellent discovery is affected; for the flint-glass which he uses is peculiarly subject to small veins, that disturb the rays in their passage, and render the vision confused. This effect is owing to the density of these veins being greater than that of the rest of the glass, as appears from their image received on white paper, when the glass is held between the paper and a candle, or other luminous object: for this image of a vein, thus received, is a line brighter than the rest of the image of the glass, and this bright line is defined by a dark edge on each side. But the bright line evidently shews a convergency of rays, which can only be effected by the veins being denser than the medium in which they are placed. The reason why flint glass is more subject to veins than other glass is, says the translator of Macquer's Chemical Dictionary, because it is composed of materials of more different densities.

Mr. Macquer, with a view of improving the manufacture of this glass, proposes to facilitate the union of the calx of lead and sand, of which it is composed, by depriving the calx of lead, as much as possible, of its phlogiston, which may be done by combining the vitriolic acid with minium, or red-lead, and exposing this composition to the operation of fire, to disengage it from the acid; and also by giving these two substances the greatest possible degrees of fluidity and mobility, which may be done by mixing with the composition of them a considerable quantity of solvents. Hist. Acad. Scienc. for 1773.

Threads in glass, are those streaky filaments which arise from the vitrification of the clay; being generally green, and rendering the glass more liable to crack at these parts. But one of the worst defects (says Aikin, *ubi supra*), is "*tears*, or drops of vitrified clay falling down from the furnace into the pots, and entangled with the glass. Articles made of glass with this defect, are always very brittle, and generally break of themselves by slight changes of heat and cold." Small bubbles appear in glass not sufficiently refined by a continuance of the melting heat; and these may be owing to a deficiency of flux, so that the glass is less fusible, and the bubbles cannot easily be disengaged. "Hence," says the author now cited, "the soft fusible glasses with much lead are much less liable to this fault than the hard, green bottle-glass, which is made only of alkali

and earth." The *knots* in glass "arise either from a portion of sand that has escaped vitrification, and remains entangled in the glass, or from a remaining quantity of glass-gall; or from bits of the crucible which may be accidentally knocked off by the iron instruments used in the working."

GLASS of Borax. See *BORAX*.

GLASS, Colouring of, to imitate gems. See *GEM*.

GLASS, Gold-coloured. This kind of glass may be made by taking ten pounds of either of the compositions for hard glass, omitting the salt-petre; and for every pound adding an ounce of calcined borax; or, if this quantity doth not render the glass sufficiently fusible, two ounces; ten ounces of red tartar, of the deepest colour, two ounces of manganese, and two drams of charcoal of fallow, or any other soft kind. Precipitate of silver baked on glass will stain it yellow, and likewise give a yellow colour on being mixed with and melted with forty or fifty times their weight of vitreous compositions; the precipitate from aqua-fortis by fixed alkali seems to answer best. Yellow glasses may also be obtained with certain preparations of iron, particularly with Prussian blue. But Dr. Lewis observes, that the colour does not constantly succeed, nor approach to the high yellow of gold, with silver or with iron. The nearest imitations of gold which he has been able to produce, have been effected with antimony and lead. Equal parts of the glass of antimony, of flint calcined and powdered, and of minium, formed a glass of a high yellow; and with two parts of glass of antimony, two of minium, and three of powdered flint, the colour approached still more to that of gold. The last composition exhibited a multitude of small sparkles interspersed through its whole substance, which gave it a beautiful appearance in the mass, but were really imperfections, owing to air-bubbles.

Neri directs, for a gold-yellow colour, one part of red tartar, and the same quantity of manganese, to be mixed with a hundred parts of frit. But Kunckel observes, that these portions are faulty; that one part, or one and a quarter of manganese, is sufficient for a hundred of frit; but that six parts of tartar are hardly enough, unless the tartar is of a dark red colour, almost blackish; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds, that the glass swells up very much in melting, and that it must be left unstirred and worked as it stands in fusion. Mr. Samuel More, in repeating and varying this process, in order to render the colour more perfect, found that the manganese is entirely essential to the gold colour, and that the tartar is no otherwise of use, than in virtue of the coaly matter, to which it is in part reduced by the fire; the phlogiston or inflammable part of the coal appearing in several experiments to be the direct tinging substance. Mr. Pott also, in his *Neue Wichtige Physikalisch-Chymische Materien*, &c. printed in 1762, observes, that common coals give a yellow colour to glass; that different coaly matters differ in their tinging power; that caput mortuum of foot and lamp-black answer better than common charcoal; and that the sparkling coal which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the most active of these preparations. This preparation, he says, powdered, and then burnt again a little in a close vessel, is excellent for tinging glass, and gives yellow, brown, reddish, or blackish colour, according to its quantity: but the frit must not be very

hard of fusion; for, in this case, the strong fire will destroy the colouring substance before the glass melts, and he has found the following compositions to be nearly the best; viz. sand two parts, alkali three parts; or sand two, alkali three, calcined borax one; or sand two, alkali two, calcined borax one; and though salt-petre is hardly used at all, or very sparingly, for yellow glasses, as it too much volatilizes the colouring substance; yet here for the most part a certain proportion of it, easily determined by trial, is very necessary; for without it, the concentrated colouring matter is apt to make the glass too dark, and even of an opaque pitchy blackness. It does not certainly appear that there is any material diversity in the effects of different coals; the difference being probably owing to the different quantities of the inflammable matter which they contain; so that a little more shall be required of one kind than of another, for producing the same degree of colour in the glass. Nor does the softness or fusibility of the frit appear to be in any respect necessary.

Gold-coloured spangles may be diffused through the substance of glass, by mixing the yellow tales with powdered glass, and bringing the mixture into fusion. See Lewis's Com. Phil. Techn. p. 223, 626, &c.

GLASS for counterfeiting lapis lazuli. See LAPIS LAZULI.

GLASS resembling opal. See OPAL and GEMS.

GLASS, Ruby. The way to give the true fine red of the ruby, with a fair transparency, to glass, is as follows. Calcine in earthen vessels gold dissolved in aqua regia, the menstruum being evaporated by distillation, more aqua regia added, and the abstraction repeated five or six times, till it becomes a red powder. This operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be used, melt the finest crystal glass, and purify it, by often casting it into water; and then add, by small quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect transparency. Neri. See GEMS.

The process of tinging glass and enamels by preparations of gold, were first attempted about the beginning of the 17th century. Libavius, in one of his tracts, entitled *Alchymia*, printed in 1626, conjectures that the colour of the ruby proceeds from gold, and that gold dissolved, and brought to redness, might be made to communicate a like colour to facitious gems and glass. On this principal Neri, in his "Art of Glass," dated 1611, gives the process above recited. Glauber, in 1648, published a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect glass. For this purpose he ground powdered flint or sand with four times its weight of fixed alkaline salt; this mixture melts in a moderately strong fire, and when cold looks like glass, but exposed to the air runs into a liquid state. On adding this liquor to solution of gold in aqua regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple; by mixing this powder with three or four times its weight of the alkaline solution of flint, drying the mixture, and melting it in a strong fire for an hour, a mass is obtained, of a transparent ruby colour, and of a vitreous appearance, which nevertheless is soluble in water, or by the moisture of the air, on account of the redundancy of the salt. The honourable Mr. Boyle, in a work published in 1680, mentions an experiment, in which a like colour was introduced into glass without fusion; for, having kept a mixture of gold and mercury in digestion for some months, the fire was at last immoderately increased, so that the glass burst with a violent explosion; and the lower part of the glass was found tinged throughout

of a transparent red colour, hardly to be equalled by that of rubies. See Porosity of Bodies, in Shaw's Abridgment of Boyle's Works, vol. 1. p. 459; and Appendix to the Sceptical Chemist.

About the same time Cassius is said to have discovered the precipitation of gold by tin, and that glass might be tinged of a ruby colour by melting it with this precipitate: though he does not appear, says Dr. Lewis, from his treatise *De Auro*, to have been the discoverer of either. He describes the preparation of the precipitate and its use, but gives no account of the manner of employing it; only that he says, one dram of gold, duly prepared, will tinge ten pounds of glass. See GOLD precipitate with tin.

This process was soon after brought to perfection by Kunckel; who says, that one part of the precipitate is sufficient to give a ruby colour to 1280 parts of glass, and a sensible redness to upwards of 1000 parts; but that the success is by no means constant. Kunckel also mentions a purple-gold powder, resembling that of Neri, which he obtained by inspissating solution of gold to dryness, abstracting from it fresh aqua regia three or four times, till the matter appears like oil; then precipitating with strong alkaline ley, and washing the precipitate with water. By dissolving this powder in spirit of salt, and precipitating it again, it becomes, he says, extremely fair; and in this state he directs it to be mixed with a due proportion of Venice glass.

Orselhal in his treatise entitled *Sol sine Vesle*, gives the following process for producing a very fine ruby. He directs the purple precipitate, made by tin, to be ground with six times its quantity of Venice glass into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous composition to be tinged. His frit consists of equal parts of borax, nitre, and fixed alkaline salt, and four times as much calcined flint as of each of the salts; but he gives no directions as to the proportion of the gold precipitate, or mode of fusion. Hellot describes a preparation, which mixed with Venice glass, was found to give a beautiful purple enamel. This preparation consists of equal parts of solution of gold, and of solution of zinc in aqua regia, mixed together with the addition of a volatile salt prepared from sal ammoniac, in quicklime, in sufficient quantity to precipitate the two metals. The precipitate is then gradually heated, till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on glass or enamels, and introduced into the mass by fusion, the way of equally diffusing such a colour through a quantity of fluid glass is still, says Dr. Lewis, a secret. The following process for making the ruby glass was communicated to Dr. Lewis by an artist, who ascribed it to Kunckel. The gold is directed to be dissolved in a mixture of one part of spirit of salt, and three of aqua-fortis, and the tin in a mixture of one part of the former of these acids with two of the latter. The solution of gold being properly diluted with water (see GOLD precipitate, &c.) the solution of tin is added, and the mixture left to stand till the purple matter has settled to the bottom. The colourless liquor is then poured off, and the purple sediment, while moist and not very thick, is thoroughly mixed with powdered flint or sand. This mixture is well ground with powdered nitre, tartar, borax, and arsenic, and the compound melted with a suitable fire. The proportions of the ingredients are 2560 parts of sand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arsenic, 5 of tin, and 5 of gold. Lewis's Com. Phil. Techn. p. 171. 621, &c.

GLASS, white-opaque, and semi-transparent, may be made of ten pounds of either of the compositions for hard glass, and

one pound of well calcined horn, ivory, or bone; or an opaque whiteness may be given to glass, by adding one pound of very white arsenic to ten pounds of flint glass. Let them be well powdered and mixed, by grinding them together; and then fused with a moderate heat, till they are thoroughly incorporated. A glass of this kind is made in large quantities at a manufacture near London, and used not only for different kinds of vessels, but as a white ground for enamel in dial-plates and snuff-boxes, which do not require finishing with much fire, because it becomes very white and fusible with a moderate heat.

GLASS, Yellow. See **Golden-coloured GLASS.**

GLASS-balls, which are circular or otherwise shaped hollow vessels of glass, may be coloured within, so as to imitate the semi-pellucid gems. The method of doing it is this: make a strong solution of ichthyocolla, or isinglass, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glass vessel; shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red lead, shake it and turn it about, throw it into many places with a tube, and the moisture will make it flick and run in waves and pretty figures. Then throw in some of the painter's blue smalt, and make it run in waves in the ball as the red-lead; then do the same with verdigris, next with orpiment, then with red lake, all well ground; always casting in the colours in different places, and turning the glass, that the moisture within may run them into the waves. Then take fine plaster of Paris, and put a quantity of it into the ball; shake it also nimbly about; this will every where flick firmly to the glass, and give it a strong inner coat, keeping all the colours on very fairly and strongly.

These are set on frames of carved wood, and much esteemed as ornaments in many places. Neri.

GLASS, Foliated of. See **FOLIATING and LOOKING-GLASS.**

GLASS-gall, or sandiver, is the scum of the glass pots, which arises during the vitrification of the frit. See **GLASS,** *supra.*

GLASS, gilding of. See **GILDING of enamel and glass.**

GLASS, grinding of. See **GRINDING.**

GLASS-house Furnace, is the place in which the ingredients or materials of glass are fused and vitrified. There are three kinds of furnaces used in the glass-works. The *first*, called the "calcar," serves for preparing or calcining the frit. It is made like an oven, 10 feet long, seven broad, and two deep. The fuel, which is sea-coal, is put in a trench, on one side of the furnace; and the flame reverberates from the roof back upon the frit. The coals burn in an iron grate, and the ashes fall thence into holes underneath.

The *second* is the "working furnace," in which the ingredients are melted, and the glass is made. Its figure is round, resembling a dome, three yards in diameter, and two high, supported on arches, beneath which is a large space for a brick and copious draught of cold air from without: round the inside there are arranged eight or more pots, and on these piling-pots, every where closed except at one side opening, which communicates with a small recess formed by the alternate projections of the masonry and flues of the oven or kiln, in which recess the workmen stand. The furnace has two partitions; the lower, separating the pots from the fire-place, has a circular hole in the centre covered with a grate, through which the flame passes from the fire-place into the furnace, being afterwards reverberated from the arched sides and roof to the melting-pots, and passing out with the smoke through the top of the dome, which is lengthened into a chimney for

the space of a few feet. The *second* partition divides this from the leer or annealing furnace; through the boccas, or working holes, when there are more than one, the metal is taken out of the pots, and the pots put into the furnace: these boccas are stopped with moveable covers, made of lute and brick to screen the eyes of the workmen from the fire; and sometimes on each side of the bocca is a boccella, out of which coloured glass, or finer metal is taken from the piling-pot. To the furnace likewise occasionally belong ovens, or holes near the leer, for the calcining of tartar, iron, &c.

The leer, which serves to anneal and cool the vessels, and which Agricola makes a particular furnace, consists of a tower, besides the leer; the tower lies directly over the melting furnace, with a partition betwixt them about a foot thick, having an aperture called *occlusio*, or *lumella*, through which the flame or heat ascends out of the furnace into the tower: on the floor or bottom of this tower, the vessel, fashioned by the artist, are set to be annealed; and as the flame has here a less degree of intensity than that which is sustained by the pots, the vessels, after they have been formed, cool slowly and gradually. This has usually two boccas, or mouths, by which the glasses are put in with a fork, and placed on the floor. The *leer* is an avenue, five or six yards long, continued to the tower; through this the glasses, when annealed, are drawn in iron pans, called *fractus*, by which they come to cool by degrees, being quite cold by the time they reach the mouth of the leer, which enters the "farosel," or room where the glasses are to be set.

The *third* is the "green-glass furnace," which is a kind of compound of all the former. It is made square, (the two former being circular,) having an arch at each angle for annealing and cooling the glasses. The metal is wrought on two opposite sides, and on the other two they have their calcars, into which are made linnet-holes for the fire to come from the furnace, to bake the frit, and also to discharge the smoke. Fires are made in the arches to anneal the vessels, so that the whole process is done in one furnace. The materials with which the insides of these furnaces are constructed are not ordinary brick (which would soon melt down into glass, as would also all the softer stones,) but hard and sandy kinds, called by Imperatus "pyramachia." But when bricks are used, they should be formed of an earth which possesses in the highest degree the qualities of density and infusibility, for resisting the fire, which continues to act upon them, without cessation for a long time; as the fires in a glass-house are seldom suffered to go out, from the time when the furnace is first employed till it needs repair, and the interval may be two or three years; the walls of the furnace, for this reason, as well as the pots, are constructed chiefly of clay, mixed with sand, and other materials of a refractory kind, in due proportion. See **GLASS-pots.**

GLASS of lead, a glass made with the addition of a large quantity of lead, of great use in the art of making counterfeit gems. The method of making it is this: put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey loose powder: then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps; continue this several hours, till the powder becomes of a fair yellow; then take it out and sift it fine: this is called calcined lead.

Take of this calcined lead fifteen pounds, and crystalline, or other frit, twelve pounds; mix these as well as possible together; put them into a pot, and set them in the furnace for ten hours; then cast the whole, which will be now perfectly melted, into water; separate the loose lead from it, and return the metal into the pot; and after standing in
fusion

fusion twelve hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon. Neri.

It is well known, that cerufs, or white lead, minium, litharge, and all the other preparations and calces of lead, are easily fused by a moderate fire, and formed into a transparent glass of a deep yellow colour. But this glass is so penetrating and powerful a flux, that it is necessary to give it a greater consistence, in order to render it fit for use. With this view, two parts of calx of lead, *e.g.* minium, and other parts of sand, or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated, for an hour, or an hour and a half; and afterwards let the heat be increased, so as to obtain a complete fusion, and continued in that state for the same time: let this crucible remain to cool in the furnace, and when it is broken, a very transparent yellow-coloured glass will be found in it. Some add nitre and common salt to the above mixture, because these salts promote the fusion and the more equal distribution of the sand. This glass of lead has a considerable specific gravity, and its lowest part is always the heaviest. It is an important flux in the assays of ores to facilitate their scorifications.

Glass of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take pulverine frit twenty pounds, lead calcined sixteen pounds; sift both the powders very fine; then melt them into a glass, separating the unmixed lead, by plunging the mass in water; after this return it into the pot, and add brass thrice calcined six ounces, and one penny-weight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally settle an hour, then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined brass the same quantity of the caput mortuum of the vitriolum veneris be used, the green is yet much finer.

For topaze-colour take crystal frit fifteen pounds, calcined lead twelve pounds; mix them well together, by sifting the powders through a fine sieve; then set them in a furnace not too hot, and separate the superfluous unmixed lead, by casting the whole into water: repeat this twice; then add half gold yellow glass, and let them incorporate and purify, and they will be of the true and exact colour of the original topazes.

For sea-green, take crystal frit sixteen pounds, calcined lead ten pounds; mix and sift them together, and set them in a pot in a furnace: in twelve hours the whole will be melted; then cast it into water and separate it from the loose lead; put them into the furnace again for eight hours; then separate the loose lead by washing a second time, and return it to the pot for eight hours more. Neri. See GEMS.

GLASS, Painting in. The primitive manner of painting in glass was very simple, and of consequence very easy: it consisted in the mere arrangement of pieces of glass of different colours, in some sort of symmetry; and constituted a kind of what we call *Mosaic work*.

Afterwards, when they came to attempt more regular designs, and even to represent figures raised with all their shades, their whole address went no farther than to the drawing the contours of the figures in black, with water colours, and hatching the draperies, after the same manner, on glasses of the colour of the object intended to be painted. For the carnations, they chose glass of a bright red; upon which

they designed the principal lineaments of the face, &c. with black.

At last the taste for this sort of painting being considerably improved, and the art being found applicable to the adorning of churches, basilicas, &c. they found means of incorporating the colours with the glass itself, by exposing them to a proper degree of fire, after the colours had been laid on.

A French painter at Marfeilles is said to have given the first notion hereof, upon going to Rome, under the pontificate of Julius II. But Albert Durer, and Lucas of Leyden, were the first that carried it to any height.

The colours used in painting on glass are very different from those used either in painting in oil, or water.

The *black* is made of two-thirds of flakes, or scales of iron, beaten up, and mixed with another third of roccaille, or little glass beads. *White*, with sand, or little white pebbles, calcined, pounded in a mortar, and afterwards ground on marble; with one fourth-part of salt-petre, added thereto, and the mixture calcined and pulverized over again: to which, when they are ready to use it, is added a little gypsum, or plaster of Paris well ground, &c. For *yellow*, they use leaf-silver ground, mixed up in a crucible, with sulphur or salt-petre; then well beaten and ground on a porphyry stone; and, at length, ground over again with nine times as much red ochre. *Red* is made of litharge of silver, and scales of iron, gum Arabic, ferretta, glass-beads, and blood-stone, nearly in equal quantities. This is one of the most difficult colours, and the preparation only to be learned by experience. *Green* is made of *æs ustum*, one ounce; as much black lead, and four ounces of white sand, incorporated by the fire. After calcination, they add a fourth part of salt-petre: after a second calcination, a sixth part more: after which they make a third coction before it is used. *Azure*, *purple*, and *violets*, are prepared like green, only leaving out the *æs ustum*, and in the lieu thereof using sulphur for azure; perigueux for purple; and both these drugs for violet. *Carnations* are made of ferretta and roccaille. And lastly, colours for the hair, trunks of trees, &c. are made of ferretta, roccaille, &c.

This account of colours we have from M. Felbien's excellent work *Des Principes d'Architecture*, &c. though it must be owned, that all the painters on glass do not use them; there being few artists of that kind but have invented their own particular ones, whereof they usually make great secrets. But this is certain, that these above described are sufficient for the best paintings of all sorts; provided the person has but the skill to manage them.

In the windows of divers ancient churches, chapels, colleges, &c. we meet with the most beautiful and lively colours imaginable; such as far exceed any used among us: but it is not that the secret of making those colours is lost; but that the moderns would not go to the expence of them; nor take all the necessary pains; because this sort of painting is not now so much esteemed as formerly.

Mr. Walpole, in his *Anecdotes of painting in England*, has traced the history of this art from the reformation, when misguided zeal destroyed most of the monuments of it in our churches, through a series of professors to the present time. Among the later proficientes in this art were Isaac Oliver, who painted the windows at Christ-church, Oxford, in 1700; William Price, who in the same year painted the windows in Merton chapel; William Price, the son, to whose art we owe the windows at Queen's, New-college, and Maudlin, of whom Mr. Walpole says, that his colours are fine, his drawing

good, and his taste in ornaments and Mosaic far superior to any of his predecessors, and equal to the antique. In 1761, Mr. Paterfon, an auctioneer late of Essex-house in London, exhibited the two first auctions of painted glass imported from Flanders; and undertook also to establish a manufacture of painted glass: several of the pieces of this ingenious artist exhibited colours vying in perfection with the old paintings.

Those beautiful works, among the painters in glass, which were made in the glass-house, were of two kinds: in some, the colour was diffused through the whole body of glass; in others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one-third of a line; though this was, more or less, according to the nature of the colour; the yellow being always found to enter the deepest.

These last, though not so strong and beautiful as the former, were of more advantage to the workmen; because, on the same glass, though already coloured, they could shew other kinds of colours, where there was occasion to embroider draperies, enrich them with foliages, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery; grinding, or wearing down the surface of the glass, till such time as they were got through the colour, to the clear glass: this done, they applied the proper colours on the other side of the glass. By this means the new colours were prevented from running and mixing among the former, when the glasses came to be exposed to the fire, as will hereafter be shewn.

When the intended ornaments were to appear white, or silvered, they contented themselves to bare the glass of its colour with emery, without applying any new colour at all; and it was in this manner that they wrought the lights and heightenings on all kinds of colours.

The painting with vitreous colours on glass depends entirely on the same principles as painting in enamel; and the manner of executing it is likewise the same; except that in this the transparency of the colours being indispensibly requisite, no substances can be used to form them but such as vitrify perfectly: and, therefore, the great object is to find a set of colours, which are composed of such substances, as, by the admixture of other bodies, may promote their vitrification and fusion; are capable of being converted into glass; and melting, in that state, with less heat than is sufficient to melt such other kinds of glass as may be chosen for the ground or body to be painted; to temper these colours, so as to make them proper to be worked with a pencil; and to burn or reduce them by heat, to a due state of fusion, without injuring or melting the glass which constitutes the body painted. The first thing to be done, in order to paint on glass, in the modern way, is to design, and even colour, the whole subject on paper. Then they make choice of pieces of glass proper to receive the several parts, and proceed to divide or distribute the design itself, or the paper it is drawn on, into pieces suitable to those of glass; having always a view that the glasses may join in the contours of the figures, and the folds of the draperies; that the carnations and other finer parts may not be damaged by the lead wherewith the pieces are to be joined together.

The distribution being made, they mark all the glasses, as well as papers, with letters, or numbers, that they may be known again; which done, applying each part of the design on the glass intended for it, they copy or transfer the design upon this glass, with the black colour,

diluted in gum-water; by tracing and following all the lines and strokes, as they appear through the glass, with the point of a pencil.

When these first strokes are well dried, which happens in about two days, the work being only in black and white, they give it a slight wash over, with urine, gum Arabic, and a little black; and this several times repeated, according as the shades are desired to be heightened; with this precaution, never to apply a new wash, till the former is sufficiently dried. This done, the lights and risings are given, by rubbing off the colour in the respective places, with a wooden point or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side, especially yellow, which is very pernicious to other colours, by blending therewith.

And here too, as in pieces of black and white, particular regard must be always had, not to lay colour on colour, or lay on a new lay, till such time as the former are well dried. It may be added, that the yellow is the only colour that penetrates through the glass, and incorporates therewith by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven, to anneal or bake the colours. The furnace here used is small, built of brick, from eighteen to thirty inches square: at six inches from the bottom is an aperture, to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces, to examine how the coction goes forward.

On the grate is placed a square earthen pan, six or seven inches deep; and five or six inches less, every way, than the perimeter of the furnace. On one side hereof is a little aperture, through which to make the trials, placed directly opposite to that of the furnaces destined for the same end.

In this pan are the pieces of glass to be placed in the following manner; first, the bottom of the pan is covered with three strata, or layers of quicklime, pulverized; those strata being separated by two others, of old broken glass: the design whereof is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last, or uppermost, layer of lime.

The first row of glass, they cover over with a layer of the same powder an inch deep; and over this they lay another range of glasses: and thus alternately, till the pan is quite full; taking care that the whole heap always ends with a layer of the lime-powder.

The pan thus prepared, they cover up the furnace with tiles, on a square table of earthen-ware, closely luted all round; only having five little apertures, one at each corner, and another in the middle, to serve as chimnies.

Things thus disposed, there remains nothing but to give the fire to the work. The fire for the two first hours must be very moderate; and must be increased in proportion as the coction advances, for the space of ten or twelve hours; in which time it is usually completed. At last,

the fire; which at first was only of charecoal, is to be of dry wood: so that the flame covers the whole pan, and even issues out at the chimnies.

During the last hours, they make assays from time to time, by taking out pieces laid for that purpose, through the little aperture of the furnace, and pan, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses. See PAINTING.

GLASS, *painting on, by means of prints.* See BACK-painting.

GLASS, *polishing of.* See POLISHING and GRINDING.

GLASS-porcelain, the name given by many to a modern invention of imitating the china-ware with glass. The method given by M. Reaumur, who was the first that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris, to this effect. This change of glass was first taken notice of by Neumann, who, in distilling milk in a glass retort, observed, that the bottom of the vessel acquired the appearance of porcelain, which he attributes to the fine white earthy matter of the milk forced into the glass by heat. Neum. Chem. Works by Dr. Lewis, p. 571.

The mixing of glass reduced to powder, with other less easily vitrifiable substances for forming a paste, to be afterwards made into a sort of a porcelain, has been a contrivance long practised, but it is very troublesome, and the result subject to many faults; but this new ware is made of glass alone, and that with much less trouble, and without the reducing it to powder. By this art, vessels of glass are changed into vessels of a sort of porcelain, without altering their form, and the meanest glass made only of sand, lime, and saline ashes, serves as well as the best for that purpose: our common coarse green quart-bottles, or the great bell glasses with which gardeners cover their melons, &c. being by this means changeable into a beautiful white sort of porcelain ware; and this is to be done in so easy a manner, and with so small expence, that it requires no more trouble or charge, than that of baking a common vessel of our coarse earthen-ware; and for this reason the vessels of this sort of ware may be afforded extremely cheap.

It is very certain, that all porcelain ware is a substance in the state of semi-vitrification: and in order to bring glass, which is a wholly vitrified substance, into the condition of porcelain, there requires no more than to reduce it to a less perfectly vitrified state.

The question which would naturally be started on this occasion, is, whether it be possible to reduce glass to a less vitrified state, it having already undergone what is esteemed the last change by fire. But when we consider, that the mass of antimony, the vitrifications of many of the metals, as the glass of lead, and the counterfeit gems coloured by the metals, are more or less easily reduced again by chemistry to metals, &c. the reducing of sand, flints, &c. after they are vitrified, at least a little way back toward their native or pristine state, may appear not wholly impracticable, and the attempts which M. Reaumur made on this occasion, were what gave him the first hints of the glass-porcelain; called from his name "Reaumur's porcelain."

The method of making it is this. The glass vessels to be converted into porcelain are to be put into a large earthen vessel, such as the common fine earthen dishes are baked in, or into sufficiently large crucibles; the vessels are to be filled with a mixture of fine white sand, and of fine gypsum or plaster-stone burnt into what is called plaster of Paris, and

all the interstices are to be filled up with the same powder; so that the glass vessels may no where touch either one another, or the sides of the vessel they are baked in. The vessel is to be then covered down and luted, and the fire does the rest of the work; for this is only to be put into a common potter's furnace, and when it has stood there the usual time for the baking of the other vessels, it is to be taken out, and the whole contents will be found no longer glass, but converted into a white opaque substance, which is a very elegant porcelain, and has almost the properties of that of China. Memoirs Acad. Sciences Par. 1739.

The powder which has served once, will do again as well as fresh, and that for a great many times: nay, it seems, ever so often. The cause of this transformation, says Macquer, is probably that the vitriolic acid of the gypsum quits its basis of calcareous earth, and unites with the alkaline salt and saline earth of the glass, with which it forms a kind of salt or selenites, differing from the calcareous selenites, by the interposition of which matter the glass acquires the qualities of porcelain. Dr. Lewis, from a variety of experiments on the nature and qualities, and method of producing this porcelain, has deduced the following conclusions: 1. Green glass cemented with white sand received no change in a heat below ignition: in a low red-heat, the change proceeded very slowly; but in a strong red-heat, approaching to whiteness, the thickest pieces of glass bottles were thoroughly changed in three hours. 2. The glass sustained the following progression of changes. Its surface first became blue; its transparency was diminished, and when held between the light and the eye, it appeared of a yellowish hue: afterwards it was changed a little way on both sides into a white substance, externally still blueish: and as this change advanced still farther and farther within the glass, the colour of the vitreous part in the middle approached nearer to yellow: the white coat was of a fine fibrous texture, and the fibres were disposed nearly parallel to one another, and transverse to the thickness of the piece: by degrees the glass became throughout white and fibrous, the external blueness at the same time going off, and being succeeded by a dull whitish or dun colour: by a still longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into grains; and the texture then was not unlike that of common porcelain. The grains, at first fine and somewhat glossy, appeared afterwards larger and duller, and at length the substance of the glass became porous and friable, like a mass of white sand slightly cohering. 3. Concerning the qualities of the converted glass Dr. Lewis observes, that the whiteness of the internal part was not inferior to that of porcelain, but that its surface was the least beautiful; that the thick pieces were quite opaque, and that several thin pieces were semi-transparent: that while it remained in a fibrous state, its hardness became greater than that of glass, or of the common kinds of porcelain; it was capable of sustaining sudden changes of heat and cold better than any porcelain; and in a moderate white heat, it was fusible into a substance not fibrous, but vitreous and smooth, like white enamel: that when its texture had been coarsely granulated, it was now much softer and unfusible; and, lastly, that when some coarsely granulated unfusible pieces which, with the continuance of a moderate heat, would have become porous and friable, were suddenly exposed to an intense fire, they were rendered remarkably more compact than before; the solidity of some of them being superior to that of any other ware. 4. No differences appeared in the internal colour, hardness, texture, or the regular succession of changes, from the use of different cementing substances; though

though in external appearances the differences were considerable. All the pieces which had been surrounded with charcoal or with soot were externally of a deep black colour, which did not disappear by exposure to a strong fire during an hour, with free access of air. Coloured clays and sands communicated different shades of a brown colour; and white earths gave whitish, greyish, or brownish tinges. White sand, calcined flints, and gypsum, gave in general the greatest whiteness, and tobacco-pipe clay the greatest glossiness and brightness. Glasses composed of earths without alkaline salt, glass of lead, flint-glass, crown-glass, looking-glass plates, a glass prepared with calcined flints and a fixed alkaline salt, and even green glass which had been fused together with a ninth part of alkaline salt, suffered none of the above alterations by cementation. Green bottle-glass and common window-glass were most susceptible of these alterations. 6. The changes produced by cementation could not proceed from any absorption of matter from the cementing substance; because no increase of weight was given, and because the same changes were produced upon a piece of glass merely by heat, without any cementing substance. See Com. Phil. Techn. p. 230—255.

Mr. Gregory Watt, in his valuable paper on basalt (Phil. Trans. for 1804, cited by Aikin,) alleges this porcellanous change of glass as an illustration of his important principle, *viz.* "that bodies whose fibres have a natural tendency to a crystalline arrangement, or a polarity, when vitrified by a sufficient heat and cooled hastily in the vitreous state, are able subsequently to return to their natural crystalline arrangement of fibre, when exposed to a heat merely sufficient to soften the texture, though not enough for fusion. This, in the instance of basalt, he shews by the singular crystallizations formed in the cells of fused basalt, long after it had lost the liquidity of fusion. The circumstance of no material change occurring in the weight of glass by this conversion into the fibrous state, shews incontestably that it cannot be owing either to any thing gained during the process, nor to any material loss of the alkali; and this is also rendered manifest by its return to the vitreous state and vitreous qualities when again melted. This too may again be porcellanized in the same way, and again be melted into glass, and so on alternately." See PORCELAIN.

GLASS-pots, the vessels in the glass manufacture used for melting the glass. Those for the white glass works are made of a tobacco-pipe clay, brought from the Isle of Wight, which is first well washed, then calcined, and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till it is of a proper consistence, to mould with the hands into the proper shape of the vessels. When these are thus made, they are afterwards annealed over the furnace. Those for the green-glass work are made of the nonsuch, and another sort of clay from Staffordshire; they make these so large as to hold three or four hundred weight of metal. And besides these, they have a small sort called piling pots, which they set upon the larger, and which contain a finer and more nice metal fit for the nicest works. Neri.

The clay that is used for this purpose should be of the purest and most refractory kind, and well cleansed from all sandy, ferruginous, and pyritous matters; and to this it will be proper to add ground crucibles, white sand, calcined flints duly levigated, or a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exposed to a great heat, is not absolutely determined, but depends on

the quality of the crude clay, which is more or less fat. M. D'Autic, in a memoir on this subject, proposes the following method of ascertaining it: the burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried, and exposed to a violent heat, till they become as hard and as much contracted as possible, and in this state be examined; and the cake, he says, which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays require that the proportion of the burnt should be to the fresh as four to five.

It is of great importance that the material of which the pots are made should be carefully selected, as they are exposed to the action of a very fierce fire, and also to the solvent activity of the glass with its powerful fluxes. They should also be made very thick and strong, as they are intended to last for many months. When finished, they are placed in a warm room in order to discharge their moisture, and any small fissures arising from the unequal shrinking of the clay are closed by gently beating with a mallet. They are afterwards gradually heated in a small oven, constructed for this purpose, and slowly brought to a red heat; and after remaining for some time in this state, they are removed to the furnace, and fixed down in their places by fire-clay. Here, on account of a further shrinking, they remain for a day or two before they are fit for receiving the glass materials. Pots of this kind are said to last, at an average, about a year.

GLASS Tubes are of various lengths, diameters, and forms, according to the purposes to which they are applied. These are often formed with the lamp and blow-pipe, in the manner described under the article **LAMP-blowers**. In this way tubes are sealed hermetically (see **HERMETICAL Seal**), tubes are bent, others are joined, bulbs are annexed to tubes for thermometers, &c., and glass is drawn out into threads.

It has been observed, that glass tubes laid before the fire in an horizontal position, and with their extremities supported, have had a rotatory motion about their axes; and also a progressive motion towards the fire, even when their supports are inclined from the fire, so that the tubes will move a little upwards. See Phil. Trans. N^o 476. § 1.

When the progressive motion of the tube is stopped by any obstacle, its motion about its axis will still continue. When the tubes are placed in a nearly upright posture leaning to the right hand, the motion will be from east to west; but if they lean to the left, the motion will be from west to east; when the nearer they are placed to the perfectly upright posture, the less the motion will be either way.

If the tube be placed horizontally on a glass plane, the fragment, for instance, of coach window-glass, instead of moving towards the fire, will move from it, and about its axis, in a contrary direction to what it had done before. Nay, it will recede from the fire and move a little upwards, when the plane inclines towards the fire.

Neither the draught of air up the chimney, nor attraction or repulsion, are the cause of these phenomena. It seems rather owing to the swelling of the tube towards the fire; for allowing such swelling, gravity must pull the tube down, when supported near its extremities horizontally; and a fresh part being exposed to the fire and swelling out again, must fall down again, and so on successively; which will produce a rotatory motion towards the fire.

If the tube be supported by two other tubes, and these be brought near to each other, and to the centre of the supported tube, then its parts hanging over on each side, being larger than the part which lies between the supporters, will

by their weight, pull downwards, and consequently force the middle part, resting upon its two props, upwards: and being less advanced towards the fire, as being less heated, will, by their oblique situation, pull the middle part backwards also from the fire, which will cause a rotatory regressive motion, quite contrary to what the tube had when supported near its extremities. And when a single tube lies inclining opposite to the fire, either to the right hand or to the left, out of a plane perpendicular to the surface of the fire, gravity will not permit the curved part to rest, but pull it down till it coincides with a plane perpendicular to the horizon; and consequently, as new curves are generated, new motions will be so too; that is, the tube will be made to move about its axis, with this difference, when the tube inclines to the right hand, the motion will be from east to west; when to the left hand, from west to east. The justness of this reasoning is made manifest, by bending a wire, and supporting it first near its extremities, then near its centre on each side, afterwards inclining it to the right and to the left; the bending in every case representing the curved part of the tube next the fire. This solution of the phenomena is rendered the more probable from hence, that when four supporters were made use of, one at each extremity, and two near the middle, there was no motion at all, either backward or forward. Nor does the increase of contact hinder the motion, because the plate of glass was so broad as to have a much greater contact with the tube, and yet both the rotatory and regressive motions were manifest.

These experiments succeeded best with tubes about twenty or twenty-two inches long; the diameter about one-tenth of an inch: and they had in each a pretty strong pin fixed in cork, for an axis to roll with on the supporting tubes. Phil. Trans. N^o 476.

GLASS receivers, how to cement the cracks of. See CEMENT and RECEIVER.

GLASS, how to take the impression of antique gems in. See GEM.

The property which glass possesses in common with other substances of being expanded by heat, and contracted by cold, was long ago observed and evinced by Mr. Hook. See Birch's Hist of the Royal Society, vol. i. p. 411. See THERMOMETER.

GLASS, *Laws relating to.* No glass shall be imported into Ireland, other than the manufacture of Great Britain, on pain of forfeiting the same, and ship, and 10s. a pound. 19 G. II. c. 12. If any foreign glass shall be landed or unshipped before entry and payment of the duties, or without warrant from the proper officer, the same shall be forfeited, or its value; and the master or other person having command of the vessel, and every other person concerned in such landing or unshipping, shall forfeit 100*l.* 17 G. III. c. 39. And by 38 G. III. c. 33. for preventing the fraudulent importation of glass, every package containing any plate or plates of glass unframed, being *plate, crown, or sheet glass*, which shall be imported, or brought into this kingdom for exportation, shall be marked on the outside in Roman letters four inches long at least, with the word GLASS, on pain of forfeiture, together with the package, and all goods contained in it. The master of the vessel importing such package, shall, in reporting his cargo, express every such package of glass, on pain of forfeiting the same, and also 100*l.* Nor shall any such package be imported, which shall not contain 500 weight, on pain of forfeiture; but not extending to any plate of glass 60 inches in length or upwards, on account of the package not being marked. By 43 G. III. c. 69. For every 100 weight of materials, &c. that shall be made use of in Great Britain for the making of *plate or flint glass*,

or *enamel, stained, or paste glass, or phial glass*, shall be paid by the maker thereof 1*l.* 12*s.* 8*d.*; for every hundred weight of materials used in making *spread window glass*, commonly called *broad glass*, 8*s.* 2*d.*; for every hundred weight of materials used for making all other *window glass* (not being spread glass), whether flashed, or otherwise manufactured, commonly called *crown glass*, or *German sheet glass*, 1*l.* 4*s.* 6*d.*; for every hundred weight of materials used in making *common bottles* (not being phials), and of vessels used in *chemical laboratories*, and of *garden glasses*, and of all other vessels or utensils made of common bottle metal, 4*s.* 1*d.*; and for every hundred weight of plate glass, and of all other glass manufactures, which shall be imported into Great Britain, the same not being flasks, in which wine or oil is imported, nor foreign green glass bottles, nor Irish glass, or glass manufactures imported directly from Ireland, to be paid by the importer before the landing thereof, 2*l.* 2*s.* And any glass-maker shall take out a licence, for which he shall pay 10*l.*, to be renewed annually ten days at least before the end of the year, on the penalty of 50*l.* 24 G. III. c. 41. 43 G. III. c. 69. The place of making glass shall be entered, before the commencement of manufacture, and all work-houses, furnaces, pots, annealing arches, &c. &c. on pain of forfeiting 200*l.* 19 G. II. c. 12. 17 G. III. c. 39. 35 G. III. c. 114. Officers may enter and survey, and mark pots; and any person counterfeiting or altering such mark, or conniving at its being done, shall forfeit 500*l.*; or defacing, or causing to be defaced or obliterated such mark, incurs a forfeiture of 200*l.* 35 G. III. c. 114. Notice of beginning to work shall be given in writing, on pain of forfeiting 20*l.* 19 G. II. c. 12. And notice of filling every pot shall be given twelve hours before the operation is begun, on pain of 50*l.* 19 G. II. c. 12. 17 G. III. c. 39. Annealing arches are to be made of a certain form, and numbered, on pain of forfeiting 100*l.* Annealing arches are to be locked, except at certain times; and breaking such lock, &c. incurs a forfeiture of 200*l.* 35 G. III. c. 114. The same act comprehends several other provisions, enforced by certain penalties. Bottles are not to be removed till they are weighed, (penalty 100*l.*) which are to be kept separate from those that are unweighed, on pain of forfeiting 50*l.* No phials, &c. are to be made in places entered for making common glass bottles, on pain of forfeiting 200*l.* Entry shall be made of the glass manufactured every month within the bills, and elsewhere every six weeks, on pain of 20*l.* The maker, within the bills, shall, in four weeks, and elsewhere in six weeks after entry, pay off the duties, on pain of double duty. If glass, shipped for exportation, shall be re-landed, it shall be forfeited, and every person concerned therein shall forfeit 100*l.* 17 G. III. c. 39. For the drawbacks on exportation of glass, see 43 G. III. c. 69. Obstructing officers in securing the duties incurs a forfeiture of 50*l.* 19 G. II. c. 12. 17 G. III. c. 39. Penalties are appropriated, half to the use of the king, and half to him that shall sue.

GLASS-Carrick Point, in *Geography*, a cape of Ireland, on the eastern coast of the county of Wexford. N. lat. 52^o 35'. W. long. 6 12'.

GLASS-Case, in *Gardening*, a light sort of erection formed with glass sashes in proper frame-work, mostly upright in the front part and ends, but sloping at top from a back wall, or other convenient building, to the fore-part; the front, top, and both ends being of glass-work. The situation for this purpose should face the south, in order to have the full influence of the sun. Constructions of this nature are useful for protecting many sorts of curious tender plants in winter which want it only occasionally from severe frost, and other similar causes.

Buildings of this kind may be constructed, occasionally, either against some ready-built south wall, which serves for the back, all the other parts forward being wood-work and glass; or detached in a similar situation, so as that the whole front may stand to the south; the back being framed of brick-work, &c. or of wood double planked; but the former is preferable; the whole being generally ranged lengthways, nearly in an east and west direction.

The dimensions may be from five or six, to eight or ten feet in width, by ten, fifteen, or twenty feet in length or more, as may be required; and from six or eight, to ten feet high behind, by five or six to seven or eight in the front, both ends in proportion with the top, sloping gradually, as just noticed, from the back, having an entrance, or door, in front, or at one end. The glass-work should be made to slide readily backwards and forwards.

Sometimes fire-flues are carried along the back and front internally, proceeding from an external furnace, for occasional fire-heat in winter, which render them more convenient and useful for different purposes.

These cases, as mentioned above, are used as preservative departments, in which to winter many sorts of curious exotics of the hardier green-house kinds, which only want protection from severe cold, as well as many choice kinds of the open ground, which are rather tenderish in their minor growth, or any other particular or curious hardy plants, whether flowers, shrubs, or young trees, especially the choice evergreen kinds, which require effectual protection from the ravages of rigorous frosts or cutting winds, in winter or early spring; and, at the same time, in mild open weather, to enjoy the full air by opening the glasses; all which, being in pots, can be readily placed in this preservative at the approach of severe weather, and be thus kept in good condition till settled weather in spring, &c.; then removed into the full air. In summer and autumn, when unoccupied in this way, these cases may be of some utility to place some curious kinds of tender plants in, when in flower for seeding, to guard them from heavy or incessant rain, or cold night dews in autumn, which, in many sorts retard, or sometimes wholly frustrate their production of good seed, as in many sorts of curious tender annuals; particularly the fine double balsams, cock's-combs, tricolors, double stramoniums, diamond ficoides, and various others.

They are also capable of being used in spring and the early part of summer, as in April, May, and June, as a kind of drawing-frames, for some particular sorts of curious annuals to bring them to a tall growth, such as the large or giant cock's-combs, tricolors, double stramoniums, double-striped balsams, egg-plants, &c. the plants being first raised in hot-beds, under garden-frames, till of twelve or fifteen inches growth, then a hot-bed made in the glass-case, earthed at top, and the plants in pots, singly plunged into the earth of it; the glasses, in these cases, should be shut close, only a necessary admission of fresh air being given every day, by which they run up to a tall stature in the best perfection of strength for flowering. See *Annual PLANTS*.

These sorts of glass-cases are also sometimes made use of as a kind of appurtenances to hot-houses, or stoves, detached from them, having, as observed above, internal flues for fire-heat, when necessary, serving as preservatives for many sorts of exotics, which are tenderer than common green-house plants, but do not require the constant full heat of the more tender hot-house kinds, but only the assistance of moderate fire-heat in winter, in cold nights, or when very damp, cloudy, foggy-weather and severe frosts prevail. They are sometimes used in the business of forcing different kinds

of flowering plants and esculents, either by means of an internal bark-bed, or flues for fire-heat.

When intended for this purpose, it is convenient to have both an internal pit for a bark-bed, and flues for fire-heat, in order to use either separately, or sometimes both, as may be found necessary. See *HOT-HOUSE*.

GLASS-Faces, in *Mining*, is a term for the polished surfaces, or slickensides, which are found in some of the mineral veins in Derbyshire, something like the polishing which is seen often on the sides of faults. See *SLICKENSIDE*.

GLASS Isle, called also *Scalpey*, in *Geography*, one of the Hebrides, near the N.E. extremity of Harris. It is a small, low, round island, covered with heath, and indented by the sea. Near its western extremity are two good natural harbours, and on its east point a light-house was erected A. D. 1788. It lies at the entrance of East Loch Tarbot. N. lat. 57° 50'. W. long. 6 40'.

GLASS-Lead, in *Mining*, according to Mr. Mawe, "*Mineralogy of Derbyshire*," p. 105, is an opaque waxy lead-ore found in that county; sometimes also it is transparent and crystallized, appearing as though it had undergone the action of fire.

GLASS-Lough, in *Geography*, a lake of Ireland, in the county of Monaghan, near which is a village of the same name, about five miles from the town of Monaghan. The lake contains 120 acres; and a wood, spreading over a fine bold hill, hangs down to the water in one deep shade, the effect of which is remarkably beautiful. The county around is very fine. Young.

GLASSES are distinguished, with regard to their form, use, &c. into various kinds, as drinking-glasses, optic-glasses, looking-glasses, burning-glasses, &c.

GLASSES, Drinking, are simple vessels of common glass or crystal, usually made in form of an inverted cone.

Each glass consists of three parts, *viz.* the calyx or bowl; the bottom, and the foot; which are all wrought or blown separately.

Nothing can be more dexterous and expeditious than the manner wherein these parts are all blown; two of them opened, and all three joined together. An idea is only to be had thereof, by seeing them actually at work.

The glasses chiefly used in England are made of the ashes of fern; crystal glasses being less frequent in use. The exceeding brittleness of this commodity, notwithstanding the easy rate of each glass, renders the consumption thereof very considerable. For the method of gilding the edges of drinking-glasses, see *GILDING on Enamel and Glass*.

GLASSES, Metallic, in *Chemistry*, are the oxyds, or sometimes the sulphuretted oxyds of the different metals, vitrified by heat.

GLASSES, Optic, are those made use of to strengthen, improve, or preserve the sight. See *OPTIC Glasses*.

GLASSES, Convex. See *CONVEXITY*.

GLASSES, Concave. See *CONCAVE*.

GLASS, Infernal. See *INFERNAL*.

GLASSES, Lenticular. See *LENS*.

GLASSES, Meniscus. See *MENISCUS*, &c.

GLASSES, Plain. See *PLAIN Glass*.

GLASSES, Plano-Concave. See *PLANO-CONCAVE*.

GLASSES, Plano-Convex. See *PLANO-CONVEX*.

GLASSES, Telescope. See *TELESCOPE*.

GLASS, Object. See *OBJECT-Glass*.

GLASSES, Eye. See *EYE-Glass*.

GLASS, Magnifying. See *MAGNIFYING*.

GLASS, Multiplying. See *MULTIPLYING*.

GLASSES, Musical. See *ARMONICA*.

GLASS, *Perspective*. See PERSPECTIVE.

GLASS, *Looking*. See LOOKING-Glass, MIRROR, and FOLIATING.

GLASS, *Burning*. See BURNING-Glass.

GLASS, *Weather*. See WEATHER-Glass.

GLASS, *Cupping*. See CLIPPING-Glass.

GLASS, *Window*. See WINDOW and GLASS, *supra*.

GLASS, *Axis of a*. See ANIS.

GLASS, *Pole of a*. See POLI.

GLASS, *Hour*. See HOUR-Glass.

GLASS, *Tin*. See BISMUTH.

GLASS, *Watch*. See WATCH.

GLASS-Wort. See KALI.

GLASS-Wort, *Berry-Bearing*, in *Botany*. See ANABASIS.

GLASS-Wort, *Jointed*. See SALICORNIA and KELP.

GLASSHATTEN, or GLASITTEN, in *Geography*, a town of Hungary, celebrated for its hot-baths, and having near it some rich gold mines; 7 miles from Schemnitz.

GLASS-HOUSE BAY, a bay on the E. coast of New Holland, between cape Moreton, and the Glas-houses, which are three hills, so called by captain Cook in 1770, situated in S. lat. 26° 28'.

GLASSHUTTEN, a town of Saxony, near which is a silver mine; 8 miles S. of Dresden.

GLASSIUS, SOLOMON, in *Biography*, was born in the year 1593, and it is supposed he was educated at Jena, where he was admitted to the degree of doctor of divinity, and for some time filled the theological chair with distinguished reputation. He was appointed superintendent of the churches and schools in the duchy of Saxe-Gotha, and exercised the duties of his function with prudence, equity, and impartiality. He died at Gotha in 1656, and left behind him, as a memorial of his fame and learning, a work published in quarto in 1623, entitled "Philologia Sacra," which is pronounced by Mosheim an inestimable and immortal work, than which none can be more useful for the interpretation of Scripture, as it throws much light upon the language and phraseology of the inspired writers. He was author, likewise, of "Onomatologia Messicæ Prophetica;" "Chritologia Mosica et Davidica;" "Esegesis Evangeliorum et Epistolarum," and some other pieces. Moreri.

GLASSNEVIN, in *Geography*, a village near Dublin, in Ireland, remarkable for the very extensive and valuable botanical garden belonging to the Dublin society. See DUBLIN Society.

GLASSY HUMOUR. See EYE and VITREOUS.

GLASTONBURY, in *Geography*, a market town in the hundred of Glaston, and county of Somerset, England, is situated on the great road from Wells to Exeter. The site occupied by it was originally called Ynyfwytryn, or the Glas Island, and in Latin Avalonia.

A town is said to have been built here, and largely endowed by king Ina about the year 708: in the next century it was laid waste by the Danes, and rebuilt by king Edmund, who granted it many additional privileges. In 1184 it was destroyed by fire, and was again restored by the munificence of Henry II. The chief celebrity attached to the town was derived from its abbey; which, during six centuries, surpassed in authority and revenues every other in England, excepting that of Westminster. The abbots enjoyed a state of regal splendour, with an income of nearly 40,000/ per annum, had the title of lords, and sat with the barons in parliament. The abbey and its offices occupied an area of land of nearly sixty acres within the walls.

The last abbot, Richard Whiting, who was the sixtieth

in succession, refusing to surrender his abbey to king Henry VIII. was, with two of his monks, drawn on a hurdle to the Torr, near the town, and there hanged: the abbot's head was set on the gate of the abbey, and his quarters were sent to Bath, Wells, Bridgewater, and Ilchester.

It being traditionally recorded, that this was the burial place of king Arthur, Henry II. ordered a search to be made, when a leaden cross was discovered with a Latin inscription in rude characters, thus translated; "Here lies the famous king Arthur, buried in the isle of Avalon." Beneath was found a coffin hollowed out of the solid rock, wherein were the bones of a human body, supposed to be those of Arthur; which were then deposited in the church under a monument. Scarcely any vestige remains of these extensive buildings, except some ruins of the church, part of a chapel dedicated to Joseph of Arimathea, and the abbot's kitchen, which seems to be of a more recent structure than the other offices.

Among the religious relics with which the town and its environs abound, the most conspicuous is the Torr, or St. Michael's Tower (on which abbot Whiting was executed,) standing on an eminence east of the town, where was formerly a small oratory, dedicated to St. Michael the archangel.

The town of Glastonbury consists of two principal streets, and is divided into two parishes, St. John's and St. Benedict's. It was formerly a parliamentary borough, but was disfranchised on the confiscation of the abbey in 1539. A charter of incorporation was granted by queen Anne, by which the civil government was vested in a mayor, a justice, eight aldermen, and sixteen burgessees. The principal buildings are the two parish churches, two meeting-houses, two alms-houses, and a free school. The George, a respectable inn, was anciently an hospital for the accommodation of pilgrims resorting to the shrine of St. Joseph. In the centre of the town was formerly a large stone cross, originally appropriated to shelter persons who attended the market. It was taken down about five years ago; but a plate and description are preserved in the first volume of the Architectural Antiquities of Great Britain. Glastonbury is 130 miles distant from London; has a market on Tuesdays, and four annual fairs: the population return, in 1801, was 410 houses, and 2035 inhabitants, of whom only 104 were employed in trade, which is chiefly that of manufacturing worsted stockings.

South-west of the town is Wearyall hill, so called from a tradition that St. Joseph and his companions, weary with their journey, rested here; and that St. Joseph stuck his hawthorn staff in the earth; it took root, and constantly budded on Christmas day. This famous thorn had two trunks, of which one was destroyed in queen Elizabeth's reign, the other in the great rebellion: but there are trees, originally from the old stock, still growing in the gardens of Glastonbury, and in various other parts of the kingdom. Collinson's Hist. Somersetshire, 3 vols. 4to. Maton's Western Counties, 2 vols. 8vo.

GLASTONBURY, a township of America, in the county of Bennington, and state of Vermont; having only 48 inhabitants.—Also, a handsome little town in Hartford county, Connecticut, situated on the E. side of Connecticut river, opposite to Weathersfield; containing 2718 inhabitants.

GLASTONBURY Thorn, in *Botany*. See MESPILUS.

GLASTUM, from the German word *Glast*, an old name for Woad; (see ISATIS.) Hence several plants have the specific name of *glastifolia*, on account of the similitude of their leaves to that herb.

GLATT,

GLATT, in *Geography*, a river of Germany, which runs into the Neckar, 2 miles N. from Sultz in Wurtemberg.

GLATT, or *Glatton*, a town of Germany, in the county of Fugger; 4 miles E. of Dornstetten.

GLATT, a river of Switzerland, which runs into the Rhine; 2 miles below Eglisau.

GLATTEN, a mountain of Switzerland; 10 miles S. S. W. of Glaris.

GLATZ, a principality of Silesia, bordering on Bohemia, and surrounded by mountains. The internal territory is mountainous, intersected with vallies, meadows, corn-fields, woodlands and small rivers. It produces wheat, generally sufficient for its inhabitants, and has pasture for a great number of cattle. It contains quarries of mill-stones, free-stone, and marble; as well as a great variety of precious stones. It has also mines of coal, copper, and silver; with several mineral springs. From 1561 to 1742, Glatz was annexed to the crown of Bohemia; in 1742 it was ceded by the empress Maria Theresa to Frederick II. king of Prussia, and his heirs. It forms one circle, divided into six districts.

GLATZ, the capital of the principality above-mentioned, is situated on the Neisse, and built on the side of a mountain, having upon its summit a strong castle. The town contains about 400 houses within the walls, and as many in four faubourgs. It is a place of considerable trade. It has been frequently pillaged and burnt; 54 miles E. of Breslau. N. lat. 50° 16'. E. long. 16° 26'.

GLATZ *Kogel*, a mountain of Austria; 12 miles S. of Steyr.

GLAVACIA, a town of Walachia; 35 miles W. of Bucharest.

GLAUBER, JOHN RODOLPH, in *Biography*, a celebrated chemist of Amsterdam, who was esteemed the Paracelsus of his age, was born in Germany in the beginning of the sixteenth century. He travelled much in the pursuit of chemical knowledge, and collected many secret processes; and his experiments contributed to throw much light on the composition and analysis of the metals, inflammable substances, and salts. In fact he passed the greater part of his life in the laboratory. He did not always see the proper application of his own experiments, and vainly fancied that he had discovered the panacea, and the philosopher's stone, which were at that time objects of pursuit; and the disappointment of many persons, who had been seduced by his promises, contributed to bring the art of chemistry into contempt. His theory is full of obscurity; but his practice has perhaps been misrepresented by those who listened to his vain and pompous pretensions; and who accuse him of a dishonourable traffick, in first selling his secrets to chemists at an enormous price, of again disposing of them to other persons, and lastly, of making them public in order to extend his reputation. Glauber published about twenty treatises; in some of which he appears in the character of physician, in others in that of an adept or metallurgist; in the latter he most particularly excelled. However, it would be unjust not to give him the praise of acuteness of mind, of facility and address in the prosecution of his experiments, and of extensive chemical knowledge. He was the inventor of a salt, which to this day retains his name in the shops of our apothecaries. The works of Glauber have appeared in different languages; the majority of editions are in German, some in Latin, and others in French. A collection of the whole in Latin was published at Frankfort in 1658, in 8vo. and again 1659 in 4to. An English translation was published by Christopher Pack, London, 1689, in folio, Eloy. Dict. Hist.

GLAUBER Salt, native or natural, in *Mineralogy*, the sulphat of soda of chemists, was discovered by baron Born in the salt mines of Upper Austria; after which Monnet, Volta, Suckow, Gmelin, Breislak, Pallas, and others have added to the list of the localities of this saline substance, which is more frequently found in a native state than has been supposed by some writers. It generally occurs as mealy efflorescence; sometimes massive, seldom stalactitical or crystallized: in which latter case the crystals are described as acicular and as six-sided prisms, more or less flatly acumined by three planes, set on the lateral edges, or sometimes on the lateral planes: they are shining; their internal lustre is vitreous. Fracture of the crystals small conchoidal. It varies from transparent to opaque according to its freshness. It is brittle. Its taste is a mixture of salt and bitter. Besides in the above forms, it occurs also, and most frequently, dissolved in certain mineral waters, in the neighbourhood of salt mines and salt lakes, where also the efflorescence is mostly found on moorish ground, sand stone, marble slate, and new walls. For the chemical character of this salt, see SODA, Sulphat of.

Brongniart has given the most complete list of the localities of Glauber salt. In solution it occurs in the waters of several lakes of Austria and Lower Hungary, especially in that of Neufiedel, between the counties of Oedenburg and Wieselburg. It is met with in Switzerland; in Spain, round a source in the neighbourhood of Aranjuez, and near Vacia-Madrid, as efflorescence, at the bottom of a ravine: the source which issues from the ravine contains a great proportion of this salt. Also the water of the Tagus is said to hold it in solution. In France it has been found near Grenoble. The steep sides of the Solfatara of Pouzzole yield this salt, in one place, on the north side. It is common in the lakes of Siberia; and it has been observed that the bottom of the lake Gunikoi, between Tojon and Ilynskoy, is covered with a crust of Glauber salt as soon as the temperature is below the freezing point. Pallas tells us that the apothecaries of Orenburg annually collect a quantity of this salt, which is deposited in autumn at the bottom of a lake between the Tobol and Mioss. It is also found in a lake near Gourief; in another between Utoiska and Miniufkaia, in the neighbourhood of Enissey; likewise at the foot and in the middle of the chains of the Ural mountains, near Theliabinsk: in the last of these places, the salt issues in the spring season out of the earth in the form of efflorescence or froth. The clayey soil of that neighbourhood does not contain any Glauber salt; whence this is supposed to be formed, in the same manner as salt-petre is, at the surface of the earth, and by the action of the atmosphere. Lastly, this salt is also obtained from the alun-slate of Duttweiler, near Saarbrück, in the department of la Sarre, and from the alumiferous waters of Freyenwalde, in Brandenburg.

GLAUBER'S Salt, in *Chemistry* and *Materia Medica*. See Sulphat of SODA.

GLAUBER'S Spirit of Marine Salt. See MURIATIC Acid.

GLAUBER'S Spirit of Nitre. See NITRIC Acid.

GLAUBERITE, a lately discovered mineral, belonging to the class of salts, and of which M. Brongniart has given the description and analysis. This substance (called glauberite by its discoverer, both in honour of the well-known Glauber, and on account of its containing a considerable quantity of the salt which bears the name of that alchemist) was found among pieces of rock-salt brought from Ocaña in New Castile, in crystals resembling those of thumston, or axinite. They were (chiefly on account of their mode of occurring) mistaken in Spain for gypsum-crystals.

The form of these secondary crystals, is that of an oblique

very short prism with rhomboidal base. The planes of the base are generally smooth and shining; the lateral planes striated parallel to the edges of the base. Cleavage double, the one parallel to the bases, the other less distinct and parallel to the edges of the base; in all other directions the fracture is vitreous. Hence the primitive form is an oblique prism with rhomboidal base, the obtuse angles of which correspond with the obtuse angles of the secondary prism. The crystals are from topaze yellow to nearly colourless; they are transparent, and, provided they are kept dry, preserve their transparency and solidity though exposed to the air. Their hardness surpasses that of sulphat, but is inferior to that of carbonat of lime.

Exposed to an intense heat, the glauberite decrepitates and melts into a white enamel. Immersed in water, its surface is covered by a milk-white crust, which penetrates deeper and deeper, till the whole crystal is white and opaque throughout: taken out of the water and dried, the white crust crumbles into dust, leaving the nucleus, if there be any remaining, unaltered and perfectly transparent. Specific gravity about 2.73.

From M. Brongniart's experiments it appears, that glauberite is essentially composed of anhydrous sulphat of lime and of sulphat of soda, equally anhydrous. 2. That these two salts exist in this substance nearly in the following proportions:

Anhydrous sulphat of lime	-	-	-	0.49
Anhydrous sulphat of soda	-	-	-	0.51
			—	100

A trace of water, indicated by the calcination, is not brought into account, as little as the accidental admixture of a scarcely perceptible quantity of iron, to which the yellowish colour of this substance appears to be owing.

Mr. B. adds the following observations: the above-mentioned pieces of salt from Ocana, which contain this substance, have generally some clay adhering, which penetrates into the stræ of the surfaces, but seldom into the substance of the glauberite.

The efflorescence on glauberite, when moistened, and the property this salt possesses of becoming opaque in water, proceed from this, that the water, by dissolving the sulphat of soda, transforms the sulphat of lime into a spongy substance, and thus produces a phenomenon which is the reverse of that exhibited by the hydrophane.

The existence of native sulphat of soda, or Glauber salt, is well known to mineralogists, and, indeed, it has been met with in the neighbourhood of beds of rock-salt; but this was only as solution in the water of salt-springs, or as efflorescence near salt-mines: in a solid and crystallized state, entirely destitute of water of crystallization, and intimately united with selenite, it had never before been observed. Even the anhydrous sulphat of soda was almost entirely unknown, till Berthier proved that it constitutes nearly the fifth part of those hard scales found at the bottom of the pans in which the sea-salt is obtained by evaporation.

It remains to be ascertained, under which circumstances the rock-salt occurs which contains the glauberite, and particularly in what relation this latter stands to it, and whether it occur in the rents or on the surface of the beds. See Journal des Mines for 1808.

Häuy places the glauberite separately at the end of the *substances acidifères*; and it appears to this mineralogist, that the integrant molecules of the two salts of which it is composed exist together in the glauberite. He refers, for an analogous combination, to Leblanc's experiments, according

to which a solution of sulphat of copper and sulphat of iron mixed, yielded crystals composed of these two substances, while their primitive form proved to be that of the latter, which had impressed on this mixture the character of its particular crystallization. The question, therefore, is, whether the glauberite be in a similar case. Its form has, indeed, nothing in common with that of the anhydrous sulphat of lime; but we are totally unacquainted with the crystalline form of the anhydrous sulphat of soda. But even if it should be found that in this case the two molecules combine in such a manner as to produce a third of a different form from either, this circumstance could, according to Häuy's opinion, not be adduced as an objection against the theory of crystallization, and must be considered as a problem, the solution of which is more interesting to the chemist than to the mineralogist.

GLAUBOTTE, in *Geography*, a town of Prussia, in Natanen; 14 miles S.E. of Bartenstein.

GLAUCEDO, in *Surgery*. See GLAUCOMA.

GLAUCHA, in *Geography*, a town of Saxony, in the lordship of Schonburg, on the Mulda, containing about 600 houses; the inhabitants are employed in the manufacture of stuffs; 46 miles W. of Dresden. N. lat. 50° 45'. E. long. 12° 25'.

GLAUCHE, a town of Germany, in the duchy of Magdeburg, adjoining to the town of Halle, but governed by its own magistrates; in which are four seminaries, where the languages, theology, mathematics, music, &c. are taught by 120 preceptors.

GLAUCION, in *Ornithology*, a species of *Anas*, the grey-headed duck. See DUCK.

GLAUCIUM, in *Botany*, is so named from its glaucous, or sea-green, colour. Whether the plant intended by Pliny be the Yellow Horned Poppy, according to the opinion generally received, or any maritime species of *Euphorbia*, seems a point not easily determined. Γλαυκίον of Dioscorides appears to be the juice of the first-mentioned in its wild state, though he compares it to his *μικρον κερδισιον*, (which is evidently the Yellow Horned Poppy itself,) saying the plant which yields the *γλαυκιον*, and grows at Jerusalem, has almost the leaves of the *μικρον κερδισιον*, but thicker, and spread on the ground, strong smelling, and more bitter, yielding plenty of saffron-coloured juice. Possibly this may refer to one of our other species of *Glaucium*, if not to the common wild *luteum*. Most commentators have taken *Argemone mexicana* for the plant of Dioscorides; but that is a tropical production, unknown in Europe, as we presume, previous to the discovery of America, though now naturalized in the East Indies; see ECHINUS. Neither does the above description suit this plant, for its leaves are much thinner than those of the Horned Poppy, and their juice pale yellow; nor are they spread on the ground. Matthioli seems to take the drug Gamboge for *γλαυκιον*, but this does not at all help us, as to the botanical question, nor has it any probability in its favour.—Tourn. Inst. 254. t. 130. Sm. Fl. Brit. 563. Prod. Fl. Græc. v. 1. 357. Juss. 236. Gartn. t. 115. (Chelidonium; Linn. Gen. 262. Schreb. 350. Willd. Sp. Pl. v. 2. 1141. Lamarck. Illustr. t. 450. f. 2. Mart. Mill. Dict. v. 2.)—Class and order, *Polyandria Monogynia*. Nat. Ord. *Rhæadæe*, Linn. *Papaveraceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of two ovate, concave, bluish, deciduous leaves, often tipped with a point near the summit. *Cor.* Petals four, large, roundish, slightly concave, nearly equal, with a shining spot near the base. *Stam.* Filaments numerous, shorter than the corolla, flat, incurved, rather dilated upwards; anthers erect, roundish, of two lobes. *Pist.* Germen nearly cylindrical, curved, longer than the

the stamens; style none; stigma with two or three lobes, downy. *Peric.* Pod linear, curved, very long, of two or three cells, and as many concave valves. *Seeds* numerous, globular, dotted. *Receptacle* linear, spongy, parallel to the valves, its surface cellular to receive the seeds.

Eff. Ch. Calyx of two leaves. Petals four. Pod superior, linear, of two or three cells and two or three valves. Seeds numerous, dotted.

Obs. This genus is very naturally distinguished from *Chelidonium* by its habit, and essentially characterized by having more than one cell in its pod, and no creel to its seeds.

1. *G. luteum*. Yellow Horned-Poppy. Scop. Carn. v. 1. 369. Gærtn. v. 2. 166. (*G. flore luteo*; Tourn. Inst. 254. *Chelidonium glaucium*; Linn. Sp. Pl. 724. Engl. Bot. 1. 8. *Papaver cornutum, flore luteo*; Ger. em. 367)—Stem smooth. Stem-leaves rounded, waved. Pods roughish with minute tubercles. Flowers stalked.—Native of sandy fea-shores throughout Europe, flowering in summer and autumn. *Root* perennial, tap-shaped. *Whole herb* roughish and very glaucous. *Stems* three feet high, spreading, branched, leafy, smooth. *Radical leaves* numerous, pinnatifid in a lyrate form; the rest rounded, wavy or sinuated, alternate, sessile, clasping the stem. *Flowers* solitary, on axillary or terminal stalks, two inches broad, of a full shining yellow. Their calyx is hispid and deciduous, and the petals last but one day. The *Pods* are often near a foot long, cylindrical, but compressed.

2. *G. fulvum*. Orange Horned-Poppy. Sm. Exot. Bot. v. 1. 11. t. 7. (*G. glabrum, flore phœniceo*; Tourn. Inst. 254? *Chelidonium corniculatum*; Donn. Cant. ed. 5. 131.)—Stem smooth. Stem-leaves rounded, waved. Pods rough. Flowers nearly sessile.—Supposed to be a native of the south of Europe, but we know it as a garden plant only. This differs from the former in the rather more blue cast of its herbage, nearly or quite sessile flowers, and smaller petals of a rich tawny orange-colour. We have thought the *root* annual, but we find it will survive a mild winter, about as well as the first species, which indeed is often killed, and never lives many years, at least in a garden. The *G. fulvum*, whether a distinct species or only a permanent variety, propagates itself by seed and remains unaltered. Its flowers, contracted with the leaves, have a singularly elegant effect. Their petals fall, in hot weather, before noon, but in the autumn will endure till the next morning, or longer, which is also the case when they are gathered and placed in a room.—If our quotation of Tournefort be right, our plant is figured in Lobel's *Icones* 271, f. 2, but not happily.

3. *G. rubrum*. Red Horned-Poppy. Sm. Prodr. Fl. Græc. v. 1. 357. (*G. orientale, flore magno rubro*; Tourn. Cor. 18)—Stem hairy. Stem-leaves pinnatifid, cut. Pod slightly hairy.—Gathered by Dr. Sibthorp by the way-side between Smyrna and Burfa, as well as in the isle of Rhodes. The *root* seems to be annual. *Stems* spreading, or nearly prostrate, clothed with soft expanded hairs. *Stem-leaves* elongated, and deeply pinnatifid, by which it essentially differs from both the preceding, as it does from the following in the soft hairs, instead of rigid bristles, which clothe the pods and stem. The *flowers* are stalked, with obovate petals, narrower and flatter than in either of the former, of a tawny red, with a violet spot on the claw. *Lobel's* *Papaver corniculatum phœniceum alterum*, Ic. 271, f. 2, agrees with this rather than with the last in its petals, and somewhat in its leaves; but if Tournefort be correct, it cannot be designed for the present species, which he gives in his *Corolla* as different from all he had previously enumerated, including Lobel's plant.

Vol. XVI.

4. *G. phœniceum*. Scarlet Horned-Poppy. Sm. Fl. Brit. 964. Prodr. Fl. Græc. v. 1. 357. Engl. Bot. t. 143. (*G. hirsutum, flore phœniceo*; Tourn. Inst. 254. *G. corniculatum*; Curt. Lond. fasc. 6. t. 32. *Chelidonium corniculatum*; Linn. Sp. Pl. 724. *Papaver cornutum, flore phœniceo*; Lob. Ic. 271, f. 1)—Found in cultivated fields in the south of Europe; a doubtful native of *Erignia*, though easily naturalized in a garden. Its annual flowering in summer and autumn, and grows rather more erect and bushy than the last, from which it differs in the remarkable-pretted bristles which clothe the *Pods*. The *petals* moreover are larger, rounder, and of a rich scarlet, though each marked with a violet spot like the last; and the *flowering* bristles on the *stem* are very different from the soft hairs of that species.

5. *G. violaceum*. Violet Horned-Poppy. Sm. Fl. Brit. 565. Prodr. Fl. Græc. v. 1. 358. (*G. flore violaceo*; Tourn. Inst. 254. *Chelidonium hybridum*; Linn. Sp. Pl. 724. Engl. Bot. t. 207.)—Leaves bipinnatifid. Linear. Pods of three valves. Native of hills in the south of Europe; rare in England. The *root* is annual. *Stems* branched, upright and bushy, a foot high, occasionally smooth, or clothed with spreading hairs, as is likewise the case with the *leaves*, which are twice, or even thrice, pinnatifid; their segments linear and acute. *Flowers* rather large, of a fine violet colour; their *Pods* of three valves, though scarcely three-celled, except in an early stage of their formation.

GLAUCIUM, in *Ornithology*, a name given by Brisson to the ANAS Fuligula or tufted duck. See DUCK; and also to the ANAS Marila, or scaup-duck. See DUCK.

GLAUCOMA, or GLAUCOSIS, a term, in *Surgery*, importing, with the Greeks, according to Mr. Samuel Sharp, what the Latin writers understand by *ſphæra*, and what we call a cataract. This disease, as we have elsewhere explained, is an opacity of the crystalline lens. (See CATARACT.) Maître-Jean, St. Yves, and other oculists, however, think, that glaucoma is a cataract complicated with the gutta serena, or an insensible state of the retina and optic nerve. (See GOTTA SERENA.) The word is derived from *γλαυκος*, blue, the pupil frequently having that colour. Some writers have regarded glaucoma as a defect of sight, originating from an opaque, or otherwise morbid state of the vitreous humour. Such a case is uncommon; but were an opacity of this kind to invade vision, an endeavour should be made to disperse it with small doses of calomel, and by exposing the eye to the vapour of ether. In the event of these means failing, the opacity might be broken and disturbed with a couching-needle. The fungus hæmatodes of the eye must be discriminated. See FUNGUS.

GLAUCOPIS, in *Ornithology*, a genus of the order PISCÆ. The bill is incurvate and arched; the lower mandible shorter, and carunculate beneath at the base; nostrils depressed, and half-covered by a firm but cartilaginous membrane; tongue subcartilaginous, divided at the end, and ciliated; legs formed for walking; toes three before and one behind.

The only species of this extraordinary genus at present known, is the wattle-bird of Dr. Forster, described in the Voyages of Captain Cook, and which appears from the later observations of other naturalists, to be exclusively confined to the Australasian regions. Its *beak* is equal to that of the jay, the length from the bill to the tail seven inches. The bill remarkably strong, an inch and a quarter in length, and of a black colour. The nostrils are situated in a hollow at the base of the bill, and are half-covered by a membranous cartilage which falls over as a cover. Its wings

are pendent from the base of the lower mandible on each side, and in texture resemble the wattle of the common cock; the colour at first blue, and afterwards fine orange. The irides fine blue. From the forehead to the eye the colour is deep black: the other parts of the plumage dark ash-colour. The tail long, wedge-shaped, and composed of twelve feathers. Legs long, and the hind claw much longer than the rest.

This bird inhabits New Zealand, where it subsists on berries and insects, and is sometimes seen perched on trees, though rarely, as it is usually seen walking on the ground; its note is a kind of whistling or rather murmuring noise; and the flesh flavoury and delicate.

GLAUCUM, in *Ancient Geography*, a promontory of the Libyan nome, on the confines of Marmarica and Egypt, upon which was a town of the same name. Ptolemy.

GLAUCUS, a river of the Peloponnesus, in Achaia, near Patras. Pausanias.—Also, a river of Asia Minor, in Lycia, having its mouth N. E. of the town of Telmissus, in the gulf of Glaucus.—Also, a river of Asia, in the territory of Colchis, where it discharges itself into the Phasis. Pliny.—Also, a gulf of Asia Minor, in a direction from N. W. to S. W. More anciently this gulf was denominated the gulf of Telmissus, from the name of the town, situated near its termination in the eastern part of it.

GLAUCUS, in *Ichthyology*, a species of *Chatodon*; which see.—Also, a species of *Scomber*.—Also, a species of *Falco*, which see respectively.

GLAUX, in *Botany*, so called by Pliny, and Γλαυξ by Dioscorides, is of uncertain derivation, though some have deduced its name from γλαυξ, milk. Most probably the word *glaucous* is similarly derived, as it conveys the idea of a milky green colour.—Linn. Gen. 114. Schreb. 159. Tourn. 60. Willd. Sp. Pl. v. 1. 1210. Sm. Fl. Brit. 268. Mart. Mill. Dict. v. 2. Lamarek Dict. v. 2. 722. Juss. 333.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Salicariae*, Juss.

Gen. Ch. *Cal.* none: unless the corolla be considered as such. *Cor.* of one petal, five-cleft, bell-shaped, erect, permanent, with obtuse revolute lobes. *Stam.* Filaments five, awl-shaped, erect, the length of the corolla; anthers roundish. *Pist.* Germen ovate; style filiform, as long as the stamens; stigma capitate. *Peric.* Capsule globose, pointed, of one cell, with five valves. *Seeds* five, roundish; receptacle very large, globose, hollowed for the seeds.

Eff. Ch. Calyx of one leaf. Corolla none. Capsule of one cell, with five valves and five seeds.

1. *G. maritima*. Black Salt-wort. Linn Sp. Pl. 301. Engl. Bot. t. 13. This is the only species known, being very frequent in salt-marshes throughout Europe, and flowering in summer. The root is perennial and creeping. Stem about four inches high, erect, somewhat branched, thickly covered with ovate, sessile leaves, and flesh-coloured, purplish, or whitish flowers. Dr. Withering has remarked that cows eat this herb, and that it is used for a pickle, being found every where from Lapland to the Archipelago. The description in Dioscorides, book 4. chap. 141. is so exact that it is impossible to be mistaken; yet we do not find this plant in the Prodomus Floræ Græcæ, because Dr. Sibthorp did not himself observe it in his journey.

GLAZIC, in *Geography*, a small island in the English Channel, near the coast of France. N. lat. 47° 26'. W. long. 2° 56'.

GLAZIER, an artificer or dealer in glass.

GLAZING. The Roman method of glazing some of their urns might give our workmen a hint toward a method greatly superior to any thing now in practice for the glaz-

ing of earthen-ware. There is a sort of red urns found in Yorkshire, which are, instead of glazing, covered all over inside and out with a fine coral-coloured varnish, that gives them a beauty, which no earthen-ware of our times can attain; and is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more safe and wholesome; and being well known to be a vapourable metal, and its fumes very noxious, there is great reason to suspect that it must be unwholesome when brought to the fire. This ancient glazing seems to have been done either by the brush, or else by dipping, for both the inside and outside are varnished with equal regularity; and something may be guessed at as to the materials they used in it, from what Pliny has left us. This author occasionally observes, that such earthen-ware as was painted with bitumen never lost its beauty; and afterwards, that it was a custom to cover over whole statues with this sort of glazing, which he observes did not only make a smooth coat, but sunk into the matter of the stone or earth, and therefore this could not be likely to crack and fly off like our lead-coats on plates, &c. which is merely a crust laid over them. Hook's Philos. Collect. p. 89.

A common glazing for any kind of earthen-ware may be made of white sand forty pounds, of red-lead twenty pounds, of pearl-ashes twenty pounds, and of common salt twelve pounds. Powder the sand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for some time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for use, temper it with water. The proportion of these ingredients may be occasionally varied. We may observe, in general, that lead ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. See *COLICA Dammoniorum*.

A transparent glazing may be prepared, without lead, by calcining forty pounds of white sand, twenty-five pounds of pearl-ashes, and fifteen pounds of common salt; and proceeding as before: and a more perfect transparent glazing may be made of sand forty pounds, of wood-ashes perfectly burnt, fifty pounds, of pearl-ashes ten pounds, and of common salt twelve pounds. The following recipes are taken, for the most part, from Kunckel, who says that they are the true glazings used at Delft, and other Dutch manufactories.

GLAZING, *Black*, is made of eight parts of red-lead, iron filings three, copper-ashes three, and zaffre two measures. This, when melted, will make a brown black; and if you want it blacker, add more zaffre to it.

GLAZING, *Blue*, is thus prepared: take lead-ashes, or red-lead, one pound, clear sand, or powdered flints, two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glass half a pound, zaffre half a pound: mix them well together, and melt them for several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffre, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last recipe. Or, take two pounds of calcined lead and tin, add five pounds of common salt, five pounds of powdered flints, and of zaffre, tartar, and Venetian glass, each one pound. Calcine and fuse the mixture as before.

Or, again, take of red-lead one part, of sand three parts, and of zaffre one part. For a violet blue glazing, take four

GLAZING.

ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

GLAZING, Brown, is made of red-lead and flints, of each fourteen parts, and of manganese two parts, fused: or, of red-lead twelve parts, and manganese one part, fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white glass, of each one part, twice fused.

GLAZING, Flesh-coloured, is made of twelve parts of lead-ashes, and one of white glass.

GLAZING, Gold-coloured. To make gold-coloured glazing, take of litharge three parts; of sand, or calcined flint, one part: pound, and mix these very well together; then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtil powder, which moisten with a well saturated solution of silver; make it into a paste, which put into a crucible, and cover it with a cover. Give at first a gentle degree of fire; then increase it, and continue it till you have a glass, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with some beer, so that by means of an hair pencil you may apply it upon the vessels, or any piece of earthen ware. The vessels that are painted or covered over with this glazing, must be first well heated, then put under a muffle; and as soon as the glass runs, you must smother them, by holding them over burning vegetables, and take out the vessels. Mr. Heinsius of Petersburg, who sent this receipt to the Royal Society, uses the words *afflare debes sumum*, which is rendered *smother them*, in the Transactions, Phil. Trans. N^o 465. § 6.

Kunckel gives several preparations for a gold-coloured yellow glazing. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of saffron of Mars; by again melting the powdered mass, and repeating the operation four times; or, by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of scales of iron half an ounce: or by calcining and fusing together eight parts of red-lead, six parts of flints, one part of yellow ochre, one part of antimony, and one part of white glass. A transparent gold-coloured glazing may be obtained by twice fusing red-lead and white-flints, of each twelve parts, and of filings of iron one part.

GLAZING, Green, may be prepared of eight parts of litharge, or red-lead, eight parts of Venice glass, four parts of brass-dust, or filings of copper; or, of ten parts of litharge, twelve of flints or pebble, and one of *as ustum*, or copper-ashes.

A fine green glazing may be produced by using one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian glass; or by fusing one part of white glass, the same quantity of red-lead, and also of filings of copper; powdering the mass, and adding one part of Bohemian granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any of the yellow glazings with equal quantities of the blue glazings; and all the shades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

GLAZING, Iron-coloured, is prepared of fifteen parts of lead-ashes, or red-lead, fourteen of white sand, or flints, and five of calcined copper. This mixture is to be calcined and fused.

GLAZING, Liver-coloured, is prepared of twelve parts of litharge, eight of salt, six of pebble or flint, and one of manganese.

GLAZING, Purple-brown, consists of lead-ashes fifteen parts, clear-sand, or powdered flints, eighteen parts, manganese one part, and white glass fifteen measures; to which some add one measure of zaffer.

GLAZING, Red, is made of antimony three pounds, litharge, or red-lead, three, and rust of iron, one; grind them to a fine powder. Or take two pounds of antimony, three of red-lead, and one of calcined saffron of Mars, and proceed as before.

GLAZING, Sea green, is made of five pounds of lead ashes, one pound of tin-ashes, three pounds of flint, three quarters of a pound of salt, half a pound of tartar, and half a pound of copper dust.

GLAZING, White. A fine white glazing for earthen-ware is thus prepared: Take two pounds of lead, and one of tin; calcine them to ashes: of this take two parts, calcined flint, white sand, or broken white glass, one part, and salt one part: mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented, by procuring them in a proper state.

The white glazing for common ware is made of forty pounds of clear sand, seventy-five pounds of litharge, or lead-ashes, twenty-six of pot-ashes, and ten pounds of salt: these are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of fifty pounds of clean sand, seventy of lead-ashes, thirty of wood-ashes, and twelve of salt.

A very fine white glazing may be obtained by calcining two parts of lead, and one part of tin; and taking one part of this mass, and of flints and common salt, of each one part, and fusing the mixture. See *DELFT-WARE*.

A white glazing may be prepared by mixing one hundred pounds of masticot, sixty-pounds of red-lead, twenty pounds of calcined tin or putty, and ten pounds of common salt; and calcining and powdering the mixture several times.

GLAZING, Yellow, is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds: or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times: or, it may be made of fifteen parts of lead-ore, three parts of litharge of silver, and fifteen parts of sand.

A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of sand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white glass, one part of antimony, three parts of red-lead and one part of iron scales, and fuse the mixture: or, fuse sixteen parts of flints, one part of iron-filings, and twenty-four parts of litharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glass, and two parts of calcined tin. See *Gold-coloured GLAZING*.

GLAZING, Citron-yellow, is made of six parts of red-lead, seven parts of fine red brick-dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ash-hole of a glass-house furnace, and at last urged to fusion.

GLAZING of Delft-ware. See *DELFT-WARE*.

GLAZING of Porcelain. See *PORCELAIN*.

GLAZING of Stone-ware, and Queen's ware. See *PORCELAIN*.

GLAZING for Tobacco Pipes. See *TOBACCO-PIPES*.

GLAZING, in Painting, a term of the art, expressive of a peculiar mode or variety in the practice of it. It consists in laying a transparent colour, made very thin by a great quantity of oil, or other vehicle, over a solid body of opaque colour.

colour; and its intent is, to give a greater degree of clearness and brilliancy to the colour produced by this process, than can be obtained by mixing together in substance the two colours thus employed. In this mode their hues are blended, without disparagement of each other; whereas, in mixing them in the ordinary way, a certain diminution of their brilliancy takes place, produced by the dissimilar nature of their qualities.

Glazing appears to have been practised very early in oil-painting; and probably the use of varnishes over pictures painted with water-colours may have first shewn its utility. Indeed it could not fail to be the case, if the varnish employed happened to be tinged with any colour; for the lustre pictures acquired by that circumstance must be strikingly engaging: a harmony and sweetness are thereby gained, which all other means are vainly employed to obtain. It is therefore surprizing that all those who practised the art of painting after the discovery of the use of oil, should not have given in to the application of it. Yet it is certain that the Roman school is remarkably deficient in the knowledge of the value of this practice, and most frequently neglected to use it; owing probably to the employment painting found in fresco. The Venetian and Dutch schools, on the other hand, employed it in perfection, and it is in their works that a knowledge of it may best be acquired.

The principal difficulty attending the use of glazing, is to avoid the too common application of it; as it does not suit the representations of all substances, in its more immediate sense; though one general glaze over a picture, completed in its forms, will at all times benefit the work; if it happens not to be too low, or insipid, in its tones of colour.

All kinds of gems and polished substances, such as metals, silks, velvets, &c. are imperfectly wrought to effect, when it is not employed; and flesh, which is in nature compounded of a great variety of colours, is seldom quite perfect in its hue, when glazing is not employed to finish with. It is a species of it, produced by the yellow varnish being but partially removed from old pictures, which gives them their peculiar and brilliant lustre. It is quite impossible to make any effect exactly like it with fresh colours, unless some artifice be used to fore-run the effects of time; such as rubbing in dirt, and then partially removing it, &c. tricks which picture dealers are perfectly conversant with; and by which many an ingenious copy is passed off upon the unlearned amateur, to the enrichment of the dealer, and the future annoyance of the buyer, when time and improved information let him into the secret.

Glazing is the most valuable part of the practice of painting, when judiciously employed; as it produces clear broken tones of colour, which leave no remembrance of the palette, but deceive the eye by the variety of hues, and dazzling effect of light, produced by one colour shining through another in different degrees of illumination; much more like the effects of natural objects, than the use of opaque colours can possibly produce. But then great dexterity and judgment are required to use it properly in so general a manner. A well-informed and scientific artist knows the tone which one colour glazed over another will produce; and without that knowledge, a dirty dulness may be the effect, instead of the clearness required; and if not successful, it is always injurious; there is no medium in the application of it. If the under colour is not improved, it is sure to be deteriorated; and it will require repainting, to restore its original freshness. So that when a painter has prepared a work for glazing, (which should always be done with great clearness and precision,) the most extreme caution is requisite in adapting the tone of the glaze

which he proposes to use to the general hue of the picture before he applies it. It is not possible to give rules more explicit on this matter; the indefinite subdivisions of hues which all colours are capable of, must for ever leave to the feeling and judgment of the artist their peculiar application. It is hardly necessary to state that a glaze of red, over blue, will produce purple; of blue, over yellow, green; and of red, over yellow, orange; but it may aid the student in his practice, if he considers, that all the varieties of tone the original colours are capable of, will, when equally employed, produce a corresponding compound; and, of course, if his picture be of too red a hue, though of a light tone, a corresponding one of blue, or of yellow, will change it to the one he may require; and if he use the blue and yellow together as a green, it will produce a negative colour; totally destroying the red: but the varieties are too complicated and numerous to follow.

GLAZING of Cloth. The process of glazing is used for all the stout fabrics of cotton goods, and sometimes for those of linen. It is a part of the general processes of finishing goods for the market, and which is carried on by those who are generally called cloth-lappers, or calendermen. The glazing is done by putting on the cloth a small quantity of white wax, such as that used in the manufacture of wax candles, and the gloss is afterwards effected by the friction of any smooth body on the surface of the cloth. By the ordinary process the apparatus is very simple, consisting merely of a smooth table, a little inclined towards the operator, like a common writing desk, upon which the cloth to be glazed is spread smoothly, and drawn over, as occasion requires, from one end of the piece to the other. Above this is a lever, suspended from any convenient fixture to the roof, the lower end hanging in contact with the cloth, and by moving this backward and forward, the necessary friction is produced. The end of the lever next to, and in contact with the cloth, is faced with a smooth piece of flint or pebble, finely polished, and of a cylindrical form, the under surface of which is in contact with the cloth. This lever being drawn backward and forward by the operator's hands, the whole cloth is polished or glazed in succession, the joint at the top of the lever being fitted into a horizontal slider, which allows the polisher or flint to be moved from one side of the cloth to the other. In this way of glazing, the whole is performed by the power of a man's arms and hands; and, from the position of his body being constantly inclined over the table, is found to be a very laborious and fatiguing operation. The great number of people necessarily employed by this operation, and the difficulty of getting large quantities of goods rapidly glazed to answer the demands of hurried shipments for exportation, suggested lately the idea of a more speedy and efficacious manner of performing the operation of glazing by an improvement and alteration in the construction of the common five-lowl calender. This improvement was planned and executed at the extensive works of the late Mr. John Miller of Glasgow, who furnished the inventor with the means of carrying his plan into effect, and upon a proof of its efficacy on trial, his majesty's royal letters patent for its exclusive use to the inventor or his assignees within Scotland were obtained in the usual form. Two or three machines were then constructed for his own works, to which, as far as we know, they are still confined; and these machines have given the most universal satisfaction to all who have had their goods glazed by them, while at the same time an immense reduction of labour has been effected by their use.

The patent glazing machine, like the common calender, consists of five bowls, or cylinders, four of which are of cast

cast iron, smoothly turned, and finely polished on the surface, and the large or intermediate cylinder is generally of paste-board on an iron axis. In the common operation of smoothing by means of the calender, the velocity of the cylinders revolving upon their own axes, is in the ratio of their respective diameters, so that an equal quantity of superficies is constantly exposed of each. In the glazing-calender, or machine, it is only necessary that the motions of one of the cylinders should be so much accelerated as to produce the friction necessary to effect the glazing by rubbing against the other cylinders with which it is in contact, so as not to be liable to tear or otherwise injure the fabric. This motion is produced by means of wheels placed in the following manner: On the axis of the main cylinder A, is a cast iron wheel of any convenient diameter and number of teeth. This wheel works into the stud-wheel B, the number of whose teeth is not material to the speed, and whose diameter may be regulated so as to pitch well into the remaining wheels. The wheel is placed to revolve loosely on an iron stud, screwed into the frame-work of the machine. The stud-wheel B gives motion to the second stud-wheel C, and it continues the motion to the wheel D, which is fastened on the axis of the first iron cylinder. The upper cylinder works merely by friction, as in a common calender, and when the intermediate stud-wheel B is removed by being taken off the stud, the whole cylinders will revolve exactly as in the common machines, without producing any glazing effect. The simplicity of this machine, the regularity of the gloss which it gives, and the immense saving of labour, are powerful recommendations in its favour. The great quantity also which may be effected by it in a very limited time, renders it peculiarly adapted to meet the occasional exigencies of the exporter; and the additional advantage of its facility of adaptation to the purposes of the common calender, when glazing is not required, adds to its value and utility. Upon pressing occasions, one of these engines, by being constantly employed night and day, will glaze from 600 to 800 pieces of cloth, of 28 yards each, weekly.

Those employed in the late Mr. Miller's works are driven by means of a steam engine, by which also various other kinds of machinery, adapted to the various operations of the business, are set in motion. Should any machinery of this description be constructed in works where there may be a general necessity of keeping them constantly employed for the purpose of glazing, it will be very necessary that care should be taken that the moving power, whether water, steam, or horses, should be ample; as it must be evident, even to those who are not practically conversant with the calculation of power and resistance, that this calender, when employed to glaze, must require considerably greater force to keep it in motion, than when the cylinders revolve in the ratios of their diameters, for the mere purpose of common calendaring or smoothing.

We are not in possession of sufficient data to enable us to ascertain, with any tolerable precision, the quantum of resistance added by the friction; nor are we aware that any accurate experiments have been made for that purpose: but it is evident that it must be very great in all cases. It is reasonable also to infer, that it may be considerably increased or diminished by the texture or fabric of the stuff upon which the glazing operation is performed. Hence, if these machines be employed constantly in large works, and set in motion by the same power, which also drives machinery adapted to other purposes, care must be taken that the power be sufficient to effect all the various purposes to which it is applied. And should this be attempted, under the impression that the glazing might be performed by the same power as common calender-

ing, a deficiency would be found, which must render it necessary to disengage part of the machinery, in order to give sufficient momentum to the rest. This is, perhaps, one of the most common, and at the same time, most ruinous errors into which the projectors of large works, who are not mechanics, are apt to fall. In the first instance, desirous that a large establishment should be set to work at the least possible expence, they too frequently calculate too barely, and are then obliged either to abandon their whole scheme at a great loss, to work it under serious and ruinous inconveniences, or to repair, at a triple expence, what they have left deficient at first.

GLAZOV, in *Geography*, a town of Russia, in the government of Viatka, on the Tchevtza; 56 miles E.S.E. of Viatka. N. lat. 58° 5'. E. long. 51°.

GLEAD, or GLADE, in *Ornithology*, a name used in the northern parts of the kingdom for the *milvus*, or *lit.* See *FALCO Milvus*.

GLEAM is popularly used for a ray or beam of light. Among falconers, a hawk is said to gleam, when the calls or throws up filth from the gorge.

GLEAN, in *Geography*, a river of England, which rises about four or five miles N. of Stamford in Lincolnshire, and runs into the estuary called the Wash, five miles N.E. of Spalding.

GLEANNING, the act of gathering or picking up the ears of corn left behind, after the field has been reaped, and the crop carried home.

By the customs of some countries, particularly those of Meun and Estampes, all farmers and others are forbidden, either by themselves or servants, to put any cattle into the fields, or prevent the gleanings in any manner whatever, for the space of twenty-four hours after the carrying off the corn; on penalty of confiscation, &c. It hath been said, that by the common law and custom of England the poor are allowed to enter and glean upon another's ground after the harvest, without being guilty of trespass. *Gilb. Jo. 253. Trials per pais, ch. 15. 438.* This humane provision seems to be borrowed from the Mosaic law. *Levit. xix. 9. xxiii. 22. Deut. xxiv. 19, &c.*

Gleaning is a practice that is little heard of in the more northern parts of the kingdom, but which prevails greatly in some of the southern districts. The custom is of great antiquity; and whether or not the poor have any legal right, in this country, to glean, except by the express permission of the farmer, it has however been so long functioned by its continuance, that it is but rarely interrupted or put a stop to by him.

In some places where it is carried on to excess, it would seem necessary for the farmers to make regulations in respect to it, that should not be broken through on any account whatever. If this be not the case, the abuse is frequently so great that they are much injured by it, "as the poor glean among the sheaves, and too often from them," as is notorious to those who have attended to the practice. It has been therefore suggested to make it a rule not to suffer a gleaner to enter a wheat field until it is wholly cleared of the crop, which would, no doubt, prove a very beneficial regulation. It does not, however, upon the whole, appear that much benefit is derived to the poor from the custom, while it evidently leads to idleness, immorality, pilfering, and a looseness of disposition.

GLEBA ALANA, a name by which some call the yellowish white tripoli.

GLEBAE, *Additi.* In the civil law, slaves were said to be annexed to the glebe; *i. e.* they went with it, were sold with it, &c.

The right of patronage should be annexed to a glebe.

GLEBE, *GLEBA*, in *Natural History, Chemistry, &c.* a clod, or piece of stone or earth, frequently containing some metal, or mineral.

The glebes are carried to the forges to be washed, purified, and melted, &c.

GLEBE, or *Glebe-land*, is properly used for church-land; "D*os vel terra ad ecclesiam pertinens.*"

Glebe-land is most commonly used for land belonging to a parish-church, beside the tithes.

Thus, Lindwood: "Glebe est terra in qua consistit dos ecclesie; generaliter tamen sumitur pro solo, vel pro terra culta." Though in the most general, and extensive use of the word, glebe is applicable to any land or ground belonging to any benefice, fee, manor, inheritance, or the like.

If any parson, vicar, &c. hath caused any of his glebe lands to be manured and sowed at his own costs, with any corn or grain, the incumbents may devise all the profits and corn growing upon the said glebe by will. (Stat. 28 H. 8. cap. 11.) And if a parson sows his glebe and dies, the executors shall have the corn sowed by the testator. But if a glebe be in the hands of a tenant, and the parson dies after severance of the corn, and before his rent due; it is said, neither the parson's executors nor his successor can claim the rent, but the tenant may retain it and also the crop, unless there be a special covenant for the payment to the parson's executors proportionably, &c. Wood's Inst. 163.

GLEBEC, in *Geography*, a town of America, in the state of Virginia; 10 miles S.E. of Tappahawoc.

GLEBOUS, in *Rural Economy*, a term sometimes provincially signifying the turf or grassy surface.

GLEBOW, in *Geography*, a town of the duchy of Courland; 18 miles S. of Mittaw.

GLECHOMA, in *Botany*, is derived from Γλεχων in Dioscorides, though the latter is usually taken for *Pulegium*, or Penny-royal.—Linn. Gen. 291. Schreb. 388. Willd. Sp. Pl. v. 3. 85. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 625. Juss. 113.—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, cylindrical, striated, very small, permanent; its mouth having five sharp unequal teeth. *Cor.* of one petal, ringent; tube slender, compressed; upper lip erect, obtuse, lower lip spreading, larger than the upper one, obtuse, three-cleft, its middle lobe larger, emarginate. *Stam.* Filaments four, under the upper lip, two of which are shorter; each pair of anthers forming themselves into a cross. *Pist.* Germen four-cleft; style thread-shaped, bending under the upper lip; stigma cloven, acute. *Peric.* none; the calyx nourishing four, ovate seeds in its bosom.

Eff. Ch. Calyx five-cleft. Each pair of anthers converging in form of a cross.

1. *G. hederacea*. Ground-ivy. Linn. Sp. Pl. 807. Engl. Bot. t. 853.—"Leaves kidney-shaped, crenate."—Found in woods and hedges, flowering in April and May. *Root* perennial, and creeping. *Leaves* on foot-stalks, dotted beneath with glandular points. *Flowers* axillary, about three to each leaf, prettily speckled with white and blue. *Calyx* striated. *Anthers* white. Ground-ivy has been so long and so generally known, that it has obtained various appellations, such as Ale-hoof, Gill, Robin-run-in-the-hedge, Cat's-foot, &c. Before the introduction of Hops its leaves seem to have been used for flavouring and clarifying ale. Gerarde has enumerated a long train of "Vertues" supposed to be possessed by this plant; and when infused into tea or honey, it is still a favourite medicine with the common people for coughs. Many animals eat it, though it is said to injure

horses if taken too copiously. The specific character is now superfluous, as two species enumerated in the first edition of the *Species Plantarum* are now referred to other genera.

GLECHOMA *Hederacea*, ground-ivy or gill, in the *Materia Medica*, is a well known plant, growing commonly under hedges and flowering in April. Ground-ivy has a peculiar strong smell; the leaves, according to Dr. Withering, being beset underneath with hollow dots, in which are glands secreting an essential oil, and above with little eminences, which do not secrete any odoriferous oil; for this surface, when rubbed, yields no peculiar scent, whereas the under surface affords a pleasant reviving scent. The taste is bitterish, and somewhat aromatic. This plant was formerly supposed to possess great medicinal powers, not discovered by later experience; accordingly it is omitted in the *materia medica* by the London college. Its qualities have been described by different authors, as pectoral, detergent, aperient, diuretic, vulnerary, corroborant, errhine, &c. and it has been recommended for the cure of those diseases to which these powers seem to be most adapted, but chiefly in pulmonary and nephritic complaints. In obstinate coughs it is a favourite remedy with the poor, who, probably deriving benefit from it, persist in its use. Ray, Mead, and some others, speak of its being usefully joined with fermenting ale; but Dr. Cullen observes, "it appears to me frivolous. In short, in many cases where I have seen it employed, I have had no evidence either of its diuretic or of its pectoral effects. In common with many others of the *verticillata*, it may be employed as an errhine, and in that way cure a head-ache, but no otherways by any specific quality." It is usually taken in the way of infusion, or decoction, as tea. Woodville Med. Bot.

GLECHONITES, a name given by the ancient *Physicians*, to a sort of wine impregnated with penny-royal, much recommended in all obstructions. It takes its name from *glechon*, the Greek name of penny-royal, or *pulegium*.

GLEDITSIA, in *Botany*, named by Clayton, and adopted by Linnæus, in honour of Dr. John Gottlieb Gleditsch, professor of medicine and botany at Berlin, an advocate of Linnæus against Sigesbeck, and author of a *Systema Plantarum*, founded on the insertion of the stamens, as well as of an arrangement of *Fungi*, and various other botanical treatises in Latin and German. He died in 1786, aged 72. Linn. Gen. 549. Schreb. 735. Ait. Hort. Kew. v. 3. 444. Mart. Mill. Dict. v. 2. Juss. 346. Lamarck Illustr. t. 857. Gærtn. t. 146. Class and order, *Polygamia Diacia*; or rather *Diccia Hexandria*. Nat. Ord. *Lomentacea*, Linn. *Leguminosa*, Juss.

Gen. Ch. Male. Perianth of three small, spreading, acute leaves. *Cor.* Petals three, roundish, sessile, spreading, resembling the calyx-leaves. Nectary turbinate, united by its border to the other parts of fructification. *Stam.* Filaments six, thread-shaped, longer than the corolla; anthers oblong, compressed, two-lobed, incumbent.

Female, on a separate plant, *Cal.* Perianth like the male, but of five leaves. *Cor.* Petals five, long, acute, rather spreading. Nectaries two, short, like abortive filaments. *Pist.* Germen superior, broad, compressed, longer than the corolla; style short, reflexed; stigma thick, the length of the style, to which it is longitudinally affixed, downy in the upper part. *Peric.* Legume very large, broad, compressed quite flat, divided by numerous transverse partitions, and filled with pulp. *Seeds* solitary, roundish, hard, and polished.

At the summit, generally, of the male spike is an united flower, with four calyx-leaves and as many petals, with a nectary and stamens like the male, but with a pistil, producing perfect fruit, as in the female. Hence Linnæus referred this genus to his class *Polygamia*, but if it remains there

there it must rather be on account of the difference of structure in its male and female flowers, than for their slight sexual anomalies. Even for this difference of structure we should rather place it in *Diacia*. See Sm. *Introd. to Botany*, 479, 485.

Obf. This genus has considerable affinity with *Ceratonia*, especially in the fruit. We cannot apply the term *amentum* to its inflorescence, which is a spike.

Ess. Ch. Male, Calyx of three leaves. Petals three. Nectary turbinate. Stamens six.

Female, Calyx of five leaves. Petals five. Nectaries two. Pistil one. Legum.

Some flowers united, four-cleft.

The species of *Gleditsia* are as yet a mass of confusion. *G. triacanthos*, Linn. Sp. Pl. 1509, the original one, a native of North America, was cultivated by bishop Compton in 1700, and is a tall handsome tree, which bears our climate well, except being sometimes broken, like *Robinia Pseudo-acacia*, by strong winds. It is remarkable for its large trifid or compound spines, which grow on the trunk to the length of six or eight inches, from a very slender base. The leaves are deciduous, bipinnate, large, consisting of innumerable elliptical, slightly toothed, nearly smooth leaflets, half an inch or near an inch long. Flowers greenish, in axillary spikes. Some leaves appear to be simply pinnate, but we know not whether this is a specific difference or not.

A very distinct species is cultivated with us by the name of *G. chinensis*, which Linnaeus also had at Upsal, but he does not seem to have described it. The spines are compound. Leaves simply and abruptly pinnate, of seven or eight pair of thin, squarish, unequal-sided, crenate leaflets, gradually larger upwards, the terminal pair being sometimes twice the dimensions of the next.

In Sion gardens, belonging to the duke of Northumberland, is a tree of another species, of which we find no mention. Its leaves are simply pinnate like the last, and the leaflets also gradually larger upwards, but they are coriaceous, elliptical, their sides very seldom unequal. The calyx-leaves and petals are narrower, shorter, and blunter than in *G. triacanthos*. Of its spines we have no account, but the leaves and flowers were communicated to us by Mr. Hoy, in August 1796, as a *Gleditsia* not in the *Hortus Kewensis*, where, indeed, all that are known are made varieties of the *triacanthos*. From the new edition of this valuable work perhaps more information may be expected.

G. inermis, first mentioned by Linnaeus in the second edition of Sp. Pl. 1509, seems to have been adopted without a specimen, from Plukenet's t. 123. f. 3, to which is added Miller's t. 5, which last represents a *Mimosa*, nor does any subsequent writer appear to know any thing of this species.

It would be a tedious and unprofitable task to attempt a determination of the synonyms of this genus, even if the species were defined. The latter is a desirable object, and worthy the attention of those who have perpetual access to the old botanic gardens about London, and can observe these trees at different periods of growth. It is necessary to determine whether the simply or doubly pinnated leaves mark a specific distinction; whether the spines vary according to the age of the tree; and whether the legume is, in any species, constantly single-seeded, or merely from accidental abortion. Travellers in America can scarcely be expected to throw any light on such botanical questions as these, though a careful observer, resident there, might render highly important services to botany, and to the most useful arts of life, by determining first the specific differences, and then the economical qualities, of all the American trees, among which the *Gleditsia* claim a distinguished place. The

labours of a Lambert among the Pines, and a Michaux among the Oaks, are models for future enquirers.

GLEDITSIA, in *Gardening*, comprehends a plant of the deciduous tree or shrub kind; of which the species usually cultivated is the three-thorned acacia (*G. triacanthos*), which seldom rises higher than a shrub in this country.

There are several varieties with different numbers of spines, and with stronger and weaker spines.

Method of Culture.—These trees are capable of being increased by sowing the seeds, which are obtained fresh from America, in a bed of light earth, in the early spring season, watering them occasionally when the season is dry. It is, however, a much more expeditious practice to sow them in pots, and plunge them in a moderate hot-bed. The plants should be kept clean during the first summer after they appear, and in the succeeding winter be well protected from severe frosts, especially such as are in pots.

The young plants may, most of them, in the following spring, be removed and set out into nursery rows, at a 100 or eighteen inches distant from each other, and eight or ten inches in the rows. Such small plants as remain, may be put out in the same manner in the next autumn or spring.

The plants should continue in this situation till they have had two or three years growth, after which they may be transplanted into the situations in which they are to remain any time towards the latter part of the spring season.

These plants are found to succeed best in situations where the soils are of the more light deep kinds, and rather sheltered from the inclemency of the atmosphere.

They are all very ornamental trees, and well adapted to large shrubberies, plantations, and pleasure grounds. When planted alone, on lawns, and large open spaces that are kept in short grass, they produce a fine appearance. They have, however, the disadvantage of putting forth their leaves at rather a late period.

GLEE, a musical term derived by Skinner, Junius, Johnson, and all the etymologists, from $\gamma\beta\delta\zeta\epsilon$, Saxon, *joy, mirth, sport*.

His merry men commanded he
To make him both game and glee.

Chaucer, *Rim. S.* Tap. v. 126.

The term, we believe, is not to be found in music-books, or musical writers, before the middle of the 17th century. The first time it appears in the title of a collection of canons, rounds, and catches, is in a publication by John Playford, 1667, under the title of "*Dialogues, Glee's, Ayres, and Ballads, of two, three, and four Voyces.*"

A glee in music implies nothing more in its original sense, in our printed music-books, than "a song of three or more parts, upon a gay or merry subject, in which all the voices begin and end together, singing the same words." When subjects of fugue or imitation occur, and the composition is more artificial than simple counterpoint, it less resembles a glee than a madrigal, which it might, with more propriety, be called, if the words are serious: for a serious glee seems a solecism, and a direct contradiction in terms. The word glee, in Saxon, German, and English dictionaries, ancient and modern, implying *mirth, merriment*, and in Chaucer and other old authors, *music* itself.

GLEET, in *Surgery*, commonly signifies the continuation of a thin discharge from the urethra, after the inflammatory symptoms of a clap have for some time ceased. However, the running which takes place from the urethra, in cases of strictures, diseased prostate gland, &c. is also frequently called a gleet. A mere gleet, unattended with any other disease of the parts, is not accompanied with the remarkable

pain

pain and scalding sensation in making water, which are produced by gonorrhœa. The latter affection may be considered as *acute*, while the gleet is quite of a *chronic* nature. It was one of the opinions of Mr. Hunter, that a gleet differed from a gonorrhœa, likewise, in not being infectious. It is well known that it was one of the doctrines of this eminent surgeon, that the poison of gonorrhœa, and that which is productive of lues venerea, are of the same quality, and that the different effects are owing to the different structure of the parts concerned in the two diseases. We need not here enter into an investigation of this part of the subject. All that we wish to observe is, that if Mr. Hunter means, when he states, that a gleet differs from a gonorrhœa in not being infectious, that a gleet is *not capable of communicating the venereal disease*, no one can question the accuracy of the observation. But, on the contrary, if the assertion implies that the matter of a gleet, when applied to the pudenda muliebria, will not bring on a pain in making water, a discharge, &c. then we dissent from the opinion altogether. We have known an instance, in which a gentleman, who had had a gleet upon him for upwards of a year, and who, on the presumption that it was not infectious, ventured to have connection with a young woman, of whose continency, with regard to other men, we ourselves entertain no doubt. However, there may be gleans of various kinds, and some of them may be infectious, and others not so. When, after a gonorrhœa, a thin discharge continues, for a long while, to take place from the urethra, the complaint may depend upon a weakness of the vessels, or, as Mr. Hunter expresses it, upon a habit of action, which the parts have contracted. When a gleet arises from a stricture in the passage, or from a disease of the prostate gland, the cause must be referred to irritation, and the cure depends on the removal of the original complaint.

Gleans, which are the consequence of gonorrhœa, are often exceedingly difficult of cure, and what is very curious, it frequently happens, that, after they have resisted every sort of remedy, and after the patient has long given up the use of medicines and injections, a sudden cure spontaneously occurs. Many gleans undergo a temporary stoppage under particular modes of treatment; but, as soon as this is removed, regularly return again. A vast number of gleans depend upon the presence of a stricture in the urethra, and of course are not curable by injections. We have often thought that in all cases of gleans, it should be the invariable custom of the surgeon to introduce a bougie, for the purpose of ascertaining whether there is any obstruction in the passage; for, when the discharge depends on a stricture, the patient might make use of balsams, turpentine, and bougies, for years, and yet receive no benefit whatever. At all events, whenever a gleet resists ordinary means, the state of the urethra and of the prostate gland ought to be examined. See PROSTATE GLAND, *Disease of*; and STRICTURE.

Mr. Hunter was of opinion, that the spontaneous disappearance of a gleet, after a long resistance to every sort of medicine and application, very frequently depended upon accidental changes in the patient's constitution. It was another sentiment of this celebrated surgeon, that some gleans were connected with scrofula. This idea is founded on the circumstance, that more gleans may be cured by sea bathing, than any other kind of bathing. It is also supported by the fact, of sea water being sometimes an effectual means of cure, when employed as an injection.

We have always found fault with this plan of judging of the nature of diseases. If a disorder yields to mercury, practitioners are apt to decide immediately, that the complaint is venereal. If a malady, like a gleet, gives way to

sea bathing, which benefits scrofulous complaints, such surgeons, as reason on Mr. Hunter's principles, will immediately set down the case as scrofulous. It is never remembered in this calculation, that mercury cures many diseases besides the venereal; and so does sea bathing many complaints besides those which are of a scrofulous nature.

Gleans have also been represented as always connected with a relaxed constitution, though we think we have seen the complaint in subjects, who were strong, robust, and young, with every appearance of general health, and whose state seemed to us a striking contradiction to the foregoing observation.

Gleans, as we have before stated, are often exceedingly difficult of removal. Sometimes, indeed, they may be got rid of with tolerable ease; but in other instances, they completely frustrate the art of surgery, and the patient, tired of the inefficacy of different remedies, relinquishes the trial of all. In slight cases, and occasionally in inveterate ones, a cure may be effected by exhibiting internally the balsam of copaiva, the oleum terebinthinæ, or the tincture of lyttæ (cantharides). It is well worthy of notice, that when a cure can be accomplished by these means, benefit is soon derived from their employment. For this reason, when they neither diminish, nor remove the gleet in the course of five or six days, Mr. Hunter made it a rule never to continue their use any longer, but have recourse at once to other methods. We have already remarked the great tendency of many gleans to return, after being for a time stopped by different modes of treatment. Hence practitioners should never discontinue the successful plan immediately the discharge ceases, but persist in its adoption for ten days or a fortnight, after all the symptoms have entirely gone off.

In relaxed habits, gleans are very likely to be cured by the cold bath, sea bathing, bark and steel medicines. Cold bathing indeed often succeeds in every kind of constitution, when other methods are of no avail. We have known strong young men labouring under gleans, who could not get rid of them in any way in London; but who got well almost immediately on going to the sea side, and bathing there. There can be no doubt also, that some beneficial revolution in the system, arising from the change of air, might have a considerable share in the cure. We lately had under our care a gentleman with a gleet, which had lasted nine months, but disappeared all at once on the patient going for a short time to a part of the country which was not near the sea.

There are two principal kinds of injections in use for the cure of gleans, *viz.* astringent and irritating ones.

The astringent ones are, for the most part, such as the decoction of bark, and solutions of zincum vitriolatum, alum, or acetite of lead. An injection of proper strength, containing cuprum vitriolatum, bolus gallicus, and camphor, is also an exceedingly eligible one.

The best irritating injection which we know of, is that made by dissolving two grains of the hydrargyrus muriatus in eight ounces of distilled water.

Bougies may also be considered as acting on the urethra as irritating applications, and hence they are occasionally recommended to be worn for the cure of gleans. In general, common bougies are employed; but sometimes others, medicated with camphor or turpentine, are used.

In irritable constitutions, the latter kind of injection and the bougies may excite a good deal of irritation, pain, strangury, &c. so that some circumspection is necessary in the employment of such means. We may state, indeed, that no endeavour should ever be made to cure a gleet, by exciting irritation in the urethra with stimulating injections, or bougies, before milder means have failed. We have found a weak

weak injection of the hydrargyrus muriatus more frequently successful than any other. One grain to six ounces of water is quite strong enough to begin with, and the strength may be gradually augmented, in proportion as the urethra appears capable of bearing it. The practitioner must not leave off the injection as soon as the discharge ceases; for if he does so, the gleet will generally recur. The plan should still be followed up for about a fortnight.

When gleans are to be cured by bougies, it is necessary to wear these instruments about a month or six weeks before any dependence can be put in the permanence of the cure.

Neither the surgeon nor the patient should be deterred from persisting in the trial of irritating injections or bougies, by the circumstance of their appearing to increase the discharge at first. This they always do.

Mr. Hunter thought that moderation and regularity in diet were conducive to the cure of gleans. So is a quiet kind of life in the generality of cases, but there are instances in which gleans seem to be benefited and cured by rough exercise on horseback.

A return or an increase of a gleet is very apt to be the consequence of intercourse with women, and the patient often thinks that he has received a fresh infection. Mr. Hunter thought that the case might be discriminated by the short time which intervenes between the connection and the re-appearance of the discharge. Gleans are often so exceedingly obstinate, that the surgeon cannot be informed of too many modes and principles of cure. On this account we deem it right to mention that gleans seem to be curable on the principle of counter-irritation. Hunter has seen a gleet stop on the breaking out of two chancres on the glans penis, and the discharge has been known to stop as soon as a blister was applied to the under part of the penis.

Gleans have likewise been cured by electricity.

Women are liable to gleans, and the disease being situated in less irritable parts, whatever injections are used, may be made stronger than for male patients.

It is almost unnecessary to remark, that balsams and turpentine, internally given, can have no specific effect on the parts affected in women, as they have on the urethra in men. Hence it would be absurd to prescribe such medicines for female patients.

GLEIBERG, or GLITZBERG, in *Geography*, a town of Germany, in the principality of Nassau Weilburg; eight miles N.E. of Wetzlar.

GLEICHAN, a county of Germany, in the principality of Gotha, divided between the princes of Gotha, Hohenloc, Hatzfeld, and Schwartzburg, situated on the banks of the Ohr, between Erfurt and Gotha.

GLEICHEN, FREDERIC VON, in *Biography*, was born in the year 1714. He was intended and educated for the profession of arms, and spent the early part of his life as an officer in the service of Bayreuth, and was distinguished by his attention to military discipline. He rose to the rank of lieutenant-colonel, and obtained the favour of the margrave. His honours did not sit easy upon him, he sighed for retirement, and in 1756 his wishes were accomplished; he obtained a dismissal from the service with a handsome pension, to which was afterwards added the rank of privy counsellor. He now had leisure to distinguish himself as a philosopher, a naturalist, and a writer. His attention was accidentally excited to microscopical observations, and not satisfied with the instruments already in existence he constructed a universal microscope, with which he combined the solar microscope. His principal observations relate to feminal animalcula, and infusion animals: he would sit day

after day at his glass, and was always displeased if he experienced any interruption while engaged in his favourite pursuit. By daily practice he had acquired uncommon acuteness of sight, which was of the greatest advantage to him in his researches. Though he had an ardent attachment to science for the love of it, yet he devised various economical plans, from which he expected to derive great emolument, but they were the schemes of a theorist, and did not prove of real advantage either to himself or the world. He died in June 1783, leaving behind him numerous works in natural history, as "Observations on the Parts of Fructification in Plants when in bloom, and on the Insects found in them;" "History of the Common House Fly;" "Treatise on feminal Animalcula and infusion Animals;" "Essay towards the History of the Tree-house of the Elm;" this insect, the *aplus ulmi campestris*, cost our author the labour of eight years; it is the cause of the bladders on the leaves of the elm-tree during the spring. *Gen. Biog.*

GLEICHENBERG, in *Geography*, a town of the duchy of Stiria; 10 miles N. of Raasdorfburg.

GLEICHENBERGAN, or GLEICHBERG, a town of Germany, in the county of Henneberg; four miles E. of Ronhild.

GLEICHENIA, in *Botany*, named by the writer of this article in honour of Philip Frederick, Baron von Gleichen, author of a splendid microscopical work on the structure and physiology of the parts of fructification in several plants, published at Nuremberg, in folio, with coloured plates, in 1764. As the seeds of ferns were among the subjects to which Baron Gleichen paid great attention, a genus belonging to this curious tribe was judged peculiarly proper to commemorate him. Smith in *Mem. de l'Acad. de Turin*, v. 5. 419. t. 9. f. 10. *Tracts*, 258. t. 1. f. 10. Swartz. *Fil.* 165. Brown. *Prod.* v. 1. 160. (*Mertensia*; Willden. in *Act. Holm. ann.* 1804. 165. t. 4, 5. Swartz. *Fil.* 163.)—Class and order, *Cryptogamia Filices*: sect. *Annulate*. Nat. Ord. *Filices dorsiferae*.

Ess Ch. Capsules in a simple, concentric, orbicular series: each series constituting a round separate dot, on the back of the leaf. Cover none.

This genus was first founded on the *Onoclea polypodioides* of Linnæus, an elegant and singular fern, native of the Cape of Good Hope. In this the capsules are usually three, rarely four together, half immersed in the under side of the frond, and as each bursts by a longitudinal suture, they all together have exactly the appearance of a single capsule, or three cells, and three valves, the partitions seeming to originate from the centre of each valve. Traces of a jointed ring appear on some of the valves only, and rather resemble the corrugations of those ferns termed *sporiosus annulatus*. Several other species, strictly allied to the original one in habit and appearance, so as to be at first sight scarcely distinguishable from it, have been found in New Holland, and have been defined by Dr. Swartz and Mr. Brown. In these the capsules are not immersed in the leaf, though each series stands in a slight depression. In *G. dichotoma* of Brown there are only two together; in others three, four, or even six. These new discovered species evince the propriety of Mr. Brown's measure, of reducing the *Mertensia* of Willd now and Swartz to *Gleichenia*, as their fructifications exactly agree. *Diagnosis* of Bernhardt does not in our opinion so well assort with them, having an irregular accumulation of stalked capsules in each dot, though its habit is precisely that of *Mertensia*. Mr. Brown, having examined these ferns alive, determines them to be furnished with a complete, striated, transverse, rarely oblique, ring.

This genus naturally divides itself into two sections. The original *Gleichenia*, of which there are five species, have the ultimate branches of their repeatedly forked stem pinnate, their leaflets or *pinnae* deeply pinnatifid, with short, triangular, or rounded segments, each segment bearing a single dot or series of capules. The *Mertensiae* have their ultimate branches deeply pinnatifid, the segments linear, with a row of numerous dots on each side of the midrib of each segment, especially at its lower half. Of these we are acquainted with five or six species, all natives of the East or West Indies, or of New Holland and its neighbourhood.

GLEICHENSTEIN, in *Geography*, a town and castle of Germany, in the territory of Eichsfeld; seven miles S. E. of Heiligenstadt.

GLEINSTOLLEN, a town of the duchy of Stiria; 14 miles S. E. of Voitsberg.

GLEISS, a town of Switzerland, in the Valais; 26 miles E. of Sion.

GLEIWITZ, or **GLIWICE**, a town of Silesia, in the principality of Oppeln; 20 miles N. E. of Ratibon. N. lat. $50^{\circ} 17'$. E. long. $18^{\circ} 35'$.

GLEN RIVER, is a river of Lincolnshire, which rises near Ropley, and pursues a course nearly S. S. E. to Bracebrough, when, turning suddenly N. E., it passes to Kates bridge and through the Fens, by Surfleet, to the sea at Fofdyke Wash; for the greater part of its course through the Fens this river is navigable for barges, a circumstance which was over-looked in compiling the alphabetical list of inland navigations in our article CANAL. The small river or drain called the Bourne, which branches from the Glen and proceeds up to Bourne town, is also navigable for some distance upwards. The South Forty-foot navigable drain commences very near to this river, below the mouth of the Bourne, and proceeds by a circuitous route to Boston. See SOUTH FORTY-FOOT.

GLENAA, a mountain in the county of Kerry, Ireland. See KILLARNEY.

GLENAN ISLANDS, a cluster of small islands in the Atlantic, near the coast of France. N. lat. $47^{\circ} 43'$. W. long. $3^{\circ} 55'$.

GLENARM, a post town of the county of Antrim, Ireland, on the east coast of it, adjoining which is Glenarm castle, the seat of the counts of Antrim. The town is pleasantly situated on the sea-shore, near the bay of the same name. It is 104 miles N. from Dublin, and 24 N. from Belfast.

GLENNAVY, a post-town of the county of Antrim, Ireland, situated near the eastern border of Lough Neagh. It is 77 miles N. from Dublin on the road to Antrim.

GLENCOE, a vale of Scotland, in the county of Argyle, near Loch Leven, where, in the year 1691, the inhabitants were massacred contrary to the faith of a royal proclamation; 17 miles N. of Inverary.

GLENDALOUGH, **GLANDELOUGH**, or *Glendaloch*, commonly called the *Seven Churches*, an interelling object to travellers in the county of Wicklow, Ireland, 22 miles S. from Dublin, and about seven or eight miles west from Rathdrum. Its name is derived, according to Mr. Ledwich, from its being situated in a valley with lakes, from *glen*, a valley, and *loch*, a lake. That this was the true origin of the name seems to be confirmed by Hoveden, who was chaplain to Henry II., and who calls it equivalently in Latin, *Episcopatus Billagenfis*, the bishopric of the two lakes. Glendalough is surrounded on all sides, except to the east, by stupendous mountains, whose vast perpendicular height throws a gloom on the vale below, well fitted to inspire religious dread. From these, many mountain-

streams fall into the valley, and, forming a junction, assume the name of Avonmore. One of these streams, called St. Kevin's keeve, is still an object of superstition; weak and sickly children being dipped in it every Sunday and Thursday before sun-rise, and on the third of June, which is St. Kevin's day. The two lakes in the vale are divided from each other by a rich meadow; the rest of the soil is so rocky as to be incapable of tillage by the plough. The names of the adjoining mountains, in which the word *Derry* often occurs, are supposed to denote that they were formerly covered with wood; at present they have only brown heath, or more sable peat. Between the cathedral and upper lake is a group of thorns of great size; and near the cathedral the trunk of an aged yew, which measures three yards in diameter. From the remains of walls above, and the traces of foundations below the surface of the earth, the town is supposed to have been once pretty large, but the only street appearing is the road leading from the market place into the county of Kildare. It is in good preservation, being paved with stones placed edgewise, and ten feet in breadth. There are seven churches of considerable antiquity, and some chapels which appear to be of later construction. St. Kevin was the patron saint, and his name consequently is given to many of the surrounding objects. He is said to have founded the town or monastery in the sixth century; but Ledwich attributes the erection to the Oslmen, who infested Ireland, in the ninth century. Some figures in a chapel, containing the tomb of St. Kevin, furnish some plausible arguments in support of this opinion. There are two round towers at Glendalough, both of which are adjoining churches, but neither the cathedral nor abbey has such an addition, though if a belfry were the object of these buildings, the preference would probably have been given to them. These towers were also, in Mr. Ledwich's opinion, the work of the Oslmen. The arguments for and against this opinion will be considered under the article ROUND TOWERS. A monastery having been founded here, and the supposed miracles of St. Kevin having been proclaimed, numbers flocked to his shrine; as Girald Cambrensis says, in what had been a barren wilderness, were to be found, after a few years, not only churches and good houses, but much wealth. According to the Irish annals, the town thus founded was often plundered by the piratical freebooters of the north, who, as they subsisted solely by depredations, without reluctance, frequently pillaged their own countrymen. In 1162, Laurence O'Toole, afterwards archbishop of Dublin, was elected abbot; and in a few years after earl Strongbow granted the abbey and parsonage to Thomas, the nephew of Laurence. The charter is one of the most valuable and ancient in Ireland, as it preserves the possessions, privileges, and immunities of the abbey. Previous to this, Glendalough had also had a bishop; but, in 1152, Cardinal Paparon endeavoured to unite it to the see of Dublin. This was refused, and, in 1179, pope Alexander III. confirmed the city to its bishop, saving the rights of the abbot. A letter, written in 1214, is quoted by Ledwich, to shew that Glendalough was at that time become a nest of thieves and robbers. In the reign of king John, the see was united to that of Dublin; but the sect of the O'Tooles, who were very powerful, kept it, in some degree, independent until 1497, when the bishop formally surrendered his right and claim in the Chapter-house of St. Patrick, Dublin. The Seven Churches, when approached by the bridge of Derrybawn, form a very picturesque and pleasing scene. The bridge is thrown over the Avonmore, and is composed of three elliptic arches. Derrybawn, covered to a great extent with an oak coppice on one side, and the huge broccagh on the other,

other, confines the view up the river to the valley; at the end of which the great round tower, and the other ruins, appear to great advantage. As the new military road has made Glendalough easily accessible, it is frequently visited by travellers. Ledwich's Antiquities.

GLENE, Γλινν, properly signifies the cavity or socket of the eye.

GLENE is more frequently used by anatomists for the shallower cavities of bones, into which some other bone is received and articulated.

By which it stands distinguished from *cotyle* or *acetabulum*, which is a deeper cavity, intended by nature for the like purpose.

GLENEGAD HEAD, in *Geography*, a cape of Ireland, in the peninsula of Inis Lowen, county of Donegal. W. long. 7° 41' from Greenwich, N. lat. 55° 20'.

GLENGARRIFF, a harbour of Ireland, in the county of Cork, on the north-east part of Bantry-bay. The arbutus grows in this neighbourhood in great perfection.

GLENGARY, the name of a county in Upper Canada, bounded on the E. by the line which separates Upper from Lower Canada; on the S. by the river St. Lawrence; and on the W. by the township of Cornwall, running N. 24° W., until it intersects the Ottawa or Grand river, thence descending the said river till it meets the fore-mentioned separating line. Glengary county comprehends all the islands contiguous to it in the river St. Lawrence.

GLenicZA, a river of the duchy of Warsaw, which runs into the Odra, near Koiten.

GLENKEN'S CANAL, is the parliamentary name of an inland navigation, made since the year 1802, in Kirkcudbright county in Scotland. See **CANAL**.

GLENLUCE, a town of Scotland, in the county of Wigton, which sprang from an abbey of Cistercians, founded in 1190, called "Vallis Lucis." It is situated at the northern extremity of a large bay to which it gives name; 18 miles W. of Wigton. N. lat. 54° 58'. W. long. 4° 27'. The bay extends on the S. coast of Scotland from the Mull of Galloway to Burrowhead. N. lat. 54° 50'. W. long. 4° 50'.

GLENMORE, a small island on the W. coast of Scotland, at the mouth of Loch Suart. N. lat. 56° 38'.

GLENOID, in *Anatomy*, from γλινν, the articular cavity of a bone, and εὐδοξ, form, a term applied to certain articular surfaces, particularly where the hollow is not deep.

GLERS, in *Geography*, a town of Germany, in the county of Tyrol; 21 miles W. of Bolzano.

GLESE, a river of Louisiana, which runs into the Mississippi, N. lat. 37° 15'. W. long. 90° 14'.

GLESUM, or **GLESUM**, in *Natural History*, a name given by many of the ancients to the common yellow amber or succinum. The word seems to have been originally German, and to have been adopted by the Romans in their conquests in that part of the world. They seem to have used the word in general for any transparent substance, and thence to have applied it to amber as a transparent stone. See **GLASS**.

GLETCHERHORN, in *Geography*. See **JUNGFRAU**.

GLIANY, a town of Poland, in Galicia; 20 miles E. of Lemberg.

GLIESA, a town of Sweden, in West Bothnia; 25 miles W. N. W. of Tornea.

GLICVI, a town of Asia, in Daghestan; 90 miles N. of Teblis.

GLIKEON, a town of European Turkey, in the province of Epire; 26 miles W. of Arta.

GLIMS HOLM, one of the small Orkney islands, which

affords pastures; 2 miles S. of Pomona, between that and Barry.

GLIMMER, or **CAT-SILVER**, in *Mineralogy*, according to Dr. Woodward, "Method of Fossils," p. 14, are names for *Mica*, which see. Glist, spangles, daze, and silver, are other names by which the miners and quarrymen designate the shining plates of this substance which they meet with dispersed in the earths and stones in their works. The late Mr. William Martin observes, "Outlines," p. 141, "Glimmer is frequently dispersed through the sand-stones and clay, forming vegetable petrifications, but never constitutes their whole substance." In Derbyshire, it is not uncommon to find nodules, or round nests or masses of mica, in thin and separate plates, in the first, or millstone grit, which fall out on exposure, and leave spherical holes, a circumstance which has, according to Mr. Farcy, given rise to rock-basins or holes on the tops of large loose blocks of stone where the water stands in many instances after rain, but not perpetually, as the vulgar opinion is. See **ROCK-BASINS**.

GLINA, in *Geography*, a river of Croatia, which runs into the Save; 12 miles W. of Patrinya.

GLINLOUGH, a lake of Ireland, in the northern part of the county of Leitrim, from which a small river flows to Sligo bay.

GLINNINO, a town of Russia, in the government of Novogorod, on the Msta; 12 miles S. E. of Borovitchi.

GLINSK, a town of Russia, in the government of Tchernigof, on the river Sula; 80 miles S. E. of Tchernigof.

GLINUS, in *Botany*, derives its name from γλιννος or γλίννος, a word used by Theophrastus, and denoting a kind of maple, though we cannot trace any similitude between that tree and the little herbaceous plant, to which the name was applied by Loefling; but it was adopted by Linnæus. — Linn. Gen. 243. Schreb. 328. Loefl. Iter. 145. Willd. Sp. Pl. v. 2. 929. Mart. Mill. Dict. v. 2. Lamarck Dict. v. 2. 728. Gærtn. t. 130. Juss. 316. — Class and order, *Dodecandria Pentagynia*. Nat. Ord. *Caryophyllei*, Linn. *Ficoideæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of five ovate, acute, concave leaves, coloured within, permanent, and downy. Cor. none; nectaries about five, resembling narrow petals, shorter than the calyx, and unequally two or three-cleft. Stam. Filaments about fifteen, awl-shaped, flat, as long as the calyx; anthers incumbent, oblong, compressed, two-lobed. *Pistl.* Germen of five sides; styles five, short; stigmas simple. *Peric.* Capsule ovate, with five cells, five sides, and five valves. Seeds numerous, roundish, in a single row at the base of the valves, tubercled, each attached by a long thread-like stalk.

Ess. Ch. Calyx five-cleft. Corolla none. Nectaries cloven bristles. Capsule five-cornered, five-celled, five-valved, with many seeds.

1. *G. totoides*. Linn. Sp. Pl. 663. Burm. Ind. 112. t. 36. f. 1. "Stem hairy. Leaves obovate." — Native of Spain, and found by Loefling in a gravelly soil near Talavera del Badajoz, also in a dried-up rivulet between Merida and Truxillo. Root annual. Stems procumbent, jointed, hairy. Leaves obovate, on short stalks. Flowers nearly sessile, crowded together, sometimes on very short hairy stalks. A figure of this species is destined to appear in the *Flora Græca*, t. 472, from a drawing made at Smyrna, and from which it appears that what Gærtn. considered as petals, are more probably nectaries, as not being external to the stamens; after all, they ought perhaps to be called

barren filaments. They seem, from the dried specimens, to be ranged alternately with the real stamens.

2. *G. dictamnoides.* Willd. Sp. Pl. v. 2. 929. Pluk. Amal. 10. t. 356. f. 6.—“Leaves round, hairy. Stem shrubby, prostrate. Leaflets of the calyx lanceolate.”—Native of India. It seems doubtful whether *G. dictamnoides* be not merely a variety of *lotoides*; but as Willdenow still keeps them separate, on the authority of a dried specimen, we have retained the species.

3. *G. setiflorus.* Willd. Sp. Pl. v. 2. 929. Vahl. Symb. 3. 64.—“Leaves obovate, plaited. Stem shrubby. Leaflets of the calyx ovate.”—Native of inundated woods in Arabia Felix during the rainy season. The whole plant is hoary, from very thick hairs, which are longer than in *G. lotoides*. This species was first described by Vahl, from Forskal's specimen which we have examined. The pubescence is beautifully stellated and very dense.

GLINUS, in *Ichthyology*, a name by which Bellonius and some other authors have called a small sea-fish, more commonly known by the name of the *dracunculus*.

GLIS. In the common acceptation of the word, this only signifies the dormouse; but Linnæus has used *glires* in a larger sense: and, in his System of Zoology, makes it the name of the fourth order of the mammalia class of animals. The characters of the creatures of this class are, that they have only two fore-teeth in each jaw; they have no *dentes canini*, or dog-teeth; and the feet have toes, and are formed for leaping when they run. The animals of this class are the several species of the *Hystrix*, *Cavia*, *Cassor*, *Mus*, *Arctomys*, *Sciurus*, *Myoxus*, *Dipus*, *Lepus*, and *Hyrax*; which see respectively.

GLIS, a name given to several species of *Myoxus*; of *Didelphis*; of *Mus*; and of *Arctomys*; which see respectively.

GLIS Volans. See VESPERTILO *Spafina*.

GLISCHROMICTHES, in *Natural History*, the name of a genus of compound earths. The word is derived from *γλίσχρον*, touch, and *μεικτός*, mixed. The bodies of this genus are loams composed of sand and a more viscid clay, and are of a tough and firm texture.

The earths of this genus are used in making bricks, and on some other occasions; and are of several distinct species.

GLISSA, in *Ichthyology*, the name of a sea-fish of the tunny kind, but of a perfectly smooth skin, and wholly free from scales. It usually grows to the length of two cubits, and the thickness of a man's body: it is of a very round body, and has very rough jaws, but no distinct teeth; its tail is forked, but not so arched or lunated as that of the tunny; it lives in deep water, and is a fish of very delicate taste. Gesner. De Pisc. p. 1158.

GLISSON, FRANCIS, in *Biography*, was born at Rampisham, in Dorsetshire, in the year 1597, and educated at Caius college, Cambridge, of which he became a fellow, and in 1627 was incorporated M.A. in Oxford. He then applied himself to the study of physic, in which faculty he took his degree of doctor at Cambridge, and in that university was made regius professor of physic, which office he held about 40 years. He settled in London for the practice of his profession, and was admitted a fellow of the College of Physicians in 1635. In 1639 he was chosen reader of anatomy in the college, and in that department acquired great reputation by his lectures “De Morbis Partium,” which he was particularly requested by his colleagues to make public. During the civil wars he retired to Colchester, where he practised with great credit in those times of confusion, and was in the town at its memorable siege by the par-

liamentary forces in 1648. He was one of that small, but illustrious society, who instituted a weekly meeting in London about the year 1645, for the purpose of promoting inquiries into natural and experimental philosophy, which, after having removed to Oxford during the troubles, was augmented in London after the restoration, and became ultimately the Royal Society. He was afterwards several years president of the College of Physicians, and died in 1677, in the parish of St. Bride's, London, aged 80. Glisson left the following works: 1. “Tractatus de Rachitide, seu morbo puerili Ricketts dicto,” first published in 1650; it went through several editions abroad, and two translations into English the year after its publication, by Philip Armin, and Nicholas Culpepper. 2. “Anatome Hepatis, &c.” London, 1654; afterwards reprinted at Amsterdam and the Hague. This work contains a much more exact description of the liver than had before appeared. The capsule of the *vena portarum* was supposed to be first discovered by him, and has ever since borne his name; but Wæver and Pecquet had seen it a short time before, and he has only the merit of having first examined and described it with accuracy. Dr. Glisson's largest work is a metaphysical piece, viz. 3. “Tractatus de Natura Substantiæ Energetica, seu de Vita Naturæ, ejusque tribus primis Facultatibus,” Lond. 1672, in 4to., a profound and laborious performance, in the very depths of the Aristotelic philosophy, with all its numerous divisions, and an extraordinary effort of the understanding in a man of an advanced age.—4. His last publication, “Tractatus de Ventriculo et Intestinis, cui præmittitur alius de partibus continentibus in genere, et in specie, de iis Abdominis,” Lond. 1676, 4to., Amst. 1677, 12mo, contains every thing at that time known concerning the alimentary canal, arranged in a clear manner, with various new observations. In a word, Glisson was exceeded in judgment and accuracy by none of that group of English anatomists, who followed the steps of Harvey with great ardour and success; inasmuch that Boerhaave terms him “omnium anatomicorum exactissimus,” and Haller speaks in praise of all his writings. Aikin Biog. Mem. of Med. Eloy. Dict. Hist.

GLISTER. See CLYSTER.

GLITNESS, in *Geography*, one of the smaller Shetland islands, on the E. coast of Shetland; 11 miles N. of Lerwick. N. lat. 60 22'. W. long. 1 16'.

GLUBEN, a town of European Turkey, in Dalmatia; 18 miles S.E. of Mostar.

GLIZADE, in *Fencing*, is an operation performed by dextrously making your blade slip along that of your adversary by a movement of the wrist, and a quick forward extension of the arm, without deviating from the line of direction. This is a simple, and at the same time a masterly movement in fencing.

GLOBBA, in *Botany*, a Malay name adopted by Rumphius and Linnæus, under which, however, they have included a very heterogeneous assemblage of species. We shall speak only of such as agree in generic character with the original one, seen and described by Linnæus, and preserved in his herbarium. Linn. Mant. 2. 143. Schreb. 25. Willd. Sp. Pl. v. 1. 153. Mart. Mill. Dict. v. 2. Roscoe in Tr. of Linn. Soc. v. 8. 355. t. 20. f. 13. Ait. Hort. Kew. ed. 2. v. 1. 9. Juff. 63. Lamarck Dict. v. 2. 729.—Class and order, *Morandria Monogynia*. Nat. Ord. *Sitamineæ*, Linn. *Canna*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, tubular, permanent; its border three-lobed. *Cor.* of one petal; tube long, cylindrical, slender; outer limb in three, nearly equal, ovate, spreading lobes; inner of two similar lobes, and a central,

central, vertical, prominent lip, cloven at each extremity. *Stam.* Filament one, prominent, long, linear, channelled, dilated at its summit; anther oblong, of two distinct parallel lobes, attached by its back to the dilated part of the filament. *Pist.* Germen inferior, roundish; style thread-shaped, the length of the filament and embraced by it; stigma obtuse. *Peric.* Capsule roundish, of three cells and three valves. *Seeds* numerous.

Eff. Ch. Anther in two parts. Filament elongated, incurved, bearing a lobed appendage. Style thread-shaped, embraced by the anther. Corolla with three outer lobes and three inner, the middlemost vertical and cloven.

1. *G. marantina.* Linn Mant. 2. 170 Sm. Exot. Bot. v. 2 85 t. 103 (Colebrookia bulbifera; Donn Cant. 1.)—Appendage of the filament four-lobed, divaricated, terminal. Spike not taller than the leaves. Bractæas elliptical, broad, longer than the calyx—Native of Bengal, from whence it was sent by Dr. Roxburgh to the late lady Amelia Hume in 1800. It flowers in the stove in July and August. *Root* perennial, tuberous. *Stems* several, herbaceous, about two feet high, simple, leafy. *Leaves* elliptical, acute, entire, with one rib and numerous parallel simple veins; smooth above; soft and finely downy beneath; their footstalks long, sheathing, bearded at the top, which is extended upwards into a pair of rounded auricles. *Spike* terminal, solitary, simple, erect, more or less lax, about as tall as the leaves, or rather under that height. *Bractæas* alternate, sessile, elliptical, broad, concave, many-ribbed, somewhat downy, minutely dotted; the lower ones each bearing one ovate bulb; the upper ones a cluster of several flowers, each of which is accompanied by its own smaller bractæa. These flowers are very transient, slender, orange-coloured, with a deeper spot in the centre of the lip.

2. *G. racemosa* Sm. Exot. Bot. v. 2. 115. t. 117. (Deofara; of the inhabitants of Nepal.)—Appendage of the filament arrow-shaped, narrower than the anther. Cluster elongated, cylindrical. Bractæas shorter than the calyx, deciduous.—Gathered by Dr. F. Buchanan in the woods of Upper Nepal, flowering in June. Habit of the last, but taller, with larger more pointed leaves. The inflorescence is much more striking, and consists of a long terminal racemus of numerous orange-coloured flowers, which are twice the size of the former, and essentially distinguished from that by the arrow-shaped form of the appendage to their filament, which does not extend beyond the anther, except at its rounded termination.

3. *G. versicolor.* Sm. Exot. Bot. v. 2. 116. t. 117. a, b, c, (Hura Siamensis; Kœnig in Retz. Obs. fasc. 3. 49)—Appendage of the filament four-lobed, divaricated. Cluster somewhat corymbose. Bractæas shorter than the calyx. Lip towards the middle of the filament—Found by Kœnig plentifully in grassy shady parts of the island called Young Ceylon, in the East Indies. The cluster of flowers is shorter and more corymbose than in *G. racemosa*, and the corolla is variegated with orange, white, and different shades of violet. The appendage of the filament nearly resembles that of *G. marantina*, but the situation of the lip, thrust, as it were, half way up the filament, above the other lobes of the corolla, is altogether peculiar. For this, however, we depend on a drawing made by Mr. Sidney Parkinson, and communicated by Sir Joseph Banks, of the accuracy of which we have no reason to doubt. Kœnig mentions a more dwarf variety, found near the town of Malacca. Can this be what has lately been introduced into the stoves about London by Dr. Roxburgh, and which we have seen and examined at Sir Abraham Hume's, and at Messrs. Lee and Kennedy's, flowering in June 1810? It is figured in Curtis's Magazine,

t. 1320, where Dr. Sims has, we think, justly made this pretty plant a new genus, by the name of *Manifisa saltatoria*. It differs from *Globba* in having a radical, not terminal, inflorescence, which, as far as we know, is an infallible indication of a generic difference in this natural order, and therefore the flower affords, as was necessarily to be expected, clear essential characters of distinction, in the two long linear appendages to the lower part of the filament, which supply the place of two of the inner segments of the corolla, while the lip, which makes the third, is not bifid at its upper extremity. The large purple bractæas, and the branched flower-stalk, are also remarkable. S.

GLOBE, in *Geometry*, a round or spherical body, more usually called a *sphere*; which see.

The earth and water together are supposed to form a globe; hence called the *terraqeous globe*.

The planets, both primary and secondary, are supposed, as well as our earth, to be solid globes.

The earth is, in a particular sense, called the globe, or globe of earth; though it is now well known that this is not its true figure. See *Figure of the EARTH*.

GLOBE, *Resistance of a.* See *RESISTANCE*.

GLOBE is more particularly used for an artificial sphere of metal, plaster, paper, or some other matter; on whose convex surface is drawn a map, or representation, either of the earth or heavens, with the several circles conceived thereon.

GLOBES are of two kinds, *terrestrial* and *celestial*: each of very considerable use, the one in astronomy, and the other in geography, to perform many of the operations thereof in an easy, sensible manner, so as to be conceived without any knowledge of the mathematical grounds of those arts.

The fundamental parts, common to both globes, are an axis, representing that of the world, and a spherical shell or cover, which makes the body of the globe, on whose external surface the representation is drawn.

Globes, we have observed, are made of divers materials, viz. silver, brass, paper, plaster, &c. Those commonly used are of plaster and paper; the construction whereof is as follows.

GLOBES, *Construction of.* A wooden axis is provided, somewhat less than the intended diameter of the globe; and into the extremes hereof two iron wires are drawn for poles: this axis is to be the beam or basis of the whole structure.

On the axis are applied two spherical, or rather hemi-spherical caps, formed on a kind of wooden mould or block. These caps consist of pasteboard and paper, laid, one lay after another, on the mould, to the thickness of a crown piece; after which, having stood to dry and embody, making an incision along the middle, the two caps, thus parted, are slipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on those of the mould; and to fix them in their new place, the two edges are sown together with packthread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are halped in a metalline semi-circle of the size intended; and a kind of plaster, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper surface. In proportion as the plaster is applied, the ball is turned round in the semi-circle, the edge whereof pares off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are short of it.

After such application of plaster, the ball stands to dry: which done, it is put again in the semi-circle, and fresh matter

matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball everywhere accurately touches the semi-circle; in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores or gussets, all which join accurately on the spherical surface, and together cover the whole ball. To direct the application of these gores, lines are drawn by a semi-circle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to resist dust, moisture, &c.

The globe itself thus finished, they hang it in a brass meridian, with an hour circle and quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, Description of the. The things common to both globes are either delineated on the surface, or added as appendages without it.

Without the surface are, 1. The two poles whereon the globe is turned, representing those of the world. (See **POLE**.) 2. The brazen meridian, which is divided into degrees, and passes through the poles. 3. The wooden horizon, whose upper side represents the horizon, and is divided into several circles; the innermost whereof contains the twelve signs of the zodiac, subdivided into their degrees; the next the Julian; and the third the Gregorian calendar; without side of all these, are drawn the points of the winds. 4. A brass quadrant of altitude, divided into 90 degrees, to be fastened on the meridian at the distance of 90 degrees from the horizon. 5. The hour-circles, divided into twice twelve hours, and fitted on the meridian, round the poles, which carry an index pointing to the hour. A mariner's compass is sometimes added on the bottom of the frame, and sometimes a semi-circle of position.

On the surface are delineated, 1. The equinoctial line, divided into 360 degrees, commencing from the vernal interfections. 2. The ecliptic, divided into twelve signs, and these subdivided into degrees. 3. The zodiac. 4. The two tropics. And, 5. The polar circles. All which see under their proper articles.

What else belongs to globes, either as to construction or description, is different as the globe is either *celestial* or *terrestrial*.

Our common globes, though instructive instruments for explaining the first rudiments of geography and the spherical doctrine of astronomy, yet labour under several defects; as they do not shew how the phenomena, illustrated by them, arise from the motion of the earth, which is the principal thing beginners especially should have in view, and as they are only formed for the present age, and do not serve the purposes of chronology and history, which they might be made to do, if the poles, whereon they turn, were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

Mr. John Senex, F.R.S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass, at the distance of $23^{\circ}\frac{1}{2}$ from the poles of the ecliptic. These shoulders are strongly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very stiff motion; so that when it is adjusted to any point of the ecliptic, which the equator is made to intersect, the diurnal motion of the globe on its axis will not be able to

disturb it. When it is to be adjusted for any time, past or future, one of the brazen shoulders is brought under the meridian, and held fast to it with one hand, whilst the globe is turned about with the other, so that the point of the ecliptic, which the equator is to intersect, may pass under 0 degree of the brazen meridian: then holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required; and transferring the pencil to $23^{\circ}\frac{1}{2}$, and $66^{\circ}\frac{1}{2}$ on the brazen meridian, the tropics and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the risings and settings of the stars, in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex's celestial globes, especially the two greatest, of seventeen and twenty-eight inches in diameter, have been constructed on this principle: so that by means of a nut and screw, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Trans. N^o 447, p. 201. 203. or Martyn's Abr. vol. viii. p. 217. and N^o 493, art. 18 in Phil. Trans. vol. xli. p. 290.

Mr. Joseph Harris, late assay-master of the mint, contrived to remedy the former of the defects above-mentioned, by placing two horary circles under the meridian, one at each pole; these circles are fixed tight between two brass collars placed about the axis, so that when the globe is turned, they are carried round with it, the meridian serving as an index to cut the horary divisions. The globe, in this state, serves readily for solving problems in north and south latitudes, and also in places near the equator; whereas, in the common construction, the axis and horary circle prevent the brass meridian from being moveable quite round in the horizon. This globe is also adapted for shewing how the vicissitudes of day and night, and the alteration of their lengths, are really occasioned by the motion of the earth; for this purpose, he divides the brass meridian, at one of the poles, into months and days, according to the sun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will represent the circle separating light and darkness, and the upper half of the globe the illuminated hemisphere, the sun being in the zenith.

Mr. Harris also gives an account of a cheap machine for shewing how the annual motion of the earth in its orbit causes the change of the sun's declination, without the great expence of an orrery. Phil. Trans. N^o 456, p. 321, &c. or Martyn's Abr. vol. viii. p. 352.

The late Mr. George Adams, mathematical instrument maker to his majesty, has made some useful improvements in the construction of the globes. His globes, like others, are suspended at their poles in a strong brass circle, and turn therein upon two iron pins, which are the axis. They have besides a thin brass semi-circle, moveable about the poles, with a small, thin, sliding circle upon it. On the terrestrial globe, the thin brass semi-circle is a moveable meridian, and its small sliding circle the visible horizon of any particular place to which it is set. On the celestial globe, the semi-circle is a moveable circle of declination, and its small annexed circle an artificial sun or planet. Each globe hath a brass wire circle, placed at the limits of the twilight, which, together with the globe, is set in a wooden frame, supported by a neat pillar and claw, with a magnetic needle at its base. On the terrestrial globe the division of the earth into land and water is laid down from the latest discoveries; there are also many additional circles, as well as the rhumb-lines, for solving all the necessary geographical and nautical

nautical problems. On the celestial globe, all the southern constellations, lately observed at the Cape of Good Hope by M. de la Caille, and all the stars in Mr. Flamsteed's British Catalogue, are accurately laid down and marked with Greek and Roman letters of reference, in imitation of Bayer. Upon each side of the ecliptic are drawn eight parallel circles, at the distance of one degree from each other, including the zodiac; and these are crossed at right angles with segments of great circles at every fifth degree of the ecliptic, for the more readily noting the place of the moon, or of any planet upon the globe. The author has also inserted, from Ulugh Beigh, printed at Oxford in 1665, the mansions of the Moon of the Arabian Astronomers, so called, because they observed the moon to be in or near one of these every night during her monthly course round the earth, to each of which the Arabian characters are fixed. On the strong brass circle of the terrestrial globe, and about $23^{\circ}\frac{1}{2}$ on each side of the north pole, the days of each month are laid down according to the sun's declination; and this brass circle is so contrived, that the globe may be placed with the north and south poles in the plane of the horizon, and with the south pole elevated above it. The equator, on the surface of either globe, serves the purpose of the horary circle, by means of a semi-circular wire placed in the plane of the equator, carrying two indices, one of which is occasionally to be used to point out the time. For a farther account of these globes, with the method of using them, the reader may consult Adams's Treatise on their Construction and Use, &c. 1769.

GLOBE, Celestial, is an artificial sphere, on whose convex surface the fixed stars are laid down, at proportionable distances, together with the principal circles of the sphere.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for if the eye were placed in the centre of it, and the globe made of glass, the stars that are drawn upon it would appear in a concave surface, exactly corresponding to those in the heavens. The use of these globes is to exhibit the phenomena of the motions of the sun and stars, in an easy and obvious manner; which, though somewhat inaccurate, is yet exact enough for the common uses of life, and may save the trouble of trigonometrical calculations.

To exhibit the stars, circles, &c. on the surface of a given sphere or ball, and fit for the uses of astronomy.—1. Assume any two points diametrically opposite to each other, as P and Q (*Plate XIV. Astronomy, fig. 117.*) and in these fix up axes, P A and Q C, for the ball to turn round on. The points P and Q, or A and C, will exhibit the poles of the world.

2. Divide a brazen circle A B C D into four quadrants, A E, E C, C F, and F D; and subdivide each quadrant into 90 degrees, numbered from the points E and F, towards the poles A and C.

3. Inclose the globe in this circle, as in a meridian, at the points A and C, so as it may freely turn therein.

4. Apply a style or pin to the surface of the globe, in the first degree of the meridian, and turn the ball round; by this means will a circle be described on the surface, representing the equator to be divided into degrees.

5. From the pole of the world P towards M, and from the other pole C towards N, number $23\frac{1}{2}$ degrees; the points M and N will be the poles of the ecliptic.

6. Apply a style to the meridian, in the point M, and turn the globe round; by this rotation will the arctic polar

circle be described: and after the same manner is the antarctic polar to be described about the point N.

7. Number $23\frac{1}{2}$ deg. from the equator towards the poles P and Q, and note the points H and I; then applying a style to the meridian, as before, two circles will be described parallel to the equator, whereof that drawn through H will be the tropic of Cancer, and the other through I the tropic of Capricorn.

8. Hang the globe within the meridian, in the poles of the ecliptic, as before in the poles of the world; and applying a style to E, turn it round: by this means will the ecliptic be delineated, which remains to be divided into twelve signs; and each of these, again, divided into thirty degrees.

9. While the globe remains thus suspended, bring the degree of longitude of any star under the meridian; and in the meridian, number as many degrees towards the pole as is the degree of latitude of the place: the point of intersection is the place of that star on the surface of the globe. After the like manner may the place of the star be determined from the right ascension and declination given, the globe being supposed suspended from the poles of the world, or the equator.

10. All the stars of a constellation thus laid down, the figure of the constellation is to be designed; after which it may either be coloured or engraven.

11. Place the globe with the meridian, in a wooden frame or horizon, D B L, supported on four feet, in such manner as to be divided thereby into two hemispheres, and that the pole A may be raised or depressed at pleasure.

12. On the limb or edge of the horizon describe a circle, which divide into 360 degrees, and insert the calendars and winds.

13. Lastly, To the pole A fit a brazen circle, divided into twenty-four horary parts, and numbered twice twelve, so that the line of division of XII. may be in the plane of the meridian, on either side the pole; and on the pole itself apply an index, to turn round with the globe. See *Horary CIRCLE*. Thus is the globe complete.

It may be here observed, that as the longitude of the stars is continually increasing, a common globe does not remain of perpetual use: but the increase in seventy-two years only amounting to a degree, the whole will make no considerable error in a hundred years; the design of a globe being only to represent things something near the truth.

GLOBE, to make a celestial. This method is that the most frequently used; and we only premised the former as being the most easily conceived, and leading more naturally to this.

1. From the given diameter of the globe, find a right line A B, *fig. 118.* equal to the circumference of a great circle, and divide it into twelve equal parts.

2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of ten of them, describe arches, mutually intersecting each other in D and E: these figures or pieces, duly pasted or joined together, will make the whole surface of the globe.

3. Divide each part of the right line A B into thirty equal parts, so that the whole line A B, representing the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, *fig. 119.* with the interval of $23\frac{1}{2}$ deg. describe arches *a, b*; these will be twelve parts of the polar circles.

5. After the like manner, from the same poles D and E, with the interval of $66\frac{1}{2}$ deg. reckoned from the equator, describe

describe arches *c, d*; these will be twelfth parts of the tropics.

6. Through the degree of the equator *e*, corresponding to the right ascension of any given star, and the poles *D* and *E*, draw an arch of the circle, and taking in the compasses the complement of the declination from the pole *D*, describe an arch intersecting it in *i*; this point *i* will be the place of that star.

7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed.

8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic *d g* to be determined.

9. The surface of the globe thus projected on a plane is to be engraven on copper, to save the trouble of doing this over again for each globe.

10. A ball, in the mean time, is to be prepared of paper, plaster, &c. after the manner above directed, and of the intended diameter of the globe: on this, by means of a semi-circle and style, is the equator to be drawn: and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, they are to be cut from the printed paper, and pasted on the ball.

11. Nothing now remains but to hang the globe, as before, in a brazen meridian and wooden horizon; to which may be added a quadrant of altitude *H I*, *fig. 120.* made of brass, and divided in the same manner as the ecliptic and equator.

If the declinations and right ascensions of the stars be not given, but their longitudes and latitudes in lieu thereof, the surface of the globe is to be projected after the same manner as before: except that, in this case, *D* and *E*, *fig. 121.* are the poles of the ecliptic, and *sb* the ecliptic itself; and that the polar circles and tropics, with the equator *g d*, and the parallels thereof, are to be determined from their declinations.

One of the fullest catalogues of the stars is that of Mr. Flamsteed; wherein the right ascensions and declinations, as well as the longitudes, latitudes, &c. are every where expressed.

GLOBE, use of the celestial. The use of this instrument is very extensive; there being scarcely any thing in the spherical astronomy but may be exhibited thereby.

The principal points are contained in the following problems, with their solution; which will let the reader enough into the nature and reason of this noble instrument, to apply it, of his own accord, in any other cases.

To find the right ascension and declination of a star, represented on the surface of the globe.—Bring the star to the graduated side of the brazen meridian: then the number of degrees intercepted between the equator, and the point on the meridian cut by the star, gives its declination; and the degree of the equator which comes under the meridian, together with the star, is its right ascension.

To find the longitude and latitude of a star.—Apply the centre of the quadrant of altitude over the pole of the ecliptic in the same hemisphere with the star, and bring its graduated edge to the star: the degree on the quadrant cut by the star is its latitude, reckoned from the ecliptic; and the degree of the ecliptic cut by the quadrant its longitude.

To find the sun's place in the ecliptic.—Seek the day of the month in the proper calendar on the horizon, and against the day in the circle of signs is the sign and degree the sun is in for that day; this done, find the same sign upon the

ecliptic, on the surface of the globe; this is the sun's place for that day.

To find the declination of the sun.—The sun's place for the day given being brought to the meridian, the degrees of the meridian intercepted between the equinoctial and that place, are the sun's declination for that day at noon.

To find the place of a planet, with its right ascension and declination; its longitude and latitude for the time being given.—Apply the centre of the quadrant of altitude on the pole of the ecliptic (the pole, we mean, of the same denomination with the latitude), and bring it to the given longitude in the ecliptic: this point is the planet's place; and bringing it to the meridian, its right ascension and declination will be found, as already shewn of a star.

To rectify the globe, or adjust it to the place, &c. so as it may represent the present state or situation of the heavens.—

1. If the place be in north latitude, raise the north pole above the horizon; if in south, raise the south pole; till the arch intercepted between the pole and horizon be equal to the given elevation of the pole. 2. Fix the quadrant of altitude on the zenith, *i. e.* on the latitude of the place. 3. By means of a compass or meridian line, place the globe in such a manner as that the brazen meridian may be in the plane of the terrestrial meridian. 4. Bring the degree of the ecliptic the sun is in to the meridian, and set the horary index to twelve; thus will the globe exhibit the face of the heavens for the noon of that day. 5. Turn the globe till the index come to any other given hour: thus will it shew the face of the heavens for that time.

To know all the stars and planets by means of the globe.—

1. Adjust the globe to the state of the heavens for that time. 2. Look on the globe for some one star which you know, *e. gr.* the middlemost star in the tail of the Great Bear. 3. Observe the positions of the other more conspicuous stars in the same constellation; and by transferring the eye from the globe to the heavens, you will easily note the same there. 4. After the same manner may you proceed from this to the neighbouring constellations, till you have learned them all.

If the planets be represented on the globe, after the manner above described, by comparing them with the neighbouring stars you will likewise know the planets.

To find the sun's oblique ascension, his eastern amplitude, and azimuth, with the time of rising.—1. Rectify the globe for the hour of twelve, and bring the sun's place to the eastern side of the horizon: then the number of degrees, intercepted between that degree of the equator now come to the horizon and the beginning of Aries, is the sun's oblique ascension. 2. The degrees on the horizon, intercepted between the east point thereof and the point wherein the sun is, is the oblique or rising amplitude. 3. The hour, pointed to by the index, is the time of the sun's rising. 4. Turning the globe till the index points to the present hour, lay the quadrant to the sun's place: the degree cut by the quadrant, in the horizon, is the sun's azimuth.

To find the sun's oblique descension, western amplitude, and azimuth, with the time of setting.—The solution of this problem is the same as that of the former; excepting that the sun's place must be here brought to the western side of the horizon, as in the former it was to the eastern.

To find the length of day and night.—1. Find the time of the sun's rising, which being numbered from midnight, the double thereof gives the length of the night. 2. Subtract the length of the night from the whole day, or twenty-

twenty-four hours, and the remainder is the length of the day.

To find the rising, setting and culminating of a star; its continuance above the horizon for any place and day; together with its oblique ascension and descension, and its eastern and western amplitude and azimuth.—1. Adjust the globe to the state of the heavens at twelve o'clock that day. 2. Bring the star to the eastern side of the horizon: thus will the western amplitude and azimuth, and time of rising, be found, as already taught of the sun. 3. Bring the same star to the western side of the horizon: thus will the western amplitude and azimuth, and the time of setting, be found. 4. The time of rising, subtracted from that of setting, leaves the continuance of the star above the horizon. 5. This continuance above the horizon, subtracted from twenty-four hours, leaves the time of its continuance below the horizon. 6. Lastly, the hour to which the index points, when the star is brought to the meridian, gives the time of its culmination.

To find the altitude of the sun, or star, for any given hour of the day or night.—1. Adjust the globe to the position of the heavens, and turn it till the index point at the given hour. 2. Fix on the quadrant of altitude, at 90 degrees from the horizon, and bring it to the sun's or star's place; the degrees of the quadrant, intercepted between the horizon and the sun or star, is the altitude required.

The altitude of the sun by day, or of a star by night, being given, to find the time of that day or night.—1. Rectify the globe as in the preceding problem. 2. Turn the globe and quadrant, till such time as the star, or degree of the ecliptic the sun is in, cut the quadrant in the given degree of altitude; then does the index point at the hour sought.

The azimuth of the sun or a star given, to find the time of the day or night.—Rectify the globe, and bring the quadrant to the given azimuth in the horizon; turn the globe, till the star come to the fame: then will the index shew the time.

To find the interval of time between the risings of two stars, or the culminations.—1. Raise the pole of the globe so many degrees above the horizon, as is the elevation of the pole of the place. 2. Bring the first star to the horizon, and observe the time the index points to. 3. The same do by the other star: then subtracting the former time from the latter, the remainder is the interval between the risings.

After the like manner is the interval between two culminations found, by bringing both stars to the meridian.

The day of the month being given, to find when any star will come to the meridian.—Rectify for the sun's place; turn the globe till the given star comes to the meridian; then the index will point to the time sought.

To find when any given star will come to the meridian, at any given hour of the night.—Bring the given star to the meridian; set the index to twelve at noon; then turn the globe eastward, till the index points to an hour as far distant in the forenoon from twelve as the given hour is in the afternoon, observe the degree of the ecliptic then at the meridian, over-against which degree, in the calendar, is the day of the month, when the given star will be upon the meridian at the given hour.

By observation of a star upon the meridian, to find the hour of the night.—Rectify for the latitude and the sun's place; bring the given star to the meridian, and the index will shew the hour of the night.

VOL. XVI.

To find the beginning and ending of the crepusculum or twilight.—1. Rectify the globe, and set the index to the twelfth hour, the sun's place being in the meridian. 2. Note the sun's place, and turn the globe westward, as also the quadrant of altitude, till the point opposite the sun's place cut the quadrant of altitude in the eighteenth degree above the horizon: the index will then shew the time when the twilight commences in the morning. 3. Taking the point opposite to the sun, bring it to the eastern hemisphere, and turn it, till it meet with the quadrant of altitude in the eighteenth degree: then will the index shew the time when the twilight ends.

Given the sun's longitude and the obliquity of the ecliptic, to find the sun's right ascension and declination.—Find the sun's longitude or place on the ecliptic, and bring it to the brazen meridian. Then the arc of the equator, between the first point of Aries and the brazen meridian, shews the sun's right ascension; and the arc of the brazen meridian between the equator and the ecliptic shews the declination.

Given the obliquity of the ecliptic and the sun's declination, to find the sun's longitude and right ascension.—Mark the sun's declination on the brazen meridian, and turn the globe till the ecliptic comes under the figure; then will the distance from the meridian to the first point of Aries shew the sun's longitude on the ecliptic, and its right ascension on the equator.

Given the obliquity of the ecliptic and the sun's right ascension, required the sun's declination and longitude.—Bring the sun's right ascension in the equator to the brazen meridian, then will the intercepted arc of the ecliptic to Aries shew the sun's longitude; and the arc of the meridian, that is between the sun's right ascension and longitude, will shew the declination.

To find on what day the sun begins to shine constantly at any given place in either of the frigid zones, and how long he continues to shine without intermission at the same place.—Subtract the latitude of the given place from 90°, and find in what two days of the year the sun's declination is exactly equal to the remainder, and of the same kind as the latitude of the place; then on the first of those days in the spring quarter, the sun ceases to set at the given place, and shines without intermission there till he arrives at another point of the ecliptic, as many degrees on the other side of the summer solstice, when his declination is again equal to the complement of the latitude: the space of time between those two days is the length or duration of the longest day.

To find the latitude of those places in the north frigid zone, where the sun begins to shine constantly on any day between the vernal equinox and the summer solstice, or in the south frigid zone on any day between the autumnal equinox and the winter solstice.—Find the sun's declination for the given day; subtract it from 90°, and the remainder will be the latitude of those places: where the sun begins to shine constantly the latitude is of the same kind as the sun's declination.

To determine under what latitude two given stars rise or set at the same instant.—Bring one of the stars to the horizon, and, keeping it there, raise or depress the pole till the other is on the horizon at the same time, observing whether this is effected on the east or west position of the horizon: then the degree of the meridian, intersected by the horizon, will be the latitude of the place required.

To find at what place a given star is vertical at any given hour at London; e. g. at what place will Capella be vertical the 2d of March at 10 o'clock afternoon, at London time.

N. B.—This problem requires the assistance of both the terrestrial and celestial globes.

1. Find, as above, the time of the meridian passage of the star:

star: in the present instance Capella passes about 6 o'clock in the afternoon.

2. Find under what meridian they reckon 6 o'clock when it is to with us, which will be four hours to the west.

3. Observe under this meridian the place whose latitude is equal to the declination of the star, which, in this example, is nearly 46: and this place, which is near Louisburg, in North America, will be the place required.

To explain the phenomena of the harvest-moon by the globe, see MOON.

GLOBE, Terrestrial, is an artificial sphere, on whose surface are delineated the principal places of the earth, in their proper situations, distances, &c. together with their circles imagined on the surface of the terrestrial sphere. The use of the terrestrial globe, is to exhibit the several affections and phenomena of the different places of the earth, depending on magnitude, &c. in an easy obvious manner, without the trouble of trigonometrical calculations.

GLOBE, To construct a terrestrial.—The construction of a terrestrial globe, whether of metal, plaster, paper, &c. is the same as that of a celestial. The same circles are delineated on both: and as for the places, viz. cities, towns, &c. they are laid down from the longitudes and latitudes given, as the stars are from their right ascensions and declinations.

Hence all problems, depending on the circles, may be equally wrought on either globe; as the ascensions, descensions, amplitudes, azimuths, risings, settings, altitudes, &c. of the sun; the lengths of day and night; hours of the day and night; crepuscula, &c.

We shall here, therefore, only give what is peculiar to the terrestrial globe.

GLOBE, Use of the terrestrial. To find the longitude and latitude of any place delineated on the globe.—Bring the place to the graduated side of the brass meridian: the degree of the meridian it cuts is the latitude required; and the degree of the equator, at the same time under the meridian, is the longitude required.

The longitude and latitude given, to find the place on the globe.—Seek, in the equator, the given degree of longitude, and bring it to the meridian: then count from the equator on the meridian the degrees of latitude given, towards this or that pole, as the latitude is either north or south: the point under this is the place required.

The hour being given at any place, to find what hour it is in any other part of the world.—Bring the given place to the meridian, and set the hour-index to the given hour; then, by turning the globe, bring any place to the meridian, and the index will point to the hour of that place.

To find the antæci, periæci, and antipodes of any place.—1. The given place being brought to the meridian, count as many degrees on the meridian from the equator towards the other pole: the point which is thus arrived at is the place of the antæci. 2. Note the degree of the meridian over the given place and its antæci, and turn the globe till the opposite degree of the equator come under the meridian; or, which amounts to the same, till the index, which before stood at twelve, come to the other twelve: then will the place, corresponding to the former degree, be the periæci; and the latter, that of the antipodes.

To find what place of the earth the sun is vertical to at any time assign'd.—1. Bring the sun's place found in the ecliptic to the meridian, and the index to the hour of twelve, noting what point of the meridian corresponds thereto. 2. If the given hour be before noon, subtract it from twelve hours, and turn the globe towards the west, till the index points at

the hours remaining: thus will the place required be under the point of the meridian before noted. 3. If the hour be after noon, turn the globe in the same manner towards the west, till the index points at the given hour: thus, again, will the place required be found under the point of the meridian before noted.

If, at the same time, you note all the places which are under the same half of the meridian with the place found, you will have all the places to which the sun is then in the meridian; and the opposite half of the meridian will shew all the places in which it is then mid-night.

A place being given in the torrid zone, to find the two days in the year wherein the sun is vertical in the same.—1. Bring the given place to the meridian, and note the degree of the meridian corresponding thereto. 2. Turn the globe about, and note the two points of the ecliptic passing through that degree. 3. Find on what days the sun is in these points of the ecliptic: for on those days he is vertical to the given place.

To find those places in the torrid zone to which the sun is vertical on a given day.—Bring the sun's place in the ecliptic to the meridian; then turning the globe round, note all the places which pass through that point of the meridian: those are the places required.

After the same manner may be found what people are ascen for any given day.

The day and hour at any place being given, to find where the sun is vertical at that hour.—Bring the sun's place to the meridian, and the degree over it is the sun's declination at that time: then bring the given place to the meridian, and set the index to the given hour; turn the globe till the index points to twelve at noon, and the place on the globe which lies under the degree of the sun's declination has the sun then vertical.

A place being given in the frigid zone, to find the time when the sun begins to appear above the horizon, and when it begins to disappear; and also the length of the longest day or night in that place.—Rectify for the latitude; bring the ascending part of the ecliptic, i. e. for latitudes north of the tropic of Cancer the semicircle intercepted between Capricorn and Cancer, to the south point of the horizon; observe the degree of the ecliptic which cuts that point, and find when the sun enters that degree, and this will give the time when the sun begins to appear in that latitude. Bring the descending part of the ecliptic to the same point of the horizon, and the calendar will shew when the sun leaves that latitude and disappears. Again, bring the ascending part of the ecliptic to the north point of the horizon, and the degree, as before, will shew in the calendar when the longest day begins; and by bringing the descending part of the ecliptic to the same north point, we shall find, in the same manner, when the longest day ends.

To find the latitude of the places wherein any given day is of any given length.—1. Bring the sun's place for the given day to the ecliptic, and set the index to the hour of twelve. 2. Turn the globe, till the index points at the hour of rising or setting. 3. Raise and depress the pole till the sun's place appear in the eastern and western side of the horizon: then will the pole be duly elevated, and, consequently, the latitude given.

To find the latitude of those places in the frigid zone where the sun does not set for a given number of days.—1. Count so many degrees from the next tropic, towards the equinoctial point, as there are units in half the number of the given days; because the sun, in its proper motion, goes nearly a degree every day. 2. Bring the point of the ecliptic, thus found, to the meridian; and its distance from the pole will

will be equal to the elevation of the pole, or latitude of the places required.

Any hour of the day or night being given, to shew all those places to which the sun rises and sets; where it is noon or midnight; and where day or night.—1. Find what place the sun is at that time vertical to, as already taught. 2. Let this place be brought to the zenith of the wooden horizon, *i. e.* elevate the pole as the latitude of that place requires; then will the places on the eastern side of the horizon be those the sun is setting to; and on the western side, those he rises to: those under the upper semi-circle of the meridian have it noon; and those under the lower, midnight. Lastly, to those of the upper hemisphere it is day; and to those in the lower, night.

Hence, as in the middle of an eclipse, the moon is in that degree of the ecliptic opposite to the sun's place; by the present problem it may be shewn what places of the earth then see the middle of the eclipse, and what the beginning or ending.

To find what places of the earth a planet, e. gr. the moon, is vertical to any day of the year.—1. Mark the planet's place on the globe, as above taught. 2. Bring this place to the meridian, and note the degree over it. 3. Turn the globe round, and the places which pass under the point are those required.

The declination of a star, or any other phenomenon, given, to find what parts of the earth the same is vertical to.—Count as many degrees in the meridian, from the equator towards one pole, as are equal to the given declination; *viz.* towards the north, if the declination be to the northward; and towards the south, if the declination be south. Then turning it round, the places that pass through the extremity of this arch in the meridian are the places required.

To determine the place of the earth where any star, or other celestial phenomenon, will be vertical at a given hour.—1. Elevate the pole according to the latitude of the place, from whose noon or midnight the hours are numbered. 2. Bring the sun's place for that day to the meridian, and set the index at twelve o'clock. 3. Determine the place of the star on the surface of the globe, and bring it to the meridian; the index will shew the difference of time between the impulse of the sun and star to the meridian of the place: note the point of the meridian over the place of the star. 4. Find in what places of the earth it is then noon, and set the index to twelve o'clock. 5. Turn the globe towards the west, till the index has passed over the interval of time between the culmination of the sun and star. Then, under the point of the meridian, before observed, will the place required be found. And hence may always be found what place a star, or other phenomenon, rises or sets to at any given time.

To place the globe in such manner, under any given latitude, as that the sun shall illuminate all those regions which he actually illumines on earth.—1. Rectify the globe, *i. e.* elevate the pole according to the latitude of the place; bring the place to the meridian, and set the globe north and south by the compasses; thus, the globe having the same situation with regard to the sun as the earth has, that part thereof will be illuminated which is illuminated on earth. Hence also the globe being situate in the same manner, when the moon shines, it will shew what parts are then illuminated by the moon.

And in the like manner, we may find when the sun and moon rise and set at any given time.

To find the distance of two places on the globe.—Take the given places in the compasses, and apply them to the equa-

tor: the degrees which there subtend being reduced into miles, leagues, or the like, give the distances required.

The same may be done, and that more commodiously, by laying the graduated edge of the quadrant of altitude over the two places, and noting the degree intercepted.

To find how any one place bears from another.—Bring one place to the meridian, and lay the quadrant of altitude over the other, and it will shew on the horizon the point of the compass on which the latter bears from the former.

Problems on the terrestrial globe may sometimes be advantageously solved, by considering the horizon as the circle of illumination, and bringing the sun's place to the zenith.

To find for any given day and hour those places where the sun is then rising or setting; those places where it is noon, and in particular that place where the sun is vertical; those places that have morning or evening twilight; and those places where it was midnight.—Find the sun's place in the ecliptic for the given day, bring it to the brazen meridian, and mark its declination.

Elevate the (north or south) pole as many degrees above the horizon as are equal to the sun's declination (north or south). Bring the given place to the meridian, and set the index to the given hour, then turn the globe on its axis, till the index comes to the upper twelve, and fix the globe in that position. All these places along the western edge of the horizon have the sun rising, those along the eastern edge have the sun setting: it is noon to the places under the brazen meridian, and amongst them the sun is vertical to that place, which stands under the degree of the sun's declination.

Those places that are within 18° of the western semi-circle of the horizon have morning twilight, and those within 18° of the eastern semi-circle have evening twilight: and it is midnight at all those places under that part of the brazen meridian which is below the horizon. In short, it is day to all places above the horizon, and either twilight or dark night to all those which are below it.

The day and hour of a lunar eclipse being given, to find those places where it will be visible.—Find the place where the sun will be vertical when the eclipse begins, and rectify the globe, in respect to latitude, for the antipodes of that place. Then bring the antipodes to the upper part of the brazen meridian, and fix the globe in that position, and the beginning of the eclipse will be visible to all places which are then above the horizon.

To find the proportion which the land bears to the sea.—For this purpose Dr. Long proposes to take the papers of a large terrestrial globe, and after separating the land from the sea with a pair of scissars, to weigh them carefully in scales. This method supposes the globe to be exactly delineated, and all the papers of equal thickness. By an experiment on the papers of Mr. Senex's seventeen inch globe, he found that those comprehending the sea weighed 349 grains, and the others only 124; whence he infers, that almost three-fourth parts of the surface of our earth between the polar circles are covered with water, and that little more than one-fourth is dry land. Dr. Long omitted weighing the papers within the polar circles, because the proportion which the land bears to the sea within them is not ascertained. Long's Astron. vol. i. p. 163. See *Magnitude of the EARTH.*

GLOBE, *To construct a dial by the.* See DIAL.

The celestial globe has been improved by Mr. Ferguson: in this globe, (*Plate XV. Astronomy, fig. 122.*) an arch MKH, of 23½°, is fixed on the north pole of the axis, above the hour circle; and at the end is fixed an upright pin HG, standing

standing directly over the north pole of the ecliptic, and perpendicular to that part of the surface of the globe. On this pin are two moveable collets at D and H, to which are annexed the quadrantal wires N and O, carrying two little balls representing the sun and moon. The collet D is fixed to the circular plate F, on which are engraven the 29½ days of the moon's age, beginning under the wire N, which wire, as it turns round, carries with it the plate F. These wires are fixed or slackened by the screw G, and the two little balls are made to rise and set at the same time and on the same point of the horizon, for the day to which they are rectified, as the sun and moon do in the heavens. The ball representing the moon may be screwed as many degrees to either side of the ecliptic, as her latitude amounts to at any given time; and for this purpose, S is a small piece of pasteboard, the curved edge of which at S is to be set upon the globe at right angles to the ecliptic, and the dark line over S to stand upright upon it: from this line, on the convex edge, are drawn the 5¼ degrees of the moon's latitude on both sides of the ecliptic; and when this piece is set upright on the globe, its graduated edge reaches to the moon on the wire O, by which means she is easily adjusted to her latitude found by an ephemeris. The horizon of this globe is supported by two semi-circular arches, because pillars would stop the progress of the balls, when they go below the horizon in an oblique sphere. This globe is rectified by elevating the pole to the latitude of the place, bringing the sun's place in the ecliptic for the given day to the brazen meridian, and setting the hour-index to twelve at noon; then, setting the sun directly over his place in the meridian, and the moon over her place in the ecliptic, by fixing her wire under the number that expresses her age for that day on the plate F; and, lastly, laying the curved edge of the pasteboard S over the ecliptic below the moon, and adjusting the moon to her latitude over the graduated edge of the pasteboard. Having thus rectified the globe, turn it round, and observe on what point of the horizon the sun and moon balls rise and set; for these agree with the points of the compass on which the sun and moon rise and set in the heavens on the given day: and the hour-index shews the times of their rising and setting, and also the time of the moon's passing over the meridian. This globe is also contrived for exhibiting the phenomena of the harvest-moon, &c. Phil. Transf. N^o 483. art. 21. in vol. xlv. p. 535, or Ferguson's Astron. p. 291.

GLOBE, *Dialling*. See DIALLING.

GLOBES, *Patent*, are those with the improvements of Mr. Neale, for which he obtained his majesty's letters patent; by means of which he solves several astronomical problems, which do not admit of solution by the common globes.

GLOBE, *Planetary*, is a machine contrived and described by Mr. Ferguson; in which T (Plate XV. *Astronomy*, fig. 123) is a terrestrial globe fixed on its axis standing upright on the pedestal CDE, on which is an hour circle, having its index fixed on the axis, which turns somewhat tightly in the pedestal, so that the globe may not be liable to shake: to prevent which, the pedestal is about two inches thick and the axis goes quite through it, bearing on a shoulder. The globe is hung in a graduated brazen meridian, much in the usual way; and the thin plate N, NE, E, is a moveable horizon graduated round the outer edge, for shewing the bearings and amplitudes of the sun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a slender semi-circle of brass, the ends of which are fixed to the horizon in its north and south points: this semi-circle slides in the groove as the

horizon is moved in rectifying it for different latitudes. To the middle of the semi-circle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude *q* turns; the lower end of which, in all positions, touches the horizon as it is moved round the same. This quadrant is divided into 90 degrees from the horizon to the zenithal pin on which it is turned, at 90. The great flat circle or plate AB is the ecliptic, on the outer edge of which the signs and degrees are laid down; and every fifth degree is drawn through the rest of the surface of this plate towards its centre. On this plate are seven grooves, to which seven little balls are adjusted by sliding wires, so that they are easily moved in the grooves, without danger of starting out of them. The ball next the terrestrial globe is the Moon, the next without it is Mercury, the next Venus, the next the Sun, then Mars, then Jupiter, and lastly Saturn; and in order to know them, they are separately stamped with the following characters: ☾, ☿, ♀, ☼, ♁, ♃, ♄, ♅. This plate or ecliptic is supported by four strong wires, having the lower ends fixed into the pedestal at C, D, and E, the fourth being hid by the globe. The ecliptic is inclined 23½ degrees to the pedestal, and is therefore properly inclined to the axis of the globe which stands upright on the pedestal.

To rectify this machine.—Set the Sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris; then set the north point of the horizon to the latitude of your place on the brazen meridian, and the quadrant of altitude to the fourth point of the horizon; which done, turn the globe with its furniture till the quadrant of altitude comes right against the Sun, *viz.* to his place in the ecliptic; and keeping it there, set the hour index to the XII. next the letter C.

By this machine the following problems, as well as many others, may be resolved.

To find the amplitude, meridian altitudes, and times of rising, culminating, and setting of the sun, moon, and planets.—Turn the globe round eastward, or according to the order of the signs; and as the eastern edge of the horizon comes right against the sun, moon, or any planet, the hour-index will shew the time of its rising; and the inner edge of the ecliptic will cut its rising amplitude in the horizon. Turn on, and as the quadrant of altitude comes right against the sun, moon, or planets, the ecliptic cuts the meridian altitudes in the quadrant; and the hour-index shews the times of their coming to the meridian. Continue turning, and as the western edge of the horizon comes right against the sun, moon, or planets, their setting amplitudes are cut in the horizon by the ecliptic; and the times of their setting are shewn by the index on the hour-circle.

To find the altitude and azimuth of the sun, moon, and planets, at any time of their being above the horizon.—Turn the globe till the index comes to the given time in the hour-circle; and keep the globe steady, and moving the quadrant of altitude to each planet respectively, the edge of the ecliptic will cut the planet's mean altitude on the quadrant, and the quadrant will cut the planet's azimuth, or point of bearing on the horizon.

The sun's altitude being given at any time either before or after noon, to find the hour of the day, and the variation of the compass, in any known latitude.—With one hand hold the edge of the quadrant right against the sun; and, with the other hand, turn the globe westward, if it be in the forenoon, or eastward if it be in the afternoon, until the sun's place at the inner edge of the ecliptic cuts the quadrant in the sun's observed altitude; and then the hour-index will point out the

the time of the day, and the quadrant will cut the true azimuth, or bearing of the sun for that time: the difference between which, and the bearing shewn by the azimuth compass, shews the variation of the compass in that place of the earth. Fergufon's Astron. p. 292, &c.

GLOBE *Amaranth*. See COMPUR.ENA.

GLOBE *Animalcule*, in *Natural History*, is a singular, minute, aquatic animal, whose form seems exactly globular, without either head, tail, or fins. It moves in all directions, either rolling like a bowl, or gliding along smoothly without turning itself at all. Its whole body is transparent, except where it is covered with circular black spots; some of which have six or seven, some one, two, three, four or five, and others none at all. These spots are probably the eggs or young ones of the animal. The general appearance of the body exhibited a kind of short moveable hairs or bristles, by means of which it is conjectured the motions of the animal may be performed. Baker's Microf. 1753, p. 322, &c.

GLOBE, *Daisy*. See GLOBULARIA.

GLOBE *Fish*, in *Ichthyology*, a name by which some species of the ostracion are called. See OSTRACION.

GLOBE *Flower*, in *Botany*. See SPHERANTHUS.

GLOBE *Ranunculus*. See TROLLIUS.

GLOBE *Thistle*. See ECHINOPS.

GLOBULAR CHART, a representation of the surface, or some part of the surface, of the terraqueous globe upon a plane; wherein the parallels of latitude are circles nearly concentric: the meridians, curves, bending towards the poles; and the rhumb-lines also curves.

The merits of this chart consist in this, that the distances between places on the same rhumb are all measured by the same scale of equal parts; and the distance of any two places in the arch of a great circle, is nearly represented in this chart by a straight line. Hence land-maps, made according to this projection, would indisputably have great advantages above those made any other way. See MAP.

But for sea charts, and the use of navigation, it is yet controverted, whether the globular chart be preferable to Mercator's, where the meridians, parallels, and particularly the rhumb-lines, are all straight lines; inasmuch as straight lines are found more easy to draw and manage than curves, especially such as rhumb-lines on the globular chart are. This projection is not new, though not much taken notice of till of late. It is mentioned by Ptolemy in his Geography; as also by Blundeville, in his Exercises. See CHART.

GLOBULAR *Projection*. See PROJECTION.

GLOBULAR *Sailing*. See Great-circle SAILING.

GLOBULARIA, in *Botany*, was so called by Tournefort, because its flowers grow in the shape of a little globe or ball.—Linn. Gen. 47. Schreb. 63. Willd. Sp. Pl. v. 1. 539. Ait. Hort. Kew. ed. 2. v. 1. 222. Mart. Mill. Dict. v. 2. Lamarck Dict. v. 2. 730. Illustr. t. 56. Tourn. t. 265. Garta. t. 44. Juss 97.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Aggregata*, Linn. *Lyfmaehia*, Juss.

Gen. Ch. *Cal.* Common perianth imbricated, with equal scales, the length of the disk; proper perianth of one leaf, tubular, five-cleft, acute, permanent. *Cor.* General one nearly equal; proper one of a single petal, tubular at the base; limb in five segments; the upper lip very narrow, cleft, shortest; the lower consisting of three larger, equal segments. *Stam.* Filaments four, simple, as long as the proper corolla; anthers distinct, incumbent. *Pist.* Germen superior, ovate; style simple, the length of the stamens; stigma obtuse. *Peric.* none; proper calyx shutting up and

enclosing the solitary, ovate seeds. Common receptacle oblong, divided by scales.

Ess. Ch. Common calyx imbricated; proper one tubular, inferior. Partial corollas with the upper lip cleft; under one three-cleft. Receptacle chaffy.

1. *G. longifolia*. Long-leaved Globularia. Willd. Sp. Pl. v. 1. 539; (Alypum five Herba terribilis; Sloan. Jam. v. 1. 19. t. 5. f. 3.)—"Stem shrubby. Leaves linear-lanceolate, entire. Heads of flowers axillary."—This green-house shrub is a native of Madeira, flowering in July and August. The wood of this plant is hard and white, with a very large pith, and an unequal light brown or grey bark. Leaves growing very thick towards the ends of the branches. Flowers consisting of several spherical heads, of a blueish colour. Seed pappous, all over downy.

2. *G. Alypum*. Herb Terrible. Linn. Sp. Pl. 139. (Alypum montis Ceti; Ger. em. 506.)—"Stem shrubby. Leaves obovato-lanceolate, three-toothed or undivided. Heads of flowers terminal."—A green-house shrub, found in various parts of the south of Europe, flowering from August to November. Root woody. Leaves alternate, fasciculated in the lower axilla, near an inch long, glaucous, some are undivided, others three-toothed. Flowers blue or purple. The whole plant is bitter, and purgative in a violent degree.

3. *G. bifnagarica*. Linn. Sp. Pl. 139. (Scabiosa bifnagarica five *G. frutescens*; Pluk. Amalth. t. 58. f. 5.)—"Stem shrubby. Radical-leaves wedge-shaped, abrupt; stem-leaves lanceolate."—Native of the woods of India. Stem of many straight, hard, leafy branches, each about five or six inches high. Flowers in a blue terminal head.

4. *G. vulgaris*. Blue Daisy. Linn. Sp. Pl. 139. (Aphyllanthes anguillare; Camer. Hort. t. 7.)—"Stem herbaceous. Radical-leaves three-toothed. Stem-leaves lanceolate."—A hardy perennial, common in some parts of Europe, and flowering in May and June. Root woody. Stem a span high, terminated by a head of deep blue flowers. Willdenow mentions two varieties of this species, one with a leafless stem, the other with white flowers.

5. *G. spinosa*. Linn. Sp. Pl. 139—"Radical-leaves crenate-prickly; stem-leaves entire, pointed."—Native of Spain, Albinus having gathered it in Granada. It flowers in May.—Radical-leaves numerous, small, stiff and notched, each notch ending in a prickle. Flowers composing an oblong sphere, hairy.—We are not acquainted with any figure of this species.

6. *G. cordifolia*. Linn. Sp. Pl. 139. Jacq. Austr. t. 245.—"Stem nearly naked. Leaves wedge-shaped, with three points; the middle one very small."—Native both of hills and vales in Hungary, Austria, and Switzerland, flowering from April to July. Root creeping, each joint throwing out a cluster of leaves, from the centre of which springs a smooth purplish stem about four inches long, terminated by a head of blue flowers.

7. *C. nana* Willd. Sp. Pl. v. 1. 542.—"Flower-stalks naked, very short, leaves spatulate, somewhat ovate, entire."—Found in the south of France, and on the Pyrennes, where our dried specimen was gathered by Dr. Noehden.—Root woody and very thick, bearing numerous tufts of little leaves, among which arise the short, solitary flower-stalks. Flowers forming a terminal head.—It has never been figured.

8. *G. nudicaulis*. Linn. Sp. Pl. 140. Jacq. Austr. t. 230.—"Stem naked, leaves entire lanceolate."—Native of mountainous and stony places in Austria and Switzerland, flowering in July.—Root perennial, fibrous, creeping, throwing out numerous, thickish, firm Laves, darker on the upper

per side. *Flower-stalk* about six inches long, smooth, striated, purplish towards the top, bearing a roundish head of blue flowers.

9. *G. orientalis*. Linn. Sp. Pl. 140 — "Stem nearly naked. Heads of flowers alternate, sessile, leaves ovate, somewhat lanceolate, entire." — This species is a native of Natolia. — *Root* perennial. *Leaves* numerous, obovate, running down into the foot-stalks, acute, undivided, naked. *Stem* a foot high, herbaceous, perfectly simple. *Leaves* alternate, small, lanceolate, remote. *Heads of flowers* alternate, sessile, from seven to ten, at the summit of the stem. — Linnæus described *G. orientalis*, having received it from M. Biorling, but it is nowhere figured.

GLOBULARIA, in *Gardening*, contains plants of the herbaceous, showery, perennial kind; of which the species chiefly cultivated are the three-tooth-leaved globularia (*G. alypum*); and the common globularia or blue daisy (*G. vulgaris*); but others may be easily raised.

There are two varieties of the last sort, one with a white flower, and another that has a leafless stem.

Method of Culture. — In the first it may be effected by planting cuttings of the young branches in April, just before they begin to shoot, in pots of light fresh mould, plunging them in a very moderate hot-bed, and giving them due water and shade, till they have stricken root. After this they should be removed from the bed, and be gradually hardened to the open air, being protected during the winter months.

The second sort may be readily increased by parting the roots, as in the common daisy, planting them out in the early part of the autumn, in moist shady situations. They succeed best in such loamy soils as are rather moist in their quality.

The first affords variety among potted plants, and the latter in the fronts of the more moist and shady borders and clumps of pleasure-grounds.

GLOBULE, **GLOBULUS**, a little *globe*; otherwise called a *spherule*.

Thus the red particles of the blood are called globules of the blood, on account of their redness and smallness. (See **BLOOD**.) The Cartesianians call the particles broken off the matter of the first element, *globules of the second element*. See **CARTESIAN**, &c.

GLOBULUS NASI, is used for the lower, flexible, cartilaginous part of the nose.

GLOCHIDION, in *Botany*. See **BRADLEJA**.

GLOESZTI, in *Geography*, a town of Walachia; 50 miles N. of Bucharest. N. lat. 49° 13'. E. long. 26 16'.

GLOGAU, a principality of Silesia, on the E. side of the Oder, bordering on Poland; producing corn and wine in abundance, in some parts affording mines of iron. The pastures feed many sheep, and the wool is wrought into different manufactures. It is divided into six circles. In the year 1241, it was governed by its own princes; but afterwards it belonged to the king of Poland, to the king of Bohemia, to the emperor, and last of all to the king of Prussia.

GLOGAU, *Gros* or *Great*, the capital of the principality of the same name, built in 1110 on the S. side of the Oder, taken by the Prussians in 1741, and strengthened by new fortifications. It is the seat of a governor, a commandant, divers tribunals, and a bishop's court, &c. It contains two Catholic churches, of which one is collegiate, three convents, a Lutheran church and school, and a chapel for Calvinists; 62 miles N.W. of Breslau. N. lat. 51° 39'. E. long. 16 5'.

GLOGAU, *Ober*, or *Little*, a town of Silesia, in the prin-

cipality of Oppeln; 19 miles S. of Oppeln. N. lat. 50° 16'. E. long. 17° 48'.

GLOGNITZ, a town of Austria; 28 miles S. of Vienna.

GLOKEN-SPEISSE, in *Minerology*, a term used by the Germans to express a sort of impure regulus of bismuth, obtained by accident, sometimes in the making of steel. The bismuth ores are often so intimately mixed with the cobalt, that they cannot be separated from them. In this case, the arsenic being raised in the flowers, there remains at the bottom, instead of the fixed vitrifiable earth of the cobalt, a sort of impure regulus of a reddish colour. This is bismuth, with an admixture of the earth of cobalt, and other extraneous matter. They sometimes call this whole matter by the common name of speisse; but more usually they separate it into two parts, and call the under part, which is most solid, *gloken-speisse*, and the upper part they distinguish by the name of *as caldarium*.

GLOMERELLS, in our *Old Writers*, commissaries appointed to determine differences between scholars of a school or university, and the townsmen of a place. In the edict of the bishop of Ely, anno 1276, there is mention of the master of the glomerells.

GLOMME, or **GLOMEN**, in *Geography*, called also the *Stor Elv*, or great river, the chief river of Norway, springs from the lake of Oresund on the north of the Fœmund, and after running a course nearly south about 300 British miles, discharges itself into the Northern Ocean near Frederikstadt, to which town about 50,000 trees are annually floated upon it. This river, being full of cataracts and shoals, is not navigable. Before it receives the Worme, which issues from the lake Miosf, it is about as broad as the Thames at Henley. In its course it presents a broad surface, sometimes watering pleasant vallies, sometimes intercepted by sand-banks, over which it frequently shifts its course, sometimes winding between rocky cliffs, and precipitating itself in frequent cataracts. Near Kongswinger it is as broad as the Thames at Putney. Its rugged course, however, must render it a tremendous torrent.

GLOM, a river of Bavaria, which runs into the Ammer, near Crantzberg.

GLONS, a town of France, in the department of the Ourte, and chief place of a canton, in the district of Liege. The place contains 1,500, and the canton 8,850, inhabitants, on a territory of 107½ kilometres, in 23 communes.

GLOR-FAT, in *Rural Economy*, a term applied to animals that are extremely fat.

GLORIA PATRI, in the *Liturgy*, a formula of words repeated at the end of each Psalm, and on other occasions, to give glory to the Trinity; called also the *Doxology*. It is thus denominated, because it begins in the Latin office with these words; *Gloria Patri*, q. d. *Glory be to the Father*, &c.

Pope Damasus is commonly said to have first ordered the rehearsal, or rather, singing the Gloria Patri at the end of Psalms. Baronius, indeed, will have it to have been used in the times of the apostles; but its use, then, he allows to have been more obscure, and that it did not become popular till after the rise of Arianism, when it was made a kind of symbol of orthodoxy.

The fifth canon of the council of Vaison, held in 529, decrees, "that the name of the pope shall always be rehearsed in the churches of France, and after the Gloria Patri shall be added *sicut erat in principio*, as is done at Rome, in Africa, &c. on account of the heretics, who say,

say, that the Son of God had his beginning in time." Fleury.

GLORIA in *excelsis* is also a kind of hymn rehearsed in divine service, beginning with the words *Gloria in excelsis Deo, &c. in terra pax hominibus, &c. Glory be to God on high, on earth peace, &c.*

GLORIOSA, in *Botany*, so named on account of the splendour and magnificence of its flowers. Tournefort, objecting to the name given by Linnæus because it is an adjective, called this genus *Methonica*, in which he has been followed by Jussieu, and indeed by all French botanists, though the Linnæan school have refused to adopt this barbarous name.—Linn. Gen. 164. Schreb. 220. Willd. Sp. Pl. v. 2. 95. Ait. Hort. Kew. v. 1. 434. Mart. Mill. Dict. v. 2. Gærtn. t. 18. Juss. 48.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Lilia*, Juss.

Gen. Ch. *Cal.* none. *Cor.* Petals six, oblong-lanceolate, waved, very long, entirely bent back, furnished at the base of their inside with a honey-bearing furrow, between two ridges. *Stam.* Filaments six, awl-shaped, shorter than the corolla, horizontal; anthers incumbent. *Pist.* Germen globose; style thread-shaped, longer than the stamens, horizontal; stigmas three, thread-shaped. *Peric.* Capsule superior, oval, with three lobes, three cells, and three valves. *Seeds* numerous, globular, covered with pulp, and disposed in two rows.

Ess. Ch. Corolla of six waved and reflexed petals. Style oblique.

1. *G. superba*. Superb Lily. Linn. Sp. Pl. 437. Redout. Liliac t. 26.—“Leaves furnished with tendrils.”—Native of Malabar and Guinea. It was introduced into Kew Garden in 1690 by the first earl of Portland. A tender stove plant, flowering in July and August. The *stem* is herbaceous, about a fathom high, round, having two opposite lateral *branches*, and putting forth a flower-stalk from the bosom of each leaf. *Leaves* alternate, smooth, each ending in a *tendrill*. *Flowers* pendent, of a most beautiful red and yellow colour. *Petals* lanceolate, long, waved at the edge, reflexed near the base. This remarkably handsome plant requires excessive heat to make it flower.

2. *G. simplex*. Linn. Mant. 62. Willd. Sp. Pl. v. 2. 96.—“Leaves pointed.”—Native of Senegal. The *leaves* are not furnished with tendrils. *Flowers* blue.—There is no figure of this species known. It was merely taken up from Miller, nor has any thing been found which answers to the description.

Obs. This very beautiful genus is nearly allied to *Erythronium*.

GLORIOSA, in *Gardening*, comprises a plant of the herbaceous, flowering perennial kind; of which the species cultivated is the superb-lily (*G. superba*.)

Method of Culture.—It is capable of being increased by planting the offsets from the old roots, either in the autumn after the stems decay, or in the early spring before they shoot, in pots filled with light earth, plunging them in the bark-bed of the stove. The old roots, when taken out of the ground, should be preserved in dry sand during the winter in the stove, or in a dry warm room. It is the practice of some to let the roots remain during the winter in the mould, keeping the pots in the tan-bed; planting out the offsets early in the spring. In either way they should have very little water given them.

When the stems appear they should be supported by sticks, and in hot dry weather a little water should be sparingly given, as there may be occasion. And the pots in which they are planted should be small, that they may be confined, and put forth stronger stems. Two-penny pots will be large

enough for the roots of the greatest sized plants of this nature.

The plants afford much effect by their beautiful flowers among those of the stove kind, when properly intermixed with them.

GLORIOUS ISLANDS, in *Geography*, two small islands in the Indian sea. S. lat. 11 32'. E. long. 47° 15'.

GLOSKAR, a small island in the Baltic, E. of Aland. N. lat. 60 20'. E. long. 20 13'.

GLOSS, GLOSSA, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language, or in any other. See COMMENTARY.

The word, according to some, comes from *γλωσσα*, *tongue*; the office of a gloss being to explain the text, as that of the tongue is to discover the mind. Others derive it from the Latin *gloss*, of *γλωσσω*, a *syller-in-law*, which among lawyers sometimes stands for *sister*; the gloss being, as it were, *sister* to the text.

Nic de Lyra composed a postil or gloss on the Bible, in six volumes folio. The French say, proverbially of an ill comment, that it is *gloss d'Orleans, plus obscure que le texte*.

GLOSS is also used for a literal translation, or an interpretation of an author in another language, word for word. Young scholars need an interlinary gloss for the understanding of Juvenal, Horace, Sallust, Persius, &c.

GLOSS is also used in matters of *Commerce*, &c. for the lustre of silk, stuff, or the like.

GLOSSARY, GLOSSARIUM, a kind of dictionary for explaining the obscure, ancient, and barbarous words and phrases of an altered, corrupted, or refined language.

Speiman's glossary, entitled *Archæologicum*, is an excellent work; though that author did not begin to study in this way till fifty years of age. M. Du Cange's Latin Glossary in six volumes, Paris, fol. 1733, Basil, fol. 1762, is a work in high estimation, and containing a fund of the most curious and amusing intelligence. Charpentier's supplement to this work, in 4 volumes, fol. Paris, 1766, is necessary to render this set of books complete. Du Cange's Greek Glossary in two volumes, fol. Lugd. 1688, is an excellent performance, full of uncommon erudition.

The Greek, Latin, and French glossaries of Du Cange form a series of the most instructive articles in the study of jurisprudence and belles lettres. There is an abridgment of this work in 6 vols. 8vo.; which, however, contains some matter not common to either of the preceding. This abridgment is exceedingly rare. As a caution to the purchasers of the Greek Glossary, we inform them that in the article “*Moneta*” (Coins, vol. iv. p. 924.) there should be 10 plates of engravings of coins, and monograms of various princes and sovereigns of Europe, which are sometimes wanting, and thus the value of the edition is materially depreciated.

Lindembroek has a Glossary on the laws of Charlemagne, &c.

GLOSSOCATOCHOS, in *Surgery*, an instrument for depressing the tongue. It is described by Paulus Ægineta, and the term is derived from *γλωσσα*, *the tongue*, and *καίω*, *to press*.

GLOSSOCELE, denoting a swelling and protrusion of the tongue. The word comes from *γλωσσα*, *the tongue*, and *κελε*, *a tumour*.

GLOSSOCOMA, a retraction of the tongue.

GLOSSOCOME, in the *Instrumental Music of the Greeks*; a name given by the ancients to a kind of cane for the glottis, or tongues of their flutes, which probably were lautboys, and, consequently, their glottis was a reed. See GLOTTIS.

GLOSSOCOMON, in *Mechanics*, is a name given by Hiero,

ero, to a machine composed of divers dented wheels, with pinnions serving to raise huge burdens.

GLOSSOCOMON, a term in *Surgery*, derived from *γλωσσαι*, *the tongue*, and *κρυμνω*, *to guard*; originally a case for the reed of a hautboy, but used metaphorically to signify a case for a fractured limb.

GLOSSODIA, in *Botany*, (*γλωσσοειδης*, having the form or appearance of a tongue; in allusion to the peculiar appendage to the internal part of the flower, which resembles the tongue of a serpent, and affords the essential character. Brown Prod. Nov. Holl. v. 1. 325.—Class and order, *Gynandria Monogynia*. Nat. Ord. *Orchideæ*.)

Gen. Ch. *Cal.* Perianth superior, of three equal spreading leaves. *Cor.* Petals two, equal to and resembling the calyx. Nectary of a different form, shorter, undivided, not glandular, accompanied, at its base above, by a cloven tongue-shaped appendage, between it and the style. *Stam.* Anther terminal, its cells close together; masses of pollen two in each cell, compressed, powdery. *Pist.* Germen inferior: style columnar, with a dilated membranous border at each side. *Peric.* Capsule. *Seeds* numerous.

Eff. Ch. Calyx and Corolla equal. Lip shorter, undivided, without glands, with an appendage at its base. Style dilated at each side. Anther vertical.

1. *G. major*. Brown 326.—“Appendage cloven half way down; its lobes spreading, acute.”

2. *G. minor*. Ibid.—“Appendage cloven to the base; its lobes parallel, obtuse.”

Both species are natives of the country near Port Jackson, New South Wales. Their *bulbs* are undivided, with a laminated coat, and grow in the earth, not parasitically. *Herb* hairy. *Leaf* solitary, radical, its base enclosed in a membranous sheath. *Stalk* radical, bearing generally one blue flower, rarely two, and furnished with one *bractea* besides what accompanies each flower. *Brown*.

GLOSSOIDES, in *Natural History*, a name given by some authors to a species of stone, resembling the figure of the human tongue. This is a mere accidental configuration of a common flint or pebble, perfectly indeterminate in size and colour, and owing its form to no animal mould, as the stones found in shells usually do, but is a mere *lusus naturæ* in the concretion of the stone.

GLOSSOMA, in *Botany, so named by Schreber, from *γλωσσα*, *the tongue*, and *ωμος*, *the shoulder*, alluding to the tongue-shaped appendages borne by the anthers. Schreb. 792. Willd. Sp. Pl. v. 1. 664. Mart. Mill. Dict. v. 2. (Votomita; Aubl. Guian. v. 1. 90. Juss. 382.) Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rhannis affine*, Juss.*

Gen. Ch. *Cal.* Perianth superior, of one leaf, turbinate, four-toothed, permanent. *Cor.* Petals four, equal, lanceolate, acute, much longer than the calyx, recurved. Nectary a ring round the base of the style. *Stam.* Filaments four, very short; anthers oblong, nearly united into a cylinder, elongated at the top into a membranous lanceolate expansion of two cells, opening inwardly. *Pist.* Germen inferior, obovate; style thread-shaped, as tall as the stamens; stigmas four, acute. *Peric.* Drupa pear-shaped, of one cell, crowned by the calyx. *Seed* solitary, ovate, striated.

Eff. Ch. Calyx superior, four-toothed. Petals four. Anthers cohering, each crowned with a lanceolate membrane. Stigmas four. Drupa with one furrowed nut.

Obs. The above characters appear to be taken by Schreber from Aublet, nor have we any better materials. The only species known is,

1. *G. arborefcens*; Willdenow. (Votomita guianensis; Aubl. v. 1. 91. t. 35.)—A *shrub* of a middling size, whose trunk is five or six feet high, and five or six inches thick;

the wood yellow, hard and compact. *Branches* knotty, spreading variously, leafy. *Leaves* opposite, elliptical, pointed, entire, six inches long, thick and firm, of a shining green, placed on short stalks, with a deciduous stipula at each side of their base. *Flowers* white, on short, umbellate, axillary stalks, their petals about half an inch long. This plant is found in the extensive forests of Guiana, about the habitations of the natives. Nothing is recorded respecting its qualities or uses.

GLOSSOPETALUM, so denominated by Schreber from the tongue-like appendages to the petals. Schreb. 205. Willd. Sp. Pl. v. 1. 1521. Mart. Mill. Dict. v. 2. (Goupia; Aubl. v. 1. 295. Juss. 378. Lamarck. Illustr. t. 217.)—Class and order, *Pentandria Pentagynia*. Nat. Ord. *Dumoseæ*, Linn. *Rhamnii*, Juss.

Gen. Ch. *Cal.* Perianth half inferior, of one leaf, minute, five-toothed, permanent. *Cor.* Petals five, lanceolate, spreading, acute, much longer than the calyx, each bearing at its point a linear-lanceolate, abrupt appendage, almost the length of the petal, bent back and lying upon it. *Stam.* Filaments five, very short; anthers roundish. *Pist.* Germen roundish, encircled by a glandular ring, which bears the petals and stamens; style none; stigmas five, acute. *Peric.* Berry roundish, with five furrows, of one cell. *Seeds* five, angular.

Eff. Ch. Calyx half inferior, with five teeth. Petals five, each bearing an inflexed longitudinal appendage. Berry with five seeds.

Obs. Schreber, p. 826, suspects this genus not to be distinct from *Aralia*, but the habit confirms Jussieu's opinion, who separates them widely. Two species are described by Aublet.

1. *G. glabrum*. (Goupia glabra; Aubl. v. 1. 296. t. 116.)—“Leaves smooth.”—Native of the forests of Guiana, 30 leagues from the sea, bearing flowers and fruit in November. The *trunk* is 60 feet or more in height, and two or three feet in diameter, serving to make canoes; the bark smooth and grey; the wood white and light. *Branches* drooping, furnished with alternate *leaves* of an ovate, pointed, somewhat unequal figure, entire, rigid, shining, and smooth, with a branching rib, and fine transverse veins at the back. *Flowers* yellow, small, many together in solitary axillary umbels. *Berry* black, globular.

2. *G. tomentosum*. Willd. Sp. Pl. v. 1. 1522.—“Leaves downy.”—Native of the forests of Cayenne and Guiana. Not half so lofty as the former. The *bark* is wrinkled and dark-coloured. *Leaves* clothed on both sides with some short hairs. Their juice, which, as well as the bark, is bitter, is used to cure inflammations of the eyes.

GLOSSOPETRA, or **GLOTTOPETRA**, in *Natural History*, called also *ichthyodontes*, *shark's teeth*, *dog-fish's teeth*, &c. a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta and divers other parts. Some of them are in a high state of preservation, having their enamel and points perfect, and their sharp edges finely serrated as in the recent teeth.

Naturalists have been much divided as to the nature and origin of these bodies. Steno, De Corpore solido intra folium contento; Ol. Wormius, Dissert. de Glossopetra; and Reyfchius, De Glossopetris Lunebergensibus, treat of them at large.

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of *γλωσσα*, *tongue*, and *πετρα*, *stone*. Hence, also, their traditional virtue in curing the bites of serpents.

The general opinion of naturalists is, that they are the teeth

teeth of fishes, left on land by the waters of the deluge, and since petrified.

They even specify the very kind of fish, and take it to be that which Theophrastus and the Greek writers call *καρχαρία*, and the moderns the *shark* or *sea-dog*.

Camerarius cannot persuade himself that the glossopetræ found in England, Malta, and round Montpellier, were ever the teeth of a sea-dog, or any other fish. The chief difficulty, he suggests, is the small quantity of volatile salt and oil which they afford by distillation. To which Dr. Woodward answers, in defence of the common system, that having lain so long buried under ground, it is no wonder they should have lost the best part of their volatile principles. It is certain, that human bones and skulls, long interred, do not afford nearly the quantity of those principles that they would have done immediately after the person's death.

Another scruple, proposed by Camerarius is, that the glossopetræ, when exposed to the naked fire, turn to a coal; and not to a calx; contrary to what is asserted by Fabius Columna. Dr. Woodward answers, that it is likely enough the glossopetræ, in burning, may assume the form of a coal, before it arrive to that of a calx.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, blueish, whitish, yellowish, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are tricuspidate, having a small point on each side of the large one; many of them are quite straight, but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain: some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller of less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes also in other substances, and are frequent in the clay-pits of Richmond and of Sheppy island, and in other places. They are very frequent also in Germany, but nowhere so plentiful as in the island of Malta. In the British strata they rarely occur. Mr. Farey has found them in these strata only in five places, *viz.* in the London clay, probably obtained from the clay-pits above-mentioned; in a bed of the soft or upper chalk in Kent, at Harefield, near New Malton, &c.; in a green sandy stratum below the chalk, N. of Dunstable, &c.; in the Stonesfield and Collyweston slate series, above the Bath free-stone rocks, at Enstone in Oxfordshire, where Woodward procured specimens of these teeth in the jaw, &c.; and in the thick grey lime-rock which lies under and surrounds the South-Wales coal basins (Phil. Trans. N^o 334.) Glossopetræ are sometimes found in gravel-pits and other collections of alluvial matters. It is seldom possible to determine to what place in the series of strata these belong, and they should therefore be carefully distinguished from such as are actually found in the strata.

The Germans attribute many virtues to these fossil teeth; they call them cordials, sudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their children's necks to promote dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner that the child can get them to its mouth, may, by their hardness and smoothness, be of the same use as a piece of coral. See *Serpent's Tongues*.

GLOSSO-PHARYNGEUS, in *Anatomy*, from *γλωσσα*,
Vol. XVI.

the tongue, and *φαρυγξ*, a name given to those fibres of the constrictor pharyngis superior, which arise from the side of the tongue.

GLOSSO-SPATHA, in *Surgery*, an instrument, called by some *speculum lingue*, and used to depress the tongue, in order to look into the fauces.

There are many inflammatory disorders of the mouth, fauces, and palate, which require a depression of the tongue, while they are inspected and treated with proper remedies. The handle of a silver spoon is made to supply the place of this instrument in most cases, and answers the purpose very well. Whichever is used, care should be taken to depress very gently, to avoid giving the patient pain, as also to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this instrument or the spoon should also be applied, and the syringe should be conveyed into the mouth over it.

GLOSSO-STAPHYLINUS, in *Anatomy*, from *γλωσσα*, the tongue, and *σταφυλη*, the uvula, another name for the constrictor isthmi faucium. See *DEGLUTITION*.

GLOTTIDIS RIMA, the same opening as the glottis. The term rima particularly denotes its slit-like form.

GLOTTIS, from *γλωσσα*, the tongue, is the opening through which the air passes to and from the lungs in respiration. In this passage the voice is formed. See *DEGLUTITION* and *LARYNX*.

Julius Pollux makes the glottis a joint or part of a flute, and Hefychius says that the glott were little tongues, acted upon by the breath of the player. This description of Hefychius seems to confirm the idea of the ancient nominal flutes being a kind of hautboys.

GLOTTIS, in *Ornithology*, a name given by many authors to a bird of the long-legged kind, approaching to the nature of our red-shank, but larger and longer legged, and generally known by the name *limosa*. See *SCOLOPAX Glottis*.

GLOUCESTER, in *Geography*, a city in Gloucestershire, England, is situated in a vale, on a gentle eminence, rising, on the east side, from the river Severn. This opulent city appears to have originated in a Roman station which was situated at King's Holm, near the north-eastern extremity of the present city. The Romans continued to occupy this spot till the distractions of their own empire occasioned them to quit the island. Its government then reverted to the British princes, under whose domination it continued till about the year 577, when, according to the Saxon Chronicle, it was surrendered to the West Saxons, and was reputed one of their principal cities: it was afterwards subjugated by the Mercians, who also obtained possession of the other parts of the county. Under the Saxons it acquired the appellation of Gleau-cestre. The strength and consequence of the city rendering it an object of frequent enterprise, its vicinity was several times the scene of action between the Britons and Saxons. By these conflicts, its buildings were nearly ruined; and the whole place might have sunk into complete decay, if Wolphere, son of king Penda, had not enlarged and adorned it, about the year 679. This restoration was so perfect, that Bede informs us, it was esteemed, about the commencement of the 8th century, as one of the noblest cities in the kingdom. Its early importance is evinced by its having been the residence of various Saxon monarchs; and hence it was denominated a royal city, as it is expressly termed in a grant made by king Edgar to the monks of Worcester, dated at Gloucester in the year 964. By this monarch a battle was fought here with the Danes, who had twice plundered the city in the preceding reigns, and who again ravaged, and partly consumed it by fire, in that of his son Ethelred. Several of

the Norman and English kings also occasionally resided and transacted public business in this city. A memorable era in the eventful history of Gloucester originated in a contest between Henry III. and the barons. That monarch, in 1263, appointed sir Maci de Beſile, a French knight, sheriff of the county, and constable of the castle within the city. The preference thus given to a foreigner was violently resented by the indignant nobles, who immediately made choice of sir William Tracy, a native of the shire. He accordingly proceeded to exercise the duties of his office in holding a county court, but was suddenly interrupted by De Beſile, who, entering with a party of the king's troops, seized the knight, and, with circumstances of peculiar cruelty, hurried him to the castle, where he was committed to close confinement. After this outrage, the barons deputed sir Roger de Clifford, and sir John Giffard, with their dependants, to besiege the castle, for the double purposes of rescue and revenge; in a few days they obtained an entrance, and compelled De Beſile to retire to the keep; he afterwards surrendered, and was sent as a prisoner to Erdesley castle, in the marches of Wales. In the year 1278 Edward I. assembled a parliament here, and several laws, connected with the statute of Quo Warranto, were enacted, and have, from that period, been known under the general appellation of the Statutes of Gloucester. In the course of the two next centuries, four parliaments were held here. The opposition of the Gloucesterians to the royal cause, during the reign of Charles I., is generally supposed to have operated fatally against his interest throughout the kingdom: so early as the year 1641, they declared for the parliament; raised a company of volunteers, which they added to their trained bands; procured cannon from London and Bristol, and repaired and strengthened the fortifications: though frequently besieged by the royalists, they successfully resisted every attack.

The ecclesiastical state of Gloucester, during the Roman and former part of the Saxon period of its history, is involved in much obscurity: but in the year 657, Edwy, king of Northumberland, having subdued Mercia, erected Litchfield into a bishop's see, and included Gloucestershire within its diocese. This bishopric was soon afterwards divided into the five smaller of Litchfield, Dorchester, Leicester, Hereford, and Worcester; to the last of which this district was annexed, and continued subject, till the reign of Henry VIII., who, by letters patent, dated September 3d, 1541, and afterwards confirmed by act of parliament, erected "the city of Gloucester, the county of that city, and all the county of Gloucester, into a bishopric, with a dean and chapter, by the name of the diocese of Gloucester; and ordained that such part of the then vill and county of Bristol, as formerly was in the diocese of Worcester, should be from thenceforward in the diocese of Gloucester for ever." The church appointed for the cathedral of the new see, was that belonging to the abbey, founded by Wolphere, first Christian king of Mercia, and Ethelred, his brother and successor, in the year 681. The New Minster, as it is termed in the records, was burnt, with the monastery, in 1087 or 1088; probably at the same time that the city was partly destroyed by the adherents of Robert, brother to William Rufus. Serlo, then abbot, began a new church in June, 1089; the first stone was laid by Robert, bishop of Hereford; and on the completion of the edifice, in the following year, it was dedicated to St. Peter, by the bishops of Worcester, Rochester, and Bangor. The abbey was again destroyed by fire in 1101 or 1102, but the church was saved. The present magnificent and interesting edifice has been erected at different periods, and consequently dif-

plays various specimens of ancient ecclesiastical architecture, in the Saxon, Norman, and English styles. The conversion of the abbey church into a cathedral was the chief cause of its preservation at the reformation; and, to the honour of the inhabitants of Gloucester, it became the object of their peculiar care during the civil wars, after which they obtained a grant of it from Oliver Cromwell. Hence the cathedral has been transferred to the present age, as nearly perfect in all its parts, with regard to its general construction, as it was left by the most favoured of its architects. The eras of erection of the principal parts are known; and hence the characteristic styles of each can be satisfactorily ascertained. The lower part of the nave, the chapels that surround the choir, and the crypt, are presumed to have belonged to the building erected by bishop Aldred, before 1089: the roof of the nave obtained its finishing and form in 1248. In 1310 the south aisle was begun; and part of the south transept was added in 1330. The building of the north transept and choir commenced about the same year; the latter was completed in 1457. Between the years 1351 and 1390, the elaborate cloisters were finished. The chapel of our Lady was built between the years 1457 and 1498; and the centre tower between 1457 and 1518. The interior of this splendid fabric consists of a nave, choir, side-aisles, and transepts, with a chapel of our Lady, and several smaller chapels or oratories. From the intersection of the nave and transepts rises a high tower, and on the south side is a handsome projecting porch. The roof is sustained on twenty-eight columns, which extend in two rows from the west end to the high altar, where the presbytery forms nearly a semi-circular sweep: the transepts have no isolated pillars. The chapel of our Lady is, as usual, attached to the presbytery; and there are chapels in the north-east and south-east angles of the transepts and choir, with two others projecting in the sweep between those and the chapel of our Lady. The outline, or ground plan of the cathedral, is probably the same at present as designed by bishop Aldred previous to the year 1089; and the crypt remains almost as perfect as the masons left it. The architecture of this subterraneous and gloomy place is massy, and suited to the immense weight resting on the arches, which are turned upon huge short pillars, and strengthened by groins of proportionate solidity. The nave is an interesting specimen of the style which continued to prevail for nearly two centuries after the Norman conquest. The arcade of ponderous round columns, and the rows of semi-circular arches above, impress the mind with ideas of the strength, solidity, and profound solemnity which must have accompanied its original state. The architecture of the west end is very different from the other parts of the nave; and the vault is covered by intersecting ribs, and ornamented key-stones; but the remainder is of the plainest description, with three ribs only to each pillar; yet the key-stones are carved. On each side are eight massive columns; the arches between them are bounded by large mouldings, carved into zig-zags, and other ornaments. Directly over each column, and at some distance, is a range of heads of various characters; some serene, and others terrific. These serve as brackets to clusters of short pillars, whose capitals display the most beautiful variety of foliage, on which zig-zag strings extend, serving as a base to other clustered pillars with equally elegant capitals: from those the ribs of the vault commence. The gallery windows, pierced through the wall above the arches, are divided by short thick pillars, and bounded by others, with zig-zag arches: a twisted string separates them from the clerestory windows. The north and south aisles of the nave are nearly in the style of the west end, with pointed windows, rich ramifications in the arches from the mullions, and fillet-

GLOUCESTER.

ed vaults. The arch of entrance to the cloisters from the north aisle is most elaborately and exquisitely adorned by pillars, buttresses, niches, pinnacles, foliage, and pannels, and the singular ornament of twisted pinnacles under the arch. In the south aisle, nail-headed mouldings are introduced as embellishments on each side of the windows. An advanced gradation of style is exhibited in the interior of the south transept; but the most perfect and ornamental degree is displayed in the chapel of our Lady. The choir is divided from the nave by a screen, designed by Kent.

The dimensions of the cathedral and its several parts are as follow: entire length, inside, four hundred and twenty-three feet: length of the nave, one hundred and seventy-one feet; breadth, forty-one feet two inches; height, sixty-seven feet seven inches: breadth of the north aisle, twenty feet ten inches; height, forty feet six inches: breadth of the south aisle, twenty-two feet; height, forty feet: length of the south transept, fifty-six feet; breadth, forty-three feet six inches; height, eighty-five feet: length of the north transept, sixty-six feet; breadth, forty-three feet six inches; height, seventy-eight feet: length of the choir, one hundred and forty feet; breadth, thirty-four feet six inches; height, eighty-six feet: length of our Lady's chapel, ninety-two feet; breadth, twenty-four feet four inches; height, forty-six feet six inches: height of the tower, including the pinnacles, two hundred and twenty-five feet. The great cloisters, which were completed by abbot Frouceller, are the most elegant and perfect of the kind: the sides and roof are profusely embellished, and the windows are filled with mullions and tracery.

This cathedral contains several curious specimens of monumental sculpture. On the tomb of Edward II., which was erected by his son and successor, and exhibits great perfection of art, is a recumbent figure, in alabaster, of the deceased monarch, regally robed and crowned. Another monument, worthy of notice, is that to the memory of alderman Black-leach, and his wife, whose figures, in white marble, lie on a table tomb, dated 1639, and seem accurate copies of the portraits by Vandyck: they are evidently the work of a skilful artist. A third, deserving observation for its design and classic style, displays a group by Flaxman, erected to commemorate Mrs. Morley, who died at sea, in childbed: she is represented as rising from the waves with her infant in her arms, and conducted by two angels. Between the north aisle and the choir is a monument, erected by abbot Parker to perpetuate the memory of king Osric: and in a chapel nearly opposite, is a figure, supposed to represent the unfortunate Robert Curtois, duke of Normandy, and eldest son of William the Conqueror.

The walls that surrounded Gloucester are mentioned in an ancient prophecy, attributed to Merlin; and tradition ascribes them to Cissa, the second king of the south Saxons. The Norman conqueror caused them to be strengthened and embattled: and they were again repaired in the nineteenth of Edward III. Leland describes Gloucester as "well-built of tynbre, and strongly defended with walles, where it is not fortified with the deepe streame of Severn water." The walls were completely demolished after the Restoration; and the only memorial of their former strength now remaining is the West Gate: this is embattled; and was erected in the time of Henry VIII. The castle, was probably built about the period of the Norman invasion; the remains were lately destroyed; and on its site was built the county gaol, which was completed in 1791: it consists of three divisions, respectively named the Penitentiary House, the Bridewell, and the Sheriff's Prison: these all have their dis-

tingt and appropriate regulations. The gaol contains 203 separate cells; 164 for sleep, and 39 for employment.

In this city and its suburbs were formerly eleven parochial churches: but only six are now standing; those of St. Michael, St. Mary de Crypt, St. Nicholas, St. Mary de Lode, St. John, and St. Aldate; the others having been either destroyed at the siege in 1643, or since taken down. In St. Michael's parish is a Blue Coat hospital, so called from the similarity of its regulations to those of Christ Church, London, founded and endowed in 1666 by sir Thomas Rich, bart. Among other benevolent establishments that confer honour on the inhabitants of Gloucester, may be mentioned the county infirmary, erected by voluntary contributions, and opened in the year 1755. Its annual receipts, arising from donations and the interest of funded property, amount to between two and three thousand pounds.

The principal trade of Gloucester results from the navigation of the Severn, from the hemp and flax-dressing business, and from the pin manufacture. The latter, which is the principal source of labour to the inhabitants, appears to have been introduced into this city by John Tillsby, in the year 1626, and is now carried on to a far greater extent than at any other place in England; there being nine manufactories, which furnish employment to about 1500 persons. The pins conveyed annually to the metropolis, are said to amount to the value of 20,000*l.*; but the principal demand is from Spain and America. A bell-foundry has been established here above three hundred years. The clothing trade, formerly the chief support of the inhabitants, is now nearly lost: one fulling mill only remains.

Various and important privileges have been granted to Gloucester by several monarchs: it was erected into a borough by charter from king John; Henry II. granted the burgesses the same liberties and customs as had been enjoyed by the citizens of London; by the act 33 Hen. VIII, which established the bishopric of Gloucester, it is ordered that the town should thenceforth be termed a city. It is also privileged as a county within itself. The corporation, acting under a charter of Charles II., consists of a mayor, twelve aldermen, a high steward, recorder, town clerk, two sheriffs, common-council, &c. The title of mayor first occurs in the year 1483. The high stewards have generally been persons of great eminence. Two representatives to parliament are elected by the inhabitants and freemen; the number of voters is about 3,000; the earliest return was made in the twenty-third year of Edward I. The elections are carried on in an ancient structure, called the Booth-hall, which is also appropriated to the assizes and other county business. The public affairs of the city are transacted at the Tholsley, a building supposed to have derived its name from the toll formerly received in it by the lords of the manor. Very considerable improvements have been made, within the last seventy years, in the appearance and buildings of this city. It consists, principally, of four spacious streets, meeting each other at right angles, and taking their names from the situation of the gate which originally stood at the bottom of each, as East Gate street, West Gate street, North Gate street, and South Gate street. At the intersection of the streets, formerly stood a large and beautiful cross; but falling to decay, and impeding the passage of carriages, it was removed in 1750: its site still retains the name. The city is well paved and lighted: and its elevated situation, with a gradual descent on every side, greatly contributes to health and cleanliness. The markets had long been established by prescriptive right; but those now held, on Wednesdays and Saturdays, were chartered by Henry III. Three fairs are held annually and much frequented. The

GLOUCESTER.

houses and population have varied considerably in different ages, according to the degree of security or danger which the inhabitants experienced: the progress has been several times interrupted by fires and civil commotions. Since the siege in 1643, the increase has been regular. On the last enumeration, under the act of 1801, the houses, in the city alone, amounted to 1368, the population to 7265: the inhabitants of the suburbs being 1500 more. Gloucester is situated 106 miles W. from London.

Among the more eminent natives of this city is Robert of Gloucester, who wrote a chronicle of Britain in verse, from the age of Brutus to his own time, the reign of Henry III.

On the north-west side of Gloucester is the celebrated isle of Alney, a small tract, formed by the separation of the stream of the Severn into two channels. This was the scene of a combat between Edmund Ironside and Canute the Dane, in the year 1016.

In the southern suburbs of Gloucester are the remains of Lanthony priory, founded in 1187. After the dissolution, the monastic buildings were converted into the offices of a farm. The only parts now left are a large barn, and the principal entrance, or gateway; on which are the arms, among others, of the Bohuns, earls of Hereford, who were great benefactors to the priory. Rudder's History, &c. of Gloucester. Beauties of England and Wales, vol. v.

GLOUCESTER and Berkley Canal, is the parliamentary name of a canal of very large dimensions, following the E. side of the Severn river between Berkley and Gloucester, of which Mr. Robert Mylne and Thomas Dadford were the engineers; the other particulars will be found in our article CANAL.

GLOUCESTER, or *Cape Ann*, a township of America, in Essex county, Massachusetts, whose east point forms the N. side of the bay of Massachusetts. It contains 5313 inhabitants, and is divided into five parishes, besides a society of Universalists. It is a post-town and a town of entry. The harbour is open and accessible to large ships, and it is one of the most considerable fishing towns in the commonwealth. At the harbour, properly so called, are fitted out annually from 60 to 70 bankers, and from Squam and Sandy bay, two small out-ports, the bay fishery is carried on with great spirit, and to a large amount. Thatcher's island, on which are two lights, lies close to the S.E. side of the township, which is itself joined to the continent by a bank of sand, that is rarely overflowed with the water. Here is a fine white sand, fit for the manufacture of glass. The harbour is defended by a battery and citadel erected in 1795:—16 miles N.E. by E. of Salem, and 34 N.E. of Boston.

GLOUCESTER, the N. westernmost township, and the largest, in Providence county, Rhode island, being 11½ miles square, containing 4009 inhabitants.

GLOUCESTER, the name of a county in New Jersey, bounded N. by Burlington county, S. by Salem, Cumberland, and Cape May counties, E. by the Atlantic ocean, and W. by Delaware river. Its length on the Delaware is about thirty miles, and on the sea it is about 22 miles. Great and Little Egg harbour rivers are both navigable for vessels of about 200 tons about 20 miles from their mouths. The streams which fall into Delaware river are navigable for small vessels, a few miles up from their mouths, and afford some shad, roach, herrings, and perch. Its adjacent islands are Red Bank, Pett, and Old Man's creek. The soil of the county is a mixture of sand and loam, and the tract bordering on the Delaware is in a high state of cultivation. The chief productions are beef, pork, fish,

hay, corn, lumber, butter, cheese, &c. It is divided into ten townships, viz. Woodbury, Waterford, Newtown, Gloucester township, Gloucester town, Deptford, Greenwich, Woolwich, Egg harbour, and Galloway. Mulicus river divides the county from Burlington, and is navigable 20 miles for vessels of 60 tons. Maurice river runs southerly about 40 miles through Cumberland county into Delaware bay, and is navigable for vessels of 100 tons 15 miles, and for shallops 10 miles further. It contains 16,115 inhabitants, of whom 61 are slaves. In this county are found quantities of bog-iron ore, which is manufactured into pig and bar iron, and hollow ware. Here is also a glass-house. The chief town is Woodbury, nine miles S. of Philadelphia.

GLOUCESTER, a small town in the above-mentioned county, on the E. side of Delaware river, three miles below Philadelphia.—Also, a post-town in Virginia, in the county of its own name, on a point of land on the N. side of York river, 17 miles distant from York town.

GLOUCESTER, a county in Virginia, fertile and well cultivated, bounded N. by Piankitank river, which separates it from Middlesex, E. by Matthews county and Chesapeake bay, N.W. by King and Queen, S. and S.W. by York river, which divides it from York county. It is about 55 miles long and 30 broad, and contains 3272 free inhabitants, and 4909 slaves. The low lands produce excellent barley, and Indian corn, the staple produce of the county.

GLOUCESTER House, a station belonging to the Hudson-bay company, situated in New South Wales, on the N. side of the waters which form a communication through a chain of small lakes, between Winnipeg lake and Albany river. Henley house lies N.E. of this, nearer the mouth of Albany river in James's bay. N. lat. 54°. W. long 87° 30'.

GLOUCESTER, a township in the county of Dundas in Upper Canada, which is the seventh in ascending the Ottawa river; E. of, and contiguous to, the river Rondeau.

GLOUCESTER Cape, a cape on the S. coast of Terra del Fuego.—Also, a high promontory on the E. coast of New Holland. S. lat. 19° 59'. E. long. 148° 11'.—Also, a cape on the coast of New Britain. S. lat 5° 54'. E. long. 148° 15'.

GLOUCESTER Island, an island in the S. Pacific ocean, about six miles long, and from one to a quarter of a mile broad, discovered and so called by captain Wallis in 1767. It is surrounded by rocks, full of trees, and inhabited by persons who appeared armed with long pikes or poles, but destitute of canoes. S. lat 19° 11'. W. long. 140° 4'.

GLOUCESTER, Duke of, Islands, two islands in the S. Pacific ocean, discovered and so called by Captain Carteret in 1767, which were covered with trees, but appeared to be uninhabited. The southernmost of them was a slip of land in the form of a half-moon, low, flat, and sandy; the appearance of it was pleasant, but it had neither vegetables nor water; but it abounded with birds, so tame that they might be taken by the hand. The other island very much resembled this, and is distant from it about five or six leagues; they lie W.N.W. and E. S. E. of each other. One of them is in S. lat. 20° 38'. W. long. 146°: the other in S. lat. 20° 34'. W. long. 146° 15'; the variation 5° E. These islands are probably the land seen by Quiros, as the situation is nearly the same.

GLOUCESTERSHIRE, one of the western counties of England, is surrounded by Herefordshire, Oxfordshire, Berkshire, Wiltshire, Somersetshire, and Monmouthshire. It comprehends an area of nearly seventy miles in one direction, by forty in a transverse line. This district, during the Roman domination in Britain, was much occupied

GLOUCESTERSHIRE.

pied by the Romans. Mr. Fosbrooke (one of the historians of the county) observes, "from the ruins which have at various times been excavated, it is evident that this county, from Cirencester to Painswick, Bitley, Sapperton, Woodchester, Uley, Kingcote, and other adjoining places, was much peopled with Romans, or Romanizing Britons; that Cirencester was the great metropolis, or resort of pleasure and amusement; while Gloucester, and the hills about the Severn, were the great military positions; the city, on account of the river, having peculiar advantages with respect to commerce." The principal Roman roads which passed through this county, were the Ikenild street, the Iriming or Erming street, the Foss-way, and the Via Julia. Under the dominion of the Saxons, Gloucestershire formed part of the Mercian kingdom, and Winchcombe and Kingstanley are mentioned as residences of the Anglo-Saxon monarchs. On the division of Mercia into five bishoprics, after the conversion of the Saxons, the greatest part of this county was included under that named Wiccica, and from this appellation the Dobuni, the early inhabitants of this part of Britain, were afterwards termed Wiccii. Gloucestershire is separated into four divisions; these are subdivided into twenty-eight hundreds, containing 320 parishes, one city, and twenty-eight market towns. The number of houses, as returned under the population act, amounted to 37,276; of inhabitants, 187,164; of which 90,237 were males, and 96,927 females. The whole county, with the exception of the chapelries of Icomb, and Cowhonyborn, is included within the diocese of Gloucester; which comprehends one arch-deaconry, and ten deaneries. The number of representatives returned to parliament are eight; two for the shire, two for the city, two for Tewkesbury, and two for Cirencester. The general aspect of Gloucestershire is greatly diversified; nature having divided it into three districts of very dissimilar character, respectively named the Hill, the Vale, and the Forest. The Hill district, including the Cotswolds, and the Stroudwater hills, may be regarded as a continuation of the central chain proceeding south from Derbyshire, and passing through this county with a smaller elevation into Wiltshire; there swelling into the Salisbury Downs, and afterwards running west towards the Land's End in Cornwall. The extent of the Cotswold hills, from Broadway hill to near Tetbury, is thirty miles; and from Birdlip hill to Burford, about twenty miles: the area they include is estimated, by Mr. Marshall, to contain nearly 200,000 acres. The surface is billowy; and the climate, considering the natural elevation of the land, unusually mild. The sides of the hills abound with springs; and almost every dip has its rill, and every valley its brook. The primary object of the Cotswold husbandry is sheep; these have been long famous; and it is a prevailing tradition, that the Spaniards originally procured their breed of fine woolled sheep from these hills, though this assertion is contradicted by several modern writers. The inclosures are chiefly stone walls, about four feet and a half high, exclusive of a coping of flat stones. The Vale district includes the entire tract bounded on the east by the Cotswold hills, and by the river Severn on the west; and is usually subdivided into the Vales of Evesham and Gloucester, and the Vale of Berkeley; the latter of which is separated from the former by a natural interfection, and is very different in produce and rural management. The Forest district is separated from the rest of the county by the river Severn; and is principally comprehended by the Forest of Dean, which was formerly of particular value, for the goodness and strength of its timber. Its oaks were so greatly renowned that Evelyn observes, that in Elizabeth's reign,

an ambassador was purposely sent from Spain to procure its destruction, either by negotiation or treachery. It also abounds in beech; and the soil is considered as peculiarly favourable for the growth of the Stire apple. Its principal minerals are iron, ore, and coal: iron appears to have been wrought here even in the time of the Romans; and so early as the reign of Edward I. seventy-two furnaces, for melting iron, are recorded to have been built here. In a survey made in the seventeenth year of Charles I. the forest is estimated as originally containing upwards of 43,000 acres, of which above 14,000 were woodland. Several thousand acres have, however, been granted away, by different sovereigns, and disafforested. The miners have distinct courts, and, like those of Derbyshire and Devonshire, are governed by their own customs.

The principal rivers connected with Gloucestershire, are the Severn, the Frome, the Wye, and the Isis or Thames. The canals that intersect the county are distinguished by the names of the Thames and Severn, the Stroudwater, the Berkeley, and the Hereford and Gloucester. The Severn, the second commercial river in England, renders essential service to a large portion of this county. It enters Gloucestershire near the ancient town of Tewkesbury, where, uniting its waters with the Upper Avon, and pursuing a south-westerly course, it traverses a wide vale, which is rich in pasturage, and in some places abundantly wooded. About one mile above Gloucester, it divides into two streams: these again unite a little below the city, forming the tract of land called Alney island. In the course of its passage through the county, it receives the streams of the Upper Avon, the Chelt near Wainlode, the Leden near Over's-bridge, the Frome at Framilode, the Avon at Berkeley, and the Lower Avon below Brillol. The Wye separates part of this county from Monmouthshire and Herefordshire, and forms the grand natural western boundary to the forest of Dean, whose noble wooded eminences constitute many fine features on its meandering banks. The Thames, the most important of the British rivers, has its source in this county, at a place called the Thames-head, near the village of Cotes, about two miles south-west of Cirencester. Near this place the Thames and Severn canal emerges from under ground, and receives a considerable quantity of water, occasionally from this spring. The junction of the Thames and Severn was an object of favourite speculation with the London and Bristol merchants for many generations; but was not completed till near the close of the last century, an act for that purpose was obtained in 1783, and the design was brought to perfection in 1792, when the first vessel passed from the Severn into the Thames. This canal begins at Wallbridge, near Stroud, (at the place where the Stroud navigation ends,) and proceeds in a devious course through the county to Lechlade, where it joins the Thames. This course includes a distance of thirty miles, seven chains and a half. The water, in its progress from Stroud to Sapperton, (seven miles three furlongs), is raised by means of locks 241 feet 3 inches: between Sapperton and Lechlade it falls 130 feet 6 inches. The Stroudwater canal encounters many obstacles; yet in defiance of all opposition, an act was obtained in 1775, under the operation of which it was finished.

The manufactures of Gloucestershire are numerous: clothing stuffs, blankets, rugs, carpets, stockings, &c. are made in different parts of the county. Bar iron, edge tools, wire, nails, and many other articles, are also manufactured in large quantities. Near Bristol are some extensive founderies, as well as different works for making brass and wire, vitriol, red-head, sal-ammoniac, &c. At Gloucester, vast quantities of pins are made; and at Frampton-Cotterel is a considerable

considerable manufactory of felt-hats. Several authors have employed their pens in describing the topography and antiquities of this county: the principal of these are fir Robert Atkins's "Ancient and present State of Gloucestershire," fol. 1712, second edit. 1768. Rudder's "New History of Gloucestershire," fol. 1779; Bigland's "Historical, Monumental, and Genealogical Collections," &c. folio, one volume and part of a second, 1791; Lysons's "Collection of Gloucestershire Antiquities," folio, 1801; Rudge's "History of the County of Gloucester, compressed and brought down to the Year 1803," 2 vols. 8vo. Forbroke and Yates's "History of Gloucestershire," 2 vols. 4to. 1805. "Beauties of England and Wales," vol. v. contains a concise and general account of the county.

GLOVE, *Ситрубеа*, a habit or covering for the hand and wrist, used both for warmth, decency, and as a shelter from the weather.

Gloves are distinguished, with respect to commerce, into leather gloves, silk gloves, thread gloves, cotton gloves, worsted gloves, &c.

There are also gloves of velvet, satin, taffety, &c. Leather gloves are made of shamoy, kid, lamb, doe, elk, buff, &c. There are also perfumed gloves; washed, glazed, waxed gloves; and white, black, snuff-colour, &c. gloves; single, lined, topped, laced, fringed with gold, silver, silk, fur, &c.

It is a proverb for a glove to be good and well made, three kingdoms must contribute to it; Spain to dress the leather, France to cut it, and England to sew it. But, of late, the French seem to have appropriated the functions of the other two; the gloves of the French manufacture being now said to have the advantage, in point of dressing and sewing, as much as of cutting.

By 34 Geo. III. c. 10. the British duty on gloves and mittens imposed by 25 Geo. III. c. 55. is repealed, except the duty on licences; and by 36 Geo. III. c. 80. the said duty on licences is also repealed. By 6 Geo. III. c. 19. and 25 Geo. III. c. 55. foreign manufactured leather gloves or mitts shall not be imported, under the penalty of forfeiture; and the importer or seller incurs, besides forfeiture, a penalty of 200*l.* with double costs.

GLOVE, *to throw thr.* was a practice or ceremony very usual among our forefathers, being the challenge whereby another was defied to single combat. It is still retained at the coronation of our kings, when the king's champion calls his glove in Westminster-hall.

Favyn supposes the custom to have arisen from the eastern nations, who, in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7 where the Chaldee paraphrase calls glove what the common version renders by shoe. He adds, that the rabbins interpret by glove, that passage in the eighth Psalm, "In Idumeam extendam calcamentum meum, Over Edom will I cast out my shoe." Accordingly, among us, he who took up the glove, declared thereby his acceptance of the challenge; and as part of the ceremony, continues Favyn, took the glove off his own right hand, and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side to meet at the time and place which should be appointed by the king, parliament, or judges.

The same author asserts, that the custom which obtained of blessing gloves, in the coronation of the kings of France, is a remain of the eastern practice of giving possession with the glove. Lib. xvi. p. 1017, &c.

The delivery of a glove was in frequent use formerly, as a symbol of investiture. See Du Cange, Gloss. Lat.

Gloves were also used to signify the steward's or bailiff's fee, or part of the price of the investiture or purchase-money of the land. "Si aliquam territorii partem venditari contigerit, domini venditiones habebunt; scilicet, tot denarios quot venditor inde habuerit solidos. Major vero terræ illius pro *avantis* accipient duos donarios." Where *avantis* signifies *gloves*, or, in French, *gants*.

Hence the common custom, in many bargains, of giving servants money for a pair of gloves.

Anciently it was prohibited the judges to wear gloves on the bench; and at present, in the stables of most princes, it is not safe going in without pulling off the gloves.

GLOVER, RICHARD, in *Biography*, was born at London in 1712. He received the elementary instructions in classical learning at Cheam, and exhibited a considerable taste for the classics, and an attachment to science. When he was only 16 years old, he wrote a copy of verses "To the memory of sir Isaac Newton," which is prefixed to Dr. Pemberton's view of the Newtonian philology. He engaged in commercial pursuits, and became eminent in the mercantile world, to which he was introduced by his father. In 1737, he married a lady with a handsome fortune; and in the same year he published his epic poem of Leonidas. Glover had joined the opposition of the day, at the head of which was Frederic prince of Wales, and his poem, founded on the struggles of free Greece against Asiatic despotism, was calculated in a high degree to serve a generous cause. It abounds in noble sentiments, and is considerably varied by incident and description. Its plan is admirably adapted for poetical effect: it was received by Lyttleton and others with high applause, and very soon passed through three editions. "But it labours," says the critic, "under that want of interest which attends all modern epics, especially such as are built upon some of the subaltern events of ancient history; and its poetry is not of a character sufficiently elevated to engage the reader by the beauty of detached passages." The reputation which it first acquired soon subsided, and it now lives rather in memory than in the actual acquaintance of readers. He published in 1739, his poem, entitled "London, or the Progress of Commerce;" and the ballad of "Hosier's Ghost." Mr. Glover was not only a poet but an ardent politician, and was distinguished in various instances for his eloquence in the cause of freedom. His talents gained him great credit, and he was appointed by the merchants of London to conduct an application to parliament, complaining of the neglect with which their trade had been treated. The speech which he pronounced at the bar of the house of commons on this subject, in January 1742, was greatly admired, and was published. His celebrity as a public character, did not favour his progress in commerce; his affairs became embarrassed; he was, to use a modern fashionable phrase, obliged to suspend his payments, and at length retreated from active life, to practise economy in an obscure situation. The duchess of Marlborough bequeathed him, and Mallet, five hundred pounds each on condition of their joining to write the history of the great duke. Glover renounced the talk, and Mallet never executed it. He now wrote several pieces for the stage, which being successful to a considerable degree his circumstances became so much improved, that he ventured to return to public life, and sat as member for Weymouth, in the parliament of 1761. His commercial knowledge made him extremely useful on several important occasions. In the year 1775, he took an active part in an application to parliament on behalf of the West India merchants, and for his zeal and assiduity he was complimented with a valuable present of plate. He died in
November

November 1785, and left behind him another poem, entitled the "Athenaid," relating, in thirty books, the wars between the Greeks and Persians. This was published in 1788, in three volumes 12mo., but it failed completely in attracting public attention.

GLOVER, in *Geography*, a township of America, in the state of Vermont and county of Orleans, N. E. of Craftsborough, adjoining. It has 36 inhabitants.

GLOVER'S Reef, rocks on the bay of Honduras. N. lat. 16°. W. long. 88 20'.

GLOW-WORM, in *Entomology*. See CICINDELA. *Cantharis* and *Cicindela* have been often used, indiscriminately, for the glow-worm; but they form two distinct genera of the same order in the Linnæan system. See CANTHARIS. The glow-worm is often seen in the day time.

The male and female differ greatly in this species of insect. The male has wings, and is a small fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and somewhat flattened; the wings are shorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light issuing from it, and is not commonly supposed to be at all of kin to the glow-worm.

The female is what we expressly call by this name; this is a very slow-paced animal, without wings, and somewhat resembling a caterpillar; the head is small, flat, hard, and black, and sharp towards the mouth: it has short antennæ, and six moderately long legs; the body is flat, and is composed of twelve rings, whereas the body of the male consists only of five; it is of a dusky colour, with a streak of white down the back. It is often seen in the day-time, but it is not known except in the dark; at which time it is easily distinguished by the glowing light, or lambent flame, that is seen near the tail, issuing from the under part of the body.

The common glow-worm is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on fresh turfs of grass; all which time it will continue to shine in the dark.

The light of this little insect is so strong, that it will shew itself through several substances, in which the creature may be put up; a thin pill-box easily shews it through, and even though lined with paper, the light is not impeded in its passage by both. The creature is sluggish, and appears dead in the day-time, and its light is not distinguishable, even if carried into a darkened room, unless the creature be turned upon its back, and disturbed, so as to be put in motion, and then it is but very faint; after sun-set the light begins to return, and with it the life and motion of the animal. The motion and light of this creature seem, in some measure, to depend upon one another; it never shines but when the body is in some sort of motion; and when it shines most, the body is extended to one-third more than its length in the day-time. In the time of brightest shining, it will sometimes on a sudden turn its body about, and the light will not be larger than the head of a pin; and, on being touched, it will then immediately extend itself, and the light will become as large and bright as ever. Phil. Trans. N^o 71.

Two points seem to be agreed upon by naturalists, with regard to the light issuing from the tail of a glow-worm; first, that it is phosphoric, and secondly, that its use is to attract the male insect. Should the singularity, if any such there be, in the natural history of this animal, which should render a provision of this kind more necessary for the glow-worm, than for other insects, be a subject of inquiry; it may be observed that this singularity seems to be the

difference, which subsists between the male and the female, which difference is greater than what is found in any other species of animal whatever. The glow-worm, as we have observed, is a female caterpillar, the male of which is a fly; lively, comparatively small, dissimilar to the female in appearance, probably also as distinguished from her in habits, pursuits, and manners, as he is unlike in form and external constitution. Hence it appears, that the caterpillar cannot meet her companion in the air. The winged rover disdain the ground. They might never therefore be brought together, did not this radiant torch direct the volatile mate to his sedentary female.

"In this example," says the ingenious author now cited, "we see the resources of art anticipated. One grand operation of chemistry is the making of phosphorus; and it was thought an ingenious device, to make phosphoric matches supply the place of lighted tapers. Now this very thing is done in the body of the glow-worm. The phosphorus is not only made, but kindled; and caused to emit a steady and genial beam, for the purpose which is here stated, and which I believe to be the true one." Paley's Natural Theology, p. 363.

GLOW-WORM, *Flying, cicindela volans*. In the warmer months of the year, this creature is sometimes caught in our houses flying to the flame of a candle, and when examined in the dark, it is found luminous at these times, though perhaps less, or not at all so, at others; which may be a reason of its not being known, though caught in the fields; and to this it may be owing, that many who have described it have thought it not a native of England. Without wings it is frequently enough found in form of the common glow-worm, and then always shines. Aldrovand has very well described the *cicindela volans*, and says, that it lays eggs which hatch into small worms, and that these after a time become flies, by the same sort of change which happens to caterpillars and other reptiles which become butterflies, and other species of winged insects. Moussett, and Thomas Bartholine, both describe the animal much as Aldrovand has done, but they allow the male only to have wings; but Julius Scaliger contradicts this, and says, that he has caught them both winged in the act of generation: this is a plain proof that both sexes are winged; yet it has not happened that both sexes have been acknowledged to be so, even by those who have quoted this passage. And Mr. Waller, who gives an account of them in the Philosophical Transactions, observed them in the same manner in the act of copulation both winged, and with no other difference between them but that the female was the larger of the two, which is the case in regard to many insects. Julius Scalig. Exerc. 191. Phil. Trans. N^o 167, p. 841.

The male and female in this winged state both shine in hot weather, and their light is so vivid as to be easily seen even while there is a candle in the room; the vibrations of it are irregular and its colour greenish. The luminous parts are two small specks under the tail at the end, and the light continues in these some time after the tail is cut off, but then gradually goes out.

The parts of insects continue alive in some degree for a considerable time after they are cut off, and probably the light in the tail of this animal continues just as long as that sort of life remains in it. Moussett, cap. 15.

The use of this light seems to be to direct the animal in its course, and in the taking of its prey, and to this purpose it is admirably placed. The tail is easily beat under the belly, and then throws the light full upon any object about or under the head of the animal, and the eyes are placed not on the upper part but on the under side of the head; so that they have

all the advantages of it, while the light in this part is not offensive to the eyes, as it naturally would have been if carried before the head. The creature can, upon occasion, cover this light, so as not to be known, or pursued by it, by its enemies. Thomas Barthol. de Luce Anim. lib. ii. cap. 12.

This insect is of the beetle kind, of a brown and dusky colour. It has hard case or shell wings, as the other beetles have, and when these are expanded, there appear a pair of very large membranous ones; its head is covered with a sort of shield or broad-brimmed hat: under this hat are placed the eyes, which are black and large, and are moveable, so that the creature can, upon occasion, thrust them forward: it has two hairy antennæ, and its legs are like those of the common fly, hard, shelly, and hairy. Its eyes afford an elegant object for the microscope, being composed of an infinite number of lenses, as those of the libellæ and other insects. Aldrovand. de Insect. lib. i. cap. 8.

GLOXINIA, in *Botany*, named by the late M. L'Heritier in honour of Dr. Benjamin Peter Gloxin, a native of Colmar, in whose inaugural dissertation, published at Strasburg in 1785, are given the characters of *Martynia* and some neighbouring genera, among which the plant now under our consideration is comprehended. The same work also contains the first description and figure of the *Salvia leuoroides*, unnecessarily changed by L'Heritier afterwards to *S. formosa*; and one of *Cyperus ægyptiacus*, which proved the *Schoenus mucronatus* of Linnæus. L'Herit. Stirp. Nov. 149. Ait. Hort. Kew. v. 2. 331. Willd. Sp. Pl. v. 3. 229. Mart. Mill. Dict. v. 2. Class and order, *Didymia Angiospermia*. Nat. Ord. *Personate*, Linn. *Campanulaceæ*, Juss.? or rather a new order, distinguished by lateral, not marginal, receptacles of the seeds. *Juss.*

Gen. Ch. Cal. Perianth superior, of five oblong, spreading, nearly equal leaves. Cor. of one petal, obliquely bell-shaped; gibbous at the base; its border in five rounded obtuse lobes, the four uppermost recurved, the lower one prominent, concave and inflexed. Stam. Filaments four, much shorter than the corolla, with the rudiment of a fifth; inserted into the receptacle, connected with the base of the corolla, incurved, downy, converging laterally in the upper part, two of them rather the shortest; anthers ovate, peltate, two-celled, cohering together, their lobes diverging. Pist. Germen inferior, turbinate, furrowed; style cylindrical, as long as the stamens; stigma capitate. Peric. Capsule imperfectly two-celled, with two valves, and two lateral divided receptacles. Seeds numerous.

Eff. Ch. Calyx superior, of five leaves. Corolla bell-shaped, with an oblique irregular border. Filaments, with the rudiment of a fifth, inserted into the receptacle. Capsule with many seeds, inserted into lateral receptacles.

1. *G. maculata*. Curt. Mag. t. 1191. (*Martynia perennis*; Linn. Sp. Pl. 862. Hort. Cliff. t. 18. Ehret. Piët. t. 9. f. 2. Mart. Mill. Dict. v. 3.—Native of South America; the seeds having been sent from Carthage by Mr. Robert Millar, before 1739. It requires with us the constant heat of a bark stove, by means of which it flowers late in autumn. It is propagated abundantly by the little tuberous roots, which are perennial. The stem is herbaceous, simple, leafy, round, very smooth, spotted with purple. Leaves large, opposite, recurved, stalked, broad-ovate, acute, serrated, smooth and shining, pale at the back, with prominent veins. Flowers axillary from the diminished leaves, or bractæas, at the upper part of the stem, solitary, stalked, large, drooping, of a fine blue with a dark spot at the bottom within. Their scent is very peculiar, resembling mint, which no writer seems to have noticed.

GLUBOKAIA, in *Geography*, a town of Russia, in the government of Kolyvan; 72 miles E. of Semipolatonoi.

GLUCHOV, or GLUKHOR, a town and district of Novogorod Severskoi, situated on the river Yefma, falling into the Seim; 40 miles E.S.E. of Novogorod Severskoi.

GLUCK, le Chevalier CHRISTOPHER, in *Biography*, a musical composer of great fire and originality, who, during the last 30 or 40 years of the preceding century, acquired great renown, but chiefly in France, by a species of composition, congenial to the national taste, which Lulli and Rameau had formed, and in which the short and simple airs required no great abilities in the fingers; but the dramas being written in the language of the country, and the poet being regarded as a much more important personage than the composer of the music, the several characters required great actors rather than great singers.

This eminent composer was born in the Palatinate, of a poor family, about the year 1716. His father, during the infancy of his son, removed into Bohemia, where he died, leaving his offspring in early youth, without any provision, so that his education was totally neglected; but nature had given him an instinctive love for music, which is taught to all children, with reading and writing, in the Bohemian schools, whether of charity or superior foundations, in all the towns and villages; in churches and in the streets, men, women, and children sing in parts, and play upon some instrument, and often on many instruments. This was the case with the young Christopher, who travelled about from town to town, supporting himself by his talents till he had worked his way to Vienna, where he met with a nobleman who became his patron, took him into his service, carried him into Italy, where he procured him lessons in counterpoint, at Naples, by which he profited so well, that before he left Italy he composed several dramas for different theatres, which acquired him reputation sufficient to be recommended to lord Middlesex as a composer to our lyric theatre in the Haymarket, then under his lordship's direction. But, unluckily, arriving in England in 1745, after his first opera of "Artamene" had been performed ten nights, in which the famous air "Rasserena il mesto ciglio," sung by Monticelli, was constantly encored, the rebellion broke out, and the great Opera-house was shut up, on account of the popular prejudice against the performers, who, being foreigners, were chiefly Roman Catholics. Nor was the Opera-house allowed to be opened again, till January 7th, 1746, when "la Caduta de' Giganti," set by Gluck, was performed before the duke of Cumberland, in compliment to whom the whole was written and composed. The singers were Monticelli, Jozzi, and Ciacchi; with signora Imer, Pompeati, afterwards better known by the name of madame Cornelia, and Frasi. The first woman, Imer, never surpassed mediocrity in voice, taste, or action; and the Pompeati, though nominally second woman, had such a masculine and violent manner of singing, that few female symptoms were perceptible. The new dances by Auretti, and the charming Violetta, afterwards Mrs. Garrick, were much more applauded than the songs, which, however, for the time, had considerable merit. The first air in G. minor is of an original cast, but monotonous. The second air has genius and design in it. Then a duet, in which he hazarded many new passages and effects. The following air, for Monticelli, is very original in symphony and accompaniments which a little disturbed the voice-part in performance, we well remember, and Monticelli called it *aria tedesca*. His contemporaries in Italy, at this time, seemed too much siled down; and he wanted the file, which, when used afterwards in that country, made him one of the greatest composers of his time. The next air printed, is in a very peculiar measure,

sure, and like no other that we recollect: it has great merit of novelty and accompaniment; the voice-part wants only a little more grace and quiet. The following song, set for Jozzi, a good musician with little voice, is full of new and ingenious passages and effects; we should like much to hear this air well performed at the opera; it is kept alive from beginning to end. Something might be expected from a young man able to produce this opera, imperfect as it was. It had, however, but five representations.

From London he returned to Italy, and composed several operas in the style of the times, such as that of *Terradeglas*, *Galuppi*, and *Jomelli*; and we heard little of him till he enlisted with the Italian poet *Calfabigi*, with whom he joined in a conspiracy against the poetry and music of the melo-drama then in vogue in Italy and all over Europe.

It is extraordinary that *Calfabigi*, editor of the beautiful Paris edition of the works of *Metastasio* in 1755, in the preface to which there is the highest and seemingly most cordial praise of the works of the imperial laureate, should be the first, ten years after, to find them so defective; writing his "*Orfeo*" in a different style, and joining with *Gluck* in decrying the lyric style both of the music and poetry of the Italian opera.

In 1764, the year in which the late emperor *Joseph* was crowned king of the Romans, *Gluck* was the composer, and *Guadagni* the principal singer. It was in this year that a species of dramatic music, different from that which then reigned in Italy, was attempted by *Gluck* in his famous opera of "*Orfeo*," which, with *Guadagni's* admirable action, succeeded so well, that it was soon after attempted in other parts of Europe, particularly at *Parma* and *Paris*. This is not the place to discuss its merit; we shall here only observe, that the simplifying dramatic music in *Gluck's* manner, in favour of the poet, at the expence of the composer and singer, is certainly very rational, where an opera is performed in the language of the country, and the singers have no great abilities to display, as in France; but in England, where we have frequently singers of uncommon talents, and where so small a part of an opera audience understands Italian, by abridging the symphonies, and prohibiting divisions and final cadences, in favour of an unintelligible drama, we should lose more than we should gain.

After its success at *Parma* and *Paris*, "*Orfeo*" was exhibited at *Bologna*, *Naples*, and in 1770 in *London*; when the principal parts were filled by *Guadagni* and *Grassi*, afterwards *Mrs. Bach*.

The unity, simplicity, and new dramatic excellence, which at *Vienna*, and afterwards at *Paris*, rendered this drama so interesting as to make the audience think more of the poet than the composer, were greatly diminished here, by the heterogeneous mixture of music of other composers in a totally different style.

In 1769, *Calfabigi* and *Gluck*, encouraged by the success of "*Orfeo*," produced "*Alceste*," a second opera, on the reformed plan, at *Vienna*, which received even more applause than the first. In 1771, the same poet and musician brought a third opera, "*Paride ed Helena*," on the stage at *Vienna*, written and composed in the same new, or rather old, French style, with better music, in which *Millico* was the principal singer, and which afforded the audience such pleasure as seemed to have impressed the lovers of music in the imperial capital with a partiality for that species of dramatic music, which was not likely to be soon obliterated.

In 1772, *Gluck* set to music an opera taken from *Racine's* "*Iphigenie*," in which he so far accommodated himself to the national taste and style of France, as frequently to imi-

tate and adopt them. And as this opera was intended for *Paris*, his friends feared for its success, as there was frequently melody, and always measure, in his music, though set to French words, and for a serious French opera.

But the year 1774 was rendered a remarkable era in the annals of French music, by the arrival of the chevalier *Gluck* at *Paris*, whose operas, by his conforming to the genius of the French language, and flattering the ancient national taste, were received with acclamation. He began his career in this capital by his celebrated opera of "*Orphée*," of which the reputation was already established; and this was followed by "*Iphigenie*," taken from one of *Racine's* best tragedies, which had all the success that may be imagined from the force of his genius applied to a favourite drama, set in the style of their favourite composers, *Lulli* and *Rameau*.

In his opera of "*Cythere Assiegée*," 1775, where more delicacy and tenderness, than force, were required in the composition, he was not so successful. Nor was his "*Alceste*," the year following, received with the same rapture as at *Vienna*. Indeed his "*Armide*," in 1777, did not quite fulfil the ideas of grace, tenderness, and pathos, which some of the scenes required, and auditors accustomed to Italian music expected; however, his operas were excellent preparations for a better style of composition than the French had been used to; as the recitative was more rapid and the airs more marked, than in *Lulli* and *Rameau*: there were likewise more energy, fire, and variety of movement, in his airs in general, and infinitely more force and effect in his expression of grief, fear, remorse, vengeance, and all the violent passions.

Gluck's music is so truly dramatic, that the airs and scenes, which have the greatest effect on the stage, are cold, or rude, in a concert. The situation, context, and interest, gradually excited in the audience, give them their force and energy.

Indeed, he seems so much the national musician of France, that since the best days of *Rameau*, no dramatic composer has excited so much enthusiasm, or had his pieces so frequently performed. It has been said in the "*Journal de Paris*," that each of his pieces had supported two or three hundred representations. The French, who feel very enthusiastically whatever music they like, heard with great rapture the operas of *Gluck*, which even the enemies of his genre allowed to have great merit of a certain kind; but though there is much real genius and intrinsic worth in the dramatic compositions of this master, the congeniality of his style with that of their old national favourites, *Lulli* and *Rameau*, was no small merit with the friends of that music. The almost universal cry at *Paris* was now, that he had recovered the dramatic music of the ancient Greeks; that there was no other worth hearing; that he was the only musician in Europe who knew how to express the passions; these and other encomiums preparatory to his apotheosis, were uttered and published in the journals and newspapers of *Paris*, accompanied with constant and contemptuous censures of Italian music, when *Piccini* arrived. This admirable composer, the delight and pride of *Naples*, as *Gluck* of *Vienna*, had no sooner erected his standard in France, than all the friends of Italian music, of *Roussseau's* doctrines, and of the plan, if not the language, of *Metastasio's* dramas, enlisted in his service. A furious war broke out, all *Paris* was on the *qui vive*? No door was opened to a visitor, without this question being asked previous to his admission: "*Monsieur! estes vous Picciniste ou Gluckiste?*" These disputes, and those of musical critics, and rival artists throughout the kingdom, seem to us to have soured and diminished the pleasure arising from music in proportion as the art had advanced to perfection. When every plebeian passage in a musical composition is to be analysed and dissected during performance, all delight and enthusiasm

enthusiasm vanish, and the whole becomes a piece of cold mechanism. It is certainly necessary for professors to study cause and effect, and to make themselves well acquainted with the fundamental rules of their art; but we would advise true lovers of music to *listen* more than talk, and give way to their feelings, nor lose the pleasure which melody, harmony, and expression ought to give, in idle enquiries into the nature and accuracy of their auricular sensation.

The chevalier Gluck, after returning to Vienna from Paris, and being rendered incapable of writing by a paralytic stroke in 1784, only lingered in a debilitated state till the autumn of 1787, when he died at the age of seventy-three.

Gluck had great merit as a bold, daring, nervous composer; and as such, in his French operas, he was unrivalled. But he was not so universal as to be exclusively admired and praised at the expence of all other composers ancient and modern. His style was peculiarly convenient to France, where there were no good singers, and where no good singing was expected or understood by the public in general; and where the poetry was set up against music, without allowing equality, or even an opportunity of manifesting her most captivating vocal powers.

It is, however, allowed by an exclusive admirer of Gluck, in the Encycl. Meth., that "the Italians have the glory of having furnished examples of almost every kind of beauty of which music is susceptible, and of having disseminated their taste in every part of Europe;" but adds, that "France will owe to the celebrated Gluck the having first conceived the system of a music truly dramatic, and our theatre will furnish true models of it to other nations, and to posterity. Let us hasten to steal from the Italians and the Germans the glory of laying the true foundation of a musical system and of transferring the most amiable and touching of arts, into a science as interesting as it is fertile."

Gluck, in a moment of *franchise*, over a bottle, said "the French are a very good sort of people, who love music, and want *songs* in their operas; but they have no singers." And Sacchini, being asked how his operas were executed at Paris, said, "God forbid I should ever go to hear them performed!" And these are the people who are to furnish models of dramatic music to Italy, and to all the rest of Europe!

GLUCKSBURG, in *Geography*, a town of Denmark, with a fortress, in the duchy of Sleswick; nine miles E. of Flensburg.

GLUCKSTADT, a sea-port town of Germany, in the duchy of Holstein, belonging to Denmark, situated on the Elbe. This town is regular and well-built, and its market place commands the chief streets. Several canals run through it, and the principal one crosses near the market place, and is here connected with another, which divides the town into two nearly equal parts. On the land side it may be laid under water. Gluckstadt is the seat of the king's regency, and of the offices and courts connected with it. Here is also a grammar-school. The Calvinists are permitted to have a church, the Roman Catholics a chapel, and the Jews a synagogue. In 1738 a commercial college was instituted here by king Christian VI., as it was a place of some trade; and in 1750, king Frederic V. established an office for keeping the harbour, adjoining to which is a basin for the reception of vessels, in good condition. Gluckstadt was built in 1620 by permission of Christian IV. in a waste called the Wilderness, and in the patent granted to it, he ordered that it should be called Gluckstadt, or the Fortunate Town; he also conferred upon it many customs, rights and privileges, such as were enjoyed by the town of Wiltter; and it was soon after invested with the Lubeck and Ham-

burgh rights. It is distant 28 miles N.W. from Hamburgh. N lat. 53 51'. E. long. 9 20'.

GLUE, GLUTEN, a viscid, tenacious matter, serving as a cement to bind or connect divers things together.

There are divers kinds of glues made use of in the divers arts; as the common glue, glove glue, parchment glue: but the two last are more properly called *size*.

The common or strong glue is a commodity used by numerous kinds of artificers; as joiners, cabinet-makers, case-makers, hatters, book-binders, &c. and the consumption thereof is very considerable. The best is that made in England, in square pieces of a ruddy brown colour: Flanders glue, which is whitish and transparent, is held the next after the English. The most ordinary glue of France is black and opaque.

Glue is made of the skins of all kinds of beasts; as oxen, cows, calves, sheep, &c. The older the beast is, the better is the glue that is made of its hide. Indeed, it is rare they use whole skins for this purpose; these being capable of being applied to better purpose: but they make use of the shavings, parings, or scraps of the hides, and also horns; and sometimes they make it of the feet, sinews, nerves, &c. of beasts; and also of the pelts obtained from furriers.

That made of whole skins is the best, and that of sinews, &c. the worst: and hence, chiefly, arises the difference of glues, and the advantage of English and Flemish glues.

GLUE, *method of making*.—Mr. Clemell, in the Monthly Magazine for 1802, gives the following statement of the general mode of its manufacture. The materials above enumerated are "first digested in lime-water, to cleanse them from grease or dirt; they are then steeped in clean water with frequent stirring, and afterwards laid in a heap and the water pressed out. They are then boiled in a large brass cauldron with clean water, scumming off the dirt as it rises, and it is further cleansed by putting in, after the whole is dissolved, a little melted alum or lime finely powdered. The scumming is continued for some time, after which the mass is strained through baskets, and suffered to settle, that the remaining impurities may subside. It is then poured gradually into the kettle again, and further evaporated by boiling and scumming, till it becomes of a clear dark brownish colour. When it is thought to be strong enough, it is poured into frames or moulds about six feet long, one broad, and two deep, where it gradually hardens as it cools, and is cut out when cold by a spade into square cakes. Each of these is placed in a sort of wooden box open in three divisions to the back; in this the glue, while yet soft, is cut into three slices, by an instrument like a bow, with a brass wire for its string. The slices are then taken out into the open air, and dried on a kind of coarse net-work, fastened in moveable sheds four feet square, which are placed in rows in the glue maker's field. When perfectly dry and hard it is fit for sale. That is thought to be the best glue which swells considerably without melting by three or four days' immersion in cold water, and recovers its former dimensions and properties by drying. Glue that has got frost, or that looks thick and black, should be melted over again. To know good from bad glue, the purchaser should hold it between his eye and the light, and if it appears of a strong dark colour, and free from cloudy and black spots, the article is good." When glue is used by the carpenters, they break it and soak it for about 24 hours in cold water; and then melt the soaked pieces, causing it to simmer for a quarter of an hour over a slow fire and frequently stirring it. When cooled it becomes a firm gelly, which may be cut by any instrument. It is merely warmed for use, and in this state spread over the surface of the wood with a stiff brush. In an interval from

one to three days the pieces of wood will be so perfectly cemented, that boards, thus cohering, will as readily break in any part as separate at the junction. Glued boards will not set in a freezing temperature; the stiffening being occasioned by the evaporation of the superfluous matter of the glue, which is prevented by a considerable degree of cold.

GLUE, *Bees*. See WAX.

GLUE, *Fish*, is a sort of glue made of the nervous and mucilaginous parts of a large fish, found chiefly in the Russian seas.

These parts, being boiled, bear a near resemblance to that viscid matter found on the skins of cod-fish. When boiled to the consistence of a jelly, they spread it on a leaf of paper, and form it into cakes; in which state it is sent to us.

Fish-glue is of considerable use in medicine, and divers others arts; where it is better known under the name of isinglass and ichthyocolla. See ISINGLASS.

A strong and fine glue may be prepared with isinglass and spirit of wine thus: steep the isinglass for twenty-four hours in spirit of wine or common brandy. When the menstruum has opened and mollified the isinglass, they must be gently boiled together, and kept stirring till they appear well mixed, and till a drop thereof, suffered to cool, presently turns to a strong jelly. Then strain it, while hot, through a clean linen cloth, into a vessel to be kept close stopped. A gentle heat suffices to dissolve this glue into a transparent and almost colourless fluid, but very strong; so that pieces of wood, glued together with it, will separate elsewhere than in the parts joined. Boyle's Works abridg. vol. i. p. 130.

A strong compound glue may be made by infusing a mixture of common glue, in small pieces, with isinglass glue, in as much spirit of wine as will cover them, for about twenty-four hours: then melt the whole together, and add as much powdered chalk as will make it an opaque white.

A strong glue, that will resist moisture, may be obtained by dissolving gum sandarac and mastic, of each two ounces, in a pint of spirit of wine, and adding about an ounce of clear turpentine: then take equal parts of isinglass and parchment glue, and having pounded them into small pieces, pour the solution of the gums upon them, and melt the mixture in a covered vessel, with a heat less than that of boiling water: then strain the glue through a coarse linen cloth, and putting it again over the fire, add about an ounce of powdered glass.

Or, a strong glue, that will resist water, may be made by adding half a pound of common isinglass glue to two quarts of skimmed milk, and evaporating the mixture to a due consistence.

A glue, that will hold against fire and water, may be made by mixing a handful of quick-lime with four ounces of linseed oil, boiling them to a good thickness, and spreading the mixture on tin plates in the shade: it will thus become exceeding hard, but will easily be dissolved over a fire, and be fit for use. See CEMENT.

GLUMA, a *Husk*, in *Botany*, is the peculiar calyx of grasses and grass-like plants, and indeed their corolla, at least what is so termed by Linnæus, is of the same chaffy nature. Husks or Glumes are usually compressed, embracing each other at the base; more rarely they are depressed, flattened vertically, as in *Quaking-grass* or *Briza*. To the husk belongs the *arista* or *awn*, (see *ARISTA*), which is a bristle-shaped appendage, usually spiral, and possessing the properties of an hygrometer. It originates from the midrib or keel of the husk, and is either terminal or dorsal, being in the latter case placed sometimes very far down the back of the husk, as in many species of *Aryna*, and in these instances

it belongs to the glumes that constitute the corolla, not the calyx. The *arista*, though so remarkable, is by no means always constant in the same species, though nearly invariably so in the flowers of the same individual plant.

Husks are mostly furnished with one central longitudinal rib, though the inner *gluma* of the corolla in grasses have two nearly marginal ones. They have in most instances, besides the central rib, a greater or less number of lateral ones, all likewise longitudinal, of great use in distinguishing species of *Poa* and other difficult genera. Their margin is commonly thin and more or less membranous or scarious. Some *glumæ* always remain separate and distinct from the seed which they commonly envelop; others are closely incorporated with that part as it ripens, of which a curious example may be seen in *Briza*.

Some sorts of viviparous grasses exemplify the transformation of glumes into leaves in a remarkable manner, the awn remaining at the summit being perhaps the only indication of their original nature. See *Aira lewigata*, *Engl. Bot. t. 2102*. The same metamorphosis of a petal into a leaf is indeed not rarely seen in a Tulip and other cultivated flowers. We have a wild specimen of a similar change in the *Anemone alpina*, part of whose leafy involucre is become a perfect petal.

Glumes are, we believe, invariably permanent, never deciduous, till the seed ripens, when those of the corolla fall off along with the seed, serving the purpose of a *pericarpium*.

GLUMACEOUS FLOWERS, a term applied by some botanists to the flowers of the natural order of grasses, expressive of their chaffy nature.

GLUMMEN, in *Geography*, a town of Prussia, in the province of Natangen; 24 miles S. of Königsberg.

GLURANTZ, or GLURS, a town of the county of Tyrol, situated on the river Adige, built in 1362, and surrounded with walls in 1530. It was taken by the French in 1799; 36 miles W. of Brixen. N. lat. 46° 38'. E. long. 10° 26'.

GLÛS, in *Surgery*, a species of dysuria, attended with a copious quantity of mucus in the bladder. Hence, the malady has been named *dysuria mucosa*.

GLUT, among *Falconers*, the slimy substance that lies in a hawk's paunch.

GLUT, in *Rural Economy*, a term sometimes provincially applied to a large wooden wedge.

GLUTA, in *Botany*, so called by Linnæus, from the Latin word *glutus*, thrust close together, in allusion to the close application of the claws of the petals to the stalk which elevates the organs of fructification. Professor Martyn seems not to have been aware of this derivation. We are led to it by the repeated indication of the circumstance in Linnæus, and his use of the word *adglutinata*, even in the generic character, as well as in his subsequent observations. *Linn. Mant. 2. 160. Syst. Veg. Ed. 14. 821. Schreb. 146. Willd. Sp. Pl. v. 1. 1120. Mart. Mill. Dict. v. 2. Juss. 427. Class and order, Pentandria Monogynia. (Linnæus refers it to *Gynandria Pentandria*.) Nat. Ord. *Capparides*, Juss.?*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, membranous, bell-shaped, obtuse at the base, cloven half way down into two lobes, deciduous. *Cor.* Petals five, equal, lanceolate, bluntish, somewhat oblique, four times the length of the calyx; their upper part spreading horizontally; their claws cohering round the stalk of the germen, and attached to it. *Stam.* Filaments five, bristle-shaped, rather shorter than the petals, inserted into the summit of the stalk of the germen; anthers versatile, rather oblong. *Pist.* Germen obovate.

obovate, standing on a cylindrical stalk, which is rather longer than the calyx; style thread-shaped, equal to the filaments; stigma simple, obtuse. *Peric.* and *Seeds* unknown.

Ess. Ch. Calyx bell-shaped, cloven, deciduous. Petals five; their claws cohering round the stalk of the germen. Stamens inserted into the top of that stalk, below the germen.

1. *G. Benghas.* Linn Mant. 2. 293. Native of Java, where it is called *Benghas*, and, if we mistake not, in the Malay language *Dodec*. This plant is unknown to all botanists except Linnæus, by whose herbarium alone it can be determined. His remarks have led the students of natural orders wide of the truth concerning it, for nothing can be more unlike *Passiflora*. To *Sterculia* it has some resemblance, and we have been much inclined to refer it to Jussieu's *Malvaceæ*, especially from its likeness in some respects to the *Affonia* of that author and of Cavanilles; but on examination this likeness proves fallacious. The most probable place for it is amongst or near the *Capparides*, but the fruit being unknown, leaves this matter in great doubt. After all, it may be thought to belong to some new order, which the students of natural arrangement are but too prone to make on every emergency, and the French in particular seem to think they shew their skill by their refinements on this head; whereas it is but an easier fault, though a more fatal one, than that of making too many genera, and ought to be watched with tenfold care.

The *Gluta Benghas* appears to be a *shrub* or *tree*, with slightly pubescent branches and buds. *Leaves* scattered, most numerous about the ends of the branches, from three to ten inches long, elliptic-lanceolate, bluntish, entire, tapering down at the base into a short footstalk; they are smooth on both sides, furnished with one rib and many transverse veins connected by innumerable reticulations. *Stipules* none. *Flowers* nearly the size of *Cl. matis Flammula*, or, as Linnæus says, of a cabbage blossom, in a corymbose panicle; whether terminal or axillary cannot be determined from the specimen, though he asserts the former. There is some appearance of a glandular depression at the back of the footstalk where it joins the leaf. S.

GLUTEA, ARTERIA, in *Anatomy*, a large artery distributed chiefly among the glutei muscles. See ARTERY.

GLUTEN, ANIMAL, in *Chemistry*. See ANIMAL FIBRE and BLOOD.

GLUTEN, *Vegetable*, a substance resembling the former, and found in several vegetables. (See *Vegetable FIBRE*.) Beccari first found that wheat-flour contained gluten in considerable quantity, and from this it is obtained by the following process. (Aikin's Dict.) "Moisten any quantity of wheat-flour with a little water, and knead it with the hand into a tough ductile paste, then let a very slender stream of water keep dropping on the paste, while it is incessantly worked about with the hands, and the water will run off white and turbid, owing to the fecula or starch which it carries off. The paste in the mean time gradually becomes more of a grey and almost semi-transparent appearance; and when the water runs off quite clear, nothing is left in the hands but pure gluten. No other precaution is required in this preparation but that of not drenching the flour at first with water, but only using a very small quantity with much kneading, that the gluten may not be carried off along with the starch. Good wheat-flour will yield in this way about a fourth of its weight of gluten, and no other flour but that of wheat will yield it, except in a very small proportion, and hence probably the peculiar property of wheat-flour to make

bread without any other addition than a ferment." See BREAD.

Gluten is contained in small quantity in several vegetable juices and other parts, and may be separated from them. Bird-lime is supposed to be chiefly gluten, and the green fecula of plants abounds with it. See BIRD-LIME and FECULA.

GLUTEUS, in *Anatomy*, a name given to three large muscles, concerned in the motions of the pelvis and thigh, and distinguished from each other by the epithets magnus, medius, and minor. They occupy the outer and posterior part of the pelvis, from which they arise, and form the large fleshy prominences named the buttocks.

The *gluteus magnus*, or maximus, le grand fessier, ili-facro-femoral, is a very broad, thick, and bulky muscle, composed of large fasciculi loosely connected together, and separated to a considerable depth by adipose and cellular substance, of an irregularly quadrilateral figure, and situated obliquely at the outer and back part of the hip. The rounded swelling, which forms the outline of the buttock at its back part, and the projection of which hides the termination of the large intestine, is formed entirely by this muscle. Its external surface has the same degree of convexity as that of the buttock; the internal, which covers the tuberosity of the ischium, and the great trochanter, is proportionally concave. It arises, 1st. By short aponeurotic fibres, from about one inch of the posterior extremity of the crista ili, where the bone extends beyond the sacrum, and from the neighbouring part of the immediately subjacent notch. At this origin an aponeurosis may be observed, continuous with that of the thigh, and of the vertebral muscles. 2dly. From the ligament connecting the posterior end of the iliac crista, to the back of the sacrum; and here it is continuous with the tendinous origin of the latissimus dorsi, longissimus dorsi, and sacro-lumbalis. 3dly. From the external margin of the sacrum, near its last foramen, from the tubercle at the side of the termination of the canal containing the medulla spinalis, and from the articulation between the sacrum and coccyx. 4thly. From the posterior surface of the coccyx. 5thly. From the surface of the great sacro-sciatic ligament. From these points the fibres all proceed obliquely downwards and outwards, nearly parallel to each other; the muscle is at first rather thinner and narrower, and grows broader and thicker as it proceeds. Its upper margin is closely attached to that part of the femoral fascia which covers the gluteus medius. The superior fibres, having turned over the great trochanter, join the upper part of the common tendon. The latter is most intimately connected to the fascia lata, so that, on the first inspection, the gluteus magnus appears to be inserted into this fascia, throughout the whole line of its front edge: we cannot, however, easily distinguish these parts by cutting through the muscle, and turning it aside. The common tendon receives the muscular fibres from above the trochanter, to below the quadratus femoris, where it begins to be attached to the bone. It is very firmly attached to the rough line, which commences at the root of the trochanter, and joins the linea aspera, occupying by its insertion a space of about three inches; it is situated here between the vastus externus and adductor magnus, to the former of which it is connected by tendinous and muscular fibres.

The exterior convex surface of this muscle is covered for a small space towards its upper part by a thin plate of the fascia lata, and is every where else immediately subjacent to the integuments. The inner surface covers the os innominatum, the sacrum and coccyx, the origin of the vertebral muscles, the gluteus medius, the pyramidales, the gemini, the obturator internus, the quadratus femoris, the tuberosity of the

the ischium, the origins of the semitendinosus and biceps, the adductor magnus, the sciatic nerve, and the great trochanter. A large synovial membrane, placed between this muscle and the last-named eminence, favours their reciprocal motions. The cavity does not in general contain much fluid; and it sometimes exhibits internal folds.

The *gluteus medius*, le moyen fessier, ilio-trochanterien, is a thick and broad muscle, flattened and triangular, partly covered by the preceding, but placed more at the side of the pelvis. It arises by very short aponeurotic fibres from the external surface of the os innominatum, immediately under the crista ilii, running forwards to the front as far as the anterior superior spine, and backwards to the sacro-sciatic notch: downwards it is bounded by the curved line, which marks the circumference of the glutens minimus. Another origin of this muscle is from the fascia lata, where that aponeurosis is fixed to the crista ilii, and where it separates this muscle from the tensor vaginæ. From this double origin the fibres all take their course downwards, the anterior or shortest being at the same time directed obliquely backwards; the middle, which are longer, passing perpendicularly, and the posterior or longest, coming obliquely forwards. In this way they all converge to meet in a broad aponeurosis in the radiate fibres, beginning in the substance of the muscle, higher behind than before, and descending, as it receives the muscular fibres successively, to the great trochanter, to be fixed to the upper and anterior part of that eminence. Many of the anterior fibres are mixed with those of the glutens minor; so that the two cannot be completely separated without dividing some of the muscular substance.

Its external surface is covered behind by the glutens magnus, in front by the fascia lata. The inner surface covers the glutens minor, the gluteal artery, and the surface of the bone. Its front edge is in contact with the tensor vaginæ; the posterior with the pyramidalis.

Gluteus minor, or minimus, le petit fessier, ilio-ischii-trochanterien. This is the smallest of the three glutei, and covers the os innominatum by its whole inner surface, being equally covered on the outside by the preceding muscle. It is thick and flattened, and has a triangular figure. It arises from the surface of the os innominatum by very short aponeurotic fibres; beginning at the anterior superior spine, and following a curved line, which extends from the latter process to the sacro-sciatic notch. From this line, of which the convexity is turned upwards, it covers the bone as far as the edge of the acetabulum. The muscular fibres all descend in a converging manner; the middle taking a perpendicular course, while the anterior are directed backwards, and the posterior forwards. They are all implanted in a broad radiated aponeurosis, which lies on the external surface of the muscle, except towards the front, where it is covered by a few fibres of the preceding muscle. This aponeurosis, as it descends, forms a strong tendon implanted immediately within the former, in the upper and anterior portion of the great trochanter. It has some connection to the capsular ligament of the hip; and a small synovial membrane is interposed between it and the trochanter. It is covered by the glutens medius, and very slightly by the pyramidalis: it lies on the bone, on the capsular ligament of the hip, and the origin of the rectus cruris.

Motions produced by the glutei.—The muscles, which we have just described, move the thigh and pelvis reciprocally on each other. Their action on the pelvis may be observed both in standing and walking. When we support the trunk in the erect attitude on both feet, the glutei magni fix the pelvis firmly behind, and counteract that tendency which the body naturally has to fall forwards. Hence the

bulk and power of these very muscles in the human subject afford a clear proof that man was designed for the attitude on two feet; this gives to the human frame the buttocks, which are seen in no other animal, because man is the only biped among the mammalia. In the case now under consideration the glutei magni are assisted by the semi-tendinosi, semi-membranosi and bicipites; and antagonized by the psoæ and iliaci, which possess a force much inferior to that which opposes them behind, because they are aided by the weight of the trunk. When the pelvis has been bent forwards, the glutens magnus will restore it; and if the circumstances admitted of this part being carried backwards, the same muscle would produce that motion. The other two glutei are not essentially concerned in the attitude of standing on both feet; but they are the principal agents in supporting and balancing the trunk on one foot, by inclining the pelvis over the head of that thigh bone on which the body rests, so that the centre of gravity of the trunk may be in a line drawn through that lower extremity. In this case their exertion counteracts the tendency of the trunk to fall on that side which is not supported. These muscles are further employed in the same kind of way in progression: the glutens magnus balances the pelvis while one leg is carried before the other, and brought to the ground; and the two others support the trunk laterally, while the limb of the opposite side is in the air. In the attitude on one leg, the glutens magnus can rotate the pelvis on the thigh-bone of its own side, so as to turn the symphysis pubis towards the opposite side. When the glutei move the thigh on the pelvis, the magnus restores the bone to its former position, where it had been previously bent: and, if the pelvis be carried forwards, it may move the former still farther in the direction of extension; the medius and semi-medius move the thigh away from the opposite limb. The g. magnus has the effect also of rotating the thigh outwards; while the anterior fibres of the two smaller muscles will rotate it inwards. The former is a tensor of the fascia lata.

GLUTTON, in *Zoology*. See *Ursus Gula*.

GLYCAS, MICHAEL, in *Biography*, a Greek historian, who is supposed to have flourished in the 12th or 13th century, though by some others he is referred to the 15th. He was a native of Byzantium, but spent a great part of his life in the island of Sicily. He is principally known by his "Annals," in four parts, containing the history of the world, from the creation to the birth of Christ, and that of the Byzantine emperors down to the death of Alexius Comnenus in 1118, interspersed with a number of theological, philosophical, and physical discussions. An edition of the "Annals" in Greek and Latin was given to the public by father Labbe, in 1660. The third part has been published separately by Meursius, with a version and scholia. Several letters of Glycas have been published in different collections. He was undoubtedly a very learned man, and the correspondence which he maintained with the literati of his age shew that he stood in very high reputation. Moreri.

GLYCERIA, in *Botany*, from γλυκερός, *sweet*, the seeds being eaten in Germany, and called Manna-seeds, on account of their sweet taste. Brown Prod. Nov. Holl. v. 1. 179.—Class and order, *Triartria Dignia*. Nat. Ord. *Gramina*. This new genus of grasses is founded by Mr. Brown on the *Festuca fluitans* of Linnæus, *Poa fluitans*, Sm. Fl. Brit. 95, with the following characters.

"Glume (Calyx) of two valves, containing many flowers. Spikelet cylindrical, awnless. Perianth (Corolla) beardless, its valves of equal length. Scale under the germen solitary, fleshy, like a half shield. Stigma doubly compound. Seed uncon-

GLYCINE.

unconnected, oblong, with a furrow at one side. *Flowers* somewhat panicled."

We cannot but assent to the propriety of separating the grafs in question from *Poa* and *Festuca*, as far as habit is concerned, but we are very certain that *Poa difflans*, *maritima*, *procumbens*, and *rigida* of Fl. Brit. and *Cynofurus durus* of Linnæus cannot fail to go along with it, though we fear the characters given by the sagacious writer above quoted will not be found to hold good in all, if in any, of these. Perhaps the following definition of *Glyceria*, formed on simple and obvious Linnæan principles, may be unexceptionable, as embracing them all, and preserving an analogy with genera already established.

Calyx of two valves, containing many florets. Spikelet linear. Corolla of two oblong, obtuse, beardless valves. S.

GLYCINE, from γλυκύς, *sweet*, the particular application of which is not very obvious, having originated merely from the sweet taste noticed by Cornuti in the leaves and tuberous roots of *G. Apios*. This indeed is the original, and perhaps the only true *Glycine*, the numerous assemblage of species ranged under this genus, by recent writers, being very anomalous in fructification, especially those of New Holland, as will appear by Mr. Brown's definitions when the second part of his valuable work appears.—Linn. Gen. 373. Schreb. 495. Willd. Sp. Pl. v. 3. 1053. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 34. Juss. 357. Lamarck Illustr. t. 609. Gærtn. t. 154. Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, compressed, two-lipped; upper lip notched, obtuse; lower longer, three-cleft, acute, its middle tooth longest. *Cor.* papilionaceous. Standard inversely heart-shaped, deflexed at the sides, gibbous at the back, emarginate at the top, and straight, till driven back by the keel. Wings small, oblong, ovate towards the extremity, bent downwards. Keel linear, falcate, curved upwards, pressing the standard upward by its obtuse and dilated extremity. *Stam.* Filaments in two sets, (one simple, the other in nine divisions,) slightly separated at the top, revolute; anthers simple. *Pist.* Germen oblong; style cylindrical, rolled spirally; stigma obtuse. *Peric.* Legume oblong. *Seeds* kidney-shaped.

Ess. Ch. Calyx two-tipped. Stamens in distinct sets. Keel of the corolla forcing back the standard with its point.

Obs. *Glycine Apios* and *frutescens* have a two-celled legume. *G. monoica* is a singular instance of a separation of sexes in flowers of this tribe.

This genus has accumulated from two species (*G. Apios* and *frutescens*) in the *Hortus Cliffortianus*, to eight in the first edition of *Species Plantarum*, nine in the second, fifteen in the fourteenth and last edition of *Systema Vegetabilium*, and finally to forty-four in Willdenow. These now form a very heterogeneous assemblage, and the New Holland ones constitute a distinct genus, the *Kennedia* of Ventenat, distinguished by its spontaneously reflexed standard, and legume of many cells. The whole requires a thorough revision. Some are of opinion that *G. Apios* is generically distinct from all the others, and if so it would be most convenient, though this is one of the original species, to give it the generic name of *Apios*, retaining *Glycine* for such more common and more numerous ones as may answer to the usual idea of the genus, an essential character being selected to combine them together.

GLYCINE, in *Gardening*, contains plants of the shrubby climbing kind; of which the species cultivated are the

shrubby *glycine*, or Carolina kidney-bean tree (*G. frutescens*); the two-spotted *glycine* (*G. bimaculata*); the reddish-flowered *glycine* (*G. rubicunda*); and the scarlet *glycine* (*G. coccinea*.)

Method of Culture.—In the first it may be effected by laying down the young branches in the early autumnal season. When well-rooted in the following autumn, they may be taken off and planted where they are to remain, or in nursery-rows, being watered when the weather is hot, and the roots protected in the winter by some sort of straw material. They are found to succeed best in dry, warm, light sorts of ground.

And the other kinds may be raised by sowing the seeds when they can be obtained from abroad, or produced here in pots of light earth, in the early spring, being afterwards removed into other pots, and placed in the green-house, or Cape stove. It has been supposed by Mr. Curtis, that the two last may succeed in the open air, when planted out in warm sheltered situations, and protected during the winter season by some convenient matting or other means.

All the sorts are ornamental in their flowery climbing growth; the first in the open ground, and the latter in the green-house and stove collections.

GLYCINE, *Glucine*, Fr. in *Chemistry*. This earth was first discovered by M. Vauquelin in 1798. He detected it in the analysis of the beryl, undertaken at the desire of Haüy, who wished to have it ascertained by a strict chemical inquiry, whether the beryl and emerald were as similar in their composition as in the form of their crystallizations. The results of this inquiry were conformable to the expectations which gave rise to it, and the existence of a new earth in the beryl and emerald was confirmed by the experiments of Klaproth. Vauquelin, in the memoir in which he announced his discovery, called the new substance merely the earth of the beryl: afterwards, with his associates, Guyton, Fourcroy, and Chaptal, he determined on the name *glucine*, derived from the Greek γλυκύς, *sweet*, because all the soluble salts of this earth have the property of producing a certain sweet astringent taste. When the name was selected, the character on which it was founded was peculiar; but though it ceased to be so on the discovery of yttria, yet as the name conveys no erroneous ideas of the body, to which it is applied, there is no impropriety in adhering to it: besides, the taste still serves as a physical characteristic; for, according to Vauquelin, the sweetness of the salts of *glycine* has a sensible difference from that of the salts of yttria, particularly of the sulphat.

Glycine, in its pure state, has not yet been discovered in nature: indeed, its occurrence in compound minerals is exceedingly rare, for it has only been found in the beryl, or ultramarine, the emerald and the gadolinite; and it enters but sparingly into the composition of these bodies; the beryl, in which it is most abundant, containing, according to the analysis of Vauquelin and Rose, no more than 14 per cent. From the analogy which exists between *glycine* and alumine, the former is very liable to be taken for the latter by chemists who do not pay particular attention to accuracy in their analytical inquiries. The first analyses of the emerald made by Klaproth and Vauquelin afford an instance of this kind: and M. Bindheim committed a similar error in his analysis of the beryl.

To obtain *glycine* in a state of chemical purity, finely powdered beryl is to be fused with three times its weight of caustic potash in a silver or platina crucible; the crucible is to be exposed for two hours to a strong red heat, and the mixture in fusion is to be frequently stirred with an iron rod, in order to keep the earth as much as possible suspended

GLYCINE.

suspended and exposed by an extent of surface to the action of the alkali. If the treatment described is properly conducted, the fused mass, when softened with water, will be entirely dissolved by muriatic acid, assisted by a slight digesting heat: the muriatic solution thus procured must be evaporated to dryness. A large quantity of water will dissolve the soluble salts, and leave the principal part of the flux, which is to be separated and well washed on a filter. The filtered solution is to be precipitated by carbonate of potash. The precipitate, consisting principally of alumine and the earth in question, is to be dissolved in dilute sulphuric acid, and evaporated to the proper consistence to afford crystals of alum. If the precipitate produced by carbonate of potash has been well washed, it is necessary to add a little potash to the sulphuric solution. When the solution, on a second or third evaporation, and addition of potash, ceases to yield any more crystals of alum, the mother liquor is to be mixed with a solution of carbonate of ammonia, greatly exceeding the quantity necessary to saturate the acid, and to be transferred to a bottle having a ground stopple: the mixture is to be well agitated, and carbonate of ammonia is to be added till the precipitate which first appeared is re-dissolved, or no longer diminished by fresh portions of the carbonated alkali. The solution of the triple compound of glycine carbonic acid and ammonia is to be filtered in order to separate the small remaining quantity of alumine, and then boiled till the vapour ceases to change the colour of turmeric paper, or till it no longer has an ammoniacal smell; when all the carbonate of ammonia being driven off, the whole of the glycine will be found precipitated in the form of a white granular powder combined with carbonic acid. This powder is to be washed in a filter, till the water ceases to afford a precipitate with muriat of barytes and lime-water; it is then to be dried, and heated to redness: by this means, the water and carbonic acid, amounting to about half the weight of the whole, will be expelled, and the glycine, if it does not effervesce with acids, will be left in a perfectly pure state.

Glycine thus procured, is a snow-white powder, soft and somewhat unctuous between the fingers, very adhesive to the tongue, and destitute both of smell and taste. Its specific gravity is 2.976. It produces no change in the colour of vegetable blues. Neither oxygen nor nitrogen has any action on it, nor does it suffer any change by exposure to the atmosphere; as carbonic acid and moisture do not appear to be absorbed by it. It forms, with a small quantity of water, a slightly ductile paste, that possesses much less tenacity than that of alumine. Glycine has not yet been fused; it neither contracts nor hardens when heated, nor is it altered by exposure to the most intense fire. With borax it forms a white transparent glass, which does not become opaque on cooling. It refuses to combine directly with sulphur or phosphorus, but it appears from Fourcroy that a sulphuret may be formed by decomposing the sulphat of glycine by charcoal. Glycine is soluble in a saturated solution of sulphuretted hydrogen. A hydro-sulphuret of this earth, it is likewise said, may be obtained by dissolving the sulphuret in water. In these properties it approaches the alkaline earths, and constitutes apparently the link of union between them and the class to which it belongs. It is dissolved by both the fixed alkalies in their liquid state, but in a less degree than alumine, and, like alumine, it is not taken up by ammonia. It is dissolved in a solution of carbonate of ammonia, as has already been mentioned. It very readily unites with acids. All its soluble salts produce, when first tasted, the sensation of sweetness, which gradually becomes astringent.

In relation to its affinity for acids, glycine appears to be intermediate between alumine and magnesia, for it decom-

poses only the salts of alumine, yttria, and zircon. And the order of its affinities is much the same, according to Fourcroy, as that of the other earths, sulphuric acid holding the first place, and nitric, muriatic, phosphoric, fluoric, boracic, and carbonic following. No experiments have been undertaken yet, to ascertain what combinations glycine is capable of forming with the earths and metallic oxyds.

Yttria and alumine are the only earths for which glycine is liable to be mistaken: the properties in which it resembles them are, rather unfortunately, of a most striking kind, but it has a number of other characters which are very distinct, and fully demonstrative of its peculiar nature. Glycine is similar to alumine, in being soluble in caustic solutions of the fixed alkalies, and in some of its physical qualities; but it differs from alumine in affording with acids sweet astringent salts; in not yielding alum with sulphuric acid and potash; in possessing a greater affinity for acids; in being entirely soluble in carbonate of ammonia; and lastly, in not being precipitated from its solutions by oxalat, tartrat, or prussiat of potash. It is to be distinguished from yttria, by its greater solubility in carbonate of ammonia, the latter requiring for its solution five times as much carbonated alkali as glycine, by its salts occasioning a precipitate, when added to any of the succinats, by the insolubility of yttria in fixed alkaline solutions, and by the precipitate which the salts of yttria afford with prussiat of potash.

Glycine was considered as a simple body till the important discoveries of Mr. Davy gave rise to new analogies; and though the compound nature of this earth is not yet fully demonstrated, yet there is every reason to believe that glycine, like the alkalies and alkaline earths, is a metallic oxyd: and the results of the experiments which Mr. Davy made on this body are explained best on such a supposition. This gentleman negatively electrified glycine, slightly moistened in contact with an amalgam of potassium, under naphtha, by a battery of 500 plates. After an hour the amalgam was thrown into water, and an alkaline solution was produced, which became cloudy when neutralized by acid, thus indicating the presence of the earth. Mr. Davy, following the nomenclature which he has adopted in respect to the new metals, has proposed glucium for the name of the metal of glycine, when its existence is no longer doubtful.

Carbonat of glycine, as well as all the other salts of this earth, has not yet been discovered ready formed in nature. It is procured by precipitating the sulphat, nitrat, or muriat of glycine, by either of the carbonated fixed alkalies. The precipitate, which is the salt sought after, being well washed and dried, appears in the form of soft white powder, having a greasy feel and great lightness. Carbonat of glycine is insoluble in water, and it is unaltered by exposure to the air. It is decomposed by all the acids; and by the action of a red heat: most probably all the alkaline earths deprive it of carbonic acid in the moist way. According to Klaproth it is composed of

Glycine	-	-	-	53
Carbonic acid and water	-	-	-	47
				100

Phosphat of Glycine.—Phosphat of soda, added to a neutral solution of nitrat of glycine, throws down this salt either in a white pulverulent form, or in a mucilaginous state. It is insoluble in water, insipid and uncrystallizable.

It is not decomposed by a violent heat, but it fuses into a white transparent glass, that does not become opaque on cooling. Phosphat of glycine is soluble in phosphoric acid. The sulphuric and nitric acids first dissolve this salt, and

and afterwards decompose it. Muriatic acid produces a similar effect, but in a less degree. It is likewise readily decomposed by the carbonated alkalies and by all the carbonated earths, except carbonat of magnesia. With the sulphat, nitrat, and muriat of alumine, it suffers decomposition, a mutual exchange of acids taking place between the two earths.

Sulphat of Glycine.—Glycine, both in its pure and carbonated state, dissolves very readily in dilute sulphuric acid. The solution by spontaneous evaporation affords octahedral crystals, composed of two oblique four-sided pyramids joined base to base, with their edges and solid angles truncated. It also, but with difficulty, yields when evaporated on a sand bath small needle-form crystals. The solution, when evaporated nearly to dryness, assumes a syrupy consistence. Sulphat of glycine, has a remarkable sweet and astringent taste. It is very soluble in water. Heated, it intumescs, suffers the watery fusion, and becomes pulverulent from the dissipation of its water. It is completely decomposed by a strong red heat, the acid being expelled and the earth left in its pure state. It has been already observed that sulphat of glycine is converted, when heated with charcoal, into a sulphuret: but this sulphuret, according to Fourcroÿ, does not become a pyrophorus, like alum thus treated, though sulphat of potash be present. A solution of nut-galls, added to this salt dissolved in water, produces immediately a white precipitate. Previous to the knowledge of this fact, such a property was conceived to be peculiar to metallic salts.

Sulphat of glycine, slowly evaporated with a small quantity of sulphat of potash, forms minute crystalline grains, which dissolve with ease in seven or eight times their weight of cold water. Glycine, added to a solution of alum, precipitates the alumine, and most probably produces a compound, similar to the preceding one. Sulphat of glycine is decomposed by all the alkalies and earths, excepting alumine, yttria, zircon, and silic.

Nitrat of glycine is procured by saturating nitric acid with glycine. The solution of this salt does not afford crystals by evaporation, but produces a ductile and adhesive mass, which, when further dried, falls into powder. It is very soluble in water and deliquescent in the air. It attracts moisture so strongly, that it might, if easily procured, be advantageously employed for absorbing the hygrometrical water of gases. Its taste is saccharine and astringent. Tincture of galls dropt into a solution of this salt produces a yellowish brown precipitate. Nitrat of glycine fuses at a low heat, but if the heat is increased, the acid is expelled. It is decomposed in the moist way by sulphuric acid, and by the same alkalies and earths as the sulphat. The proportions of its component parts are not known; but Vauquelin has observed that a given quantity of nitric acid requires rather more glycine than alumine for its complete saturation; yet the former earth, though in combination with nitric acid more soluble than the latter, decomposes, with the assistance of heat, nitrat of alumine, precipitating the alumine, and forming nitrat of glycine.

Muriat of glycine is procured by dissolving glycine in muriatic acid. It is in some respects similar to the nitrat, but differs in its solution, affording by careful management small crystals, the form of which, on account of their size, have not yet been determined; and in not being subject to deliquesce on exposure to the atmosphere. Its taste is similar. A solution of this salt in dilute alcohol is said to be an agreeable sweet liquid. When distilled *per se*, the acid flies off, and leaves the earth in a state of purity. It is also decomposed when heated with phosphoric acid. The

same effect is produced by sulphuric and nitric acids, and by the alkalies, and all the earths that decompose the nitrat.

Acetat of glycine, which is prepared by dissolving the earth in acetic acid, has not yet been procured in a crystalline form. Its solution, when evaporated, acquires a glutinous consistence, and the salt becomes brittle as it slowly dries.

Succinat of Glycine.—Any of the succinats added to the nitrat, muriat, or sulphat of glycine, precipitate the salt in question. Its properties have not yet been enquired into.

We are indebted for the imperfect knowledge we have of the combinations of glycine, with the several acids above-mentioned, principally to the celebrated discoverer of this earth. Glycine, in no form as yet, has been usefully employed; yet Vauquelin conceives that the earth itself and some of its salts, when they can be procured with facility, may admit of such an application in chemistry, in medicine, and the arts. Its marked attraction for animal and vegetable colouring substances induced him to think that there was a probability of its being serviceable as a mordant; and the peculiar taste of some of its salts gave rise to the hope that these combinations might produce salutary effects on the animal system. If his expectations should be realized, we must agree with Vauquelin, that these salts will be some of the most agreeable medicines that exist. *Ann. de Chem.* vol. xxvi. 155. xlii. 277. *Fourcroÿ Connaissance Chem.* vols. ii. iii. *Aikin's Chem. Dict.* vol. ii. *Philosoph. Trans.* part. ii. 1808. p. 352.

GLYCONIAN, GLYCONIUS. in the Greek and Latin poetry.

A Glyconian verse is that consisting of two feet and a syllable; at least this is Scaliger's opinion: who adds, that the Glyconian verse was also called the Euripidean verse. See VERSE.

Others hold, that the Glyconian verse consisted of three feet, a spondee and two dactyls; or rather a spondee, choriambus, and an iambus or a pyrrhic: which opinion is the most followed.

"Sic te diva potens Cyprî," is a Glyconian verse.

GLYCYRRHIZA, in *Botany*, Liquorice, γλυκύριζα of Dioscorides, who describes the plant very faithfully and accurately; but it is remarkable that he says the flower is like a hyacinth, which can allude to the colour only, whether his ὑάκινθος be the *Delphinium* or *Hyacinthus* of modern botanists. The word is composed of γλυκύς, *sweet*, and ῥίζα, *a root*; and the name in apothecaries' Latin, *liquiritia*, as well as the English one, liquorice, the French *reglisse*, the Italian *regalizza*, &c. with all their corruptions, originate from it.—*Linn. Gen.* 380. *Schreb.* 502. *Willd. Sp. Pl.* v. 3. 1143. *Mart. Mill. Dict.* v. 2. *Ait. Hort. Kew.* v. 3. 56. *Juss.* 359. *Tourn.* t. 210. *Lamarck. Illustr.* t. 625. *Gærtn.* t. 148.—Class and order, *Diadelphia Decandria*. *Nat. Ord.* *Papilionacea*, *Linn. Leguminosæ*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, two-lipped, permanent; upper lip in three deep segments, of which the lateral ones are linear, the central one broadest and cloven; lower perfectly simple, linear. *Cor.* papilionaceous. Standard ovato-lanceolate, straight, longest. *Wings* oblong, very like the keel, but rather larger. Keel of two petals, acute, its claw the length of the calyx. *Stam.* Filaments in two sets, (one simple, the other in nine divisions,) straight; anthers simple, roundish. *Pist.* Germen shorter than the calyx; style awl-shaped, as long as the stamens; stigma obtuse, ascending. *Peric.* Legume ovate or oblong, compressed, acute, of one cell. *Seeds* very few, kidney-shaped. Efl.

GLYCYRRHIZA.

Eff. Ch. Calyx with two lips; the upper three-cleft; lower simple. Stamens in distinct sets. Legume ovate, compressed, of one cell. Seeds one or two.

1. *G. echinata*. Linn. Sp. Pl. 1046. Jacq. Hort. Vind. v. 1. t. 95. (Dulcis radix; Matth. Valgr. v. 2. 16. Camer. Epit. 423.)—"Legumes prickly. Flowers capitate. Stipulas lanceolate. Leaflets smooth; the terminal one nearly sessile."—Native of Italy, as well as of Tartary and the confines of China; also abundantly, according to Dr. Sibthorp, on the sandy shores of Crete, Samos, and other Greek islands, where it still retains its ancient name unchanged. The long pliant perennial roots, deeply descending into the ground in a favourable soil, are cultivated for their sweet taste and pectoral virtues, and are sufficiently well known. The stems are two or three feet high, nearly simple, leafy, round and striated. Leaves of several pair of equal, elliptical, entire, acute leaflets, the odd one on a little stalk only like the rest, not on an elongation of the main footstalk. Stipulas lanceolate, acute. Flowers several, in axillary, solitary, stalked heads; their colour a dull purple. Legumes clothed, in their upper part especially, with numerous long rigid prickles, resembling the fruit of *Xanthium strumarium*. Dioscorides compares them to that of the Plane-tree. The whole herb is destitute of pubescence, but somewhat clammy to the touch.

2. *G. fistida*. Desfont. Atlant. v. 2. 170. t. 199.—Legumes prickly. Flowers spiked. Stipulas lanceolate. Leaflets scaly beneath; the terminal one nearly sessile.—Found by Desfontaines on mount Atlas, and in cultivated fields near Mayane in Africa. We have it from Aleassar. Whole plant extremely fetid. Leaves much like the last in size and shape, but the flowers are pale yellow, in long spikes. Legumes crowned with the permanent style, which is longer in this than in the former. The stems, as well as both sides of the leaves, is besprinkled with minute scales.

3. *G. glandulifera*. Walldt. and Kitaib. Hungar. v. 1. 20. t. 21. Willd. Sp. Pl. v. 3. 1144.—Legumes clothed with glandular bristles. Flowers spiked. Stipulas obsolete. Leaflets emarginate, glutinous and downy beneath.—Native of Hungary. Flowers violet-coloured.

4. *G. glabra*. Linn. Sp. Pl. 1046. Woodv. Med. Bot. t. 167. (*G. vulgaris*; Dod. Pempt. 341. Ger. em. 1302.)—Legumes smooth. Flowers spiked. Stipulas scarcely discernible. Leaflets blunt; the terminal one on a long stalk.—Native of the south of Europe. Most commonly cultivated with us. The leaflets are large, glutinous beneath. Flowers pale purple, in long-stalked axillary spikes. Legumes oblong, smooth. We have a specimen of this species gathered in Circassia, by the celebrated traveller Dr. Clarke of Cambridge.

5. *G. asperima*. Linn. Suppl. 330. Pallas. Reis. v. 3. t. G. g. 1. 1, 2. (*G. hispida*; *ibid.* 754.)—Legumes smooth, beaded. Flowers spiked. Stipulas lanceolate. Leaflets roundish, prickly beneath. Stem and footstalks prickly.—Found by professor Pallas "in sandy ground between the river Volga and the Tanais." Pallas MSS. The root is extremely sweet, especially in the spring. Stems usually two, rarely three, ascending, a span high, nearly simple, leafy, rough with numerous little rigid prominent prickles, as are the footstalks, and backs of the leaflets. The latter are roundish or obovate, obtuse with a little point, smooth and veiny above. Flowers longish, pale violet, with whitish wings and keel, in one or two thick spikes about the top of each stem. The legumes are drawn by Pallas above an inch long, recurved, of a necklace-like form, and smooth, containing many seeds. The calyx is

oblong, purplish, rather hairy. It has the habit of a *Glycyrrhiza*, flowers of an *Astragalus*, and fruit apparently of a *Coronilla*; nor does the calyx answer to the generic character, being five-cleft.

6. *G. hispida*. Linn. Sp. Pl. 1046. (*G. orientalis*, siliquis hirsutissimis; Tourn. Cor. 26.)—"Legumes hairy. Leaflets oblong-lanceolate, the terminal one on a long stalk. Flowers spiked."—Found by Tournefort in the Levant. Root perennial. Of this we have seen neither a specimen, figure, nor any further description.

GLYCYRRHIZA, in Gardening, furnishes a plant of the herbaceous perennial kind, the common liquorice (*G. glabra*).

It is a plant which has the roots running very deep into the ground, and creeping to a considerable distance, especially where they stand long unremoved.

Method of Culture.—A light sandy soil is the most adapted to the growth of this sort of crop, as its goodness consists in the length of the roots. The ground in which it is intended to be planted should be well dug and dunged the year before planting, that it may have become perfectly mellow, and the dung well rotted and mixed with the earth, otherwise it will be apt to stop the roots from running down and being properly supported; and immediately before planting it should be well dug again to the depth of three spades, and be laid very light and open.

When the land is thus prepared, fresh plants taken from the sides or heads of the old roots should be provided, care being taken that they have each a good bud or eye, being about ten inches long and perfectly sound.

The operation of planting them should be performed about the middle of March, which is done in this manner: a line is first set across the ground, then, with a long dibble made on purpose, the shoots or cuttings are put in, so that the whole plants may be set into the ground, with the heads about an inch under the surface, in a straight line about a foot asunder in the rows, and a foot and a half or two feet row from row.

When the whole spot of ground has been thus planted, a thin crop of onions may be sown over the land. These must be kept perfectly clean by the hoe, care being taken not to cut off the top shoots of the liquorice plants, as it would greatly injure them. All the onions which grow near the heads of the liquorice should also be removed. In October, the shoots of the liquorice should be removed, and a little very rotten dung spread upon the surface.

In the following spring, about March, the ground should be slightly dug between the rows of liquorice, burying the remaining part of the dung, being very careful not to cut the roots.

During the summer they must be kept quite clean by occasional hoeing. The same operations must be annually performed, so as to keep the ground and plants in perfect order.

These plants must remain three years from the time of planting, when they will be fit to take up for use, which should be done when the stalks are perfectly decayed; as, when taken up too soon, the roots shrink greatly, and lose in weight.

In taking up the roots the ground is trenched over, row after row, to the full depth, and the young shoots taken from the old roots cut into sets for new plantations; which should be made annually, in order to keep a constant succession of roots fit for being taken up.

The great art in this culture is to have the earth well trenched to a proper depth, to have good sets, and to keep

the ground afterwards quite clean by hoeing and other proper means.

The liquorice is a native of the south of Europe, but it has been cultivated in Britain ever since the time of Turner. (See Tourn. Herb. p. 2. fol. 12. published in 1562.) The chief places in which it has been long propagated for sale are, Pontefract, in Yorkshire; Worktop, in Nottinghamshire; and Godalming, in Surry; but it is now planted by many gardeners in the vicinity of London, who supply the metropolis with the roots.

GLYCYRRHIZA, in the *Materia Medica*. The root of the common liquorice, boiled slightly in a little water, gives out nearly all its sweetness. The decoction, pressed through a strainer, and inspissated with a gentle heat, till it will no longer stick to the fingers, affords a better extract than that brought from abroad, and particularly from Spain, whence our shops are chiefly supplied with it, and its quantity amounts to near half the weight of the root. The extract that is prepared here, is made by macerating, for four hours, liquorice root sliced, a pound, in a gallon of boiling water; then boiling down to four pints, straining the hot liquor, and evaporating it to a proper consistence. A purer extract may be made by a repetition of the processes of solution and evaporation; and it is kept in the shops under the name of "refined liquorice." Rectified spirit takes up the sweet matter of the liquorice equally with water; and as it dissolves much less of the insipid mucilaginous substance of the root, the spirituous tinctures and extracts are proportionably sweeter than the watery. This root contains a great quantity of saccharine matter, less disposed to run into fermentation than that of other vegetables, which is joined with some proportion of mucilage, and hence has a viscid sweet taste. From the time of Theophrastus it has been a received opinion that it very powerfully extinguishes thirst; accordingly it was named *αδύρα*, and the root directed to be chewed in dropries and other disorders where great thirst prevailed. If this fact be true, it is the more remarkable, as sweet substances in general have a contrary effect. Accordingly Dr. Cullen observes, that the sweet of liquorice, separated from the root, does not quench thirst more than other sweets: and he ascribes the error respecting it to this circumstance, that if a piece of the root is chewed till the whole of the sweetness is extracted, farther chewing brings out the acrid and bitterish matter, which stimulates the mouth and fauces, so as to produce an excretion of fluid, and thereby takes off the thirst which the sweetness had produced. Liquorice is in common use as a pectoral or emollient in catarrhal defluxions on the breast, coughs, hoarsenesses, &c. Infusions or extracts from it afford likewise very commodious vehicles for the exhibition of other medicines. Lewis's M.M. Cullen M.M. Woodv. Med. Bot.

GLYN, in *Geography*, a county in the lower district of Georgia, in the United States, bounded E. by the ocean, N. by Alatomaha river, which separates it from Liberty county, and S. by Camden county. It contains 1374 inhabitants, including 1092 slaves. Its chief town is Brunswick.

GLYPH, in *Architecture* or *Sculpture*, is any canal or cavity used as an ornament.

The Greek word is *γλυφή*, which literally signifies *graving*, *notching*.

Γλυφίς is properly a notch or indenture made in graving; or, more properly, it is the notch in the end of an arrow, in which the string goes.

GLYPTIC ART, the art of engraving precious stones. See GEMS.

GLYSTER. See CLYSTER.

GMELIN, JOHN GEORGE, in *Biography*, a physician and eminent botanist, was born at Tubingen on the 12th of August, 1709. He was distinguished by his diligence and early attainments at school, and at the age of fourteen was deemed ready for entrance upon the academical studies of his native place. In 1727, he took the degree of doctor of physic, and went to Petersburg, whither some of his teachers had been invited. Here he gained many favours from Blumentrost, the director of the academy, and was so highly esteemed, that, in 1729, he was elected one of the members of the academy, and in 1731 was appointed professor of chemistry and natural history. In 1733, he was selected for the department of natural history, in a commission formed by the Russian government, for the purpose of exploring the boundaries of Siberia; and set out on the 10th of August, with G. F. Muller, and Louis de l'Isle de la Croycere, and a party of twenty-eight persons, consisting of draughtsmen, miners, hunters, land surveyors, and twelve soldiers, with a serjeant and drummer. In the month of February, 1743, Gmelin returned safe to Petersburg, after having employed nine years and a half in this long and dangerous journey, which proved highly interesting to the sciences, and he resumed the offices which he had before filled. In the year 1749, he entered upon a new professorship, to which he had been appointed, on the death of Bachmeister, while on a visit to Tubingen. He died of a fever in May, 1755, in the forty-sixth year of his age. The works, which were the result of his travels through Siberia, obtained for him a considerable celebrity, especially his "*Flora Siberica, seu Historia Plantarum Siberiæ*," Petersburg, 1747, 1749, in two parts, large 4to. with one hundred plates: the third and fourth parts were published by S. G. Gmelin. He also published his "*Reise durch Sibirien*," &c.; or Travels through Siberia between the Years 1733 and 1743, Göttingen, 1751, 1752, in four parts, 8vo. with plates. Gen. Biog.

GMELIN, SAMUEL GOTTLIEB, son of Philip Frederick Gmelin, was born at Tubingen in 1743; where he obtained both his scholastic and academical education, and graduated M. D. in 1763. He gave early proofs of genius, and during his travels in France and Holland distinguished himself so much by his knowledge of natural history, that he was appointed professor in the Academy of Sciences at Petersburg. Like the subject of the preceding article, he spent several years in travelling through the distant provinces of the Russian empire, for the purposes of scientific investigation; but ultimately with a less fortunate result. He was appointed, together with professor Guldenstadt, to explore the province of Astracan, at the time that the transit of Venus over the sun's disk was expected, and set out in June, 1768. Having examined the countries on the western side of the Don, the Persian provinces on the south and south-west side of the Caspian sea, the banks of the Wolga, and, lastly, the eastern side of the Caspian, so dangerous to travellers, he was recalled to Petersburg. But when he had arrived within three days journey of Kiflar, a fortress on the Russian borders, he was seized by the khan of Chaitaks; who plundered him of all his property, treated him with great barbarity, and imprisoned him. The health of Gmelin suffered considerably at this time, and he laboured under a flux, brought on by improper food and the effects of climate; yet the barbarian chief intercepted the provisions sent to him from Kiflar. The empress gave orders that he should be rescued by force; but this was rendered impossible at that time by the rebellion of Pugatchef; and Gmelin died in confinement, on the 27th of July,

July, 1774. His death was much regretted by Catherine II., who made a liberal provision for his widow.

His works are; "Historia Fucorum," printed at Peterburgh in 1768, 4to.; a subject to which botanists had paid little attention before him. "Reisen durch Russland, &c.;" or, Travels through Russia, for the purpose of exploring the three kingdoms of nature. This work was published in separate parts, as follows:—Part I. Journey from St. Peterburgh to Tscherkask, in the years 1768 and 1769. Peterburgh 1771 with thirty-two plates. Part II. Journey from Tscherkask to Astracan, from August 1769 to June 1770; *ibid.* 1774, with forty plates. Part III. Journey through the northern districts of Persia, from that period to April 1772; *ibid.* 1774, with fifty-one plates.—Part IV. edited after the author's death, by professor Pallas, Journey from Astracan to Czarizyn: and also a second Persian Journey, 1772-74; *ibid.* 1786, with eighteen plates. The various and important information, contained in these publications, renders the imperfections of the style of this author of little moment. Gen. Biog.

GMELINA, in Botany, received its name from Linnæus, in honour of John George Gmelin, a native of Tübingen, professor of chemistry and natural history at Peterburgh, who spent ten years in travelling through Siberia, at the expense of the Russian government, and whose *Flora Sibirica*, in four vols. quarto, with plates, is a book of great reputation and merit. The first and second volumes were published in his lifetime; the third and fourth long after his death, which happened in 1755, at the age of 46. He took his arrangement from Van Royen. Haller says the plates are unworthy of the beautiful drawings, which he himself had seen.—This genus also serves to commemorate four or five more botanists of the same family, especially Samuel Theophilus Gmelin, nephew of the former, and his successor in the professorship, who published a *Historia Fucorum*, with plates, in 1768, one of the most popular books on submarine botany, and who died in 1774, aged 31.—Linn. Gen. 315. Schreb. 412. Willd. Sp. Pl. v. 3. 313. Mart. Mill. Dict. v. 2. Juss. 108. Lamarck. Illustr. t. 542. Gærtn. t. 56. (Michelia; Amman. in Act. Petrop. v. 8. 218. t. 18.)—Class and order, *Didymia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Vitices*, Juss.

Gen. Ch. Cal. Perianth very small, inferior, of one leaf, nearly globular, with four small unequal teeth, permanent. Cor. of one petal, ringent, inflated; its limb four-cleft; the upper segment large and vaulted; lower, and lateral ones, smaller, obtuse, rounded, spreading. Stam. Filaments four; the two uppermost thicker and shorter; two lowermost curved upwards; anthers two-lobed; two of them sometimes smaller and simple. Pist. Germen superior, roundish or obovate; style as long as the longer stamens, ascending; stigma acute. Peric. Drupa ovate, of one cell. Nut obovate, smooth, of three cells, the lowermost abortive. Seeds solitary.

Ess. Ch. Calyx with four slight teeth. Corolla four-cleft, ringent, bell-shaped. Anthers cloven. Drupa superior. Nut of two fertile cells.

1. *G. asiatica*. Linn. Sp. Pl. 873. Burm. Ind. 132. (Jambusa sylvestris parvifolia; Rumph. Amb. v. 1. 129. t. 40.)—Leaves roundish, somewhat three-lobed, acute, downy beneath.—Native of Java, Amboina, and other parts of the East Indies. A tree, with straight, roundish, slightly downy branches. Leaves opposite, scarcely two inches long, of a roundish or elliptical form, acute, most generally furnished with a short broad lobe at each side, entire; smooth above; pale and downy beneath; the midrib sending off two principal lateral ones, a little above its base, and to-

veral smaller ones higher up, all which are branched. Foot-stalks downy, various in length, often nearly equal to the leaf, each with a small hairy bud above its insertion, and above that usually a straight, downy, horizontal spine. Flowers in a short, simple, downy, terminal racemus. Calyx downy, besprinkled with several large, shield-like, smooth glands. Corolla large, yellow.

Rumphius's figure unquestionably belongs to this plant, but his description seems that of an *Eugenia*. Plukenet's t. 305. f. 3. is certainly *Gardenia dumetorum*, and resembles our *Gmelina* only in being thorny; his t. 97. f. 2. may possibly be intended for *Gmelina parvifolia*, but is of no use as to determining it.

2. *G. elliptica*.—Leaves elliptical, undivided, obtuse, downy beneath. Thorns none.—Native, we presume, of the East Indies, confounded in the Linnæan herbarium with the foregoing, from which it differs in having rather larger leaves, which are exactly elliptical and blunt, more densely downy beneath, and not lobed. There are no traces of thorns. The inflorescence is rather more compound, but the remarkable glandular calyx is the same. If a variety it is a very extraordinary one.

3. *G. parvifolia*. Roxb. Corom. v. 2. 31. t. 162. (*G. coromandelica*; Burm. Ind. 132.)—Leaves obovate, undivided or three-lobed, smooth on both sides.—Common in every forest and uncultivated place on the coast of Coromandel, flowering in October and November. Roxburgh. It is often intermixed with *G. asiatica*, from which it differs in its more humble size, larger and constant thorns, and especially in its smaller leaves, which are smooth on both sides. Their flowers and fruits are alike, the latter being yellow, obovate, the size of a small cherry. We perceive on one calyx in our specimen a solitary gland, like those described in the two former.—Dr. Roxburgh mentions that cold water, stirred with a leafy branch of this shrub, becomes thick, from the abundant mucilage of the leaves, and is used in that state as a remedy for the heat of urine which accompanies gonorrhœa. Water stirred with branches and leaves of *Petalium Murex* becomes in like manner mucilaginous, and is used for the same purpose, but soon loses its consistency, which is not the case with such as is prepared with this *Gmelina*. The Telingas call the plant *Shieri goomoodoo*. It may possibly be Plukenet's *Lycium Maderaspatanum*, t. 97. f. 3, as Burmann takes it to be, but Sloane's *Rhamnus*, Hist. of Jamaica, v. 2. t. 207. f. 1, cannot be the same, though his vile figure affords no distinct indication of what he means.

4. *G. arborca*. Roxb. MSS. (Cumbulu; Rheede Hort. Mal. v. 1. 75. t. 41.)—Leaves heart-shaped, undivided, pointed, downy beneath; their lateral ribs cloven. Thorns none.—Sent from the coast of Coromandel by the Rev. Dr. Rottler, with the above name of Dr. Roxburgh; Gærtner has most justly pointed out the *Cumbulu* of Rheede as a *Gmelina*, though quoted by Linnæus, doubtfully indeed, for his *Bignonia Catalpa*. This is a tall and upright tree, growing in sandy ground, with downy branches, and large, opposite, stalked, heart-shaped, entire leaves, downy and veiny beneath. Thorns none, as far as we can learn. The flowers are numerous and handsome, yellow, growing in compound, hairy, terminal clusters. Fruit yellow, obovate, rather small.

5. *G? indica*. Burm. Ind. 132. t. 39. f. 5. (*Dory Zaccan* of the Malays.) Leaves alternate, heart-shaped, crenate, smooth on both sides.—Native of Java. *Herb. Linn.* A shrub or tree, with round, somewhat zig-zag, slightly downy branches. Leaves from half an inch to an inch long, alternate, on short hairy stalks, veiny, bluntly crenate. Thorns straight,

straight, slender, acute, mostly longer than the leaves. The flowers and fruit seem to be unknown. We have only Burmann's very feeble authority for making this a *Gmelina*, which its alternate crenate leaves strongly discountenance, nor did Linnæus ever venture to adopt it. S.

GMUND, in *Geography*. See GEMUNDEN.

GNAA, a town of the duchy of Stiria; 24 miles S.E. of Gratz.

GNADENHUETTEN, a settlement of the Moravians in America, situated on Muskingum river, opposite to Salem, in the lands which belonged to the Mahikan Indians.—Also, the name of a Moravian settlement, on the S.W. bank of Lehigh river, in Pennsylvania, about 29 miles N.W. of Bethlehem.—Also, a Moravian settlement, called *Neu Gnadenhuetten*, on Huron river, about 22 miles from lake St. Clair, in the county of Wayne, and 28 N.W. of Detroit.

GNAPPEZEIK, a town of Birmah, on the Irawaddy; so called from Gnapee, or Napee, a sort of sprat, half pickled and half putrid, used as a sauce by the Birmans, and forming an extensive branch of trade: 110 miles N.N.W. of Rangoon.

GNAPHALIUM, in *Botany*, γναφαλίον, an ancient Greek name, from γναφάλιον, *soft down or wool*, such as is plucked from cloth in dressing it, alluding to the wooliness of the herbage. Many writers have contended that *Santolina maritima* of Linnæus, and Sm. Fl. Brit. 860, is the true γναφαλίον of Dioscorides, an opinion extremely difficult to establish or to contradict, as all he says of it is, that "its leaves are white and soft, useful for stuffing." However this may be, Tournefort, and lately Gærtner, have retained that plant, as the true and only species of *Gnaphalium*. The *Gnaphalium* of Linnæus however is a very extensive and comprehensive genus, from which some species have of late been separated. See ELICHRYSUM.—Cud-weed.—Linn. Gen. 419. Schreb. 550. Willd. Sp. Pl. v. 3. 1849. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 173. Sm. Fl. Brit. 867. Juss. 179. (Elichrysum; Gærtner. t. 166. Antennaria; Gærtner. t. 167. Anaxeton; Gærtner. t. 166? Filago; Gærtner. t. 166. See FILAGO.) Class and order, *Syngenesia Polygamia-supérflua*. Nat. Ord. *Compositæ Nucamentaceæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* imbricated, rounded; scales numerous, the marginal ones rounded, scariose, coloured. *Cor.* compound; *florets* of the disk perfect, tubular, funnel-shaped, in five equal reflexed marginal segments; some female ones, without a corolla, are often intermixed towards the margin. *Stam.* (in the perfect florets) Filaments five, very short, capillary; anthers forming a cylinder. *Pist.* (in the same florets) Germin ovate; style thread-shaped, the length of the stamens; stigma cloven. In the female ones the same. *Peric.* none, except the permanent shining calyx. *Seeds* in both kinds of florets alike, solitary, oblong, small, crowned with capillary or feathery down. *Recept.* naked.

Ess. Ch. Receptacle naked. Down capillary or feathery. Calyx imbricated, its inner scales rounded, scariose, coloured.

Willdenow reckons 146 species of *Gnaphalium*, of which 32 are shrubby, with silvery, white or crimson flowers, or rather without any golden tinge; 12 are of a yellow or golden colour, likewise shrubby; 19 are herbaceous, with yellowish flowers; 28 herbaceous, with white or reddish ones; and 29 have the inconspicuous whitish blossoms of the *Filago* family. The remaining 26 are species defined by Thunberg, without any attention to these leading sections of the genus, so that it is impossible to say to which

they belong. Ten species, all herbaceous, are described as natives of Britain.

In this large genus it is by no means certain that all the species correctly answer to the generic character, particularly in the receptacle, which is not always strictly naked, but bears a few bristles towards the margin, thus becoming an *Anaxeton* of Gærtner.

The marginal scales also, being sometimes a little pointed and reflexed, intrench upon the proper character of *Elichrysum*; see that article. In fact these genera are naturally one and the same, but, on account of their great extent, are conveniently separated by the character, though an imperfect one, of the more radiating calyx of *Elichrysum*. Linnæus's error consisted in referring the latter to *Xeranthemum*, which has a different habit and a chaffy receptacle.

The first species in Willdenow, *G. eximium*, Linn. Mant. 573. Curt. Mag. t. 300, is one of the most splendid. The leaves are clothed with very thick white wool, and the shrubby stem is terminated by a large corymbus of flowers, whose calyx is the size and shape of a raspberry-fruit, of a rich shining crimson. The florets are orange-coloured. It grows about 500 miles up the country above the Cape of Good Hope, and was for a long time known to European botanists merely by dried specimens, (one of which is figured by Edwards in his History of Birds, t. 183), brought occasionally to the Cape by the distant settlers.

Several others of the shrubby kinds are very ornamental to our green-houses.

Of the herbaceous sorts *G. fatidum*, whose flowers, usually yellow, are occasionally white or silvery, always very splendid, is one of the most remarkable, but the strong smell of its viscid herbage when touched is offensive to most people. *G. orientale* is somewhat shrubby, though ranged with the herbaceous ones. Its shining lemon-coloured flowers frequently serve for ornamental purposes, and are known by the name of *Everlasting*, a name appropriate to the whole genus.

G. margaritaceum, Engl. Bot. t. 2018, serves in Wales, where it grows wild, to adorn the graves of the departed, elegantly alluding to immortality by the unfading nature of its flowers, and to spotless purity by their snowy whiteness. This plant is often cultivated in cottage gardens.

G. dioicum, Engl. Bot. t. 267, the *Antennaria* of Gærtner, so called from its plummy crown to the seed, is one of our most elegant species, found on dry rather mountainous heaths. The flowers are of a beautiful rose-colour.

The Cape of Good Hope is most fertile in this genus, but several fine species grow in South America, and there are some from New Holland to be added to what are enumerated in Willdenow. The mountains and fields of different parts of Europe produce various species, but few of the more handsome, except *G. arenarium*, Fl. Dan. t. 641, and its near relation *G. olympicum* of our gardens, gathered about the Bithynian Olympus by Dr. Sibthorp; both which vie with *G. orientale* in their shining golden or lemon colour, and the *olympicum* at least is a hardy perennial, of easy culture.

GNAPHALIUM, in *Gardening*, affords plants of the herbaceous and under shrubby kinds: of which the species mostly cultivated are, the tree everlasting (*G. arborescens*); the red-flowered everlasting (*G. ignescens*); the eastern everlasting, or immortal flower (*G. orientale*); the sweet-scented everlasting, or eternal flower (*G. odoratissimum*); the American everlasting, or eternal flower (*G. margaritaceum*);

taceum); the plantain-leaved everlasting (*G. plantagineum*); the common shrubby everlasting, or stæchas (*G. stæchas*). Many of these are curious plants.

Method of Culture.—The first four sorts may be increased by slips from the heads or cuttings; by planting them in pots of light earth in the spring or summer months, and plunging them in a moderate hot bed, refreshing them often with water. When they have taken full root, they may be removed into separate pots, and be placed among other plants of the hardy exotic sort. They require the protection of a frame in the winter season.

The seventh species may be increased in the same manner, being placed at once where it is to remain, in a shady sheltered border, or other place that is proper.

The fifth and sixth sorts may be easily raised by dividing and planting their creeping roots where they are to grow, either in the autumn or spring months.

These three last are sufficiently hardy to stand the open air in warm situations.

They are all ornamental plants, the former in the greenhouse collection, and the latter in the open ground.

GNAPHEUS, in *Icthyology*, a name given by Athenæus and other of the Greek writers to the tench.

GNARP, in *Geography*, a town of Sweden, in the province of Helsingland; 20 miles N. of Hudwicksfal.

GNAT, in *Entomology*. See CULEX.

There is no species of insect that we have so much reason to dislike in regard to the injury it does us as the gnat. Others indeed give us more pain with their stings, but it is but by accident that we are struck by them; the gnats thirst for our blood, and follow us about in whole companies for it. There are many marshy places where the legs and arms are all the summer swelled to an enormous size by the repeated bitings of these insects, and in many other countries they are much more troublesome than with us.

But as troublesome enemies as these little creatures are to us, there is that about them which is extremely worthy our admiration; nor can we indeed fail greatly to admire even the very instrument of the mischief they do. They have beside this many very observable particulars in the course of their lives.

All the naturalists of late years have applied the microscope to the examination of the parts of this little animal, and Swammerdam, Hook, Bonanni, Leeuwenhoeck, &c. have given very good accounts, and very valuable drawings of the creature.

There is a great number of very small species of gnats, and though some are considerably large, yet none even of these approaches to the size of the tipula, or father long-legs, as commonly called. The larger tipulæ are therefore easily distinguished from the gnats; but Swammerdam, Goedart, Lister, and others, have very often given us the smaller tipulæ among the species of gnats. Both have long slender bodies, and both prominent corcelets, which make them look hump-backed; but when either of these insects is taken into the hand it is very easily known, the gnat having a very long trunk, and the tipula no trunk at all.

There is a prodigious number of species of the gnat kind, comprehending the smaller ones; Dr. Derham observed near forty different species about Upminster in Essex; but of those of a size to be remarked with ease, and without the help of glasses, there are three principal kinds: the one has its body variegated with white and black; this is the larger kind, and its corcelet is streaked with black or deep brown, and white lines or greyish ones; these have brown eyes; another is smaller than this species, and has a plain brown body,

the colour of the corcelet, and that of the eyes is the same as in the larger or first species; the third kind is the smallest of the three and the most common, has its corcelet reddish, or of a faded reddish yellow, and the body whitish, and on the under part of the belly every ring has one single brown spot; the rest is grey: the eyes of this species are of a very pleasant green.

All the gnats have a long cylindric body composed of eight rings; their corcelet is short but large, in proportion to the size of the fly, and to this are fixed the six legs, which are hairy, with six joints to each, and at the end two little claws, the wings, and the balancers: four stigmata are also found here, as is the case in other flies: the two first of these are placed near the head, and have been mistaken for ears.

The antennæ of gnats are extremely worth observation, and differ much from one another. Some of them are elegantly feathered; these belong to the males of certain species, for the antennæ of the females are not so beautiful. The brush-horned or male gnat has two pair, one of which is surrounded, at small distances, with long hair, issuing out circularly, each circle lessening as it approaches the extremity of the antennæ; the other pair are longer and much thicker, and hairy from end to end. In the great bellied or female gnat, the first pair of antennæ, though of the same figure as the male's, has hairs not near so long, and the second pair is shorter than the first by at least three parts in four. Reaumur, *Hist. Inf.* vol. iv. p. 574, &c. Baker's *Microsc.* 1743, p. 203, &c. For the trunk and wings of the gnat, see TRUNK and WINGS.

GNATS, *Eggs of*. See EGGS.

For the *Eyes of GNATS*, see EYES of Flies.

GNAT-worm, in *Natural History*, a small water insect, produced from a gnat, and which is, after its several changes, transformed into a gnat again.

From the eggs, deposited by the gnat on the surface of the water, proceed a number of minute worms, which sinking to the bottom of the water, form for themselves coverings of fine sand or earth, cemented together with a sort of glue, but open at both ends, that they may come out and enter as occasion requires.

These worms do not frequent rivers; but ditches, ponds, and other standing waters, afford them in vast abundance, from the middle of May till toward the beginning of winter. This is the reason why watery and marshy places are found most to abound with gnats, and why the wet summers are found to produce the greatest numbers of them; because in dry seasons, the ponds and ditches, where they are to pass their worm-state, are dried up, and the worms killed. These are creatures, however, that one need not go far to seek, since a vessel of water, exposed in any open place in the summer months, will not fail to afford plenty of these worms in a little time.

Before these worms are arrived at their full growth, though they are then but small, they are easily found, because they are under a necessity of coming frequently to the top of the water, by having occasion for frequent respiration; and to do this, they are obliged to keep the end of a small pipe they are furnished with, from the last ring of their body, above water. The end of this pipe is hollow and indented, and forms a sort of funnel on the surface of the water: it is of the length of about three rings of the body, and is somewhat thicker at its insertion than at its extremity.

As there is a vast number of species of gnats, there is no less of the worms from whence they are produced; and to this is in a great measure owing the variety in the figures given

of the worms by the authors who have treated of them; which may also be not a little added to by the particular views in which those draughts have been taken. Notwithstanding all the variations of these figures, the general form of the animal is however the same in all, and the species cannot but be known from any of them. While the worm is young, the body is whitish or greenish; but when it is at its full growth, and draws near the time of its changes, it becomes greyish. The great transparency of the body of this worm gives a fine view of what passes within it; it is at any time easy to see into the motion of the intestines, by which the food is pushed on towards the anus. The two principal tracheæ are also seen very distinctly in this creature; they are two white tubes placed in a parallel direction one to another, and run from the first ring to the tube of respiration.

The great worm several times changes its skin in the course of its life. After three changes of this kind, which usually happen in the space of three weeks, or thereabout, it undergoes a fourth, where the old skin is as easily thrown off as in the rest, but the animal now appears in a new form, that of a nymph; it is now shorter and rounder than before, and the body is so bent that the tail is applied to the under part of the head; this, however, is only its form in a voluntary state of rest, for it can yet move, and when it pleases extends its tail, and swims about as swiftly as when in its other state.

When the creatures have quitted their first habitations and the figure of worms, they re-ascend to the top of the water, inclosed in a kind of shell, with a large head and mouth, two black eyes, two horns, several tufts of hairs on different parts of the body, and a tail with a brush of hair at the end of it, which, being smeared over with an oily fluid, serves to keep them above water; their heads being sometimes lifted in the air, and sometimes plunged into the water, while the tail slides along the surface: and when the oil on the tail begins to dry, they shed from their mouth a fresh supply, which renders it capable of steering where they please, without being wetted and damaged by the water.

All the parts of the future gnat may be seen in this nymph; the skin of it is extremely thin and transparent, yet sufficiently tough and firm for the use it is intended for. It is uncertain how long exactly the animal lives in this nymph state; but after the time is accomplished, its change into a gnat is very quick, and is attended with great danger to the animal, since multitudes are drowned in the act of getting out and springing into the air. Reaumur, Hist. Inf. vol. iv. Baker's Microf. 1743, p. 88.

GNAT, in *Rural Economy*, a small well-known insect, which is said to destroy the leaves of some tender vegetables as soon as they appear, such as the turnip, &c.

GNEISS, in *Mineralogy*, a primitive rock, composed of feldspar, quartz, and mica; ingredients which are likewise those of granite, from which it differs in the arrangement of those parts; for while in the latter rock they usually appear as granular aggregations, those of gneiss are disposed in such a manner as to exhibit a more or less slaty structure. This structure passes through various degrees of distinctness; on one hand it approaches so near to the granular texture, that the distinction between gneiss and granite ceases to exist, while, on the other hand, when its peculiar texture is very obvious, and becomes what is termed *thin slaty*, a passage is formed into the primitive rock, next to it in antiquity, called mica-slate. In its progress towards the nature of granite, the feldspar is generally predominant with regard to the mica; while those varieties approaching mica-slate gradually exhibit a smaller proportion of feldspar and much mica. Sometimes, however, the mica is only apparently predominating, owing to the circumstance, that on breaking a mass of gneiss, the

line of separation will more frequently pass through the mica than through the other layers, and display a whole surface of that substance; but another fracture, perpendicular to the first, will, in this case, soon undeceive the observer. Though feldspar is, generally speaking, the predominant ingredient of gneiss, yet the proportion of mica in this rock is, upon the whole, greater than what we see it in granite: and the less this is the case, the more the mass appears granular, and the more it approaches to granite. It is often a matter of difficulty, in viewing small specimens only, to distinguish some kinds of gneiss from the last-mentioned primitive rock; when the inspection of the former in their natural situation, and on a large scale, would have left but little doubt in the mind of the examiner.

Gneiss, viewed in the large, as a mountain mass, always exhibits thick and distinct strata, whose outgoings, or upper terminations, are generally lower than the subjacent granite, and higher than those of the superincumbent mica-slate.

Werner (to whom we owe more correct ideas respecting this rock,) distinguishes four kinds of gneiss, viz. that approaching the granular structure, the waved or undulated, the common, and the thin slaty gneiss. As particular varieties of these, we have 1. The striped gneiss, in which the quartz is disposed in narrow bars, surrounded by feldspar, producing, on its longitudinal fracture, a striped appearance, not unlike that of some kinds of petrified wood; while its transversal fracture exhibits a granular disposition of the parts. This striped variety generally occurs together with the waved; such as at Ober-Newshöberg, Reiland and Hartmansdorf, near the Bohemian frontiers. 2. The sprinkled, or that kind of gneiss in which the feldspar and mica exhibit themselves in the form of small nests: such as that found at Hartmansdorf and Bobritsch, near Freiberg, and at Kuffenberg in Bohemia. 3. The short lamellar or flaky variety, such as it is found at Marienberg.

The colour of the ingredients of gneiss is not subject to great variation. The feldspar is generally of a greyish, yellowish, and reddish-white colour, seldom yellowish-grey, or deep flesh-red, as it appears in many varieties of granite; upon the whole, its tint resembles that of the quartz with which it is accompanied, and which seldom appears smoke-grey or brown. The colour of the mica is generally black or brownish-black, sometimes brownish, yellowish, and ash-grey, and rarely silver-white or of a golden hue.

These component parts are found to vary also in regard to their *freshness*; in general the feldspar is perfectly foliated and shining; but sometimes it appears in incipient decomposition, or even converted into petunze; in the same manner as the mica is now and then seen passing into a greenish substance resembling steatite. Dr. Reufs found that the porcelain earth dug at the Galgenberg, near Puschwitz, in the Saatz district of Bohemia, where it is used for white-washing walls, is the result of the highest stage of decomposition of gneiss; it forms thick strata, and contains a great quantity of small greyish white, light grey, and pale clove-brown grains of quartz. In the same manner this mineralogist observed in that country frequent proofs of the conversion of the feldspar of gneiss into a ferruginous clayey mass. Near Klosterly it is seen converted into burnt-thon or variegated clay.

Besides the more essential feldspar, quartz, and mica, the following *accidental ingredients* are now and then met with in gneiss. 1. Shorl: both the common and black tourmaline shorl, sometimes occur in the gneiss of Freiberg, and particularly of Spain. 2. Garnet: rarely, but much more frequently than in granite; it occurs at Wiefenthal in Saxony, in Norway, in the island of Zealand, in Moravia, &c. 3. Horn-

blende: is but seldom found, and only in the thin slaty variety of gneiss, which passes into mica and hornblende slate.

4. Steatite: occurs principally in the gneiss forming the walls of the metalliferous veins in the Freiberg district; it is considered by some as mica thus transformed by sulphuric acid.

5. Actinote: is said sometimes to constitute an ingredient of gneiss in Switzerland and Hungary. Metallic substances that are sometimes found disseminated in gneiss, in the vicinity of veins, cannot properly be enumerated even as accidental component parts of this rock.

Gneiss abounds in metals more than any other rock, as may be seen from the richness of the Saxon and Bohemian mines, those of Salzburg, &c. There are but few among the known metals that are not found in it, either in veins or beds. "The oldest gneiss in the Saxon Ertzgebirge," says Mr. Jameson, "that with reddish-coloured feldspar, is the least productive in ores; but the newer, with white coloured feldspar, is the most productive; and the veins, though small, are numerous. The oldest venigenous formation appears to be that which contains tin-stone. The tin-ore is accompanied with wolfram, molybdena, arsenic-pyrites, fluor-spar, chlorite, topaze, and opal. The second venigenous formation appears to be a lead-glance formation. The third formation consists principally of copper, and the ores are grey copper-ore, copper-glance, copper-pyrites, and variegated copper-ore. The fourth formation, which is very extensive, contains ores of cobalt. The newest formation is that which contains ores of silver. Veins containing antimony, and red iron-stone occur in gneiss, and these are supposed to be newer than any of the preceding. The metalliferous beds that occur in this rock contain argentiferous lead-glance, blende, copper and iron-pyrites. It sometimes also contains formations of gold."

There are three considerable beds of rocks subordinate to, and synchronic with, gneiss, and which are therefore not seen in granite, viz. granular limestone, as it is observed; for instance, near Freiberg; primitive trap, such as hornblende-slate, at Kutenberg in Bohemia, at Kongsberg in Norway, &c.; and the older porphyry. (See LIMESTONE, TRAP, and PORPHYRY.) Also small beds of common garnets, actinote, with magnetic iron-stone, iron-pyrites, galena, &c. now and then occur in gneiss.

Gneiss being generally superincumbent on granite, is hence considered as next to this primitive rock in point of age: there is, however, also a difference in the relative antiquity of the different kinds of gneiss, and on the whole it may be said that the nearer it approaches in its texture to *Mica-slate*, (see that article,) the more recent is its origin. From this it does not, however, follow that there should not be found kinds of gneiss which surpass in antiquity even some kinds of real granite. (See GRANITE.) The very thick flaky varieties of gneiss, with black mica and a small proportion of mica, may, in general, be said to be of more ancient formation.

Gneiss, though far less widely distributed than granite, has still a considerable range; it extends over the greatest part of the Saxon Ertzgebirge: the country about Freiberg, Glashütte, Marienberg, Ehrenfriedersdorf, consisting almost entirely of it. In the same manner it is the characterizing rock of the Bohemian mountainous mining district. It is also found in Silesia, Carinthia, in some parts of the Black Forest in Suabia; nor is it wanting in the Tauriscian mountains, in Salzburg, in the Swiss Alps, the Pyrenees and Vosges, in Scandinavia, Greece, &c. In Great Britain it has been observed particularly in Scotland, in the islands of Coll, Tiree, Rona, and in the Shetland islands. It should

however be observed, that frequently other rocks have been described as gneiss by topographical writers.

The *economical use* made of gneiss is that for paving, and for the construction of walls; for both which purposes it is extremely well calculated, by reason of the facility with which it is wrought by the mason. Hence in the Saxon mining district not only almost all buildings are constructed of gneiss, but also the walling of the shafts and levels is most advantageously executed in this useful rock.

GNEMON, in *Botany*, a tree so called in the island of Ternate and others of the Moluccas, which is named in the Malay language *Menijo*, or *Meningo*, a word apparently of the same derivation, whatever that may be. See **GNETUM**.

GNERDEN, in *Geography*, a town of Persia, in the province of Irak; 150 miles E. of Ispahan N. lat. 32° 20'. E. long. 55°.

GNERROUTOOH, a town of Birmah, on the Irrawaddy; 10 miles N. E. of Paghiam.

GNESEN, or **GNESNA**, a city of Poland, in the duchy of Warsaw, built, as it is said, by king Lechus I., founder of the monarchy, and called *Gnesna*, from an eagle's nest found there, denominated in the Polish language *Gn. siad*. The kings of Poland were crowned in this city, and the regalia were kept here till, in the year 1320, they were removed to Cracow. During the independent existence of Poland, it was famous as the see of an archbishop, who was primate of Poland, and who acted as interrex or regent upon the king's demise; and who also announced the event, convoked the diets and dietines of convocation, and performed the functions of royalty. Gnesna is 100 miles N. E. from Breslaw, and 150 W. from Warsaw. N. lat. 52° 26'. E. long. 17° 42'.

GNETUM, a name contrived by Linnæus, as we presume from *gnomon*, *brotherhood*, alluding to the situation of the numerous male and female flowers, several of each together in each whorl. Linn. Mant. 18. Schreb. 659. Willd. Sp. Pl. v. 4. 591. Mart. Mill. Dict. v. 2. Juss. 406. (Thoa; Aubl. Guian. v. 2. 874. Schreb. 650. Juss. 406. Lamarek Illustr. t. 784.) Class and order, *Monœcia Monadelphica*. Nat. Ord. *Urticis affine*, Juss. or rather, as he himself hints, to be referred to a new order, which he proposes to term *Piperis*.

Gen. Ch. *Cal.* Catkin composed of several remote, callos, thickened whorls, each subtended by a small *partial calyx*, which is peltate, orbicular, flat, entire, containing several fertile florets, the male ones inferior, the females superior, in the same whorl. Perianth of the male a minute, ovate, coloured scale. *Cor.* none. *Stam.* Filament one, thread-shaped, longer than the scale; anthers in pairs, connected.

Perianth of the female a rude, lacerated scale. *Cor.* none. *Pist.* Germea ovate, superior, immersed in the receptacle of its own whorl, the length of the stamens; style conical, short; stigma three-cleft, acute. *Peric.* Drupa ovate, of one cell. *Seed.* Nut solitary, oblong, striated, of one cell.

Ess. Ch. Male, Calyx an undivided scale of a whorled catkin. Corolla none. Filament one, with a pair of anthers. Female, Calyx a torn scale of the same whorl. Corolla none. Stigma three-cleft. Drupa with one seed.

Obs. Linnæus observes that Rumphius makes his plant dioecious, but he found it monoecious, and even saw one catkin entirely male, standing on its own footstalk, near a female floret. The *Thoa* of Aublet, though somewhat differently described, is undoubtedly the same genus, and indeed so like the original *Gnetum* in foliage, that it is not very easy to distinguish them.

1. *G. Gnemon*. Linn. Mant. 125. (*Gnemon domestica*; Rumph. Amboin. v. 1. 181. t. 71, 72. *Beretus fructus*; Clus. Exot. 55.)—Lateral veins of the leaves prominent, inter-branching archwise half way towards the margin. Catkins opposite, axillary, on simple stalks—Native of the Molucca islands, and other parts of the East Indies. We have it from Java. A tree, with straight, round, slender, smooth branches, swelling at each joint, under the insertion of the leaves, and somewhat forked at the ends. Leaves opposite, stalked, ovate, inclining to lanceolate, pointed, entire, smooth and shining, three or four inches long, furnished with a midrib, channelled above, prominent beneath, sending off several alternate, spreading, prominent though slender veins, which meet rather more than half way towards the margin in one common arching vein, whence numerous reticulations originate. *Stipules* none. *Footstalks* half an inch long, channelled and keeled. *Catkins* axillary, shorter than the leaves, two together from each opposite leaf, on simple stalks, their whorls when young crowded, but soon becoming distant and bead-like, every whorl bearing numerous female as well as male flowers. What Linnæus describes as a torn scale in the former, seems rather a very dense assemblage of short tufted fibres. *Fruit* the size of an ordinary acorn or silberd, its coat thin, sweetish according to Rumphius, but with too much acrimony to be eaten raw; as is also the case with the leaves, which, when dressed, are in almost daily use among the natives of Amboyna, though thought mawkish and insipid by Europeans.

2. *G. Thoa*. (*Thoa urens*; Aubl. Guian. v. 2. 874. t. 336.)—Lateral veins of the leaves obsolete, inter-branching archwise. Catkins on simple stalks, from the repeated forks of the branches.—Gathered by Aublet in the woods of Guiana, where the natives call it *Thoa*. His own specimen in our possession has no fructification nor inflorescence, so that we have been obliged to take part of our character from his figure. The leaves seem in general to be rather shorter and broader than in the former, but the chief distinction is observable in their lateral veins, which though they do in a similar manner run into one common arching vein, above half way towards the margin, are all together far more slight and less prominent than in the first species. The fruit is like the former, reddish, and elliptical. Aublet says that when its outer skin is taken off, a dry substance is found underneath, composed of stiff depressed hairs, which easily separate from each other, and if any of them fall upon the human skin, they cause a great itching. The kernel of the nut, boiled or roasted, is good to eat. Birds of the fowl or pleasant tribe feed in the woods upon this fruit, which they swallow whole. The same author assures us that a clear gum issues from the bark and branches, but that when the main trunk or great branches are cut, a clear tasteless watery liquor runs out, which may be drunk by those who are distressed for water. This tree is almost always in flower and fruit. Aublet describes the catkins as male, with two female flowers at their base. This is so different from our specimens of *G. Gnemon*, that it might almost afford a specific character, but Rumphius describes the same circumstance in what he terms his male *Gnemon*, and Linnæus adverts to something like it. It should seem therefore that in the first, if not in every species, the genus is imperfectly dioecious, one tree bearing catkins with female flowers, with perhaps less perfect males, in every whorl, while on another are found more efficient males in every whorl, with females at the base only, as in Aublet's *Thoa*. Such examples throw great light on the physiology of vegetable generation, and confirm the Linnæan theory.

3. *G. funicularis*. Buchanan MSS. (*Gnemon funicularis*;

Rumph. Amboin. v. 5. 12. t. 8. Ula; Rheed. Hort. Mal. v. 7. 41. t. 22.)—Lateral veins of the leaves separate to the margin. Catkins opposite, axillary, on branched stalks.—Native of Amboyna and other places in the East Indies. This is a long trailing branched smooth shrub, turning black in drying, which the two former do not. The leaves are four or five inches long, various in breadth, pointed, firm, shining, distinguished by their veins continuing distinct to the edge of the leaf. The flower-stalks are axillary, in pairs, more or less branched and forked; each catkin being about an inch long, composed of numerous orbicular imbricated scales concealing the flowers, and not unaptly compared in the Hortus Malabaricus to Long Pepper. Each stands on a partial stalk, of about its own length. The fruit resembles that of the foregoing, and is roasted over the fire, which renders the kernel eatable. The tender leaves serve for a pot-herb, like those of *G. Gnemon*. The bark of the young twigs, split into thread, serves to make nets.

Rumphius's vol. 5. t. 7, which he calls *Funis Gnemoniformis*, but of which he seems not to have known the flowers, may possibly be the male plant of our last-described species, bearing only one or two female flowers at the bottom of the stalks of the male catkins, according to the analogy observed in the foregoing ones. S.

GNAIFDA, in *Geography*, a town of Hungary; 7 miles W.S.W. of Palotza.

GNIDIA, in *Botany*, from *Gnidus*, where Venus had her temple. A seed, reported to be brought from thence, had been called *Coccognidium*, and there is a *γνιδιον*, or *Kudion*, supposed to be a kind of Orache; but Linnæus probably had not these so much in view as the affinity of this genus to *Passerina*, named after a favourite bird of the goddess, in allusion to which indeed it was first named *Struthia* by Van Royen. It is moreover akin to *Daphne*, one species of which, *Daphne Gnidium*, has been taken for the ancient *γνιδιον*.—Linn. Gen. 193. Schreb. 260. Willd. Sp. Pl. v. 2. 424. Mart. Mill Dict. v. 2. Ait. Hort. Kew. v. 2. 27. Juss. 77. Lamarek Illustr. t. 291.—Class and order, *Oleaceæ*, *Monogynia*. Nat. Ord. *Vepreculæ*, Linn. *Thymelææ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, funnel-shaped, coloured; its tube thread-shaped, very long; limb flat, in four deep segments. *Cor.* Petals four, sessile, flat, inserted into the edge of the tube of the calyx, and shorter than its limb. *Stam.* Filaments eight, bristle-shaped, erect, inserted into the tube in two rows, the uppermost reaching nearly to the top; anthers roundish, erect, simple, of two cells. *Pist.* Germen ovate, superior; style thread-shaped, as long as the tube, inserted laterally into the germen; stigma capitate, hispid. *Peric.* a dry berry, with a thin coat. *Seed* solitary, ovate, obliquely pointed.

Eff. Ch. Calyx funnel-shaped, four-cleft, withering, including the stamens. Petals four, inserted into the calyx. Style lateral. Seed coated.

Obs. It differs from *Passerina* only in having petals; which are often rather of a glandular appearance. The habit is altogether that of *Daphne* and *Passerina*. Willdenow enumerates sixteen species, but of these *G. pinifolia* and *radiata* are one and the same, and *G. daphnefolia*, Linn. Suppl. 225, seems rather to belong to *Dais*.

All the genuine species are natives of the Cape of Good Hope, of a humble shrubby growth, with white or yellowish sweet-scented flowers.

GNIEWE, or MEVE, in *Geography*, a town of Prussia, in the province of Pomerelia, on the Vistula; 30 miles S.S.E. of Dantzic.

GNOIEN, a town of the duchy of Mecklenburg; 21 miles E.S.E. of Rostock. N. lat. $53^{\circ} 59'$. E. long. $12^{\circ} 52'$.

GNOLL RAIL-WAY. This is an establishment in Glamorganhire, in South Wales, which we had not heard of at the time of compiling our article CANAL; it is called an iron *waggon-way*, the flanch being on the wheels of the waggons, instead of being on the tram-plates, as is more common in that district. It commences at the shipping-place 200 yards below Neath bridge, on the Neath river; crosses the Neath canal on a wooden bridge, and proceeds about E. half a-mile to the late fir Herbert Mackworth's Gnoell collieries, of run coals, which are drawn up forty fathom, to be loaded into the waggons on this waggon-way, which has for regular a descent, as to require no inclined planes, or other considerable works.

GNOMES, GNOMI, a name which the Cabbalists give to certain invisible people, whom they suppose to inhabit the inner parts of the earth, and to fill it to the centre.

They are represented as very small of stature, tractable, and friendly to men; and are made the guardians of mines, quarries, hidden treasures, &c. Vigenere calls them Gnomons: the females of this species are called Gnomides.

Vigneul de Marville, in his *Melange de Histoire et de Literature*, tome i. p. 100, gives a relation of a conference with a philosopher of this class, who held, that an infinity of spirits inhabited each of the four elements, fire, air, water, and earth, under the denomination of *Salamanders*, *Sylphs*, *Oudins*, and *Gnomes*; that the Gnomes are employed in working or actuating the machines of brutes upon earth.

He added, that some philosophers of that sect held that these spirits were of two sexes, for the two sexes of beasts or moving machines; that they were more or less perfect as the brutes were; and that there was an infinite number of exceedingly small ones, to actuate the infinite number of insects and animalcula, both those that are visible, and those which are too small to come under our senses; that all these spirits, in general, govern their respective machines according to the disposition of the parts or organs, the humours, temperaments, &c. that they do not lay hold of all machines indifferently, but of those suited to their own character, element, &c. that a haughty one, for instance, seizes a Spanish gennet; a cruel one a tyger, &c.

GNOME, Γνωμοίς, or *chria*, is also used for a short, pithy, and sententious observation, reflection, or the like, which is worthy to be treasured up and remembered.

Such is that of Juvenal, "Orandum est, ut sit mens sana in corpore sano." The writers of rhetoric distinguish several kinds of gnomes, according as they turn on words, on actions, or both; denominating them *verbal*, *active*, and *mixed gnomes* or *chrie*. See APOPHTHEGM.

GNOMON, in *Dialling*, is the style, pin, or cock of a dial, the shadow whereof pointeth out the hours.

The word is Greek, γνομώνη, which literally imports somewhat that makes a thing known; because the style or pin indicates or makes the hour, &c. known.

The gnomon of every dial is supposed to represent the axis of the world; and therefore the two ends or extremities thereof must directly answer to the north and south poles. See DIAL and DIALLING.

GNOMON, in *Geometry*. If a parallelogram be divided into four lesser ones, by two lines intersecting each other, and one of these parallelograms be retrenched or taken away, the other three will make a gnomon, ordinarily called a *square*.

Or, a gnomon, in a parallelogram, may be said to be a figure formed of the two complements, together with either of the parallelograms about the diameter. Thus, in the parallelogram A C, *Plate VIII. Geometry, fig. 96*, the gnomon is $M + x + z + N$; or $M + N + X + Z$.

GNOMON, in *Astronomy*, the name given to any upright pillar, when used for the purpose of determining the altitude of a celestial object, but particularly the sun.

The extreme simplicity of this instrument renders it very probable, that it was the first ever used for astronomical purposes. It fortunately happened for the science, that it was capable likewise of being a very exact one; and all the knowledge the ancients had of the solar theory seems to have been derived from this instrument. The principle of it is so simple, as hardly to require explanation. If the height of a vertical pillar be compared with its shadow on a horizontal plane, the altitude of the sun may be deduced by trigonometrical calculation, since these two quantities are to each other, as the tangent to the radius, or as the sine to the cosine of the altitude required. The ancient obelisks found in Egypt and the East were probably instruments of this kind: it would be too much to conclude that every one was erected for astronomical purposes, but this was probably their original destination; and the figure of an obelisk being rather pleasing to the imagination, it was adopted as an ornament to public squares and buildings. As practical astronomy advanced to accuracy and perfection, however, the gnomon appeared to be subject to considerable defects. The shadow is found to be generally ill defined, so that its length cannot be very accurately measured; and to obviate this, the gnomon must be of greater height than is easily practicable. In modern Europe, therefore, the original gnomon has been almost entirely abandoned, and a new one substituted upon principles nearly similar, but of a somewhat different construction.

The gnomons of modern Italy are usually constructed in very large edifices; a small aperture is made in the upper part of the building, which permits a luminous circular image of the sun to be formed on the pavement, on which a meridian line is accurately traced: a plumb line is suspended from the aperture to the floor, and thus both the height of the aperture, and the distance of the solar image from the point immediately beneath it, is very accurately ascertained.

There are upon record some very ancient observations made with instruments of this kind, particularly of Pythias, who observed the solstices at Marseilles above three centuries before the Christian era. Pliny mentions an obelisk erected by Augustus: this obelisk was brought from Egypt, and was said to have been made by Sesostris, near a thousand years before Christ. It was used by Manlius for the same purpose for which it was originally destined, namely, to measure the height of the sun.

The Chinese have from the earliest time been in the constant practice of making use of a gnomon.

In the year 1278, a gnomon 40 feet high was erected at Peking, by the Chinese emperor Co-cheou King.

Ulugh Beigh, in the year 1437, observed the solstices at Samarcand by the shadow of a gnomon 165 feet high: and similar instruments are even said to have been used by the ancient inhabitants of Peru.

The gnomons to which modern astronomy is the most indebted, are chiefly those of France and Italy.

Paul Toscanelli constructed a gnomon in the cathedral of Florence, whose height was 280 feet. Ximenes repaired this, and published an account of it in 1757.

Gassendi constructed a gnomon of 50 feet in the "College de l'Oratoire" at Marfeilles, and observed the solstices with it in 1636.

Ignatius Dante, in 1575, a Dominican friar, and afterwards bishop of Alatri, first constructed the celebrated gnomon in the church of St. Petronius, at Bologna: it was originally only about 70 feet high, but was raised by Cassini, in 1653, to the height of 90 feet, and it was with this that his valuable solar observations were made.

Most of these gnomons are accompanied by a meridian line, often highly ornamented with the names of the months and signs of the zodiac, so as to serve the purpose of a calendar. One of the finest in Italy is in the Carthusian convent at Rome, built on the ancient Thermæ of Diocletian. There are two, one to the north 62 feet, another on the south 75 feet high: they were constructed by Bianchini in 1701.

Picard erected a gnomon in the royal observatory at Paris, which still exists.

The meridian line in St. Sulpice, at Paris, was begun in 1727 by Sully, a watchmaker, and has since been much improved and highly ornamented: its height is 80 French feet.

M. de Cefaris and Reggio in 1786, constructed a gnomon and meridian line in the cathedral at Milan: its height is 73 feet.

The reason why none of these gnomons are to be found in England, is that we do not regulate our clocks by solar, but by mean time: to this may be added our unfavourable climate, which would very much diminish the interest which they obtain in other countries, where they are made to serve the useful purposes of civil life.

Notwithstanding the great attention that has been paid to the construction of these gnomons, their use has been entirely superseded by modern instruments of small dimensions, so that to the astronomer they are now become merely objects of curiosity: yet to no instrument has astronomy greater obligation. The solar theory was first brought to a very improved state by the use of this simple instrument alone. The length of the year, and the obliquity of the ecliptic, were determined by it with very great exactness. The ancient method of deducing the solar theory was nearly as follows.

To determine the obliquity of the ecliptic, the length of the shadows were observed at the period of the solstices, and the extreme points to which the longest and shortest shadows extended at the moment of noon were carefully observed, and the altitudes of the sun deduced at each of these periods: half the difference of the greatest and least altitudes would be the obliquity of the ecliptic, subject to a small error arising from refraction, the effects of which were not known at that early period, nor were they very considerable in those southern portions of the globe in which astronomy had its origin. But though it was not difficult to deduce the length of the solstitial shadows, it was by no means easy to determine the day on which either of the solstices actually happened, because the length of the shadow would appear to be the same at those seasons for several successive days. It appears, by some very ancient Chinese observations still on record, that this inconvenience was remedied by observing the length of the shadow, ten or twenty days before the solstice; then waiting till they found the meridian shadow again of the same length, they concluded that the moment of the solstice happened on the intermediate day between these corresponding observations.

The length of the year was determined from observations of the equinoxes, which could be much more exactly ob-

erved; for the obliquity of the ecliptic being determined by the method above described, the length of the equinoctial was known, and the day on which the shadow corresponded to the computed shadow was evidently the day of the equinox.

It was by examining a succession of these simple observations, that Hipparchus first discovered the great inequality in the length of the four seasons, arising from what is now called the equation of the orbit: and from the discovery of this important fact, we may date the origin of physical astronomy.

GNOMONIC COLUMN. See COLUMN.

GNOMONIC, *Polyhedron*. See POLYHEDRON.

GNOMONIC, or *Gnomonical projection*, that which represents the circles of a hemisphere, upon a plain touching it in the vertex, by lines or rays from the centre of the hemisphere to all the points of the circles to be projected.

In this projection, all the great circles of the sphere are projected into right lines. Any lesser circle parallel to the plane of projection is projected into a circle. And any lesser circle not parallel to the plane of projection, is projected into a conic section.

The gnomonic projection is also called the "horologigraphic projection," because it is the foundation of dialling. In other respects it is not much used, because the circles of the sphere are projected into conic sections, which are difficult to be described. However, this projection has its conveniences in the solution of some problems of the sphere, on account of the great circles being all projected into right lines.

Mr. Emerson, known by an ingenious Treatise upon Fluxions, and a variety of other publications, has given the theory and practice of the gnomonic projection, in his Treatise on the Projection of the Sphere, Lond. 1749, 8vo. See PROJECTION.

GNOMONICA, Γνωμωνικη, or *Gnomonics*, the art of dialling, or of drawing sun and moon-dials, &c. on any given plane.

It is thus called, as it shews how to find the hour of the day, &c. by the shadow of a gnomon or style.

GNOSIMACHI, in *Ecclesiastical History*, an ancient sect in religion, whose distinguishing character was, that they were professed enemies of all studied knowledge in divinity.

The word is γνωσιμαχος, *q. d.* an enemy of wisdom or knowledge.

Damascenus says, that they were perfectly averse from all the gnoses of Christianity, *i. e.* all the science or technical knowledge thereof. They held it an useless labour to seek for gnoses in the holy scriptures; and said, that God requires nothing of men but good works; that it were, therefore, much better to walk with more simplicity, and not to be so solicitous about the dogmata of the gnostic life.

GNOSSUS, in *Ancient Geography*, a town of the island of Crete, more anciently called "Cæratius," from the name of the river which watered it. It was the fixed residence of Mithras, once the capital of the island, and, according to Strabo, a wealthy and populous place, being 30 furlongs in compass, and full of inhabitants. This writer places it 20 furlongs from the Ægean or Archipelago, and 90 from the African sea. Its port, called Heraclæum, was at a considerable distance, according to Olivier about four or five leagues to the eastward. Pausanias (*Attic.*) says, that it had a labyrinth. From this town Ariadne, so much celebrated by the poets, derived the name of Gnoslis. When the island was reduced by the Romans, Gnossus was humbled, and Gortyna, her rival, raised upon her ruins. Sonnini says, that a small village, Cnosson, near Candia, would recall to mind the site of the ancient town, were it not discoverable, in a manner no

less certain than afflicting, from the rubbish which covers it, and a great part of which has served for the buildings of modern *Candia*, which see. See also CRETE.

GNOSTICS, in *Ecclesiastical History*, ancient heretics, famous from the first rise of Christianity, principally in the East.

It appears from several passages of the sacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many persons were infected with the Gnostic heresy in the first century; though the sect did not render itself conspicuous, either for number or reputation, before the time of Adrian, when some writers erroneously date its rise.

The word is formed of the Latin *gnosticus*, and that of the Greek γινωσκω, *knowing*, of γινωσκω, *I know*.

The name Gnostic was adopted by those of this sect, as if they were the only persons who had the true knowledge of Christianity. Accordingly they looked on all the Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings, in a too low, literal, and unedifying signification.

At first, the Gnostics were only the philosophers and wits of those times, who formed for themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of scripture. These enthusiastic and self-sufficient philosophers boasted of their being able to restore mankind to the knowledge (*gnosis*) of the true and Supreme Being which had been lost in the world. They also foretold the approaching defeat of the *evil principle*, to whom they attributed the creation of this globe, and declared, in the most pompous terms, the destruction of his associates, and the ruin of his empire. But

GNOSTICS afterwards became a general name, comprehending divers sects and parties of heretics, who rose in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They were such as corrupted the doctrine of the gospel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of evil and the creation of the world, with its divine truths.

It was one of the chief tenets of the philosophy of the Christian Gnostics, that rational souls were imprisoned in corrupt matter, contrary to the will of the Supreme Deity. In conformity to the opinion of the oriental sages, who expected an extraordinary messenger from the Most High, endowed with wisdom and invested with authority to communicate to miserable mortals just notions of the Supreme Being, and to deliver them from the chains of the tyrants and usurpers of this world, they believed, when Christ appeared and wrought miracles of the most astonishing and salutary kind, that he was the expected and wished-for messenger. Accordingly they imagined that he would rescue men from the power of the malignant genii, or spirits, to which, agreeably to their doctrine, the world was subjected, and so free their souls from the dominion of corrupt matter. Having admitted this supposition, they interpreted, or rather corrupted, all the precepts and doctrines of Christ and his apostles, in such a manner as to reconcile them with their own erroneous tenets.

Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c.

GNOSTICS, a denomination sometimes also more particularly attributed to the successors of the first Nicolaitans and Carpocratians, in the second century, upon their laying aside the names of the first authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and visions, may consult St. Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St. Epiphanius; particularly the first of these

writers, who relates their sentiments at large, and confutes them at the same time: indeed, he dwells more expressly on the Valentinians than any other sort of Gnostics; but he shews the general principles whereon all their mistaken opinions were founded, and the method they followed in explaining scripture. He accuses them with introducing into religion certain vain and ridiculous genealogies, *i. e.* a kind of divine processions or emanations, which had no other foundation but in their own wild imagination.

In effect, the Gnostics confessed, that these æons or emanations were no where expressly delivered in the sacred writings; but insisted, at the same time, that Jesus Christ had intimated them in parables to such as could understand him. They built their theology not only on the gospels and the epistles of St. Paul, but also on the law of Moses and the prophets.

These last laws were peculiarly serviceable to them, on account of the allegories and allusions with which they abound; which are capable of different interpretations.

However, their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted this idle fiction, and filled them with an abhorrence of Moses and the religion he taught; alleging, that he was actuated by the malignant author of this world, who consulted his own glory and authority, and not the real advantage of men. Their persuasion that evil resided in matter, as its centre and source, made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body and its re-union with the immortal spirit. Their notion, that malevolent genii presided in nature, and occasioned diseases and calamities, wars and desolations, induced them to apply themselves to the study of magic, in order to weaken the powers or suspend the influence of these malignant agents.

The Gnostics considered Jesus Christ as the Son of God, and, consequently, inferior to the Father, who came into the world for the rescue and happiness of miserable mortals, oppressed by matter and evil beings: but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and, therefore, the greatest part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St. John, where they fancied they saw a great deal of their æons or emanations under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, *viz.* *hylis*, or material; *psychic*, or animal; and *pneumatic*, or spiritual.

On the like principle they also distinguished three sorts of men; *material*, *animal*, and *spiritual*. The first, who were material, and incapable of knowledge, inevitably perished, both soul and body; the third, such as the Gnostics themselves pretended to be, were all certainly saved; the psychic, or animal, who were the middle between the other two, were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greatest part of this sect adopted very austere rules of life, recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exalting the mind. However, some maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a loose rein to all the passions, and asserted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They supported their opinions and practice by various authorities: some referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaster, Christ,

and his apostles; others boasted that they had deduced their sentiments from secret doctrines of Christ, concealed from the vulgar; others affirmed, that they arrived at superior degrees of wisdom by an innate vigour of mind; and others asserted, that they were instructed in these mysterious parts of theological science by Theudas, a disciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient Gnostics were revived in Spain, in the fourth century, by a sect called the *Priscillianists*. (See Mosheim's *Ecl. Hist.* vol. i.)

The appellation Gnostic sometimes also occurs in a good sense, in the ancient ecclesiastical writers, and particularly in Clemens Alexandrinus, who, in the person of his Gnostic, describes the characters and qualities of a perfect Christian. This point he labours in the seventh book of his *Stromata*, where he shews, that none but the Gnostic, or learned person, has any true religion. He affirms, that were it possible for a knowledge of God to be separated from eternal salvation, the Gnostic would make no scruple to choose the knowledge; and that if God would promise him impunity in doing of any thing he has once spoken against, or offer him heaven on those terms, he would never alter a whit of his measures.

In this sense the father uses Gnostics, in opposition to the heretics of the same name; affirming, that the true Gnostic is grown old in the study of the holy scripture; and that he preserves the orthodox doctrine of the apostles, and of the church; whereas the false Gnostic abandons all the apostolical traditions, as imagining himself wiser than the apostles.

At length the name Gnostic, which originally was the most glorious, became infamous, by the idle opinions and dissolute lives of the persons who bore it; much as, in the present age, it has fared with the name *quietist*, *pietist*, &c.

GNU, in *Zoology*, a species of Antelope, having horns thick, rough, and bent much forwards at the base, then suddenly turned backwards, a ferruginous body, a neck with a mane, and a tail whitish. This animal inhabits the country of the great Namaquas, to the north of the Cape of Good Hope. It feeds in large flocks in the plains: is exceedingly fierce, very swift, and fights with its horns; it frequently drops on its knees, runs quickly in that posture, furrowing the ground with its horns and legs. It is a singular animal, having the body like a horse, with a thick bull-like head, elegant taper legs like a deer, and the lachrymal furrows of the Antelope tribe. It is about 6½ feet long, and 3½ high at the shoulders; of a rusty brown colour, having its hair tipped with white, but on the breast and fore-legs long and black; the head is large and clumsy, with a square mouth and broad flaps over its nostrils; on the chin and gullet is a long hanging beard, or bunch of white hairs; the neck is short, thick, and somewhat arched, with an erect ash-coloured mane; the tail is long, white, and flowing like that of a horse; the feet have only one spurious hoof on each. The flesh is reckoned very good.

GO is sometimes used in *Law*, in a special signification. Thus, to go *without day*, and to go *to God*, denote as much as to be dismissed the court, and to be acquitted.

GOA, in *Geography*, an island in the East Indian sea, near the west coast of Hindoostan, separated from the continent by a river called "Mandova;" about eight leagues in circumference. The soil, especially in the vallies, is fertile; the trees are always covered with leaves, flowers, and fruit; and springs in abundance issue from the mountains. The rainy season continues here from June till September or October; and the land-floods bring down such quantities of mud and sand as stop up the haven and impede the

navigation. In the months of April and May the weather is sultry, but from October to March it is very moderate.

GOA, a city and capital of the Portuguese settlements in India, the seat of a viceroy, and see of an archbishop, taken by the Portuguese general Albuquerque in 1510 from a prince of Saracen extraction. The port of Goa is naturally, and still more by the improvements of the Portuguese, one of the best in India; it is fortified with many castles and towers, and furnished with abundance of good cannon. Beyond these castles the channel becomes narrow, straitening sometimes to one, sometimes to two miles, and its banks are planted with the best fruits and finest trees which India affords. Eight miles up the channel is the town of Goa. About the middle of this distance is a palace, now serving as a barrack for the garrison; and here begins a strong broad wall, two miles in length, which is a foot-walk when the country is overflowed, and in the vicinity of it a great quantity of salt is collected. This channel, which forms so excellent a port, runs many miles into the country, dividing it into several fruitful islands and peninsulas, which plentifully furnish the city with necessaries. Adjoining to this port is the haven of Murrugon, formed by the other channel, that runs between the island of Goa and peninsula of Salfete, and affords a safe retreat to the Portuguese and other ships, when they are shut out of the port by the sands which are brought down by the river Mandova, in consequence of the first rains of June, and till the passage is opened in October. This port of Murrugon is defended by a castle on the island of Salfete, and a good garrison. At the south entrance into the channel are the ruins of Old Goa; and from thence to the new city is a commodious road, elegantly adorned with trees for fruit and shade. The walls of the new city, which is decaying, include a space of 12 miles in circuit; and the public structures that remain sufficiently evince its former grandeur as well as extent. The number of inhabitants is said to be about 20,000; they consist of native Portuguese, Mestizos, and Canarians, or natives, who are black as jet, with long black hair, and fine features; here are also many negro slaves, and Pagans of different nations. As to the character of the inhabitants, the men are said to be, for the most part, proud, indolent, jealous, revengeful, and indigent; the women lazy, lascivious, and as well skilled in poisoning as any in the world;—215 miles S.S.E. from Bombay. The inquisition, formerly existing in this place, is now abolished. N. lat. 15° 28' 20". E. long. 73° 45' 45".

GOA, or *Goach*, a kingdom on the west and south-west coast of the island of Celebes, which, after various conflicts and revolutions, is now dependent on the kingdom of Boni. The capital of the same name stands on a little island, on the banks of a river, whence the kingdom derives its denomination. It was built about the same period as Samboupo and Tello; and was taken by the Dutch in 1778. S. lat. 5° 12'. E. long. 119° 51'.

GOACHO, a town of Peru, in the diocese of Lima, near the Pacific ocean; 65 miles N.N.W. of Lima. S. lat. 11°.

GOAD, in *Rural Economy*, a term applied to a pointed instrument, by which oxen are driven when employed in team-labour. It has frequently, likewise, a leather thong attached to the contrary end of it, so as to form a sort of whip.

GOAFFL, in *Geography*, a town of Africa, in the kingdom of Mandinga, on the Senegal.

GOAHIROS, a nation of South America, situated between the jurisdiction of Maracaibo and the Rio, or river

de la Hache: they occupy the coast for more than 30 leagues, and extend equally far into the interior part of the country. They have at all times been considered as the most ferocious of the maritime Indians. The Spaniards never even attempted to conquer them. Some missionaries have made efforts for instructing and proselyting them to the Christian faith, but without any permanent effect. Their number amounts to 30,000. They are governed by a cazique, for whom they have erected a citadel upon a small eminence, called "La Teta," the Pap; at the distance of some leagues from the sea. They breed horses upon which they ride with incredible rapidity. Their troops are all mounted, each soldier carrying a carbine, cartridge-box, bow and quiver. They experience much friendship from the English of Jamaica. They assist them with advice, and supply them with arms. These marauders have rarely any communication with Maracaibo, because, as its jurisdiction is the principal scene of their robberies and atrocities, the inhabitants are obliged to be continually on their guard, so as to be always ready to repel the aggressions of such troublesome neighbours. The Spanish city to which they chiefly resort is Rio-de-la-Hache, depending upon the vice-royalty of Santa Fé, where they barter their commodities. They set out in bands, most commonly preceded by their wives, who carry their children upon their backs, besides other loads, too heavy even for beasts of burden. Dreading imposition, they have never adopted the use of specie, but barter their horses and oxen chiefly for spirituous liquors, to the use of which they are much addicted. Urged by their necessities they recur to arms, and threaten the nearest city or village. After some hostilities, the Spaniards sue for peace, and obtain it in consideration of some pipes of brandy and other smaller articles. Although these Indians are well received in the Spanish cities, they will not admit any Spaniard into their country; and yet some Spanish smugglers contrive, for pecuniary considerations, to obtain a passport and escort for traversing the country of the Goahiros, and they have thus acquired many partizans among the Spaniards themselves; but their principal and most useful connection is formed with the English of Jamaica. By them they are supplied, not only with arms and ammunition, but with the stuffs that clothe them. Their dress is ornamented by a great variety of feathers, fragments of shining metals, and gold ridiculously fixed to their ears, nose, and arms. The articles with which they furnish the English in exchange for the merchandize they receive are pearls, which they fish in their own ports, and horses, mules, and oxen. Their ferocity is such, that even the English will seldom so far confide in them as to venture on shore, but the business of bartering is transacted on board, and the ships hasten to depart. The ships that are accidentally cast upon the coast, immediately become the prey of these cannibals, who massacre the crew and devour their flesh; dividing the cargo among those who are present on the occasion. The Goahiros are said to be a formidable nation, well mounted, armed, and disciplined; and able to bring into the field 40,000 effective men.

On the eastern part of the territory of the Goahiros are the "Cocinas" Indians, who live like savages, but are so cowardly and pusillanimous as to allow the Goahiros to exercise an authority, which the bold always acquire over the timid. These savages are, in fact, merely the slaves of other savages. Depons's travels, vol. i.

GOAL. See GAOI.

GOAL-PARAH, in *Geography*, a town of Hindoostan, in Bengal, situated on the Burhampooter, and on the borders of Assam; where the Europeans have factors, who carry

on a considerable trade with Assam, Bootan, Thibet, &c.; 32 miles E. of Rangamatty.

GOAN, the name of a Persian tree, of the ashes of which they make a sort of antispodoric, or medicinal powder, for diseases of the eyes.

GOANAGOODY, in *Geography*, a town of Hindoostan, in Marawar; 8 miles E. of Tripalore.

GOANDA, a naked, savage and ferocious race, who inhabited the extensive and unexplored wilderness, E. of Nagpou, in Hindoostan, which is pervaded by the great river Bain, or Baun Gonga, and terminates in the mountains bounding the English circars.

GOAR, St. a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Simmern, situated on the west side of the Rhine, in which there is, near this place, a water-fall; 16 miles S. of Coblentz. N. lat. 50° 8'. E. long. 7° 43'.

GOAR-Vetch, a name sometimes applied to the summer vetch. See TAKE and VETCH.

GOARING, on *Ship-board*. The seamen say a sail is cut *goaring*, when it is cut sloping by degrees, and is broader at the clew than at the ear-ring, as all top-sails and top-gallant-sails are.

GOAS, in *Geography*, a town of Bengal; 11 miles E. of Moorshedabad.

GOAT, in *Zoology*. See CAPRA.

GOAT, in *Rural Economy*, is an animal, that in particular situations may be kept with advantage by the farmer, as where the country is rocky and barren, and there is but little keep for any other sort of animal. The goat is capable of climbing the steepest rocks, and of browsing upon the briers, heath, and shrubs of several different kinds, which are rejected by other sorts of animals. When turned into pasture grounds they should consequently be prevented from nipping the young shoots of trees and other woods, as they prefer them to the grass.

They are beneficial in several different points of view, as in their milk, which they afford plentifully, and which is of a very excellent quality. In some cases, this and cow's milk are mixed together, and a highly valuable cheese prepared from them.

The young kids are likewise very excellent food, and two or three are frequently brought forth at a time, often twice in the course of the year.

The hair of the goat is also very valuable for different purposes, as the making of ropes to be used in the water, which are extremely durable. A sort of stuff is also formed from it in some places. It may be sheared in the same manner as wool from the sheep.

The suet of the goat is excellent, the animals being in some places, as in Caernarvonshire, killed merely for the object of their suet; which is capable of being made into candles of a superior quality to those of the common kind.

Their horns constitute valuable handles for tucks and pen-knives. The skin of the young kid is well suited to the glove manufactory, from its taking on a dye better than any other sort of skin. The old skin is highly useful also, being in many cases preferred to that of the sheep; besides, the flesh affords a cheap and abundant food for the winter months, especially when the kids have been sent early to market. The haunches of the goat are often salted and dried, and supply all the uses of bacon; and are known by the Welch under the name *coch yr wden*, or hung venison.

In choosing goats for keeping, the following directions should

should be attended to. The male should have a large body, with long hair, and straight stiff legs, the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long.

The female ought to have a large udder with well sized teats, and with none or very small horns.

Goats are best kept in flocks, in order that they may have the less disposition to straggle; and they should have good shelter both for summer and winter, great heat and cold being equally injurious to them.

The period of coupling them is about December.

They are mostly kept without litter in the winter season, in clean paved yards or other places.

The kids may be prepared for the table in a manner similar in some degree to that of the lamb.

They have been vulgarly supposed useful in stables from the disagreeable odour that issues from the males at particular seasons, but there are probably no real grounds for such a conclusion.

GOAT-fish, *Caprificus*, in *Ichthyography*, the name of a fish, called also by some *caper*. It is a species of *BALLISTES*. In the middle of its back it has three very strong and large prickles, the first of which is three times as large as any of the others, and all are connected by a membrane.

The whole fish is covered with a scaly skin; but the scales have more the appearance of those of a serpent than those of the fish; for they are placed in cancellated lines intersecting one another, and are so well fixed, that they with difficulty come off; and wood or ivory may be polished with the skin, as with the common fish-skin used by the turners, &c. It is of a blueish-green colour, spotted with a fine blue, and the back and belly fins are black, with some blue and red spots. Its whole figure is very broad and flat, as well as short, so that it approaches to a round form. It seldom exceeds two pounds in weight. It is caught in the Mediterranean, but not commonly. The skin of it is frequently found in the cabinets of the curious.

GOAT Islands, in *Geography*, two small islands near the S. coast of Jamaica, they are denominated *Great* and *Little*; the former is situated in N. lat. 17° 53'. E. long. 76° 51'; and the latter about a mile N. W. from it.

GOAT Island, the southernmost of the Bashee islands, in the East Indian sea. N. lat. 20° 6'. E. long. 121°.—Also, a small island among the Philippines, near the S. W. coast of Luçon. N. lat. 13° 52'. E. long. 120° 13'.—Also, a small islet of America, in the state of Rhode island, opposite to the town of Newport, and on which is Fort Washington.

GOAT's Beard, in *Botany*. See *TRAGOPOGON*.

GOAT's Eye, in *Surgery*. See *EYE*.

GOAT's Horns, petrified. In Dr. Grew's "Rarities of Gresham College," p. 257, a *Tephritis bætii*, or goat's horn, in that collection, is described as broken at both ends, about six inches long, and 2½ inches across at the broadest part, the belly an inch over and furrowed, the back somewhat edged, of an ashen colour, inwardly blueish grey, outwardly mixed with oblique and white streaks, bended, one end thicker than the other: it is added, that such are found in Germany, Moravia, Silesia and other parts, and effervesce with nitric acid.

In the Analysis of the Labours of the French national Institute for 1809, it is mentioned that M. Cuvier in the alluvial soils near Etampes had discovered horns, some of which do not seem to differ essentially from the horns of the existing species of goats. The evidence in neither of

the above cases, or any other which we have seen, is sufficiently strong to prove the fossil horns of this class to have really belonged to goats: and analogy would justify us rather, in referring them to the extinct race of animals, fish, and vegetables with which the strata are so abundantly stored, in some parts of the series.

GOAT's Rue. See *GALEGA*.

GOAT, *Scape*. See *SCAPE-COAT*.

GOAT's Sucker. See *CAPRIMULGUS*.

GOAT's Stones, greater. See *SATYRIUM*.

GOAT's Stones, lesser. See *ORCHIS*.

GOAT's Thorn. See *ASTRAGALUS*.

GOATFIELD, in *Geography*, a mountain of Scotland, in the island of Arran; the summit of which is 2845 feet above the level of the sea.

GOAVE, GRAND, a town of the island of Hispaniola; 10 miles S.W. of Leogane.

GOAVE, Petit, a sea-port town of the island of Hispaniola, with a harbour capable of receiving vessels of the largest size safe from winds; in its environs are plantations of sugar, coffee, indigo, and cotton. The town is the emporium to which the inhabitants of Grand Goave, and other places, send their commodities; 20 miles W.S.W. of Leogane. N. lat. 18° 26'. W. long. 73° 37'.

GOBAN, a town of Persia, in the province of Chufistan; 75 miles S. of Sufter.

GOBAN, or *Geban*, a small island in the mouth of the Euphrates, or Shat el Arab, at the entrance into the gulf of Persia, with a town upon it; 50 miles E.S.E. of Bassora. N. lat. 30° 10'. E. long. 48° 25'.

GOBANNIUM, in *Ancient Geography*, a town of Britain, placed in Antonine's Itinerary between Barrium or Ulk, and Magnis or Kenchester, 12 miles from the former and 22 from the latter, and supposed to be Abergavenny, which see.

GOBBI, in *Geography*, a country of Africa, between that of Camma, and cape Lopez Gonfalvo; the chief trade of which consists in elephants and ivory. The chief town is about a day's journey distant from the Atlantic. N. lat. 1° 30'. See *CAMMA*.

GOBBINS, in *Mining*, is a name with the colliers of several districts for the hole-ing stuff and other refuse of their works; as also for the hollows or spaces behind them, into which they throw the refuse coal, earth, and stones: which last are also called wastes and old-hollows.

In the coal-pits about Wednesbury in Staffordshire, and at Donithorp, Danby-Hall, &c. in Derbyshire, the gobbins take fire spontaneously after some time, unless the air is excluded from them, owing to duns, tow, tawe or cat-dirt, a thin stratum found near the coal, which heats, swells, and spontaneously inflames, by the contact of air and moisture. At Donithorp they encase their gobbins in walls of tempered clay at certain distances, for excluding the air.

GOBBS, otherwise *Cobbles*, are pieces of coal from the size of walnuts to that of a man's fist or larger, which are occasionally picked or raked out of the fleck or refuse small coals at the collieries, either by poor persons, who are allowed to do so, or for sale. These are what in London, and many places in the east and south of England, would be called round-coals and highly valued, on account of the absence of very small or dust coals among them. Where the rage among the buyers and dealers is for large coals, as about Wednesbury in Staffordshire, and the Erewash vale in Derbyshire and Nottinghamshire, an inconceivable waste is made of cobbles and fleck; in working the thick coal about Wednesbury a heap of such, six or seven yards thick, is said to be left and wasted on the floor of their works: and

and to occasion a further waste of a rib or wall of solid coal, round each stall or chamber, for excluding the air, which would otherwise fire these waste heaps. See **GOBBINS**.

GOBELINS, a celebrated manufactory, established at Paris, in the Fauxbourg St. Marcel, for the making of tapestry, and other furniture for the use of the crown. The house where this manufactory is carried on was built by two brothers, Giles and John Gobelins, both excellent dyers; and the first that brought to Paris, in the reign of Francis I. the secret of dyeing that beautiful scarlet colour still known by their name; as well as the little river Bievre, on whose banks they fixed their dye-house; and which is now known by no other name than that of the river of the Gobelins.

It was in the year 1667 that this place, till then called "Gobelins' Folly," changed its name into that of "Hotel Royal des Gobelins," in consequence of an edict of Louis XIV. Monf. Colbert having re-established, and with new magnificence enriched and completed the king's palaces, particularly the Louvre and Thuilleries, began to think of making furniture suitable to the grandeur of those buildings: with this view he called together all the ablest workmen in the divers arts and manufactures throughout the kingdom; particularly painters, tapestry-makers, sculptors, goldsmiths, ebonists, &c. and by splendid offers, pensions, privileges, &c. called others from foreign nations.

And to render the intended establishment firm and lasting, he brought the king to purchase the Gobelins, for them to work in, and draw up a system of laws, or policy, in seventeen articles.

By these it is provided, that the new manufactory shall be under the administration of the superintendent of the king's buildings, arts, &c. that the ordinary masters thereof shall take cognizance of all actions and processes brought against any of the persons in the said manufactory, their servants and dependants; that no other tapestry work shall be imported from any other country, &c.

The Gobelins has ever since remained the first manufactory of this kind in the world. The quantity of the finest and noblest works that have been produced by it, and the number of the best workmen bred up therein, are incredible; and the present flourishing condition of the arts and manufactures of France is, in a great measure, owing thereto.

Tapestry work, in particular, is their glory. During the superintendance of M. Colbert, and his successor M. de Louvois, the making of tapestry is said to have been practised to a degree of perfection, scarce inferior to what was before done by the English and French.

The battles of Alexander, the four seasons, four elements, the king's palaces, and a series of the principal actions of the life of Louis XIV. from the time of his marriage to the first conquest of Franche Comté, done from the designs of M. Le Brun, director of the manufactory of the Gobelins, are master-pieces in their kind.

GOBEMOUCH, the *fly-catcher lizard*, a species of American lizard that is always employed in catching of flies. It is the smallest of all the lizard kind, and is very beautiful, its skin often appearing as if covered with leaf-gold, or leaf-silver, and in some others of a green, or red and gold, wonderfully bright and beautiful. They are not at all shy or fearful of men, but as they do not hurt, so they seem to dread none; they enter chambers and closets, and do no sort of damage, but destroy the flies and other troublesome ver-

min they find there. Their whole lives seem spent in the chase of these insects, and it is a very pleasing thing to observe the various ways they have of catching them. They are very cleanly creatures, and may be suffered to run over the table at meal time; where, if they see a fly, they will pursue it over the very hands or cloaths of people, or over the dishes, without doing the least hurt.

Notwithstanding their great beauty while alive, they are only of a dusky grey when dead; all their other colours immediately vanishing.

GOBE-MOUCHE, in *Ornithology*, a name given by Buffon to several species of *Lanius*, *Turdus*, *Muscicapa*, and *Motacilla*, which see respectively.

GOBIN, ST., in *Geography*, a town of France, in the department of the Aisne; celebrated for its manufacture of plate-glass; 4 miles S. of la Fere. See **GLASS**.

GOBIO, in *Ichthyology*, a species of *Cottus*; and also of *Cyprinus*; which see respectively.

GOBIUS, a genus of the thoracic order, possessing, according to Linnæus, the following essential character. Head small, eyes approximated, with two punctures between; gill-membrane four-rayed; body small, compressed on each side, covered with small scale, and furnished with a small tubercle behind the vent; the ventral fins united into an oval or funnel shape; and the dorsal fins two in number.

At the time Linnæus wrote his *Systēma Naturæ*, the above character was probably found sufficiently explicit to embrace, in a correct and lucid order, all the species of this natural tribe of fishes at that period known. This, however, it must be confessed, is not precisely the case at present. The number of species has been materially augmented by the recent discoveries of naturalists, and among these are certain kinds which exhibit differences essentially dissimilar from each other; though still, in the idea of the Linnæan student, they can be only referable to the genus *Gobius*; while others, no less intimately allied, cannot, without a palpable innovation on the order of nature, be assigned to that genus. The later French writers, as Latreille, Bosc and others, after the example of Lacépède, divide the Linnæan *Gobii*, and their natural affinities, into four distinct genera, namely, *Gobius*, *Gobioides*, *Gobiomorus*, and *Gobiomoroides*, an extension perhaps requisite, or at least admissible. This extension is indeed, in our own opinion, rather desirable, and we refrain from adopting it only to avoid that degree of perplexity which might probably result from the dispersion of the species into the several distinct articles, which would then become necessary. For this reason, we propose to concentrate the whole in one point of view, observing only to refer the species respectively to their different genera as we proceed, and by this means leave it to the judgment of the reader, whether those recently established genera ought to be in reality considered essentially distinct, or as only constituting the natural subdivisions of the Linnæan genus *Gobius*.

The habits of these fishes in general appear to correspond; they are chiefly inhabitants of waters contiguous to the shores, and lie concealed among the rocks, under stones, or in the sand and mud of seas and rivers; they feed on worms, insects, and the spawn and fry of fishes; and adhere firmly to the rocks or other hard substances by means of their ventral fins.

Species.

Genus *Gobius* — Ventral fins united; dorsal fins two + Section. Pectoral fins attached close to the body.

BODDARTI. Rays of the anterior dorsal fin circumflex, the third very long. Pallas.

A native of the Indian seas, in common about six inches in length, and never exceeding eleven or twelve inches. The head thick, blunt, and somewhat convex, with spots of brown and white; crown convex, and gradually sloping down; jaws of nearly equal length; lips thick and fleshy; eyes vertical and oblong; gill-membrane livid. The body is rather convex, tapering slightly towards the tail, and covered with small and soft scales; the colour blueish brown above, beneath pale yellow, inclining to whitish; the back marked with a longitudinal series of seven brown spots, beneath which, on the sides, are seven other spots of the same colour, but these latter are speckled with white; the vent, which is situated rather nearer the head, is surrounded by a black circle, behind which is a conic peduncle. The dorsal fins are blueish black, the first including five rays, has the membrane spotted with white; the membrane of the second is remarkable in having six white lines between each ray, these rays are fetaceous, and amount to twenty-five in number; the pectoral fin is roundish, and includes twenty-one rays; ventral, thirty-four; anal, twenty-five; and the tail, which is blueish white, eighteen rays.

LAGOCEPHALUS. Upper jaw hemispherical; no tongue and lateral line. Pallas.

The native place of this species is uncertain; it was first described by Kolreuter, in the Transactions of the Royal Academy of Petersburg, and afterwards by Pallas in his "Spicilegia Zoologica." The head is short, thick, and destitute of scales, the mouth transverse; eyes distant, small, and covered with a common skin; upper jaw very thick, the lower with a few larger teeth, which are a little hooked; the lips cleft in the middle, doubled, the upper fleshy and very thick, and also reaching much beyond the jaw; palate with numerous crowded teeth of small size on the margin. The body round, compressed towards the tail, of a grey or brown colour, and covered with minute scales; vent in the middle of the body. The first dorsal fin contains six rays of a simple form, the rays in the second fin, like those of the tail, are branched, and amount in number to eleven; the pectoral fin lanceolate oval, with fifteen rays; ventral, with eight short crowded rays; anal, ten rays; and caudal, twelve. The total length of this fish about three or four inches.

CYPRINOIDES. Body covered with large sub-ciliated scales; tail rounded; the membrane connecting the rays testellate with brown. Pallas.

About the size of a finger, the body of a compressed form, thickish, convex, grey brown above, beneath whitish; skin soft and cancellated with fine lines; teeth minute and nearly equal; tongue flat, soft, and obtuse; eyes lateral and between them a blackish semi-lanceolate crest; rays of the fins mostly branched; lateral line obsolete. The species inhabits Amboina.

LANCEOLATUS. Tail very long and acutely pointed. Bloch. *Gobius oceanicus*, Pallas.

Inhabits the brooks and rivers of Martinico, where Plumier saw it in great abundance. The body is oblong, and covered with round imbricated scales, which are larger on the posterior part. The head is long and truncated; the eyes vertical with black pupil, and golden iris; jaws equal; tongue loose and acute; cheeks blueish edged with red; lateral line in the middle of the body, and the vent nearer the head; dorsal and anal fins with simple, soft, distant rays, connected by a thin membrane; rays of the first dorsal membrane extended far beyond the membrane; between the dorsal fins on each side a brown spot; pectoral fin yellow edged with blue; tail at the base greenish yellow, the edge violet. The flesh excellent.

MINUTUS. Whitish, spotted with ferruginous; rays of the dorsal and caudal fins obscurely streaked with the latter. *Donov. Gobius minutus; albicans ferrugineo-maculatus, radiis dorsalibus, et caudalibus ferrugineo obsolete striatis, Pallas. Minute or spotted goby, Pennant.*

"The minute or spotted goby is a pretty, delicate, little creature, whose usual length very rarely exceeds two inches and a half, or at the utmost three inches. Pallas, who describes this species, defines its character with much precision; he speaks especially of the obsolete streaks across the rays of the two dorsal fins and tail, which are sufficiently distinct, except when the fins happen to be considerably expanded, at which time they indeed appear as so many series of unconnected dots. These streaks or dots are uniformly constant in all the specimens of the fish that have fallen under our observation, varying a trifle only in the tint or density of colour.

"Bloch does not include this species in either of his works on fishes. Pennant considers it as the *Gobius aphyæ* of Linnæus, in which particular later writers are mistaken; it must however be confessed, that there still remains some little doubt as to the precise difference between the *aphyæ* and *minutus*; Linnæus tells us the former has the body and fins barred with brown, and this will, in a certain degree, apply to the characters of *minutus*. That the spotted goby is the *minutus* of Pallas cannot admit of doubt.

"It has been imagined, on the authority of Mr. Pennant, that the spotted goby appeared on our coasts only during the summer months, and was besides extremely local. This idea is certainly unfounded, for we have received them from various parts of the sea-coast in all seasons of the year. In the wide sweep of sands, called Traeth Levan, which extends along the south-side of Beaumaris bay; upon the shores of the Severn; and also many other of our sandy coasts, this diminutive fish has attracted our remark swimming or lurking among the shrimps in the shallow pools left by the sea at ebb-tide. The same species is likewise not unfrequently captured with the sprats, at a short distance from the shore.

"In the first dorsal fin are six rays, in the second eleven; the pectoral fin contains twenty rays; the ventral, nineteen; anal, eleven; and tail sixteen."

We have been the more explicit in detailing the character and history of the spotted goby, in order to enable the reader to comprehend the precise difference between this and the following species.

APHYÆ. Body and fins barred with brown. Linn. Mus. Ad. Fr. *Gobius uncialis, pinna dorsi secunda officulorum 17, Art*

Described as a very small species found in the Nile and some parts of the Mediterranean; the length about an inch. The first dorsal fin, as in *minutus*, contains six rays, the second sixteen or seventeen; pectoral, according to Linnæus, eighteen, or one less, as Artedi mentions. Linnæus states the number of rays in the ventral fin at twelve, Artedi at only six, and in describing those of the anal fin they differ again, these being, as Artedi informs us, no more than eleven, though Linnæus says they amount in number to no less than fourteen.

Jozo. Rays of the dorsal fin fetaceous, and extending above the membrane. Linn. Jozo, Salv. *Gobius albus*, Ron-del. *Gobius tertius*, Will.

This is an inhabitant of the European and Mediterranean seas; its length is from four to six inches; the body above brown, beneath whitish, and the whole covered with scales. The head is compressed; pupil of the eye black with the iris white; the back slightly arched; jaws of equal length, and armed with numerous small teeth; the lateral line straight,

GOBIUS.

straight, blackish, and placed in the middle of the body. The colour of the fins, which is blue, constitutes, according to Bloch, the characteristic distinction of this particular species. Its haunts are the sandy shores of the sea, and its food testaceous animals, crabs, and other marine creatures. Though highly prolific, it is observed not to multiply very fast, its eggs being eagerly fought after by the larger kinds of fishes. The flesh is indifferent, being hard and meagre.

ELEOTRIS. Anal fin with nine rays; tail roundish. Lagerström. *Gobius Chinenfis*, Osbeck.

Whitish, covered with large, round, and smooth scales, and marked on the back near the gill-covers with an ample violet spot; both the dorsal fins of equal height, the first containing six rays, the second eleven; pectoral fin twenty; ventral, ten; anal, nine; and tail ten. The species inhabits China.

PECTINIROSTRIS. Teeth in the lower jaw horizontal. Gmel.—Lagerstr. *Apocryptes Chinenfis*, Osbeck.

A fish of small size found in China: the first dorsal fin contains five rays, the second twenty-six; pectoral, nineteen; ventral, twelve; anal, twenty-five; and caudal, fifteen.

BICOLOR. Fuscous; all the fins black. Linn.—Brünn pisc.

Length from three to four, or rarely exceeding six inches, and inhabits the Mediterranean sea. The rays of the fins project very inconsiderably above the connecting membrane.

CRUENTATUS. Mouth pustulate with red; rays of the dorsal fins reaching above the membrane. Brünn.

About a span in length, the mouth, gill-covers, chin, and fins pustulate with sanguineous red spots; beneath the eyes a transverse membranaceous line, and two others placed longitudinally before the dorsal fin; fins generally brownish, with setaceous rays; pectoral rounded; ventral blueish, with the rays split at the end; tail pointed and slightly banded with black. Gmelin is inclined to think this may be only a variety of the species Jozo.

PAGANELLUS. Tail and second dorsal fin purplish at the base; the first dorsal fin edged with a yellowish line. Linn. *Gobius paganellus*, Hasselquist.

Length three, four, or six inches; the body slightly compressed and whitish, with a green tinge, and marked with blackish dots or small spots. Native of the Mediterranean.

ARABICUS. Five posterior rays of the first dorsal fin terminating in a red filament twice the length of the membrane. Forst.

Native of Djidda in Arabia. The body is about the size of the little finger, and of a greenish-brown colour, with numerous confluent violet spots and specks of blue; skin soft and covered with minute firm scales; fins spotted; tail cuneated.

NEBULOSUS. Second ray of the first dorsal fin ending in a black filament twice as long as the body. Forst.

Inhabits the same sea as the former, and nearly the same size; body whitish, with brown clouded confluent spots, beneath white without spots; scales rhombic and rigid; pectoral fins glaucous, with obsolete brown spots at the base; ventral brownish; dorsal fin and tail transparent, dotted with brown; anal fin hyaline, with the outer edge black.

PLUMIERI. Upper jaw prominent. Bloch.

This, according to Plumier, inhabits the rivers of the Antilles in great numbers, and is in much esteem for the table, its flesh being of good flavour, and very wholesome. The body is round, fleshy, above tawny, yellow on the sides and white beneath; the whole covered with small scales; head large; vent in the middle of the body; lateral line straight;

fins yellow; pectoral and caudal yellow at the edge, with branched rays; dorsal and anal with simple rays.

OCELLATUS. Upper jaw longer; first dorsal fin six-rayed, with a black ocellated spot near the base on the posterior part. Broussonet.

Found in the fresh waters of Otaheitee. The head is rather compressed, sub-conic, blackish, above slightly curved, obtusely carinated in the middle; teeth unequal, and minute, those of the lower jaw smaller; body compressed, lanceolate, covered on the posterior part with imbricated, ciliated scales, and obscurely clouded with olive and black; beneath glaucous.

NIGER. Blackish varied, second dorsal fin with about fourteen rays. Artedi. *Gobius niger*, Donov. Brit. Fishes.

Apocryptes Cantonensis, Osbeck. *Black goby*.

Native of the European and Asiatic seas. Length six inches; colour blueish black, varied.

BOSCH. Body and tail grey, speckled with brown; the former marked with seven transverse whitish bands. Lacépède.

Described and figured in the work of Lacépède, on the authority of Bose, who observed it on the coasts of North America; it grows to the length of four inches; the head is broader than the body; the first four rays of the anterior dorsal fin terminate in a filament; and the body, which is smooth, is apparently without scales. The flesh is never eaten.

CERULEUS. Body blue; caudal fin red, with black border. Lacépède.

Inhabits the seas on the eastern coasts of Africa, where it was observed by Commerfon, who describes its appearance in the water, when the sun shines, as splendid in the highest degree, though its size is small, the total length not exceeding three inches. The first dorsal is somewhat triangular, with the rays terminating in filaments, the second contains fourteen rays, the filamentous appendice of the last ray in which is thrice the length of the rest. The flesh is not eaten by the natives, but is used as bait in fishing.

** Section. *Pectoral fins attached or placed on a fleshy process or elongation.*

SCHLOSSERI. Blackish-brown, beneath whitish; rays of the first dorsal fin spinous. Pallas. *Schlosserian goby*.

This is about a span in length, the body, rather compressed, decreasing in an inconsiderable degree towards the tail, and covered with large round coriaceous scales; the head long, much thicker than the body, and sloping in front; the mouth transverse; lips thick, fleshy, granulous within, and the upper one folded; teeth large, unequal, distant, and irregularly alternate; palate fleshy; tongue thick, soft, and fleshy; the eyes vertical and placed forward, protuberant, the pupils turned to the sides with a large lunate cavity beneath each; gill-covers oblong and fealy; tail ovate-acute; and the vent in the middle of the body. In the first dorsal fin are eight rays, in the second thirteen; pectoral, sixteen; ventral, twelve; anal, twelve; and tail nineteen. The species inhabits the fresh waters in the island of Amboina, generally residing in the soft mud at the bottom, and subsisting on worms; the flesh is excellent. The same fish occurs also in many parts of China. In the Gmelinian Syst. Nat. the species is described under two distinct names, *schlosseri* and *barbatus*, the latter of which Linnæus defines as having the pectoral fins fan-shaped, and the first dorsal fin with twelve rays, the second thirteen. Lacépède, Bose, and other late writers agree in considering them the same.

Genus *Gobioides*.

Ventral fins united; dorsal fin one; head small; gill-covers closed nearly throughout their contour.

MELANURUS.

MELANURUS. Dorsal fin single; tail black. Gmel. *I. e. gobioides queue noire*, Brouss. *Black tailed goby.*

Described by Gmelin on the authority of Broussonet's Ichth. dec. 1.; it is mentioned as a small species, the habitat of which is unknown. Bosc believes it was brought from the South sea.

AMGUILLARIS. Dorsal fin single; tail red. Gmel.

The general figure of this species is somewhat anguilliform, or shaped like an eel, and like that fish the body is fat and slippery; the teeth are small, and project out of the mouth; the dorsal and anal fin are large, and extend to the tail, with the fin of which they are united; the colour of the body is pale brown, of the fins red; the first dorsal fin includes fifty-two rays; the pectoral, twelve; ventral, ten; anal, forty-three; and tail twelve. The fish is a native of the coast of China and other parts of India.

SMYRNEENSIS. Edge of the jaws formed of a bony plate, and destitute of teeth. Lacépede.

Described on the authority of the new memoirs of the Transactions of the Academy of Petersburg. It is a native of the Mediterranean; the skin very viscous, and the dorsal fin furnished with forty-three rays.

BROUSSONETTI. Body very long and compressed; tail elongated. Lacépede.

Supposed to be a native of the Indian seas. The example described by Lacépede appertained to the stadtholder's museum. The dorsal fin contains thirty-three rays, and extends nearly to the tail, as does likewise the anal fin; the body nearly transparent, and the jaws furnished with small teeth.

Genus *Gobiomorus*.

Head small; eyes approximated; gill-covers closed nearly throughout their contour; dorsal fins two.

* Section. *Pectoral fins connected close to the body.*

STRIGATUS. Ventral fin divided; first caudal fin six-rayed. Broussonet.

Native of the Pacific ocean, near Otaheitee. The head is compressed, yellow, streaked and spotted, and greenish yellow above; body compressed, lanceolate and covered with imbricated, subquadrated, and slightly crenated scales; colour pale bluish-green; beneath whitish, with brownish streaks behind the pectoral fins; beneath the lateral, on the hind part, varied with obsolete reddish spots; first dorsal fin green, with red rays and four fillets of the latter colour; the second dorsal fin with nine red fillets; pectoral fin pale greenish, the marginal rays shorter and simple; ventral whitish; anal long, greenish-red; tail round-oval, yellowish-green, the rays red and simple, with a broad oblique, slightly curved reddish fillet each side.

DORMITOR. Upper jaw longest; tail rounded. Lacépede.

Described from the drawing of Plumier, who saw it in the fresh waters and rivers in the marshes of South America. The second dorsal fin contains eleven rays, and each of the pectoral fins eight.

GRONOVII. Ventral fins divided; first dorsal fin ten-rayed; tail forked. Gmel. *Cestius argenteus*, &c. Klein. *Mugil Americanus*, Ray. *Harder*, Maregr.

Inhabits the seas of South America. The body is silvery above, black, and spotted on the sides with black; scales small and imbricated. The head of this species is naked; eyes large and lateral; mouth narrow; teeth equal, in the jaws and palate; tongue rounded, thin, smooth; gill-covers smooth and roundish; back a little convex; lateral line curved and parallel to the back; vent in the middle of the body.

** Section. *Pectoral fins attached or placed on a fleshy process or elongation.*

KOELREUTERI. Ventral fins divided; first dorsal fin with eleven rays. Pallas.

Length about nine inches, the body soft, fat, and whitish-grey; head long, thick, and convex in front; eyes on the top of the head; lips doubled and fleshy; teeth unequal, conic, the anterior ones larger, and one larger on each side above; aperture of the gills lunated; lateral line impressed; vent about the middle of the body with a peduncle behind; fins soft; the first on the back large and brown, with a black terminal band, the rays spinous; the second narrower, yellowish, with a longitudinal deep brown band, and branched rays; pectoral fan-shaped or oval, and placed on a broad pedicle; tail oval and lanceolate, with ramose rays.

Genus *Gobiomoroides*.

Head small, with the eyes approximated; gill-covers closed nearly throughout their contour; dorsal fin one.

PISONIS. Ventral fins divided; lower jaw longer. Gmel. *Amore pixuma*, Pifo.

A small species found in South America. The head is depressed and covered with scales in size equal to those on the back; the mouth furnished with several rows of teeth; and the tail rounded.

GOBIUS Asper, a name given by Gesner and others to a species of perch called by many *asper pisciculus*, a name confounding it with many other different fishes, and by Linnæus *perca asper*. It is distinguished among the perch tribe by Artedi under the name of the perch with eight or nine black lines on each side. See PERCA.

GOBIUS Fluvialis, or *Gudgeon*. See CYPRINUS *Gobio*.

GOBIUS Marinus, or *Goget*. See **GOBIUS Niger**.

GOBLET, or **GOBELET**, a kind of drinking cup, or bowl; ordinarily of a round figure, and without either foot or handle.

The word is French, *gobelet*; which Salmasius, and others, derive from the barbarous Latin *cupa*. Budæus deduces it from the Greek *κοπελλιον*, a sort of cup.

GOBLETS, made of the wood tamarisk, are ranked among medicinal drugs; because the liquors infused a while therein, are supposed to acquire a quality which renders them good in diseases of the spleen.

GOBONE, or **GOBONY**, in *Heraldry*, the same as *conspous*.

GOBYGANGE, in *Geography*, a town of Bengal; eight miles S. E. of Goragot.

GOCEY, a town of Hindoostan, in Allahabad; 30 miles N. of Gazypour.

GOCH, a town of France, in the department of the Roer, and chief place of a canton, in the district of Cleves, situated on the Niers, surrounded with walls in 1291, and containing three churches; six miles S. of Cleves. The place contains 2412, and the canton 12,728 inhabitants, in 19 communes.

GOCHLENIUS, **RODOLPHUS**, in *Biography*, a physician, was born at Wittenberg in 1572. His father was professor of logic at Marburg, where the subject of this article studied medicine, and obtained the degree of doctor in May, 1601; and was himself elected professor of philosophy in 1608, and also professor of mathematics in 1612. He died on the 2d of March 1621, at the age of 49. Although his life was not long, by extreme industry he had written a considerable number of treatises, in which he evinced much of the spirit of Paracelsus, of whom he was a zealous follower. It is unnecessary to enumerate the long list of titles to his works, which relate to philosophy, magnetism,

netism, astrology, chiromancy, &c. as well as to medicine. Eloy.

GOCIANO, in *Geography*, a town of the island of Sardinia; 30 miles E. of Algeri.

GOCKEL, or **GOKELIUS**, CHRISTIAN LOUIS, in *Biography*, of Gotha in Thuringia, was born on the 31st of December, 1662. In 1685, he was appointed physician to the city of Herspruck, where he acquired great reputation by his practice, and obtained the confidence of several German princes, especially of the duke of Wirtemberg. His publications likewise contributed to extend his fame, consisting of a "Medical Surgery," in German, and of some papers in the Memoirs of the German academy. He died in August 1736, aged 74.

With the preceding physician we must not confound another, called *Everard Gokelius*, who was born at Ulm, in 1636, and practised physic at Giengen in Suabia. Besides some essays in the German language, he published, 1. "Enchiridion Medico-practicum de Peste," 1669.—2. "Consiliorum et Observationum Medicinalium Decades VI." 1682.—3. "Gallicinium Medico-practicum, five, Consiliorum, Observationum, et Curationum Medicinalium novarum Centuriz duæ cum dimidia," Ulmæ 1704. Eloy. Dict. Hist.

GOCULGUR, in *Geography*, a town of Hindoostan, in the subah of Agra; 16 miles N. W. of Agra.

GOD, an immaterial, intelligent, and free being; of perfect goodness, wisdom, and power; who made the universe, and continues to support it, as well as to govern and direct it by his providence.

The Rabbins and Hebraists, particularly St. Jerom, and the interpreters, reckon up ten different names of God in Scripture; which are אֱלֹהִים, *El*, אֱלֹהִים, *Elohim*, אֱלֹהִי, *Elohi*, or in the singular, אֱלֹהִי, *Eloah*, אֱלֹהִי, *Tjebaoth*, אֱלֹהִי, *Eliou*, אֱלֹהִי, *Ehjeb*, אֱדֹנָי, *Adonai*, יְהוָה, *Jah*, אֱלֹהֵינוּ, *Shaddai*, אֱלֹהֵינוּ, *Jehovah*: but it is wrong to divide אֱלֹהֵינוּ, *Elohejebaoth*, i. e. *God of hosts*. Of these names there are three which express the essence of God, and are proper names; viz. אֱלֹהֵינוּ, *Ehjeb*, יְהוָה, *Jah*, and אֱלֹהֵינוּ, *Jehovah*: the others are only names of attributes. St. Jerom gives a particular explanation of these ten names, in his epistle to Marcella; and Buxtorf the younger has an express dissertation on the same, "Dissertatio de Nominibus Dei." The Jesuit Souciet has three several discourses on the three names, *El*, *Shaddai*, and *Jehovah*, printed at Paris, 1715. The Hebrews call the name of God בְּרֵאשִׁית אֱלֹהֵינוּ, and the Greeks, after this example, Τετραγλωσσισμος; as consisting of four letters, which it is observed to do in most languages: thus, in the Hebrew God is called אֱלֹהֵינוּ, *Jehovah*; in the Greek, Θεός; in Latin, *Deus*; in Spanish, *Dios*; in Italian, *Idio*; in French, *Dieu*; in the ancient Gaulish, *Dies*; in ancient German, *Diet*; in the Slavonic, *Buch*; in Arabic, *Alla*; in the Polish, *Bung*; in the Pannonian, *Illu*; in the Egyptian, *Tenu*; in the Persian, *Sire*; in the language of the Magi, *Orsi*. But a distinction ought here to be made between the name God, and the name of God; it being the latter, not the former, that in the Hebrew consists of four letters. The name or word God, in the Hebrew, is אֱלֹהִי, *Eloah*, which consists but of three letters; or in the plural, אֱלֹהִים, *Elohim*, which consists of five. The name of God is אֱלֹהֵינוּ, *Jehovah*; which is the true Τετραγλωσσισμος, or the name of four letters among the Hebrews and Greeks. But it is not this name that answers to the Greek Θεός, Latin *Deus*, English *God*, &c. In reality, none of these languages have any proper name of God, as אֱלֹהֵינוּ, *Jehovah*, is in the Hebrew.

M. Hallenberg, a Swedish writer, in a work published at Stockholm in 1796, and entitled "Dissertatio historica et philologica de origine nominis Dei *Gud*," &c. suggests that the names given by different nations to the deity might denote *unity*; as the word *God* itself, by which in all the Teutonic dialects the Supreme Being is denominated.

Philologists have hitherto considered the word *God* as being of the same signification with *Good*; and this is not denied by M. Hallenberg. But he thinks, that both words, originally denoted *unity*; and that the root is אָחָד *achad*, *unus*; whence the Syr. *Chad* and *Gada*; the Arab. *Ahd* and *Gabd*; the Persic *choda* and *chuda*; the Greek ἀγᾶθος, and γὰρ; the Teutonic *Gud*; the German *Gott*; and our Saxon *God*. The other names of God, this author thinks, are referable to a similar origin.

By his immateriality, intelligence, and freedom, God is distinguished from fate, nature, destiny, necessity, chance, anima mundi, and from all the other fictitious beings, acknowledged by the Stoics, Pantheists, Spinofists, and other sorts of atheists.

The knowledge of God, his nature, attributes, word and works, with the relations between him and his creatures, makes the subject of the extensive science called *theology*. In scripture God is defined by, "I am that I am; Alpha and Omega; the Beginning and End of all things."

Among philosophers, he is defined a being of infinite perfection; or in whom there is no defect of any thing which we conceive may raise, improve, or exalt his nature.

Among men, he is chiefly considered as the first cause, the first being, who has existed from the beginning, has created the world, or who subsists necessarily, or of himself.

Sir Isaac Newton chooses to consider and define God, not as is usually done, from his perfections, his nature, existence, or the like; but from his dominion. "The word God, according to him, is a relative term, and has a regard to servants; it is true, it denotes a being eternal, infinite, and absolutely perfect; but a being however eternal, infinite, and absolutely perfect, without dominion, would not be God.

"The word God," the same author observes, "frequently signifies *Lord*; but every lord is not God: it is the dominion of a spiritual being or lord, that constitutes God; true dominion, true God; supreme, the supreme; feigned, the false god.

"From such true dominion it follows, that the true God is living, intelligent, and powerful; and from his other perfections, that he is supreme, or supremely perfect; he is eternal, and infinite; omnipotent, and omniscient; that is, he endures from eternity to eternity, and is present from infinity to infinity.

"He governs all things that exist, and knows all things that are to be known: he is not eternity, or infinity, but eternal and infinite: he is not duration or space, but he endures, and is present: he endures always, and is present every where; and by existing always, and every where, he constitutes the very thing, duration and space, eternity and infinity.

"Since every particle of space is always, and every indivisible moment of duration every where, the Creator and Lord of all things can never be *nunquam*, or *indefinitum*.

"He is omnipresent, not only virtually, but also substantially: for power without substance cannot subsist. All things are contained, and move, in him; but without any mutual-passion: he suffers nothing from the motions of bo-

dies; nor do they undergo any resistance from his omnipresence.

“It is confessed, that God exists necessarily; and by the same necessity he exists always, and every where. Hence, also, he must be perfectly similar; all eye, all ear, all brain, all arm, all the power of perceiving, understanding, and acting; but after a manner not at all corporeal, after a manner not like that of men, after a manner wholly to us unknown.

“He is destitute of all body, and all bodily shape; and therefore cannot be seen, heard, or touched; nor ought to be worshipped under the representation of any thing corporeal.

“We have ideas of the attributes of God, but do not know the substance even of any thing; we see only the figures and colours of bodies, hear only sounds, touch only the outward surfaces, smell only odours, and taste tastes; and do not, cannot, by any sense, or any reflex act, know their inward substances; and much less can we have any notion of the substance of God.

“We know him by his properties and attributes; by the most wise and excellent structure of things, and by final causes; but we adore and worship him only on account of his dominion: for God, setting aside dominion, providence, and final causes, is nothing else but fate and nature.” *Newt. Philos. Nat. Princip. Math. in calce.*

An ingenious divine has wrought these thoughts of that admirable philosopher into form, and ripened them into a more express system, in a discourse on this subject. *Maxwell's Disc. concerning God.*

We shall here subjoin a compendious abstract of the principal arguments that have been alleged in proof of the existence of God. The admirable metaphysician and divine, Dr. Clarke, has demonstrated this truth, with that clearness and force of reasoning, for which he is so eminently distinguished, by a series of propositions, mutually connected and dependent, and forming a complete and unanswerable argument in proof both of the being and attributes of the Deity. 1. Something has existed from all eternity; for, since something now is, something always was: otherwise the things that now are must have been produced out of nothing, absolutely and without cause; which is plain contradiction in terms. 2. There has existed from eternity some one unchangeable and independent being: or else, there has been an infinite succession of changeable and dependent beings produced one from another in an endless progression, without any original cause at all. From without, this series of beings can have no cause of its existence, because it includes all things that are or ever were in the universe: nor is any one being in this infinite succession self-existent or necessary, and therefore it can have no reason of its existence within itself; and it was equally possible, that from eternity, there should never have existed any thing at all, as that a succession of such beings should have existed from eternity. Consequently, their existence is determined by nothing; neither by any necessity of their own nature, because none of them are self-existent; nor by any other being, because no other is supposed to exist. 3. That unchangeable and independent being, which has existed from eternity, without any external cause of its existence must be self-existent, *i. e.* it must exist by an absolute necessity originally in the nature of the thing itself, and antecedent in the natural order of our ideas to our supposition of its being. For whatever exists must either have come into being out of nothing without cause; or it must have been produced by some external cause; or it must be self-existent: but the two former suppositions are contrary

to the two first propositions. From this last proposition it follows, that the only true idea of a self-existent, or necessarily existing being, is the idea of a being, the supposition of whose non-existence is an express contradiction; and this idea is that of a most simple being, absolutely eternal and infinite, original and independent. It follows also, that nothing is so certain as the existence of a supreme independent cause; and likewise that the material world cannot possibly be the first and original being, uncreated, independent, and of itself eternal; because it does not exist by an absolute necessity in its own nature, so as that it must be an express contradiction to suppose it not to exist. With respect both to its form and matter, the material world may be conceived not to be, or to be in any respect different from what it is, without a contradiction. 4 and 5. The substance or essence of the self-existent being is absolutely incomprehensible by us; nevertheless, many of the essential attributes of his nature are strictly demonstrable, as well as his existence. The self-existent being, having no cause of its existence but the absolute necessity of its own nature, must of necessity have existed from everlasting, without beginning; and must of necessity exist to everlasting, without end. 6. The self-existent being must of necessity be infinite and omnipresent. Such a being must be every where, as well as always, unalterably the same. It follows from hence, that the self-existent being must be a most simple, unchangeable, incorruptible being; without parts, figure, motion, divisibility, and other properties of matter, which are utterly inconsistent with complete infinity. 7. The self-existent being, must of necessity be but one; because in absolute necessity there can be no difference or diversity of existence; and, therefore, it is absolutely impossible, that there should be two independent self-existent principles, such *e. g.* as God and matter. 8. The self-existent and original cause of all things must be an intelligent being. This proposition cannot be demonstrated strictly and properly *à priori*; but a *posteriori*, the world affords undeniable arguments to prove that all things are the effects of an intelligent and knowing cause. The cause must be always more excellent than the effect; and, therefore, from the various kinds of powers and degrees of excellence and perfection, which visible objects possess; from the intelligence of created beings, which is a real distinct quality or perfection, and not a mere effect or composition of unintelligent figure and motion; from the variety, order, beauty, wonderful contrivance, and fitness of all things to their proper and respective ends; and from the original of motion, the self-existent creating being is demonstrated to be intelligent. 9. The self-existent and original cause of all things is not a necessary agent, but a being endued with liberty and choice. Liberty is a necessary consequent of intelligence: without liberty, no being can be said to be an agent, or cause of any thing; since to act necessarily is really and properly not to act at all, but to be acted upon. Besides, if the supreme cause be not endued with liberty, it will follow, that nothing which is not could possibly have been; that nothing which is could possibly not have been; and that no mode or circumstance of the existence of any thing could possibly have been in any respect otherwise than it now actually is. Farther, if there be any final cause in the universe, the supreme cause is a free agent; and on the contrary supposition, it is impossible that any effect should be finite; and in every effect, there must have been a progression of causes *in infinitum*, without any original cause at all. 10. The self-existent being, the supreme cause of all things, must of necessity have infinite power; since all things were made by him, and are entirely dependent upon him; and all the powers of all things are derived from him, and perfectly sub-

je& to him; nothing can resist the execution of his will. 11. The supreme cause and author of all things must of necessity be infinitely wise. This follows from the propositions already established; and the proof *a posteriori*, of the infinite wisdom of God, from the consideration of the exquisite perfection and consummate excellency of his works, is no less strong and undeniable. 12. The supreme cause and author of all things must of necessity be a being of infinite goodness, justice, and truth, and all other moral perfections; such as become the supreme governor and judge of the world. The will of a being, infinitely knowing and wise, independent and all-powerful, can never be influenced by any wrong affection, and can never be misled or opposed from without; and, therefore, he must do always what he knows fittest to be done; that is, he must act always according to the strictest rules of infinite goodness, justice, and truth, and all other moral perfections, and more particularly, being infinitely and necessarily happy and all-sufficient, he must be unalterably disposed to do and to communicate good or happiness. See Clarke's Demonstration of the Being and Attributes of God, passim.

To this more abstruse argument *a priori*, for the existence of God, we may add another, more generally obvious, and carrying irresistible conviction, which is deduced from the frame of the universe, and from the traces of evident contrivance and fitness of things for one another that occur through all the parts of it. These conspire to prove, that the material world, which in its nature is originated and dependent, could not have been the effect of chance or necessity, but of intelligence and design. The beautiful, harmonious, and beneficial arrangement of the various bodies that compose the material system; their mutual dependence and subserviency; the regularity of their motions, and the aptitude of these motions for producing the most beneficial effects; and many other phenomena resulting from their relation, magnitude, situation, and use, afford unquestionable evidences of the creating power and wise disposal of an intelligent and almighty agent. The power of gravity, by which the celestial bodies persevere in their revolutions, deserves our particular consideration. This power penetrates to the centres of the sun and planets, without any diminution of its virtue, and is extended to immense distances, regularly decreasing, and producing the most sensible and important effects. Its action is proportional to the quantity of solid matter in bodies, and not to their surfaces, as is usual in mechanical causes; and, therefore, seems to surpass mere mechanism. But however various the phenomena that depend on this power, and may be explained by it, no mechanical principles can account for its effects; much less could it have produced, at the beginning, the regular situation of the orbs, and the present disposition of things. Gravity could not have determined the planets to move from west to east in orbits nearly circular, almost in the same plane; nor could this power have projected the comets with all the variety of their directions. If we suppose the matter of the system to be accumulated in the centre by its gravity, no mechanical principles, with the assistance of this power, could separate the huge and unwieldy mass into such parts as the sun and planets; and, after carrying them to their different distances, project them in their several directions, preserving still the equality of action and re-action, or the state of the centre of gravity of the system. Such an exquisite structure of things could only arise from the contrivance and powerful influences of an intelligent, free, and most potent agent. The same powers, therefore, which at present govern the material universe and conduct its various

motions, are very different from those which were necessary to have produced it from nothing, or to have disposed it in the admirable form in which it now proceeds.

But we should far exceed the proper limits of this article, if, confining our observation to the earth, our own habitation, we were to enumerate only the principal traces of design and wisdom, as well as goodness, which are discernible in its figure and constituent parts, in its diurnal and annual motion, in the position of its axis with regard to its orbit, in the benefit which it derives from the light and heat of the sun, and the alternate vicissitude of the seasons; in the atmosphere which surrounds it, and in the different species and varieties of vegetables and animals with which it is replenished. No one can survey the vegetable productions of the earth, so various, beautiful, and useful, nor the various gradations of animal life, in such a variety of species, all preserved distinct, and propagated by a fitted law, each fitted to its own element, provided with proper food, and with instincts and organs suited to its rank and situation, and especially with the powers of sensation and self-motion, and all more immediately or remotely subservient to the government and use of man, without admiring the skill and design of the original Former. But these are more signally manifested in the structure of the human frame, and in the noble powers and capacities of the human mind; more especially in the moral principles and faculties, which are a distinguishing part of our constitution, and lead to the perception and acknowledgment of the existence and government of God. In those instances that have now been recited, and a variety of similar instances suggested by them, or naturally occurring to the notice of the curious and reflecting mind, contrivance is manifest, and immediately, without any nice or subtle reasonings, suggests a contriver. It strikes us like a sensation; and artful reasonings against it may puzzle us, without shaking our belief. No person, for example, that knows the principles of optics, and the structure of the eye, can believe that it was formed without skill in that science, and therefore, Sturmius held that the examination of the eye was a cure for atheism; and another excellent writer, cited below, observes, that if there were no example in the world of contrivance, except that of the eye, it would be alone sufficient to support the conclusion which we draw from it, as to the necessity of an intelligent creator: nor can it be supposed that the ear was formed without the knowledge of sounds; or that the male and female, created and preserved in due proportion, were not formed for each other, and for continuing the species. All our accounts of nature are full of instances of this kind. The admirable, and beautiful structure of things for final causes exalt our idea of the contriver; and the unity of design shews him to be one. The great motions in the system, performed with the same facility as the least, suggest his almighty power, which gave motion to the earth and the celestial bodies, with equal ease as to the minutest particles; the subtilty of the motions and actions in the internal parts of bodies, shews that his influence penetrates the inmost recesses of things, and that he is equally active and present every where. The simplicity of the laws that prevail in the world, the excellent disposition of things, in order to obtain the best ends, and the beauty which adorns the works of nature, far superior to any thing in art, suggest his consummate wisdom. The usefulness of the whole scheme, so well contrived for the intelligent beings who enjoy it, with the internal disposition, and moral structure of those beings, shews his unbounded goodness. These are arguments which are sufficiently open to the views and capacities of the unlearned, while at the

same time they acquire new strength and lustre from the discoveries of the learned. The Deity's acting and interposing in the universe shew that he governs it as well as formed it; and the depth of his counsels, even in conducting the material universe, of which a great part surpasses our knowledge, tends to preserve an inward veneration and awe of this great being, and disposes us to receive what may be otherwise revealed to us concerning him. His essence, as well as that of all other substances, is beyond the reach of all our discoveries; but his attributes clearly appear in his admirable works. We know that the highest conceptions we are able to form of them are still beneath his real perfections; but his dominion over us, and our duty towards him, are manifest. See Maclaurin's Account of Sir I. Newton's Phil. Disc. book iv. chap. 9.

Those who wish to see the argument, which has been now sketched out in some of its leading outlines, more fully illustrated and urged, may consult the works of Ray, Nicuwentyt, Baxter in his *Matho*, Derham, De la Pluche in his *Nature displayed*, &c.; and more especially archdeacon Palsey in his "Natural Theology, or Evidences of the Existence and attributes of the Deity, collected from the appearances of Nature." This admirable work, if our limits would allow it, would enable us very much to enrich this article. One atheistic way, says this much approved and popular writer, of replying to our observations upon the works of Nature, and to the proofs of a Deity which we think that we perceive in them, is to tell us, that all which we see must necessarily have had some form, and that it might as well be in its present form as any. Let us now apply this answer to the eye.—"Something or other must have occupied that place in the animal's head; must have filled up, we will say, that socket; we will say also, that it must have been of that sort of substance, which we call animal substance, as flesh, bone, membrane, cartilage, &c.; but that it should have been an eye, knowing as we do what an eye comprehends, *viz.* that it should have consisted, first, of a series of transparent lenses, (very different, by the bye, even in their substances from the opaque materials of which the rest of the body is, in general at least, composed; and with which the whole of its surface, this single portion of it excepted, is covered): secondly, of a black cloth or canvas (the only membrane of the body which is black) spread out behind these lenses, so as to receive the image formed by pencils of light transmitted through them; and placed at the precise geometrical distance at which, and at which alone, a distinct image could be formed, namely, at the concurrence of the refracted rays; thirdly, of a large nerve communicating between this membrane and the brain; without which the action of light upon the membrane, however modified by the organ, would be lost to the purposes of sensation. That this fortunate conformation of the parts should have been the lot, not of one individual out of many thousand individuals, like the great prize in a lottery, or like some singularity in nature, but the happy chance of a whole species; nor of one species out of many thousand species, with which we are acquainted; but of by far the greatest number of all that exist, and that under varieties, not casual or capricious, but bearing marks of being suited to their respective exigencies; that all this should have taken place, merely because something must have occupied these points in every animal's forehead; or that, all this should be thought to be accounted for by the short answer, "that whatever was there must have had some form or other," is too absurd to be made more so by any argumentation."—"Nor does it mend the answer to add, with respect to the singularity of the conformation, that, after the event, it is no longer to be

computed what the chances were against it. This is always to be computed, when the question is, whether an useful or imitative conformation be the produce of chance or not. I desire no greater certainty in reasoning than that by which chance is excluded from the present disposition of the natural world. Universal experience is against it. What does chance ever do for us? In the human body, for instance, chance, *i. e.* the operation of causes without design, may produce a wen, a wart, a mole, a pimple, but never an eye. Among inanimate substances, a clod, a pebble, a liquid drop, might be; but never was a watch, a telescope, or organized body of any kind, answering a valuable purpose by a complicated mechanism, the effect of chance. In no assignable instance hath such a thing existed, without intention, somewhere." Some have said "that the eye, the animal to which it belongs, every other animal, every plant, and every organized body which we see, are only so many out of the possible varieties and combinations of being, which the lapse of infinite ages has brought into existence; and that the present world is the reliet of that variety."—But "there is no foundation whatever for this conjecture in any thing which we observe in the works of nature: no such experiments are going on at present! No such energy operates as that which is here supposed, and which should be constantly pushing into existence new varieties of beings; nor are there any appearances to support an opinion that every possible combination of vegetable or animal structure has formerly been tried." Should it be said that the parts of animal bodies "were not intended for the use, but that the use arose out of the parts; this distinction is intelligible."—But "there is little place for it in the works of nature. When roundly and generally affirmed of them, as it has sometimes been, it amounts to such another stretch of assertion, as it would be to say, that all the implements of the cabinet-maker's workshop, as well as his fish-skin, were substances accidentally configurated, which he had picked up and converted to his use; that his adzes, saws, planes, and gimlets, were not made, as we suppose, to hew, cut, smooth, shape-out, or bore wood with; but, that these things being made, no matter with what design, or whether with any, the cabinet-maker perceived that they were applicable to his purpose, and turned them to account." If this kind of solution "be applied to those parts of animals, the action of which does not depend upon the will of the animal, it is fraught with still more evident absurdity. Is it possible to believe that the eye was formed without any regard to vision, that it was the animal itself which found out, that though formed with no such intention, it would serve to see with; and that the use of the eye, as an organ of sight, resulted from this discovery, and the animal's application of it? The same question may be asked of the ear: the same of all the senses," none of which depend upon the election of the animal; nor consequently upon his sagacity or experience. "Others have chosen to refer every thing to a *principle of order* in nature. A principle of order is the word; but what is meant by a principle of order, as different from an intelligent creator, has not been explained either by definition or example; and without such explanation, it should seem to be a mere substitution of words for reasons, names for causes."—"Was a watch ever produced by a principle of order; and why might not a watch be so produced as well as an eye?"—"The confidence," continues the author now cited, "which we place in our observations upon the works of nature, in the marks which we discover of contrivance, choice, and design, and in our reasoning upon the proofs afforded us, ought not to be shaken, as it is sometimes attempted to be done, by bringing forward to our view our own ignorance, or rather the general imperfection of

our knowledge of nature."—"True fortitude of understanding consists in not suffering what we know to be disturbed by what we do not know. If we perceive an useful end, and means adapted to that end, we perceive enough for our conclusion. If these things be clear, no matter what is obscure. The argument is finished."—"Our ignorance of many points need not suspend our assurance of a few."—"Contrivance," says our author, "if established, appears to me to prove every thing which we wish to prove. Amongst other things, it proves the *personality* of the Deity, as distinguished from what is sometimes called nature, sometimes called a principle: which terms, in the mouths of those who use them philosophically, seem to be intended, to admit and express an efficacy, but to exclude and deny a personal agent. Now that which can contrive, which can design, must be a person. These capacities constitute personality, for they imply consciousness and thought. They require that which can perceive an end or purpose; as well as the power of providing means, and of directing them to their end. They require a centre, in which perfections unite, and from which volitions flow; which is mind. The acts of a mind prove the existence of a mind;" and that, whatever it be, in which a mind resides, is a person,—"Whenever we see marks of contrivance, we are led for its cause to an *intelligent* author. And this transition of the understanding is founded upon uniform experience."—"There may be many second causes, and many causes of second causes, one behind another, between what we observe of nature and the Deity; but there must be intelligence somewhere; there must be more in nature than what we see; and amongst the things unseen, there must be an intelligent designing author;"—"after all the struggles of a reluctant philosophy, the necessary resort is to a deity. The marks of *design* are too strong to be got over. Design must have had a designer. The designer must have been a person. That person is God." But we must content ourselves with earnestly recommending the works from which these detached extracts are made, to the perusal of our readers; for we cannot do justice to the author's admirable reasoning.

Another argument to prove the existence of God, as the creator and governor of the universe, may be deduced from the universal consent of mankind, and the uniform tradition of this belief through every nation and every age; it is impossible to conceive, that a fallacy so perpetual and universal, should be imposed on the united reason of mankind. No credible and satisfactory account can be given of this universal consent, without ascribing it to the original constitution of the human mind, in consequence of which it cannot fail to discern the existence of a deity, and to the undeniable traces of his being, which his works afford. Fear, state-policy, and the prejudices of education, to which the concurrence of mankind in this principle has been sometimes resolved, are founded on this universal principle, suppose its being and influence, and are actuated by it. It is much more reasonable to imagine, that the belief of a God was antecedent to their operation, than that it should have been produced by them; and that it was dictated by reason and conscience, independent of the passions and policy of men. The uniform and universal tradition of this belief, and of the creation of the world by the divine power, affords concurring evidence both of the principle and of the fact.

The existence of God is also farther evinced by those arguments which have been usually alleged to prove, that the world had a beginning, and, therefore, that it must have been created by the energy of divine power. In proof of this, the history of Moses, considered merely as the most

ancient historian, deserves particular regard. His testimony is confirmed by the most ancient writers among the heathen, both poets and historians. It may be also fairly alleged, that we have no history or tradition more ancient than that which agrees with the received opinion of the world's beginning, and of the manner in which it was produced; and that the most ancient histories were written long after that time. And this consideration is urged by Lucretius, the famous Epicurean, as a strong presumption that the world had a beginning.

"———Si nulla fuit genitalis origo
Terrarum et cœli, semperque æterna fuere:
Cur supra bellum Thebanum, et funera Trojæ,
Non alias alii quoque res cecinere poetæ?"

Besides, the origin and progress of learning, and the most useful arts, confirm the notion of the world's beginning, and of the common era of its creation; to which also may be added, that the world itself, being material and corruptible, must have had a beginning; and many phenomena occur to the observation of the astronomer and natural historian, which furnish a strong presumption that it could have had no long duration, and that it gradually tends to dissolution. From all these considerations we may infer the existence, attributes, and providence of God. If we admit miracles, as facts authenticated by credible history, these, considered as deviations from the established course of nature, afford independent evidence of the being of God. See *MIRACLE*.

God is also used in speaking of the false deities of the heathens, many of which were only creatures to which divine honours and worship were superstitiously paid.

The Greeks and Latins, it is observable, did not mean, by the name God, an all-perfect being, whereof eternity, infinity, omnipresence, &c. were essential attributes: with them, the word only implied an excellent and superior nature; and, accordingly, they give the appellation gods to all beings of a rank, or class, higher and more perfect than that of men; and especially to those who were inferior agents in the divine administration, all subject to the one supreme.

Thus men themselves, according to their system, might become gods, after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life.

The first divines, father Bossu observes, were the poets: the two functions, though now separated, were originally combined; or, rather, were one and the same thing. Now the great variety of attributes in God, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put these poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons: because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature. Thus the omnipotence of God came to be represented under the person and appellation of Jupiter; the wisdom of God under that of Minerva; the justice of God under that of Juno.

The first idols, or false gods, that are said to have been adored, were the stars, sun, moon, &c. on account of the light, heat, and other benefits which we derive from them. (See *IDOLATRY*.) Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then fire and water became objects of divine worship, for their usefulness to human life. In process of time, and by degrees, gods became multiplied to infinity; and there was scarce any thing but the weakness, or caprice of

some devotee or other, elevated into the rank of deity; things useless, or even destructive not excepted.

The principal of the ancient gods, whom the Romans called *dii majorum gentium*, and which Cicero calls *caelestia gods*, Varro *selecti gods*, Ovid *nobiles deos*, others *confentes deos*, were Jupiter, Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercury, Neptune, Vulcan, and Apollo. Jupiter is considered as the god of heaven; Neptune as god of the sea; Mars as the god of war; Apollo of eloquence, poetry, and phylie; Mercury of thieves, Bacchus of wine, Cupid of love, &c.

A second sort of gods, called *demigods*, *femi-dii*, *dii minorum gentium*, *indigetes*, or gods adopted, were men canonized and deified. As the greater gods had possession of heaven by their own right; these secondary deities had it by right and donation; being translated into heaven because they had lived as gods upon earth.

The heathen gods may be all reduced to the following classes:

1. Created spirits, angels, or dæmons: whence good and evil gods; Genii, Lares, Lemures, Typhones, guardian gods, infernal gods, &c.

2. Heavenly bodies; as the sun, moon, and other planets: also the fixed stars, constellations, &c.

3. Elements; as air, earth, ocean, Ops, Vesta; the rivers, fountains, &c.

4. Meteors: Thus the Persians adored the wind: thunder and lightning were honoured under the name of Geryon; and several nations of India and America have made themselves gods of the same. Castor, Pollux, Helena, and Iris, have also been preferred from meteors to be gods; and the like has been practised in regard to comets: witness that which appeared at the murder of Cæsar. Socrates deified the clouds, if we may give credit to Arilophanes; and the primitive Christians, Tertullian assures us, were reproached with the same thing.

5. They erected minerals, or fossils, into deities. Such was the Bætylus; the Finlanders adored stones; the Scythians iron; and many nations silver and gold.

6. Plants have been made gods. Thus leeks and onions were deities in Egypt; the Slavi, Lithuanians, Celts, Vandals, and Peruvians, adored trees and forests; the ancient Gauls, Britons, and Druids, paid a particular devotion to the oak; and it was no other than wheat, corn, feed, &c. that the ancients adored under the names of Ceres and Proserpina.

7. They took themselves gods from among the waters. The Syrians and Egyptians adored fishes; and the Tritons, Nereids, Syrens, &c. what were they but fishes? Several nations have adored serpents; particularly the Egyptians, Prussians, Lithuanians, Samogitians, &c.

8. Insects, as flies and ants, had their priests and votaries: these among the Thebans, and those in Acarnania, where bullocks were offered to them.

9. Among birds, the stork, raven, the sparrowhawk, ibis, eagle, griffon, and lapwing, have had divine honours; the last in Mexico, the rest in Egypt, and at Thebes.

10. Four-footed beasts have had their altars; as the bull, dog, cat, wolf, baboon, lion, and crocodile, in Egypt, and elsewhere; the hog in the island of Crete; rats and mice in the Troas, and at Tenedos; weasels at Thebes, and the porcupine throughout all Zoroaster's school.

11. Nothing was more common than to place men among the number of deities; and from Belus or Baal, to the Roman emperors before Constantine, the instances of this kind are innumerable: frequently they did not wait so long as their deaths for the apotheosis. Nebuchadnezzar procured his statue

to be worshipped while living; and Virgil shews that Augustus had altars and sacrifices offered to him, Eclog. i 6, 7. As we learn, from other hands, that he had priests called *Augustales*; and temples at Lyons, Narbona, and several other places; and he must be allowed the first of the Romans, in whose behalf idolatry was carried to such a pitch. The Ethiopians deemed all their kings gods: the Velleda of the Germans; the Janus of the Hungarians; and the Thaut, Woden, and Asa, of the northern nations, were, indisputably, men.

12. Not men only, but every thing that relates to man, has also been deified: as labour, rest, sleep, youth, age, death, virtues, vices, occasion, time, place, numbers, among the Pythagoreans; the generative power, under the name of Priapus. Infancy, alone, had a cloud of deities; as Vagetanus, Levana, Rumina, Edufa, Potina, Cuba, Cumina, Carna, Ostillago, Statulinus, Fabulinus, &c.

They also adored the gods health, fever, fear, love, pain, indignation, shame, impudence, opinion, renown, prudence, science, art, fidelity, felicity, calumny, liberty, money, war, peace, victory, triumph, &c.

Lastly, nature, the universe, or $\tau\omicron\ \pi\alpha\upsilon\varsigma$, was reputed a great god.

Hesiod has a poem under the title of $\Theta\epsilon\omicron\gamma\omicron\nu\iota\alpha$, i. e. the generation of the gods; wherein he explains their genealogy and descent; sets forth who was the first, and principal; who next descended from him, and what issue each had: the whole making a sort of system of heathen theology.

Beside this popular theology, each philosopher had his system: as may be seen from the Timæus of Plato, and Cicero De Natura Deorum.

Justin Martyr, Tertullian in his Apologetics, and in his book Contra Gentes; Arnobius, Minutius Felix, Lactantius, Eusebius, Præpar. & Demonst. Evangel. St. Augustine De Civit. Dei, and Theodoret Advers. Gentes, shew the vanity of the heathen gods.

It is very difficult to discover the real sentiments of the heathens with respect to their gods: they are exceedingly intricate and confused, and even frequently contradictory. They admitted so many superior and inferior gods, who shared the empire, that all was full of gods. Varro reckons up no less than 30,000 adored within a small extent of ground, and yet their number was every day growing. The way to heaven was so easy for the great men of those days, that Juvenal brings in Atlas complaining he was ready to sink under the load of such a number of new gods as were daily placed in the heavens: yet father Mourgues seems to have proved that all the philosophers of antiquity have acknowledged that there was but one God. GODAGARY, in Geography, a town of Bengal; 18 miles N. of Moorshedabad.

GODALMING, a market town and parish in the county of Surry, England, contains 474 houses and 3405 inhabitants. The town is built in a valley, on the banks of the river Wey, which is divided into several small streams here. The chief of these is navigable to Weybridge, where it unites its waters with the Thames. In the vicinity of the town are some corn-mills, and paper-mills. Here are several manufactories for weaving stockings, patent fleecy hosiery, and coarse woollen cloths; wool-combing and spinning of worsted also constitute part of the trade of the place. The parish

parish of Godalming is divided into nine tythings, and the whole is governed by a warden, eight assistants, and a bailiff. The church is distinguished by its handsome spire. In the town are a quakers' meeting-house, two chapels for dissenters, a charity school, and in the immediate vicinity is an hospital for the accommodation of ten poor men. A singular imposition on public credulity and curiosity was practised in this town about the year 1726. A female, named Mary Tofts, circulated a report that she was pregnant with rabbits, and also excited a very general belief that she had actually been delivered of some of these animals. The imposition, like that of "the Cock-lane ghost," was supported with so much cunning and address, that many persons, among whom were some of the faculty, were deceived, and, for some time, credited the tale. Godalming has a weekly market on Saturday, and two annual fairs. Manning's *History and Antiquities of Surrey*, folio.

GODAMA, GODEMA, Gaudma, Gotma, or Goutam, in *Indian Mythology*, different names applied in various parts of India, and particularly in the Birman empire, to their deity Budha, or Boodh. (See **BOODH**) Godama or Kodama is the most common appellation among his worshippers in India beyond the Ganges; it seems also to be common among the Hindoos, who, according to the idiom of the Sanferit, write it Gotamas. This name, as some say, literally signifies cow-herd, but metaphorically king; and, according to others, the meaning of Godama is eminently wise, or a sage. Many other appellations are given to this deity derived from the postures in which his various images represent him. Godama was probably an Indian prince, deified by superstition; and in an ancient treatise, giving an account of the religion of Godama, entitled "Zarado;" Godama is said to have attained divinity at the age of 35 years, to have preached his law for 45 years, and to have brought salvation to all living beings. Dr. Buchanan, who cites this treatise (*As. Res.* vol. vi.) places the death of Godama 546 years B. C. The doctrine and laws, said in this treatise to be delivered by Godama, consist chiefly in observing the five commandments, and in abstaining from the ten sins. The five commandments are as follow: 1. From the meanest insect up to man, thou shalt kill no animal whatever. 2. Thou shalt not steal. 3. Thou shalt not violate the wife or concubine of another. 4. Thou shalt tell nothing false. 5. Thou shalt drink neither wine, nor any thing that will intoxicate; thou shalt not eat opium, or any other inebriating drug. The person who keeps these five commandments shall attain high rank, and shall not be liable to poverty, nor to other misfortunes and calamities. The ten sins are the killing of animals— theft—adultery—falshood—discord—harsh and indignant language—idle and superfluous talk—the coveting of your neighbour's goods—envy, and the desire of your neighbour's death, or misfortune—and the following of the doctrine of false gods. Every one who abstains from these sins, will successively increase in virtue through all his successive transmigrations, till at length he will become worthy of beholding a God, and of hearing his great voice; and he will be exempted from the four human miseries, *viz.* weight, old age, disease, and death. The good works required are giving alms, and thoughtfully pronouncing three words. Whoever dies without the abstinence and good works here prescribed, will certainly pass into one of the infernal states, and be doomed to certain transmigrations. The priests of Godama are called Rahans in the Birman language, and they have also bestowed upon them the title of Somona or Samana, which is likewise applied to the images of the divinity when he is represented,

as he commonly is, in the priestly habit. (See **RAHANS**.) Godama commanded his images and relics to be worshipped. The largest and most celebrated temples are generally in the form of a pyramid; and contain some of these relics, such as a tooth, a bone, a hair, or a garment. To these temples the prayers of the devout are addressed, and their offerings presented. The images of the god are of very various materials; clay, copper, silver, and alabaster. Many of them are richly gilt, and adorned with paintings of flowers; they are of different sizes, some being not above six inches high, and others of a colossal stature. Other objects of great veneration among the worshippers of Godama are stones of large dimensions, carved with various hieroglyphics, and said to represent, or to be the impressions of his feet. The principal disciples of Godama are by his followers considered as saints; and many images of these, in a priestly habit, accompany that of their master. Every true worshipper of Godama prays before he goes to sleep, and before he rises in the morning, which is generally at the dawn of day.

Besides their private devotions, which are numerous and regularly performed, it is customary to make offerings at the temple; the seasons for which are those of the four phases of the moon, especially the full and change, which may be considered as the Birman sabbaths. Friday is with them reckoned an unfortunate day, and therefore on this day they undertake no business; but they keep holy no particular day of the week. The sect of Godama esteem the opinion of a divine being, who created the universe, to be highly impious; and accordingly the followers of Godama are, strictly speaking, atheists, as they suppose every thing to arise from fate; and their gods are merely men, who by their virtue acquire supreme happiness, and by their wisdom become entitled to impose a law on all living beings. See **BIRMAN Empire**, and **BOODH**.

GODANA, in *Geography*, a town of Persia, in the province of Irak; 105 miles E. of Ispahan.

GODAVERY, or **GONGA GODOWRY**, a river of Hindoostan, sometimes called the *Gang* in Ferishta's History, was, till very lately, considered as the same with the Cattaek river, or Mahanuddy; but it is now ascertained to be a different river, which has its source about 70 miles N.E. of Bombay; on the western Gaults, more properly called the Sukhien mountains; and, in the upper part of its course, at least, is esteemed a sacred river by the Hindoos; that is, ablutions performed in its stream have a religious efficacy superior to those performed in ordinary streams. The Godavery, after traversing the Dowlatabad soubah, and the country of Tellingana, from west to east, turns to the south-east; and receiving the Bain Gongga, about 90 miles above the sea, besides many smaller rivers, separates into two principal channels at Rajamundry; and thence subdividing again, they form altogether several tide harbours, for vessels of moderate burden. Ingeram, Coringa, Yanam, Bandarmalanka, and Narfapour, are among the places situated at the mouth of this river; which appears to be the most considerable one between the Ganges and cape Comorin. Extensive forests of teak-trees border on its banks, within the mountains, and supply ship-timber for the use of the ports above-mentioned. The Kistnah and Godavery rivers, however remote at their fountains, approach within 80 miles of each other in the lower parts of their course; and form an extensive tract of country, composed of rich vegetable mould, such as is usually found at the mouths of large rivers. Rennell. See **DELTA**.

GOD-BOTE, in our *Ancient Saxon Customs*, an ecclesiastical or church fine, for crimes and offences committed

against God. These, according to Blackstone, are *apostacy* and *heresy*: which see.

GODDARD, JONATHAN, in *Biography*, an eminent physician and chemist, was born at Greenwich in the year 1617. After studying for four years at Oxford, he set out on his travels, and on his return he settled in practice in London, having taken his degree at Cambridge. He was elected a fellow of the College of Physicians in 1646, and in 1647 was appointed lecturer on anatomy. In conjunction with some friends, he formed a society for experimental inquiry, which met at his lodgings in Wood-street, and in promoting the objects of which he was extremely assiduous. Having gained considerable reputation, and having, with the rest of his party, sided with parliament, he was appointed by Cromwell chief physician to the army, and in this capacity accompanied the usurper to Ireland in 1649, to Scotland in the following year, and thence returned with his master, who, after the battle of Worcester, rode into London in triumph, September 12th, 1651. He obtained many favours from Cromwell, who first made him warden of Merton college, Oxford, afterwards sole representative of that university in the Short Parliament in 1653; and in the same year one of the council of state. These favours were sufficient to procure for him the displeasure of Charles II.; and, being driven from Oxford, he removed to Gresham college, where he had been chosen professor of physic in November 1655. Here he continued to frequent those meetings, which gave birth to the Royal Society, and was nominated one of the first council of that institution in the charter. Dr. Goddard was a conscientious and able practitioner. Partly from the love of experimental chemistry, principally from a distrust in the knowledge of apothecaries, he prepared his own medicines, and recommended the practice to be adopted by physicians in general. Finding numerous obstacles, however, in his way, he published "A Discourse, setting forth the unhappy condition of the practice of physic in London," 1669. But this was of no avail. He died on the 24th of March, 1674, being seized with an apoplectic fit in Cheap-side, when returning from one of the philosophic meetings. Two papers of his were published in the *Philosophical Transactions*, N^o 137, 138; and many others in Birch's *History of the Royal Society*.

GODDESS, DEA, *Divia*, a heathen deity, to whom they attributed the female sex.

The ancients had almost as many goddesses as gods. Such were Juno, the goddess of air; Diana, the goddess of woods and chastity; Proserpina, the goddess of hell; Venus, of beauty; Thetis, of the sea: such also were Victory, Fortune, &c.

Nay they were not contented to make women gods, and admit both sexes into the roll; but they had also hermaphrodite gods. Thus Minerva, according to several of the learned, was both man and woman, and worshipped both under the appellation of Lunus and Luna. Mithras, the Persian deity, was both god and goddess, and the sexes of Venus and Vulcan are very dubious: whence, in the invocations of those deities, they used this formula; "Be thou god or goddess;" as we learn from A. Gellius. It was a privilege peculiar to goddesses, that they might be represented, on medals, naked. The imagination, it was supposed, must be awed, and kept from taking liberties, by the consideration of the divine character.

GODEAU, ANTHONY, in *Biography*, was born at the city of Dreux in the year 1605. He was educated for civil and active life, but having met with a disappointment in the object of his affections, he repaired to Paris, where

he cultivated the society of men of letters, and was one of the first of those who established the French academy of belles lettres. This society suggested to the cardinal Richlieu the foundation of the French academy, of which M. Godeau was an original member. He took orders in the year 1735, and having enriched his own mind with the most pure maxims of Christian morality, he taught them from the pulpit with much eloquence, and he is said to have practised them in all his actions. In the year 1636 he was, by the influence of cardinal Richlieu, nominated to the bishopric of Grasse, and from this time he divided his time between his studies, and the diligent discharge of his episcopal functions. He found the state of ecclesiastical discipline exceedingly relaxed, and set about its reformation; he personally examined the qualifications of the clergy, and enquired in what manner they discharged the important duties of their office; he frequently preached in different parts of his diocese, and exhibited in his own life an admirable model of those virtues which he was anxious to recommend to the attention of his flock. He was in high favour with pope Innocent X. who granted him bulls of union of the bishopric of Venice with that of Grasse, but when he found that the people and clergy opposed the measure, he chose rather to give up his pretensions, than break in upon the peace of the church. He died in 1672, at the age of sixty-seven years. He was a considerable writer, chiefly on subjects connected with his profession, but his most important work was "The History of the Church from the commencement of the World to the end of the Ninth Century," in three volumes, folio. This is the first ecclesiastical history written in the French language; and though composed with less precision than that of the abbé Fleury, it possesses considerable merit. It is characterized by Dupin as "exact, faithful and agreeable:" he farther adds, that it always will have a merit, which neither time, nor any other history will be able to efface. Besides the history, we may notice M. Godeau's "Paraphrases on the Epistles of St. Paul;" "The New Testament translated and explained;" "The lives of St. Paul, St. Augustine, and St. Charles Borromeo, &c." Moreri.

GODEFROI, DENYS, a very learned jurist, was born at Paris in 1549. He studied at Louvain, Cologne, and Heidelberg, and upon his return to France acquired a high reputation in the parliament, in which he was nominated to a counsellor's place. In 1580 his religious principles obliged him to seek a refuge at Geneva, where he was admitted a burgher, and a professor of the law. In 1589 Henry IV. created him bailiff of some villages at the foot of mount Jura, and a supernumerary counsellor in the parliament of Paris. After this he was deprived of his employment and his valuable library by the invasion of the duke of Savoy, and in 1594 he accepted the professorship of the law in the university of Strasburg. In 1604, at the invitation of Frederick, elector-palatine, he went to settle at Heidelberg, and in 1618 that prince sent him on an embassy to Lewis XIII., who received him with marks of high esteem. He died at Strasburg in 1622, leaving behind him many works that testify to his great learning. The titles of these are enumerated by Moreri and others, and a few of the principal may be mentioned here: "Corpus Juris civilis cum notis;" this treatise has been frequently reprinted: the best edition is said to be that from the Elzevir press in two volumes folio. "Notæ in IV. Libros Institutionum;" "Praxis Civilis ex antiquis et recentioribus Scriptoribus."

GODEFROI, THEODORE, the eldest son of the preceding, was born at Geneva in 1580. He pursued his studies first

in that city, then at Strasburg, and afterwards at Paris, where he embraced the Catholic religion. In 1643 he obtained the office of counsellor of state, and acted during the six last years of his life as counsellor and secretary to the French embassy for the general peace at Munster. Here he died in 1649. He was particularly versed in the genealogical and ceremonial history of France, and published several learned works for its illustration; such are "Le Ceremonial de France," 4to. "Mem. concernant la Prefféance des Rois de France sur les Rois d'Espagne:" "De la véritable Origine de la Maison d'Autriche:" "Traité touchant les Droits du Roi Tres-chretien sur plusieurs Etats voisins," &c. Moreri.

GODEFROI, JAMES, brother to Theodore, was born at Geneva in 1587. He followed the steps of his father by a strict adherence to the reformed religion, and by pursuing the studies of law, history, and philosophy. In 1619 he was created professor of the law at Geneva, and was called to a seat in the council in 1629. He filled with the greatest zeal and ability every public office with which he was entrusted. He was five times elected syndic of the republic, and was made secretary of state. He was chosen as a fit person to conduct various negociations in France, Piedmont, Switzerland, and Germany; and, at the same period, he devoted all his leisure to public lectures in jurisprudence, and composed a variety of learned works. He maintained a correspondence with the most learned men of the age, by whom he was greatly respected. He died in 1652, and his works bear testimony to his profound erudition, and to his great and unwearied industry; among them may be mentioned "Fragmenta Duodecim Tabularum;" "Animadversiones Juris Civilis;" "De Jure Præcedentiæ;" "Codex Theodosianus," a posthumous work, regarded as a most valuable monument of ancient jurisprudence. He edited the works of Cicero, "cum notis Lambini et Gothofredi." He had likewise made large collections for the history of Geneva, which were afterwards used by Spon. Moreri.

GODEFROI, DENYS, son of Theodore, born at Paris in 1615, was an able French historian. He was author of "Memoires et Instruções pour servir dans les Negociations et les Affaires concernant les Droits du Roi," a work, which has sometimes been attributed to the chancellor Seguier, by whose order it was compiled. He re-edited many of his father's works, adding to them new illustrations with learned notes. He continued to his own time Féron's "Hist. des Officiers de la Couronne." As a public man he was appointed in 1668 the director and keeper of the chamber of accounts at Lille in Flanders, where he died in 1681. Moreri.

GODEFROI, JOHN, son of the preceding, succeeded his father in the direction of the chamber of accounts at Lille, where he died, much advanced in years, in 1732. He published an edition of the "Memoirs of Philip de Comines," in five volumes 8vo. "The Journal of Henry III." "The Memoirs of Queen Margaret." He is said to have contributed more than any other writer to the elucidation of the affairs of the League. Moreri.

GODERVILLE, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of La Havre; 9 miles N. E. of Montvilliers. The place contains 650, and the canton 12,539 inhabitants, on a territory of 150 kilometres, in 31 communes.

GODESCHALC, in *Biography*, a Benedictine monk, who flourished in the ninth century, was born in Saxony, and was brought up, contrary to his own inclination, to the

profession, in the convent of Fulda. He was ordained priest when he was about forty years of age, and in 846 we find him at Rome visiting the holy places there; thence he proceeded to Pannonia and Dalmatia, where he commenced preaching the doctrine of predestination with much fervour, which it is supposed he imbibed from the works of St. Augustine. Upon his return to his own country he had a conference with Nothingus, bishop of Verona, before whom he maintained that God, from all eternity, had pre-ordained some to everlasting life, and others to everlasting punishment and misery. Nothingus, astonished and terrified at so daring, and, as he thought, impious a position, complained of it to Rabanus, archbishop of Mentz, who undertook to confute his error, in writing. Dissatisfied, perhaps, with his own arguments, Rabanus summoned a council to meet at Mentz, in the year 848, to which, however, Godeschalc presented a justification of his opinions, and resolutely persisted in maintaining them to be consistent with the scriptures and the sense of the orthodox fathers. The council passed sentence of condemnation upon him, and sent him prisoner to Hinemar, archbishop of Rheims, within whose jurisdiction he had received the priesthood. Hinemar, who was devoted to the interest of Rabanus, assembled a council in 849, in which the monk was a second time condemned, and rendered liable to a punishment repugnant to all the principles of religion and humanity. Godeschalc, however erroneous his sentiments might be, was not to be intimidated; he believed what he asserted, and he firmly adhered to the doctrine in spite of the higher powers. Hinemar accordingly proceeded to put the sentence into execution, degraded the monk from the priesthood, and ordered him to be scourged with the utmost severity. It appears that he was not prepared for so grievous a trial of his fortitude; the force of the pains inflicted on him obliged him, in compliance with the dictates of his persecutors, to throw into the fire the justification of his opinions which he had delivered into the council. The infamous persecutors were not contented with this triumph; they committed him close prisoner to the monastery of Hautvilliers, in the diocese of Rheims. In this, as in every other case of a similar kind, the sufferings of Godeschalc gained him followers and adherents, and many became advocates for his cause. A considerable schism was produced in the Latin church. Some confined themselves to the defence of his person and conduct, while others employed all their zeal and talents in the vindication of his doctrine. The spirit of the controversy ran so high between the contending parties, that Charles the Bald, in 853, summoned the council to meet at Quiercy. Here the suffering monk was again condemned, but the decrees of this council were declared null and void, and Godeschalc and his doctrine vindicated and defended, in a council at Valence, in Dauphiny, in 855, the decrees of which were confirmed in the council of Langres, and in that of Toufi. Such was the origin of the disputes concerning the doctrines of predestination and grace, which, from time to time, have divided the Catholic world into two parties, and which have subsisted in full force among the Protestants. The unfortunate Godeschalc died in prison about the year 869, maintaining with his last breath the doctrine for which he had suffered. The only writings of this monk that have come down to the present times are, two "Confessions of Faith," inserted in archbishop Usher's "Historia Godeschalcæ," printed at Dublin in 1641; an epistle to Ratramnus, published in Cellot's "Historia Godeschalcæ," at Paris, in 1655, and some fragments of other pieces, noticed by Cave. Godeschalc has immortalized his name by setting on foot the controversy.

and Bulgaria, taking care to abstain from those acts of hostility and rapine which characterized, and had caused the destruction of the fanatics of Peter the Hermit. It was not till June 1099, that Godfrey was able to lay siege to the renowned city, and though his army was greatly diminished in point of numbers, he was able to succeed, and on July 15th Jerusalem was taken by storm. The fanaticism and madness of the victors indulged themselves in a horrible massacre of the vanquished, which, it is believed, their general and leader was unable to prevent. Godfrey was almost immediately proclaimed sovereign of the new acquisition, but he refused to assume the title and ensigns of royalty in the place where Christ, in whose cause he was acting, had been crowned with thorns, and he governed under the modest appellation of "Defender and Baron of the Holy Sepulchre." He was soon after attacked by the sultan of Egypt, but the Christians soon put him and his numerous forces to flight, and the whole of Palestine was reduced under the power of Godfrey. He established the feudal institution in his kingdom; and a code of jurisprudence, under the title of "The Assize of Jerusalem," gave a model of the purest form of European liberty in the midst of Asiatic despotism. He died, after he had sat on the throne about a year, and was succeeded by his brother Baldwin. The celebrity of Godfrey is immortalized as the hero of Tasso's "Jerusalem Delivered," one of the noblest of epic poems; nor has the bard found it necessary to borrow the colours of fiction, in order to throw splendour round a character so truly estimable: "Godfrey," says the historian in describing his character, "was the first who ascended the walls of Rome, and his sickness, his vow, perhaps his remorse for bearing arms against the pope, confirmed an early resolution of visiting the holy sepulchre, not as a pilgrim, but a deliverer. His valour was matured by prudence and moderation; his piety, though blind, was sincere, and in the tumult of a camp he practised the real and fictitious virtues of a convent. Superior to the private factions of the chiefs, he reserved his enmity for the enemies of Christ; and though he gained a kingdom by the attempt, his pure and disinterested zeal was acknowledged by his rivals." Gibbon Univer. Hist. See also the article **CROISADE**.

GODFREY of Viterbo, an Italian historian of the 12th century, was chaplain and secretary to the emperors Conrad III., Frederick I., and Henry IV. According to his own account he was a great traveller for knowledge; and was conversant in several languages. His principal work was a "Chronicle," entitled the "Pantheon," as treating on the "Gods of Earth," is dedicated to pope Urban III., and is a general historical record from the creation of the world to the year 1186. It is written in the Latin language, and is deemed very worthy of credit for the events of his own time. It was first printed at Basil in 1559; then at Frankfurt in 1584, and afterwards at Hanover in 1613, in the collection of German historians, edited by Pistorius. Godfrey was author of a work intitled "Speculum Regum, sive de Genealogia omnium Regum:" the MS. is preserved in the Imperial library of Vienna.

GOD-GILD, in our *Ancient Customs*, that which is offered to God, or for his service.

GODHEAH, or **GOOD HOPE**, in *Geography*, a settlement in West Greenland. N. lat. 64° 25'. W. long. 50° 10'.

GODIN, **LOUIS**, in *Biography*, was born at Paris in 1704. He studied astronomy under de Pilles, and in 1725 was made adjunct of the Academy of Sciences. To him was entrusted the care of editing its memoirs, and under his direction the first eleven volumes were published. In 1735 he was sent, with other members of the academy, to measure a degree of the meridian at Peru. He was some time professor of mathematics at Lima, and on his return in 1751, he was appointed a colonel in the Spanish service, and director of the naval academy at Cadiz, where he died in the year 1760. He was author of several astronomical papers in the memoirs of the academy from 1726 to 1739; and he published "Machines et Inventions approuvées par l'Académie des Sciences," in 6 vols. 4to. "Connoissances des Temps," which he conducted five years. "Cours des Mathématiques," 1756. Gen. Biog.

GODING, or **HODONING**, in *Geography*, a town of Moravia, in the circle of Brunn; 16 miles E.S.E. of Auspetz.

GODO, a town of Arabia, on the S. coast of the Persian gulf; 140 miles W. of Julfar.

GODOUA, a small town of Fezzan; 30 miles N. of Mourzouk, and about the same distance from Sebbah, which see.

GODRA, a town of Hindoostan, and capital of a circle of the same name in Guzerat; 55 miles E. of Amedabad. N. lat. 22° 50'. E. long. 73° 45'.

GOD'S HOUSE, *League of*, a territory of Switzerland, formerly under the dominion of the bishop of Coire, until the people, oppressed by their rulers, threw off the yoke, and, forming a general league, compelled the bishop to ratify their independence. The revolution, which finally exalted this league into its present state of freedom, probably took place between 1424, the era of the formation of the Grey league, and 1436, the year in which the ten jurisdictions rose into independence. This league is denominated in Romanish "La Ligia de la Chiada," in German "Gottshausband," whence is derived the appellation of the "league of the house of God," which it takes from the cathedral situated in its capital, as well as because it was once under the jurisdiction of the bishop of Coire. This league is divided into eleven districts, each of which (Coire excepted) is subdivided into two little republics, or communities, and sends 22 deputies to the general diet. Formerly the burgo-master of Coire was perpetual chief of the league without election; but in the latter end of the 17th century the other communities claimed a power of nominating to this office in their turn. At length, by the arbitration of Zurich, it was decided, that the 22 deputies should chuse two candidates from the members of the senate of Coire, who should draw lots for the charge. The chief thus appointed is called "Bunds-president," has several privileges which distinguish him from the chiefs of the two other leagues; he receives all the letters addressed to the republic of the Grisons from foreign powers, and is perpetual president of the congress, because that assembly is always held at Coire. See **COIRE**.

The league of God's house is divided into 11 high jurisdictions, and comprehends 21 communes.

God's Mercy, *Islands of*, three or four small islands at the N.W. extremity of Hudson's straits. N. lat. 63° 45'. W. long. 73°.

GODWIN, EARL, in *Biography*, a powerful Saxon baron, was the son of Wolfnoth, governor of Suffex, and he himself, at the accession of Canute, was earl of Kent, and lord of very great possessions. When the Danish possessions of Canute were attacked by the king of Sweden, Canute took over as auxiliaries a body of English commanded by the earl of Godwin, who obtained a complete victory, which so delighted the king, that he bestowed his daughter in marriage upon him, made him large grants of land, and admitted him to the closest confidence. After the death of Canute, the succession being disputed between Harold Harefoot and Hardicanute, Godwin espoused the part of the latter, and was instrumental in preventing a civil war. It is reported that he afterwards concurred with Harold, in a plan for destroying the two English princes, sons of Ethelred II. and Emma, and the murder of one of them, *viz.* Alfred, is imputed to the vassals of Godwin. In the reign of Hardicanute the surviving prince Edward preferred an accusation against the earl for the murder of his brother, and loudly demanded justice for the crime; Godwin, to appease the king, made him a present of a galley finely gilt and decorated, rowed by fourscore men, each of whom wore on his arm a gold bracelet, weighing sixteen ounces, and they were all armed and clothed in the most sumptuous manner. Hardicanute, delighted with the spectacle, forgot his brother's murder, and on Godwin's own testimony he was allowed to be acquitted. In 1041, he was so completely reconciled to Edward, that on the death of Hardicanute he was the chief instrument of promoting him to the succession of the crown: he now acquired much influence in the state, and was created duke of Wexsex, and the counties of Kent and Suffex were annexed to his government. The friendship between Godwin and the king was not of long continuance. Upon his refusal to act against the inhabitants of Dover, who had incurred Edward's displeasure, he was threatened with the royal vengeance. The earl, feeling his own power, actually excited a rebellion against his sovereign. Edward now summoned to his aid the dukes of Northum-

berland and Mercia, and being thereby superior to Godwin and his sons, he marched to London and summoned a great council to pass judgment upon the rebels. Godwin, with three of his sons, took refuge with Baldwin earl of Flanders, while Harold and another fled to Ireland. Godwin, after many misfortunes, sailed with a powerful force to London, and forced the king to an accommodation: Edward consented to banish his Norman favourites, who had been, in a great measure, the cause of the discontents, and Godwin and his sons were restored to their estates, and the high offices which they had formerly held. Godwin's death, which happened soon after this, while he was sitting at table with the king, prevented him from making farther inroads on the sovereign's authority, or from reducing him to still greater subjection. He was succeeded in the government of Wexsex, Suffex, Kent, and Essex, and in the office of steward of the household, by his son Harold, who was actuated by an ambition equal to that of his father, and was superior to him in address, in insinuation, and in virtue. With respect to Godwin, his character is blackened by the monkish historians, who pretend that his sudden death was the effect of a miraculous interposition from heaven. With great abilities, Godwin possessed an ambitious spirit, which rendered him a subject of wavering fidelity, and made him but little scrupulous in means that tended to his aggrandizement. Hume's Hist. vol. i. Biog. Brit.

GODWIN, THOMAS, was born at Oakingham, in Berkshire, in 1517, where he received at the free-school the elements of a learned education. His rapid proficiency in grammar-learning attracted the notice, and secured to him the patronage of Dr. Layton, archdeacon of Bucks, who received him into his house, and took care of his farther instruction. In 1538, he was sent by his friend and patron to Magdalen college, Oxford: here he pursued his studies, and in 1543 he took his degree of B. A. and in the following year he was elected fellow of his college, which rendered him independent of the pecuniary assistance of his friends. His steady regard to the principles of the reformation rendered his situation at college in many respects very uneasy, and he gladly embraced the opportunity of a vacancy in the mastership of the free-school of Brackley in Northamptonshire, which

which was in the gift of the college, to resign his fellowship. He retired to this situation in 1549, and having married, continued there peaceable and happy during the reign of king Edward, devoting what time he could spare from the duties of his office to the study of theology and physic, and on the accession of Mary, he became an object of Bonner's fury, and was obliged to resign his school, and turn his attention to physic. By the practice of this, he maintained his family till Elizabeth ascended the throne. He now resolved to follow the bent of his inclination, devoted his whole time to theological studies, was admitted to holy orders, and appointed chaplain to the bishop of Lincoln. He was shortly after introduced to the queen, who made him one of the Lent preachers. This post, which was probably attended with little emolument, he filled eighteen years, with very high reputation, during which he received no preferment in the church; but, in 1565, he was promoted to the deanery of Christ-church, Oxford, and in the same year a prebend was conferred on him. In 1566, he was advanced to the deanery of Canterbury, and attended the queen in her visit to the university of Oxford, on which occasion he took his degree of D.D. with great applause. In 1584, after eighteen years residence at Canterbury, he was nominated by the queen to the vacant see of Bath and Wells. This honour did not augment the happiness of Dr. Godwin: in resisting the unjust claims of one of Elizabeth's favourites, he lost the favour of the queen herself, which so affected his mind, as to render him incapable of performing his episcopal functions. The affairs of his diocese, being left to the management of others, fell into such disorder, that his metropolitan, archbishop Whitgift, thought proper to visit it in the year 1587. At this time Dr. Godwin's health was in a very bad state, and he gradually became worse till he sunk under the effects of disease, in his seventy-third year. He is highly spoken of for learning and unaffected piety, and was beloved and respected for his cheerful hospitality, benevolence, and charity. *Biog. Brit.*

GODWIN, FRANCIS, the son of the preceding, was born at Havington, in Northamptonshire, in the year 1561, and having been carefully educated in grammar learning, he was sent to Christ-church college, Oxford, when he was in his sixteenth year, and in 1578 he was elected a scholar of that institution. In 1580, he took his degree of B.A., and three years after he proceeded to his degree of M.A. About this time he wrote an entertaining philosophical fiction, which he did not at that period publish, because it contained ideas at variance with the systems then prevalent in the schools. It was given to the world five years after his death, under the title of "The Man in the Moon, or a Discourse of a Voyage thither by Domingo Gonzales." The hints, conjectures, &c. contained in this piece, prove that the author was not ignorant of the writings of Copernicus, and was probably a convert to his doctrines. In 1587, he was a canon in the cathedral church of Wells, and promoted to the subdeanery of Exeter. The history and antiquities of his country became favourite subjects of his enquiries, and in the year 1590 he accompanied the celebrated Camden into Wales, in search of objects to illustrate them. In 1595, he took the degree of doctor in divinity, being in possession of very considerable and lucrative preferment in the church. He published, in 1601, "A Catalogue of the Bishops of England, since the first Planting of the Christian Religion in this Island, together with a brief History of their Lives and memorable Actions, so near as can be gathered out of Antiquity." As a reward for the great diligence used in the composition of this catalogue, the queen promoted him, the same year; to the

vacant see of Landaff; being allowed to retain, in connection with the bishopric, the subdeanery of Exeter, and a good rectory in the diocese of Bath and Wells. He now employed himself in improving his "Catalogue," and in making collections relative to civil and ecclesiastical history. In 1615 he published a new edition of his "Catalogue," to which he prefixed a discourse "Concerning the first Conversion of our Britain unto the Christian Religion." It was afterwards republished in Latin, under the title of "De Præfulibus Angliæ Commentarius." In the same year he published "Rerum Anglicarum Henrico VIII., Edwardo VI., et Maria, regnantibus, Annales," which was much admired for the elegance of the style. By king James he was translated from Landaff to the bishopric of Hereford in the year 1617, and from this period, he devoted such time as the discharge of his episcopal functions would permit, chiefly to the improvement of his former works; but in 1629 he published a discourse on the several methods of conveying secret and speedy intelligence, with the title of "Nuncius Inanimatus, Utopia." It has been suggested that this was written in obscure and enigmatical language, with a design of concealing the author's secret; but from certain expressions, it should seem, that the hints contained in it might have led to an earlier establishment of public telegraphs. Besides several editions of the *Annales*, and a translation into English of the same work, we have a learned dissertation by the bishop, on the value of the Roman sesterce and attic talent, which was printed at the end of Hakewell's "Apology of Divine Providence." This was his last labour in the field of literature. He died in 1633 in his seventy-second year. Of his learning and classical taste, his works bear most decisive evidence, and they exhibit him as a zealous friend to the establishment, of which he was a member. According to Anthony Wood, "he was a good man, a grave divine, a skillful mathematician, an excellent philosopher, a good preacher, and a strict liver; but so much employed in his studies and matters of religion, that he was a stranger to the world and the things thereof." *Biog. Brit.*

GODWIN, THOMAS, a learned English divine and writer on Jewish antiquities, was born in Somersetshire in the year 1587. In his fifteenth year, he was sent from the grammar-school to Magdalen-hall, in the university of Oxford, where he was entered a scholar. Here, in due course, he took his degrees, and soon after was chosen master of the free-school at Abingdon, in Berkshire. In this situation he distinguished himself by his diligence and assiduity in forming good scholars, who afterwards became eminent in various departments of literature, and in posts of honour and emolument in the church and state. In 1613 he published "Romanæ Historiæ Anthologia,"—an English exposition of the Roman antiquities, which went through several editions. Shortly after this, he entered into orders, and was appointed chaplain to Dr. James Montague, bishop of Bath and Wells, and in 1616 he was admitted to the degree of bachelor of divinity, and published a work, entitled "Synopsis Antiquitatum Hebraicarum ad Explicationem utriusque Testamenti valde necessaria, &c." lib. 3. 4to. About this period he resigned his school, upon obtaining a presentation to the rectory of Brightwell, near Wallingford, in Berkshire. In the year 1625, he published the work by which he is chiefly known, *viz.* "Moses and Aaron; civil and ecclesiastical Rites, used by the ancient Hebrews, observed, and at large opened, for the clearing of many obscure Texts, throughout the whole Scripture." This work was immediately regarded as a standard book in our places of academical education, and has been repeatedly printed. In 1656, Mr. Godwin was admitted to the degree of doctor of divinity. He died

in 1642. Besides the works already noticed, Dr. Godwin was the author of "Florilegium Phrasicon,"—or A Survey of the Latin Tongue. And Three Arguments to prove election upon foresight of faith. Gen. Biog.

GODWIN, or *Goodwin Sands*, in *Geography*, a bank in the sea, about five miles from Deal, near the coast of Kent, England, were formerly part of the estate of the celebrated earl Godwin, but were separated and overwhelmed by a sudden inundation of the sea, about the end of the eleventh century. These sands are frequently fatal to mariners, but, notwithstanding, are of considerable use, as it is by them alone that the Downs are constituted a road or harbour for shipping. In all easterly winds they serve as a pier, or break-water, and greatly mitigate the force and immensity of the waves, which, in stormy weather, would otherwise roll upon this shore with unabated fury. The sands extend in length about ten miles; the north sand-head being nearly opposite to Ramsgate, and the south sand-head to Kingfdown. The danger of striking upon them arises from their nature, which Mr. Smeaton describes as that of a quick-sand, clean and unconnected, yet lying so close, as to render it difficult to work a pointed bar to the depth of more than six or seven feet. Their ingurgitating property is so powerful, that even the largest vessel driven upon them would, in a few days, be swallowed up, and seen no more. At low-water they are in many parts dry, and parties frequently land upon them; but when the tide begins to flow, the sand becomes soft, and is moved to and fro by the waves. The largest portion of this bank which becomes dry, is known to seamen by the name of the Jamaica island. Some years ago, in order to prevent the many accidents which occur to shipping on these sands, the Corporation of the Trinity-house formed the design of erecting a light-house on them; but after the sand had been penetrated by boring augers to a great depth, the scheme was given up as impracticable, as no solid foundation could be obtained. Floating lights have, however, been placed off these sands, consisting of three distinct lights in the form of a triangle, of which the middle one is considerably the highest; when they are obscured in hazy-weather, a bell is kept constantly ringing.

GODWIT, in *Ornithology*. See *SCOLOPAX Aegoccephala*.

GODWIT, *Great*, or *American*. See *SCOLOPAX Fedoa*.

GODWIT, *Lesser*. See *SCOLOPAX Limosa*.

GODWIT, *Red*. See *SCOLOPAX Lapponica*.

GODWIT, *White*. See *RECURVIROSTRA Alba*.

GOELANS, **POINT AU**, in *Geography*, a promontory on the N. side of lake Ontario; about 33 miles S. W. of fort Frontinac.

GOELHEIM, a town of France, in the department of Monte Tomerrie, and chief place of a canton, in the district of Kaiferlautern. The place contains 860, and the canton 4999 inhabitants, in 16 communes.

GOELICKE, **ANDREW ORTON**, in *Biography*, a German physician, who acquired considerable reputation at the beginning of the eighteenth century, and taught the science of medicine at Halle, in Saxony, and at Franckfort on the Oder, with distinction. His writings were in high estimation among the followers of the doctrines of Stahl, of whom he was one of the ablest defenders. Nothing more is known respecting his life. He left several works, which relate principally to the history of anatomy, of ancient and modern surgery, and of medicine. His "Historia Medicinæ Universalis, quæ celebriorum quorumcumque Medicorum, qui a primis Artis natalibus ad nostra usque tempora incluserunt, vitæ, nominum, dogmata singularia, ratiocinia, hypothesef, sectæ, &c. accurate pertractantur," was printed in six different portions or

epochs, between the years 1717 and 1720. The first four brought down the history to Hippocrates; the fifth treated of the Hippocratic medicine alone; and the last part included a sketch of the descendants of the father of medicine, until the time when the art was divided into three professions. Eloy. Dict. Hist.

GOELL, in *Geography*, an island of Denmark, in Lymford gulf, about 10 miles in circumference; on which are a town and a village or two; 6 miles W. of Aalborg. N. lat. 57° 5'. E. long. 9° 49'.

GOELMA, a port of Egypt, in the Red sea, capable of accommodating only small vessels.

GOELWARA, a circar of Hindoostan, in Guzerat, on the W. coast of the gulf of Cambaye.

GOEREE, **WILLIAM**, in *Biography*, who flourished in the 17th century, was born at Middleburg, in Zealand, in the year 1635. He had a decided turn for literature, but by the death of his father while very young, he was consigned to the care of an illiterate step-father, who would not permit him to pursue the bent of his mind. Being obliged to fix upon a trade, instead of studying for one of the learned professions, he fixed on that of a bookfeller, as that which he imagined best adapted for the improvement of his leisure hours in the acquisition of knowledge. His various works will shew how well he filled his time, and to what advantage he turned those intervals from occupation, which are too frequently spent in listlessness or devoted to pleasure. He died at Amterdam in 1711, leaving his "Jewish Antiquities," in two volumes, folio. "The History of the Jewish Church," in four volumes folio. "History Sacred and Profane." "An Introduction to Painting." "A Treatise on Architecture;" and some other useful works. Moreri.

GOERZEOD GHEZERE, in *Geography*, a town of Asiatic Turkey, in Natolia; 25 miles S. of Sinob.

GOES, a town of Portugal, in the province of Beira; 9 miles E. of Coimbra.—**ALIO**, a town of Holland, in Zealand, called "Ter-Goes," situated on the N. coast of the island of South Bevelandt, on an arm of the Scheldt, with which it is connected by means of a canal. The great church is a handsome structure; and though the town is not large, it carries on a considerable trade, particularly in salt and grain; 10 miles E. of Flushing. N. lat. 51° 33'. E. long. 3° 46'.

GOETIA, *Goniesæ*, a species of magic, opposed to Theurgia, the object of which was mischief; and accordingly it invoked only the malevolent geni.

GOEZ, **DAMIANA**, in *Biography*, a learned Portuguese, of the 16th century, was born at Alenquer, and educated in the court of the king Emanuel, to whom his brother was gentleman of the chamber. He was, as he advanced in life, employed in various negotiations from his court to the court of France, Germany, Poland, and the Low Countries. In 1534, we find him at the university of Padua, in which he studied some years under Buonamico, and contracted a friendship in Italy with Bembo, Sadoleto, and other great men. He carried forward his studies at Louvain, where he fixed his residence after his marriage, and was the principal means of defending the city against the attack of Martin van Rossem. He was, however, seized by the enemy, under the pretence of a violation of the truce, and obliged to ransom himself. He was after this recalled by the king of Portugal, who wished to employ him to write the history of that country. The materials put into his hands were in so confused a state, and so scanty in regard to quantity, that he was able to perform but a small part of the task. He was malignantly accused, arrested, and thrown into prison. At length, as there was nothing found against him, he was liberated, and return-

ed to his own dwelling, where he was shortly after found burnt to death, the consequence, probably, of an apoplectic fit. His works are, "Legatio magni Indorum Imperatoris ad Emanuelem Lusitanæ Regem." "Fides, Religio, Moreque Æthiopum." "Hispaniæ Laudatio." "Urbis Lovaniensis Obsidio." "Comment Rerum Gestarum in India à Lusitanis." "Urbis Ulyssiponenfis Descriptio." "Historia del rey Dom. Manuel." "Chronica de Principe D. Juao II." Moreri.

GOEZE, JOHN AUGUSTUS EPHRAIM, was born at Ascherlen in the year 1731, where he received the elements of a learned education. He was afterwards sent to Halle to pursue his studies preparatory to the exercise of the profession of preacher. In 1751 he settled in that capacity at Quedlingburg, which he retained till the period of his death. It was not till he was about forty years of age that he turned his attention to the microscope and natural history, for his skill in which he afterwards became so famous. At first he made use of his microscope only for amusement, but in a short time he possessed himself of the very best instruments of the kind that had been manufactured, and his researches led him to the study of the natural history of insects. Baker's description of certain water insects induced him to explore the ditches, rivulets, and ponds. He wrote down his observations for his own private use, and caused many of the objects which he saw to be delineated. The facts thus collected he published in the Hanoverian magazine, which attracted the notice of the learned, from whom he received many flattering and highly complimentary letters on the subject. He translated Bonnet's treatise on insectology, which met with a very favourable reception from naturalists. He set out without regard to system or order, but soon found that systematic knowledge was necessary in his pursuits; and completely acquainted himself with the Linnæan arrangement; and his "Entomological Collections" were intended as a supplement to the works of the Swedish naturalist. The next considerable work of Goetze was on the natural history of intestinal worms, which he published in quarto in 1782. This work contributed greatly to increase his reputation as a naturalist, and entitles him to an honourable place among the discoverers of modern times. The interest which he took in the education and improvement of his own children led him to publish some works on natural history, intended particularly for young persons in general, and being a very agreeable as well as learned writer, his productions were all well received, and to his honour it must be spoken that he never forgot to inculcate the duties of religion and morality while he was descending on the wonders of the natural world. After he had communicated to the public the result of his observations on intestinal worms, he sent his collection to Pavia, where it was sold for a thousand dollars. His fame, however, had extended much beyond his own country, and within a very few weeks after he had parted or at least agreed to part with his curious collection for the above named price, he received a letter from Dr. Hunter, offering him nearly double the sum for it. He died in June 1786. Gen. Biog.

GOFABAD, in *Geography*, a town of Persia, in the province of Irak: 55 miles E. of Isfahan.

GOFFE. See GEOFF.

GOFFSTOWN, a town of America, in Hillsborough county, New Hampshire, situated on the western bank of Merrimack river, 3 miles from Amulkeag falls, or 60 miles W. of Portsmouth. It was incorporated in 1761, and contains 1612 inhabitants.

GOG and MAGOG, in *Scripture History*, are names gene-

rally connected in the sacred writings. (See Ezek. xxxviii. 2, 3, &c. xxxix. 1, 2, Rev. xx. 8.) Moses (Gen. x. 2) speaks of Magog, the son of Japheth, but says nothing of Gog. According to Ezekiel, (ubi supra,) Gog was prince of Magog; the latter signifying the country or people, and the former, the king of it. The ancients generally represent Magog as the father of the Scythians or Tartars; and traces have been found of the name in the provinces of Great Tartary. Others say that the Persians are descendants of Magog; and to this purpose people have been found there called Magusians, and philosophers called Magoi or Magi. Some have imagined that the Goths were descended from Gog and Magog: and that the wars described by Ezekiel, and undertaken by Gog against the saints, are those which the Goths carried on, in the 5th century, against the Roman empire. Bochart has placed Gog in the vicinity of Caucasus; and he derives the name of this celebrated mountain from the Hebrew גֹּג־כַּסְפָּן, gog-casfan, the fortress of Gog. He also says, that Prometheus, said to be chained to Caucasus, is Gog; and it may be observed, that there is a province in Iberia S. of Caucasus, called the Gogarene. Most persons are of opinion, that Gog and Magog, in Ezekiel and the Revelations, are taken, allegorically, for such princes as were enemies to the church. Accordingly many, by Gog in Ezekiel, understand Antiochus Epiphanes, the persecutor of the Jews; and Gog in Revelations, they suppose to represent Antichrist. Calmet apprehends that the Gog of Ezekiel and Canbyfes, king of Persia, were the same persons. The Arabians are of opinion that the descendants of Gog and Magog inhabit the northern parts of Asia, beyond the Tartars and Sclavonians: and hence it is probable that Gog and Magog, according to the notions of the Arabians, formerly inhabited the mountains of the Hyperboreans, and that they were known to the ancients by this name. This nation is unquestionably famous in antiquity, and there is reason for imagining, that they were some of the Scythians, and confounded among the Great and Little Tartars, and perhaps among the Muscovites, and other northern people. Calmet.

GOG-MAGOG Hills, in *Geography*, hills so called, about three miles from Cambridge, remarkable for the intrenchments and other works found there, and supposed by some to be a Roman camp, and by others, a work of the Danes.

GOGA, a town of Abyssinia; 30 miles S. of Gondar — Also, a small town of India, on the western side of the gulf of Cambaya, about 28 or 30 leagues from Cambaya, abounding with banians and sea-men.

GOGARD, a town of Sweden, in East Gotland, 23 miles N.N.W. of Linkioping.

GOGARENA, in *Ancient Geography*, a country of Asia, in Armenia. Strabo.

GOGARY, in *Geography*, a town of Bengal; 24 miles N.W. of Boglipour. N. lat. 25° 26'. E. long. 86° 36' — Also, a town of Hindoostan, in Bahar; 10 miles N. E. of Monghir.

GOGAVINUS, ANTONIUS GRAVIENSIS, or ANTHONY GOGAVIN DE GRAVI, in *Biography*, a laborious writer, who, according to the insinuations of the famous Helms, published *in corpore* all the ancient authors on medicine, at Venice, 1562, 4to.

His compilation contains the books of Aristotenus and Ptolemy, and the fragment of Aristotle, with the Commentary of Perphyry, the whole enriched with notes by Bottrigari. See MELBOMIUS, and BELTRIGARI.

GOGET, in *Ichthyology*. See GENUS *Ajzer*.

GOGGLES, in *Rural Economy*, a morbid affection in sheep,

Sheep, which is sometimes extremely destructive to them. It is suggested in the Bath papers as first shewing itself, by a dropping of the ears, and frequent rubbing of the tail; but not to have any relation or affinity to giddiness, as the sheep do not run round as in that disease. It appears to have the greatest resemblance to the disorder called the staggers in lambs; but differs inasmuch, as that the itaggery lambs display weakness before, and of course fall in that direction, while the goggly sheep shew weakness behind, and when forced to run fall backwards. Sheep under this disorder constantly get poorer and poorer, and become more weak, until they are not able to drag their limbs after them, and consequently die. Some have contended that it is a disease of the paralytic kind, and that the seat of the complaint is in the spinal marrow. It was formerly either wholly unknown, or unattended to by sheep-farmers, as it is never mentioned.

Hitherto no satisfactory method of cure has been pointed out for the disease, but warmth and frequent change of pasture have been found beneficial in it.

GOGGLES, in *Surgery*, are instruments used for curing squinting, or that distortion of the eyes which occasions this disorder. They are short conical tubes, composed of ivory stained black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the day-time, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forwards; and by these means the cure will be sooner or later effected. Warner on the Eye, p. 32.

GOGMOW, in *Geography*, a town of Hindoostan, in Oude; 35 miles N. of Maniakpour.

GOGO. See **GOGA**.

GOGODUNGA, a town of Bengal, on a small island formed by a branch of the Hoogly; 45 miles S. of Calcutta.

GOGOROMOW, a town of Guzerat, on the coast; 50 miles W. S. W. of Noanagur.

GOGRA, also called *Devah* and *Soorjezo*, a river of Hindoostan, which proceeds from a lake named Laukedhe, having to the E. of it another larger lake, named Manfawar, both situated on the western side of Thibet, and forces its way through the vast ridge called Himmaleh, and afterwards joins the Ganges. See **DEWAN**.

GOGUET, ANTONY-YVES, in *Biography*, was born at Paris in 1716, where his father was an advocate. He himself became a counsellor to the parliament. By close study and by great assiduity in his pursuits, he produced in the year 1758, a work that has obtained a high reputation, and which has been translated into the English and other languages. It is entitled "Origine des Loix, des Arts, des Sciences, et de leur Progrès chez les anciens Peuples," in three volumes 4to. It was printed in 1778, in six volumes 12mo. This work treats of the origin and progress of human knowledge, from the creation to the age of Cyrus, and displays much erudition in historical discussions, though less of science and philosophy than might have been expected. He died of the small-pox almost immediately after the publication of this valuable work. He was a man of much private worth, modest and unassuming. He had begun another work on the Origin and Progress of the Laws, Arts, Sciences, &c. in France, from the commencement of the monarchy.

GOHANNA, in *Geography*, a town of Hindoostan, in Ballogistan; 54 miles W. S. W. of Delhi.

GOHEE, a town of Hindoostan, in Babar; 35 miles W. N. W. of Saferam.

GOHUD, a circar of Hindoostan, in the soubah of Agra, lying on the right side of the river Jumnah. It is bounded on the N. by the Chumbal, on the E. by Dooab and Oude, on the S. by Bundelcund, and on the W. by Rantampour and Cottah.--Also, a town of this circar, the revenues of which are estimated at 20 or 30 lacks of rupees per annum; 55 miles S. E. of Agra. N. lat. 26° 24'. E. long. 78° 44'.

GOJAK, a town of Croatia, on the river Mrefnuitza; 18 miles S. of Carlstadt.

GOJAM, a province of Abyssinia, about 80 miles in length, and 40 in breadth. It is a very flat country, altogether appropriated to pasture; it has few mountains, but these are very high, and are chiefly on the banks of the Nile, to the south, which river surrounds the province. Gojam is full of great herds of cattle, which are the largest in the high parts of Abyssinia. The country is populous, but the men are in the lowest estimation as soldiers. The Jesuits were settled in many convents throughout the province, and are held in the utmost detestation. The monks are those of St. Eustatius, which may be called the Low Church of Abyssinia; they are said to be much inclined to turbulence in religious matters, and are, therefore, always made tools by discontented people who have no religion at all. On the S. E. of Gojam is Damot; which see. Bruce.

GOIAS. See **GOYAS**.

GOIAVA, a town of Africa, on the Grain coast; 25 miles S. E. of Grand Sesto.

GOJEIDA, or **GOGIDA**, a town of Algiers; 90 miles S. E. of Oran.

GOING, in the *Manege*, called in French *alleure*, is the pace or gait of a horse.

GOIT, **GURT**, *Gorl*, *Leat*, &c. are names for a ditch or trench for conveying water, used by engineers and miners of different districts.

GOITO, in *Geography*, a town of Italy, in the department of the Mincio, situated on the river Mincio, between the lake of Mantua and that of Garda; 9 miles N. N. W. of Mantua.

GOITRE, or **GOUTIER**, in *Surgery*, names sometimes applied to a morbid enlargement of the thyroid gland. See **BRONCHOCELE**.

Persons labouring under this complaint are found in various mountainous districts of Europe, in China, in Bootan, and many other regions of the East, in Sumatra, &c. (See **CRETINS**.) Turner, in his "Account of an Embassy to Tibet," says, that in Bengal this unsightly tumour is known by the name of "Gheig," and "Aubi," and in Bootan is called "Ba," or "Ke Bá," the neck-swelling, and that it forms itself immediately below the chin, extending from ear to ear, and sometimes growing to such an enormous size, as to hang from the throat down upon the breast. It is particularly observable, he says, among the inhabitants of the hills of Bootan, immediately bordering upon Bengal, and in the tract of low country watered by the rivers that flow from them to the south, beyond the space of a degree of latitude. The same malady prevails among the people inhabiting the Morung, Nipal, and Almora hills, which, joined to those of Bootan, run in continuation, and bound, to the northward, that extensive tract of low land embraced by the Ganges and the Berhampooter. The same disease is also more particularly met with in the low lands adjoining to these hills. From the frontier of Affam, N. lat. 27°. E. long. 91°, it is to be traced through Bijne, Gooch Bahar, Rungpore, Dinagepore, Purnea, Tirreoto, and Betiah;

along the northern boundary of Oude, in Gooracpore, Barraitch, Pillibeat, and on the confines of Rohileund, to Hurdewar, situated in N. lat. 30°. E. long. 78° 25'. It has the effect, he adds, or rather is accompanied with the effect, arising from the same cause, of debilitating both the bodies and the minds of those who are affected with it. Marsden, in his "History of Sumatra," observes, that it has been usual to attribute this affection to the badness, thawed slate, mineral quality, or other peculiarity of the waters: "My experience," he adds, "enables me to pronounce without hesitation, that the disorder, for such it is, though it appears here to mark a distinct race of people, (*orang goonong*.) is immediately connected with the hilliness of the country, and, of course, if the circumstances of the water they use contribute thereto, it must be only so far as the nature of the water is affected by the inequality or height of the land. But in Sumatra neither snow nor other congelation is ever produced, which militates against the most plausible conjecture that has been adopted concerning the alpine goitres. From every research that I have been enabled to make, I think I have reason to conclude, that the complaint is owing, among the Sumatrans, to the fogginess of the air in the vallies, between the high mountains, where, and not on the summits, the natives of these parts reside. I before remarked, that between the ranges of the hills, the "caboot," or dense mist, was visible for several hours every morning; rising in a thick, opaque, and well-defined body, with the sun, and seldom quite dispersed till afternoon. This phenomenon, as well as that of the wens, being peculiar to the regions of the hills, affords a presumption that they may be connected; exclusive of the natural probability that a cold vapour, gross to an uncommon degree, and continually enveloping the habitations, should affect with tumours the throats of the inhabitants. I cannot pretend to say how far this solution may apply to the case of the goitres, but I recollect it to have been mentioned, that the only method of curing these people is by removing them from the vallies to the clear and pure air on the tops of the hills; which seems to indicate a similar source of the distemper with what I have pointed out. The Sumatrans do not appear to attempt any remedy for it, the wens being consistent with the highest health in other respects."

GOKAUP, in *Geography*, a town of Hindoostan, in Visiapour; 16 miles S.S.E. of Raiboug.

GOKIA, a town of Turkish Armenia; 30 miles E.S.E. of Akalzick.

GOLABAD, a town of Persia, in the province of Irak; 45 miles E. of Ispahan.

GOLAH, a town of Hindoostan, in Bahar; 10 miles E. of Ramgur.

GOLAN, a town of the duchy of Warfaw; 10 miles N.E. of Posen.

GOLAPILLY, a town of Hindoostan, in the circar of Guntoor; 10 miles W. of Inaconda.

GOLAWARRY, a town of Bengal; 48 miles N.W. of Midnapour.

GOLCONDA, a province of Hindoostan, part of the possessions of the Nizam, or Soubah of the Deccan, our firm ally, corresponds to the ancient province of Tellingana, or Telling, situated between the lower parts of the courses of the Kuluah and Godavery rivers; and is bounded on the N. by Berar, on the E. by the Circars, on the S. by the Mysore country and the Carnatic, and on the W. by Dowlatabad and Visiapour. It takes its name from a famous fortress. The kings of this country were, at a former time, immensely rich and powerful; as they maintained in their pay 500,000 soldiers, and derived very large revenues from

their lands, customs of merchandizes and provisions, but chiefly from the diamond mines, for which this country has been singularly famous. The winter in Golconda begins in June with rain and thunder; the rain pouring down, accompanied by violent storms of wind, till the middle of July, with occasional intervals of fine weather. In August, September, and October, the rains again fall, and very much swell the rivers. These rains render the land exceedingly fertile, particularly in fruits. Vines are plentiful, and of the grapes, which ripen in January, they make white wine. Two crops of rice are produced annually, and the country affords other kinds of grain. The capital of Golconda is Hydrabad.

GOLCONDA is also the name of a fortress, surrounded by stone walls and deep ditches, which was formerly the residence of the kings of the country. This fortress, on account of its extent, might be denominated a city; a hill rose in the middle of it like a sugar-loaf, and the sides of it were encompassed by the king's palace, which was very large and well situated for air, and which had a good view of Hydrabad. When Aurungzebe conquered the kingdom of Golconda in 1687, this fortress was taken by treachery; the king offered to pay a tribute of 3,700,000 rupees, and become the vassal of the conqueror; but he refused, and entered the palace in triumph.

GOLD. *Gold*, Germ.; *Guld*, Swed. Dan.; *Or*, Fr.; *Arany*, Hung.; *Soloto*, Russ.

Mineralogical Description.—This metal never having been found in a mineralized state, we are acquainted with one species only, namely,

Native gold, which is subdivided by Werner into three sub-species, viz. *gold-yellow*, *brass-yellow*, and *greyish-yellow gold*. Though this subdivision may appear arbitrary, and not founded on constant characters exclusively belonging to each of the above varieties or sub-species, it is nevertheless entitled to attention, since colour, however unimportant it may be in the classification of earthy fossils, constitutes a character of considerable value in native metallic substances, the range of whose colours is confined to a narrow compass. But also their geognostic relation appears to constitute a distinction, at least between the two first of the Wernerian sub-species; for as to the third, or the *greyish-yellow gold*, its claims to be kept separate from the two others appear doubtful: all we know of it is its being found in small flat particles, along with that mixture of different metals called platinum in grains, of whose colour it partakes in general, and with which it is supposed to have occurred also originally under the same geognostic relations.

1. *Light or Brass-coloured native Gold*. Messing-gelbes gediegen gold of Werner. Its colour is pretty well indicated by its name; but it varies in intensity from what may be called pale-gold yellow to yellowish-silver white. It is also sometimes found with deep-yellow, and with pavonine tarnish.

It occurs massive, disseminated in angular and amorphous particles, but more frequently in films, membranes, and plates even and curled or twilled, and with smooth or drused surface; also capillary, tooth and wire-shaped, shrub and fern-like, and as moniform strings; often imitating reticulated and filigree work; all which forms are generally produced by the aggregation of minute imperfect crystals. Among these, perfect crystals are not unfrequently seen, sometimes single, oftener in groups, on the margin of the plates, &c. The following secondary forms have been observed: the cube; the octahedron; the garnet-dodecahedron; the leucite-dodecahedron with trapezoidal planes. Also modifications intermediate between the cube and the octahedron occur, but they

are scarce. The minute three-sided pyramids, which are often seen to druse the membrane, and the simple triangular marks on the plates of the Transylvanian native gold, are the results of hurried and disturbed crystallization; the former of them being the solid angles of the cubical, and the latter the rudiments of the octahedral variety.

The crystals are minute (those described by Mr. Esmark as octohedra and cubes of two lines in diameter, have never before been heard of); their surface is always smooth.

Lustre metallic: externally splendid: while that of the grains is sometimes glistening, sometimes approaching to dull; internally it is glimmering and glistening.

The fracture of gold is fine hackly. Its fragments are indeterminately angular.

It is soft, highly flexible, malleable, and ductile.

The specific gravity of pure gold is from 19.253 to 19.640; but that of the brass-yellow variety, owing to a greater proportion of silver with which it is alloyed, is generally considerably less, though always above twelve.

The light, or brass-yellow gold, occurs almost always in veins in greywacke, greywacke slate, and newer porphyry; seldom, as the following sub-species, in primitive rocks, or under other circumstances that bespeak a similar remote antiquity.

It occurs chiefly with quartz and iron pyrites, and not unfrequently with grey antimony. Other concomitant substances are, among the earthy fossils, calcareous spar, brown spar, barytes, selenite, and seldom small quantities of bole, lithomarge, and common garnet; of metallic substances, red and vitreous silver ores, (seldom native silver), copper pyrites, grey copper ore, copper green, brown iron stone, galena, green lead ore, blende, with occasional traces of white cobalt, copper nickel, red orpiment, native arsenic, and arsenical pyrites.

2. *Deep or Gold-yellow Native Gold.*—Gold-gelbes geliegen-gold of Werner.

Its colour is the highest gold-colour, seldom verging on brass yellow.

It occurs massive and in small roundish and flattened pieces, as also in grains of various dimensions, detached or disseminated; seldom in particular external forms, such as in leaves and laminæ, filiform and mosslike; scarcely ever crystallized: almost all the crystalline forms described by authors belonging to the light-coloured sub-species.

External lustre glistening, sometimes (as in the variety called Spanish snuff) divested of all lustre. Its specific gravity is rather greater than that of the light or brass-coloured gold, with which it agrees in the remaining characters.

It occurs mostly loose, in alluvial situations, and in the sand of rivers, and, as such, appears to have been originally disseminated in rocks of ancient formation: it is, however, also found in veins in Norway, Siberia, Bohemia, Hungary, in the East Indies, &c. almost always disseminated in quartz, accompanied by iron-pyrites; but nothing is as yet known respecting the age of these veins. At Fatzebay it is found in minutely mosslike external forms, often of a dull powdery appearance, on common quartz sometimes mixed with iron pyrites; in this state it is by the miner called Spanish snuff.

Geographical situation.—The following localities comprehend both the sub-species into which native gold is divided by Werner. By far the greater part of that found in Europe belongs to the brass-yellow sub-species, except the gold of rivers and alluvial soil, which is principally deep yellow, and to which the immense quantities of this precious metal, furnished by the other parts of the world, appear likewise to be referable.

Europe.—Hungary, the Banat, and principally Transylvania. In Upper Hungary it occurs in gneiss: at Scheinitz, in Lower Hungary, it is found accompanied with several silver ores, and with galena; at Kremnitz, in and on cellular and shattered quartz, lamellar barytes, with vitreous silver and grey copper ore, copper pyrites, brown spar, &c.; at Oravizza, in the Banat, it occurs filiform and disseminated in pale flesh-red and greenish-white limestone, with white cobalt ore and copper nickel. In Transylvania, the richest country of Europe in this metal, it principally occurs in a kind of clay-porphry of different degrees of freshness, which is the Saxum metalliferum of Born, in grauwacke and grauwacke slate: at Kapnik it is sometimes found with red orpiment: at Stanisha in calcareous spar, mixed with arsenical pyrites, &c.: other places of Transylvania abounding in gold (which is for the greater part brass-yellow), are Vereşpatak, Abrudbanya, Boiza, Oştenbanya, Fatzebay, Toplitz, Treshtyan, &c. Also the rivers, both of Hungary and Transylvania, are richly auriferous; gold sand is found in the Nera, and underneath a stratum of chalk on the plain traversed by this river. The richest river of Transylvania is the Aramosh, and the plain bordering on the river Morosh, contains likewise gold in grains, between a stratum of mould, and another of schistus, neither of which strata is in the least auriferous. Also at Olapian, gold is obtained by washing; it is there mixed with magnetic ironstone, titanium, garnet, and cyanite. The gold of the great rivers of Transylvania is generally of 21 carats, that of Olapian and Rohinar is even of 23 carats, six grains.

In Germany it is found in several places, at Johangeorgensstadt in Saxony, in Carinthia, where it accompanies copper-ores, in Tyrol and Saltzburg; but it is only in the last of these districts, or rather in the chain of mountains, separating Tyrol from Carinthia, that gold-mines are worked: in the Zillerthal it is found in various external forms, and accompanied with iron-pyrites, &c. in mica slate. In Bohemia gold occurs in quartz.

Spain is probably very rich in gold; certain it is that considerable gold mines were worked there in former times, and, according to Diodorus Siculus, as far back as the time of the Phœnicians, after whom the Romans undertook to work them; and Pliny informs us, that those nations derived great profit from them. Asturia was the province which furnished most of this metal. After the discovery of America these mines were entirely given up and lost. The Tagus and some other rivers of Spain are likewise auriferous.

France has no gold mine that is worthy to be worked; the first discovery of gold in that country was made in 1781, at la Gardette, in the valley of Oisans, in the present department of the Isère: the mine was worked for six years, but the produce in gold and accompanying minerals was too small to compensate for the expence of obtaining them, and, indeed, the loss amounted to upwards of 21,000 livres. It occurs there, with rock crystals and iron pyrites, in gneiss. The sand of several rivers of France is auriferous, such as that of the Arrièze near Mirepoix, the Gardon and Cèze in the Cévennes, the Rhone in the Pays de Gex, the Rhine between Straßburg and Philippsburg, the Salat in the neighbourhood of St Giron, in the Pyrenees, the Garonne near Toulouze, and the Hérault at Montpellier. Also most of the black sand and of the bog-iron found in the neighbourhood of Paris is said to contain a small quantity of gold.

In Piedmont veins of auriferous pyrites and quartz are found near Macugnaga, at the foot of Monte Rosa: which mountain consists of veined granite in horizontal beds. The veins of pyrites and quartz have upon the whole a perpendicular direction, but in some parts they cross each other,

and where this takes place, *gruppi*, or nests, are found which contain the greatest proportion of gold. The proprietor of these mines extracted out of such nests, in no more than twenty-two days, 189 marcs of pure gold, although a hundred weight of the ore yields no more than from 10 to 12 grains of that metal. Formerly upwards of a thousand workmen were employed in these gold-mines; and the proprietors still possess 86 mills, by which from 10 to 12 pounds (of 12 ounces) of mercury impregnated with gold are produced per day. Twelve pounds of mercury contain two marcs of gold. There are likewise several auriferous rivers on the S. side of the Apennine Alps, between mount Rosa and the valley of Aosta, such as the Avanson, which runs from the valley of Challant into the Doire; and where some gold-mines were also worked by the Romans; the Orco, &c.

Sweden has a gold mine at Edelfors in Smoland: the gangue, a brownish quartz, is said to be in a kind of hornblende slate, which also contains the metal disseminated.

Gold has also been found in Great Britain: in Cornwall; at Lead-hills, in Scotland, disseminated in quartz; at Wicklow, in Ireland, under the soil, and in a stream which runs over rocks of clay-slate with veins of quartz. It belongs to the deep yellow variety.

Asia—The gold-ores of Siberia are partly of the light coloured, but principally of the deep coloured variety: that of Berezof, which occurs in pyrites, or rather brown iron stone, and iron shot quartz, and in the rock which serves as gangue to the red lead ore, belongs to the latter. Patrin mentions a specimen of gold in spangles on hornsilver, found in one of the silver mines of Schlangenberg.

The geognostic relation of the gold found in several parts of India, in Japan, the Philippine and Maldivé islands, Sumatra, Borneo, &c. is not known; all the specimens from India, that have come under our inspection, were in the form of small rounded and amorphous particles in quartz, and belonged to the deep yellow variety.

Africa.—Of the occurrence of gold in this part of the world we know so much, that the greatest part, at least of that which comes to Europe, is deep yellow and in grains. African travellers have made us acquainted with a few of its localities, but not with any particulars relating to its geognostic habitudes. Though the commerce of gold-powder extends almost over the whole of Africa, yet, according to Heeren, there is none to be found in its northern parts. Among the principal African gold mines are those of Kordofan, between Darfur and Abyssinia, mentioned by Browne. The ancients, says Brongniart, appear to have been acquainted with these mines: they considered Ethiopia as a country rich in gold; and we find in Herodotus, that the king of that country exhibited to the ambassadors of Cambyses all the prisoners of war fettered with chains of gold.

A second most considerable district for gathering gold-powder appears to be southward of the great desert of Zahara, in the west of Africa, at the foot of those lofty ridges of mountains on which originate, among many smaller rivers, the Senegal, the Gambier, and Niger. The country of Bumbouk, at the N.E. of these mountains, is, according to Golberry, that which furnishes the greatest quantity of gold which is found on the west coast of Africa, from the mouth of the Senegal to the Cape Palmas. This gold is found in spangles and small lumps, principally near the surface of the earth, in the beds of rivulets, and always in a ferruginous soil. In some parts of the country the negroes sink something like shafts, but without giving any support to the sides of the pit; nor are they wont to follow up the vein, if any should appear, or to make galleries. The metal is obtained by repeated washing of the earth that includes it. The same country furnishes likewise

the greatest part of the gold carried to Morocco, Fez, and Algiers, by the caravans which, from Tombuctoo, travel through the great desert of Zahara. The gold which is brought to Cairo and Alexandria from Senaar comes likewise from these. See Parke's travels, where also an interesting account is to be found of the gold in Manding, and of the process by which the negroes obtain it.

The third principal district of Africa, for collecting gold, is on the S.W. coast between 15° and 22° S. lat. opposite Madagascar. This gold comes principally from the country of Sofala. According to the relation of some travellers in this part of the world, the gold is found there not only in powder, but likewise in veins. Some are of opinion that the country of Ophir, from whence Solomon obtained gold, was situated on this coast.

America.—The gold of this part of the world, as far as we are acquainted with it, is so equally the production of the sand of rivers and of alluvial land; but it is also, though rarely, found in veins. South America, particularly Brazil, Choco, and Chili, are the countries that yield most; but some is also found in North America, particularly in Mexico, where it occurs along with silver-ores. The annual produce of these Mexican mines is valued at from 12 to 1500 kilograms. All the rivers of the Caraccas, 10° north lat. are auriferous.

The gold of Chili, according to Frezier, is lodged in the alluvial formation.

The Peruvian gold occurs in ferruginous quartz; that of Choco, the richest province in gold in South America, is found as grains in alluvial country, and in rocks belonging to the newest stetz-trap formation. Almost all we know respecting the geognostic situation of the gold of Spanish America, we owe to M. de Humboldt.

Brazil furnishes gold in abundance, and it is from thence that the greatest part actually seen in commerce is brought to Europe. There are, however, properly speaking, no gold-mines in that country; the gold is not found there in veins, but disseminated in sand and other alluvial depositions, out of which it is obtained in the usual manner.

The gold that has been furnished by Brazil within 120 years, may be valued (according to Correa) at 2,400,000,000 of French livres; and, according to other authors, the amount is calculated to be 24,000,000 per annum. Brongniart. See ORES.

Observations—1. It would appear that most writers who adopt Werner's distinction between gold-yellow and brass-yellow gold, have mistakenly described the one sub-species for the other, and some even speak of "grey-yellow gold from Transylvania." The sub-division alluded to may be deemed inadmissible; but if it be at all adopted, by far the greater part of the native gold of Transylvania and Hungary, and consequently almost all crystallized gold, must necessarily be referred to the light-coloured, and that found in the sand of rivers to the deep-coloured sub-species; and this not on account of their colour only, usually indicative of differences in the chemical composition of metals, but principally on account of the geognostic relations under which they respectively occur, and on which great stress appears to be laid by Werner.

2. Iron pyrites, containing not unfrequently a considerable portion of gold, in most cases invisibly dispersed and distinguished, has by some been considered as a species of gold ore; a distinction to which (though such auriferous pyrites are often subjected to metallurgical treatment for extracting the metal, as will be seen hereafter) it cannot be considered as entitled. See PYRITES, *Auriferous*.

The brown cubic crystals from Beresof, in Siberia, which contain grains of gold, are considered by some as decomposed, by others as hepatic pyrites, and by some as brown iron stone in supposititious crystals. Whatever they may be, they are certainly not what Werner means by hepatic pyrites.

3. The native gold of Transylvania is often accompanied, and sometimes incruited, by particles of a pale yellow earthy substance, which was considered by Hacquet as an oxyd of gold. Muller and others have described it as iron-ochre, from which, however, it appears to differ both in colour and consistence. It is almost always to be met with in the specimens of native gold from Vereshpatak, but sometimes in such fine particles as to appear merely as a tarnish on the metal. It is to this dust probably that the gold ore, called Spanish snuff, owes its mat, yellowish-brown colour. It deserves further examination.

4. The grey metallic substance occurring as acicular indeterminate crystals, along with the gold of Siberia, in quartz, and which has been described as tellurium, as grey copper ore, &c. appears to be native bismuth.

For the *chemical characters* of gold, and the *uses* to which it is applied, see the sequel of this article.

Extraction of Gold—This metal is obtained separate from foreign substances, with which it is mixed by amalgamation with quicksilver. After it has been freed, by pounding and washing, from the stony matter, it is triturated with about ten times its weight of mercury. The more fluid part of the amalgam is forced through leather, while that which is more consistent, and which contains the chief part of the gold, remains. This is subjected to distillation, the quicksilver is separated and evaporated, and the gold remains in a state of fusion. When this metal is found in other ores, they are first roasted, to disperse the volatile principles, and to oxidize the other metals. The gold, which is but little subject to oxydation, is extracted by amalgamation, by cupellation, or other methods adapted to each ore, according to its properties or constituent parts. The metal obtained in these ways is always more or less alloyed, particularly with silver and copper. The first step in its purification is the process of *Cupellation*, to which article in our Cyclopædia the reader is referred for accurate information on this part of the subject.

The gold, after it has been submitted to this process, is often alloyed with silver, which, being nearly as difficult of oxydation, is not removed by the action of lead, and hence the necessity of the operations denominated *Parting* and *Quartation*, which may be explained in a few words.

In *Parting*, the metal is rolled out very thin, and cut into small pieces, which are digested in diluted nitric acid moderately hot. The acid has an action upon, and dissolves the silver, leaving the gold undissolved in a porous mass. When, however, the proportion of silver is very small in comparison of the gold, the latter sometimes protects the former from the action of the acid; in such cases the previous step of *Quartation* is employed, which is so named on account of the proportion of materials employed, *viz.* three parts of silver, with one of gold, and then subjecting the alloy, rolled out, to the operation of the acid. Sometimes they are melted together, and sulphur thrown in, the sulphur combines with the silver, and the gold falls to the bottom. It is observed by Lagrange, that rolling and annealing are operations very necessary to the success of the parting process, and which require some precautions. 1st. The plate must not be too thin, lest it should break in consequence of the motion communicated to it by the action of the acid; if it is too thick the acid could not penetrate to its centre.

2dly. The annealing of the plate, at the same time that it gives pliability, facilitates its being rolled without cracking; it also opens the pores of the metal, which the rolling may have pressed together, and by these means favours the action of the acid.

The process recommended by Bergman is this: first to dissolve it in nitro-muriatic acid; the silver is deposited spontaneously in the form of muriate of silver, which is insoluble; the gold is precipitated in fine powder by the sulphate of iron. Each of the above-mentioned processes is performed in such a manner as to lead to an estimate of the quantity of gold, and also of the different metals with which it is alloyed.

Gold, it is said, by some able French chemists, as Le Sage and Rouelle, exists in the vegetable kingdom, it having, in experiments instituted for the purpose, been extracted from the ashes of certain plants; the quantity, however, being, of course, too trifling to be sought after for practical purposes, it is sufficient merely to mention the fact in this place.

GOLD, Chemical Properties of.—Gold melts at the temperature of 32 of the scale of Wedgwood; and what is very remarkable is, that it is more difficult of fusion in the state of filings and grains, than in larger masses; and that the small fragments, even after they are fused, remain in separate globules: and in order to make them run into one mass, a little nitre or borax is thrown into the crucible. Gold, which has only been subjected to a degree of heat barely necessary for its fusion, is brittle after cooling. To preserve its ductility, which, as will be seen farther on, is one of the more important mechanical properties of gold, the temperature must be raised much higher. It is brittle also when it is too suddenly cooled after fusion. By an increase of temperature while the gold is in fusion, it becomes convex on the surface, and when it cools, it sinks, circumstances which are ascribed to the expansion and contraction of the metal. When it is gradually and slowly cooled, it crystallizes in the form of quadrangular pyramids, or regular octahedrons. If the heat be continued while it is in perfect fusion, it seems to undergo a kind of ebullition. This circumstance was noticed by Homberg and Macquer, as well in the application of the burning-glass, as when a small globule of the metal was acted on by the blow-pipe. Macquer asserts that it rose in vapour to the height of five or six inches, and attached itself to the surface of a silver plate, which it completely gilded.

The strongest heat of a furnace, which has been applied to gold in fusion, has been found incapable of producing the smallest change or the least tendency to oxydation; but, by the action of a very powerful burning-glass invented by Tschirnhausen, and which has been described under the article BURNING-GLASS, Homberg found that gold, placed in its focus, not only rose in vapour, but that it was covered with a violet-coloured vitreous oxyd. The experiment was frequently repeated, so as to ascertain the fact most completely. The same thing has been done by means of the electric discharge, by which gold-leaf, placed between two cards, has been converted into a violet-coloured powder. These instances of real oxydation were, at first, regarded, by some who witnessed the experiments, as merely minute mechanical divisions of the metal, but this apparent objection has been removed by the experiments of Van Marum on the combustibility of gold by means of the large electrical machine at Haerlem. A strong electrical shock was passed through a golden wire suspended in the air. It kindled, burned with a perceptible green flame, and was reduced to fine powder, which was dissipated in the air. A similar oxydation has been observed to take place on the gilding in the inside of houses,

houses, or on the furniture which has been struck with lightning. The purple oxyd of gold, thus obtained, contains five or six *per cent.* of oxygen. By precipitation from some of its saline combinations, a yellow oxyd has been obtained, in which the proportion of oxygen amounts to ten *per cent.* The oxyd in both instances may be decomposed, and the oxygen completely expelled, by an elevation of temperature not much superior to that of ignition.

The attraction of gold to oxygen is so weak, that it is scarcely affected by the greater number of acids. It was formerly supposed to be perfectly insoluble in the nitrous and nitric acids, which in general part with oxygen with so much facility, and when gold leaf is put into the acid cold, it seems to suffer no change, but when nitric or nitrous acid is boiled on gold, it is capable of dissolving a small portion of it. The quantity dissolved is, however, so inconsiderable, and depends on so many conditions, which it is needless to enumerate, that the accuracy of the processes of assaying can scarcely be affected by it.

When gold is dissolved in the nitro-muriatic acid, or in a mixture of equal parts of nitric and muriatic acids, an effervescence takes place, and the solution becomes of a yellow colour. In this process the nitric acid is decomposed, its oxygen combines with the gold, and the oxyd, as it is formed, is dissolved in the muriatic acid. By adding lime-water a precipitate is formed, which is the yellow oxyd of gold, consisting of from eight to ten parts of oxygen in the hundred. There is no action between gold and azote, hydrogen, carbon, or sulphur: but the oxyds of gold are readily decomposed by hydrogen, as will be soon seen.

Phosphorus combines with gold by heating together in a crucible a mixture of one part of gold in filings, with two parts of phosphoric glass, and an eighth part of charcoal. Great part of the phosphorus is separated from the acid, and driven off, but there remains a small quantity united with the gold, forming a phosphuret of gold. It may be done also by adding phosphorus to gold in a red heat in a crucible. It is, in this state, pale coloured, granulated, brittle, and a little more fusible. The proportion of phosphorus is not more than one part in twenty-four; and the fusibility may be decomposed by being kept in fusion; the phosphorus is driven off in the state of vapour, and inflamed. Bergman has arranged the affinities of gold and its oxyds in the following order:

<i>Gold.</i>	<i>Oxyds of Gold.</i>
Mercury,	Muriatic-acid,
Copper,	Nitric,
Silver,	Sulphuric,
Lead,	Arsenic,
Bismuth,	Fluoric,
Tin,	Tartaric,
Antimony,	Phosphoric,
Iron,	Prussic.
Platine,	
Zinc,	
Nickel,	
Arsenic,	
Cobalt,	
Manganese.	

Salts of Gold.—These are the nitrate and muriate.

1. *Nitrate of Gold.* When concentrated nitric acid is several times successively poured upon gold, boiled and distilled to dryness, the gold is dissolved, and the solution assumes a yellowish colour. This solution is more readily effected in proportion to the quantity of gas or nitrous gas which the acid contains. Gold-leaf, according to Fourcroy, is dissolved in

nitric acid, impregnated with nitrous oxyd, and he supposes that it is owing to the nitrous oxyd that the gold is oxydated, this oxyd being so much more easily decomposed than the nitric acid. The acid which, at first, is deprived of its colour by the oxydation of the gold, as this oxyd is dissolved, assumes an orange-yellow colour, holding in solution the nitrate of gold with an excess of acid. The nitrate cannot be obtained in crystals, and it is decomposed by heat or by being exposed to the light of the sun; it is also decomposed by the alkalies, or by introducing a plate of tin or silver into the solution, and the purple oxyd is precipitated in the form of powder; and likewise by muriatic acid, which at the instant of combination converts the orange-colour to a pure yellow.

2. *Muriate of Gold*—Muriatic acid of itself has no action on gold, or on its purple oxyd, but gold is immediately oxydated and then dissolved in oxymuriatic acid; or if nitric acid be added to the muriatic in certain proportions, the solution of gold in the mixture is readily effected: hence the nitro-muriatic acid was distinguished by the name of "aqua regia," because it dissolved gold, which was regarded by the alchemists as the king of metals. The nature of the chemical action is thus explained. Gold is oxydated with great difficulty, but it is effected by oxymuriatic acid, which readily parts with its oxygen, or by the addition of the nitrous to the muriatic, the former of which is decomposed, giving out its oxygen to the gold, which being now oxydated is dissolved in the muriatic acid, forming with it a muriate of gold. This solution of the muriate of gold is of a deep yellow colour, extremely acrid and caustic; has an astringent metallic taste, and stains the skin of a deep purple colour, which becomes darker by exposure to the air and light. It produces a similar effect on all vegetable and animal matters, and on marble and siliceous stones. By evaporating the solution to one half, nitric acid is disengaged, and crystals are obtained. These assume a red colour by the action of strong light. They attract moisture from the air, and spontaneously become liquid. When oxymuriatic acid is used, the oxygen of this acid being retained even by a weaker affinity than the nitric acid, the gold attracts it, and combines with the muriatic acid. In this case the solution is slow, and but a very small quantity of gold can be dissolved, partly from the oxymuriatic acid not being in a very concentrated state, and partly, it is supposed, from the quantity of oxygen present not being such as to form a sufficient quantity of oxyd to saturate the acid. It ought, however, to be observed, that if the late discoveries of professor Davy be established, which make the oxy-muriatic acid a simple substance, and even possessing no oxygen whatever, then a new theory must be introduced to account for the facts above-stated. In oxy-muriatic gas, gold-leaf is instantly fused with inflammation, and dissolved.

Gold cannot be dissolved by the other acids when in its metallic state, but its oxyds may be combined with them, and a number of the salts of gold be formed. The sulphate and nitrate also, as we have seen, do not crystallize: the phosphate of gold may be fused, and in this state it forms a fine red glass. We shall now briefly notice some of the properties of the muriate of gold. In connection with this subject, we must not omit the experiments of Mrs. Fulham, which she announced in an "Essay on Combustion," with a view to a new art of dyeing and painting, &c. in the year 1794, and which were, at that period, expected to lead to some important practical results.

The muriate of gold is very soluble in water, and is decomposed in hydrogen gas. If a piece of silk be moistened with

with a solution of muriate of gold, the salt is decomposed, and the gold, reduced to the metallic state, attaches itself to the silk. It is decomposed also by phosphorus. If a stick of phosphorus be introduced into a saturated solution of muriate of gold, the salt is decomposed, and the gold, being reduced to the metallic state, forms a cylindrical covering to the phosphorus, which may be separated by dissolving the latter in hot water. A similar effect is produced by burning sulphur, by sulphurated and phosphorated hydrogen gases, and by sulphurous acid. If a solution of muriate of gold be cautiously added to sulphurous acid, a fine pellicle of gold appears on the surface, which is instantly precipitated in the form of small grains. These, and many other experiments equally curious and interesting, were first described by the lady above-mentioned, and the rationale of the subject is thus explained. All the substances which have been enumerated have a stronger affinity for oxygen than gold, so that the oxyd of gold, in combination with the acid, is decomposed; the oxygen combining with the hydrogen, and forming water, or with the phosphorus or sulphur, and forming sulphuric or phosphoric acid.

The muriate of gold is soluble in ether, and forms with it a solution of a golden yellow colour, which floats on the top of the fluid. By the addition of ether to a solution of gold, and agitating the mixture, as soon as it is left at rest, the two liquids separate, the ether rises to the top, and assumes a yellow colour, while the nitro-muriatic acid remains below and becomes white. By a process of this kind a tincture of gold was prepared, called "potable gold." The solution of gold in ether is not permanent: it is quickly reduced to the metallic state, and is sometimes found crystallized on the surface. The ethereal solution is used by Mr. Stodart for defending lancets, and other surgical instruments, from injury by a moist atmosphere.

The muriate of gold is decomposed by all the alkalies and earths, and is reduced to the state of yellow oxyd.

Most of the metals decompose the muriate of gold: copper, iron, zinc throw down the gold in its metallic state: other metals, as silver or lead, in the state of purple oxyd. The precipitate obtained by means of tin is valued for the beauty of the colour which it gives to glass or enamel. This preparation is known to artists by the name of the "Purple powder of Cassius," and it may be obtained by various processes. That which is commonly resorted to, is to dissolve pure gold in a nitro-muriatic acid, which is composed of three parts of nitric and one of muriatic acid. A solution of tin is to be prepared by dissolving the metal, in small portions at a time, in an acid containing two parts of nitric and one of muriatic acid, previously diluted with an equal weight of water. This solution, after it is saturated, is largely diluted, perhaps with a hundred parts of distilled water: to this the solution of gold equal in quantity to half the quantity of solution of tin, is added, and the precipitate is obtained after it is allowed to subside, which is to be washed and dried. This is the only known preparation capable of giving a red colour to glass; and if the experiment be performed with accuracy and judgment, the glass so treated serves as a capital imitation of the ruby. The process is, however, attended with considerable difficulty, owing to the colour of the precipitate being various, from circumstances not easily discovered. According to Pelletier, it is a compound of oxyds of tin and gold; and its formation is owing to the strong attraction of the tin for the oxygen, with which it is disposed to combine in large quantities. When the solutions, above described, are mixed, the oxyd of tin, which is nearly at the minimum of oxydization, at-

tracts part of the oxygen of the oxyd of gold: the two oxyds thus brought to states of oxydization, different from those in which they existed in the separate solutions, and probably likewise exerting mutual affinities, are no longer soluble, and are precipitated in combination. Muriate of gold is decomposed by some other metallic salts, in consequence of similar actions; the oxygen of the oxyd of gold being attracted by the oxyd of the other metal, which hence passes to a higher state of oxydization. Those which have a strong tendency to exist in such a state, are capable even of completely de-oxydizing the oxyd of gold. Example.—If a solution of the green sulphate of iron be added to the solution of muriate of gold, the gold is precipitated in very minute particles in the metallic state, while the iron passes to the state of a red sulphate. A solution of muriate of gold, when concentrated by evaporation, yields beautiful yellow crystals, not unlike topazes.

Gold, as we have seen, does not combine with sulphur by fusion, and on this is founded a method of freeing it from silver or other metals, the alloy being fused with sulphur, the silver, &c. unite with the sulphur, leaving the gold separate. But gold and sulphur may be united by the medium of an alkali. Example.—Let a sulphuret of potash be fused with one-eighth of its weight of gold-leaf, and the combination is even soluble in water, the solution being of a green colour.

Alloys of Gold.—Gold forms alloys with the greater number of the metals, which produce on the metal so alloyed a very particular change in its properties. An extensive and accurate series of experiments on these alloys was made by Mr. Hatchet, with the view of determining some important and interesting facts relating to the use of gold as a coin. Of these we shall give a brief abstract, referring our readers for a more particular account to the Transactions of the Royal Society for the year 1803.

The chief enquiry of Mr. Hatchet, as connected with the alloys of gold, was, whether soft and ductile gold, or gold made as hard as is compatible with the process of coining, suffers most by wear. His experiments were intended to examine the effects which various metals produce upon gold, when combined with it in given proportions, beginning with $\frac{1}{12}$ th, which is the standard proportion of alloy, and gradually decreasing to $\frac{1}{100}$ th part of mass. The results drawn from the trials were, that fine gold, alloyed with silver, with copper, and with tin, did not suffer any loss during the experiment. The gold alloyed with lead only lost three grains, chiefly by vitrification; with iron it lost 12 grains, which formed scoria; with bismuth it lost 12 grains, chiefly by vitrification; with zinc it lost a pennyweight by volatilization; and with arsenic, it not only lost the whole quantity of alloy, but also two grains of the gold which were carried off in consequence of the rapid volatilization of the arsenic. Hence it was inferred that only two metals are proper for the alloy of gold coin, namely, silver and copper; as all the others either considerably alter the colour, or diminish the ductility of gold. In respect to the latter quality, the different alloys employed in this series of experiments appear to affect gold nearly in the following decreasing order: 1. Bismuth. 2. Lead. 3. Antimony. 4. Arsenic. 5. Zinc. 6. Cobalt. 7. Manganese. 8. Nickel. 9. Tin. 10. Iron. 11. Platina. 12. Copper, and, 13. Silver. The three first have nearly the same effect on gold, and bismuth is found to render gold brittle when the proportion of that metal is to gold only as 1 to 1920; even the vapour arising from bismuth, lead, and antimony in fusion, produces these changes.

The alloy with platina is of a yellowish white colour, very ductile, and of a considerable specific gravity. The alloy with silver in the standard proportion, or 1 to 12, approaches, as we have seen above, the nearest to the ductility of fine gold of any alloy, and its specific gravity differs but little from the mean specific gravity of the two metals. When the silver amounts to $\frac{1}{4}$ th, the colour of the alloy approaches to green, and forms the green gold of the goldsmiths. In combination with copper, gold has its colour rather heightened than impaired; its hardness is increased and its ductility very little lessened, when the standard proportion of 1 part in 12 is not exceeded. This alloy of 22 carats fine is generally used, when gold is fabricated into plate or ornaments, and likewise forms the gold coin of the country. With quicksilver, gold unites with great facility, making with it an amalgam which will be described hereafter. The alloy with iron is much harder than gold, very ductile and malleable; but the colour is debased to a dullish grey, inclining to white. Tin was formerly regarded as the metal which rendered the alloy with gold the most brittle of all the alloys, but the experiments of Mr. Bingley and Mr. Hatchett have shewn that this notion is to a certain extent erroneous, and that the effects produced by the mixture of tin with gold, ought probably to be ascribed to other metals, with which the tin was contaminated, such as bismuth, antimony, lead, and zinc. The alloy, consisting of equal parts of zinc and gold, is very hard and susceptible of a fine polish, and not being subject to much alteration from the air, it is recommended for the fabrication of the mirrors of telescopes. The alloy of gold with silver, in which there is only $\frac{1}{4}$ th part of silver, changes the colour of the gold very sensibly; and the alloy is employed for foldering gold, being more fusible than this metal.

GOLD, Physical properties of. *Gold, aurum*, a yellow metal, heavy, pure, ductile, malleable, and shining; and on those accounts, the most valuable of all metals. In fusibility it ranks between silver and copper; it is not oxydable by fusion in atmospheric air; nor is it acted upon by any of the acids, except the oxy muriatic and nitro-muriatic.

The yellow colour of gold is rendered paler by fusion with borax; but this may be prevented or corrected by fusion with nitre, or sal ammoniac. The colour of gold is heightened by an alloy of copper, and this property of copper has given rise to sundry processes for exalting the colour of this noble metal. Other metals render it paler. The alchemists call gold, *sol*, the sun; to denote its pre-eminence over the other metals, which are called by the names of the planets. Its symbol, or character, is O; which, in their hieroglyphical way of writing, denotes perfection, simplicity, solidity, &c.

The weight of gold is to that of water, according to some statements, as 19.637 to 1000. Fine gold, immersed in water, weighs nearly one nineteenth part less than in air, and consequently it is upwards of nineteen times heavier than its own volume of water. However, the specific gravity of gold, or its comparative weight with an equal volume of water, has been variously assigned: some have made it 19.637, others 19.640, and in the Swedish Transactions it is made no less than 20.000; that of water being 1000. Others again have made it as low as 18.75. But from the experiments of Mr. Ellicot, it does not appear to have exceeded 19.207; and from those of Dr. Lewis, on the purest gold, well hammered, its gravity is stated between 19.300 and 19.400. In all experiments of this kind, the result should be specified with an account of the sensibility of the balance, and the quality and warmth of the water. An increase of heat rarefying water more than it does gold, the

gold must turn out proportionably heavier than an equal volume of the expanded fluid; and this difference is a considerable one than it has generally been supposed. From freezing to boiling water, or by an augmentation of heat equivalent to 180 of Fahrenheit's thermometer, Dr. Lewis found that a rod of gold was lengthened about one part in 700, and consequently its volume increased about one part in 233, while the volume of water is increased one twenty-sixth or more; hence it appears, that by an augmentation of 40° of the thermometer, or from a little above freezing to the summer heat, the volume of gold, if its expansion be uniform, is increased one part in 1048, and that of water one in 117; and the gravity of gold, weighed in the water so warmed and expanded, should be greater than when the gold and water are 40° colder, in the proportion of about 19.265 to 19.400: and this calculation gives a difference, in the gravity, of 0.034 for every 10° of the thermometer; but some trials seemed to make it greater. It has been imagined, that the comparative gravity of gold to brass weights, which are more than double in volume to an equal weight of gold, must be so far influenced by the variable gravity of the atmosphere, that there must be an advantage in buying gold by weight when the air is lightest. But Dr. Lewis observes, that this difference appears too inconsiderable to be regarded in a commercial view. For the loss of weight of the two metals in the air being as much less than their loss in water, as air is lighter than water; and air, if we admit the accuracy of the conclusion deduced from an experiment of Mr. Hawkbee, being in its lightest state about a 937th, and in its heaviest state about an 848th part of the weight of water; it will be found, on calculation, that the gold preponderates above the brass, in the heaviest more than in the lightest air, only by one part in 145,000, or one grain in about 302 ounces; which is a difference too minute to be sensible in the nicest balance. If the mean gravity of gold be reckoned 19,300, as a cubic inch of water weighs about 254 grains, a cubic inch of gold will consequently weigh about 4902 grains, or 10 ounces, 102 grains. The pound weight, or twelve ounces Troy, of gold, is divided into twenty-four carats. Dr. Lewis states the specific gravity of fine gold at 53° Fahrenheit, to be 19.376. According to Brillon the specific gravity of fine gold in ingot is 19.258, and when hammered 19.701. The specific gravity of gold made standard by British copper, was found by Mr. Hatchett (see Phil. Trans. for 1803) to be 17.281, when cast in an iron mould; but when the same was cast in sand, it was only 16.994. (See SPECIFIC GRAVITY.) The softness of gold, for it is nearly as soft as tin, and its toughness, adapt it for receiving the impressions of dies, and of course to be reduced to the state of coin, and for various other purposes in the arts. It is but slightly elastic and sonorous. With regard to tenacity, it is inferior to iron, copper, platina, and silver, and therefore the assertions of former chemists and philosophers have been contradicted by later experiments, for gold has been usually represented as the most tenacious as well as the most ductile of all metals. Its malleability and ductility are sufficiently evinced by the *GOLD-leaf* and *GOLD-wire*, which see. See also DUCTILITY.

The value of gold to that of silver, was anciently only as twelve to one. Indeed, this proportion varies as gold is more or less plentiful: for Suetonius relates, that Cæsar brought such a quantity of gold from Italy, that the pound of gold was only worth seven pounds and a half of silver. In our coinage, the value of fine gold to fine silver is nearly as 15 to 1. (See COIN and STANDARD.) Sir Isaac Newton observes, in a representation to the lords of the treasury

in the year 1717, that in the mints of Spain and Portugal the value of gold is sixteen times that of silver; but that in those countries, payments in silver bearing generally a premium of six per cent. the proportion may be considered as fixed by commerce at $15\frac{1}{2}$ to 1; that in the other parts of Europe, the value of gold is at most fifteen, and in China and Japan but nine or ten times that of silver; so that gold is rated higher in England than in any other part of Europe, and higher in Europe than in the Eastern countries. Hence, in great measure, arise the profits of exchanging gold for silver in one place, and re-exchanging them in another; and hence the greater disparity between the relative quantities of gold and silver in one commercial nation than in another; this metal being brought in most abundance which is rated highest in proportion to the other, and that which is rated lowest being drained away. There are various ways of determining the fineness of gold; or the proportion of alloy which it contains. Those who are used to this business can judge nearly the proportion of alloy from the colour of any given mass, provided that the species of alloy be known. For the method of doing this, see *Touch-needles*. The great excess of the weight of gold, above that of the metals used for its alloy, affords another method of determining the quantity of alloy in any given mass, where the species of alloy is known. Thus fine gold loses in water one grain in every 19.3 nearly; and fine silver loses one grain in about eleven; from whence it is easy to find the loss of any number of grains of each, and consequently of any assignable mixture of the two metals. Thus, fifty grains of gold will lose above $2\frac{1}{2}$, and fifty grains of silver somewhat more than $4\frac{1}{2}$; so that a mixture of equal parts of the two will lose above seven in a hundred, or one in fourteen. A mixture of gold with half its weight of silver will lose one part in 15.4; with a third of silver, one in 16.2; with a fourth, one in 1.67; and with an eleventh of silver, which is the standard proportion of alloy, one in 18 1. On this principle, the specific gravity or proportional loss in water, of gold alloyed with different quantities of silver, copper, and mixtures of both, may be computed and formed into tables for use. The accuracy of this method, it should be observed, depends on the supposition that each of the two metals, that are melted together, retains its own proper gravity, which is the case in mixtures of gold and silver; but gold and copper, melted together, are specifically lighter than if they were weighed separately; or the specific gravity of the alloy is less than that of the mean of its ingredients; the case is the same with the alloys of nickel and gold, of lead and gold, of iron and gold; but the reverse happens in mixtures of gold with zinc, bismuth, and tin. It appears, therefore, that the hydrostatic balance cannot discover, with certainty, the exact fineness of gold, unless when silver is the metal mixed with it.

There are various methods of separating gold from gilt works: it may be separated from the surface of silver, either by spreading over the gilt silver a paste made of powdered sal ammoniac moistened with aquafortis, and heating it till the matter smokes, and is nearly dry; throw it into water; and the gold will easily come off by rubbing it with a scratch brush: or, by putting the gilt silver into common aqua regia, nearly boiling, and turning the metal frequently, till it becomes all over black; then wash it with water, and rub it with the scratch brush, which will disengage the gold left by the aqua regia. See *GILDING*.

Gold may be separated from gilt copper, by applying a solution of borax to the gilt parts with a pencil, and sprinkling over the place thus moistened a little powdered sulphur; when the piece is made red-hot and quenched in water, the gold may be wiped off with a brush.

Gold may be recovered from wood, gilt on a water size, by steeping it for a quarter of an hour in a quantity of very hot water, sufficient to cover it; then scrub the wood in a little warm water, with short stiff bristle brushes of different sizes: boil the whole mixture of water, size, gold, &c. to dryness; make the dry matter red-hot in a crucible to burn off the size, and grind the remainder with mercury. The gold will be more easily laid hold of by the mercury, by the addition of some clean sand.

GOLD, Alchemical History of. See *PHILOSOPHER'S Stone*, and *TRANSMUTATION*.

GOLD, Amalgam of, is a preparation of gold much used by the gilders (see *GILDING*); and it is made by heating some pure quicksilver in a clean crucible, and adding to it, when it is nearly boiling, about a sixth of its weight of fine gold in thin plates that are hot; after this mixture has been kept hot for a few minutes, it becomes an homogeneous substance; and when cold, it is put into a piece of soft leather, and which is gradually pressed till the fluid part of the amalgam, consisting almost wholly of mercury, is forced through the pores of the leather; while the gold, combined with about twice its weight of mercury, will remain in the state of a yellow silvery mass, of the consistence of soft butter; when this mass has been bruised in a mortar, or shaken in a phial, with repeated portions of salt and water, till the water receives no foulness from it, it is fit for use, and may be preserved for any time in a corked phial. For the purposes of gilding it is of great importance, that this amalgam should be formed of pure materials, as any portion of lead or bismuth would deteriorate the colour of the gold, and tarnish it with black specks. The mercury should therefore be previously distilled from the red precipitate (nitrous red oxyd of mercury), either alone or mixed with a little charcoal powder. See *AMALGAM* and *MERCURY*.

GOLD-beating, and GOLD-beater's skin. See *GOLD-leaf*.

GOLD, Burnished, is that which is polished with a steel instrument, called a burnisher, if it be wrought gold, or gilding on metal; or with a wolf's tooth, if it be gilding in water. See *GILDING*.

GOLD Chain. See *CHAIN*.

GOLD Coin, or species of gold. See *COIN* and *COINAGE*.

GOLD Colour on Glass and China. See *GEMS, GLASS, GILDING, and PORCELAIN*.

GOLD-coloured Glazing. See *GLAZING*.

GOLD-coloured Metal is produced by melting zinc with copper. According to the purity of the zinc and copper, the proportions in which they are mixed, and the intimacy of their union, the compound metal proves more or less malleable, and approaches more or less to the colour of gold. Some direct the zinc to be taken only in a fifth or sixth part of the weight of the copper, and others in an equal weight or more. Dr. Lewis observes, from the result of many experiments, that both with the smallest and largest of these quantities of zinc, the metal proves more like gold than with the intermediate proportions.

The colour of these compounds is improved by a small mixture of some other metallic bodies. Cramer recommends the addition of a small quantity of pure tin to copper, melted with a fourth or sixth part of zinc, which forms a compound metal, that acquires, on being well cleaned, and laid in the air for some days, a superficial colour of fine gold. Geoffroy says that iron has the best effect: with the proportions of ten parts of zinc, eight of copper, and one of iron-filings, he produced a metal of a fine smooth grain, compact, hard, and bright, and of a beautiful gold colour. By making the copper first into brass, and then melting it with a suitable quantity of zinc, a metal may be obtained of su-

perior quality to that produced either by melting the copper and zinc, or by impregnating the copper with zinc, by cementation and fusion with calamine; which is a method sometimes practised. A very ingenious artist, says Dr. Lewis, who now prepares a gold-coloured metal in great perfection, has a fine kind of brass made on purpose for this use. The union of the copper and zinc in fusion, succeeds best and with least loss of the zinc, according to Dr. Lewis, by using a mixture of black flux and borax, or a composition of twelve parts of green glass powdered, six parts of potash, two of borax, and one of powdered charcoal: when this flux is fused in the crucible, the copper and zinc are dropped into it; and when they appear perfectly melted, they are to be well stirred together with an iron rod, and expeditiously poured out. The same flux will serve for melting several fresh quantities of the metal. Dr. Hooke gives the following receipt for making a gold-coloured metal: eight parts of distilled verdigris, *i. e.* of verdigris purified by solution in distilled vinegar and crystallization, and four parts of Alexandrian tutty, with two of nitre, and one of borax, are directed to be mixed with oil to the consistence of pap; then melted in a crucible, and poured into a flat mould first well warmed. A composition of this kind is called *aurum sophisticum*.

The following method is recommended by Homberg for giving a gold colour to copper, without the addition of zinc; make an amalgam of one part pure copper, and three parts quicksilver; boil this in river-water for two hours, then distil off the quicksilver in a retort, and cohobate it once; take out the copper and fuse it, and it will be found of a beautiful gold colour, more ductile than common copper, and extremely well fitted for watch-work, gilding, and the finer machines and utensils. The celebrated Mr. Pott affirms that a gold-coloured metal may be made from a mixture of copper and tin, and directs it to be compounded in the following manner: Take one half ounce of tin ashes, and four half ounces of copper; melt them well together in a close luted crucible, with a strong fire; or take one half ounce of the purest tin cut in pieces, and sixteen half ounces of pure copper beaten into thin plates; lay the tin between the copper-plates, lute the crucible close, and melt with a strong fire. See *Prince's METAL* and *TOMBAC*.

Silver is tarnished superficially, by certain vapours, as that of putrid urine, to a colour so like that of gold, that several edicts have been issued in France to prevent frauds of this kind with regard to wire and laces.

GOLD-coloured Pigments. See *PIGMENTS*.

GOLD-coloured Varnish. See *LACQUER*.

GOLD, Crown. See *COIN* and *STANDARD*.

GOLD, Dutch, is a kind of leaf used in gilding, &c. which is copper gilt, or brass beaten into leaves like the genuine gold-leaf. It is said to be made from copper-plates, by cementation with calamine, without subsequent fusion. The thickness, compared with that of leaf-gold, is as nineteen to four, and under equal surfaces it is considerably more than twice as heavy as the gold.

GOLD, Farthing of. See *FARTHING*.

GOLD, Fine or Pure, is that purged by the fire of all its impurities, and all alloy. The Latins call it *aurum purum*, *aurum primum*, *aurum obrizum*, *aurum coctum*.

The moderns frequently call it *gold of twenty-four carats*; but, in reality, there is no such thing as gold so very pure; and there is always wanting at least a quarter of a carat. Gold of twenty-two carats has one part of silver, and another of copper: that of twenty-three carats has half a part, *i. e.* half a twenty-fourth of each.

Buteroué maintains, that the electrum of the ancients

was gold of nineteen carats; or four parts gold, and a fifth silver.

From an ordinance of king John of France, it appears that the gold then struck at Paris was of nineteen carats one-fifth; and yet it is added that it was the best and finest gold then known on earth. See *STANDARD*.

GOLD, Fulminating, aurum fulminans, a precipitate of gold from its nitro-muriatic solution by ammonia, which possesses a most remarkable explosive property. See *ART. V.*

It is prepared by diluting a solution of muriated gold with six or eight times its bulk of distilled water, adding drop by drop liquid ammonia, till the precipitation ceases; then let the yellow powder thus obtained be separated by a filter, well washed in hot water, and afterwards dried. The fulminating gold, thus procured, will exceed the weight of the original gold by about 33 parts in 100. If a small quantity, *e. g.* half a grain, of this powder be held over a candle, in a spoon or on the blade of a knife, it presently explodes with a very loud report. This powder should be very cautiously used; the temperature requisite for its explosion is stated at above 250° of Fahrenheit. Before it explodes, its yellow colour changes to black, and at the moment of its decomposition an instantaneous flash is observed. The principal energy in explosion is directed downwards, inasmuch that two or three grains of it exploded on a moderately thick sheet of copper will burst a hole in it. This salt is decomposed by an electrical shock, but it cannot be ignited by a spark from electricity or from flint and steel. It will vehemently explode by sudden friction, and therefore, in order to avoid dangerous accidents of this kind, it should never be kept in a ground-stoppered bottle. The facility of its explosion is very much increased by high drying; so that if it be heated till it becomes black, and is immediately removed from the fire, it will frequently go off by a mere touch. If the fulminating gold be mixed with four or five times its weight of chalk, or sulphat of potash, or with any pulverulent substance neither fusible nor decomposable at a moderate temperature, and exposed gradually to a low heat, it will be quickly decomposed, leaving merely the purple oxyd of gold. The same effect may be produced by very cautiously heating the fulminating gold without any addition, removing it from the fire when it has changed its colour, and when cold heating it again, and proceeding in this way till the powder becomes purple, in which state it will have entirely lost its explosive faculty. A similar change occurs by melting sulphur at the lowest possible heat, and dropping in the fulminating gold by half a grain at a time, well mixing it; the sulphur may then be burnt off without danger, and minute grains of metallic gold will be left behind. "The true theory of the decomposition of fulminating gold was partially discovered by Bergman, and has since been fully illustrated by Berthollet. The former of these able chemists shewed that this salt when decomposed in close vessels was reduced to gold, partly in the metallic state and partly in that of purple oxyd, and at the same time a gas was extricated in bulk about a thousand times as great as that of the original fulminating salt, and which extinguished flame and animal life, was not absorbed by water, and gave no precipitate with lime-water. Berthollet, by decomposing the same substance in a copper tube, connected with a jar inverted in mercury, obtained azotic gas and a few drops of water, and the gold was reduced to the metallic appearance. Now as ammonia is composed of hydrogen and azot, and as the affinity of gold for oxygen is very slight, it is manifest that the decomposition and explosion, under the circumstances already mentioned, are occasioned by the oxygen of the

gold and the hydrogen of the ammonia combining to form water, and to the liberation of the azot and its sudden assumption of the gaseous state." Aikin's Dict.

GOLD, Leaf, or beaten gold, is gold beaten with a hammer into exceedingly thin leaves. It is astonishing to consider the fineness to which a body of gold is thus reduced. In an experiment of Reaumur's, forty-two square inches and three tenths of gold-leaf weighed one grain Troy; and Mr. Boyle found that fifty and seven tenths weighed but a grain. As a cubic inch of gold weighs 4902 grains, the thickness of the gold-leaf examined by the one was the 207355th, and of that by the other only the 248532nd part of an inch. See *DUCTILITY of Gold*.

This gold is beat on a smooth block of black marble, from two hundred to six hundred pounds in weight, and about nine inches square on the upper surface, fitted into the middle of a wooden frame, about two feet square, so as that the surface of the marble and frame form one even plane. Three of the sides are furnished with a high ledge, and the front, which is open, has a leather flap fastened to it, which the gold beater uses as an apron, for preserving the fragments of gold that fall off. Three hammers are employed in this business, having two round and somewhat convex faces: the first, called the cutch hammer, is about four inches in diameter, and weighs fifteen or sixteen pounds: the second, called the shoddering hammer, weighs about twelve pounds, and is about the same diameter: the third, called the gold or finishing hammer, weighs ten or eleven pounds, and is nearly of the same width. The French use four hammers, differing both in size and shape from those of our workmen.

The gold beaters also use three kinds of animal membranes; some of which are laid between the leaves to prevent their uniting together, and others over them to defend them from injury by the action of the hammer. For the outside cover, they use common parchment made of sheep skin; for interlaying with the gold, first, the smoothest and closest vellum made of calves skin; and afterwards, the much finer skins of ox-gut, stript off from the large straight gut slit open, prepared on purpose for this use, and hence called *gold-beater's skin*. The general process of their preparation, is said to consist in applying one upon another, by the smooth sides, in a moist state, in which they readily cohere and unite inseparably, stretching them on a frame, and carefully scraping off the fat and rough matter, so as to leave only the fine exterior membrane of the gut; beating them between double leaves of paper, to force out the remaining unctuality; moistening them once or twice with an infusion of warm spices, and lastly, drying and pressing them. It is said, that some calcined gypsum, or plaster of Paris, is rubbed with a hare's foot, both on the vellum, and ox-gut skins, which fill up their pores, and prevent the gold leaf from sticking. These skins, after seventy or eighty repetitions, become unfit for use; but their virtue may be restored by interlaying them with leaves of paper moistened with vinegar or white wine, beating them for a whole day, and afterwards rubbing them over with plaster of Paris; and even holes in them may be repaired by the dextrous application of fresh skins.

GOLD, the manner of preparing and beating. They first melt a quantity of the purest gold in a black-lead crucible, with some borax, in a wind furnace, and pour it into an iron ingot mould, six or eight inches long, and $\frac{3}{4}$ of an inch wide, previously greased and heated; the bar of gold is made red-hot and forged on an anvil into a long plate, which is farther extended, by being passed repeatedly between polished steel rollers, till it becomes a ribband, as

thin as paper. This ribband is divided by compasses, and cut with shears into equal pieces, which are forged on an anvil till they are an inch square, and afterwards well annealed. Two ounces of gold, which is the quantity melted at a time, make a hundred and fifty of these squares, so that each of them weighs six grains and two fifths; and as 4902 grains of gold make a cubic inch, the thickness of the square pieces is about the 766th part of an inch. All these squares are interlaid with leaves of vellum, three or four inches square; one leaf being laid between every two of them, and about twenty more of the leaves are laid on the out-sides: over these is drawn a parchment case open at both ends, and over this another, in a contrary direction, so that the vellum and gold leaves are kept tight and close. The whole is then beaten with the heaviest hammer, till the gold is stretched to the extent of the vellum: the pieces taken out of this case or mould, are cut in four with a steel knife; and the six hundred pieces thus produced are interlaid, in the same manner, with pieces of the ox-gut skins, five inches square. The beating is repeated with a lighter hammer, till the golden plates have acquired the extent of the skin; when they are divided into four, by a piece of cane cut to an edge. The whole number of leaves is then divided into four parcels, which are interlaid, as before, and beaten separately, till they are stretched for the third time to the size of the skins. The French repeat the division and beating once more. After the last beating, the leaves are taken up by the end of a cane instrument, and being thrown flat on a leathern cushion, are cut to a size, one by one, with a square frame of cane made of a proper sharpness, or with a frame of wood edged with cane. They are then fitted into books of twenty-five leaves each, the paper of which is well smoothed, and rubbed with red bole to prevent their sticking to it. The size of the French gold leaves is from somewhat less than three inches to $3\frac{1}{2}$ square; that of our's from three inches to $3\frac{1}{2}$. We shall here observe, that the gold used for the above purpose is never pure, because pure gold is too ductile to be worked between the gold-beater's skins. The newest skins will work the finest gold, and make the thinnest leaf, because they are the smoothest. Old skins, being rough or foul, require coarser gold. The finest gold for this purpose has three grains of alloy in the ounce, and the coarsest 12 grains. In general the alloy is six grains, or one eightieth part. The alloy of leaf-gold is silver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold are delivered by the master to the workman, who, if very skilful, returns 2000 leaves, or 80 books, of gold, together with one ounce and six pennyweights of waste cuttings. Hence one book weighs 4.8 grains; and as the leaves measure .33 inches in the side, the thickness of the leaf is one two hundred and eighty-two thousandth part of an inch.

The French prepare what is called green gold-leaf, from a composition of one part of copper and two of silver, with eighty of gold; but Dr. Lewis observes, that such an admixture gives no greenness to gold, and that this kind of leaf is made from the same fine gold as the highest gold-coloured sort, the greenish hue being a superficial taint given to the gold in some part of the process; this leaf is chiefly used for the gilding of books. A kind of leaf, called *party-gold*, is formed by laying a thick leaf of silver, and a thinner one of gold, flat on one another; they are then heated and pressed together, so as to unite and cohere; and being beaten into fine leaves, as in the foregoing process, the gold, though only in quantity a fourth

G O L D.

of that of the silver, extends over it and every where covers it.

GOLD, Million of, a phrase often used to signify a million of crowns.

GOLD Money. See MONEY and COIN.

GOLD, Mosaic, is gold applied in pannels on proper ground, distributed into squares, lozenges, and other compartments; part of which is shadowed to raise or heighten the rest. See MOSAIC.

GOLD Plates for Enamelling are generally made of ducaat gold, whose fineness is from $23\frac{1}{2}$ to $23\frac{3}{4}$ carats: and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter disposes the plates to tarnish, and turn green. See ENAMELLING.

GOLD, Potable, aurum potable. See AURUM Potabile, and GOLD.

GOLD Powder, for the purposes of gilding, may be made by grinding gold leaf with honey, or thick gum-water, (see *Shell-gold*): by distilling to dryness a solution of gold in aqua regia: by evaporating the mercury from an amalgam of gold, taking care well to stir the mass near the end of the process with a glass rod or tobacco pipe; or by precipitating gold from its solution in aqua regia by applying to it a solution of common green vitriol in water, or some copper, &c.

GOLD Precipitate with Tin, called also, from its supposed discoverer, *calx Cassi*, is prepared with great care both in dissolving the tin, and diluting the solution. For this purpose, a mixture of two parts of aquafortis, and one of spirit of salt, is supposed to be the best menstruum for the tin. Into this mixture some fine block tin, granulated, is to be let fall, grain by grain, waiting till one grain is dissolved before another is dropped in, that the dissolution may go on slowly, without any heat or discharge of fumes. The gold is dissolved in common aqua regia; and a few drops of this solution being mixed with some ounces of pure water, as many drops of the solution of tin are added. If the mixture changes immediately to a clear bright purplish red colour, the due degree of dilution has been determined; if the colour appears dull, a greater quantity of water must be added for the rest of the solutions. After the mixture has deposited its red matter, and become clear, a little more of the tin solution is to be dropped in, for discovering and precipitating any gold that may still remain in it; the liquor being then poured off, the precipitate is washed and dried. Lewis's Com. Phil. Techn. p. 176. See RUBY GLASS.

GOLD, Queen. See QUEEN gold.

GOLD, Shell, is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold beater's fragments, with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper, or kept in shells; whence its name. When it is used, it is diluted with gum-water, or soap-suds. The German gold-powder, prepared from the Dutch gold leaf in the same manner, is generally used, and when it is well scoured with varnish, answers the end in japanner's gilding, as well as the genuine. See GILDING.

GOLD-size for burnished gilding, is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow; grind the

clay, chalk, and black-lead separately, very fine in water; then mix them together; add the oil and tallow, and join the mixture to a due consistence; or it may be more finely prepared by grinding together some strongly calcined red ochre with the thickest and oldest drying oil that can be procured; and, previously to use, mixing it with a little oil of turpentine for giving it a proper consistence. See OIL GILDING.

GOLD-size of Japanners may be made by pulverizing gum animi and asphaltum, of each one ounce; red-lead, litharge of gold, and umbre, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to stir them till the whole be incorporated, and appears, on growing cold, of the consistence of tar; strain the mixture through a flannel, and keep it stopp'd up in a bottle, for use. When it is used, it must be ground with as much vermilion as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil, and four ounces of gum arabic; powder the gum, and mix it gradually with the boiling oil: let it continue to boil, till it becomes of the consistence of tar; strain it through a coarse cloth, keep and use it as the other.

GOLD-smith, or as some choose to express it, *flower-smith*, the artiff who makes vessels, utensils, and ornament in gold or silver. The goldsmiths work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures are cast in moulds, and afterwards polished and finished; plates or dishes of silver or gold are beat out from thin flat plates, and tankards and other vessels of that kind are formed of plates soldered together, and their mouldings are beat, not cast. The business of the goldsmith formerly required much more labour than it does at present, for they were obliged to hammer the metal from the ingot to the thinness they wanted: but there are now invented flattening-mills, which reduce metal to the thinness that is required, at a very small expence. The goldsmith is to make his own works, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy to be able to assay mixed metals, and to mix the alloy.

The goldsmith in London employs several hands under him for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the snuff-box and toy-maker, the silver turner, the gilder, the burnisher, the chaffer, the relacer, and the gold-beater, are all employed by and under the goldsmith.

GOLD-smith, Company of, in Londn. See COMPANY.

GOLD Thread, or spun gold, is a flattened gilt wire, wrapped or laid over a thread of yellow silk, by twining it with a wheel and iron bobbins. By means of a curious but complex machinery, a number of threads is thus twisted at once by the turning of one wheel. The principal art consists in so regulating the motion, that the several circumvolutions of the flattened wire, on each thread, may just touch one another, and form, as it were, one continued covering. At Milan, it is said, they make a sort of flattened wire, gilt only on one side, which is wound upon the thread, so that only the gilt side appears. There is also a gilt copper wire, made in the same manner as the gilt silver, chiefly at Nuremberg: and the ordinances of

France

France require it to be spun on flaxen or hempen threads. The Chinese, instead of flatted gilt wire, use slips of gilt paper, which they interweave in their stuffs, and twist upon silk threads.

GOLD, Tun of, is a kind of money of account, formerly used by the Dutch, and in some other countries, containing a hundred thousand florins.

A hundred pounds of, or in, gold, is found to weigh two pounds ten ounces: the sum in silver weighs twenty-six pounds four ounces. Twenty-two pence in copper farthings and half-pence, weigh one pound avoirdupois. A tun of gold, at 4*l.* the ounce, amounts to 96,000*l.* A tun of silver, at 5*s.* 2*d.* the ounce, to 6200*l.* A pound sterling of gold to 48*l.* An ounce is worth 4*l.* The penny-weight 4*s.* One grain, 2*d.* A pound of sterling silver amounts to 3*l.* 2*s.* An ounce is worth 5*s.* 2*d.* The penny-weight, 3*d.* and something more; one grain a half-penny. A pound of silver avoirdupois comes to 3*l.* 5*s.* 3*d.* half-penny.

GOLD, Virgin, is pure gold, just as it is taken out of the mines, before it has undergone any action or preparation of fire; whence the Greeks call it *αυρος*.

Such is the *αυμοχρυσος*, or gold-dust, and that got by lotion in the lavaderos in Chili: it is added, that there are masses or lumps of pure gold found in the mines, particularly those of Hungary. Accordingly, in the emperor's collection, are still preserved several plates of gold, said to have been thus found.

Virgin gold is sometimes very pale, and so soft, that it may be moulded into any figure with the hand; it even takes an impression from a seal, like the softest wax. To harden it, as also to heighten its colour, they mix emery with it.

GOLD, White. See PLATINA.

GOLD Wire is a cylindrical ingot of silver, above an inch thick, two feet in length, and weighing about twenty pounds, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. There is very little wire made entirely of gold, and this chiefly for one particular purpose, that of filligree work.

It is amazing to what degree of fineness the gold is here drawn; and yet it still keeps firm together, and never shews the least signs of the silver underneath it. The reader may see a computation hereof, as also a more particular account of the manner of proceeding, under the article DUCTILITY of gold.

GOLD Wire flatted, is the former wire flatted between two rollers of polished steel, to fit it to be spun in silk, or to be used flat as it is without spinning, in certain stuffs, laces, embroideries, &c.

Manner of forming Gold Wire and Gold thread, both round and flat.—The first object, which is of the utmost consequence, is the choice of the purest gold; for on this chiefly depends the beauty and durability of the colour of the laces, brocades, and other commodities prepared from it. To a difference in this respect, the boasted superiority of the French laces to the generality of those made in England, till of late, has been wholly owing. With regard to the silver that forms the body of the wire, it is said that there is an advantage in its being alloyed. The French silver for gilding is said to be alloyed with five or six penny-weight, and ours with twelve penny-weight of copper, in the pound Troy. The gold is employed in thick leaves,

which are applied all over the silver rod, and pressed down smooth with a steel burnisher. Several of these leaves are laid over one another, as the gilding is required to be more or less thick. The smallest proportion allowed by act of parliament, is 100 grains of gold to a pound, or 5760 grains of silver. The largest proportion for the best double gilt wire was formerly 120 grains to a pound; but the proportion of gold has been of late increased to about 140 grains. The first part of the drawing process, as well as the preparation and gilding of the silver rod, is performed by the refiner, who uses plates of hardened steel, with a piece of tough iron welded on the back, to prevent the steel from breaking. The holes in these plates are conical, being larger in the back part than in the steel, that the rod may not be scratched against the outer edge, and that they may contain bees-wax, which makes the rod pass more freely, and preserves the gold from being rubbed off. One end of the rod, made smaller than the rest, is pushed through a hole that will admit it, when the plate has been properly secured, and laid hold of by strong pincers, called clamps, adapted to the purpose; to these pincers, which are so contrived, that the force which pulls them horizontally, serves at the same time to press them together, a rope is fastened by one end, and the other end goes round a capstan with cross bars, which requires the strength of several men to turn it. The rod, thus drawn through, is well annealed; it is then passed through the next hole; and the annealing and drawing are repeated, till, being reduced to about the size of a large quill, it is delivered in coils to the wire-drawers. The remainder of the process requires plates of a different quality, which are brought from Lyons in France, and are formed of a metallic mass, whose prevailing ingredient is iron: the holes are drilled in them here. These plates are of two sorts; some of considerable thickness, for the wire in its larger state, and others about half as thick, for the finer wire. In the use of these plates, furnished with a variety of holes, the dexterity of the workman principally consists in adapting the hole to the wire: for this purpose he uses a brass plate, called a size, on which is measured, by means of notches, like steps cut at one end, the increase which a certain length of wire should gain in passing through a fresh hole; and if the wire is found to stretch too much or too little, the hole is widened or contracted. Slits, of different widths, in thick polished iron rings, serve also as gages for measuring the degree of fineness of the wire.

The wire-drawer's process begins with annealing the large wire received from the refiner, which he does, by placing it, coiled up, on some lighted charcoal, in a cylindrical cavity, called the pit, under a chimney, and throwing more burning charcoal over it. When it is cooled by being quenched in water, one end is passed through the first hole in the thick plate, and fastened to an upright wooden cylinder six or eight inches in diameter; in the top of which are two staples, and through these is passed the long arm of a handle, by which the cylinder is turned on its axis by several men. By this process, called *degrossing*, the wire is frequently annealed and quenched, after passing through every hole, or every other hole, till it is brought to about the size of the small end of a tobacco pipe, and then cut into portions for the fine wire-drawer. In this last part of the wire-drawing process, annealing is not necessary, but the wire is waxed at every hole. The contrivance for drawing the wire through the plate in this case, when less force is needful, is a kind of a wooden wheel placed horizontally, having in its upper surface small holes at different distances from the axis, into one or other of which, according to the force required,

is inserted the end of an upright handle, whose upper end is received in a hole made in a cross bar above. From this the wire is wound off upon a smaller cylinder, called a rochet, placed on the spindle of a spinning-wheel; and this cylinder being placed behind the plate, the wire is again drawn through upon the first, and being brought to the proper fineness, it is annealed for the flattening-mill. In this annealing, the wire is wound on a large hollow copper bobbin, set upright, including small-coal, and encompassed with lighted charcoal or small-coal, communicating a gradual heat. The wire, in this state, must be watched and removed from the heat, when it appears of the proper colour. The next operation is that of the flattening-mill, which consists of two perfectly round and exquisitely polished rollers, formed internally of iron, and wetted over with a plate of refined steel: these rollers are placed with their axes parallel, and their circumferences nearly in contact; they are both turned with one handle; the lowermost is about ten inches in diameter, the upper little more than two, and their width or thickness is about an inch and a quarter. These rolls are sometimes repolished with putty, prepared by calcining a mixture of lead and tin. The wire, unwinding from a bobbin, and passing between the leaves of a book gently pressed, and through a narrow slit in an upright piece of wood, called a ketch, is directed by a small conical hole in a piece of iron, called a guide, to any particular part of the width of the rollers, some of the best of which are capable of receiving, by this contrivance, forty threads. When the wire is flatted between the rollers, it is wound again on a bobbin, which is turned by a wheel, fixed on the axis of one of the rolls, and so proportioned, that the motion of the bobbin just keeps pace with that of the rolls. Dr. Halley states that six feet in length of the finest gilt wire before flattening will counterpoise no more than a grain; and as the gold is not quite $1\frac{1}{2}$ th of the whole, a single grain of gold thus extended will be 345.6 feet long. By flattening, the length of the wire is increased about one-seventh, and its weight is equal to $1\frac{1}{96}$ th of an inch; hence the surface occupied by one grain is equal to 98.7 square inches, with a thickness of $1\frac{1}{490444}$ th of an inch. (See DUCTILITY.) See on the subject of the preceding articles, Macquer's Dict. of Chemistry, Eng. edit. 1777. and particularly Dr. Lewis's Philosophical Commerce of Arts, *passim*. See also Aikin's Dictionary.

GOLD, in *Medicine and Chemistry*. The chemists make several preparations of gold for medicinal uses; as salts, mercuries, and tinctures of gold; but it is a point not yet well agreed on, whether gold has any real property whereby it may be of use in medicine.

Some mechanical physicians have had a notion, that if the particles of gold could be rendered fine enough, so as to circulate with the blood, that it would prove more effectual in the cure of diseases than mercury. But this is a mere hypothesis. The *aurum fulminans* has been used, and other preparations of gold are to be met with in authors; but they seem to meet with little credit among modern practitioners.

GOLD, in *Heraldry*, is one of the metals, more usually called by the French name, OR.

GOLD-finch, in *Ornithology*, is the *FRINGILLA carduelis* of Linnæus; which see.

GOLD-fish, in *Ichthyology*, is the *CYPRINUS auratus* of Linnæus; which see.

GOLD-fish is also a name by which some authors have called the *alausa*, *alosa*, or *shad*, from the yellow colouring it frequently has on the covering of the gills. See *CLUPEA Aloja*.

GOLD of Pleasure, in *Botany*. See *MYAGRUM*.

GOLD Coast, or, as it is sometimes called, *Guinea proper*, a country of Guinea, on the S.W. coast of Africa, bordering on that part of the Atlantic which is called the gulf of Guinea, and extending between three and four degrees from the river Ankobar, or, as others say, from the Colla, or the Assinoc, to the Volta, and deriving its name from the quantity of gold which it produces. It is bounded on the north by Kongo or Congo, on the east by the Slave coast, on the west by the Ivory coast, and on the south by the gulf of Guinea. It comprehends a number of petty states or kingdoms, *viz.* Adomir, called like-wise Saku and Avena, Axim, Ankobar, Adom, likewise called Little Inkaïfan, or Warsher, Jabi or Jabo, Commodo or Guaffo, Fetu, Sabo, Fantin, Acron, Agonna or Anguirra, Amra or Aquamboe, Lableade, and Niugo or Lambi. Each of these provinces or kingdoms contains one, two, or more towns or villages on the sea-coast, between, or under the European forts and settlements. Eight of these are real monarchies, having their own proper kings; the rest are republics, governed by magistrates, who are subject to the laws and periodical changes. Upon the river Ankobar, or Cobre, which some reckon the first proper county of the Gold Coast, there is a number of towns, which compose three different provinces of Ankobar or Ancober, Aborrel or Abocro, and Eguira. at which latter place the Dutch had formerly a fort, and carried on a considerable trade in gold. Eight leagues E. of cape Apollonia stands the town of Axim, called by some Achembone. (See *ACHEMBONE* and *AXIM*.) See *ACRON*, *ADOM*, *ADOMIR*, *ANTA*, *COM-MENDO*, &c. &c. The country throughout the Gold Coast abounds in hills, adorned with high and beautiful trees, among which are the palm, the cocoa-nut, the papay, and the banana. The vallies between the hills are wide and extensive, and fit for the plantation of all sorts of fruit; and if they were as well cultivated as watered, they would supply half the coast with provisions. The soil produces in great abundance very good rice, the richest sort of millet with red grain, yams, potatoes, and other roots, all good in their kind. The sugar-cane grows here plentifully, and larger than any where else on the Coast of Guinea. Palm-wine and oil are very good, and very abundant; the country also has plenty of tame cattle and wild beasts. The domestic animals are bulls, cows, sheep, and goats, the last of which are numerous and their flesh is excellent; neither the mutton nor beef is good; but of all animal food dog's flesh is most preferred by the negroes. The wild animals are elephants, tygers, jackalls, hoars, deer of various sizes, cats, porcupines, monkies, rats, mice, &c. &c. Among the birds are pheasants, parrots, maccaws, turtle-doves, and several others. The reptiles are numerous; such as snakes, serpents, vipers, lizards, scorpions, spiders, &c. The coasts, lakes, and rivers abound with fish, and likewise with alligators and gunas, an amphibious animal, resembling the crocodile, and four feet in length. The climate is very hot from October to March, but during the other months tolerable. The natives are generally healthy; but to Europeans the climate is insalubrious, and often fatal, especially in the months of July and August.

It is observed that of all the countries on the coast of Western Africa, the Gold Coast experiences the most intense heat. Here, a moderate traveller, near Rio Volta, has seen Fahrenheit's thermometer as high as 95 $\frac{1}{2}$ in his chamber, and 134° in the open air; surpassing by 26 the greatest heat observed by Adanson on all the banks of the Senegal. Although this traveller advanced only 10 miles from Christianburg on this coast, his journey is curious.

The

The countries he visited during his short excursion in the interior, are represented as very beautiful, fertile, and populous; they are, in general, woody, but, nevertheless, more healthy than the shores; they are agreeably intermingled with mountains, vallies, and hills. Fresh water, which is scarce and bad on the coast, is here excellent and abundant. About five miles from Christiansburg Hiert observed a chain of mountains covered with tall trees, and composed of large grained granite, of gneiss, and of quartz.

The native negroes of the Gold Coast are in general tall, straight, and well-proportioned, with oval faces, sparkling eyes, regular, white teeth, mouths of a moderate size, and lips tinged with a better colour and thinner than those of the negroes of Angola. As to the qualities of the mind, they have a quick apprehension and ready memory, accompanied with an astonishing presence of mind, and equanimity; but they are generally so indolent that mere necessity puts them upon exerting the faculties they possess. In general, they are crafty, fraudulent, and treacherous; thieves, gluttons, and drunkards, and equally incontinent and covetous. When they obtain a victory over their enemies, they return home dancing and singing, and when defeated do the same round the graves of their friends and fellow-soldiers. Alike insensible of grief or joy, they sing till they die, and dance into the grave. The women are proportionably handsomer than the men, straight, slender, and well-limbed; their chests high, their mouths small, and their eyes indicating vivacity and spirit. They are quick, cheerful, and loquacious; gay in their disposition, and loose in their principles as to gallantry, but temperate in their diet. When the men and women overcome their natural indolence, they are laborious, industrious, and ingenious; and apply with activity and diligence to agriculture or fishing, so far as they are excited by poverty or avarice. Their dress is various according to their rank and circumstances; but the rage of dress is chiefly prevalent among the women, who are fond of adorning all parts of their bodies with gold, coral, and ivory trinkets; and this rage they derived from the Portuguese and Dutch, as before their arrival men and women went naked to the age of maturity. They are fond of frequent ablutions, and being accustomed to the use of water, they are excellent swimmers and divers from their youth. Beside the natural inhabitants of the Gold Coast, there is a great number of Mulattoes, a mixed progeny, arising from the commerce of Europeans with the black women. This spurious race forms gangs of thieves and plunderers, void of decency, honour, honesty, or principle in their dealings with each other, with the Negroes, or the Europeans. These call themselves Christians, although they are the grossest of all idolaters, and most of their women prostitute their bodies publicly to Europeans, and privately to the Negroes. The towns and villages of this coast consist of a multitude of little huts or cabins, dispersed in groups, without order or design, and communicating with each other by narrow crooked roads, which terminate in the centre of the town or market place.

It is observable that the further you remove from the sea-coast, the more civilized do the natives appear, at least so far as relates to their mode of building and of living. The common food of the Negroes, in this part of Africa, is a pot of millet boiled to the consistence of bread, yams, and potatoes, over which they pour some palm-oil, and garnish the dish with herbs and putrid fish. This is their meals on common days; and on holidays they feast upon beef, mutton, and fowls. They begin the day with drinking brandy, and conclude the evening with palm-wine, mirth, riot, and tobacco, of which they are extravagantly fond. In eating

they are temperate, but very profuse in drinking. Their marriages are encumbered with few ceremonies, and without any previous courtship; and they are as easily dissolved as contracted. Polygamy is allowed among them; and the women are generally doomed to the most laborious offices; they are obliged to cultivate the ground, sow millet, plant yams, and provide subsistence for the husband, who is idly spending his time in gossiping, drinking, and smoking. The rich, however, have two wives, who are exempted from labour and all servile employments; and to them the management of the house is intrusted, and a sort of authority over all the other women is committed. It is said to be no uncommon expedient among Negroes to marry, in order to obtain a livelihood by the prostitution of their wives. As the wealth of the Negroes consists chiefly in the number of their family, they are anxious for multiplying their children; and a pregnant woman is treated with great tenderness and respect. A child, as soon as it sees the light, is consecrated by the priest, and has three names given to it. Circumcision, it is said, though practised in other parts of Africa, is hardly known on the Gold Coast, except at Acra, where it is performed at the time of baptism or consecration. Besides their lawful wives, the Negroes often keep concubines, who are preferred to their wives, and more tenderly treated; nevertheless their children are reckoned illegitimate. But legitimate children never inherit any paternal fortune, in any kingdom on the Gold Coast, except at Acra. In the countries of Eguira, Axim, Ancobar, Anta, and Adom, there are certain women who never marry, but are dedicated by profession to the public use, and initiated in their vocation in a formal manner. Among the Negroes there is a variety of mechanical arts, in which they are expert; such as the making of wooden and earthen vessels and plates, chair-mattings, copper ointment boxes, bracelets, necklaces, rings, and ear-rings of gold, silver, or ivory; and also all sorts of weapons and instruments of war. Their tools, which are rude and simple, consist only of a stone for an anvil, a pair of tongs, a pair of bellows, a file, a saw, and a hammer. They can finish with extraordinary exactness steel-wire, and materials of gold, brass, and copper. In building canoes, which are of various sizes, from 30 to 14 feet in length, and three or four feet in breadth, the Negroes are very ingenious, and they are no less dextrous in the use of them. With regard to the husbandry of the Negroes, they sow in the rainy season, the soil at other times being unmanageably hard; and they adapt their ground to the nature of the grain; sowing maize in elevated and dry situations, and rice or millet in low marshy lands, subject to inundations. The natives of the coast, finding it easy to dispose of all their grain, have established corn markets in every village, and the price of grain, in gold-dust, cowries, &c. is rated by certain officers of police, appointed by the king. Hither the men and women meet from considerable distances, bearing heavy burdens; and the women especially submit to great labour and fatigue in this way, that they may exchange their heavy loads for European commodities, such as looking-glasses, bracelets, ear-rings, glass-beads, and other female trinkets, suited to their taste for dress and finery. The markets are exempted from all duties and imposts. Besides these frequent markets, they have also fairs twice a year for European wares. All the diversions among the Negroes consist of dances, to which they are excessively addicted, music, and mock combats, which often terminate tragically. The principal musical instruments among the Negroes are horns, made of ivory, trumpets, drums of different sizes, and a kind of harp, with six or eight strings.

The honour of the first discovery of the Gold Coast is contested between the French and Portuguese; the French pretend that they were acquainted with Nigritia and Guinea above 100 years before the Portuguese began their discoveries, or about the year 1346 or 1364, but little credit is attached to these accounts of French writers. The Portuguese, it is said, fitted out a ship at Lisbon, under the protection of Don Henry, for the sole purpose of making discoveries along the coast of Africa. At this time Alphonso I. reigned in Portugal. The navigators, it is further said, were driven on an island in the gulf of Guinea, which they called St. Thomas, and where they made a long stay, laying the first foundation of a colony in this island. Having repaired their vessel, they returned to Lisbon, and arrived there in 1454. The Portuguese soon equipped a fleet, and pushed their discoveries as far as Benin, and in process of time arrived in the road of Acra, on the Gold Coast, where they procured a quantity of gold. A number of adventurers from the island of St. Thomas arrived at Elmina four years after the departure of the French. Purchas relates, that Alphonso, having little leisure for pursuing discoveries towards the latter end of his reign, gave an exclusive privilege for five years to Fernando Gomez, a citizen of Lisbon, to sail to the coast of Africa: and a person, depicted by him, says Purchas, discovered Elmina; and during this period, were also discovered the islands of St. Thomas, St. Matthew, Annobon, and del Principe. In 1481 John II. encouraged the commercial spirit of his subjects, and projected further discoveries; and it was probably upon this occasion, notwithstanding the assertions of French writers, that fort St. George de la Mina, or Elmina, had its first rise. John, the successor of Alphonso, conferred many privileges on this new colony. A few years after, the same prince established a Guinea company, with exclusive privileges. In the reign of Henry III. of France, after the termination of the civil wars, the French began to renew their voyages to the Grain and Gold Coast. From this period the credit of the Portuguese began to decline, and other Europeans began to open a commerce with the Coast of Guinea. Among others the Dutch engaged in the warfare, which had been prosecuted between the Portuguese and other Europeans; and by perseverance they made themselves masters of the forts of Elmina and Axim; obtaining, by their courage, that security, which the Portuguese had lost by their insolence and cruelty. The first Dutchman who led the way to Guinea, was one Bernard Erick, in 1595. Running along the Gold Coast, he established a correspondence with the natives, treated them with civility, and alienated their affections from the Portuguese. At length, by their intrigues with the king of Sabo, the Dutch obtained permission to build a fort, three leagues E. of Cabo Corfo, or Cape Coast. This fort was finished in 1624, and the Dutch power founded in Guinea, at the time when the States were engaged in a war with Philip IV. of Spain. In the year 1637 they succeeded, after much resistance, in taking the fort of St. George d'Elmina, and in the year 1642 the fort of Axim also fell into their hands. The Dutch, having thus far been successful, proceeded to attack the English settlements. In tracing the first British establishments on the Coast of Guinea, we may begin with observing, that a trade here had been carried on by some private adventurers, without the aid or protection of the government. In 1585 and 1588, queen Elizabeth granted two patents to certain rich merchants of England; one for an exclusive trade to the coast of Barbary, and another for that of Guinea. In 1592 a third patent was obtained by the same body of merchants. In 1651 the republic of Eng-

land encouraged the African trade; and in 1662 Charles II. granted a charter to a body of merchants, under the name of the Royal Company of England trading to Africa, extending their limits from the mouth of the Straits to the Cape of Good Hope. The affairs of this company falling into disorder, the king erected another corporation, called the "Royal African Company," which has subsisted to this day. This charter bears date, Sept. 27, 1672. This company, with a small capital, was diligent and successful; Cape Coast was enlarged and beautified; the forts of Acra, Dixscove, Winchaw, Sukkonda, Commendo, and Anaraboa, were built or repaired, all of them on the Gold Coast, and several within musket-shot of the Dutch settlements. They bought Fredericksburg of the Danes, and built a new fort in Whidah. See *African COMPANY*.

GOLD Cronach, a town of Germany, in the principality of Bayreuth, which had formerly a gold mine; 5 miles N. of Bayreuth.

GOLDAPP, a town of Prussian Lithuania; 68 miles E. S. E. of Konigsberg—Also, a river of Prussia, which runs into the Rominte; 6 miles N. of Goldapp.

GOLDAST, MELCHIOR HEIMENSFELD, in *Biography*, a learned writer of the 16th century, was a native of Switzerland. He studied the civil law at Altdorf, but he is better known as a man of letters. His works, though not marked for originality, were highly esteemed by the learned of the period in which he flourished: the principal of these are, 1. "Monarchia Sancti Imperii Romani," in three volumes folio, published in 1611-14. These volumes consist of a collection of treatises on the civil and ecclesiastical jurisdiction of the empire. "Alemanix Scriptores," three volumes folio, 1730. "Commentarius de Bohemix Regno," 4to. "Informatio de statu Bohemix quoad Jus," 4to. "Sybilla Francica," being a quarto collection of pieces relative to the maid of Orleans: "Scriptores Rerum Sævicarum." "Collectio Consuetudinum et Legum Imperialium." "Politica Imperialia," and a collection of letters, written to him by several men of learning. This last work was printed at Frankfort in 1688. Mr. Goldast was of a capricious temper and of changeable habits, which prevented him from rising in the world. He died in 1635, having long struggled with poverty. Moreri. Bayle.

GOLDBERG, in *Geography*, a town of Silesia, in the principality of Lignitz, deriving its name from a gold-mine in its vicinity, which was formerly very rich. The earth called sigillata terra. is dug near it; and the inhabitants are employed in the woollen and linen manufactures; 12 miles S.W. of Lignitz. N. lat. 51 4'. E. long. 15 53.—Also, a town of the duchy of Mecklenburg; 15 miles E. of Wismar.

GOLDECK, a town of the archbishopric of Salzburg; 28 miles S. of Salzburg.

GOLDEN, something that has a relation to gold, or consists of gold; is valuable like gold, or the like.

GOLDEN Bull, *Bulla Aurea*. See *BULL*.

GOLDEN Calf was a figure of a calf, which the Israelites cast in that metal, and set up in the wilderness to worship, during Moses's absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of, as related *Exod. xxxii.*

The commentators have been greatly divided on this article: the pulverizing of gold, and rendering it potable, is an operation in chemistry of the last difficulty; and it is hard to conceive how it should be done at that time, before chemistry was ever heard of, and in a wilderness too! Many, therefore, suppose it done by a miracle; and the rest, who

allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process.

Moses could not have done it by a simple calcination, nor amalgamation, nor antimony, nor calcination: nor is there one of those operations that quadrates with the text.

Mr. Stahl has endeavoured to remove this difficulty. The method Moses made use of, in making his *aurum potabile*, according to this author, was the same with that which now obtains; only, instead of tartar, he made use of the Egyptian natron, which is common enough throughout the East.

GOLDEN Cape, in *Geography*, a cape of England, on the W. coast of Dorsetshire. N. lat. $50^{\circ} 43'$. W. long. $2^{\circ} 50'$.

GOLDEN Cups, a name by which some call the ranunculus, or crow-foot.

GOLDEN Eye, in *Ornithology*, the *ANAS Clangula*. See DUCK.

GOLDEN Eye, a species of fly. See CHRYSOPIS.

GOLDEN Fleece, in the *Ancient Mythology*. See ARGONAUTIC.

GOLDEN Fleece, *Order of the*, is a military order, instituted by Philip the Good, duke of Burgundy, in 1429.

It took its denomination from a representation of the golden fleece, borne by the knights on their collars, which consisted of flints and fleels. The king of Spain is now grand master of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepts contend to be no other than the secret of the elixir, written on the fleece of a sheep.

GOLDEN Flower, in *Botany*. See CHRYSANTHEMUM.

GOLDEN Flower-gentle, a name sometimes given to several species of the amaranth.

GOLDEN Head, in *Ornithology*, a water-fowl, otherwise called *anas arctica*. See DUCK.

GOLDEN Island, in *Geography*, a small island at the entrance of the gulf of Darien, in Terra Firma, S. America. N. lat. $8^{\circ} 20'$. W. long. $72^{\circ} 32'$.

GOLDEN Lake, a lake of the island of Borneo. N. lat. $3^{\circ} 55'$. E. long. $115^{\circ} 45'$.

GOLDEN Lung-wort, in *Botany*. See HIERACIUM.

GOLDEN Maiden-hair. See ADIANTUM *aureum*, and POLYTRICHUM.

GOLDEN Mouse-ear. See HIERACIUM.

GOLDEN Number, in *Chronology*. See CYCLE of the Moon, and NUMBER.

GOLDEN Prebendary of Hereford. See PREBENDARY.

GOLDEN River, in *Geography*, a river of America, which runs into the Mississippi, N. lat. $43^{\circ} 20'$. W. long. $92^{\circ} 2'$.

GOLDEN River, or *Rio del Oro*, a river of America, which runs into the Spanish Main, N. lat. $14^{\circ} 44'$. W. long. $82^{\circ} 55'$.

GOLDEN Rod, or *Saracen's Wound-wort*, *virga aurea*, in *Botany*. See SOLIDAGO.

GOLDEN Rod Tree. See BOSEA.

GOLDEN Rule, in *Arithmetic*, a rule or praxis of great use and extent in the art of numbers, whereby we find a fourth proportional to three quantities given. The Golden Rule is also called the Rule of Three and Rule of Proportion. See its nature and use under the article RULE of Three.

GOLDEN Sapphire is a species of the mola or cleampane. (See INULA.) It grows naturally on the sea-coasts in many parts of England, and is sometimes sold in the London mar-

ket for the true sapphire, though entirely destitute of its warm aromatic taste. See SAMPHIRE.

GOLDEN Saxifrage. See CHRYSOPLENIUM.

GOLDEN Stone, *order of the*. See STOLE.

GOLDEN Sulphur of Antimony. See ANTIMONY.

GOLDEN Thistle, in *Botany*. See SCOLYMUS.

GOLDENSTEIN, in *Geography*, a town of Moravia, in the circle of Olmutz; 32 miles from Olmutz.

GOLDENSTETT, a town of Germany, in the country of Diepholz; 11 miles N. of Diepholz.

GOLDENTRAUN, a town of Upper Lusatia; 16 miles S.E. of Gortitz. N. lat. $50^{\circ} 27'$. E. long. $15^{\circ} 26'$.

GOLDINGEN, a town of the duchy of Courland, situated near the river Weta, defended by an old castle, and containing two churches; 48 miles W.N.W. of Mittaw. N. lat. $56^{\circ} 51'$. E. long. $21^{\circ} 44'$.

GOLDLAUTER, a town of Germany, in the county of Henneberg, 12 miles N.E. of Meiningen.

GOLDMAN, NICHOLAS, in *Biography*, a mathematician, was born at Breslaw, in Silesia, in the year 1623, and died at Leyden in 1665. The works by which he is generally known are "Elementa Architecturæ Militaris," 1643. "De Usu Proportionarii Circuli." "De Stylometricis," 1662, and another treatise "On Architecture," published in 1696, with numerous engravings, and the life of the author. *Moreri*.

GOLDONI, CHARLES, was born at Venice in the year 1707. Almost from his infancy he gave indication of a humorous character, and a propensity to dramatic performances. Before he could well read he became an author, and wrote the plan of a comedy by the time he was eight years old. This piece possessed so much merit, that it required the testimony of respectable witnesses to verify its being the production of a child. He received the elements of education at Venice, from this city he went to the Jesuits' college at Perugia to study rhetoric, and afterwards he studied philosophy at Rimini. His mind was, however, too deeply engaged in theatrical exhibitions to make the system of Aristotle a predominant pursuit. Every leisure moment he spent at the theatre, till at length he passed from the pit to the stage, and joined a company of players. This, by his own account, was an error, which drew after it many serious consequences. He had been intended by his father for the profession of physic, which he was unable to study: he was then solicited to prepare himself for the bar, and was engaged, after many changes, in practice at the courts of Venice. After this he was appointed secretary to the Venetian resident at Milan, where he became acquainted with the manager of the theatre, and wrote a farce for him, entitled "The Venetian Gondolier," which was performed and printed: by degrees he became united to the company, and composed many pieces for them. He now turned his thoughts towards reforming the Italian stage, and so earnest was he in his projects, that it is said in a single year he wrote sixteen new comedies, besides forty-two other pieces for the theatre, and among these are reckoned some of his best productions. The first edition of his works was published in 1753 in 10 vols. 8vo. After this he published many additional pieces under the title of the "New Comic Theatre." He had composed 59 other pieces so late as the year 1761, and here closes the literary life of Goldoni in Italy. He now repaired to Paris, and was as zealous in his endeavours to reform the Italian theatre there as he had been in his own country. His first attempt was in a piece called the "Father of Love," but the bad success of this comedy was a sufficient warning to him to desist from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general taste, and published

twenty-four comedies. At the end of two years he was preparing to return to Italy, when he was suddenly urged to become Italian master to the princesses, aunts to the reigning monarch. During this engagement he lost his sight, which he never after completely recovered, and at the end of three years he received a very inadequate recompence for his labour and the time spent at court, namely, 100 louis in a gold box, and the grant of a pension of four thousand livres per ann. This, with what he was enabled to make by his works, was amply sufficient for all his wants. When he had attained his 62d year he began to publish comedies in the French language, which were well received, and some of them became extremely popular. After the death of Lewis XV. Goldoni was appointed Italian teacher to the princess Clotilde, the present princess of Piedmont, and after her marriage, he attended the unfortunate princess Elizabeth in the same capacity. His last work was the "Volponi," written after he had retired from court. It was his misfortune to live to see his pension taken away by the revolution, and, like thousands in a similar situation, he was obliged to pass his old age in poverty and distress. He died in the beginning of the year 1793, at a period when the Brissotines had the sway in the national councils, and when Goldoni would, for a short time at least, have received every attention that a grateful country could have afforded. As a comic poet, Goldoni is reckoned among the best of the age in which he flourished. His works were printed at Leghorn in 1788-91, in 31 vols. 8vo. He has been reckoned the Moliere of Italy, and he is styled by Voltaire "The painter of Nature." "Goldoni," says his biographer, "is one of those authors whose writings will be relished in the most remote countries, and by the latest posterity. His profound knowledge of the human heart, his extensive description of the vices and virtues of men, in all ages and stations, will justify my concluding this imperfect eulogy with applying to him the following lines of Horace from his first Epistle :

"Æque pauperibus prodest, locupletibus æque
Æque neglectum pueris, senibusque nocebit."

Monthly Magazine, vol. v.

His principal works are comedies in prose, for declamation, of which the exact number is not known; but they at least amounted to 120 before he left Italy at the desire of Louis XV. to write for the "Theatre Italien" at Paris, for which theatre he composed at least 30.

This fertile, natural, and pleasing writer, was ambitious at first of treating serious and tragic subjects; but finding, as he tells us himself in his life and prefaces, that Metastasio was arrived at as high a point of perfection in his serious operas as that species of drama was capable of, he pointed his thoughts wholly to comedy, which had been long treated in such a buffoon and farcical manner, as to stand in great need of reformation.

But though he had determined not to attempt serious pieces for music, yet Galuppi prevailed upon him, much against his inclination, to furnish him with three serious operas for the theatre at Venice; these were, Orontes, king of Scythia; Gustavus Adolphus; and Statira. But though they had great success, Goldoni never thought them worthy of publication. He was not more vain of his comic operas. However, he produced at different times and places 40 or 50, which, without his consent or knowledge, were collected and published in 6 vols. 12mo.; they are not very estimable works, being on the old burletta model, full of buffoonery, and a broad kind of Italian humour, tasted in no other country, though suffered for the sake of the music, which is often ingenious, imitative, and sometimes graceful, but more frequently grotesque.

Goldoni is, perhaps, the only author of comic operas in Italy, who has given them a little common sense, by a natural plot, and natural characters; and his celebrated comic opera of the "Buona Figliuola," set by Piccini, and first performed in London Dec. 9th, 1766, rendered both the poet and composer, whose names had scarcely penetrated into this country before, dear to every lover of the Italian language and music, in the nation. This admirable production, before it was brought hither, had saved the *imprejario* of the opera at Rome from ruin, and been performed in the principal cities of Italy. In the year 1760, Piccini, passing through Rome, in his way to Milan, was entreated to compose a comic opera for the Teatro delle Dame in that city, which had lately been very unfortunate. No libretto was ready, and application having been made to the poet Goldoni, at this time in Rome, he furnished the musical drama of "La Buona Figliuola," from his comedy of "Pamela," in a few days. Several of the original performers were now in London, particularly the first buffo, Lovattini, and the serious man Savoi, with the *buffo caricato* Morigi. And though females are not allowed to appear on the stage at Rome, yet signora Guadagni had previously performed the part of Cecchina in several cities of Italy, with great and well-deserved applause before his arrival here.

After the great success of the "Buona Figliuola," the public was disposed to hear with partiality any production by the same authors; and when the "Buona Figliuola Maritata," (or Pamela in high life), was brought out, the crowd at the opera-house was prodigious; but expectation, as usual, was so unreasonable as to spoil the feast; to gratify it was impossible. Some ascribed their disappointment to the composer, some to the performers, but none to themselves. The music was excellent, full of invention, fire, and new effects; but so difficult, particularly for the orchestra, that the performers forgot it was winter. The principal part of the Marchesa was given to Zamparini, a very pretty woman, but an affected singer. Music so difficult to perform was not easy to hear; and this drama was never sufficiently repeated for the public to be familiarly acquainted with it. They were glad, as well as the performers, to return to the "Buona Figliuola" for their own ease and relief from a too serious attention.

In France, Goldoni wrote several very successful comedies for declamation in the French language, but we are not acquainted with any dramas which he produced for music in that country. Poor Goldoni was in such favour with the royal family of France before the revolution, that he was never allowed to return to his own country; but died at Paris in the year of *terror*, 1793, at the age of 83.

GOLDSBOROUGH, in *Geography*, a post town of America, in Hancock county and state of Maine, incorporated in 1789, and containing 379 inhabitants; 47 miles E. of Penobscot. N. lat. 44° 19'.

GOLDSINNY, in *Ichthyology*, a fish discovered on the coast of Cornwall, in the whole form of the body, lips, teeth, and fins, resembling the *corasse*, which is said never to exceed a palm in length; near the tail is a remarkable black spot; the first rays of the dorsal fin are tinged with black. See LABRUS *Cornubiis*.

GOLDSMITH, OLIVER, in *Biography*, was born in the county of Longford, Ireland, in 1731, though, according to other accounts, this event took place at Elphin, in 1729. He was the son of a clergyman, who gave him a literary education, and sent him early to Dublin college. Being designed for the profession of medicine, he was removed to Edinburgh in 1751, where he continued till 1754, when he left that place to avoid a process against him

For debts incurred, probably to administer to his dissipation. He was intercepted at Sunderland, and thrown into confinement, from which he was released by the kindness of two fellow-collegians. After this, he determined to visit the continent, embarked for Holland, travelled through Flanders and part of Germany, passed some time at the universities of Straßburg and Louvain; at the latter place he took his degree of bachelor of physic, and thence accompanied an English gentleman to Geneva. Here he engaged himself as travelling tutor to a young man who had become possessed of a large fortune, but whose mind was ill adapted to do credit to the gifts of Providence. They disagreed in the south of France, and Goldsmith was left to contend with the hardships of indigence in a foreign country. He returned in 1758, and had in most of his peregrinations trusted for his support to his own casual efforts. His learning ensured him a favourable reception at the monasteries, and his German flute seldom failed to procure him a meal and a night's lodging from the peasantry, who were delighted with strains which a politer audience would have treated with disdain. His arrival at London with a few pence in his pocket, was not likely to be the termination of his pecuniary distresses. He attempted to get into the employ of an apothecary, but his appearance being against him, his application was treated with disdain. He at length was admitted as usher to Dr. Milner, who kept an academy at Peckham. Here he remained but a short time, and then resolved to follow the profession of an author in London. He obtained some employment in the Monthly Review, and furnished papers for the public Ledger. He published a weekly pamphlet, entitled "The Bee," and "An Enquiry into the state of Polite Learning in Europe." After he had been some time exercising his pen in obscurity, he became on a sudden celebrated as a poet, by the publication of his "Traveller, or a Prospect of Society." This work had lain by him in MS. some years, and it was at the instigation of Dr. Johnson that he prepared it for the press. That great critic declared it as his opinion, that there had not been so fine a poem since the days of Pope. In this decision the public concurred, and the author was, almost immediately, introduced to the most eminent literary characters of the age. In the following year was published his novel of the "Vicar of Wakefield," which had been sold to a bookseller some years before, but had been kept back as the work of an unknown writer, and exciting no expectations of success. It was, however, received with unbounded applause, and has ever since borne a distinguished rank among similar compositions. His next work was a "History of England," in a series of letters from a nobleman to his son, in two volumes 12mo. a work that still continues to be read with great delight. His poetical fame reached its summit in 1770, by the publication of his "Deserted Village," which was universally admired. For this he obtained of his bookseller 100*l.* a sum which appeared to the author to exorbitantly great, that he refused to take it; but the sale of the work convinced him that he might fairly appropriate the sum out of the profits. As an author of comedy, he produced in 1768 "The Good-natured Man," which was not very successful; and in 1772 another play, entitled "She Stoops to Conquer, or the Mistakes of a Night." From this Goldsmith cleared a large sum, and it is still occasionally represented to applauding audiences. Notwithstanding the success of his pieces, by some of which it is asserted he cleared 1800*l.* in a single year, his circumstances were never very prosperous, which was partly owing to the liberality of his disposition, and partly to an unfortunate habit which he had contracted of

gaming; the arts of which he knew very little of, and consequently became the prey of those who were base enough to take advantage of his simplicity. Besides the works already treated of, Dr. Goldsmith, as he was called, though he had only taken a bachelor's degree, compiled an English history in four volumes, and a Roman and Grecian history in two volumes each; and "A History of the Earth and Animated Nature," in eight volumes 8vo. Such was the confidence which he acquired in his skill at compilation, that he formed a plan for a much greater work, viz. "A Dictionary of Arts and Sciences," but this and other schemes which he had planned were cut off by his untimely death. A despondence of mind, probably occasioned by the consciousness of the bad state of his affairs, had been secretly preying upon him, when in March 1774 he was attacked with the symptoms of a low fever, under which he sunk on the 4th of April. He was buried in the Temple church-yard without much attendance, but a monument has since been erected to his memory in Westminster abbey, with a Latin inscription by Dr. Johnson.

Goldsmith, as a man, was rather admired for his genius, and beloved for his benevolence, than solidly esteemed. The best part of his moral character was a warmth of sensibility, which made him in all fortunes ready to share his purse with the indigent, and rendered him in his writings the constant advocate of the poor and oppressed. The worst feature was a malignant envy and jealousy of successful rivals, which he sometimes displayed in a manner not less ridiculous than offensive.

As a writer, no one of his time was possessed of more true humour, or was capable of more poignancy in marking the foibles of individuals. This last talent he displayed in a very amusing manner in his poem entitled "Retaliation," written as a retort to the jocular attacks made upon him in a club of which he was a member. His literary fame stands highest as a poet, in which character a place may be given him perhaps at the head of the minor class, the term minor being applied with relation to the quantity, rather than the excellence of composition. "It would not be easy," says his biographer, "to point out in the whole compass of English poetry, pieces that are read with more delight than "The Traveller;" and "The Deserted Village." The elegance of the versification, the force and splendour yet simplicity of the diction; the happy mixture of animated sentiment with glowing description, are calculated to please equally the refined and the uncultivated taste. The moral and philosophical views of society they exhibit are, indeed, objectionable; yet upon the whole they exert a favourable influence over the heart. In addition to these capital works, his pleasing ballad of "The Hermit," and some short humorous and miscellaneous pieces, complete the catalogue of his performances in verse. As a prose writer he deserves high praise for style, which he adapts with great felicity to his subject, and which, whether elevated or plain, is always clear, pure, and unaffected. Life prefixed to his poems. Europ. Mag. Ann. Regis.

GOLDWIN, JOHN, an ecclesiastical composer, was brought up under Dr. William Child, and, in 1697, succeeded him as organist at the free chapel of St. George at Windfor. In 1703 he was appointed master of the choiristers there, in both which stations he continued to the time of his death in 1719. Dr. Boyce, out of a great number of anthems by this composer, selected one for four voices, "I have set God always before me," which he has inserted in the second volume of his "Collection of Cathedral Music," and well characterized it with respect to the modulation, by saying that "it is singular and agreeable."

GOLDYLOCKS, in *Botany*. See *CHRYSOCOMA* and *GNAPHALUM*.

GOLEEAH, in *Geography*, a town of Bengal; 18 miles E. of Rangur. N. lat. 22° 28'. E. long. 85° 51'.

GOLETTA, a fortress of Africa, situated on a canal, in the kingdom of Tunis; 25 miles N. of Tunis.—Also, a narrow channel between the lake of Tunis and the sea, defended on each side by a castle.

GOLF, or **GOUF**, the name of a diversion or exercise, much used in Scotland, and played upon the lawns or links, as they are there called.

It consists of driving a ball with clubs, between two goals or holes, half a mile or a mile asunder. He who can do this with the fewest strokes of his club is the conqueror.

GOLFO TRISTE, in *Geography*, a bay on the coast of South America, in the government of Caraccas. N. lat. 10° 30'. W. long. 68° 20'.

GOLGAM, a town of Hindoostan, in Dowlatabad; 15 miles N. of Beder.

GOLGOM, a town of the island of Ceylon; 48 miles N.W. of Candy.

GOLGOTHA. See *CALVARY*.

GOLIATH, in *Scripture History*, a famous giant of Gath, who defied the armies of Israel, and was slain by David. 1 Sam. xvii. 4, &c.

GOLICH, in *Geography*, a town of Russia, in the government of Irkutsk, on the Lena; two miles S. of Or-lenga.

GOLINDA, a small island near the N. coast of Cuba. N. lat. 23° 20'. W. long. 80° 4'.

GOLISANO, a town of Sicily, in the valley of Demona; 9 miles S. of Cefalu.

GOLITZ, a town of Nubia, on the left side of the Nile; 45 miles W.N.W. of Dongola.

GOLIUS, JAMES, in *Biography*, was born at the Hague in 1596; but he pursued his studies at Leyden with the most unremitting diligence and ardour, and became distinguished for his deep knowledge of the learned languages, antiquities, philosophy, and mathematics. In 1622 he accompanied an ambassador of the United Provinces to Morocco, where he excited the admiration of the emperor Muley Zeidan, with whom he had frequent interviews. After his return to his native country he succeeded to the Arabic professorship on the death of Erpenius, under whom he had formerly studied. In 1625 he obtained permission to travel in the Levant, and passed more than a year at Aleppo, whence he made various excursions into Arabia and Mesopotamia. On his return he visited Constantinople, where he obtained very distinguished notice from the learned in that capital, by whose means he had access to the best libraries. During his absence he was appointed professor of mathematics, and returned to Leyden in 1629, and applied himself to the duties of his office. He died in 1667, having occupied with much credit the arduous situation of professor for more than forty years, and passed through all the academical honours. As an author he published the "Saracen History of Elmacin," which had been begun by Erpenius; also a life of the great Tamerlane, written by an eminent Arabian author: "The astronomical Elements of Alfergan," with a new version and learned commentaries: "An Arabic Lexicon;" a "Persian Dictionary," which was printed in London. Bayle. Moreri.

GOLUS, PETER, brother of the preceding, entered when very young among the Carmelites; like his brother he excelled in the knowledge of the Arabic language, and taught it in the seminary belonging to his order at Rome,

where those monks were educated who were intended to be sent on missions into the East. Golius was destined to this service, and having visited every part of Syria and Palestine, founded a monastery of his order on mount Libanus, over which he presided till he was recalled to Rome. Here he was employed as one of the principal assistants of Sergius Rufus, archbishop of Damascus, in preparing his edition of the Arabic bible, which was published in 1671 by the direction of the college "De Propaganda." After it was completed, Golius was appointed visitor of the missions of the East Indies. He died in this employment at Surat about the year 1673. He was author of translations into Arabic of Thomas a Kempis' imitation of Jesus Christ: of sermons on the Evangelists: an "Historic discourse of St. Gregory of Decapolis;" several small devotional pieces, and a translation from Arabic into Latin of a "Collection of Parables and Proverbs." Moreri.

GOLLI, or **COLLI**, in *Geography*, a town of Africa, near the river Grande, the inhabitants of which trade in slaves, ivory, and cotton.

GOLLING, a town of the archbishopric of Salzburg, on the Sulza; 14 miles S.S.E. of Sa'zburg.

GOLLOSING, a town of Bengal; 70 miles W. of Midnapour.

GOLNITZ, a town of Hungary, on a river of the same name; 14 miles S.E. of Kapidorff.

GOLNOW, a town of Anterior Pomerania, formerly Hanseatic, situated on the Ihna; 12 miles N. of Stargard. N. lat. 53° 37'. E. long. 24° 57'.

GOLO, a river of Corsica, which rises nearly in the centre of the island, and pursuing a N.E. course, runs into the sea; 12 miles S.S.E. of Bastia. It gives name to one of the two departments into which the island is divided; the other being Liamone. Golo comprehends the northern division of Corsica, in N. lat. 42° 30', and containing 165 square leagues, and 103,466 inhabitants, is subdivided into three circles, *viz.* Bastia, whose inhabitants are 47,842; Calvi, having 20,282 inhabitants; and Corte containing 35,342 inhabitants. There are several lofty mountains near the centre of a chain that traverses the island longitudinally. The most considerable lakes are Ino and Creno, the former of which is of unknown depth. The soil is tolerably fertile, yielding barley, millet, olives, chestnuts, wine, fruits, &c. On the hills are forests and excellent pastures. See *CORSICA*.

GOLOBGUNGE, a town of Bengal; 10 miles E. of Silhet.

GOLPHINGTON, the chief town of Washington county and state of Georgia, in America, situated near the head of Ogeechee river, about 26 miles E.S.E. of Occonee town.

GOLPS, in *Heraldry*, are roundles, or tortexaux, of a purple colour.

GOLTBURGENSES TERRA, in the *Materia Medica*, a whitish earth, used in the shops of Germany and Italy as an astringent, a cordial, and a sudorific, but little known among the English apothecaries. It is dug in many parts of Germany, as Goldberg and Strigaw, and Lignitz in Silesia; but particularly at this time in the neighbourhood of Hasselt, in the bishopric of Liege, in the circle of Westphalia. It is taken up there in considerable quantities, and usually is sealed with the impression of an eagle, and with its old name Goltbergensis terra under it. It was imagined to contain some particles of silver, and thence to derive some of its virtues: on this account Montanus called it *aurungia luna*; but experience shews that it doth not contain a particle of that metal. It is a dense compact

compact earth of a dull greyish white, soft and friable, and adheres firmly to the tongue, and makes no effervescence with acids.

GOLTIAVINA, in *Geography*, a town of Russia, in the government of Tobolsk; 188 miles E. of Eniseik. N. lat. $58^{\circ} 20'$. E. long. $98^{\circ} 14'$.

GOLTPACH, a town of Prussia, in the palatinate of Culm; 8 miles N.E. of Thorn.

GOLTVA, a town of Russia, in the government of Kiev; 112 miles S.E. of Kiev. N. lat. $49^{\circ} 15'$. E. long. $33^{\circ} 14'$.

GOLTZEN, a town of Lower Lusatia; 10 miles W. of Lubben. N. lat. $51^{\circ} 58'$. E. long. $13^{\circ} 30'$.

GOLTZIUS, HUBERT, in *Biography*, a painter, who was born at Veulo in 1520, and studied under Lambert Lombard. Becoming enamoured of the antique by having copied several works of that class, he resolved to cultivate his taste by visiting the more important Greek works preserved at Rome; and therefore travelled to that city, where he resided some time, and thence drew an ample stock of materials for his future progress in the art he professed.

He lived principally at Antwerp, where he painted the history of Jason; but as he was engaged in a variety of studies, his pictures are rare. Among other things he investigated coins and medals, and published a collection of them with critical annotations. He died at the age of 63.

GOLTZIUS, HENRY, an artist of considerable talent, who practised both painting and engraving. As a painter, he drew his resources from the study of the antique, of Raphael, Polidoro, and Michael Angelo; the last of whom appears to have been his favoured Apollo in the art, but whose faults he exaggerated in an outrageous manner, seldom attaining any of his beauties. Hence his style of design is inflated and caricature; and his expressions participate of the same taste; but his sense of hue in colour is rich, vigorous, and transparent. He died in 1617, aged 59.

GOLUB, in *Geography*, a town of Prussia, in the territory of Culm; 24 miles S.E. of Culm.

GOLUBENSKA, a town of Russia, in the country of the Cossacks, on the Don; 200 miles E.N.E. of Azoph.

GOMAHNV, a town of Hindoostan, in the circar of Mohurgunge; 45 miles N.W. of Harriopour.—Also, a town of Bengal; 8 miles S.S.E. of Goragot.

GOMAR, FRANCIS, in *Biography*, celebrated as the great opponent of Arminius, and from whom the Calvinistic party in Holland received the name of "Gomarists," was born about the year 1563 at Bruges. His parents had been brought up in the Roman Catholic religion, but having embraced the Protestant doctrines, they retired into the palatinate in 1578, for the sake of professing their principles in peace and security. Their son Francis was sent to Strasburg for his education, and pursued his studies there under the celebrated John Sturm, after which he went to Newstadt, whither the professors of Heidelberg had been obliged to retire by the elector Lewis, because they were the opponents of the Lutheran faith. In 1582 he took a journey to England, and attended the divinity lectures at the universities of Oxford and Cambridge. He was admitted to the degree of B.D. in the year 1584. By great assiduity he became very deeply learned in the Greek and Hebrew languages, and in 1537 he settled with a Dutch congregation at Frankfurt, and continued to discharge his ministerial functions, in that connection, until the year 1593, when his flock was entirely dispersed by persecution. In the following year he was invited to accept the theological professorship at Leyden, and having taken his degree of D.D. he entered upon the duties of his new station. In 1603 Armi-

nus was appointed his colleague, and openly and zealously opposed the gloomy doctrines maintained by John Calvin, and made many converts in the university. This roused the attention of Gomar, who declared himself his opponent, disputed with him in the schools of Leyden, and published treatises to excite the orthodox to make a firm stand against his doctrines, which he represented to be profane and impious; he went much farther, and endeavoured to provoke against him the indignation of the States of Holland, before whom the two combatants disputed twice in the year 1608. On one occasion, when Barneveld exclaimed that he was grateful to God that their controversies did not affect the fundamental articles of the Christian religion, Gomar protested "that he could not appear before the throne of God with Arminius's errors," thus vainly setting limits to the mercy of the most high and most merciful God. In 1611, seeing that his opponents increased in numbers and in strength, Gomar resigned his office, and retired to Middleburg. After this, he accepted the professorship of divinity, first at the academy of Saumur, and then at the university of Groningen, and at the latter place he was employed as the Hebrew professor, in addition to that of theology. He was present at the synod of Dort, and took an active part in procuring the infamous decrees by which the Arminians were condemned and proscribed as corrupters of the true faith, and enemies to their country. He died at Groningen in 1641, leaving a distinguished character for sound learning, particularly in the Oriental languages, but it cannot, and it ought not to be concealed, that he disgraced the character of a Christian minister by his bigotry and intolerance. As an author, he published many treatises, but chiefly on controversial subjects, which were collected and printed at Amsterdam in the year 1645. He was also concerned in revising the translation of the Old Testament, printed at Leyden with notes in the year 1637. Moreri. Bayle.

GOMASTAHPOUR, in *Geography*, a town of Bengal, 42 miles N.W. of Nattore.

GOMAUN, or **KEMAOON**, the name of mountains of Asia, called also those of Sewalic; an extensive ridge, which seems to form the exterior barrier of the Thibetian Alps in Sirinagar, &c.

GOMBAULD, JOHN OGIER DE, in *Biography*, a French poet of the seventeenth century, was the younger son of a gentleman of the Protestant religion, to which he adhered. He was educated at Bourdeaux, and came to Paris about the time of the death of Henry IV., and frequented the court of Mary de Medicis. Of her he obtained a pension of 1200 crowns, which was but ill-paid, and which was soon reduced nominally to one-third of that sum, so that, notwithstanding his high patrons, he passed much of his life in a state little above indigence. He was elected one of the first members of the French Academy, and was so extremely zealous for its great object, the purity of the language, that he once proposed to the academicians that they should bind themselves by oath to use no words but such as were approved by the majority of the society. He lived to a good old age, and died in 1666. He was author of many tragedies, tragi-comedies, pastorals and romances, sonnets, epigrams, &c. He also engaged in theological controversy, and wrote "Treatises and Letters concerning Religion," in favour of the Protestants. Gombault was very ready at repartee, and his wit did not leave him even in old age, for his latest publication was a collection of epigrams. Moreri. Bayle.

GOMBERT, NICOLAS, a disciple of Jusquin, who published two books of motets for many voices in 1552. He set to music a Latin epitaph on his master Jusquin;

quin; and at this time composers being scarce, he gained some reputation among those of Flanders, with very little genius. For after performing the tedious task of scoring the music of the nanna on Julquin, we found its chief merit to consist in imitations of his admirable master. This composition was in the third ecclesiastical mode of E, with a minor second, as well as third; which M. Blainville some years ago wished to pass on the public for a third or new key, different from the major and minor, which comprise all secular music at present. And it is extraordinary, that this pretension should have had any abettors in a Roman Catholic country, where old compositions in this mode are daily performed in cathedrals and collegiate churches. However, it was a matter of wonder and debate, during some time, in France. See *Mercur de France*, 1751, and *Dict. de Mus. par Rousseau*, art. *Mode*.

GOMBERVILLE, MARIN LE ROI, *Sieur de*, a man of letters, was born at Chevreuse, in the diocese of Paris. He became distinguished at the age of fourteen by a collection of quatrains in honour of old age. In 1635 he was so much distinguished for a literary reputation, that he was of the number assembled by cardinal Richieu for the purpose of founding the French academy. He had published romances and works of a light nature, of which he afterwards seemed to be ashamed, for at the age of forty-five he formed the resolution of consecrating his pen to religion. He even adopted a penitentiary course of life, and is mentioned by some of his contemporaries as having joined the Christian virtues to those of morality. He died in 1674, leaving behind him many works, of which perhaps the best is a "Discours sur les Vertus et les Vices de l'Histoire et de la Maniere de bien écrire." This is deemed a sensible and very judicious performance. Moreri.

GOMBAY, in *Geography*, a town of Africa, in Botonga, on the Zambeze. S. lat. 18°. E. long. 36° 3'.

GOMBEZCALA, a town of Persia, in the province of Farsistan; 100 miles N.N.W. of Schiras.

GOMBIN, GAMBIN, or *Gabin*, a town of Poland, in the duchy of Warsaw, situated on the river Bifura; 34 miles N.N.E. of Rawa.

GOMBRON. See GAMBROU.

GOMER, in *Scripture History*, the son of Japheth (Gen. x. 2.) and, according to Josephus, father to the people of Galatia. The ancient inhabitants of that country were called Gomares before the Galatians seized possession of it. The Chaldee places Gomer in Africa; Bochart in Phrygia, because Phrygia, in Greek, has the same signification (a coal) as Gomer, in Hebrew and Syriac. Others are of opinion that the ancient Cimbri, or Cimmerians, sprung from Gomer, and probably from them the Welsh, called Cymri. It is not improbable, that Gomer, or the Gomerites, his descendants, peopled likewise Germany and Gaul; the name German not differing much from Gomerim. Clavier (*Germ. Antiq.* l. i. c. 5. 6.) conjectures that the ancient Celtica comprehended Illyria, Germany, Gaul, Spain, and the British isles, as all these people anciently spoke the same language, farther supposes, that Gomer, or his family, peopled the countries in Asia, between the Paropamisus and mount Imaus, and between the confluence of the Oxus and Oby; whence these people are called Gomares by Ptolemy (l. vi. c. 17.) and Mela (l. i. c. 2.).

GOMER, or *Omer*, an Hebrew measure. See CORUS.

GOMERA, or VELEZ DE PEGNON, in *Geography*, a castle of Africa, in the country of Fez, built on a rock near the coast of the Mediterranean. Before this fort is there was anciently a city, called "Bedis," supposed to have been founded by the Carthaginians. The Arabs called it Belis and

Velis, whence Velez. These two places, surrounded by mountains and forests, were supported by the building of ships for fishing and piracy, before they were taken by the Spaniards. —Allo, a river of Fez, which runs into the straits of Gibraltar, near the above-mentioned fortresses.

GOMERA, or *Gemara*, one of the Canary islands, about 20 miles long and 10 broad, having a capital of the same name, situated on the east coast, with a good harbour. The island is fertile and well cultivated, and produces sugar-canes and vines in abundance, as well as silk, together with sufficient corn for the supply of the inhabitants, who amount to about 7000; 18 miles S.W. of Teneriffe. N. lat. 28° 6'. W. long. 17° 8'.

GOMETRA, one of the western islands of Scotland. This is a small island at the west end of Ulva, tolerably fertile, but without wood.

GOMEZ DE CIVIDAD REAL, ALVAREZ, in *Biography*, a modern Latin poet, was born in 1488 at Guadalaxara in Spain. He was page of honour to archduke Charles, afterwards emperor. As an author, which entitles him to a place in this work, he possessed a great facility in writing Latin verse, which is seen by his "Thalia Christiana," or the triumph of Jesus Christ, in twenty-five books: "Musa Paulina," or the epistles of St. Paul, in elegiac verse: the Proverbs of Solomon, and other works of a similar kind. His work on the order of the Golden Fleece, entitled "De Principis Burgundi Militia quam Velleris aurei vocant," is reckoned his master-piece. The subject which he chose in this instance was more favourable to poetry than the others. Moreri.

GOMEZ DE CASTRO, ALVAREZ, a native of St. Eulalia, near Toledo, was educated at Alcalá, where he obtained a high character for diligence and real learning. He was patronized by Philip II., who engaged him to prepare an edition of the works of Isidorus, which death prevented him from completing. He was author of many works; but the chief, and that which is most esteemed, is a "Life of Cardinal Ximenes," inserted in a collection of the writers on Spanish history. Gomez died in 1580, at the age of 65. Moreri.

GOMEZ, MAGDALEN-ANGELICA POISSON, born at Paris in 1684, was the daughter of Paul Poisson, an actor. Her fertile pen produced a great variety of romances and other works of the entertaining kind. The principal are, "Les Journées Amusantes," in eight volumes. "Anecdotes Persanes," two vols. "Hist. Secrete de la Conquête de Grenade." "Histoire du Comte d'Oxford avec celle d'Eustache de St. Pierre." "Les cent Nouvelles." She died in 1770, at the age of 86.

GOMEZ, SEBASTIANO, a Mulatto slave of the Spanish painter Murillio, who employed his leisure hours in painting, and obtained considerable success. The city of Seville is, or was, adorned with many of his works: the most conspicuous among them were a "Madonna with the Infant," in the portico of Los Mercenarios Descalzos, and the "Flagellation of Christ," at the Capuchins. It is not known at what period he died; but he is said to have survived his master, whose decease happened in the year 1685.

GOMGAH, in *Geography*, a town of Hindoostan, in the circar of Surgooja; 22 miles S.W. of Surgooja.

GOMI, a town of the province of Guriel, on the Black sea.

GOMMERN, a town of Saxony, on the Elbe; 8 miles E. of Magdeburg.

GOMNIALPAR, a town of Hindoostan, in the circar of Guntoor; 15 miles E. of Innaconda.

GOMORA,

GOMORA, a small island in the East Indian sea, near the west coast of Oby. S. lat. 1° 52'. E. long. 128°.

GOMORRHA, in *Ancient Geography*, a town of Palestine, and one of the principal cities of the Pentapolis, consumed by fire from heaven. It was probably the most northern of the five cities. Gen. xix. 24.

GOMOZIA, or GOMEZIA, in *Botany*. See NERTERIA.

GOMPHIA, from *γούφοι*, a nail or knob, alluding to the form of the receptacle of the fruit. Schreb. 291. Willd. Sp. Pl. v. 2. 569. Mart. Mill. Dict. v. 2. (Jabotapita; Plum. Gen. 41. t. 32. Ochna; Gært. t. 70. Juss. 282.) Class and order, *Decandria Monogynia*. Nat. Ord. *Magnoliæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, sharpish, ribbed, coloured, deciduous leaves, two of which have a membranous margin at each side, one on one side only, and two are destitute of any. *Cor.* Petals five, spreading, longer than the calyx, rather unequal; the claws are shorter than the calyx, each gradually widening into a roundish, flat, entire border. *Stam.* Filaments ten, very short, thick and angular; anthers erect, shorter than the calyx, square, tapering upwards, bursting at the top, on the outside, by two pores. *Pist.* Germen placed on a short fleshy angular receptacle, with five angles and five divisions; style longer than the stamens, marked with five furrows; stigma acute. *Peric.* Drupas from one to five, most generally two, ovate, obliquely attenuated at the base, somewhat compressed, obtuse, erect, standing on a very large globose receptacle, which is undivided, if the berry be solitary, lobed if there be more, one lobe being appropriated to each berry. *Seeds* solitary, ovate.

Eff. Ch. Calyx five-leaved, inferior. Petals five, with claws rather unequal. Anthers nearly sessile, square, opening by two pores. Drupas standing on a rounded fleshy receptacle.

Vahl and Swartz describe five species, all trees, natives of tropical climates. The chief and original one is *G. Jabotapita*, (Ochna Jabotapita; Linn. Sp. Pl. 732. Jabotapita pyramidato flore luteo, fructu rubro; Plum. Ic. 147. t. 153.) This is a native of South America, flowering in December and January. The wood is soft and tough. Leaves simple, as in the whole genus, alternate, stalked, ovate, acute, serrated. Flowers in terminal clusters, yellow, fragrant, compared by Marcgrave to those of a Wall-flower in figure, or rather colour, but he says their scent is sweeter. The fruit and its receptacle are black, juicy, astringent.

This genus is certainly very nearly related to *Ochna*, both in habit and character.

GOMPHIASIS, from *γούφοι*, a nail, a disorder of the teeth, in which they become loose and painful. The connection of the derivative with the Greek is imputable to the circumstance of the teeth being fixed in their sockets, like nails in a piece of wood.

GOMPHOCARPUS, in *Botany*, from *γούφοι*, any thing swelling upwards from a narrow base, as a nail, wedge, or club, and *καρπός*, fruit, alluding to the tumid follicles. Brown Aselepiad. (from the Wernerian Society's Transactions) 26. The genus is confounded by Linnæus under his *Aselepias*. Class and order, *Pentandria Digynia*. Nat. Ord. *Contorta*, Linn. *Apocinea*, Juss. *Aselepiadeæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, small, in five acute, permanent segments. *Cor.* of one petal, regular, in five deep, reflexed segments, deciduous. Nectary of five hooded-leaves, simple within, furnished with a tooth at each side, placed on the top of the united filaments. *Stam.* Filaments five, cohering; anthers of two cells, terminated by a

membrane, and producing two compressed masses of pollen, which attach themselves by a taper point to the stigma, and remain pendulous there. *Pist.* Germens two, superior, ovate, styles two, very short, standing close together; stigma common to the two, dilated, horizontal, flat, with five angles to receive the masses of pollen. *Peric.* Follicles two, inflated, ovate, pointed, clothed with soft spines. Receptacles membranous, longitudinal, linear, at length separate. *Seeds* numerous, imbricated, pendulous, crowned with silky down.

Eff. Ch. Corolla in five deep reflexed segments. Nectary of five hooded leaves, simple, with a single tooth on each side, crowning the filaments. Anthers terminated by a membrane. Stigma depressed, pointless. Follicles inflated, prickly. Seeds hairy.

This genus is separated from *Aselepias* by Mr. Brown, (whose essay on the whole order, and whose discovery of the mode in which the pollen is projected by the anthers upon the stigma, do him the highest honour,) on account of the inflated prickly fruit, and the singular horns which in *Aselepias* grow out from the bottom of the nectaries. It consists of *Aselepias arborescens*, Linn. Mant. 216; *fruticosa*, Linn. Sp. Pl. 315; and *setosa*, Vahl. Symb. v. 1. t. 8; and, as Mr. Brown suspects, of *crispa*, Linn. Mant. 215. Suppl. 170. *A. pubescens*, Linn. Mant. 215, is, as he justly observes, on the authority of the late excellent Mr. Dryander, borrowed from the Linnæan herbarium, the same plant as *arborescens*, with a synonym from Plukenet (t. 139. f. 1.) and Morison, which is presumed to be *crispa*.

GOMPHOLOBIUM, so named by the writer of the present article, from *γούφος*, a wedge, club, or any thing swelling upwards from a narrow base, and *λοβός*, a pod, or legume, expressive of its tumid fruit. Sm. Tr. of Linn. Soc. v. 4. 220. Ann. of Bot. v. 1. 505.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, short, bell-shaped, in five deep, oblong, pointed, unequal segments. *Cor.* papilionaceous. Standard very large, inversely heart-shaped, carinated at the back, recurved, with a short claw. Wings shorter than the standard, parallel, horizontal, with a prominent lobe on one side near the base. Keel the length of the wings, of two half-ovate, tumid, clawed petals, with a reverted tooth at the upper edge of each. *Stam.* Filaments ten, concealed in the keel, awl-shaped, distinct, ascending, rather unequal in length; anthers vertical, roundish, two-lobed. *Pist.* Germen stalked, oblong, somewhat cylindrical; style awl-shaped, ascending, as long as the stamens; stigma simple, acute. *Peric.* Legume on a stalk, nearly globular, inflated, of one cell, crowned with the style. *Seeds* several, roundish, ranged along the upper future on short stalks.

Eff. Ch. Calyx bell-shaped, simple, in five deep segments. Corolla papilionaceous. Stigma simple. Legume inflated, globose, of one cell, with many seeds.

Five species of this genus are defined in the Transactions of the Linnæan Society, v. 9. 249, *G. grandiflorum*, Exot. Bot. t. 5:—*latifolium*, (*fimbriatum*; Exot. Bot. t. 58:) *scabrum*, a species communicated by Mr. Menzies; *minus*, very near the last, except in the acute recurved points of the leaves; and *pinnatum*, a small species from Port Jackson, remarkable for its pinnate leaves, and zig-zag herbaceous stem. Probably the subsequent volume of Mr. Brown's Prodrômus will add more to this number.

The habit of *Gompholobium* is marked by the compound (ternate or pinnate) leaves, and a certain aspect of rigidity and smoothness. The stipulas are not istratiollicaceous as in

Pultenaa, but stand on each side of the base of the common footstalk, being a pair of acute flat close-pressed leaves, extremely minute, and often altogether wanting. The flowers are yellow, generally numerous, large and handsome; in *G. scabrum* they are purple when dried, but this is suspected to be an alteration of their original hue, and they are judged, from the analogy of *Daviesia*, to be yellow, with crimson keel and wings, when fresh.

All the species, as far as hitherto known, are natives of New Holland. S.

GOMPHOSIS, in *Anatomy*, from *γομφος*, a nail, denotes the manner in which the fangs of the teeth are fixed in their sockets.

GOMPHRENA, in *Botany*, a name adopted by Linnaeus from Dalechamp, and which is perverted from the *Gromphena* of Pliny. Linnæus made it classical by an allusion to *γομφος*, a nail, wedge, or club, which can but obscurely apply to the round head of flowers. See **GROMPHENA**.—Linn. Gen. 123. Schreb. 172. Willd. Sp. Pl. v. 1. 1321. Mart. Mill. Dict. v. 2. Ait. Hort. Kew v. 1. 318. Juss. 88. Lamarck. Illustr. t. 180. Gertn. t. 128. (Amaranthoides; Tournef. t. 429.)—Class and order, *Pentandria Digynia*; Nat. Ord. *Holeraceae*, Linn. *Amaranthi*, Juss.

Gen. Ch. reformed. Cal. Perianth inferior, coloured, membranous, permanent, double; the outer of two large, compressed, keeled leaves, cohering by their inner margins, and one smaller; inner in five deep, awl-shaped, upright, downy segments. Cor. of one petal, tubular, cylindrical, the length of the inner calyx; its margin equally five-cleft, spreading. Stam. Filaments five, very short, inserted into the orifice of the corolla, betwixt its segments; anthers erect, roundish, closing the mouth of the corolla. Pist. Germen ovate, pointed, superior; styles short, cohering at their bottom part; stigmas simple, obtuse, scarcely reaching to the stamens. Peric. Capsule roundish, membranous, of one cell, bursting all round. Seed solitary, large, roundish, with an oblique point.

Ess. Ch. Calyx coloured, the outer of three unequal leaves; inner in five deep segments. Corolla cylindrical, five-toothed, bearing the stamens at its orifice. Capsule bursting all round. Seed solitary.

The species of *Gomphrena* come under the denomination of Everlastings, or Amaranths, on account of the permanent nature of their calyx when dried, which retains its original colour and splendour.

G. globosa, Globe Amaranth, a native of India, is commonly raised on a hot-bed, and planted out in our borders, like other tropical annuals. It is also frequently kept in pots to decorate the stove or green-house. The original crimson sort is much more handsome than the paler variegated variety.

G. perennis, figured in Dill. Hort. Elth. t. 20, a native of Buenos Ayres, is scarcely cultivated but in curious gardens, having small heads of yellowish flowers of no remarkable beauty.

There are eight species besides in Willdenow, of which the *arborescens*, Linn. Suppl. 173, is by far the most remarkable. This was not sent to Linnæus by Mutis from New Granada, as erroneously asserted by the younger Linnaeus in the *Supplementum*, but by Vandelli, who received it from Brazil, and who has described it under the name of *Bragantia*, in his *Fasc. Plant.* p. 6. The stem is woody, round, leafy, clothed with rigid, prominent, brown hairs, as are also the leaves, which are opposite, obovate, obtuse, entire, about three inches long, and half as broad. Heads terminal, solitary, the size of an African Marigold or *Tagetes*, pale red or whitish, composed of innumerable

flowers, the segments of whose calyxes are about an inch long, linear, acute and chaffy, clothed in their lower part with long dense silky hairs. We know of no figure of this fine plant.

Mr. Brown, Prodr. Fl. Nov. Holl. v. 1. 416, adds five new species to *Gomphrena*, while he removes from it the *brassensis* and *vermicularis*, which, with two new ones from the tropical part of New Holland, he forms into a new genus, *Philoxerus*. He considers what we term corolla in *Gomphrena*, as the tube of the united filaments.

GOMPHRENA, in *Gardening*, contains a plant of the showery annual kind, of which the species cultivated is, the annual globe amaranth (*G. globosa*.)

It is a fine flowering plant, the heads of which at their first appearance are globular, but as they increase in size become oval, and, according to Martyn, the flowering heads are extremely beautiful, and, if gathered before they are too far advanced, retain their beauty several years.

There are varieties with fine bright purple heads, with white or silvery heads, which never alter from seeds, with mixed colours, with purple and with white heads, which two last are much smaller and rounder than the others; the plants also grow much larger and spread more into branches, and are later before they flower; these are called bachelor's buttons in America.

Method of Culture.—It may be increased by sowing the seeds annually, in pots of light fresh mould, in the early spring months, and plunging them in the bark hot-bed. When the plants are up, they should be watered often with care; and, after they have attained some growth, be removed with balls about their roots into other pots, and replunged in the hot-bed. When they have had some growth in this situation, they should be removed into a deep frame, being placed in a fresh hot-bed, to bring them up tall and handsome. Afterwards they should be often refreshed with water, and have air admitted freely as the summer advances, till they are capable of bearing it without injury; when about August they may be set out during the daytime, being protected in the night, and from wet weather. At this period they should be watered three or four times a week at least, in a rather sparing manner.

They afford a good effect when set out in the principal situations about the house, in assemblage with other plants of the potted kinds.

GOMRAPENDY, in *Geography*, a town of Hindoostan, in the Carnatic; 25 miles N. of Madras.

GOMS, one of the seven independent dixains or commonwealths of the Upper Vallais, in Switzerland; called *dixain*, because the Upper and Lower Vallais comprehend 10 districts, each being a dixain or tenth of the whole. Goms is situated at the foot of mount Grimsel, and extends along the bank of the Rhône; and is so called from a town, 33 miles E. of Sion. See **VALLAIS**.

GOMUT, a river of Bengal, which runs into the Magna, near Chandpour.

GOMUT Peperce, a town of Hindoostan, in Dowlatabad; six miles N. of Amednagar.

GOMUTTRA SELAGITTA, in *Natural History*, the name given by the Indians to a kind of fossil, found in great plenty on the mount Vindy in the East Indies, in places, as they observe, where the cows frequently urinate. It is a bituminous substance, and after calcination the residuum given in cases of internal ulcers and in gonorrhœas. The Indians supposed it formed by the drying up of the cow's urine.

GONAGRA, composed of *γόνυ*, knee, and *αἴμα*, capture, seizing, in *Medicine*, the gout in the knee. See **GOUT**.

GONAMBOUCH, in *Ornithology*. See EMBERIZA *Grisca*.

GONANPILLY, in *Geography*, a town of Hindoostan, in the circar of Ellore; 18 miles N. E. of Ellore.

GONAPI, one of the smaller Banda islands, in the centre of which is a volcano. The only inhabitants are wild dogs, cows and serpents. S. lat. 4° 10'. E. long. 130° 34'.

GONARCHA, a term in the ancient dialling. Mr. Perrault, in his notes on Vitruvius, lib. ix. cap. 9. takes the gonarcha to have been a dial drawn on divers surfaces or planes; some of which being horizontal, others vertical, oblique, &c. formed divers angles.

Whence the appellation, from *γων*, knee, or *γωνια*, angle.

GONARY, in *Geography*, a town of Hindoostan, in the Myfore; 12 miles S. of Rydroog.

GONAVE, LA, an island situated on the west side of St. Domingo, about 14½ leagues in length, and about three in breadth. This is called Grand Gonave by way of distinction from Petit Gonave, another small island about two miles in each direction, separated from the S. E. corner of the former, by a channel three miles wide. Gonave is 13½ leagues W. by N. W. from Port au Prince. N. lat. 18° 51'. W. long. 73° 40'. See ST. DOMINGO.

GONAVES, a sea-port in the above-mentioned island, at the head of a bay of its own name, on the N. side of a bay of Leogane. The harbour is excellent; the town has a medicinal spring, and in 1772 both were erected with lodging-houses for the accommodation of those who resort to it, and an hospital for soldiers and sailors. It lies on the great road from Port de Paix to St. Mark, 16 leagues S. E. of the former. N. lat. 19° 22'. W. long. 73° 20'.

GONCANAMA, a town of S. America, in the audience of Quito; 20 miles S. W. of Loxa.

GONCELIN, a town of France, in the department of the Isere, and chief place of a canton, in the district of Grenoble; 13 miles N. N. W. of Grenoble. The place contains 1558, and the canton 10,259 inhabitants, on a territory of 197½ kilometres, in 14 communes.

GONDAR, the metropolis of Abyssinia, is situated upon a hill, elevated 8440 feet above the ocean, and consists of about 10,000 families in times of peace. The houses are chiefly constructed with clay, and the roofs are thatched in a conical form, which is the mode of building within the tropical rains. On the west end of the town is the king's house, formerly a structure of considerable importance; it was a square edifice, flanked with square towers; formerly four stories high, and the top of it afforded a magnificent view of the whole country S. of the lake Tzana. Although the greatest part has been burnt at different times, there is ample lodging in the two lowest floors of it; the audience chambers being above 120 feet long. Annexed to this ruined palace are apartments, constructed by succeeding kings, also of clay, according to the fashion of their own country; for the palace itself, says Bruce (*Travels*, vol. iii.) was built by mafons from India in the time of Facilidas, and by such Abyssinians as had been instructed in architecture by the Jesuits, without embracing their religion, and afterwards remained in the country, unconnected with the expulsion of the Portuguese, during this prince's reign. The palace and its contiguous buildings are surrounded by a stone wall, 30 feet high, with battlements upon the outer wall, and a parapet roof between the outer and inner, by which you may pass along the whole and have a view of the street. There never appear to have been any embrasures for cannon; the four sides of this wall are above 1½ English mile in length. The mountain, on which the town is situated, is

encompassed on every side by a deep valley, which has three outlets; the one to the south, to Dembea, Maitshaw, and the Agows, the second to the N. W., towards Sennar over the high mountain Debra Tzai, or the mountain of the Sun, at the foot of which Koscam, the palace of the Iteglic, is situated, as are also the low countries of Walkayt and Wal-dubba; the third is to the N. to Woggora, over the high mountain Lamalmon, and so on through Tigré to the Red sea. The river Kahha, coming from the mountain of the Sun, runs through the valley, and covers all the south of the town; the Angrab, falling from Woggora, surrounds it on the N. N. E.: these rivers join at the bottom of the hill, about a quarter of a mile S. of the town. On an eminence opposite to Gondar, on the other side of the river, is a large town of Mahometans, consisting of about 1000 houses. They are all active and laborious, and are employed in taking care of the baggage and field-equipage of the king and nobility, when they take the field and return from it; but they never fight on either side. N. lat. 12° 34' 30". E. long. 37° 33'.

GONDEBAUD, in *Biography*, third king of the Burgundians, celebrated as a legislator among the barbarians over whom he reigned as sovereign. He obtained the crown in 491, and almost immediately, under pretence of assisting Odoacer against Theodoric, entered Italy, carrying fire and sword through Æmilia and Liguria, and made a great number of captives, many of whom he liberated without ransom, at the request of Epiphanius bishop of Pavia. He assembled, in 499, a council at Lyons, in order to effect a reconciliation between the Catholics and Arians. He was himself an Arian, from habit and education; but he was unable to effect so laudable a purpose. About this time he was attacked and defeated by Clovis king of the Franks; who made the Burgundian monarch his tributary. Clovis returned to his own country, and Gondebaud revenged himself upon his brother Godegesil, who had joined Clovis, surprised him, and put him to death. From this period he reigned in peace over his people, whom he rendered flourishing by the arts of civilization, and by a regular system of laws. These, says the historian, were in general founded on equity, and display much sagacity in preventing all causes of dispute; nevertheless, they enjoin the barbarism of judicial combats, which the legislator justified as an inference from the admitted doctrine of the interference of a particular providence in human affairs. The Burgundian code, called "La loi Gombrette," has been published in several collections of ancient laws. This prince died in 516, leaving behind him, as memorials, letters upon theological subjects to Avitus, bishop of Vienne. Univer. Hist.

GONDEGAMA, or GONDACOMMA, in *Geography*, a river of Hindoostan, which forms the nominal boundary of the Carnatic, and discharges itself into the sea at Medipelly. Cambam, or Commum, is near its source. It is sometimes called Gilligama, and Gunta-camina.

GONDICOTTA, a town of Hindoostan, in Marawar; 33 miles N. of Trumian.

GONDOLA, a little flat boat, very long and narrow, chiefly used at Venice to row on the canals.

The word is Italian, *gondola*. Du Cange derives it from the vulgar Greek *κωνδολα*; a bark, or little ship; Lancelot deduces it from *γωνδ*, a term in Athenæus for a sort of vase.

The middle-sized gondolas are upwards of thirty feet long, and four broad; they always terminate at each end in a very sharp point, which is raised perpendicularly to the full height of a man.

The address of the Venetian gondoliers, in passing along their narrow canals, is very remarkable; there are usually two to each gondola, and they row by pushing before them. The fore-man rests his oar on the left side of the gondola: the hind-man is placed on the stern, that he may see the head over the tilt or covering of the gondola, and rests his oar, which is very long, on the right side of the gondola.

GONDOLA is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLA-*shell*, in *Natural History*, a name given by authors to a peculiar kind of *concha globosa*, supposed, in some degree, to represent the shape of a Venetian boat. It is of the genus of the *dolium*, and there are seven species of it. See *DOLIUM* and *CONCHOLGY*.

GONDOMAR, in *Geography*, a town of Spain, in Galicia; 6 miles E. of Bayona.

GONDRECOURT, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Commercy. The place contains 1113, and the canton 8973 inhabitants, on a territory of 340 kilometres, in 24 communes.

GONDUFEE, a town of Africa, in the kingdom of Kong; 100 miles S. E. of Kong.

GONDWARAH, a town of Bengal; 15 miles S. S. W. of Purneah.

GONESSE, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Pontoise, nine miles N. of Paris. The place contains 2400, and the canton 14,811 inhabitants, on a territory of 182½ kilometres, in 22 communes.

GONET, JOHN BAPTIST, in *Biography*, was born at Beziers in the year 1616. He embraced the ecclesiastical life when he was young, and was admitted to the degree of doctor of divinity by the university of Bourdeaux in the year 1640. He was at the same time elected to the professorship of theology in that university, an office which he held with great dignity till the year 1671, when he was appointed provincial among the Dominican friars. In 1675 he resumed his labours as professor, which he continued about two years, and then retired to his native place, where he died in 1681. He was author of a system of divinity, entitled "Clypeus Theologiæ Thomisticæ, contra novos ejus impugnatores," first published at Bourdeaux in 1666, in eighteen volumes 12mo., but it was afterwards enlarged, and printed in five volumes folio. He was likewise author of a "Manuale Thomistarum, seu brevis Theologiæ Cursus," which has passed through different editions, of which the best was published at Lyons in 1681: and "Dissertatio Theologica de Probabilitate." Moreri.

GONFALON, or GONFANON, a kind of round tent, borne as a canopy, at the head of the processions of the principal churches at Rome, in case of rain; its verge or banner serving for a shelter, where there is not a great deal of attendance.

GONG, a Chinese metalline, musical instrument of percussion, in the form of a flat basin, with a ridge round it, and beaten by a mallet covered with several folds of woollen cloth. It is carried on a pole by two men, and beaten by the hindmost. In the march of an army, it is used as a military instrument to regulate the steps of the soldiers; when struck with great force, it is sufficiently loud to be heard at a mile's distance; but so confused is the sound, that no distinct tone can be ascertained. Yet by reiterated gentle strokes on the same part of the bottom of the basin a musical tone may be produced; but different parts of the circle produce tones of different gravity and acuteness.

It is used in processions, and at court on days of ceremony and festivals, in concert with other instruments, as a double drum. On the water, in vessels that are rowed, this instrument regulates the strokes of the oars.

It is formed of brass or bronze, and called *Lu* by the Chinese, who, from hearing it only on great occasions, regard it with reverence.

GONGA, in *Geography*, a town of European Turkey, in Romania, near the sea of Marmora; 36 miles N. E. of Gallipoli.

GONGA, or *Bair Gonga*, a river of Hindoostan, which falls into the Godavery about 50 miles from the sea. See *BAIN GONGA*, and *GODAVERY*.

GONGACA, a town of Bengal; 30 miles S. W. of Calcutta.

GONGADEE, a town of Bengal; 50 miles S. W. of Rogonauptour.

GONGOLARA, in *Botany*, a name by which Imperatus has called a very beautiful sea plant, known among botanical writers by the name of *fucus ericeæ foliis*, or *erica marina*, the sea heath.

GONGONG, is an instrument used by the Hottentots, and all the negroes on the western coast of Africa. Of this kind there are two sorts, the large gongong and the small. In the supplement to the first edition of the French Encyclopédie, a description of this instrument has been attempted, that seems totally unintelligible.

"The small gongon (say the editors) is an iron or holly bow, of which the string is the sinew of a sheep dried in the sun, or a bowel string; at the extremity of the bow is placed, on one side, the pipe of a split quill, in the hollow of which the string of the bow is lodged. The performer holds this quill in his mouth when he is playing, and the different tones of the gongon proceed from the different modulations of his breath.

"The great gongon only differs from the small by the shell of a cocoa-nut, of which the upper part has been cut off, and the string of the bow, before its tension, passed through it on each side. In touching the instrument the cocoa-shell is moved to and from the quill according to the tone which is to be produced."

We hope our readers will comprehend this description, by which we frankly own ourselves not to be much enlightened; nor can we well conceive how the motion of the split quill, or the section of the cocoa-nut, can produce different tones. Nothing that answers to this description is to be found on the plate referred to (fig. 3. Pl. II.) but in Pl. III. fig. 9. Mus. Inst. there is, we think, a very unsatisfactory representation of it. And in the rude state in which the European arts in general have been found in such parts of Africa as have already been explored, we have little reason to lament our ignorance of the construction and use of the gongong.

GONGOO, in *Geography*, an island in the Neel Abud or Guin river of Africa, in its course between Cassina or Kassina, and Mekzara. N. lat. 16. E. long. 11°.

GONGOOPOUR, a town of Hindoostan, in Oude, 12 miles S. of Kairabad.

GONGORA, LEWIS, in *Biography*, a celebrated Spanish poet, was born at Cordova in 1562. He studied at Salamanca, and being brought up to the church, was made chaplain to the king, from whom he received considerable ecclesiastical preferment. He died at Cordova, of the cathedral of which he was prebend. His reputation is built on a volume of poems, under the title of "Obras de Don Lewis de Gongora-y-Argore," &c. The poems consist of a variety of compositions, chiefly of the shorter kind, especially

lyrical, in which style he so much excelled, as to be termed by his countrymen "the prince of lyric poets." Gongora possesses, in the estimation of his countrymen, a very high rank among the Spanish poets for an artificial elevation of language, and uncommon turn of thought, which were formerly the characteristics of the poetry of that nation. So much, indeed, did he surpass in these qualities, that he had many censurers in his own country, though he also met with as many warm defenders. He is said to have enriched his native language by the introduction of many Latin words happily employed. Moreri.

GONGRÖNA, in *Surgery*, a hard tumour; but especially a bronchocele, or swelling of the thyroid gland. The word is said to be derived from $\gamma\omicron\gamma\upsilon\lambda\omicron\varsigma$, a round tubercle on the trunk of a tree.

GONHARY, in *Geography*, a town of Hindoostan, in Oude; 40 miles W. of Lucknow.

GONIA, a town of Asiatic Turkey, in Natolia; 16 miles W. of Aphium-Karahisar.

GONJAH, or KONG, supposed to be the *Conche* of D'Anville, and the *Gonge* of Delisle, a kingdom of Africa, situated to the N. of Guinea, between the meridian of Greenwich, and 5° W. long., and between the 10th and 12th degrees of N. lat. It is about 870 miles westward from Cahna or Kaffna, and between 530 and 600 miles from the Gold Coast. Some say, there is no communication between this coast and the country of Gonjah; the king of Assentoi, who possesses the intervening space, prohibiting his inland neighbours from passing through his country. Others report, that other states (*e. g.* the Pantees, and their confederates) lie between Assentoi and the sea; and that the Assentois have often unsuccessfully attempted to open a communication with the coast.—Also, the name of a town, which is the capital of the kingdom of Gonjah or Kong. N. lat. 11° 30'. W. long. 3° 30'.—Also, the name of part of a chain of mountains, extending from almost the mouth of the river Gambia, in the Atlantic, to Nigritia, towards Abyssinia.

GONIAH, a decayed town and large castle of Asiatic Turkey, belonging to the province of Guriel, at the mouth of a river which runs into the Black sea. It is garrisoned by a few Janissaries, and inhabited chiefly by seamen; 80 miles E.N.E. of Trebifond. N. lat. 41° 25'. E. long. 41° 10'.

GONJENPILLY, a town of Hindoostan, in the Carnatic; 18 miles N.E. of Nellore.

GONIOCARPUS, in *Botany*, so called from $\gamma\omicron\upsilon\gamma\upsilon\lambda\omicron\varsigma$, an angle, and $\kappa\alpha\tau\alpha\upsilon\tau\omicron\varsigma$, fruit, expressive of one of its essential characters. The name, originally contrived by Thunberg, was *Gonocarpus*, which being incorrectly constructed, and too near *Conocarpus*, was judiciously changed by Mr. König, Schreber, Willdenow, and others, have made it *Goniatocarpus*, for want of attending to its meaning and application, which has no reference to $\gamma\omicron\upsilon\gamma\upsilon\lambda\omicron\varsigma$, a knee, but to the very peculiar angles of the fruit.—König in Ann. of Bot. v. 1. 546. t. 12. f. 5. 6. (Gonocarpus; Thunb. Nov. Gen. 55. Fl. Jap. 5. Murr. in Linn. Syst. Veg. ed. 14. 164. Juss. 442. Lamarek. Illustr. t. 73. Gonatocarpus; Schreb. 86. Willd. Sp. Pl. v. 1. 690. Mart. Mill. Dict. v. 2.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Onagraceæ*, or *Onagrarieæ*, Juss. König.

Gen. Ch. *Cal.* Perianth superior, in four deep, acute, equal, upright segments. *Cor.* Petals four, equal, oblong, concave, inserted into the rim of the calyx, and twice as long as its teeth. *Stam.* Filaments four or eight, very short, inserted into the calyx, opposite to the petals if four, to the petals and calyx-teeth if eight; anthers oblong, large,

shorter than the corolla. *Pist.* Germen inferior, turbinate, with eight furrows and as many angles, crowned with the permanent calyx; style extremely short; stigmas four, obtuse, downy.

Ess. Ch. Calyx superior, in four deep equal segments. Petals four. Drupa dry, with eight angles. Nut solitary. of one cell.

Three species of this inconspicuous though curious genus are at present known.

1. *G. micranthus*. Thunb. Jap. 69. t. 15.—Leaves ovate, obtusely crenate, smooth, as well as the stem.—Gathered by Thunberg in Japan. Root fibrous, annual. Stems three or four inches high, ascending, quadrangular, smooth, leafy, simple below, panicle above. Leaves opposite, on short stalks, ovate, rather acute, half an inch long, bluntly crenate and cartilaginous in the margin, smooth on both sides, minutely dotted, furnished with a rib, but no veins; the upper ones gradually smaller and more entire. Stipules none. Flowers very small, purplish, drooping, in several slender, lax, upright spikes, forming a sort of panicle. The petals as well as calyx are sufficiently evident in Thunberg's own specimens before us. The fruit is no bigger than the smallest pin's head, and the petals scarcely longer.

2. *G. rotundifolius*.—Leaves rounded, somewhat heart-shaped, obtusely crenate, smooth. Angles of the stem rough. Spikes in a compound panicle.—Gathered near Port Jackson, New South Wales, by John White, M. D.—We are by no means certain that this is more than a variety of the former, but its different country, much more rounded leaves, heart-shaped at the base, and the bristly angles of the stem, induce us to propose it as a species. Possibly the panicle spikes may be owing to the greater luxuriance of the specimens. The fructification appears precisely like that of the first species.

3. *G. feaber*. König Ann. of Bot. v. 1. 547. t. 12. f. 6.—Leaves elliptic-lanceolate, sharply ferrated, as well as the stem.—Gathered by Mr. David Nelson, in cultivated ground in the island of China, near Macao. This appears to differ from the two former very materially, being all over rough, with depressed bristles, and having longer and narrower sharply ferrated leaves. The flowers, moreover, have eight stamens, and the angles of the fruit are wavy or crisped, not smooth and even.

We have a plant gathered by Dr. White, near Port Jackson, which seems to answer in every point to Mr. König's description and figure of the last, except that its petals have a bristly keel, and the stigmas are singularly branched and plumose, making a large tuft in the centre of each flower after the petals are fallen. Perhaps Mr. König's specimens had lost all their stigmas. We remark, however, a further difference in the fruit, whose alternate angles are less distinct, or rather more crisped and interrupted than the rest. Not having examined authentic specimens of *G. feaber*, we must leave this matter in doubt.—Possibly this may be *G. tetragynus*. Billard. Nov. Holl. t. 53.

GONIOMETER, an instrument used for the purpose of measuring solid angles (particularly of crystals), or the inclination which one plane surface makes with another. The small goniometers, as usually sold at the shops, are of a construction so simple, as to require but little description. They generally consist of a small pair of compasses or nippers, destined to receive the angle of the crystal; and the legs of these being continued in the opposite direction, beyond the angular point or joint, the angle is measured by applying them to a protractor or semicircular scale of degree.

But notwithstanding much ingenuity has been bestowed on instruments constructed on this principle, none of them have

GONIOMETER.

have been found nearly accurate enough for the purposes for which they are required, many interesting questions in the modern science of crystallography requiring a much more exact determination of the angle than can possibly be obtained by instruments of this construction.

We are indebted to Dr. Wollaston for having removed all these difficulties, by the invention of an instrument which accomplishes all that the most scrupulous naturalist can possibly desire. The principle of this invention is entirely optical, and (*Plate XIX. Miscellany, fig. 2.*) represents the instrument as made and sold by Mr. Carey, in the Strand; but the reader, when acquainted with the nature of it, will readily see that any person possessed of a graduated instrument, such as a theodolite, transit, &c. may, without great difficulty, apply it to the measurement of angles, though in a much less commodious manner than on an instrument made expressly for the purpose.

Dr. Wollaston's method consists in employing a ray of light reflected from the surface, instead of the surface itself; and thus, for a radius of 1-50th of an inch, we may substitute either the distance of the eye from the crystal, which would naturally be twelve or fifteen inches, or for greater accuracy we may, by a second mode, substitute the distance of objects seen at a hundred yards or more from us. The instrument described by Dr. Wollaston, in the *Transactions for 1809*, consists of a circle, *fig. 3*, graduated on its edge, and mounted on an horizontal axle supported by an upright pillar. This axle, being perforated, admits the passage of a smaller axle through it, to which any crystal of moderate size may be attached by a piece of wax, with its edge, or intersection of the surfaces, horizontal and parallel to the axis of motion. This position of the crystal is first adjusted, so that by turning the smaller axle, each of the two surfaces, whose inclination is to be measured, will reflect the same light to the eye. The circle is then set to zero, or 180, by an index attached to the pillar that supports it.

The small axle is then turned till the further surface reflects the light of the candle, or other definite object, to the eye; and lastly, (the eye being kept steadily in the same place,) the circle is turned by its larger axle, till the second surface reflects the same light. This second surface is thus ascertained to be in the same position as the former surface had been: the angle through which the circle has moved, is, in fact, the supplement to the inclination of the surfaces; but as the graduations on its margin are numbered accordingly in the inverted order, the angle is correctly shewn by the index, without requiring any computation.

It may be here observed, that it is by no means necessary to have a clean uniform fracture for this application of the instrument to the structure of laminated substances; for since all those small portions of a shattered surface that are parallel to one another, (though not in the same plane,) glisten at once with the same light, the angle of an irregular surface may be determined nearly as well as when the reflecting surfaces are actually in the same plane. In this method of taking the measure of an angle, when the eye and candle are only ten or twelve inches distant, a small error may arise from parallax, if the intersection of the planes or edge of the crystal be not accurately in a line with the axis of motion. But such an error may be rendered inensible, even in that mode of using the instrument, by due care in placing the crystal; and when the surfaces are sufficiently smooth to reflect a distinct image of objects, all errors from the same source may be entirely obviated by another mode of using it.

For this purpose, if the eye be brought within an inch

of the reflecting surface, the reflected image of some distant chimney may be seen inverted beneath its true place, and, by turning the small axis, may be brought to correspond apparently with the bottom of the house, or some other distant horizontal line. In this position the surface accurately bisects the angle which the height of that house subtends at the eye, or rather at the reflecting surface: then, by turning the whole circle and crystal together, the other surface, however small, may be brought exactly into the same position; and the angle of the surfaces may thus be measured, with a degree of precision that has not hitherto been expected in goniometry.

The accuracy, indeed, of this instrument is such, that a circle of moderate dimensions, with a vernier adapted to it, will probably afford corrections to many former observations. Dr. Wollaston has remarked one instance of a mistake that prevails, respecting the common carbonate of lime, which he mentions, because this substance is very likely to be employed as a test of the correctness of such a goniometer, by any one who is not convinced of its accuracy, from a distinct conception of the principles of its construction.

The inclination of the surfaces of a primitive crystal of carbonate of lime, is stated with great appearance of precision to be 104° 28' 40"; a result deduced from the supposed position of its axis, at an angle of 45°, with each of the surfaces, and from other seducing circumstances of apparent harmony by simple ratios.

But however strong the presumption might be, that this angle, which by measurement approached to 45°, is actually so, it must nevertheless be, in fact, about 45° 20'; for the inclination of the surfaces to each other is found to be very nearly, if not accurately, 105°, as it was formerly determined to be by Huygens; and since the measure of the superficial angle, given by sir Isaac Newton, corresponds with this determination of Huygens, his evidence may be considered as a further confirmation of the same result; for it may be presumed, that he would not adopt the measures of others without a careful examination.

Explanation of the Figure.

a b, Is the principal circle of the goniometer, graduated on its edge.

c c, The axle of the circle.

d, A milled head, by which the circle is turned.

e e, The small axle for turning the crystal, without moving the circle.

f, A milled head on the small axle.

g, A brass plate supported by the pillar, and graduated as a vernier to every five minutes.

h, The extremity of a small spring, by which the circle is stopped at 180, without the trouble of reading off.

i i and *k k*, Are two centres of motion, the one horizontal, the other vertical, for adjusting the position of a crystal; one turned by the handle *l*, the other by the milled head *m*.

The crystal being attached to a screw head at the point *n*, in the centre of all the motions, with one of its surfaces as nearly parallel as may be to the milled head *m*, is next rendered truly parallel to the axis, by turning the handle *l* till the reflected image of a horizontal line is seen to be truly horizontal. By means of the milled head *f*, the second surface is then brought into the position of the first, and if the reflected image from this surface is found not to be horizontal, it is rendered so by turning the milled head *m*, and since this motion is parallel to the first surface, it does not derange the preceding adjustment.

GONIOMETRICAL LINES, derived from *γωνία*, *angle*, and *μετρεω*, *I measure*, in *Geometry*, lines used for measuring or determining the quantity of angles. Such are sines, tangents, secants, versed sines, &c.

We have a paper by Mr. Jones, in the *Philosophical Transactions*, containing a commodious disposition of equations for exhibiting the relations of goniometrical lines, from whence a multitude of curious theorems may be derived. See *Phil. Trans.* N^o. 483. sect. 26.

GONIUM, in *Zoology*, a genus of *Vermes*, characterized only by their very simple, flat, and angular form, and being invisible to the naked eye. The species at present known are few, amounting to no more than five in number; and for the existence of these we rely chiefly on the microscopical researches of Muller and Schranck, the former of whom describes four of these minute creatures with great accuracy in his "*Zoologia Danica*." They are mostly inhabitants of fresh or pure water, though some of them occur in stagnant water or in dunghills.

Species.

POLYSPHERIUM. Orbicular, pellucid, with innumerable spherical molecules. Schranck.

Found in stagnant water; the colour greenish-yellow, and general appearance that of a thin membrane filled with innumerable lucid globules. Very common in the month of July.

PECTORALE. Quadrangular, pellucid, with sixteen spherical molecules. Müll. Goeze, &c.

The molecules are oval and nearly of an equal size, their colour greenish, pellucid, and disposed in a quadrangular manner within the membrane, like diamonds in a ring; or rather, as Müller compares them, to the jewels in the breast-plate of the high priest among the Jews, and reflecting light on both sides. Its progress is by an advancement alternately towards the right and left, at which time all the molecules are in motion, and assume their oval form, these molecules being round when the animal is in a quiescent state.

TRUNCATUM. Angles obtuse; posterior part arched. Müll.

This occurs in fresh or pure water, and is rarely met with; its size is rather considerable; the fore-part is a straight line, the sides forming therewith obtuse angles, the extremity of the sides being united by a curved line; the internal organs, perceptible to the eye by the assistance of the microscope, consist of a number of molecules of a dark green colour, and two vesicles of peculiar brightness in the middle. Its motion is languid.

LUNATUM. Rectangular, the posterior part arched. Müll. Gmel. *G. Rectangulum*, Adams.

The projection at the base of the body in this species is placed in a right angle; the intestines green, with the larger vesicle transparent.

PULVINATUM. Quadrangular, opaque, with four cylindrical protuberances. Müller.

This species, according to Müller, appears under a slight magnifier like a quadrangular membrane, plain on both sides, but, when a deeper lens is applied, resembles the figure of a bolster, formed of three or four cylindrical pillows, flattened or sunk in various places: this was the appearance it assumed when first examined; some days after all the sides were plain without convexity and deaerated, or divided into little squares by the intersection of straight lines. It is found in puddles under dunghills.

GONKEER, in *Geography*, a town of Chinese Tartary. N. lat. 44° 50'. E. long. 117° 51'.

GONKOFEN, or **GANKOFEN**, a town of Bavaria; 14 miles E. of Landhut.

GONNA, a town of Hindoostan, in Lahore; 12 miles W. of Nugorcote.

GONNI, or **GONNO**, in *Ancient Geography*, a town of Greece, in the Perrhæbia, situated near Pæneus, towards the strait where the Olympus and Ossa approached each other.

GONNOCONDYLUM, a town of Greece, in Macedonia, in the Perrhæbia.

GONOESSA, a town of Greece, in the Peloponnesus. In the time of Pausanias it belonged to the Sicyonians.

GONOLOBUS, in *Botany, from *γωνία*, *an angle*, and *λοβος*, *a pod*, alluding to the angles or ribs of the fruit. Michaux *Boreali-Amer.* v. 1. 119. Brown *Afcep.* 24.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*. Linn. *Apocinea*, Juss. *Afclerpiaceæ*, Brown.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, acute, spreading segments, permanent. *Cor.* of one petal, wheel-shaped, in five deep spreading segments. Necessary like a shield, crowning the stamens, lobed. *Stam.* Filaments five, thickish, united into a short tube; anthers curling transversely, terminated by a membrane, their masses of pollen attached to the outer extremity, with respect to the cell, and covered by the stigma. *Pist.* Germens two, ovate-oblong; styles two, very short, close together; stigma common to both, flattish and depressed, with five angles. *Peric.* Pouches inflated, more or less angular or ribbed. *Seeds* numerous, imbricated, oblong, crowned with down.

Eff. Ch. *Corolla* wheel-shaped, in five deep segments. Nectary a lobed shield-like crown. Anthers curling transversely, terminated by a membrane. Stigma five-angled, depressed. Pouches inflated, ribbed. Seeds with a hairy crown.

This appears to be a numerous genus, properly separated from *Cynanchum*, and consisting of climbing shrubs, with opposite broadish leaves, and flowers growing in umbels between the insertion of the foot-stalks. They are natives of America, chiefly within the tropics. Examples of it are *Cynanchum maritimum*, Linn. *Mant.* 54. Jacq. *Amer.* 83. t. 56, a hairy plant, with dark-purple blossoms: *fiberosum*, Linn. *Sp. Pl.* 310, figured in *Dill. Hort. Elth.* t. 229. f. 296, likewise a downy species, with purplish-green flowers; and *crispiflorum*, Ait. *Hort. Kew.* v. 1. 302. *Plum. Ic.* t. 216. f. 1: as well as many others presumed to have the same generic characters, but which, according to Mr. Brown, require to be thoroughly examined, as does the whole genus.—Michaux enumerates three species, natives of the warmer parts of North America, and which he calls *G. macrophyllum*, *birsutum*, and *levis*.

GONON BESAR, in *Geography*, a mountain on the E. side of the island of Java, famous for the quantity of pepper which its trees produce.

GONONG, or **GANAPEZ**, one of the group of Asiatic isles, called *Banda*, in which there is a remarkable volcano.

GONOR, a town of Hindoostan, in the circle of Gohud.

GONORHYNCHUS, in *Ichthyology*, a species of *Cyprinus*, which see.

GONORRHŒA denotes, in *Surgery*, a disease in which a kind of matter, which is either actually pus, or a fluid of very similar qualities, is discharged from the urethra of the male subject, and from the surfaces of the labia, nymphæ, clitoris, and vagina of the female, attended with more or less heat, pain, and difficulty in making water. The discharge is infectious, and capable of communicating the complaint from one person to another, whenever it comes

GONORRŪEA.

into contact with any of those surfaces, which are susceptible of contamination by it, and which, we believe, must be such as are naturally destined to secrete mucus. On the foregoing account, the disorder is almost always caught, or communicated, in the venereal connection, when some of the discharge of the diseased person is applied to the parts, which are liable to be affected in the healthy one. However, a gonorrhœa may be produced in any manner, which brings the infectious discharge into contact with the mouth of the urethra, the surfaces of the labia, &c. In the article *OPHTHALMY*, we shall have occasion to notice a particular inflammation of the eyes, attended with a copious discharge of matter from beneath the eye-lids, which is represented, by surgical writers, as originating from the inadvertent application of gonorrhœal matter to the eye-lids, the inner surfaces of which are well known to be mucous ones.

The Hunterian doctrines go so far as to assert, on the authority of experiments, that the poison of the lues venerea, and that of gonorrhœa, are in fact the same, though usually productive of opposite effects, by reason of the parts affected in a chancre, and those concerned in gonorrhœa having quite different structures. These things, if true, tend to prove, that the matter of a clap may, under certain circumstances, impart the venereal disease to the constitution. However, it should be understood, that the statement just now made can only refer to the gonorrhœa virulenta; for it is certain, that a simple discharge from the urethra, and a scalding sensation in making water, which would constitute a gonorrhœa, may be the consequence of any thing which produces mere irritation in the passage without the possibility of the venereal or common gonorrhœal virus being at all concerned. Thus, a man may have a stricture, and begin the employment of bougies for its cure; their irritation may bring on a soreness in the urethra, and excite a discharge. Here we have an instance of the complaint arising from the operation of no virus whatever; but altogether from the unequivocal, mechanical, irritation of the bougies. Doubtless, also, there are sometimes discharges both from the male and female parts of generation, which, when applied to other persons, are capable of bringing on certain kinds of gonorrhœa by the entire effect of their irritation. So were a man, with a gonorrhœa, excited by the irritation of bougies to have connection with a woman, there is no doubt that the latter would be very likely to become troubled with a discharge and scalding in making water, merely in consequence of the application of some of the matter from the male urethra to the surfaces of the labiæ, nymphæ, &c.

The arguments which have been adduced to shew that the poison of one form of gonorrhœa, and that of the venereal disease are the same, will more properly come under consideration hereafter. In the meanwhile, it is our part to enter a little more particularly into the history of gonorrhœa.

The etymological meaning of *gonorrhœa* is a running of the semen, the term being derived from *γόνος*, signifying the femal fluid, and *ῥεῖν*, to flow. The ancients are said to have entertained the very erroneous notion that the disease consisted of an oozing of the semen in a morbid and altered state. As it is long since so absurd a supposition has had any partisans, a refutation becomes superfluous, and every one now knows, that in the present, as in many other examples, truth and etymology are not coupled together. Dr. Swediaur, who has found fault with the term *gonorrhœa*, as conveying an untrue idea, has not been happy in a substitute.

He remarks, that if a Greek name is to be retained, he would call the complaint *blennorrhœa*, from *βλένω*, *mucus*, and *ῥεῖν*, to flow. Now this last expression is objectionable, on the identical principle which makes Dr. Swediaur wish for the relinquishment of gonorrhœa; for it is generally thought by all the most eminent modern surgeons, that the discharge is pus, and not mucus. Besides, we do not see much utility in abandoning the ancient appellation. The knowledge of surgery is now so highly cultivated, that there is not the least danger of any man imbibing an absurd opinion respecting this common complaint, from the etymological import of its name. Every juvenile apprentice knows that a clap is a running of matter from the urethra. Few common practitioners trouble themselves about Greek derivations; and where is the object of changing the name of one disease, while many hundred other surgical terms stand in equal, and often greater, need of alteration?

The first perceptible symptom of a gonorrhœa is generally a kind of itching about the orifice of the urethra, attended with a slight swelling of its edges, and sometimes extending over the whole of the glans penis. Very shortly afterwards the running commences, and the itching sensation changes into pain, which is severely felt at the time of making water. In some few instances, no considerable pain is experienced, till a long while after the access of the discharge and other symptoms. It is said that there are certain cases which are attended with no pain whatsoever, while other instances occur, in which patients suffer severely, even before the discharge makes its appearance.

When the inflammatory symptoms have come on, the penis seems swollen, and as if it were in a state of half-erection. The glans appears red, smooth, and enlarged, with a kind of transparency about it. Sometimes it is affected with a slight excoriation, which makes it exceedingly tender, and is the source of some trivial quantity of matter. The canal of the urethra becomes narrower than natural, if we may form a judgment from the diminution which takes place in the stream of urine. Indeed, very frequently, this fluid can only be discharged in a broken scattered current, or by drops. We have often seen severe retentions of urine attendant on the inflammatory stage of a gonorrhœa.

Small tumours may frequently be noticed along the inferior surface of the penis, in the course of the urethra. These swellings have been considered as the mucous gland of that canal in a swollen state. Sometimes they acquire a very large size, and ultimately suppurate and form abscesses, which, in some instances, burst externally, while, in others, they break into the urethra itself. In the latter event, the swelling all on a sudden subsides, as soon as the contained matter has escaped. Sometimes, after a certain interval, the tumour is seen to re-appear, which circumstance is said to be owing to a premature closure of the opening. Abscesses of the preceding kind are often met with in the situation of Cowper's glands. Here they also sometimes burst outwardly, sometimes inwardly, sometimes in both ways in the same patient. In this last case a new passage is made for the urine, termed a *fidula* in *πρινιθον*. See *FISTULA*.

A painful sensation is frequently felt by the patient along the lower surface of the penis, extending as far as the anus, and depending on the inflamed state of the urethra. In most cases the erections are frequent, and generally productive of infinite pain, particularly when a soreness exists along the track of the urethra towards the anus, or when the complaint is complicated with chordee. See *CHORDEE*.

The viscid transparent fluid which is naturally secreted by the glands of the urethra changes into a whitish aqueous liquor,

GONORRŒA.

liquor, and the secretion which takes place from the lining of this canal, and is intended for its lubrication, also becomes less transparent. At length both these fluids, becoming thicker and thicker, gradually assume more and more the qualities of pus. The discharge often undergoes an alteration in its colour and consistence, a circumstance which Mr. Hunter imputed to the disposition of the parts by which the matter is formed. Sometimes it is white, sometimes yellow, sometimes of a greenish colour. Such varieties depend upon the diminution, or increase of the inflammation, and not upon the poisonous quality of the matter; for the same appearances happen whenever the parts are irritated in a certain degree by any cause whatsoever, as several facts confirm. Dr. Swediaur injected into his urethra some caustic volatile alkali mixed with water, by way of experiment. The usual symptoms of a gonorrhœa ensued, together with a discharge which had the same appearances and alterations of colour, as the matter of the gonorrhœa virulenta. We have already stated that the same circumstances most frequently attend the employment of bougies.

In the generality of instances, the discharge does not proceed from any great extent of the urethra, not from more than an inch, or an inch and a half of that part of the passage, which is nearest the orifice in the glans penis. This distance was what Mr. Hunter used to name the specific extent of the inflammation. Before this celebrated surgeon flourished, it was commonly supposed, that the matter came from the whole of the urethra, and even from Cowper's glands, the prostate, and the vesiculæ seminales. Due attention to the symptoms, however, makes this idea seem quite improbable. If, for example, every part of the urethra, beyond the bulb, or if the bulb itself contributed to the discharge, the matter would be propelled out of the passage in the same manner as the semen, that is to say, by a sudden convulsive kind of action. It is well known that nothing can lodge in the bulb of the urethra, without immediately putting that part of the canal into action, particularly when in a state of irritation and inflammation. A drop of urine is not allowed to remain there, and if simple warm water be injected thus far, it is instantly forced out by the action of the acceleratores urinæ muscles. Therefore it seems rational to conclude, that if the membranous and bulbous parts of the urethra, Cowper's glands, the prostate, and the vesiculæ seminales, all had a share in forming the matter, no sooner would a certain quantity have collected in the bulb, than an immediate expulsion would be occasioned by the muscles of the part. No symptom of this kind, however, is usually observed, although it occasionally happens, that the acceleratores urinæ are affected with spasmodic contractions, which are particularly disposed to occur just after the patient has been making water, and do not seem to have any dependance on the discharge.

Mr. Hunter has taken notice that when the inflammation is violent, some of the vessels of the urethra often give way. Hence a hemorrhage arises, which is most profuse, just after the patient makes water, though it also continues at other times. Sometimes the blood is inconsiderable in quantity, and only just sufficient to give a red colour to the matter. The erections, which are so frequent in this complaint, are apt to occasion an extravasation of blood, a symptom which is always attended with an increase of the pain felt at the time of making water; but the bleeding always in the end lessens the inflammation, and tends to the relief of the patient.

The inflammation, accompanying a gonorrhœa, is attended with several of the characters of common inflammation;

but yet it differs also from the latter affection in many respects. It does not excite any pulsatory sensation; it causes little pain, except what arises from the irritation of the urine and the tension of the parts; and the inflammatory irritation seldom extends beyond the affected surfaces. The reason of so large a quantity of pus being secreted, in consequence of so moderate an inflammation, has been attributed to the parts being such as naturally secrete, so that they readily alter the natural into a morbid secretion.

Although the inflammation of a gonorrhœa is commonly moderate, there are instances in which it is exceedingly severe, and extends into the reticular texture of the surrounding corpus spongiosum urethræ, particularly of that which is near the glans penis. Sometimes the inflammation advances further along the corpus spongiosum, and occasions a swelling, or extravasation of coagulating lymph, which is the cause of chordee. We have already stated that the inflammation occasionally gives rise to abscesses of the glands of the urethra, particularly of those in the perinæum.

It is not decidedly known in what manner the disease communicates itself to the urethra. Some suppose that the inflammation creeps from the glans penis to the edges of the orifice of the urethra, and thence further into the passage. These reasoners will not allow the probability of a common opinion, that some of the infectious matter gets into the urethra at the time of coition. At all events it seems clear, that none of the contaminating fluid can get as far as the disease extends in ordinary instances, much less in others, where the affection reaches a great way towards the bladder. There are some facts which tend to prove that the simple application of the infectious matter to the end of the penis may give rise to a gonorrhœa. A case related by Mr. Hunter in his treatise on the venereal disease, seems to confirm the truth of what we have mentioned.

As we have already observed, the complaint seldom extends further along the urethra, than about an inch and a half, or two inches. Mr. Hunter thought, that this part of the canal appeared to be most susceptible of the particular kind of inflammation brought on by the infection, and it constituted, what he used to term, the specific distance of the disorder. However, neither the sensations of which the patient complains, nor the irritation of the parts, are confined to the real seat of the disease. The neighbouring parts are often affected with a variety of symptoms, of a nature more or less severe, such as uneasiness, and even pains every where about the pubes, scrotum, perinæum, anus, and hips. It is often necessary to suspend the testicles, which become so irritable, that the least accident, or exertion, which, in other circumstances, would have no effect, makes them swell. It frequently happens that the glands in the groin are sympathetically affected; they swell and inflame, though they do not commonly suppurate. Cases also occur in which the irritation extends to the buttocks, thighs, and abdominal muscles, occasioning acute pain, swelling, and extreme soreness of the parts, and putting the patient under the necessity of always continuing in an horizontal posture. These symptoms, however, are not strictly inflammatory: if the patient be bled, his blood does not exhibit the inflammatory crust, and the constitution is little or not at all affected.

When the case, independently of the affections arising from sympathy, is not more violent than what has been described, it is called a common gonorrhœa; but the violence of the essential symptoms of the disease will be more or less considerable, according as the patient is more or less susceptible of such complaints as depend upon irritation. Thus, in particular habits, the inflammation does not confine

fine itself to the specific distance, but reaches all along the urethra. Severe pain is also frequently experienced in the perinæum. Sometimes the acceleratores urinæ muscles are affected with the spasmodic contractions, of which some mention has already been made. Such spasm is particularly apt to come on when the patient has just finished making water; it shews itself by the manner in which the last drops of urine are expelled; and it is generally attended with contractions of the erectores muscles. Sometimes the inflammation is so great as to occasion a swelling, and even an abscess in the cellular membrane. It has already been observed, that the most common situation of such suppuration is in Cowper's glands; but the small glands of the bulb may also be affected in a similar manner, and the irritation, in certain instances, is found to extend even to the bladder itself.

When the latter organ is once affected, it becomes more susceptible of every kind of irritation, so that very distressing complaints are apt to be produced. It is no longer capable of bearing the degree of distention of which it is capable in the healthy state. Hence the patient cannot hold his water in the usual way; but no sooner does the inclination to discharge it arise, than he is immediately compelled to make the evacuation, notwithstanding the severe pain, which, while the urine is escaping, is felt in the bladder, and especially about the glans penis. This pain has been compared with what is experienced in a fit of the stone, and it lasts for some time after the evacuation is completed.

The ureters, and even the kidneys, are sometimes sympathetically affected, when the bladder is considerably inflamed or irritated. Such an occurrence, however, is exceedingly uncommon. Mr. Hunter mentions his having seen an inflammation of the peritonæum brought on by a severe affection of the bladder in gonorrhœa; and others have observed a violent inflammation of the kidneys from the same cause. (See *Encyclopédie Méthodique partie Chirurgicale*, tom. 1. p. 584.) It has already been mentioned that a chordee is one of the occasional effects of a gonorrhœa. It arises in general from inflammation; but in some cases it appears to be entirely of a spasmodic nature.

When the inflammation is not confined to the urethra and its glands, but spreads further, it attacks the substance of the corpus spongiosum, where it occasions an extravasation of coagulating lymph, which, uniting the cells together, makes the urethra incapable of yielding and being stretched in the same degree as the corpora cavernosa. Hence, during an erection, the penis becomes bent forward. The adhesion of the cells of the corpus spongiosum urethræ together, which is the cause of chordee, in general, comes on in consequence of mere inflammation of the canal; but occasionally it is the effect of a species of inflammation, which is seen accompanying certain ill-conditioned chancres. A chordee often continues after all the other symptoms of a gonorrhœa have quite ceased.

A chordee is sometimes altogether spasmodic, in which case it is seen to disappear and re-appear alternately, at indeterminate intervals. At one time the erections, which are so common in cases of gonorrhœa, happen without being attended with any curvature of the part; while at other periods the chordee takes place in a great degree; the intervals of time between these changes being sometimes remarkably short.

A swelling of the testicles is a frequent consequence of a gonorrhœa. It may happen in any stage of the disease; but, perhaps, it takes place most frequently when the complaint is on the decline. It was considered by Mr. Hunter as an affection arising from sympathy. It is seen attending

any kind of irritation in the urethra, whether occasioned by injections, bougies, or any other circumstance. In many cases, the swelling comes on and disappears very suddenly, or seems to leave one testicle to attack the other.

The swelling of the testicle generally begins with a soft, pulpy tumefaction of its glandular part, which becomes rather painful when handled. The tumour afterwards increases in size and firmness, and produces considerable pain. The inflammation seldom ends in suppuration, though some instances of this kind are met with. The epididymis (especially its lower end) is usually the hardest part; but, frequently, the induration and swelling attack the whole of the epididymis, and form a sort of knob at its upper part. The spermatic chord also is often affected, especially the vas deferens, which is thickened, and exceedingly tender. Sometimes the veins of the testicles are varicose.

The inflammation of the testicle, as well as that of the urethra, is frequently attended with sympathetic symptoms of irritation in other parts; for instance, pain at the lower end of the spine, a sense of weakness in the loins, colic pains, nausea, flatulence, disorder of the digestive organs, &c.

The swelling of the testicle is noticed to take place remarkably often just when the pain in the urethra has subsided, and the discharge has stopped; or else the truth is, that on the testicle becoming affected, the symptoms of irritation in the urethra immediately cease. Here it is somewhat difficult to determine which is the cause, and which the effect. However, it is worthy of remark, that it is not uncommon for the testicle to begin to swell at the very moment when the inflammation of the urethra, and the discharge, are becoming worse. Sometimes the epididymis alone is affected; sometimes only the vas deferens; and, on other occasions, only the spermatic chord. No reason can be assigned, why one of these parts should be affected rather than the rest. The inflammation of these organs is frequently attended with a strangury, especially when the discharge is suppressed; and, indeed, it is remarked, that the stoppage of the running generally brings on a tendency of that distressing complaint.

Another occasional effect of a gonorrhœa is a swelling of the lymphatic glands in the groin, a symptom, which is of the same nature as the inflammation of the testicle, but much more common. It has been supposed that the tumefaction of the glands depends, on the absorption of some of the matter from the urethra; but Mr. Hunter contended against this opinion. He thought that, in gonorrhœa, the matter was seldom absorbed, and he derived this sentiment partly from seeing that a lues venerea was seldom the consequence of this disease. However, this argument will have no weight with those practitioners, who disbelieve in the doctrine that the poisons of gonorrhœa and the venereal disease are of the same nature. Another consideration, which influenced Mr. Hunter, will meet with more general approbation. It was the fact, that any simple mechanical irritation of irritable organs is capable of exciting an inflammation of their absorbents, and of the glands to which such vessels run. Now, since the lymphatics and their glands usually inflame before suppuration has taken place in the part originally affected, and their inflammation often subsides as soon as this last occurrence begins, we must conclude, that the swelling of the inguinal glands, in gonorrhœa, arises altogether from the irritation in the urethra. It is observed also, that such swellings almost always admit of resolution, while those which originate from the absorption of venereal matter from chancres very frequently suppurate, burst, and turn into syphilitic ulcers. It is true, however, that swellings of the inguinal glands, induced by the irritation of gonorrhœa,

do sometimes end in abscesses and fores; but no lues venerea follows, nor is mercury requisite for the cure.

Another sympathetic affection, sometimes attendant on a clap, is a swelling of the absorbent vessels themselves. In some instances, this symptom accompanies the swelling of the glands. It makes its appearance in the form of a hard, painful cord, which, proceeding from the prepuce, extends along the dorsum of the penis, sometimes as far as the groins. This effect is not the consequence of the absorption of matter; for it is seen attending other irritations in the urethra, where no suspicion of any irritating or poisonous matter being taken up by the lymphatics can be entertained by any kind of reasoning whatsoever. The symptom is sometimes brought on by the employment of bougies, in the treatment of strictures. It was for a long while supposed, that the matter which is discharged from the urethra, in cases of gonorrhœa, was furnished from ulcers in this canal; but observation at length detected, that the opinion was destitute of all foundation. Dr. William Hunter is reputed to have been the first who asserted, that in gonorrhœa no ulcers existed in the urethra, and he is said to have begun to inculcate the fact in his lectures about the year 1750. This celebrated physician had derived his sentiment from some particular cases which he had seen, where a large quantity of pus had been formed upon the surface of the viscera, without any ulceration of these parts whatsoever. In 1753, his brother, Mr. John Hunter, had an opportunity of dissecting the bodies of two malefactors, who were executed, while it was known that they were affected with a severe gonorrhœa. After a most careful examination, no ulceration could be discovered: the urethra of each was merely found to be rather redder than natural, particularly near the glans penis. Mr. Hunter afterwards opened the urethra of many patients who had died with gonorrhœa upon them, and he never could find any vestiges of ulceration. It constantly appeared, that the membranous lining of the canal, near the glans penis, was redder than usual, and that the lacunæ were frequently filled with pus. Morgagni is said to have remarked the same fact. (*De Sedibus et Causis Morborum. Epist. 44. § 7.*)

As an attempt has been made by a late writer, Dr. Swediaur, to transfer the honour of the discovery from the Hunters to Morgagni, we deem it our duty to observe, that we cannot discover any accuracy, or justice, in the doctor's statement, since Morgagni's work was not published till 1761.

Although there can now remain no doubt, that in gonorrhœa there are no ulcers essentially, or commonly present in the urethra, to furnish the matter which is discharged, yet Mr. Hunter himself has explained, that a sore, occasioned by the bursting of an abscess in one of the glands of this passage, is sometimes produced. This kind of ulceration, however, never takes place till long after the commencement of the running, and it is quite of a different nature from such sores as were fancied to be the cause of gonorrhœa.

We shall now consider the identity of the gonorrhœa and venereal poisons. It has been represented by some surgical authors, that the essential difference between gonorrhœa and the venereal disease depends upon the circumstance of the first complaint being an affection of a secreting surface. Many other writers, and we may add, the generality of enlightened practitioners in this country, contend, that the two diseases originate from different poisons, a sentiment which is supported by the striking dissimilarity of the two affections, and the wide difference of their modes of cure.

Such authors, as maintain the doctrine of the two complaints being the consequence of different distinct poisons,

found their arguments upon various circumstances. First, the history of these diseases, and of their progress in different countries. Secondly, the phenomena peculiar to each disorder. Thirdly, the remedies necessary for the cure.

It is asserted, that the venereal disease and gonorrhœa did not make their appearance in Europe at the same period; but that the former was many years antecedent to the latter. The same thing is stated to have happened in other parts of the world, whither Europeans have conveyed the venereal virus. For instance, the venereal disease was known in China almost immediately after it had made its appearance in Europe; yet it is remarked by Astruc, that at the time when he wrote, gonorrhœa was a malady which had only been very recently observed among the Chinese. Also, in the South-sea islands, discovered in modern times, where both the venereal disease and gonorrhœa were unknown before the landing of European navigators, but where these maladies were afterwards diffused, gonorrhœa was not noticed till several years after syphilitic disorders had begun to shew themselves. Claps are said to have been yet unknown to the natives of the South-sea islands, at the period when captain Cook was performing his second voyage. (*Duncan's Medical Cases and Observations.*) All these circumstances have been adduced to prove the difference between that virus which gives rise to the venereal disease, and that from which gonorrhœa has its origin.

On the other hand, the circumstances attending the commencement of the venereal disease in these remote countries, led Mr. Hunter to draw a conclusion diametrically opposite to the one deduced by the foregoing class of reasoners; for, he observes, that it is almost impossible for a man to have a chancre during a voyage of several months, without the whole of the penis being destroyed, while it is well known, that a gonorrhœa may last an immense time, without losing the character of being virulent. It is related in the account of captain Cook's voyage, that the inhabitants of Otaheite, who were infected with the gonorrhœa, went up the country and got well; but that when the consequence of the malady was the venereal disease, the latter was incurable. Hence it is inferred, that the complaint which the Otaheiteans contracted was the gonorrhœa, since chancres and venereal affections would never have yielded to the simple means which were adopted. Besides, if the disorder had consisted of chancres, and the natives of Otaheite had been acquainted with the mode of curing such sores, it is contended, that they would likewise have understood how to cure other venereal symptoms. We find, also, from the perusal of captain Cook's third voyage, that the venereal disease afterwards raged in all its forms in the island of Otaheite. Now, since there is no document to shew, that the gonorrhœa was again introduced into that country, subsequently to Cook's second visit, it is concluded, that every form of the venereal disease which has been observed there has been derived from one source, which, in all probability, was a gonorrhœa.

Mr. Hunter mentions a gentleman who had a gonorrhœa thrice, of which he was cured without mercury. About two months after each infection, he had symptoms of lues venerea. The first were ulcers in the throat; the second were blotches on the skin; both which forms of the disease yielded to mercury. Thirdly, two punctures were made on the penis, with a lancet dipped in the matter of a gonorrhœa. One of these produced, on the part of the prepuce where it was made, a red, thickened speck, which increased and discharged some matter. This suppos'd chancre healed on having its surface repeatedly destroyed by caustic. The other puncture was made on the glans, where it was followed

by a pimple, full of yellowish matter. This pimple was touched with caustic, and healed in the same way as the fore on the prepuce. Four months afterwards the chancre on the prepuce broke out again; then it healed, and returned. This it did several times; but always healed without any application to it. While the fores remained on the prepuce and glans, a bubo formed in the groin. A sufficient quantity of mercury was given to cure the gland locally, but not to prevent the constitution from being affected. Two months after the cure of the bubo, a venereal ulcer, according to Mr. Hunter, formed on one of the tonsils. This was cured by mercury; but the medicine was purposely left off as soon as the fore was skinned over, in order to see what parts would next be affected.

About three months afterwards, copper-coloured blotches made their appearance in the skin, and the ulcer on the tonsil recurred. This disease was again only palliated by mercury; but the complaints returned in the same situation as before; and were ultimately cured by a proper quantity of mercury.

On the other hand, doubts must exist, concerning this account of the matter of gonorrhœa, when the following circumstances are taken into consideration:

1st. It is impossible to say what time may elapse between the application of venereal poison to the penis, and the commencement of ulceration. Therefore, Bougainville's sailors, alluded to by Mr. Hunter, might have contracted the infection at Rio de la Plata; but actual ulcers on the penis might not have formed till about five months afterwards, when the ship arrived at Otaheite. 2dly. The second argument adduced by Mr. Hunter is certainly inconclusive. Every ulcer in the throat is not regularly venereal. A common ulcer may heal while the patient is using mercury. Hence the cure, apparently accomplished by this medicine, is no proof that the complaint was syphilitic. 3dly. The last fact of inoculation is undoubtedly very strong. But, though the insertion of gonorrhœal matter, or any other morbid matter, beneath the cuticle, will undoubtedly produce troublesome local complaints, may we not doubt that the fores, in the above case, were actually venereal ones? Can we implicitly depend on the continence of the subject of the above remarkable experiments, during the long space of four months, between the healing of the fore on the prepuce, and its recurrence? If we cannot, the inference, in regard to the power of gonorrhœal matter to communicate the venereal disease remains unestablished. How much more conclusive in this respect, the experiments would have been, had the inoculation been practised on any other part but the penis. If the matter of gonorrhœa be capable of communicating the venereal disease, why does not the discharge commonly produce chancres on the glands and prepuce, with which parts it must lie in contact a very considerable time in every case? Why also does not the presence of a chancre frequently cause a gonorrhœa? If the infection of gonorrhœa, and the venereal disease, be really of the same identical nature, certainly, it seems very extraordinary, that the former complaint should receive no benefit from mercury, and the latter disease invariably require this specific remedy.

With respect to the venereal disease and gonorrhœa having arisen in Europe and elsewhere at different periods, it has been observed by such writers, as incline to the belief in the identity of the virus of the two affections, that every kind of contagious disease appears with greater violence in newly-infected countries, than in other situations where it has been a considerable time endemial. In this manner, an endeavour, which, in our opinion, is quite unsuccessful, is made to ex-

plain the cause why the gonorrhœa generally did not make its appearance till a long while after the venereal disease had shewn itself in much worse shapes. The same class of reasoners also assert, that, notwithstanding the diligent enquiries of many able men, there is still a degree of doubt concerning the exact time when these diseases originated, and, of course, concerning the point, whether one of them actually existed a long while before the other. As we shall have occasion to treat of the origin of the venereal disease hereafter (see *LIES VENEREA*), we shall not enter into this disquisition in the present article. We may be permitted, however, to express our suspicions, that discharges from the urethra must have been occasional diseases from time immemorial. Whether there be a species of gonorrhœa truly venereal, that is to say, one which depends upon the same virus, as syphilis, there may for ever remain doubts; but, that there are claps or discharges which arise from no poisonous or infectious matter whatsoever, but altogether from mere irritation in the urethra, as, in certain cases of strictures, is certain and undisputed. These gonorrhœa must have prevailed as long as that canal has been liable to various kinds of irritation.

One argument adduced against the identity of the virus, is derived from the striking difference observable in the progress and symptoms of the two diseases. When the venereal disease is neglected, it always grows worse and worse, and sooner or later brings on the patient's dissolution. On the contrary, a gonorrhœa tends to a natural cure, and, though left to itself, commonly ends in a favourable way.

The advocates for the identity of the poison, however, contend, that, in order to account for this last fact (which they state is not without exceptions), it is by no means necessary to suppose a different virus. They bring into consideration the circumstance of gonorrhœa depending upon an inflammation of the surface of the urethra, and not ulceration; and they maintain, that the absorption of the venereal poison generally happens much more easily from ulcerated surfaces, than from such as are simply inflamed. This mode of reasoning is brought forward as explanatory of the cause why, in the majority of cases, a gonorrhœa remains entirely a local complaint, and admits of a spontaneous cure, while the venereal disease is always prone to extend itself, and spread from one part of the body to another.

An argument against the identity of the virus is also founded on the reflection, that the venereal disease is only capable of communicating the venereal disease, and gonorrhœa of imparting gonorrhœa. The partisans of the doctrine which imputes this latter affection to the venereal virus, acknowledge, that things do usually correspond with the statement just now given; but they assert that the contrary case is also frequently observed. They remark, that we may easily convince ourselves of this circumstance, by a fact which is well known to practitioners, namely, that when persons, who have a gonorrhœa, are not particularly careful to keep the glans and prepuce clean, chancres are very apt to form upon these parts, and by one of these the whole system may become infected. It is also asserted, that, independently of the formation of any disease, there are cases proving, that the venereal disease may be the consequence of a gonorrhœa, and that every surgeon attentive practice must meet with instances of this kind. One of the most remarkable on record, is that related by Mr. Hunter; and it having been already noticed by us in the present article, we need not dwell upon it again.

With respect to chancres arising from the matter of gonorrhœa being in contact with the glans and prepuce, we do, undoubtedly, see, both in men and women who have

GONORRŒA.

claps and chaneres together; but, in our opinion, it is most rational to impute the fores to the application of venereal pus from chaneres, together with the gonorrhœal matter, at the time of coition. We have no doubt that this act is often performed, when, between the two parties, both kinds of infection are present.

Certainly it seems extraordinary, that if the virus be of the same nature in both cases, the two effects should not always occur in the same patient. We ought naturally to expect, that when a gonorrhœa makes its appearance first, it would always be the cause of a chanere; and that when a chanere is the first symptom, it would invariably be the occasion of gonorrhœa. We dismiss from present consideration the assertion of such writers as defend the identity of the virus, that, in some few instances, one malady does become the cause of the other. Mr. Hunter suspected, that the irritation of one of the parts, forming the seats of the two diseases, became the preservative of the other. He thought, that when the urethra inflames and discharges matter, the adjacent external parts might, on that very account, be exempt from a disease which they would otherwise inevitably contract, by reason of the effect of the very virus which gave rise to the gonorrhœa. The same celebrated writer also entertained a suspicion, that when a chanere attacks the glans, or prepuce, the urethra might become insusceptible of the irritation, which, without the external disease, would certainly lead to a discharge from that canal.

This mode of explanation appears to us somewhat theoretical. We are of opinion, also, that in arguing in this way, the advocates for the identity of the virus only bring forward the shadow, instead of the substance of reason. In fact, they say nothing more than that supposed venereal matter cannot make the external parts of the penis ulcerate, because there is an irritation in the urethra; and that the urethra cannot be affected with gonorrhœa, because a chanere already occupies the external parts. If this reasoning be not hypothetical and fanciful, we cannot conceive what arguments can ever be considered so. They who talk in this manner, inadvertently fall into difficulties, and make one opinion inconsistent with another. Thus, they have already told us, that, occasionally, a chanere is apt to occur, when patients with gonorrhœa neglect to keep the glans and prepuce clean; yet, according to their principles, a clap renders the external parts insusceptible of infection, and, of course, there would be no need of cleanliness as a preservative. We think that the weakness of the argument must be obvious to the youngest student, who, on his entrance into any venereal ward of an hospital, is almost sure of immediately finding a patient who has at the same time both chaneres and gonorrhœa.

The different treatment required by gonorrhœa and the venereal disease, is another argument against the identity of the virus, mercury being unnecessary in claps, and the sole specific in the other complaint. The partisans of the opposite opinion endeavour to diminish the force of this fact, by adverting to the different ways in which the two diseases affect the parts which are attacked, and by maintaining that no just inference can be drawn from the difference of treatment, while the particular action of mercury, on various parts affected with the venereal poison, is not understood. They also contend that, though mercury may have no effect in gonorrhœa, when used in the same way as for other venereal affections, yet, when applied to the urethra itself, it serves to moderate the symptoms, and accelerate the cure.

Having seen the calomel injection employed in some hundreds of cases, with less benefit than the common vitriolic one, we cannot assent to the last observation. The other

remarks, being bare opinions, may be received or not, as the judgment of the reader may incline him; but, for our own part, we have no hesitation in refusing them a place among such information as is founded on rational evidence.

We shall now say a few words, respecting the time, between the application of the infection and the beginning of its effects.

In the greater number of diseases, a certain space of time always elapses between the application of the cause and the first appearance of the effect. The time when a gonorrhœa begins, after contamination, varies considerably in different cases. In some examples, the poison takes effect in a few hours, as Mr. Hunter has seen two or three times; while, in other instances, the complaint does not shew itself till the end of five or six weeks. There are also cases to be met with, in which the disorder begins at all the intermediate periods. It is calculated, that the most common time of its origin is in the space between the sixth and twelfth day. In one instance, in which the malady did not commence till the end of six weeks, it was noticed by Mr. Hunter, that the affection was preceded by various symptoms of irritation, and uncommon sensation, in the parts. Hence, this celebrated author concluded, that the virus seldom, or never, remains so long inactive; but that the inflammatory state may exist a good while before suppuration takes place. The delay in the commencement of the discharge, however, may be owing to causes which are not understood, and this is very likely to be true, if we consider that some cases of gonorrhœa do not begin for five or six weeks after infection, and yet are not preceded by any remarkable symptom whatsoever.

The observations already made in a preceding part of this article, must have apprized the reader, that discharges from the urethra may originate from more causes than one, and from more irritations than that which is produced by one particular kind of virus. There are sometimes spontaneous discharges from this passage, while no immediate cause whatever is assignable. Such instances as occur independently of a specific gonorrhœal, or, according to the Hunterian doctrine, the venereal virus, have been termed *simple* or *benign*. Some assert, that these cases may be known by their coming on immediately after coition, and it is violent from the very beginning; while the virulent gonorrhœa does not commence till after some days, and grows gradually worse. However, this criterion is insufficient: simple gonorrhœas are not always owing to coition, nor are they always sudden in their appearance.

Mr. Hunter has seen the urethra sympathize with the gums in dentition, and all the symptoms of gonorrhœa affect the same infant several times. The author of the article *Gonorrhée*, in the *Encyclopédie Méthodique*, also mentions his having seen two female children, who were affected during dentition with a discharge from the pudenda, attended by a certain degree of inflammation, and pain in making water.

We shall next introduce a few remarks on the effect of the discharge on the parts producing it.

It was formerly not an uncommon opinion, that the discharge was a means employed by nature for carrying off the virus occasioning the complaint, and thus bringing about a cure. However, it is impossible for this to be true, with respect to inflammations, which arise from a specific virus; for, supposing the suppuration could wash away all the poison, causing the original irritation, yet, as all the matter afterwards secreted is equally virulent, no good would be done; the irritation, according to the preceding idea, would be perpetuated, and, of course, the discharge. This

GONORRŒA.

last occurrence, however, we need hardly remark, is not the case. The affection of the urethra in gonorrhœa is not kept up by the matter, but by the specific quality of the inflammation itself, which, in all probability, can never continue beyond a limited time, since the symptoms at length spontaneously subside. Had the infectious matter, which is formed in the course of the disease, the power of protracting the original irritation, the disorder would have no termination.

In gonorrhœa, as in many other diseases, the morbid action of the parts affected cannot go on for a long while in the same way. After having increased in violence to a certain degree, it naturally tends to become weaker; and the symptoms of the disorder which depend upon such action, at length, entirely cease. The time of this cessation will vary according to circumstances; for if the irritated parts be very susceptible of the specific irritation, the diseased action must be more violent and lasting; but, in all cases, this difference is always owing to some particularity of constitution, and not to any peculiarity of the virus.

The reader is aware that Mr. John Hunter regarded the gonorrhœa as one form of the venereal disease. It was the opinion of this distinguished man, that the venereal disease was only capable of a natural cessation, when it occupied a secreting surface, from which it produced pus. He believed that when the part attacked was not a secreting one, and an ulcer was formed, the disease would of itself go on for ever. He referred this difference between gonorrhœa and a chancre, however, more to the difference in the mode of action, than to that of the affected surfaces; for when the venereal virus produces an ulcer upon a secreting surface, as it sometimes does upon the tonsils, and even the urethra itself, such sores are not more disposed to heal, than if they were situated any where else in the body.

It is sometimes observed, in cases of gonorrhœa, that the parts which were first irritated get well, while the irritation is communicated to another part of the same surface, as happens, when it leaves the urethra near the glans, and affects that part of the canal which is further on towards the bladder.

Admitting that every gonorrhœa is capable of getting well, without surgical assistance, it may be doubted whether a person, who already has a gonorrhœa, is susceptible of the irritation of fresh gonorrhœal matter, or that the clap which exists could be augmented by its application. Mr. Hunter extended the same observation to every form of the venereal disease; and he states, that the matter of gonorrhœa, or of a chancre, put on an ulcerated bubo, does not in the least retard the cure, although, if venereal matter be applied to a common sore, the venereal irritation will frequently be excited. Such facts are strongly in favour of the opinion, that the matter of gonorrhœa has no effect in keeping up the complaint. The urethra is neither irritated by the infectious matter which it secretes, nor can the irritation already existing last beyond a certain period. Even were fresh matter applied to the urethra, the complaint would probably get well with equal quickness.

Mr. Hunter extended the idea further, and even conceived that a fresh gonorrhœa could not be contracted, were fresh virus applied to the parts affected, at the period when the cure was just on the point of being completed. He thought that, in time, the parts might be so habituated to the impression of the virus, as to become insensible of it, and they must have regained their natural and original state, ere the infection can again have such effect upon them as to reproduce the complaint.

The foregoing opinions do not rest altogether upon theory: they are also founded on experience and observation. Men, who have just had a gonorrhœa, have frequently been known to expose themselves to be infected again without any recurrence of the complaint taking place, while other healthy persons, who had connection with the same woman, have immediately caught the malady. Perhaps, it is on the same principle, that the first gonorrhœa is generally the most violent, and that such persons as are often affected with claps have them more and more mildly, particularly when the intervals are short.

In corroboration of these sentiments, Mr. Hunter relates several cases, among which is the following: a married man, who, for several years, had had no connection with any woman except his own wife, happened to meet with an old acquaintance, who gave him a severe gonorrhœa, though she declared her belief that she was quite well. Both adopted some means of cure; but continued to cohabit together during the treatment. The man got well, and it was presumed that the woman was also cured. They continued to live together several months, without the former experiencing any inconvenience, or having any reason to suppose that there was still any thing the matter with the latter. At length they parted, and the woman formed a new attachment. She had no sooner made this last connection, than she gave the new lover a gonorrhœa. She again consulted Mr. Hunter, whom she assured, that she had never cohabited with any others, except the preceding two; and consequently, if this be true, the infection of her last lover must have arisen from the very same gonorrhœa, of which she supposed that she had been formerly cured. However, she now used no remedies, and the man, after he was well, continued to cohabit with her for several months without receiving any new infection. But her old lover now returning, after a year's absence, and thinking that, as she was living regularly with the second, there could be no danger, ventured to have connection with her; the consequence was, that he caught another gonorrhœa.

Before describing the treatment, it is proper to say a few words of the disease in women.

The gonorrhœa in females is not so complicated as in men, the parts affected being more simple and fewer in number. In women the disease is not so easy to be ascertained, because they are also liable to a complaint, called the fluor albus, which has some resemblance. A mere running from the parts is not so much a proof of the existence of an infectious gonorrhœa in a woman, as a discharge without pain in a man; and in the former the disease will often exist, while there is no increase whatever in the natural secretion from the parts. Nor can any criterion be deduced from the kind of matter, since the discharge of the fluor albus frequently puts on all the appearances of gonorrhœal matter. Neither is pain, nor any peculiarity in the sensations of the parts, necessarily attendant upon the complaint in women. Mr. Hunter also remarks, that the appearance of the parts often gives us but little information; for he frequently examined them in patients, who complained of all the usual symptoms, such as an increased discharge, pain in making water, soreness, &c. and yet he could perceive no difference in the look of the parts and of such as are quite healthy. When the patient was not conscious of any particular symptoms, or was disposed to conceal her knowledge of them, Mr. Hunter thought that some judgment might be formed from her having had connection with men supposed to be unwell, and from her power of communicating the disease to others. However, it is acknowledged,

GONORRHOEA.

acknowledged, that as this last circumstance is derived from the testimony of another person, there are obvious reasons why it should not always be trusted.

When a woman contracts a gonorrhœa, the vagina must be first attacked, a part which is not endued with considerable sensibility. Frequently, however, the complaint extends much further, producing disagreeable sensations and soreness of the inside of the labia, nymphæ, clitoris, caruncule myrtiliformes, and meatus urinarius. The parts are sometimes so sore that the patient cannot bear them to be touched; she can hardly walk; and a great deal of pain is experienced when the urine comes into contact with the sore surfaces, as it must unavoidably do as often as the bladder is emptied.

When the disease extends to parts which are more sensible than the vagina, and more susceptible of inflammation, women have nearly the same symptoms as men; a fulness about the parts, a discharge from the urethra, violent pain in making water, and great uneasiness from the pressure on the parts in sitting. Sometimes the bladder is also affected.

The inflammation frequently extends to some depth, running along the ducts of the glands, and affecting the glands themselves, so as to occasion hard swellings under the surface of the inside of the labia. These tumours often suppurate, and burst near the orifice of the vagina. They resemble the abscesses in the glands of the urethra in men.

The time in which a gonorrhœa may be cured is exceedingly variable, some cases terminating in a week, while others continue for months under the same treatment.

According to Mr. Hunter, the object in the cure is to destroy the disposition and specific mode of action in the solids of the parts, and, as soon as that change is accomplished, the poisonous quality of the matter produced will also be destroyed. Thus the disease may be cured though not always its consequences.

A gonorrhœa is not capable of being continued beyond a certain time in any constitution, and when the complaint is violent and lasts a long while, it is owing to the parts being very susceptible of such irritation, and readily retaining it.

Since there is no specific medicine for the gonorrhœa, it is very fortunate, as Mr. Hunter observes, that time alone will effect a cure. This celebrated surgeon was inclined to think, that, in cases of gonorrhœa, medicines were seldom of service, perhaps not more frequently than once in ten instances. With the idea, that every gonorrhœa cures itself, he gave certain patients pills of bread, which were taken with great regularity. These persons all got well; but Mr. Hunter thought that some of them were not cured quite so soon as they would have been, had artificial means been employed.

The surgical methods of cure consist of internal remedies and local applications; but in putting any plan of treatment in execution, more attention should always be paid to the nature of the constitution, or to any attending disease in the parts themselves, or parts connected with them, than to the running itself.

The nature of the constitution is principally to be judged of from the local effects of the disease. These are so different in different people as to require a great variety of treatment, a circumstance, says Mr. Hunter, which has been too little attended to, every one endeavouring to attack the immediate symptoms, as if he had a specific for a gonorrhœa.

We are first to consider, whether the inflammation is vio-

lent or mild, common or irritable. When the symptoms are violent, but of the common inflammatory kind, which is to be judged of from the attending circumstances, and particularly from the extent of the inflammation not exceeding the specific distance, the local applications may be either of the irritating or soothing kind. In this example, irritating applications may be less dangerous, than when the inflammation is of the irritable sort, and may have the effect of altering the specific action, the parts afterwards recovering of themselves, as from any other common inflammation. Mr. Hunter, however, expresses his belief, that the soothing plan is the best at the beginning.

When the inflammation is great, and of the irritable kind, no violence is to be used in the treatment, as the symptoms would thus only be increased. Mr. Hunter thought, indeed, that there were some cases, which are exceptions to the latter remark, the great degree of inflammation arising entirely from a susceptibility of this irritation, and not from any general irritability in the constitution. He confesses, however, that such examples can seldom be discriminated.

When the symptoms run very high, nothing should be done to stop the discharge, as, were it to be checked, the inflammation would still continue, and no good be effected.

Mr. Hunter recommends us to alter the constitution, if possible, by remedies adapted to each disposition, with a view to alter the actions of the parts arising from such dispositions, and reduce the disease to its simple form. If the constitution cannot be altered, we can only allow the action to wear itself out.

When the inflammation has considerably abated, and the disease only remains in a mild form, its cure may be attempted either by internal remedies, or local applications. If local means are used, violence is still to be avoided, because it may bring back the irritation. At this period (continues Mr. Hunter), gentle astringents may be applied with a prospect of success; or, if the disease has begun mildly, and there are no signs of an inflammatory disposition, either of the common, or irritable kind, an irritating injection may be used, in order to get rid of the specific mode of action quickly. Such application will increase the symptoms for a time; but, when it is left off, they will frequently abate, or wholly disappear. In such a state of parts, astringents may be used: for the only thing to be done, is to procure a cessation of the discharge, which is now the principal symptom.

When the itching, pain, &c., are felt for some time before the discharge appears, Mr. Hunter rather prefers the soothing to the irritating plan of treatment. He suspected, that thus the coming out of the discharge would be promoted, which occurrence he conceived was the first step towards a resolution of the irritation. He believed that, at all events, in this case, the employment of astringents would be bad practice, as, by preventing the discharge from taking place, they might prolong the inflammation, and protract the cure. Also, in cases of strictures, and of diseased testicles, he is adverse to the use of astringents; for, says he, while the discharge lasts, both the other complaints are relieved.

The internal remedies commonly recommended in a gonorrhœa, may be divided into evacuants and astringents. The evacuants (says Mr. Hunter), are principally of the purgative, or diuretic kind, and these are not confined to any particular medicines, every practitioner supposing that he is in possession of the best. Some use mercurial evacuants; whilst others carefully avoid mercury in every form. The

neutral

neutral salts have been given from the idea of their being cooling. Some of the profession have chiefly kept to diuretics, perhaps with two views; first, as evacnants acting mechanically upon the urinary passages, so as to wash away the matter; secondly, as specifics. For this purpose, nitre has been given, a medicine which has always been thought to have great effect in lessening inflammation, though Mr. Hunter had doubts concerning the truth of the opinion. Under every mode of treatment the patients always get well, and the cures are ascribed by each practitioner to his own favourite method.

Mr. Hunter remarks, that "to keep the body open in most cases, even when the patient is in other respects in health, must, no doubt, be proper; but what idea can we form of an irritation, produced all along the intestinal canal, curing a specific inflammation in the urethra? Yet there are cases where a brisk purge has been of service, and even in some has performed a cure. But I suspect, that, in such cases, the disease had been continued by habit only, and that this practice would not have succeeded in the beginning. A gentleman had a gonorrhœa, all the symptoms of which continued for two months, and by taking at once ten grains of calomel, which purged him most violently, he was almost immediately cured. The calomel could not have acted specifically, but by a kind of derivation, that is, an irritation produced in one part, cured one that subsisted in another; but even if it should be granted, that in some constitutions purges have the power of making the solids less susceptible of this irritation, it cannot be supposed they will have this effect in every case: in some constitutions, they might debilitate, increase irritability, and of course increase the symptoms. These contrary effects must take place in different constitutions, in which a medicine has no specific action. On the supposition of the cure being promoted by an evacuation from the blood, what service can purging out some of the blood, in form of a secretion from one part, do to an inflammation of another part? On such a supposition would not a sweat, or an increase of saliva, by chewing tobacco, or stimulating the nose by snuff, all tend equally to cure a gonorrhœa? But humours having been considered as the universal cause of every disease, especially those in which pus is formed, or a discharge produced, and purging having been supposed to be the cure for humours, purgatives were of course made use of in this disease; and as the patients have always been cured, the practice became generally established.

"Those who recommended mercury in this form of the disease, did it most probably from the opinion, that this medicine was a specific for the venereal disease in all its forms. On this supposition, we can see some reason for their practice, as it would be absorbed from the intestines, circulate through the inflamed vessels of the urethra, and thereby destroy the venereal irritation. Here we can only suppose it to act by its specific virtue; but I doubt very much of mercury having any specific virtue in this species of disease; for I find, that it is as soon cured without mercury as with it; and where this medicine is only used as a purge, or purged off the next day, and therefore allowed to act merely upon the bowels, I cannot conceive that it could have any more effect upon the venereal inflammation in the urethra, than an irritation in the bowels arising from any other purgative. So little effect, indeed, has this medicine upon a gonorrhœa, that I have known a gonorrhœa take place while under a course of mercury sufficient for the cure of a chancre. Whether the gonorrhœa arose from the same infection that produced the chancre I cannot say; nor can it be easily determined in such cases. Men have also been known to contract a go-

norrhœa when loaded with mercury for the cure of a lues venerea; the gonorrhœa, nevertheless, has been as difficult of cure as in ordinary cases." P. 72, &c.

With respect to diuretics, considered as evacnants, Mr. Hunter observes, that they may have the same general remarks made on them as have been offered in regard to purgatives. It is possible, says he, that specific medicines, taken into the constitution (if we had such), and passing off by the urine, might act upon the urethra in their passage through it. The balsams and turpentine pass off in this way, and become specifics for many irritations in the urinary passages; but how far medicines which have the power of affecting particular parts when sound, or when under diseases peculiar to those parts, have also the powers of affecting a specific irritation in them, Mr. Hunter was uncertain. He conceived, however, that they might be capable of removing any attending irritation, though not the specific one. He thought, that diuretics did good inasmuch as they increased the quantity of urine; but he believed simple water was best for this purpose, or water joined with such things as encourage the patient to drink a good deal, as with tea, capillaire, orgeate, &c.

Astringents have frequently been prescribed, though without the approbation of the generality of regular practitioners. It was Mr. Hunter's opinion, that such medicines did not lessen the inflammation, but that they often lessened the discharge.

With regard to local applications, they may be either internal to the urethra, or external to the penis. In many cases both kinds are proper. One would suppose, that what is applied to the urethra, must be the most likely to effect a cure, by coming immediately into contact with the diseased parts.

Local applications to the urethra may be either in a solid or fluid form, each of which has its advantages and disadvantages. A fluid, (says Mr. Hunter) is only a temporary application, and that of very short duration.

The solid applications may remain a long time, and in this respect, would seem to be better than fluid ones; but in general they create irritation. They must be used in the form of a bougie, which Mr. Hunter imagined was commonly injurious, when the parts were in an inflamed state, though he confesses, that he never saw any harm from it in any case, when employed with caution.

Fluid applications to the inside of the urethra are usually called injections, and, like the internal remedies, are without number. However, as the inflammation is frequently removed under the use of injections of various kinds, have we not, (as Mr. Hunter notices) a strong corroborating circumstance in favour of an opinion, that every such complaint will in time cure itself? This eminent surgeon thought, however, that practice evinced, that an injection often has almost an immediate effect upon the symptoms, and, therefore, that it must have some powers, though the injection, which would have the greatest specific effect, he believed, was not yet known. If an injection has no specific powers, it must be very uncertain in its effects, and can only be of service as far as it may be adapted to a peculiarity of constitution, or parts. As injections are only temporary applications, it becomes necessary to use them often, especially in cases where they are found to be of service. They should therefore be applied as often as convenient, perhaps every hour, or even oftener; but Mr. Hunter adds, that this must be regulated in some measure by the kind of injection: for, if it be irritating, it will not be proper to use it so often, as it may be productive of bad consequences.

The same author observes, that many injections remove the

the symptoms immediately, or soon after the application, and prevent the formation of matter, which has given rise to the notion of their shutting up the disease and driving it into the constitution; but this supposition cannot be true, since the matter is the only substance in which the poison is contained, and the formation of the poison is inseparable from the formation of matter. Therefore, if we can prevent the one, the other cannot take place, and, of course, there can be no room for absorption; so that there can neither be any power of infecting the constitution in the same person, nor of communicating the infection to others.

Mr. Hunter divided injections into four kinds, namely, the irritating, sedative, emollient, and astringent. He believed that we are not acquainted with any specific one, although a mercurial injection, of some sort or another, is frequently fancied to have such a quality.

All irritating injections act upon the principle of producing an irritation of another kind, which ought to be greater than that of the gonorrhœa, by which means the lull is destroyed and the disease cured, although the pain and discharge may still be kept up by the application.

These symptoms will soon go off, as soon as the injection is laid aside, because they only arise from its irritating qualities. In this way bougies, as well as many injections, may be supposed to perform a cure; and although they increase the symptoms for a time, they never can increase the disease itself, any more (says Mr. Hunter) than the same injection, which would produce the same symptoms, if applied to the urethra of a sound man, can communicate the disease. Most of the irritating injections have an astringent effect, and, when mild, prove simply astringents; their irritating quality depending chiefly upon their strength.

Mr. Hunter was not able to determine absolutely the kind of cases in which irritating injections might be used with advantage. He thought, however, that such applications should never be used when there is already much inflammation, especially in constitutions which cannot bear a great deal of irritation, as a previous knowledge of the disease in the same person sometimes teaches us. Neither should these injections be used when the irritation has spread beyond the specific distance; when the testicles are tender, or when they have become sore upon a sudden diminution of the discharge; when the perinæum is very susceptible of inflammation, and particularly if it should have formerly suppured. Irritating injections also ought not to be employed when there is a tendency in the bladder to irritation, which is known from the patient having had, for some time, a frequency in making water. In all the preceding cases they do no good, and often do mischief: Mr. Hunter thought he had seen abscesses in the perinæum brought on by their employment.

In mild cases, and in constitutions which are not irritable, such injections often succeed, and remove the disease almost immediately. The practice, however, as the foregoing writer remarks, ought to be attempted with caution, and not, perhaps, till milder methods have failed. Two grains of corrosive sublimate (hydrargyrus muriatus), dissolved in eight ounces of distilled water, are an eligible injection of this kind; but an injection of only half this strength may be used, when it is not the design to attempt a very sudden cure. If, however, the injection thus weakened should give considerable pain, or occasion a great increase of soreness in making water, it must be still more diluted.

Sedative injections, according to Mr. Hunter, will always be of service in cases where the inflammation is considerable, not by lessening the disease itself, but by lessening

the diseased action, which always allows the natural actions of the part more readily to take place. They are likewise very useful in relieving the painful feelings of the patient. Perhaps, says this celebrated surgeon, the best sedative which we have is opium, as when given by the mouth or anus, as when applied to the part affected in the form of an injection. But even opium will not agree, nor act as a sedative in all constitutions or parts. On the contrary, it has often opposite effects, producing great irritability. Lead may be reckoned a sedative, so far as it abates inflammation, while, at the same time, it may act as a gentle astringent. Fourteen grains of saccharum saturni (acetite of lead), dissolved in eight ounces of distilled water, make a good sedative astringent injection.

Mr. Hunter next remarks, that the drinking freely of diluting liquors may, perhaps, be considered as having a sedative effect, as it in part removes some of the causes of irritation, rendering the urine less stimulating, either to the bladder, when the irritation is there, or to the urethra in its passage through it; and the plan may possibly lessen the susceptibility of irritation. The vegetable mucilages of certain seeds and plants, and the emollient genus, are recommended for impregnating the patient's drink. Such substances pass off with the urine, and render the evacuation of that fluid less painful. It is proper to notice, however, that Mr. Hunter does not appear to have a high opinion of the utility of this practice.

When the inflammation is very great, Mr. Hunter believed, that emollient injections are the most proper applications. It seems probable, that they act first by simply washing away the matter, and then leaving a soft application to the part, in which way, says this eminent writer, they can be of singular service by lessening the irritating effects of the urine. A solution of gum arabic, milk and water, or sweet oil, will frequently lessen the pain and other symptoms, when the more active injections have done nothing, or seemed to do harm.

When great irritation and soreness prevail at the mouth of the urethra, the point of the syringe cannot be introduced, and no attempt to use an injection ought to be made before the inflammation abates. Emollients may be used externally in the form of fomentation.

The astringent injections, observes Mr. Hunter, can only act by lessening the discharge. They can have no specific effect upon the inflammation. They should only be used towards the latter end of the disease, when it has become mild and the parts begin to itch. However, if the disease should begin mildly, they may be used at the very beginning; for, by gradually lessening the discharge, without increasing the inflammation, we complete the cure, and prevent a continuation of the discharge called gleet. If the astringent injections be strong, they will be irritating, and frequently increase the discharge, instead of diminishing it. When weaker, they often stop the running, without hastening, however, the cure in all cases; for the inflammation may still continue even longer than it would have done, had the tendency to secretion not been removed. But sometimes an astringent injection will cure a slight irritation in a very few days. Mr. Hunter never found one astringent more efficacious than another. The astringent genus, as dragon's blood, the balsams, and the turpentine, dissolved in water; the juices of many vegetables, as oak bark, Peruvian bark, tormentil root, and, perhaps, all the metallic salts, as green, blue, and white vitriols; the salts of mercury, and also alum; probably all act much in the same way. Mr. Hunter, however, owns that they do not act equally well in every gonorrhœa.

GONORRŒA.

norrhœa, and that changing the injection will often succeed, when a long perseverance in a previous one would not.

We have to observe, that the astringent injection, which is most generally approved of by practitioners, is that containing white vitriol (zincum vitriolatum), about half a scruple of which, dissolved in eight ounces of water, is a very good application to begin with. The strength may be increased or diminished, however, as the patient's feelings may require.

Poultices and fomentations have been used as external applications in cases of gonorrhœa; but, says Mr. Hunter, they can be of little service, except when the prepuce, glans, and orifice of the urethra are inflamed. It is now more common, in the inflammatory stage of the complaint, to surround the penis with linen kept continually wet with the saturnine lotion.

When any of the glands of the urethra remain in an indurated state, after the subsidence of the inflammation, the hardness may be removed by frictions with camphorated mercurial ointment.

It is remarked by Mr. Hunter, that in women, the mode of curing the gonorrhœa is nearly the same as in men; but the disease itself is milder, and the secondary symptoms less numerous in females. Hence the cure is more simple.

When the disease is confined to the vagina, it may be easily cured by means of injections, taking care also to wash the external parts with the application. The patient cannot, however, apply an injection to the meatus urinarius, when that passage is affected.

The same kinds of injections are proper for women as are prescribed for men; but they may be made doubly strong, as the parts in women are not nearly so irritable as the common seat of this disease in the other sex.

When the inflammation runs along the ducts of the glands, either of the mouth of the vagina, or of the urethra, or where it affects the glands themselves, the case claims the same treatment as in men. The mercurial ointment should be freely applied to the indurated parts. When the ducts and glands suppurate and form abscesses, these should be opened and dressed like a sore. The ulcer, however, is not regarded as venereal. Though Mr. Hunter entertained such a sentiment, and directed a corresponding treatment.

In plethoric constitutions, the symptoms are frequently violent, attended with a strong propensity to the inflammatory fever. The inflammation, however, does not extend beyond the specific distance. Many medicines, which might be of service in another constitution, here do harm, and increase the symptoms which they were intended to relieve. Mr. Hunter has seen opiate glysters, after at first doing good, bring on fever and an exasperation of all the symptoms. He has seen the balsam capivi render the inflammation worse. The treatment of such a constitution, when affected with this disease, should chiefly consist in bleeding and gentle purging. It is proper also for the patient to live sparingly, and use little exercise.

In the weak and irritable constitution, as Mr. Hunter observes, the symptoms are frequently very violent, and often extend beyond the specific distance, the inflammation running along the urethra, and even affecting the bladder. In this instance the foregoing author was of opinion, that a strengthening plan should be adopted.

Sometimes a gonorrhœa is so capricious in its cure, that the accession of an accidental fever stops the discharge, removes the pain in making water, and the disorder is permanently cured. Sometimes the symptoms cease on the commencement of the fever, and return when the latter complaint is well. In other examples a gonorrhœa may

begin mildly; but a severe fever coming on and continuing for several days, the symptoms of the first disorder are rendered much worse, and, on the fever going off, the gonorrhœa likewise disappears. Mr. Hunter remarks, that although a fever does not always cure a gonorrhœa, yet, as it possibly may, nothing should be done while the fever lasts; and if the local complaint should continue after the fever is gone, it is then to be treated according to the symptoms.

The same writer represents, that, unfortunately, there are cases in which no known method lessens the symptoms; evacuations, a strengthening plan, sedatives and emollients, all prove useless, and time alone seems to bring about the cure. In these instances, Mr. Hunter thought the soothing plan of treatment the most advisable, and was against the employment of astringents. Neither had he much opinion of the capivi and Canada balsams, nor of turpentine in general, though they might diminish the discharge.

A gonorrhœa is also considerably affected by the patient's way of life, during the inflammatory state. Most things which hurry or increase the circulation, aggravate the symptoms, such as violent exercise, drinking strong liquors, eating strong indigestible food, taking peppers, spices, spirits, &c.

When the complaint begins mildly, or after the violent symptoms have subsided, we may prescribe medicines which will assist the above local remedies, in checking the discharge. Mr. Hunter thought the turpentine the most efficacious. Cantharides, cuprum vitriolatum, acetite of lead, and alum, have also been recommended.

The reader is already aware, that Mr. Hunter regarded gonorrhœa as a disease arising from the venereal poison, and believed that the matter from the urethra, if introduced into the circulation, would occasion a lues venerea. In order to guard against the effects of absorption, he was an advocate for exhibiting small doses of mercury at an early period of the malady, and for continuing them even for some time after the formation of matter is at an end. He advised a grain of the hydrargyrus calcinatus to be taken every night, or every evening and morning; but frictions, with the mercurial ointment, when mercury disagreed with the stomach and bowels. Many practitioners at this day are strongly attached to the system of prescribing a grain or two of calomel every day during the treatment of a gonorrhœa, and deem it unsafe to abstain altogether from the use of mercury, in some form or another. Others give calomel with a view of its acting as an alterative and purgative. We never have seen any reason, however, for exhibiting either the hydrargyrus calcinatus, or calomel, or for employing mercury in any mode whatsoever.

Before closing the present article, it only remains for us to say a few words respecting some complaints, which are occasionally attendant on gonorrhœa.

When the inflammation is violent, or spreads along the urethra, there is frequently a discharge of blood from the vessels of that part. Mr. Hunter states, that in such cases the balsam capivi has been found serviceable; but that he did not observe any good result from the use of astringent injections.

Opium alone, or joined with camphor, is the best medicine for the prevention of painful erections. Cicuta is also said to prove useful for the same purpose.

With regard to the treatment of chordee, Mr. Hunter remarks, that in the beginning of this complaint bleeding from the arm is often of service, but that it is more immediately useful to take away blood from the part itself by leeches. Great benefit often follows the accidental bursting of a vessel, and a profuse hemorrhage. Relief is often ob-

tained from exposing the penis to the steam of warm water. Poullices and fomentations, especially such as contain camphor, are frequently productive of benefit by removing the inflammation. Opium given internally is of singular service, and is still more beneficial when joined with camphor. It lessens the pain and prevents erections, which are the immediate cause of the complaint.

When the chordee continues after all the other symptoms are gone, the only remaining object is to promote the absorption of the extravasated coagulable lymph, by friction with mercurial ointment on the parts. Mr. Hunter informs us, that in one case considerable benefit seemed to result from giving cicuta, after the common methods had failed. Electricity, he says, may also be of service. A chordee is often longer in disappearing than either the running or pain; but, like most of the consequences of inflammation, its declension is gradual and uniform.

Mr. Hunter has seen the kind of chordee, which seems to depend on spasm, relieved by bark.

When the glands of the urethra suppurate, Mr. Hunter advises the use of mercury, just as if the case were a chancre; but this practice is not deemed necessary by the most judicious surgeons of the present day. It is proper to make an early opening into the abscess, when Cowper's glands suppurate, in order to prevent the matter from making its way into the urethra or scrotum.

When the bladder is affected with irritation, in consequence of gonorrhœa, opiate clysters, the warm bath, and copious bleeding, are the chief means of relief. Leeches applied to the perinæum have also good effects. Bleeding, however, in certain constitutions, is hurtful, and should always be resorted to with caution. When the complaint lasts very long, resisting ordinary methods, Mr. Hunter suggests the trial of an opiate plaster on the pubes, or small of the back; or a small blister on the perinæum.

The mode of treating a swelling of the testicle, we shall consider under the head, *HERNIA Humoralis*.

The decline of a gonorrhœa is generally known by the pain becoming less, or changing into an itching, similar to what is often felt in the beginning of the complaint, and which at length goes away altogether. The sense of weariness about the loins, hips, testicles, and scrotum is no longer felt; and the cherry-like appearance of the glans penis gradually subsides. The running diminishes, or at all events becomes whiter, then paler, and by degrees assumes a more slimy consistence, in proportion as it becomes more like the natural secretion, which is designed to lubricate the urethra.

Recurrences of the disease every now and then are met with, after the pain, discharge, &c. have quite ceased. Such relapses, however, are more common in women than men, and the complaint is usually in a milder form than before.

GONS, a town of Hungary; 22 miles S.S.W. of Zatzmar.

GONSALVO, **HERNANDEZ DE CORDOVA**, in *Bio-geography*, an eminent Spanish commander, was born in 1443, and brought up from a very early age to the profession of arms. He signalized himself in a war against Portugal, and under the reign of the celebrated Ferdinand and Isabella he served in the conquest of Grenada. He was afterwards employed to succour Ferdinand king of Naples against Charles VIII. of France, and by his assistance the whole of that kingdom was recovered from the French. Kings, however, are not always consistent in their projects, and the

monarch of Spain who had defended and saved one king of Naples, formed a project of supplanting his successor, and making a partition of the country with Lewis XII. of France, and Gonfalso was employed to execute the attempt. The warrior was completely successful, and made Alphonso, son of the king of Naples, his captive. Elated with his success, and willing to shew his moderation, Gonfalso swore upon the holy sacrament, a wretched abuse of a religious rite, that the young prince should enjoy his liberty; but after the surrender was complete, and the time was come when he could execute his promise, he pretended that he had received new orders from his own sovereign, which obliged him to send Alphonso a prisoner into Spain. The partitioning powers soon disagreed among themselves, and the French, being in a greater state of preparation, attacked, defeated, and expelled the Spaniards from most of the places which they possessed. Gonfalso was now compelled to retire with his army, destitute of money, provisions, and ammunition. He retired, however, only to recruit himself, which he had an opportunity of doing among the Venetians, when he rallied, drove the French before him, and entered Naples in triumph. Ferdinand, in the mean time, doubtful of the event, had negotiated a treaty with Lewis, confirming their former partition; but upon the intelligence of the great success of Gonfalso, such was "Spanish honour," that he refused to sign it, and the French were, by the efforts of Gonfalso, obliged entirely to evacuate the kingdom of Naples. For these and other eminent services, he not only obtained the title of the "Great Captain," but was rewarded by his sovereign with many valuable as well as honourable posts of honour. He was made constable of the kingdom of Naples, raised to the dukedoms of Terranova, St. Angelo, and other estates. He at length fell under the suspicion of his sovereign, who sent letters to recal him, which the general repeatedly eluded upon different pretexts. The king determined to go to Naples, and was met at Genoa by Gonfalso. They entered Naples together in apparent harmony, and the king conferred an additional dukedom on his "Great Captain," but Ferdinand thought it prudent, in the following year, when he left Naples, to take his general with him. At Savona they had an interview with Lewis XII. who shewed his esteem for Gonfalso, by decorating him with a gold chain taken from his own neck, and causing him to sup at the same table with himself. At Venice also he received some magnificent presents. On his arrival in Spain, he was commanded to retire to his own estate at Grenada, where he died in 1515, at the age of seventy-two. Gonfalso is distinguished as a firm disciplinarian, a great master of the art of war, but as one who was never distinguished for generosity of sentiment. *Univer. Hist. Moreni*.

GONSALVO, *St.*, in *Geography*, a town of Brazil, in the government of St. Salvador; 40 miles W. of Sergipe.

GONUS, in *Botany*, from *γόνος*, offspring, because of its plentiful produce. *Lour. Cochin.* 658.—Class and order, *Polygamia Dioecia*, Loureiro; rather *Tetrandria Tetragynia*. *Nat. Ord. Terebinthacea*, Juss. ?

By Loureiro's description of his only species, *G. amarifinus*, a shrub with pinnated serrated hairy leaves, and by his reference to Rumph. Amboin. Append. t. 15, it should seem to be allied to *Fagara*, though the description of the pistil and fruit does not exactly answer. It agrees perhaps best with *Brucea*, Juss. 373, both in botanical characters and medical properties; see that article. Loureiro says his plant is found in the woods of China and Cochinchina, and that

the virtues of the root and fruit are diaphoretic, alexiteric, antifebrile, and anthelmintic. He adds, that "it seems to be the same drug which the Portuguese call *radix de Solor*, because it grows in the island of Solor, as well as in Timor, and which is in great use in India." Is the *Brucea*, after all, an Indian plant?

GONWA, in *Geography*, a town of Hindoostan, in Guzerat; 20 miles N.W. of Amood.

GONYALGIA, of *γόνυ*, *knee*, *αλγός*, *pain*, a term used by some authors to express a violent pain in the knee.

GONZAGA, LUCRETIA, in *Biography*, daughter of Pirro Gonzaga, lord of Gazzuolo, was distinguished as a literary lady in the sixteenth century. The celebrated Banello was one of her masters; by him she was introduced to the knowledge of the Greek tragedians. She married, at the age of fourteen, Gianpaola Manfroni of Ferrara, which proved an unfortunate union, since her husband, on account of a plot against the life of duke Hercules II. was capitally condemned in 1546. The duke did not cause the sentence to be executed, but was contented with keeping him in perpetual imprisonment, under which he died in 1552. His faithful spouse, Lucretia, employed all her powers to obtain his liberation: she is said to have addressed letters to almost all the powers in Europe, imploring their intercession, and one to the grand seignior, intigating him to make an attack upon the fortrefs where her husband was confined. It must be observed, that these letters have been imputed to Ortenfia Landi; it cannot, however, be doubted, that this lady had acquired a considerable literary reputation by being supposed capable of such productions. She was, indeed, panegyriced by most of the learned in Italy in her time, among the rest by Julius Cæsar Scaliger, and a volume of poems in her praise was published in Bologna in 1565. Several of her works were printed, one of which was a small volume of poems. She remained single after the death of her husband, and placed her two daughters in a convent. She died at Mantua in 1576. Moreri.

GONZAGA, SCIPIO, born in 1542, was son of Charles, count of St. Martino, of the branch of the Gonzagas, dukes of Sabbionetta. He was carefully instructed in letters, and sent to Padua to complete his studies, where he greatly distinguished himself in classical literature. He afterwards acquired considerable reputation for his knowledge in theology and philosophy. Muretus, in 1571, dedicated to him the first volume of his Orations, with a high panegyric: and Guarini submitted to his criticism his "Pastor Fido." He was created cardinal in 1587, and died at Samartino in the year 1593, leaving behind him commentaries of his own life, written in elegant Latin. Moreri.

GONZAGA, VESPASIAN, duke of Sabbionetta, born in 1531, is celebrated as a commander in the service of Charles V. and Philip II., but he is still more distinguished as a splendid promoter of the arts and sciences: He built from the ground the city of Sabbionetta, which, for the neatness and regularity of the streets, the architecture of the private houses, the beauty of the churches, and the elegance of the public buildings, has excited universal admiration. He also founded in it a public school for the learned languages, to which he invited as a professor Mario Nizzoli, one of the most learned men of the age. His palace was always full of men of knowledge and science, of whom he was the liberal patron. Gonzaga employed Scamozzi in the erection of a very fine theatre, for the performance of dramatic pieces, and he is himself recorded as an elegant Italian poet. He is mentioned with high respect and applause by Tasso, and other literary characters, and he is noticed as a collector of books.

GONZAGA, in *Geography*, a town of Italy, in the department of the Mincio; 16 miles S. of Mantua.

GONZAGO, ST., a town of Peru, in the audience of Quito; 60 miles N.W. of St. Josef de Huales.

GONZALES, BARTOLOME, in *Biography*, a painter, born at Valladolid in the year 1564. He frequented the school of Patricio Caxes at Madrid; in the sequel painted much for Philip III. at Burgos, Valladolid, Lerma, in the Pardo and Escorial, till 1617, when he was made painter to the court, in the place of Fabricio Castello. His portraits are admirable, especially the six whole lengths with the date 1621, possessed by the baron of Casa Davalillo. In history, his style was ornamental; his drapery, a varied imitation of stuffs, by its illusion captivated the vulgar, whilst it destroyed the dignity, simplicity, and generally the costume of the subject. He died in 1627, not, as Palomino states, in 1611. Fuseli's Pilkington.

GOOBER, in *Geography*, a country of Africa, S. of Wangara, between 10° and 12° N. lat. and 15° and 20° E. long. The mountains of Komri, so called by Abulfeda, commence in this territory.

GOOCHLAND, a county of Virginia, in America, surrounded by Louisa, Flavauna, Henrico, Hanover, and Powhatan counties; about 40 miles long and 14 broad, and containing 4893 free inhabitants, and 4803 slaves.

GOOD, or GOODNESS, denotes whatever tends or conduces to preserve or improve human nature or society; in opposition to *evil*, which tends to destroy, injure, or impair the same.

Hence good is divided by the philosophers into 1. *Bonum sui*, private good; which is that whereby a thing tends to preserve, &c. itself, under which comes that popular division of goods of body, mind, and fortune.

2. *Bonum communis*, whatever promotes the interest and welfare of society; as all the civil offices, &c.

GOOD, in *Metaphysics*, or *Metaphysical Good*, called also *absolute* or *real* good, and *good per se*, is the essential perfection or integrity of a thing whereby it has every thing that belongs to its nature.

In this sense, all things are good, inasmuch as they have the perfections naturally belonging to things of their kind. Thus, a thinking substance is good, or perfect, as it has all the essential attributes of thought; so an extended substance is good, as it possesses all the parts necessary to constitute it such.

In effect, as it is absurd to imagine a being without its essence, so is it to imagine a being without the requisites of its essence: so that it appears an error in some philosophers, who divided beings into good or perfect, and evil or imperfect. See ESSENCE.

Others define metaphysical, or transcendental goodness, by congruency with the divine will, which, they say, constitutes the measure of all real goodness.

GOOD, *Physical* or *Natural*, is that whereby a thing possesses all things necessary to its *bonè esse*, i. e. its well being, or second perfection, and to the performance of its functions and uses.

In this sense, physical goodness coincides with physical perfection.

To this are required the several powers and faculties, in their proper degree; a due situation, figure, and proportion of parts, &c.

Note, beside absolute physical goodness, there may be a *relative* one; as in foods, which to one, are salutary, to another poison, &c. To this head also belong the things good *pro tempore*, or according to circumstances; as the amputation of a mortified limb, &c.

Natural good may be otherwise defined to be that which makes or denominates a being happy, or prepares him for happiness; or, at least, prevents or removes his misery: accordingly, good is either objective or formal; *objective* good is that which makes us happy; *formal* good, or the pleasure resulting from the application of the faculty to the object, is that which denominates us happy.

Good, *Moral or Ethical*, is the agreement of a thinking, reasonable being, and of the habits, acts, and inclinations of such a being with the dictates of right reason, and the will of the Creator, as discovered by natural light. See VIRTUE.

In order to this, it is not enough that a thing done, said, thought, desired, be just and good; but it must be done, thought, &c. well, *i. e.* from good principles, and to good ends.

Others define moral good more largely. *Moral*, which they also call *relative* good, according to them, is something that is good to another, or that tends some way to the perfection thereof. In this sense they divide it into three kinds, *honestum, jucundum, and utile.*

The first, *bonum honestum*, is what agrees with right reason, and is desirable for itself; as all things virtuous; *e. gr.* to love God, respect our parents, &c. It is considered without any regard to pleasure; not but there is sincere pleasure annexed to it. Zeno and the Stoics allow of no other goods; those of the body, &c. they call *commoda, conveniences*, not goods.

Bonum jucundum is that which is good, as it tends to give us pleasure, and is desired on that account; but without any repugnancy to virtue or right reason; as music to the ears, painting to the eyes, &c.

Bonum utile, or commodum, is that which is good on account of something else for which it is desired; as money, riches, &c.

Good, *chief, sovereign, or supreme, summum bonum*, is that, the enjoyment of which renders men truly and completely happy. The schools distinguish this chief good of man into that which is simply and adequately so, and beyond which there can be no other; and an inferior, subordinate kind, which is, in some measure, attainable in this imperfect state. This last they call *felicitas viatorum*, and the former *felicitas comprehensivum*. The chief or sovereign good, according to the idea collected of it from the original, natural, and universal preconceptions of all mankind, is something agreeable to our nature, conducive to well-being, accommodate to all places and times, durable, self-derived, and indeprivable; and this consists, says Mr. Harris, in rectitude of conduct, or in living perpetually selecting, as far as possible, what is congruous to nature, and rejecting what is contrary, making our end that selecting and rejecting only. Three Treatises, &c. 1765, p. 121, &c. 205, &c.

Philosophers are divided as to what the chief good of man consists in; whether in the goods of fortune, of body, or of mind. Some hold riches and honours the supreme good; others, as Aristippus and the Cyrenaic school, bodily pleasures; and others, as Zeno and the Stoics, virtue, or living according to nature. The Peripatetics agreed with the Stoics in maintaining that virtue is the *summum bonum*: but the Stoics asserted farther, that virtue was the only good: whilst the Peripatetics denied, with reason, that virtue was self-sufficient, and therefore required several other things as auxiliaries, such as health, prosperity, friends, &c. which are to the virtuous man in the nature of instruments or ornaments to his felicity. An excellent writer lays down the following *criteria* or characteristics of the *summum bonum*, or chief good, which reason can demonstrate to be actually designed for man: it is something which all men, if not want-

ing to themselves, may be possessed of; it is one and the same to all mankind; and while in itself fitted to make the possessor happy, is not prevented in its operation by some other thing which keeps him from relishing it: and as to the highest good which it is possible for man to enjoy, it must be referred to no other, but all others must be embraced for the sake of this; and it must be sufficient to furnish a happiness adequate to the capacities of human nature, and of equal duration; *i. e.* it must be not only perfect whilst it lasts, but everlasting. According to these characters we may infer, that neither the goods of fortune, nor those of the body, nor even virtue itself, constitute the chief good. Virtue, rightly understood, is the perfection of human nature; it is the instrument of obtaining happiness: but this alone will not make a man happy; it is farther necessary that he be perfect as to life, or happy in the circumstances of his being: and, therefore, natural reason demonstrates, that the favour of God, secured by virtue, is properly man's supreme good. Grove's System of Moral Philosophy, vol. i. part. i. passim. See EPICUREANS, PERIPATETICS, and STOICS.

GOOD-will. See BENEVOLENCE.

GOOD Works. See MERIT and SUPEREROGATION.

GOOD Abearing, *bonus gestus*, in a *Law Sense*, is particularly used for an exact carriage or behaviour of a subject towards the king and his liege people; to which some men, upon their misbehaviour, are bound.

The justices are empowered by 34 Edw. III. cap. 1. to bind in this manner all them that be not of good fame; under which general expression, it is holden that a man may be bound to his good behaviour for causes of scandal, *contra bonos mores*, as well as *contra pacem*; as, for haunting bawdy-houses; for keeping bad women in his own house; or for words tending to scandalize the government; or in abuse of the officers of justice, especially in the execution of their office: a justice may also bind over all night-walkers, eaves-droppers, such as keep suspicious company, or are reported to be pilferers or robbers, common drunkards, whore-masters, the putative fathers of bastards, cheats, idle vagabonds, and any other persons, whose misbehaviour may reasonably bring them within the general words of the statute. Persons of this description may be bound, with one or more sureties, in a recognizance or obligation to the king, entered on record, and taken in some court, or by some judicial officer, whereby the parties acknowledge themselves to be indebted to the crown in the sum required, *e. gr.* 100*l.* with condition to be void and of none effect, provided that they behave themselves well, either generally or specially, for the time therein limited; as for one or more years, or for life. This recognizance, if taken by a justice of the peace, must be certified to the next sessions, by 3 Hen. VII. cap. 1. and if the condition of it be broken, the recognizance becomes forfeited or absolute; and being estreated or extracted, (*i. e.* taken out from among the other records) and sent up to the exchequer, the party and his sureties are become the king's debtors, and are sued for the several sums in which they are bound. All persons under the king's protection may obtain such security, upon due cause shewn; and the justice may be compelled to grant it by a mandatory writ, called *supplicavit*: but this writ is seldom used, for, when application is made to the superior courts, they usually take the recognizances there, under the direction of the statute 21 Jac. I. cap. 8. A recognizance may be discharged, either by the demise of the king, or by the death of the principal party bound thereby, or by order of the court to which it is certified by the justices. He that is bound to this, Lambard says, is more strictly bound than to the peace;

peace; because, whereas the peace is not broken without an affray, battery, or such like, this surety *de bono gestu* may be forfeited by the number of a man's company, or by his or their weapons or arms, by speaking words tending to sedition, or by committing any of those acts of misbehaviour which the recognizance was intended to prevent.

GOOD Aller. See ALLER.

GOOD Behaviour. See GOOD *abearing* and PEACE.

GOOD Consideration. See CONSIDERATION.

GOOD Fortune, or PARA, in *Geography*, an island in the East Indian sea, near the W. coast of Sumatra, about 36 miles long and six broad. S. lat. 1° 5'. E. long. 98° 30'.

GOOD Taste. See TASTE.

GOODALORE, in *Geography*, a town of Hindoostan, in the circar of Dindigul; 10 miles S. of Ootampaliam.

GOODENIA, in *Botany*, so named by the writer of the present article in honour of the Right Rev. Samuel Goodenough, lord bishop of Carlisle, F.R.S. and a vice-president of the Linnæan Society, author of a most valuable paper on British *Carices*, in the second volume of the Linn. Society's Transactions, and of one on British *Fuci*, in conjunction with Mr. Woodward, in the third. The name was constructed after the example of Tournefort, who, as he tells us, not without much consideration, contrived to form *Gundelia* out of *Gundelsheimer*. It did not occur to us at the time that *Goodenovia* might have come nearer to the original, and have been equally unexceptionable. It is now too late to make any such alteration. Linnæus named *Richardia* after Dr. *Richardson*, *Stillingia* after Mr. *Stillingfleet*, and these are sufficient precedents. Sm. Tr. of Linn. Soc. v. 2. 346. Brown. Prodr. Nov. Holl. v. 1. 574. Willd. Sp. Pl. v. 1. 954. Mart. Mill. Dict. v. 2. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juss. *Goodenovicæ*, Brown.

Gen. Ch. Cal. Perianth superior, of five, nearly equal, linear leaves, permanent. **Cor.** of one petal, much longer than the calyx, irregular; tube slit from top to bottom at the back; limb of five deep, firm, lanceolate segments, with thin dilated longitudinal borders, turned most to one side, forming one lip, or generally two. **Stam.** Filaments five, shorter than the tube, often projecting through its fissure, capillary, equal; anthers vertical, oblong, of two lobes. **Pist.** Germen inferior, oblong, crowned with the calyx-leaves, which run down its sides and form ribs; style taper at the base, swelling upwards, undivided, nearly as long as the tube; stigma large, firm, obtuse, enveloped with a cup-shaped cover, more or less two-lipped, its margin fringed with dense upright hairs. **Peric.** Capsule oblong or elliptical, of two valves separating at the top, and two (rarely four) cells, the partition flat, parallel to the valves. **Seeds** numerous, imbricated, compressed.

Ess. Ch. Corolla of one petal, slit longitudinally at the back; limb in five deep segments turned one way. Anthers separate, beardless. Stigma with a cup-shaped fringed integument. Capsule inferior, of two or four cells, with a parallel partition. Seeds numerous, imbricated.

Obs. Mr. Brown has remarked, in some species, a small bag of honey attached to the germen, opposite to the fissure in the corolla.

Eight species of this very curious genus were originally defined in the Linnæan Society's Transactions, three of which, having been described without a knowledge of their fruit, are now, on more full examination, removed by Cavanilles and Brown to other genera. These are the *albida*, *striata*, and *ramosissima*; the latter, which, like the *albida*, is a *Scævola*, may be seen in Sm. Bot. of N. Holl. t. 5. The *striata* belongs to Mr. Brown's *Dampiera*. But on the other

hand the discoveries of this indefatigable collector and accurate botanist have increased *Goodenia* to 32 species, all natives of New Holland or of Van Diemen's land. Of these the first 28 have a two-lipped corolla, and the first 24 of them have yellow flowers, the rest blue or purple. Of the remaining four, two have a single-lipped corolla, and the others are doubtful in this respect, it being doubtful whether these last properly belong to the genus. One of them is *Selliera radicans*; Cavan. Ic. t. 474. f. 2. *Goodenia repens*; Billard. Nov. Holl. t. 76.

Satisfactory examples of the genus are,

G. paniculata. Sm. n. 2. Cavan. Ic. t. 507. This has yellow flowers in terminal panicles. Leaves mostly radical, strongly toothed. *Herbage* hairy.

G. ovata. Sm. n. 1. Cav. Ic. t. 506. Andr. Repos. t. 68. The first species that flowered in England, and from which the genus was described. This has rather shrubby stems, ovate neatly serrated smooth leaves, and axillary forked stalks, bearing elegant yellow flowers. It is a desirable ornament for a greenhouse, and not difficult of culture.

G. grandiflora. Sims in Curt. Mag. t. 890. Differs from the last in being downy, with lyrate leaves and larger flowers, whose tube is split into four segments, and singularly rough or bearded within.

G. elongata. Billard. Nov. Holl. t. 75. Is a very slender species, with long simple flower-stalks destitute of bractææ.

GOODENOVIÆ, a natural order of plants recently established by Mr. Brown, Prodr. Nov. Holl. v. 1. 573, being separated by him from the *Campanulaceæ* of Jussieu, and essentially distinguished by a peculiar cup-shaped integument, either undivided or two-lobed, which contains the stigma, and has hitherto been described by botanists as the stigma itself. See **CAMPANULACEÆ**.

Mr. Brown describes his new order as follows:

Calyx superior or half superior, rarely inferior, five-cleft, sometimes in five or three deep divisions, sometimes short, undivided, and occasionally obsolete; its segments equal, rarely unequal, permanent.

Corolla of one petal, more or less irregular, deciduous or withering. Tube split longitudinally, sometimes separable into five portions, while the calyx is merely attached to the base of the germen. Limb in five deep segments, composing one lip or two, their disk lanceolate, flat, their sides, or wings, of a thinner texture, elevated, folded inwards when young, rarely obsolete or deficient.

Stamens five, unconnected with either corolla or style, and alternate with the divisions of the former. Filaments distinct. Anthers either separate or cohering, linear, vertical, attached by their base, undivided, two-celled, the cells opening lengthwise. Pollen simple, rarely compound.

Germen of two or four cells, rarely of one only; the rudiments of the seeds either indefinite or definite, erect; sometimes bearing a gland between the two anterior filaments. Style one, simple, very rarely divided. Stigma fleshy, obtuse, either undivided or two-lobed, encompassed from beneath with a somewhat membranous, cup-shaped, entire or two-lobed integument, the great peculiarity of the order.

Pericarp, when the number of the seeds is indefinite, a capsule of two cells, rarely four, or sometimes, from the shortness of the partition, of scarcely more than one. Partition mostly parallel, rarely contrary, to the valves, which are either undivided or cloven, bearing the seeds on its midrib. When the number of the seeds is definite, one being in each cell, the pericarp is a drupa or a nut, rarely an *utriculus* (or membranous undividing capsule), bearing the seed from its base.

Seeds often with a thickish coat, sometimes with a hard shell.

shell. Albumen fleshy, shaped like the seed, seldom wanting.

Embryo straight, about as long as the albumen. Cotyledons of a middling size, often leafy. Plumula inconspicuous.

These plants are either herbaceous or shrubby, not milky, chiefly found in the southern hemisphere, rarely within the northern tropic. Their pubescence when present is generally simple, sometimes glandular, rarely stellated. Leaves scattered, without stipulas, simple, mostly undivided, sometimes lobed, often toothed. Inflorescence terminal or axillary, various. Flowers distinct, very rarely aggregate, yellow, blue or purplish, seldom reddish.

The first section, with indefinite seeds, contains six genera; *Goodenia*, *Calogyne*, *Eutabales*, *Velleia* of Smith, *Lechenaulitia* and *Anthotium*: the second, with definite seeds, three genera; *Scævola* of Linnæus, much augmented, *Diaspasis* and *Dampiera*: the third section, with a single-seeded *utriculus*, is contrived to admit the *Brunonia*, named after the worthy and intelligent author, by Dr. Smith in the 10th volume of the Linnæan Society's Transactions not yet published. The place of this genus in a natural series is extremely difficult to determine. It agrees with the *Goodenovia* chiefly in having an integument to the stigma, but in habit, aggregate flowers, four distinct bracteas, and some other marks, agrees with the *Dipsacæ* of Jussieu, to which it is referred, not without doubt, in the Linnæan Transactions. It consists of two species, *Brunonia sericea*, and *australis*, herbaceous plants, with the aspect of simple-leaved *Scabiosa*.

GOODEROE, in *Geography*, a town of Abyssinia; 94 miles S. S. E. of Miné.

GOOD HOPE, or HOPE ISLAND, an island in the S. Pacific ocean, discovered by Le Maire and Schooten in 1616. The land is mountainous, not very high, and abounds with cocoa-nut trees; the coast affords no anchorage. S. lat. 16. E. long. 174° 15'.—Also, the name of a Danish colony in West Greenland. N. lat. 64°.

GOOD HOPE, *Cape of*. See CAPE.

GOODIA, in *Botany*, in memory of Mr. Peter Good, an industrious gardener, employed in collecting seeds in New South Wales for the Kew garden. He died, some years since, in that remote country, and Mr. Brown has always been so sensible of his merits, that he has long destined a genus to his honour.—*Salis. Parad. Lond. t. 41. Sims. in Curt. Mag. t. 958.*—Class and order, *Diadelphica Decandria*. Nat. Ord. *Epilobaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, somewhat bell-shaped; its upper lip with two, lower with three, longer and sharper, teeth. *Cor.* papilionaceous. Standard broad, inversely heart-shaped, erect. Wings horizontal, obovate, rather shorter. Keel nearly equal to the wings, abrupt, of two petals united in their lower part. *Stam.* Filaments ten, diadelphous, nine in one set, one distinct; anthers roundish. *Pist.* Germen stalked, ovate, compressed; style awl-shaped, ascending; stigma simple, obtuse. *Peric.* Legume stalked, ovate, compressed, of one cell, gibbous and flat at the back. *Seeds* two, roundish, compressed.

Ess. Ch. Calyx two-lipped; the upper cloven, broadest and shortest. Legume stalked, compressed, flat at the upper edge, of one cell. Seeds two.

Obf. This genus, as Dr. Sims observes, ought to be placed next to *Bossia*, Tr. of Linn. Soc. v. 9. 302, from which it differs essentially in its legume, which has no dilated thickened edges, nor is it internally spongy nor many-celled. The stamens are truly diadelphous, in which it

differs from *Crotalaria*, as also in not having an inflated legume, though its habit comes nearest to that genus.

Two species are known.

1. *G. lotifolia*. Curt. Mag. t. 958.—Leaflets smooth, as well as the branches and flower-stalks.—Native of Van Diemen's land. One of the first New Holland plants raised in this country, and very hardy in the green-house, possibly able to bear our climate. Mr. Aiton favoured us with specimens from Kew in 1796. It is a delicate smooth shrub, with ternate somewhat glaucous leaves, and terminal clusters of numerous yellow flowers, the base of whose standard, and part of the wings, are stained with crimson, as in many New Holland flowers of this family. The legume is somewhat ovate, with a taper base, smooth, but marked with numerous, transverse, parallel, reticulated veins. One seed only is usually perfected.

2. *G. pubescens*. Curt. Mag. t. 1310.—Leaflets downy, as well as the branches and flower-stalks.—Very like the former, and brought from the same country. It flowered at Mr. Loddige's at Hackney. We think with Dr. Sims it has sufficiently the aspect of a distinct species, though its downiness, often a variable circumstance, affords the only specific character. The leaflets in the plate do not answer to his definition of obcordate, and we believe they vary in shape, as in many leguminous plants.

GOODIANELLI, in *Geography*, a town of Hindoostan, in Mysore; 19 miles N. of Seringapatam.

GOODIMANELLE, a town of Hindoostan, in Mysore; 20 miles W. of Bangalore.

GOODINGARY, a town of Hindoostan, in Tinevelly, near the coast; 50 miles S. of Palamcotta.

GOODLUCK BAY, a small bay in the strait of Magellan, entirely surrounded by rocks. This bay supplies a little wood, and plenty of good water, but it is very difficult of access. S. lat. 53° 23'. W. long. 74° 33'. Variation two points easterly.

GOODNESS, in *Theology*, expresses one of the attributes of the Deity, sometimes denominated *Benevolence*. (See ATTRIBUTES and BENEVOLENCE.) Dr. Paley, in his "Natural Theology," illustrates and proves the divine goodness by two propositions, which may be evinced by observations drawn from the appearances of nature. The first of these propositions is, that in a vast plurality of instances in which contrivance is perceived, the design of the contrivance is beneficial. No productions of nature display contrivance so manifestly as the parts of animals, and all these parts have a real, and, with very few exceptions, a known and intelligible, subserviency to the use of the animal. Nor is the benevolent design of the creator abortive. The world, made with this design, is a happy world. The air, the earth, the water, teem with delighted existence. This argument is stated by the author in his "Moral Philosophy" in the following manner; "Contrivance proves design; and the predominant tendency of the contrivance indicates the disposition of the designer. The world abounds with contrivances, and all the contrivances which we are acquainted with are directed to beneficial purposes. Evil no doubt exists; but is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable from it; or even, if you will, let it be called a defect in the contrivance; but it is not the object of it. This is a distinction which well deserves to be attended to. In describing implements of husbandry, you would hardly say of the sickle, that it is made to cut the reaper's hand, though, from the construction of the instrument, and the manner of using it, this mischief often follows. But if you had occasion to describe

describe the instruments of torture or execution, this engine, you would say, is to extend the sinews; this to dislocate the joints; this to break the bones; this to sear the soles of the feet. Here pain and misery are the very objects of the contrivance. Now, nothing of this sort is to be found in the works of nature. We never discover a train of contrivance to bring about an evil purpose. No anatomist ever discovered a system of organization, calculated to produce pain and disease; or in explaining the parts of the human body, ever said, this is to irritate; this to inflame; this duct is to convey the gravel to the kidneys; this gland to secrete the humour which forms the gout; if by chance he come at a part of which he knows not the use, the most he can say is, that it is useless; no one ever suspects that it is put there to incommode, to annoy, or to torment."

Our author's *second* proposition is, "that the Deity has added *pleasure* to animal sensations, beyond what was necessary for any other purpose, or when the purpose, so far as it was necessary, might have been effected by the operation of pain." There is a class of properties, pertaining to animals, which may be said to be superadded from an intention expressly directed to happiness; an intention to give a happy existence distinct from the general intention of providing the means of existence, with which other capacities are connected; and that is, of capacities for pleasure, in cases, wherein, so far as the conservation of the individual, or of the species, is concerned, they were not wanted, or wherein the purpose might have been secured by the operation of pain. The provision which is made of a variety of objects, not necessary to life, and administering only to our pleasures; and the properties given to the necessities of life themselves, by which they contribute to pleasure as well as to preservation; shew a farther design than that of giving existence. This observation is illustrated by our ingenious author in a variety of familiar instances, deduced from the senses of taste, hearing, smell, and sight. The senses appear to be specific gifts, ministering not only to preservation, but to pleasure. But the senses, as they are usually called, are far from being the only vehicle of enjoyment, or the whole of our constitution, which is calculated for the purpose. We have many internal sensations of the most agreeable kind, hardly referable to any of the five senses. Besides these there are exercises of the understanding in volition, &c. of the imagination, and of other faculties of the mind, which furnish unmixed gratifications, without any counterbalancing pains. Whilst the above-stated propositions can be maintained, we are authorized to ascribe to the Deity the character of benevolence; and what is benevolence at all, must in him be *infinite* benevolence, by reason of the infinite, that is to say, the incalculably great, number of objects, upon which it is exercised. But besides the evidences of divine goodness that are furnished by a survey of the creation of the world, and especially of mankind; the same attribute is evinced in the providential government of the universe, and in the extraordinary means which the Deity has selected and pursued for meliorating the present condition of the human race, for recovering mankind from the degeneracy and misery that have prevailed in consequence of their own folly and vice, and for conducting them to the perfection of knowledge and virtue, and a happy immortality in a future world.

The character and undertaking of Jesus Christ, and all the benefits that result to mankind from his mission and mediation, reflect peculiar lustre on the benevolence of the Deity.

GOODOOR, in *Geography*, a town of Hindoostan, in Golconda; 35 miles S.E. of Warangole.—AKO, a town of

Hindoostan, in the circar of Adoni; 15 miles N.N.E. of Condanore.

GOODS, in *Mining*, signify, in Derbyshire, the large and sizable lumps of lead ore, otherwise called *bing* or *potter's ore*.

Goons, among public brewers, denote the malt or grains and liquor in their *wash-tun*.

Goons, *bona*, in *Law*, and particularly the *Civil Law*, include all kinds of effects, riches, lands, possessions, &c. There are two kinds of goods; *moveable*, *res moventes*, or *mebiles*; and *immoveable*, called *res non moventes*, or *immobiles*.

It is a maxim in the civil jurisprudence, that he who confiscates the body, confiscates the goods; meaning, that all the effects of a person condemned to a capital punishment, or perpetual banishment, are forfeited to the king.

A man is said to bind himself body and goods; meaning, that besides his goods, he obliges his person, and submits to remain in prison, provided he do not execute his promise.

Goods, again, are divided into, 1. *Proper*, *paternal*, *patrimonial*, *hereditary*; 2. *Acquired* or *acquests*, *alio quam hereditatis jure acquisita*, and, 3. *Conquests*, *viro & uxori stante societate acquisita*.

Goods, again, are divided into *real* and *personal*. (See CHATELS and ESTATE) And, lastly, into *noble* or *free*, and *servile* or *base*.

Goods belonging to the domain of the crown, *ad fiscum spectantia*, cannot be alienated for ever, unless it be done by way of exchange; they may be sold under the faculty of perpetual redemption.

Goods, *Adventitious*, *adventitia*, are those which arise otherwise than by succession from father or mother, or from direct ancestor to descendant. See ADVENTITIOUS.

Goods, *Dotal*, *dotalia*, those accruing from a dowry, and which the husband is not allowed to alienate. See DOWRY.

Goods, *Fugitivæ*. See FUGITIVE.

Goods, *Paraphernal*. See PARAPHERNALIA.

Goods, *Prohibited*. See PROHIBITED.

Goods, *Profecitious*, *profecititia*, are those arising by direct succession.

Goods, *Receptitious*, were those which the wife might reserve the full property of to herself, and enjoy them independently of her husband; so called, in distinction from *dotal* and *paraphernal goods*.

Goods, *Vacant*, *vacantia*, are those abandoned, or left at large, either because the heir renounces them, or that the defunct has no heir. See BONA.

Goods, *Allotting of*. See ALLOTING.

Goods, *Consignment of*. See CONSIGNMENT.

Goods, *Running of*. See RUNNING.

GOODWIN, JOHN, in *Biography*, a learned divine in the seventeenth century, who is said to have made more noise in the world than any other person of his age, rank, and profession. He was born in 1593, and received his academical education at Queen's college, Cambridge; and, immediately after he was admitted to orders, he was much admired for the erudition and elegance which distinguished his pulpit compositions. In 1633 he was inducted to the living of St. Stephen, Coleman street, London, from which he was ejected in 1645, because he refused to baptise the children of his parishioners promiscuously, and to administer the sacrament to his whole parish. He embraced the Arminian doctrines, and eagerly pleaded their cause in his sermons and writings; he adopted and maintained the independent form of church government;

government, and he was reckoned to be exceedingly skilful and courageous in attacking or repelling those who opposed him. His tenets were not those generally embraced, and at one period he is characterized as a man by himself; as being against every man, and having almost every man against him. He had a clear head, a fluent tongue, a penetrating spirit, and a marvellous faculty in descanting on scripture. In politics he was a decided and strenuous republican, and, being eager in whatever he engaged, distinguished himself by his discourses and writings to promote, and afterwards to justify, the condemnation of the king. He lived, however, long enough to feel the weight of government directed against himself and his writings. He was obliged to abscond for a season, and one of his pieces was burnt by the common hangman, and in the same fire which executed its commission on the "Defensio pro populo Anglicano," by John Milton of immortal memory. The friends which his Arminian principles had procured him, found means to pacify the people in power, and to assure themselves that Goodwin should not be prosecuted for the part which he had taken in the late reign. He returned from solitude, and became minister of a private congregation in the neighbourhood of Coleman street, and, disapproving of the act of uniformity afterwards passed, continued a dissenter from the established church of the Independent denomination, till his death in 1665, in the seventy-second year of his age. His works, which are chiefly theological, are very numerous, among which the following may be mentioned; "Redemption Redeemed," in folio. "The divine Authority of the Scriptures," 4to. "An Exposition of the ninth Chapter of the Epistle of St. Paul to the Romans," 4to. Neal's Hist. of the Puritans, &c.

GOODWIN, THOMAS, who is styled by Anthony Wood "One of the Atlases and patriarchs of independency," was born in the year 1600 at Rolesby in Norfolk. Having received the elements of a grammatical learning, he was sent, when he was thirteen years old, to Christ-church college, Cambridge, where he applied himself with so much diligence to his studies, as to secure the esteem of his tutors, and to attract much notice in the university. In 1619 he was removed to Catherine Hall, of which he became a fellow. He soon shewed a decided inclination to the views and sentiments of those who were denominated Puritans, and taking them as his models, he prepared himself for the office of a Christian minister. It is not known when he took orders, but he was elected lecturer of Trinity church, in Cambridge, in the year 1628, and in 1632 he was presented by the king to the vicarage of the same church. In these employments he was greatly admired and followed by the Puritans, who began to look up to him as a leader, but becoming dissatisfied with the terms of conformity, he relinquished his preferments, and quitted the university in the year 1634. In 1639 he was selected as an object of persecution by the episcopal consistories, and to enjoy liberty of conscience he fled to Holland, where he was chosen pastor to an independent congregation at Arnheim. During the fittings of the Long Parliament he returned to London and became pastor of a church there, and also a member of the assembly of divines. His conduct, in their various meetings, and his zealous support of the Presbyterians, contributed to render him a favourite with Cromwell, through whose influence he was, in 1649, made one of the commissioners for the approbation of public preachers, and also appointed president of Magdalen college, Oxford. Here he formed a church upon the independent plan, and was exceedingly diligent in promoting the interests of learning and piety. His public

duties as a preacher did not prevent him from those studies which enabled him to become distinguished as a writer. He attended Cromwell upon his death-bed, and was overheard to express himself boldly and enthusiastically confident of the protector's recovery; and it is affirmed that when the event proved him mistaken, he exclaimed in a subsequent address to God "thou hast deceived us, and we are deceived." After the restoration he was dismissed from his presidency, when he retired to London, where, however, he was permitted to continue in the exercise of the ministry till his death in 1679, when he had attained to his eightieth year. He was a considerable scholar, and a learned and eminent divine. In the common register at Oxford he is described "in scriptis in re theologica quam plurimis Orbi notus." He was a high Calvinist, but while he zealously enforced what he conceived to be the doctrines of Christianity, he did not forget to enforce by every incitement in his power the necessity of pure moral conduct. He was author of numerous pious and controversial pieces, sermons, expositions, &c. some of which were printed during his life time, and inserted, after his death, in a collection of his works published in five volumes folio, which continue to be read and quoted by Calvinists of the present day. Neal's Hist. of Puritans, by Toulmir.

GOODWIN Sands, in *Geography*. See GODWIN Sands.

GOOGINGS, in *Sea Language*, are clamps of iron bolted on the stern-post of a ship, whereon to hang the rudder and keep it steady; for which purpose there is a hole in each of them, to receive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOGOOS, in *Geography*, inhabitants of the inland territory of the island of Sumatra, covered with long hair, and little superior to the ourang outangs of Borneo. See SUMATRA.

GOOJINDERGUR, a town of Hindoostan, in Sanore; 25 miles N. N. W. of Sanore.

GOOL, a river of Hindoostan, which rises near Burawny, and runs into the Tapty, 8 miles S. of Chuprah.

GOOL, signifies a ditch or trench for water; called also a goit, gurt, leat, &c.

GOOLE, a breach in a sea-bank or wall; or a passage worn by the flux and reflux of the sea. Vide 16 and 17 Car. II. cap. 11.

The word comes from the French, *goulet*, the gullet or neck.

GOOLGUNGE, in *Geography*, a town of Hindoostan, in the circar of Chanderee; 25 miles E. of Chanderee.

GOOLLAH, a small circar or province of Bengal, situated E. of Coos-Beyhar.

GOOMAH, a town of Bengal, 45 miles N. of Ramgur. N. lat. 24° 23'. E. long. 85° 54'.—Also, a town of Hindoostan, in Bahar; 40 miles N. E. of Chittra.

GOOMBO, a town of Africa, in Bambarra. N. lat. 15° 3'. W. long. 5° 10'.

GOOMBOGANO, a town of Africa, in Kaffan. N. lat. 14° 20'. W. long. 8° 50'.

GOOMGONG, a town of Hindoostan, in Berar; 12 miles S of Nagpour.

GOOMERPUN, a town of Hindoostan, in Oude; 16 miles S. W. of Azimgur.

GOOMPINA, a town of Hindoostan, in Golconda; 20 miles N. E. of Culloor.

GOOMREPOUR, a town of Hindoostan, in Allahabad; 20 miles E. N. E. of Jionpour.

GOOMTY, a river of Asia, which rises in the mountains,

tains of Kamaoon, and crossing the country of Oude, joins the Ganges, about 15 miles N. of Benares.

GOONANGAPY, a small island in the East Indian sea, near the N. E. coast of Cumbava. S. lat. 8° 10'. E. long. 119° 24'.

GOONDWANAH, the ancient name of the province of *Nazpour*, which see.—Also, mountains of Hindoostan, called "Konduanah," situated in the S. E. part of the country of Malwa, extending from Hurlingabad to Muddellah, about 170 miles long. N. lat. 22° 40', to 23°. E. long. 78° to 81°.

GOOPAMOW, a town of Hindoostan, in Oude; 20 miles W. of Kairabad.

GOOPINGUNE, a town of Hindoostan; 32 miles W. of Benares.—Also, a town of Hindoostan, in the foubah of Agra. N. lat. 26° 24'. E. long. 79° 18'.

GOORACKPOUR, a province of Oude, bounded on the N. by Thibet, on the E. by Bettiah and Sarun, on the S. by Gazypour, and on the W. by Oude proper and Bahraitch, about 60 miles long and 50 broad. The capital of the same name is situated 65 miles E. of Fyzahad. N. lat. 26° 44'. E. long. 83° 30'.

GOORAH, the name of two towns of Hindoostan; one in Oude and another in Allahabad.

GOORUNTY, a town of Hindoostan, in the circar of Cicacole; 17 miles S. W. of Ganjam.

GOOS, a town of Nubia. N. lat. 18°. E. long. 34° 18'.

GOOSANDER, in *Ornithology*. See *Mergus Merganser*.

GOOSE, ANSER, forms an order of birds in the Linnaean system. (See ANSERES.) The several species of geese belong to the genus of *anas* or duck under this order. See DUCK.

GOOSE, a well-known bird, which, in many situations, may be highly beneficial to the farmer, as, where there are large waters and commons, and where the stubbles are abundant. It is valuable both for its flesh, fat, and feathers.

The varieties of geese are numerous, but the large common kinds are probably the best for the uses of the farmer.

GOOSE, *Ember*. See *COLYMBUS Immer*.

GOOSE, *Soland* or *Solan*, sometimes called *gannet*, the English name of a large water-fowl, called by authors *Anser Bassanus*, and by Linnaeus *PELECANUS Bassanus*, which see.

GOOSE *Creek*, in *Geography*, a river of New Jersey, which runs into the Atlantic, N. lat. 39° 53'. W. long. 74° 16'.—Also, a river of Kentucky, which runs into the Ohio, N. lat. 38° 10'. W. long. 86° 3'.—Also, a river of North Carolina, which runs into the Atlantic, N. lat. 34° 40'. W. long. 77° 21'.—Also, a river which falls into the Potowmac, about a mile S. E. of Thorpe, in Fairfax county, Virginia.

GOOSE-dung, in *Agriculture* and *Medicine*. See DUNG and CHIENOCOPRUS.

GOOSE-foot, or *Wild Orach*, or *Good Henry*, in *Botany*. See CHIENOPODIUM.

GOOSE-grass, the common name of a troublesome weed that is frequently met with on clayey soils. It is best destroyed by cutting it in the summer, and keeping the land under the plough in good condition. See GALIUM *Aparine*.

GOOSE-grass, *Great*. See ASPERUGO.

GOOSE *Island*, in *Geography*, a small island in the gulf of St. Lawrence, near the coast of Labrador. N. lat. 50° 52'.

VOL. XVI.

W. long. 59° 10'.—Also, a small island in Christmas Sound, on the coast of Terra del Fuego.

GOOSE *Lake*, a lake of North America. N. lat. 52° 55'. W. long. 94° 45'.—Also, a lake of North America. N. lat. 54° 30'. W. long. 101° 21'.

GOOSE-neck, in *Sea Language*, is a sort of iron hook fitted on the inner end of a boom, and introduced into a clamp of iron or eye-bolt, which encircles the mast, or is fitted to some other place in the ship, so that it may be unhooked at pleasure.

GOOSE *River*, in *Geography*, a river of America, which runs into the Mississippi. N. lat. 43° 14'. W. long. 93° 56'.—Also, a river of South Carolina, which runs into Cooper's river. N. lat. 33° 2'. W. long. 79° 57'.

GOOSE-wings of a sail, in *Sea Language*, denote the chuses or lower corners of a ship's main-sail, or fore-sail, when the middle part is furled or tied up to the yard.

GOOSE-wing, at *Sea*, a certain manner of fitting a sail, which is thus performed: when a ship sails before a wind, or with a quarter-wind, and in a fresh gale, the seamen sometimes, to make the more haste, unparal the mizen-yard, and then they launch out both sail and yard over the quarter on the lee-side, fitting guys at the farther end, to keep the yard steady with the boom, and this booms out the mizen-sheet. This they do to give the ship the more way, which otherwise, with these winds, the mizen-sail could not do; and this sail, so fitted, is called a *goose-wing*, and sometimes a *studding-sail*.

GOOSEBERRY BUSH, *Grossularia*, in *Botany*, is a species of the *ribes* in the Linnaean system. See RIBES.

The gooseberry-bush is propagated either by suckers or cuttings, but the latter way is preferable, as the roots are less subject to shoot out suckers afterwards.

The best season for planting the cuttings is in autumn, just before the leaves begin to fall; observing always to take the handfomest shoots, and to pick them from such branches as produce the greatest quantity of fruit. The cuttings should be about six or eight inches long, and should be planted in a bed of light earth exposed to the morning sun; they must be planted about three inches deep, and watered to help their taking root. The shoots should be rubbed off from these plants as they put out, except those at the top, that there may be a regular stem. In the October following, they should be removed to a bed of fine light earth, and planted in rows at three feet distance, and one foot asunder in the rows. They should remain here one year, and the cross branches at times be cut off, as also the lower ones, so as to keep a clean stem about a foot above the ground. They will be then fit to plant out where they are to stand, which should be in a light sandy loam. They should be kept from the shade of other trees; and to have the fruit in its utmost perfection, should be set in an exposed place in rows of eight feet asunder, and each of the shrubs six feet from the others in the rows. The best time for transplanting them is in October, when the leaves begin to decay. Miller.

GOOSEBERRY, in *Agriculture*, is a plant that may sometimes be employed in the forming of hedge-fences, especially that sort known in the North by the title of Iron-monger.

GOOSEBERRY *Caterpillar*, in *Gardening*, the common name of a very destructive insect to the gooseberry and some other plants. Many different methods of destroying it have been proposed, but with little success.

GOOSEBERRY of *Barbadoes*. See CACTUS.

GOOSEBERRY *Tree*. See MELASTOMA.

GOOSEBERRY-galls, in *Natural History*, the name given by

authors to a species of protuberances of the gall kind, found very frequently on the oak. They are of a roundish figure, and sometimes adhere to the tree by a short pedicle, but more frequently by a part of their spheric surface. They are usually found on the under side of the leaves of the oak, but sometimes on the young shoots, and sometimes on the pedicles of the leaves.

They are most frequent in spring, but they are found at all times when the leaves are upon the trees. These galls are greenish at first, and afterwards become yellowish, and finally red; in which last state they very much resemble the small red gooseberry. They are very soft to the touch, and when opened are found to contain a juicy substance, with a cavity in the midst, in which there is lodged a single insect. This, according to the time in which the gall is opened, is found in the form of a white worm, or else of a white chrysalis, or finally of a small short-bodied four-winged fly of a black colour; for the creature does not leave the gall to go through any of its changes, but passes all its states in it. The gall, in all these cases, is found whole and unhurt; but if one is opened in which there is a hole pierced, this is sure to be found empty, that being the passage by which the fly has made its way out. Reaum. Hist. Inf. vol. vi. p. 214.

GOOSEBERRY *Islands*, in *Geography*, small islands near the E. coast of Newfoundland; 24 miles N.W. of Cape Bonavista.

GOOSEBERRY *Rocks*, dangerous rocks lying on the coast of Essex county, in the state of Massachusetts.

GOOTA, a town of Hindoostan, in Goondwanah; 10 miles S. of Nagpour.

GOOTOKA, a town of Hindoostan, in the circar of Ruttunpour; 5 miles S. of Ruttunpour.

GOOTY, or GUTTI, a town and fortress of Hindoostan, the capital of a district in Mysore; 170 miles N. of Seringapatam. It is situated on a hill beyond the river Pennar, or Pen-aur, and towards Adoni; and was formerly the seat of government of a Mahratta prince; but at the death of Tippoo, the town and district were assigned to the Nizam. N. lat. 15° 15'. E. long. 77° 48'.

GO-OUT, in *Mining*, is sometimes used to express the appearance of the edge of a stratum at the surface; otherwise called the basset, crop, out-going, or out-burft of that stratum; and such strata are said to go-out, burft-out, run-out, head-out, want-cover, &c.

When the ore in a vein suddenly ends in the deads or gangue, it is said to go-out; also, when a stratum of coals ends abruptly against a fault, or wall of gravel filling a fault, or basset under a heap of gravel, as is not uncommon in the south of Derbyshire, it is said to go-out, and so of the irregular or feather-edge masses which are sometimes met with in the strata accidentally, or without being continuous like all the regular strata, however thin.

GOPALCHITTY, in *Geography*, a town of Hindoostan, in Coimbatore; 18 miles N.W. of Erroad.

GOPALGUNGE, a town of Bootan; 58 miles N. of Dinagepour.

GOPALNAGUR, the name of two towns in Bengal; one 25 miles S.S.E. of Kishenagur, and another 30 miles E.S.E. of Dacca.

GOPALPOUR, the name of several towns in Hindoostan, one 8 miles N. of Hurdah, a second, 12 miles N. of Goragot, a third, 15 miles N. of Gurrach, a fourth, 23 miles S. of Bahar, a fifth, 20 miles N.W. of Narva, a sixth, 20 miles S. of Goorackpour, a seventh, 38 miles S. of Fyzabad, an eighth, 25 miles N. of Amedabad

GOPALDROOG, a fortress of Mysore; 36 miles E. of Seringapatam.

GOPAULGUNGE; a town of Bengal. N. lat. 23° 2'. E. long. 89° 56'.

GOPALNAGUR, a town of Bengal, 42 miles S. of Burdwan. N. lat. 22° 31'. E. long. 88°.

GOPEER, a town of Bengal; 15 miles E.N.E. of Ramgur.

GOPERAPILLY, a town of Golconda; 20 miles E.S.E. of Hyderabad.

GOPHNA, GOPHNIH, or *Gaphna*, in *Ancient Geography*, a town of Palestine, and chief place of one of the ten toparchies of Judah. Eusebius places it fifteen miles from Jerusalem, towards Sichem.

GOPLO, in *Geography*, a lake of Poland, in the palatinate of Brzesc, 16 miles long, and four wide.

GOPPINGEN, a town of the kingdom of Wurtemberg, situated on the Vils, in a fertile country, having considerable woollen manufactures, and near it a medicinal spring; 20 miles N.N.W. of Ulm. N. lat. 48° 47'. E. long. 9° 41'.

GOR, a town of Persia, in the province of Farsistan; 57 miles N.W. of Schiras.—Also, a town of Italy, in the department of the Mela; 8 miles S. of Breafia.

GOR, a name given by some writers to a very lofty tree, which bears a fruit like the chestnut; it grows principally on the banks of the river Niger, and that not near the sea, but far up the country.

GOR-cock, in *Ornithology*, the name of a bird of the gallinaceous kind, called by authors the lagopus altera, and by many the moor-cock, or red game; it is of the shape of the partridge, but is half as large again. See GROUSE and TETRAO *Lagopus*.

GORA, in *Geography*, a town of Hindoostan, in the circar of Chandail; 20 miles W. of Saipour.

GORACALLY, a town of Bengal; 12 miles S.S.W. of Mahmudpour.

GORAGOT, a province of Bengal, bounded on the N. by Rungpour, on the E. by Radjoohow, Patladah, and Islamabad, on the S. by Bettoriah and Pargunnah, and on the W. by Dinagepour; about 55 miles long, and from 12 to 30 broad. Its capital, Goragot, is distant 80 miles N.N.E. from Moorshedabad. N. lat. 25° 14'. E. long. 89° 22'.

GORAI, a town of Poland, in Galicia.

GORAM, a small island, being one of the Moluccas, in the East Indian sea, S.E. of Ceram; reputed the most eastern boundary of Mahometanism. It has thirteen mosks. S. lat. 3° 42'. E. long. 121° 36'.

GORANTO, a town of Asiatic Turkey, in Caramania; 80 miles S.W. of Satalia.

GORAPARI, a town of Brazil, at the mouth of a river of the same name, which runs into the Atlantic. S. lat. 20° 40'.

GORBARA, a town of Corfica; 8 miles N.E. of Calvi.

GORBATA, a town of Africa, in Biledulgerid, anciently "Orbita;" 12 miles S.W. of Gafsa.

GORBATOV, a town of Russia, in the government of Niznei Novogorod. N. lat. 56° 5'. E. long. 43° 14'.

GORCA. See GORKAH.

GORCE, or GOURT, denotes a weir. By stat. 25 Edw. III. cap. 4. it is ordained, that all gorges, mills, weirs, &c. levied or set up, whereby the king's ships and boats are disturbed, and cannot pass in any river, shall be utterly pulled down, without being renewed. Sir Edward Coke derives this word from *gorges*, a deep pit of water, and calls it

it a *gors*, or *gulf*; but this seems to be a mistake, for in *Doomsday* it is called *gourt* and *gort*, the old French word for a *weir*.

GORCHWICH, in *Geography*, a town of Saxony, in the Vogtland, 18 miles S.S.W. of Gera. N. lat. 50° 22'. E. long. 11° 53'.

GORCUM, probably a corruption of *Gorichem*, a town of Holland, situated on the river Linge, at its union with the Wahal. From the steeple of the principal church may be seen 22 walled cities, besides a great number of towns and villages; before the revolution it had one parish-church, and three religious houses; 12 miles E. of Dort. N. lat. 51° 52'. E. long. 4° 50'.

GORDENE', in *Ancient Geography*, a country of the Greater Armenia, according to Ptolemy; which country is called "Gordyené" by Strabo and by Plutarch in his life of Lucullus.

GORDES, in *Geography*, a town of France, in the department of Vaucluse, and chief place of a canton in the district of Apt; 9 miles W. of Apt. The place contains 2812, and the canton 6430 inhabitants, on a territory of 167½ kilometres, in 8 communes.

GORDEWARE POINT, a cape of Hindoostan, on the coast of Rajamundry, at the mouth of the Godavery. N. lat. 16° 42'. E. long. 82° 28'.

GORDIÆUS Mons, in *Ancient Geography*, a mountain of the Greater Armenia. Ptol.

GORDIANI, M. ANTONIUS GORDIANUS, in *Biography*, Roman emperor, born A.D. 157, was son of Metius Marullus, a senator descended from the Gracchi, by Ulpia Gordiana, of the family of the emperor Trajan. He became possessed of a great estate, with which he lived in a style of magnificence, but without passing the bounds of moderation. He was a patron of literature and literary men, and a proficient in eloquence and poetry. He wrote a poem in thirty books, to celebrate the reigns of Titus and M. Aurelius Antoninus. When he served the office of edile, he entertained the people with a splendour which no private person had for a long time exhibited, and his shows were exhibited every month in the year while he was in office. There is, however, no reason for supposing that he was over ambitious of coming forwards into public life, for it was not till his fifty-fifth year that he was elected consul in conjunction with the emperor Caracalla. He might, perhaps, be unwilling to risque the safety of his person in those turbulent times; and it has been thought extraordinary that under so jealous a tyrant he should venture upon the profuse expences which distinguished his consulship not only in the imperial city, but in various parts of Italy also. He enjoyed the same honour a second time in the reign of Alexander Severus, who expressed his high esteem for him by confirming his nomination to the government of Africa as proconsul. In this important post he displayed so much equity and beneficence, that he was more beloved in the province than any of his predecessors. Under the emperor Maximin, in the year 237, a sedition was excited against the rapacity of an officer in the government of Africa, and the perpetrators, to avoid the vengeance of a cruel and incensed sovereign, appeared in open rebellion and insisted upon Gordian's assuming the purple. He remonstrated with the conspirators, but their resolution was formed, and at the age of fourscore he was forced to appear in a character, after which he had never aspired. They associated with him, to alleviate his cares, the younger Gordian, a man of voluptuous habits, but who was of a mild disposition, and attached to letters. A library of sixty-thou-

sand volumes, bequeathed him by his tutor Serenus Samonicus, gave him reputation in the literary world, which he maintained by writing both in prose and verse. This young man had been elevated to the office of quaestor by the despicable Heliogabalus; nevertheless, the confidence placed in his integrity, and knowledge of the laws, by Alexander, who created him prefect of Rome, and who always paid great deference to his advice, was much in his praise. He shared in the elevation of his father, and they were declared joint emperors. The Gordians removed to Carthage, whence they sent letters to Rome, announcing their election. Maximin was at that time absent, and the senate willingly sanctioned the choice of the Africans, and declared Maximin a public enemy. In the mean time, a change took place in Africa, which annulled all their projects. Capelianus, governor of Mauritania, who had been always upon ill terms with Gordian, assembled a body of veterans, declared for the reigning emperor, and marched to Carthage. The younger Gordian sallied out to oppose him with his guards, but he was soon defeated and slain. Capelianus entered the city, which so much alarmed the elder Gordian, that to prevent his falling into the hands of his enemy, he strangled himself in his apartment with his girdle. This event happened in June 237, and within a few weeks of his assuming the office of emperor. Gibbon.

GORDIAN III, Roman emperor, grandson of the elder Gordian, was but thirteen years old when he was chosen emperor, in connection with Maximus and Balbinus. He was created Cæsar, and assumed the family name. His two colleagues were in a few months murdered by the Pretorian bands, and the youthful Gordian remained sole emperor. His person and manners excited universal favour, and the senate, people, and army united in giving him the endearing appellation of their son. In the commencement of his reign he was governed by his mother's eunuchs, who abused his authority, and set the honours and offices of the empire up to sale. He was, however, happily rescued from this disgraceful condition by Mithreus, a man of learning, to whom he was also indebted for literary instruction and advice. In the year 241 he married the daughter of Mithreus; and raising his father-in-law to the post of præfect-prætoris, committed to him the principal direction of public affairs. He proved himself worthy of the important trust confided in him, and discharged the duties of a statesman and general, as well as he had maintained those of a more private station. By his persuasion, the young emperor accompanied him in 242, in an expedition to the East, for the purpose of repelling an invasion from Sapor king of Persia. Under his guidance, Gordian relieved Antioch, crossed the Euphrates, defeated Sapor, and recovered the whole of Mesopotamia. The young emperor did not assume the glory of the deeds, but, in a letter to the senate, announcing the successes, he modestly ascribes them to the conduct, the experience, and wisdom of Mithreus, who shortly after died. During the whole expedition Mithreus had watched over the safety and discipline of the army, while he prevented their murmurs by maintaining a regular plenty in the camp, and by establishing ample magazines of vinegar, bacon, straw, barley and wheat, in all the cities of the frontiers. The prosperity of the emperor expired with Mithreus; he was succeeded in the office of præfect by Philip, an Arab by birth, and consequently, says Gibbon, in the earlier part of his life, a robber by profession. He was a man of considerable military talents, but ambitious, and destitute of true moral principle. His energy and boldness prompted him to aspire to the throne, and his abilities were employed to supplant, not to serve his indulgent master. By his arts discontented were formed among

the troops, which induced them to demand that his minister Philip should be associated with Gordian as partner in the empire. This was not sufficient to satisfy his ambitious views; the young emperor was sacrificed at his instigation; he was put to death near the banks of the Euphrates, in March 244, after a reign of five years and eight months. A sepulchral monument was erected to his memory on the spot where he was killed. Gibbon.

GORDIAN, a term in *History*. Gordian knot was a knot made in the leathers or harness of the chariot of Gordian, king of Phrygia, and father of Midas; so very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he should be master of Asia who could untie this knot. Alexander having undertaken it, and fearing that, if he should not be able to effect it, it would be deemed an ill augury, and prove a check in the way of his conquests, cut it asunder with his sword; and thus, say Quintus Curtius, either accomplished the oracle, or eluded it. But Aristobulus gives a different account of this matter. See Arrian, lib. iii. cap. 20. and Plut. in Vit. Alex.

Some will have the phrase derived from Gordius who tied the fatal knot; others from Gordium, a city in Phrygia, where the knot was made.

GORDIUM, in *Geography*, a town of Asia, in Phrygia, situated on the river Sangar; afterwards called Juliodolis.

GORDIUS, in *Zoology*, a genus of Vermes, the essential character of which consists in the body being round, filiform, naked or smooth, and of equal thickness throughout.

Linnæus, and after his example the French naturalist Bruguière, has placed the animals of this genus among the intestinal vermes, an order of beings to which, from their general structure, they seem to bear no very remote alliance: and this similarity is still more strongly evinced in the habits of those species which occasionally penetrate into the flesh of men and animals, and therein for a while derive their sustenance from the blood and other fluids. Notwithstanding this analogy, under such circumstances we cannot but agree with Lamarek that it is impossible to consider them as internal vermes with propriety, since they only occasionally reside in the bodies of animals as before mentioned, and in their habits and manners of life at other periods differ most essentially: they are literally aquatic animals, with carnivorous appetites; though for a certain length of time they can subsist like the true intestinal vermes, when by any accidental circumstance they happen to insinuate themselves into the flesh of a living animal.

At the head of this tribe we may justly place the species *medinensis*, or hair worm of the Indies, a pernicious creature, referred to the genus Gordius by Linnæus in the latest edition of his Syst. Nat., but from which it was afterwards removed by his editor Gmelin to that of Filaria. This removal we deem unnecessary, and under this persuasion wish to restore the species to its former situation in the genus Gordius.

Species.

MEDINENSIS. Body entirely pale. Linn. Sloane Jam. &c.

This very remarkable creature is often from ten to twelve or even fifteen feet in length, and in thickness not exceeding a horse-hair. It is well known by its disastrous effects as an inhabitant of both the Indies, where it lives in marshy places, and is frequently observed on the ground in the morning dew. In this situation it easily creeps up, and entwines itself round the naked legs of the negro slaves, or

animals, and penetrating the skin, buries itself speedily in the flesh, where it causes the most violent pains, accompanied with troublesome itchings, and oftentimes inflammation and fever. The most certain means of extricating the worm is to make an incision in the part of the flesh at which its entrance was effected, so as to obtain secure hold of either of the extremities, or the head if possible, and this being made fast to a small stick by means of a piece of silk, the animal may be gradually drawn out of the wound by turning the stick round a little each day. The utmost circumspection is requisite in performing this operation, for if by being too much strained the worm should break, the part remaining within the flesh grows with increased vigour, gangrene appears almost immediately, and death itself ensues very shortly.

AQUATICUS. Pale brown, with blackish extremities. Linn. *Gordius seta*, Müll. *Vitulus aquaticus*, Gess. Meerzwijn, Jonst. *Chatia*, Hill. &c.

This so entirely resembles a hair of from four to six inches in length, that except by its motions it could be in no manner distinguished from a substance of that kind by the casual observer; its internal structure is equally remarkable also for its simplicity, consisting merely, as it appears, of a canal extending from one end to the other, and both the mouth and vent are the most simple possible, since a small vent constitutes the first, and a groove or hollow the latter. Its ordinary places of residence are stagnant waters, in pools and ditches, or in very tranquil rivers, as the agitation of turbulent waters would destroy its tender frame. During winter it remains buried deep in the clay, from whence it emerges in spring, and is found in the water during the summer months, where it is frequently observed, and from its appearance is vulgarly imagined to be the offspring of horse-hair dropped by accident into the water. It twirls itself into various contortions; and it is affirmed that its bite will occasion the complaint called a whitlow. A fact still more extraordinary, and which appears in some measure to be authenticated with tolerable accuracy, is the retentive power of animation, which this creature possesses in a very superior degree, though not by any means to the extent that certain naturalists conceive. Some writers affirm, indeed, that it has been known to recover the free exercise of its vital functions upon being steeped for a short space of time in water, after having remained in a dried state for weeks, months, and even years, and when of course it might be naturally conceived the most latent spark of life must be extinct. If these latter assurances have not arisen from the result of some very superficial experiments, they are at least to be received with caution, since their observers seem to believe that these animals partook also in some measure of the reproductive properties of the polype, and which more recent observations prove to be erroneous; we cannot, therefore, upon the whole, avoid concluding that although the animals of this kind are extremely tenacious of life, there is no foundation in truth for the very extraordinary assertions above related.

ARGILLACEUS. Body uniformly yellowish. Linn.

Very much resembles the last, and like that species is found in the clay at the bottom of stagnant waters.

FILUM. Body filiform and whitish. Müll.

Extremely slender, tapering at one end, and hyaline. Found in the bark of old wooden pipes which had been placed in the ground for the conveyance of water.

LACTEUS. Body uniformly white and opaque. Müll.

Occurs in myriads in stagnant water from the month of July till September. When touched, this species contracts itself in a moment, and then again expands immediately.

ARENARIUS. Fulvous and obtuse. Müll.

Inhabits

Inhabits the bottom of Christians bay, in Norway.

GORDON, BERNARD, in *Biography*, a French physician of the thirteenth century, is said to have conferred honour on the medical faculty of Montpellier, where he began to teach in the year 1275. As was the custom of the time, he took his surname from the place of his birth, (Gordon in Rouvergne,) and called himself Bernardus de Gordonio, and not Gordonus, as it is commonly written. According to the accounts of some writers, who place the death of this physician in 1305, he taught at Montpellier only twenty years; but Renchin affirms, that he was living in 1318. He left a considerable number of treatises, which were published together at Ferrara in 1487, at Venice in 1494, at Paris in 1542, and at Lyons in 1550. Eloy. Dict. Hist.

GORDON, MR., in the year 1744 played the first violin in Drury-lane play-house. He was a young man, born in Norfolk, who had travelled to Italy for improvement. He was very near-sighted, and always played in spectacles. He succeeded Charke, had a strong hand, good tone, and was well fitted to his station. He generally played a concerto in the second music, as was then the practice, which was very attractive. He was brother to the subject of the following article.

GORDON, ———, an eminent performer on the violoncello, the son of a clergyman in Norfolk, and many years the first violoncello at the opera. He was remarkable for the fulness of his tone, and perfect execution of whatever he undertook, though far surpassed by subsequent players in the use of the bow, and knowledge of the finger-board. He lived respectably, had many powerful friends, and realised a competence by his profession.

In 1765, Messrs. Gordon, Vincent, and Crawford, undertook the opera regency in the Haymarket. The two first were experienced professors, and the third had been many years treasurer under different managers. Gordon, an excellent performer on the violoncello; and Vincent, a scholar of the celebrated Martini, long a favourite on the hautbois. His father was a bassoon player in the Guards, and his brother, James Vincent, who died young, was joint organist of the Temple with Stanley, and a brilliant performer. Mr. T. Vincent, the impresario, had been in great favour with the late prince of Wales, father to his present majesty; had acquired a considerable sum of money in his profession, which he augmented by marriage. However, the ambition of command, though of so forward a family as an opera, vocal, and instrumental band, turned his head and his purse inside out; in short, he soon became a bankrupt, sculked in indigence during the rest of his life; and his colleagues, though they escaped utter ruin, were not enriched by the connection.

GORDON, ALEXANDER, a learned writer of the eighteenth century, was a native of Scotland. He was well acquainted with the Greek and Latin languages, and being a good draughtsman, he was enabled to derive peculiar advantages from a long residence in Italy, and from his travels in other parts of Europe. He was engaged as secretary to the society for the encouragement of learning; and to the Egyptian club, and to the Antiquarian society. He afterwards accompanied governor Glen to Carolina, where he occupied various posts in the province, and received a handsome grant of land. Here he died, leaving a good estate to his family. He was author of "Itinerarium Septentrionale," or a journey through most parts of Scotland, illustrated with copper plates. This was published in 1726, and in 1732 he gave additions and corrections to it, containing an account of Roman antiquities in Scotland, and ancient monuments in the north of England. He wrote likewise "The Lives of

Pope Alexander VI., and his Son Cesar Borgia." "A complete History of ancient Amphitheatres, translated from the Italian." "An Essay towards explaining the hieroglyphical Figures on the Coffin of a Mummy." "Twenty-five Plates of all the Egyptian Mummies in England, and other Egyptian Antiquities" Gen. Biog.

GORDON, ANDREW, was born in 1712 near Aberdeen. He was sent to Ratisbon, where he applied himself to polite literature. In 1731 he made a tour through Aultria, Italy, and France, and on his return in the following year entered into the order of the Benedictines in the Scots monastery, where he applied to philosophy, and was ordained priest. In 1735, he went to Salzburg to study the law, and he attended the theological lectures till he was invited, in 1737, to be professor of philosophy at Erfurt. His discoveries in electricity made his name known to the philosophers in Holland, France, Italy, and England, and he is mentioned by Dr. Priestley as the first person who used a cylinder instead of a globe in electric experiments. His first work on this subject was entitled "Phenomena Electricitatis Exposita," 1744; and in the following year he published in 3 vols. 8vo. "Philosophia utilis et jucunda." He was author of an "Impartial Account of the Origin of the present War in Great Britain," and of "Physicæ Experimentalis Elementa." Gen Biog.

GORDON, JAMES, a Scotch Jesuit, was born in the year 1543. He left his native country, and went to Rome, where he entered the society of Jesus, in 1563. He became distinguished for deep and extensive learning, and was sent on religious missions into Germany, Denmark, and the British isles, where he is said to have suffered much on account of his attachment to the Catholic faith. He died at Paris in 1620, leaving behind him a work in two volumes 8vo. entitled "Controversiarum Christianæ Fidei Epitome."

There was another Scotch Jesuit of the same name, and contemporary with the above, who wrote a commentary on the whole bible, which he published at Paris, in three volumes folio, under the title of "Biblia sacra, cum Commentariis ad sensum Literæ, et explicatione Temporum, Locorum, Rerumque omnium quæ in sacris Codicibus habent obscuritatem: una cum Textu Biblico." This work is well spoken of by Dupin. He was author likewise of a work on Chronology: and of "A System of moral Theology," &c. Moreri.

GORDON, THOMAS, a native of Kirkeudbright, in Scotland, after having received an academical education in his own country, came to London, and maintained himself by teaching the learned languages. His talents were made known to people of consequence, and he was employed by the earl of Oxford in queen Anne's reign as a political writer. He wrote in defence of bishop Broadley in the Bangorian controversy, and became the assitant and partner of Mr. Trencard, in his literary undertakings. They published, in conjunction, a series of papers, entitled "Cato's Letters;" and the "Independent Whig," which Mr. Gordon continued alone after the death of Trencard. When this event took place, sir Robert Walpole engaged Gordon as one of the writers in defence of his measure, and procured him a place, which he held as long as he lived. Mr. Gordon made himself known by translations of Tacitus and Sallust, as well as by his political pieces. To these translations he prefixed discourses relative to subjects of each original author. He died in 1750, at the age of sixty-six. Some of his posthumous tracts appeared in two works, entitled "A Cordial for Low Spirits;" and "The Pillars of Priestcraft and Orthodoxy shaken." He was a distinguished writer in favour of civil and religious liberty, and is highly

esteemed by the friends of freedom for the manly spirit with which he supported its cause against tyranny of every kind. Gen. Biog.

GORDONA, in *Geography*, a town of Naples, in the county of Molise; six miles S.W. of Molise.

GORDONIA, in *Botany*, named by Mr. Ellis, in the Philosophical Transactions for 1770, in honour of Mr. James Gordon, an eminent nurseryman at Mile-end, near London, who introduced many new plants to the knowledge of the curious, or rather cultivated with great skill and success such as were communicated to him, from various quarters, by the collectors and naturalists of that day, among whom were Bartram, Collinson, Ellis, and many others. He was a frequent correspondent of Linnæus, and sent him several living plants, especially of North American origin. Linn. Mant. 556. Syst. Nat. ed. 14. 631. Schreb. 471. Willd. Sp. Pl. v. 3. 840. L'Herit. Stirp. Nov. 156. Cavan. Diff. fasc. 6. 307. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 231. Juss. 275. Lamarek. Illustr. t. 594.† Dict. v. 2. 770. Class and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferae*, Linn. *Malvaceae*, Juss.

Gen. Ch. Cal. Perianth simple, inferior, of five roundish, concave leaves. Cor. Petals five, large, obovate, or obovate, concave, cohering at their base, somewhat unequal. Stam. Filaments very numerous, thread-shaped, united at their base into a thick cup-shaped body; anthers oval, erect. Pist. Germen superior, ovate or nearly globose; style short, columnar, obscurely five-sided, sometimes five-cleft; stigmas five, acute, horizontal. Peric. Capsule ovate or globular, of five cells and five valves, the partitions from the middle of the valves, which are deeply cleft at their base. Seeds in two rows in each cell, angular, winged, inserted into a five-angled central column.

Eff. Ch. Calyx simple. Style columnar. Stigma five-cleft. Capsule of five cells. Seeds several, in two rows, winged.

1. *G. Lasianthus*. Linn. Mant. 570. Curt. Mag. t. 668. Cavan. Diff. t. 161. (*Hypericum Lasianthus*; Linn. Sp. Pl. 1101. *Alcea floridana quinquecapularis*, &c.; Pluk. Amalth. t. 352. f. 3.) Loblolly Bay.—Flower-stalks elongated. Leaves coriaceous, smooth. Capsules ovate.—Native of swamps in South Carolina, where it forms a very handsome tree, but is with great difficulty cultivated in England. It blooms in August and September. We have seen this plant flowering in great perfection at Kew 25 years ago. The leaves are scattered, on short stalks, elliptic-lanceolate, three to five inches long, bluntish, with numerous shallow serratures, veiny, smooth on both sides, of a fine shining green, like those of *Prunus Lauro-cerasus* above, paler beneath. Stipulas none. Flowers solitary, on simple axillary stalks, thrice as long as the footstalks, as large as a moderate rose, white with yellow stamens, very handsome but inodorous. A pair of deciduous fringed bractæas, a little below the flower, are called by Cavanilles an outer calyx. Authors have differed about the class of this plant in the Linnæan system, the filaments cohering imperfectly and irregularly together in parcels, besides being connected by one common fleshy base. If this base be called a nectary, for which there is no good reason, the flower is polyadelphous, but we think, with Dr. Sims, and most others, that it is monadelphous.

2. *G. Hematoxylo*. Swartz. Ind. Occ. 1199.—Blood-red Wood Tree.—Flower-stalks very short. Leaves elliptic-lanceolate, pointed, serrated, smooth. Petals inversely heart-shaped. Style deeply five-cleft.—Native of dry woody places on lofty mountains, in the west side of Jamaica; Dr. Swartz, from whom we have specimens. A tree, whose stem is from twelve to sixteen feet high, with a smooth greyish

bark, and round slender straight compound leafy branches, Leaves two or three inches long, scattered, on footstalks, elliptic-lanceolate, tapering at both ends, with a bluntish recurved point, smooth on both sides, less coriaceous than in the former, their margin somewhat revolute, with numerous shallow serratures. Flowers from the bosoms of the upper leaves, solitary, on very short stalks, not so long as the footstalks, bearing one or two unequal bractæas; their petals pale flesh-coloured, unequal, deeply lobed, scarcely so large as those of *G. Lasianthus*, but flatter and more spreading. Germen silky, ferrowed. Style, according to Dr. Swartz, divided into five. Capsule oblong, rather pointed. Seeds two in each cell, with an abrupt wing.—This tree was omitted by Dr. Swartz in his Prodomus, and is little known to botanists, having never yet been brought to Europe. It flowers in February and March. The wood is hard and of a blood-red, valued in Jamaica for making ornamental furniture, but as yet not known, or not distinguished, by European workmen. The peculiar structure of the style does not constitute any generic distinction here, any more than in the neighbouring genus *Stuartia*. See Sm. Exot. Bot. v. 2. 101.

3. *G. pubescens*. L'Herit. Stirp. Nov. 156. Cavan. Diff. t. 162. Vent. Jard. de la Malmaison, t. 1.—Flowers nearly sessile. Leaves downy beneath. Capsules globose.—Native of South Carolina, now not uncommon in green-houses, flowering in autumn. A handsome shrub, whose branches, calyx, and the backs of its leaves, are clothed with fine white depressed down. The flowers most resemble those of the first species, but one petal is considerably more concave than the rest, shorter, and downy, approaching to the nature of the calyx. The flower-stalks are extremely short and thick. Leaves obovato-lanceolate, acute, with shallow serratures, smooth and of a fine green above. Ventenat's figure, drawn by Redouté, the first in the splendid Jardin de la Malmaison, is one of the finest representations of a plant that can any where be seen, except that the French mode of printing in colours gives indiscriminately an idea of a downy surface, so that in this case both sides of the leaves look alike.

4. *G. Franklini*. L'Herit. Stirp. Nov. 156. (*Franklinia Alatanaha*; Marshall. Arbust. 49.)—“Flowers sessile. Leaves smooth. Capsules globose.”—Native of South Carolina. Flowers sessile, solitary, large, white, very much admired in their native country, but we have not heard of their being produced in Europe, nor have we seen even a dried specimen. The capsule, according to L'Heritier, is “globose and umbilicated. Seeds numerous in each cell, imbricated in two rows, slightly angular, much like those of the Cypress, the angles somewhat bordered. Leaves alternate, on short foot-stalks, oblong, toothed, attenuated at the base, and smooth.”—Marshall and Bartram say the flowers smell like a china orange, and are often five inches in diameter, the lower petal hollow, enfolding the rest till they expand, as in *G. pubescens*. It was first observed by Mr. John Bartram in 1760, on the borders of the Alatanaha river, in Georgia.

GORDYGONG, in *Geography*, a town of Hindoostan, in Visapour; 22 miles N.E. of Poonah.

GORE, in *Heraldry*, denotes one of the regular abatements, used, according to Guillim, to denote a coward. It consists of two arches or curve lines, drawn, one from the sinister chief, the other from the sinister base, and meeting in an acute angle in the middle of the fesse-point.

GOREE, or GORREE, in *Geography*, an island in the German ocean, near the mouth of the Meuse, about 10 miles in circuit; two miles N. of Schlowen. N. lat. 51° 49' E. long.

E. long. $3^{\circ} 50'$.—Also, a sea-port town of this island, near the E. coast, on a canal communicating with the Meuse; formerly carrying on a considerable trade, but the harbour is now choaked with sand; 6 miles W. of Helvoetsluys.

GOREE, a small island in the Atlantic, within cannon-shot of the coast of Africa, about two miles in circumference. The air is cool and temperate, being refreshed by alternate breezes from the land and sea. It is almost inaccessible on account of its surrounding rocks; but it has two bays, and a fort with several new buildings constructed by a late director M. de St. Jean, who has also rendered it a very strong place. By his persevering assiduity, springs of fresh water have been discovered, and a variety of vegetables and fruit trees have been planted; so that the island, once barren and despicable, is now made one of the most safe, pleasant, and important settlements in Africa. Goree was ceded to the Dutch in 1617 by a king of Cape Verd, and by them fortified. The Dutch were driven out by admiral Holmes in 1663, and the island was garrisoned by the English. It was two years after taken by De Ruyter, and its fortifications augmented by the Dutch; but in 1667 a French squadron compelled the Dutch to abandon Orange fort, and retire to fort Nassau; but here, incapable of defending themselves, they were obliged to surrender at discretion. Upon the arrival of M. du Casse, the island was formally taken possession of in the name of the Senegal company, and a treaty was concluded with the king and negroes of the neighbouring country on the same conditions with those by which the Dutch had possessed the island. The conquest was secured to the company by the treaty of Nimeguen. The French immediately repaired the forts, and changed their names, calling the lower fort "Verinandois," and the higher "St. Michael." In 1750 Goree was taken by the English. By the treaty of 1763 Goree and its dependencies were left to the French. In 1778 it was taken by the English. N. lat. $14^{\circ} 40'$. W. long. $17^{\circ} 30'$.

GOREE, a small island on the coast of Brazil, at the mouth of the Rio dos Reyes Magos. S. lat. $19^{\circ} 10'$.

GOREING, or GORING, is said of a sail when cut slanting, so that it is broader at the clew than at the earing, as all top-sails and top-gallant-sails are.

GOREL, a name or title given to the prince of Georgia. The gorel is always a Mahometan. The sophy of Persia obliges him to observe the religion of the Alcoran, in order to preserve the dignity of gorel in his family.

GORE'S BAY, in *Geography*, a bay on the S. W. coast of the island of Tavai-Poenammoo. S. lat. $43^{\circ} 12'$. W. long. $186^{\circ} 36'$.

GORE'S ISLAND, an island in the N. Pacific ocean, so named by captain Cook in the year 1778. This is a narrow island, particularly at the low necks of lands which form a junction between the hills; it is about 30 miles long from N.W. to S.E.; and it appeared barren and uninhabited. Some sea-otters were seen. N. lat. $60^{\circ} 40'$. W. long. $172^{\circ} 30'$.

GORESBRIDGE, a small post town of the county of Kilkenny, Ireland, 51 miles S.W. from Dublin, on the road to Waterford.

GOREY, a post town of the county of Wexford, Ireland, also called Newborough, which, before the Union, was represented in parliament. It is $45\frac{1}{2}$ miles S. from Dublin, and 21 N. from Wexford.

GOREY-MOUNTAINS of Ireland, in the county of Donegal, near Raphoe.

GORGA, a town of Mingrelia, on the Black sea; 30 miles S. of Anarghia.—Also, a river of Naples, which runs into the Liban, in Calabria Citra.

GORGE, in *Falconry*, is the uppermost bag or stomach

of a hawk or falcon, being that which receives the food the first.

The gorge, *ingluvies*, is the same, in birds of prey, with what we call the *crop* or *crop*. When the bird is fed, he is said to be gorged.

GORGE, in *Architecture*, denotes a sort of concave moulding, wider but not so deep as a scotia; used chiefly in frames, chambranles, &c.

GORGE of a Chimney, is that part between the chambranle and the crowning of the mantle. Of this there are divers forms; straight, perpendicular, in form of a bell, &c.

GORGE is sometimes also used for a moulding that is concave in the upper part, and convex at bottom; more properly called gula and cymatium.

GORGE is also used for the neck of a column; more properly called colarin and gorgerin.

GORGE, in *Fortification*, the entrance of a *Bastion*, or of a *Ravelin*, or other *Out-work*. See each article.

The GORGE of a *Bastion* is what remains of the sides of the polygon of a place, after retrenching the curtains; in which case it makes an angle in the centre of the bastion.

In flat bastions, the gorge is a right line on the curtain, reaching between the two flanks.

GORGE of a *Half moon*, or *Ravelin*, is the space between the two ends of their faces next the place.

Gorge of the other out-works is the interval betwixt their sides next the ditch.

All the gorges are to be made destitute of parapets; otherwise the besiegers, having taken possession of a work, might make use thereof to defend themselves from the front of the place: so that they are only fortified with palisades, to prevent a surprize.

GORGE, *Half the Gorge*, *semi-gorge*, that part of the polygon between the flank and the centre of the bastion.

GORGED, in *Heraldry*, is when a crown, coronet, or the like thing, is borne about the neck of a lion, a swan, &c. In that case they say, the lion or cygnat is gorged with a ducal coronet, &c.

GORGED is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGED, among *Farriers*, &c. signifies as much as swelled. In which sense they say, the legs of an horse are gorged; the pattern-joint is gorged; you must walk him out, to disgorge his shoulder.

GORGED, in *Rural Economy*, a term which is sometimes applied to signify being *hoven* by fresh luxuriant green food, and relates to cattle, &c.

GORGERIN, a part of the ancient armour, being that which covered the throat or neck of a person armed at all points.

GORGERIN, or *Gorge*, in *Architecture*, the little freeze in the Doric capital, between the astragal, at the top of the shaft of the column, and the annulets.

Some call it *collarino*. Vitruvius gives it the name *hypotrachelium*.

GORGET, in *Military Affairs*, a piece of brass or silver, worn by the officers of foot upon their breasts when on duty. The gorget hangs round the neck by a ribband; they are sometimes gilded, and have commonly some device engraved on them, as the sovereign's, or even the colonel's coat of arms, crest, or cypher.

GORGET, an instrument used in *Surgery*, for the purpose of cutting an opening into the bladder, so as to enable the operator to introduce the pair of forceps and extract the stone.

It is impossible to give the reader a proper notion of the form and manner of using the gorget, without presenting him with engravings of the instrument, and entering into a description of the operation of lithotomy. Hence, we must at present content ourselves with referring to the surgical plates, and the article LITHOTOMY.

Besides cutting gorgets, constructed for the above design, there are also blunt ones, intended to be introduced into the wound, when their concavity serves as a guide for the forceps into the bladder.

The employment of gorgets for the performance of lithotomy has been objected to by several eminent surgeons of the present day, particularly by Mr. John Bell of Edinburgh. (See his *Principles of Surgery*, vol. 2.) We have seen the operation most easily executed by means of a common scalpel. Mr. Astley Cooper uses, instead of a gorget, a common scalpel with a beak, which glides along the groove of the staff into the bladder. Several other knives and instruments have been at different times invented to supersede the gorget. The principal ones will be represented in the surgical plates, and due notice will be taken of them in the article LITHOTOMY.

GORGIIAS, surnamed *Leontinus*, in *Biography*, born at Leontium in Sicily, from whence he derived his second name, was a celebrated orator and learned sophist, who flourished in the fifth century before the Christian era. He was a disciple of Empedocles, and is reckoned one of the earliest writers on the art of rhetoric. He is thought to have introduced numbers into prose, treated of common places, and shewed the use of them for the invention of arguments. Hence Plato gave the name of Gorgias to his elegant dialogue on this subject, which is still extant. He was so great an orator, that in public assemblies he would undertake to declaim extempore upon any subject proposed to him. In the war between Syracuse and Leontium, the citizens of the latter applied to the Athenians for succour, and employed Gorgias and Tisias as their ambassadors, the former of whom was peculiarly qualified to influence popular assemblies by his bold and persuasive eloquence. On their arrival at Athens about the year 427 B. C., Gorgias made an oration to the people on the grievances which their countrymen suffered from the people of Syracuse, and the advantages which would accrue to them from sending a powerful army into Sicily, by which he persuaded them to rush headlong into a war, that proved in the end more fatal to them than any in which they had engaged. Afterwards he made a display of his eloquence at the Olympic and Pythian games, on account of which a golden statue was erected to his honour at Delphi. He is said to have lived to the great age of 107 or 108.

GORGOGLIONE, in *Geography*, a town of Naples, in the Basilicata; 15 miles E. of Venosa.

GORGONA, an island of small extent and of a circular form, in the Mediterranean, about 16 miles from the coast of Etruria. The mountains, says Sonnini, seem to be of the same nature with those of the continent. This island is famous for the anchovy fishery on its coasts. N. lat. 43° 22'. E. long. 9 56'.—Also, an island in the Pacific ocean, about 18 miles from the coast of Peru, about 10 miles in circumference. N. lat. 3° 36'. W. long. 77 52'.

GORGONEUM, Γοργόνειον, in *Antiquity*, a kind of masque used on the ancient theatre to represent hideous and frightful figures, in imitation of the Gorgons. Mem. Acad. Inscript. tome v. p. 184.

GORGONIA, in *Zoology*, a genus of Zoophytes, the stem of which is coriaceous, woody, corky, horny, or somewhat bony, and in general flexible; the texture glassy,

fibrous, or like stone, striated, tapering, fixed at the base, which is dilated, and covered with vascular or cellular flesh, or bark of a spongy and friable nature in a dried state; the mouths or cells covering the surface of the stem and bearing polypes.

These marine productions were regarded by the ancients as a class of plants, and described as such by their botanists; nor was this idea, however remote from truth, exploded till so late a period as the eighteenth century, when the discoveries of Peyssonel upon the nature of coral, published in 1727, and those of Trembley on the hydra (or polype) about fourteen years after, contributed to demonstrate, in a very explicit manner, that the gorgoniae in common with other zoophytes (as these particular bodies are now denominated), do not appertain to the vegetable, but animal kingdom, or are at least the fabrication and genuine habitations of animals.

Among the various observers of this curious order of animal productions, few, if any, have pursued their investigations with greater discrimination and success than professor Pallas, or our own countryman Ellis, and his friend Dr. Solander; nor indeed can we hesitate to confess that our knowledge of the gorgoniae tribe has been enlarged only in a very inconsiderable degree by any of the subsequent authors on this subject. The latest observations tend principally to confirm the accuracy of those writers who had before assured us the gorgoniae are the habitations of various kinds of polyiferous animals, each of which resides in a distinct cell; that they lie in general dormant or contracted during winter, and, like the blossoms of plants, push forth buds, and expand in their proper season, which is constantly in summer. The stem and branches of the gorgoniae, which are most commonly of a somewhat horny and flexible nature, may be considered as the true skeleton of these nests of habitations, being covered with a fleshy or pulpy substance, the exterior surface of which is porous. These pores are the mouths or openings of the cells in which the polypes are lodged, and it is the number, disposition, and varied structure of these, in addition to the general aspect of the plant-like nest of habitations, that constitute the most material differences by which the various species are distinguished; the figure of the animal, when it can be ascertained, forming the secondary or least important character. It may be lastly observed, that the gorgoniae differ exceedingly in size, being from one to two, or perhaps three feet in height, while other species in deep bays, and similar situations of the sea, no less favourable to their growth and increase, attain to the gigantic height of ten or twelve feet, and from their number as well as magnitude; their remarkable ramose, and foliated or flabelliform appearance; interwoven structure, and coral-like texture, form a conspicuous portion of those vast submarine "groves of coral" that are sometimes seen by navigators in the hotter regions of the globe.

Species.

LEPADIFERA. Dichotomous, with crowded, imbricated, reflected, campanulated florets. Müll. *Gorgonia reseda*, Pallas. *Gorgonia resediformis*, Gunner. *Reseda marina*, Bell.

Native of the Norway seas, from eighteen inches to two feet high; flesh pale, with whitish skin or scales; stem white, with a stony base and cartilaginous branches.

VERTICILLARIS. Pinnate, ramose, with alternate parallel subdivisions, covered with verticillated incurved florets. Müll Pallas, &c. *Sea-feather*, Ellis.

From two to three feet high; stem brittle and white, with flexible branches. Native of the Mediterranean and North seas.

GORGONIA.

PLACOMUS. Branching both ways, with flexuous, and rarely uniting or anastomosing branches, covered with conic florets. Linn. *Warted-sea-fan*, Ellis. *Lithoxylon*, &c. Breyn.

Height two feet; stem erect, woody, and yellow, scarlet or reddish cinereous. Inhabits the Indian and European seas.

MOLLIS. Coriaceous, dichotomous, with perpendicular tubular florets. Pallas.

Native of the Mediterranean, and about eighteen inches in height, the colour brown violet; stem brown; branches long and slender.

SUCCINEA. Round, amber-colour, dichotomous, rigid, the stem covered with tubercular gaping florets. Pallas.

A very rare species, the native place of which is unknown; it is only six inches high, the stem testaceous.

AMERICANA. Branched and sub-divided, the sub-divisions nearly opposite, compressed, with rows of polypiferous cells on each margin; flesh yellowish, within pale purple; bone horny. Gmel. *Gorgonia pinnata*, Soland. and Ellis.

Native of the West Indies; flesh purplish or yellowish.

EXSERTA. Round, with a few alternate branches; florets alternate, eight-valved; flesh covered with minute white scales; bone brownish, horny. Soland.

Height two feet; branches long, slender, and white; polypes with eight feelers and exerted. Inhabits the West Indies.

PATULA. Compressed, with flexuous sub-pinnate branches, crimson, with two rows of florets each side, each surrounded with a whitish ring; bone brownish, horny. Soland.

Native of the Mediterranean.

CERATOPHYTA. Branched, with divaricate erect sub-divisions, each marked with two furrows; florets white, in irregular rows; flesh purple; bone black and horny. *Gorgonia ceratophyta*, Soland. *Corallina fruticosa purpurea*, C. Bauh. *Lithophyton*, &c. Geln. *Corallina fruticosa erectior*, Catesby.

Found in the Mediterranean, Atlantic, and South American seas; height twelve inches; flesh bright purple.

JUNCEA. Stem simple, round, and tapering both ways; bone dusky, horny; flesh orange-colour, with two furrows; florets longish. Soland. &c. *Junci lapidei*, Plin. *Palmjuncus albus*, Rumpf.

Inhabits the shores of the American islands adhering to stones; height about three feet, and very flexible when alive.

FLAMMEA. Compressed, branched, and sub-pinnated; bone flat and horny; flesh bright red, with minute florets. Soland. and Ellis.

A beautiful species, of a fiery red or flame-colour when recent; this kind inhabits the African coast, and appears to be found in most abundance near the Cape of Good Hope.

UMBRACULUM. Fan-shaped, and somewhat reticulated; branches numerous, divergent and round; flesh reddish, warted or covered with florets. Soland. and Ellis.

Native of the Indian sea; stem short, rising from a broad base, divided into about two or three branches, the smaller ones rising from which are numerous, and so intimately connected as to form a kind of net-work.

PURPUREA. Somewhat dichotomous, with divaricated slender branches; flesh violet and sub-verrucose. Pallas.

Round, smooth and blackish, with the extremities of the branches yellow. A South American species.

VOL. XVI.

SASAPPO. Sub-dichotomous, round, with divaricated slender branches; flesh red, with numerous hairy florets. Pallas. *Accarbaar sasappo f. virga sanguinea*, Rumpf.

About twelve inches in length, the texture horny, and colour black. The bernaclæ is frequently observed adhering to this species.

PALMA. Flat, with numerous very long and simple divisions; flesh smooth, sprinkled with simple pores. Pallas. *Chamaripha peregrina*, Clusius.

Grows to the height of six feet, though more commonly not exceeding two or three feet; the substance horny, covered with a calcareous coating, and flexible. Inhabits the Indian ocean.

RADICATA. Very much branched, and corky; with minute scattered pores, and many-cleft at the base. Pallas, Seba, &c.

Native of the African seas; sub-dichotomous, grey, with branched trunk, and in substance resembling cork.

SUBEROSA. Woody, very much branched, diffuse, the branches compressed and grooved, and covered with substellated scattered pores. Pallas.

Height three feet; flesh red, spongy; bone pale red and corky; branches long, round and erect. Found in the Indian and African seas.

CORALLOIDES. Woody, erect, sub-dichotomous, and variously formed; flesh tuberosus, with stellated tuberculated florets. Pallas. *Corallina lignum incrustans*, Boec.

Native of the Mediterranean; length one foot, very tough, pale grey, with yellow florets.

ELONGATA. Dichotomous, divaricated, with the flesh red, and covered with papillous scattered sub-imbricated pores. Gmel. &c.

Pale and brittle, with square branches with pores at the angles; grows to the height of four feet, and inhabits the Atlantic.

SCIRPEA. Very simple, straight, with a decomposite leafy base, and soft tuberculated flesh. Pallas.

Fuscous, tapering towards the tip; the flesh cinereous when dry; inhabits the Indian seas.

SETACEA. Simple, rigid, with calcareous white sub-tuberculated flesh. Pallas. *Ifidis plocanum*, Mercat.

Native of the American ocean.

VIMINALIS. Very long, depressed, branched, with erect sub-divisions; flesh yellow; florets seated along each margin of the branches, and rather prominent. Pallas. *Ifidis plocanum* II. &c. Mercat.

Height eight inches; branches long and slender; bone blackish and horny; florets white; the polype furnished with eight feelers or claws. Native of the Atlantic and Mediterranean.

MURICATA. Round, with depressed sub-divided branches; flesh thick; pores cylindrical and spinous. Pallas, Ellis, &c. *Epicorallum*, &c. Petiv. *Lithophyton*, Tournef.

Native of the American islands; height from two to three feet; coriaceous, horny, with a whitish medullary nerve.

VERRUCOSA. Bifarious, with round, sub-dichotomous flexuous branches; flesh calcareous, pores whitish and prominent. Pallas, Ellis, &c. *Lithophyton marimum*, Geln. *Corallina alba nodosa*, C. Bauh. *Frania marinus stabeliformis*, &c. Ray. *Erica marina*, &c. Petiv.

Inhabits the West Indian, Mediterranean, and rarely the British seas, adhering by the broad base of the principal trunk to the rocks, and rising to the height of twelve or

GORGONIA.

fifteen inches, and sometimes rather more, in a fan-like form; colour when dry greyish-white; bone of a texture between horn and wood.

ANTIPATHIS. Shrubby, with erect, alternate panicled branches; bone with flexuous striæ; flesh thick and smooth; pores large and scattered. Pallas, &c. *Antipathes*, &c. Lobel. *Corallium nigrum Dioscoridis*, ib. *Lithophyton nigrum arboreum*, Tournef. *Accabaar pohon*, Valent.

Grows to the height of two feet, and inhabits the Indian and Mediterranean seas. This is the black coral of the shops.

NOBILIS. Dichotomous, the branches somewhat tapering; flesh red, slippery, and soft; the surface speckled with numerous eight-valved, conic, and rather elevated, irregularly disposed pores; bone bright red, striated, and slightly punctured externally. Soland. and Ellis, &c. *Ips nobilis*, Linn. Syst. Nat. XII. *Madrepora rubra*, Linn. Syst. Nat. X. *Ips Pallas*. *Corallium rubrum*, Donat. *Red coral*, Ellis.

The bone of this species constitutes that beautiful and much esteemed marine production, the red, or true coral of the jewellers. The coral is a general inhabitant of the Mediterranean, Adriatic, and Red seas, and appears to be no where more abundant than in the sea about Marseilles, Corsica, Sicily, and the coast of Africa, in the vicinity of Barbary, the coral fisheries in those parts being carried on with great spirit, and proving highly lucrative. From the observations of Donati, an author who has devoted much attention to this curious subject of enquiry, we understand that the flesh or exterior coating of the coral is of a red colour, varying from bright to paler hues, the tint of which is uniformly less brilliant than that of the bone or coral itself. The most prevalent colour of the bone is red, exhibiting all the transitions from a pale rose colour to fine scarlet, and sometimes inclining to yellowish or fine saffron. The coral grows in a shrubby form, and not unfrequently in an inverted form, to the height of a foot or eighteen inches, which latter it rarely exceeds, nor is the circumference of the largest branches more than one inch. Externally the surface is striated, more or less nodulous or warted, and the substance when broken appearing composed of a number of concentric layers. The coral of this species is equal in hardness and durability to the most compact marble, and these material qualities, in addition to its beautiful texture or grain, and colour, have contributed to render it valuable in the estimation of the world from the earlier ages, as we learn from Pliny, and other writers of remote antiquity. At this day the true coral bears a considerable price throughout the East as well as in Europe; its supposed medicinal virtues have, however, fewer votaries at present than formerly. The polypes, by which the cells are occupied, are furnished each with eight arms or tentacula, in the centre of which the mouth is situated; these arms are retractile, contract immediately on being touched; the cells or pores are filled with a white liquor, and the polypes are likewise white.

ANGULIS. Panicled, sub-dichotomous; stem and branches compressed; flesh calcareous; margin porous. Gmel. Pallas, &c. *Sea willow*, Ellis. *Epicorallium virgulis alatis*, Petiv.

Inhabits the American, and some of the European seas: height nearly two feet; bone roundish, tapering to the ends, and violet when recent.

CRASSA. Round, dichotomous, with long, thick, divaricated, erect branches; flesh thick, violet, with small prominent, approximate, equidistant pores; bone dark brown and horny. Soland. and Ellis.

Native of the American seas.

PINNATA. Rather compressed and pinnated, with very

simple compressed branches; flesh red with oblong pores. Linn. *Palma pelagica*, Theophr. *Lithoxylon*, Breyn.

Grows to the height of from one to four feet; the texture horny and brown, the branches yellowish. Native of the African and North seas.

SANGUIOLENTA. Depressed, very ramose, and pinnated; flesh yellow, with purple pores in double rows. Pallas. *Lithophytum flavum punctatum*, Tournef.

Native of the Atlantic and Mediterranean seas; height one foot.

VIOLACEA. Rather depressed, with pinnated branches; flesh violet: nearly square, with somewhat prominent pores. Pallas. *Quercus marina*, Theophr.

Inhabits the American seas, above a foot long, and horny.

SETOSA. Round and pinnated, with diffuse branches; flesh purplish. *Antipathes hirsutum*, Pon. *Lithophytum*, Tournef.

Grows to the height of two feet; very upright, and inhabits the Mediterranean and American seas.

PETECHIZANS. Sub-dichotomous, very much branched, with a yellow bifurcated flesh covered with red pores. Pallas. Gmel. &c.

Native place unknown: bone horny, black, with amber-coloured ramifications.

PECTINATA. Round, with parallel ascending simple branches; flesh red, with gibbous scattered pores; bone white, hard, and brittle. Gmel.

Very rare, white, with red flesh; found in the Indian ocean.

ABIENTINA. Ramose pinnated; flesh yellow, with rows of purple florets each side; bone horny and yellowish. Soland. and Ellis.

Native of the African shores, and seldom exceeds a foot in height.

CALYCVLATA. Dichotomous and subdivided, with erect thick ramifications covered with truncated papillæ; flesh cinereous, within purplish; cells large and cup-shaped; bone dark brown and horny. Ellis.

Inhabits the American seas.

BRIAREUS. Subramose, round, thick; flesh pale or whitish within, externally cinereous; bone composed of small purple glassy needles, irregularly and closely disposed longitudinally. Soland. and Ellis.

Cells large, prominent, numerous, and irregularly disposed; the species inhabits the West Indies.

VENTALINA. Reticulated; branches compressed externally at the sides; bark red. Gmel. *Lithoxylon retiforme*, &c. Clifford Hort. *Gorgonia ventilabrum*, Pallas. *Flabella marina*, Rumpf.

Black or brown; the species inhabits the Indian ocean.

RETICULATUM. Reticulated, branches with very close set round ramifications, and red tuberculated bark.

Very ponderous, of a grey colour, and inhabits the Indian ocean.

CLATHRUS. Reticulated, woody; with round ramifications; flesh smooth with simple pores. Pallas.

Native place unknown; about eight or ten inches in height, pale, with a thin reddish-grey flesh.

FLABELLUM. Reticulated; branches compressed internally; flesh yellow. Gmel. *Gorgonia*, Pallas. *Flabellum veneris*, Ellis. *Frutex marinus*, Clusius. *Froncipora*, Bonann. *Keratophytum reticulatum*, Brown. *Arbre de mer*, Rochef.

The bone is black, horny, and slightly striated on the larger branches.

Found adhering to various substances, and varying in colour

colour from yellow to purple: this species inhabits moist seas.

GORGONIUM, in *Botany*, a name given by some authors to the common eryngium or eryngo, the roots of which we use candied.

GORGONS, in *Antiquity and Mythology*. Authors are not agreed in the account they give of the Gorgons. The poets represent them as three sisters, whose names were Stheno, Euryale, and Medusa, the daughters of Phorcus by Ceto; the latter of whom was mortal; and having been deflowered by Neptune, was killed by Perseus; the two former were subject neither to age nor death. They are described with wings on their shoulders, with serpents round their heads, their hands were of brass, and their teeth of a prodigious size; so that they were objects of terror to mankind. Æschylus, in his *Prometheus*, adds, that they had but one eye and one tooth among all the three, which they made use of one after the other, and that they killed men with a single glance of the eye.

Pindar (*Pyth.* 12.) improves upon Æschylus, and heightens the fable by these circumstances, unknown to his predecessors. The first is, that the Gorgons turned those into stone whom they looked upon, and that it was by this kind of death that Perseus, in presenting Medusa's head, desolated the island of Seriphus, whose inhabitants he petrified, together with their king. The second is, that Minerva, who aided Perseus while he was struggling with Medusa, being surpris'd with the melody of the Gorgons' sighs, intermingled with the hissings of their serpents, felt certain charms, in that mixed composition of doleful accents; and to renew the idea of the harmony, she invented a flute in imitation of it, which she imparted to men; and in allusion to its first model she called the various sounds it produced "a Harmony with many heads." The third is, that Pegasus, whom Hesiod represents as having taken flight to the mansion of the gods, was afterwards broke by Minerva, and given to Bellerophon, who mounted him to combat the Chimæra; but that hero having attempted to ascend to heaven on the wings of that horse, was thrown down to the earth, and Pegasus placed among the stars. (Pindar's *Ol.* iii. *Pyth.* vii.) The Latin poets, though faithful copiers of the Greek ones, have yet loaded the fable of the Gorgons with new circumstances. Homer had said, that the Gorgon's head was engraved upon the tremendous Ægis of Minerva: Virgil adds, and upon her cuirass too, in the place which covered the goddess's breast:

"—— Ipsamque in pectore Divæ
Gorgona defecto vertentem lumina collo." *Æn.* l. viii.

After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto:

"Multaque præterea variarum monstra ferarum—
Gorgones, Harpeiaque——" *Æn.* l. vi.

Ovid of all the poets has more enlarged upon the fable of the Gorgons, and added several particulars which are only found in his *Metamorphoses*, l. iv. and v.

Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women, who inhabited that part of Lybia which lay on the lake Tritonidis. The extermination of these female nations was not effected till Hercules undertook and performed it.

Pausanias says, the Gorgons were the daughters of Phorcus, probably by mistake for Phorcus; after whose death, Medusa his daughter reigned over the people dwelling near the lake Tritonidis. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries

quite waste. At last, Perseus having made war on them, and killed the queen herself, when he came to take a view of the field of battle, found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen, the Greeks, who could not behold it without being struck with astonishment.

Others represent them as a kind of monstrous women, covered with hair, who lived in woods and forests. Others, again, make them animals, resembling wild sheep, whose eyes had a poisonous and fatal influence.

Xenophon of Lampfacus, who is followed by Pliny and Solinus, was of opinion, that the Gorgons were female savages, who inhabited the islands Gorgades. Hanno, the Carthaginian general, penetrated as far as these islands, where he found women, who, in swiftness, outran the flight of birds. Gerard Vossius, in his "Origin and Progress of Idolatry," is persuaded, that the fable of the Gorgons took its rise from the relation of Hanno the Carthaginian general, above cited, from Xenophon of Lampfacus. Le Clerc, on the contrary, in his notes upon Hesiod, takes them for the mares of Lybia, which the Phœnicians in a voyage to Africa had taken away. Banier (*Mythol.* vol. iii.) is of opinion that the Gorgons dwelt in that part of Lybia, which was afterwards called Cyrenaicum; and that Phorcus, their father, had conquered Ithaca, which was not far from the coast of Africa, where he resided. It is not incredible that this prince would employ his fleet in carrying on an advantageous trade, and that Polydectes, king of Seriphus, in order to get rid of Perseus, gave him some ships for the purpose of pirating on the coasts of Africa. Perseus accordingly, thus equipped, sailed from the ile of Seriphus for the coast of Lybia, and having fallen in with the fleet of Phorcus, made himself master of some of his ships and a part of his riches. These ships, it is said, bore the names of Medusa, Stheno, and Euryale. They were loaded with the teeth of elephants, the horns of fishes, and the eyes of hyænas, which Phorcus bartered for other goods. This, it is said, is the mystery of the tooth, horn, and eye, which the Gorgons borrowed by turns; that is, the ships, when arrived in the port, took each of their goods proper for the place to which they were bound. The other fictions that accompany this history, says the author now cited, will explain themselves.

For a farther account of them, see *Mem. Acad. Inscript.* vol. iv. p. 72, seq. See *MEDUSÆ caput*.

GORGONZUOLO, in *Geography*, a town of Italy, in the department of the Olona; 10 miles N.E. of Milan.

GORGORA, an island of Abyssinia, in the lake Dembea (which see), where a palace was built, which is the usual residence of the emperor in winter.

GORHAM, a post town of America, in Cumberland county and state of Maine, on the N.E. side of Saco river. 130 miles N.E. from Boston: incorporated in 1764, and containing 2053 inhabitants.

GORIO, ANTHONY FRANCIS, in *Biography*, a learned antiquary of the eighteenth century, a native of Florence, was author of the following works, viz. "Musæum Florentinum," or a description of the cabinet of the Grand Duke, eleven volumes folio, with a great number of plates: "Musæum Etruscum," three volumes, folio. "Musæum Cortonense," folio. "Ancient Inscriptions in the Towns of Tuscany," three volumes folio.

GORITZ, or GORZ, in *Geography*, a country of Germany, in the circle of Austria; bounded to the N.E. and S. by the duchy of Carniola, and on the W. by the Venetian states. The chief produce of the country consists in wine and fruit, with some corn and silk; the horses and oxen are

few, but the goats are numerous. The language of the country is Slavonian, and the religion Roman Catholic.

GORITZ, or *Goritia*, a town of Germany, situated in the above-mentioned country, and divided into Upper and Lower town; the former is ancient, seated on a mountain, and defended by a castle; the latter is situated on a plain on the river Lifonzo. Besides the church, since the year 1784, not metropolitan, it has seven convents, nine chapels, and a college. In 1797 it was taken by the French; 20 miles N.N.W. of Trieste. N. lat. 46° 5'. E. long. 13° 33'.

GORITZ, a town of Brandenburg, in the New Mark, seated on the Oder, formerly the metropolis of the circle of Lebus.

GORKA, a town of Hindoostan, in Mewat; 12 miles S.S.W. of Cottilah.

GORKAH, a town of Asia, situated in the N.E. part of the small state so called, on the borders of Napaul; 35 miles N.W. of Catmandu. N. lat. 28° 25'. E. long. 84° 36'. The country lies between the province of Oude and Thibet, and is governed by a raja dependent of Thibet.—Also, a town of the duchy of Warfaw; 40 miles S. of Posen.

GORLÆUS, ABRAHAM, in *Biography*, a celebrated medallist, was born at Antwerp in 1549. He devoted himself entirely to the collection of ancient medals, seals, rings, and other curiosities. He died at Delft, where he spent the greatest part of his life, in the year 1609. His works are entitled "Dactylotheca seu Annulorum Sigillorumque e Ferro, Ære, Argento, atque Auro Promptuarium:" "The-saurus Numismatum familiarum Rom.:" "Paralipomena Numismatum." His works are highly valued by those who are addicted to these studies. Moreri.

GORLITZ, in *Geography*, a town of Upper Lusatia, seated on the river Neisse, and the first town in the county with regard to size, population, and wealth. Within the walls it has three churches, and as many without. The principal trade is brewing, with woollen and linen manufactures. 50 miles E. of Dresden. N. lat. 51° 9'. E. long. 15° 32'.

GOROCHOVETZ, a town of Russia, in the government of Vladimir; 72 miles E. of Vladimir. N. lat. 56° 10'. E. long. 42° 34'.

GORODITSCHKE, a town of Russia, in the government of Penza; 32 miles E.S.E. of Penza. N. lat. 53° 20'. E. long. 46° 34'.—Also, a town in the government of Kiev, 112 miles S.E. of Kiev. N. lat. 49°. E. long. 32° 54'.—Also, a town in the government of Tobolsk, 20 miles E.S.E. of Eniseisk.

GORODNIA, a town of Russia, in the government of Tver, on the Volga, 23 miles E. of Tver.

GORODNITZSK, a town of Russia, in the government of Tchernigof, on the Snov; 32 miles N.N.E. of Tchernigof.

GORODOK, a town of Russia, in the government of Poletsk; 36 miles E. of Poletsk. N. lat. 55° 36'. E. long. 29° 54'.

GORON, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Mayenne; 9 miles N.W. of Mayenne. The place contains 1800, and the canton 12,733 inhabitants, on a territory of 200 kilometres, in 11 communes.

GORONGO, a small island in the East Indian sea; 20 miles S. of Gilolo. S. lat. 1° 8'. E. long. 128° 33'.

GORONTAL, or GORONTANO, a town on the E. coast of the island of Celebes:

GORPETA, a town of Hindoostan, in Berar; 24 miles W. of Chandor.

GORRIS, JOHN DE, in *Biography*, was born at Paris in

the year 1505. He took the degree of doctor of physic in that city about 1540, and was appointed dean of the faculty in 1548. He is said to have possessed both the learning and sagacity requisite to form an accomplished physician, and to have practised with great humanity and success. His works contributed to support this reputation. The greater part of them consists of commentaries on different portions of the writings of Hippocrates, Galen, and Nicander. During the civil war, which was fatal to numerous men of letters, John de Gorris was stopped by a party of soldiers, when on his journey to Melan to visit the bishop of Paris, and the fright which he sustained is said to have deprived him of his reason. This occurred in 1561, and he lived many years in this deplorable condition, having died at Paris in 1577, at the age of 72.

His father, also John de Gorris, was a physician at Bourges, attained considerable eminence, and left two works, one on the general "practice of medicine," dated 1555; the other, a "collection of formulæ," 1560, both in Latin. Eloy Dict. Hist.

GORRITI, in *Geography*, a small island in the river La Plata.

GORSA, a small island near the S. coast of Cuba. N. lat. 21° 45'. W. long. 81° 25'.

GORSE. See FURZE and ULEX.

GORSIO, in *Geography*, a town of Sweden, in Helsingland; 30 miles W. of Hudwickswall.

GORT, a post town of Ireland, in the county of Galway. It stands on an eminence, and is a dirty straggling town, but can boast of a few good houses. Adjoining to it are the ruins of a castle, and near it is Kilmacduagh, the see of a bishop. Gort is 98 miles W. from Dublin.

GORTER, JOHN DE, in *Biography*, a physician, who, after having been a disciple of the celebrated Boerhaave, became a distinguished teacher of medicine at Harderwick, his native place; in consequence of which he was elected a member of the academies of Petersburg, Rome, and Haerlem, and obtained the title of physician to Elizabeth, empress of all the Russias. He was the author of several works, which are written with excellent method, and contain many interesting and original observations. He died on the 11th of September, 1762, at the age of 74.—His works, the titles of which are enumerated by Eloy, relate to physiological and practical subjects, as well as to the practice of the ancients. Eloy. Dict. Hist.

GORTERIA, in *Botany*, named by Linnæus after David De Gorter, professor of physic and botany in the Dutch university of Harderwick, author of several local Floras of that neighbourhood, and of *Elementa Botanica*. He died in 1783, aged 66. (Dryandr. Bibl. Banks. v. 5. 256.) Linn. Gen. 441. Schreb. 576. Willd. Sp. Pl. v. 3. 2265. Mart. Mill Dict. v. 2. Ait. Hort. Kew. v. 3. 254. Juss. 182. Gært. t. 171. Lamarck. Illustr. t. 702. (Gazania; Lamarck. Illustr. t. 702. Personaria; ibid. t. 716.) Class and order, *Syngenesia Polygamia-frustranea*. Nat. Ord. *Compositæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* of one leaf, imbricated with spinous scales, the innermost gradually longer, straight, bristle-shaped, rigid. *Cor.* compound, radiated. Florets of the disk numerous, perfect, with a funnel-shaped five-cleft corolla: those of the radius fewer, female, with a ligulate lanceolate onc. *Stam.* (in the perfect florets only) Filaments five, short; anthers united into a cylindrical tube. *Pist.* (of the perfect florets) Germen hairy; style thread-shaped, the length of its own little corolla; stigma cloven. In the female florets the germen is obsolete and abortive; style none; stigma none. *Peric.* none, except the calyx, falling-off

eff entire. Seeds to the perfect florets only, solitary, roundish. Down simple or woolly. Receptacle naked.

Eff. Ch. Receptacle naked. Down simple or woolly. Florets of the radius ligulate. Calyx of one leaf, clothed with imbricated scales.

All the plants ranged under this genus are natives of the Cape of Good Hope. In the 2d edition of Linnæus's *Species Plantarum*, where it first appears, are five; *personata*, Jacq. Coll. v. 4. t. 21. f. 1; *rigens*, Curt. Mag. t. 90; *squarrosa*, *ciliaris*, and *fruticosa*. The latter is the same plant as *G. asferoides*, Linn. Suppl. 381, but different from *Atractylis oppositifolia*, under which it is quoted in Syst. Veg. ed. 14. 730. To the above are added, in the Mantissa, p. 287, *G. setosa*; and in the Supplementum six more, *herbacea*, *bispida*, *spinosa*, *cernua*, *uniflora*, and *barbata*. Of these the *uniflora* is there suspected, we believe justly, to be a mere variety of *rigens*.

The genus thus understood undoubtedly forms a very unnatural assemblage, Linnæus having chiefly considered the simple-leaved calyx, as Gærtner long ago remarked. Willdenow accordingly has but seven *Gorteria*, the *personata*, *rigens*, and *cernua* of Linnæus, with *diffusa*, *int. grifolia*, *pechinata*, and *clivata* of Thunberg. Others are sent to his genera of *Musfonia*, whose receptacle is villous, and seed-down formed of simple hairs; and *Berebeya*, whose receptacle and seed-down are chaffy. Among the latter are the beautiful and truly wonderful *G. ciliaris*, and the *spinosa*; the latter figured in Jacq. Hort. Schönbr. t. 372. This is doubtless a great improvement, but it seems to us that the genus must, after all, chiefly depend on *G. personata*, which is an annual plant, of no beauty, with many spreading stems, about a foot high. Leaves alternate, spatulate, revolute, pinnatifid or undivided; very white and cottony beneath; and green and bristly, like the stems, above. Flowers solitary, terminal, small, yellow, with numerous prominent spines to the calyx. The seeds are crowned with wool, but have no proper pappus or seed-down. The leaves of *G. rigens* bear some analogy with this, but the large orange blossoms, unarmed calyx, and long simple seed-down, urge the propriety of separating it. The latter is Lamarck's *Gazania*, above quoted.

GORTYNA, or GORTYN, in *Ancient Geography*, an inland city of Crete, being, according to Strabo, near 90 furlongs distant from the African sea, or that part of the Mediterranean which washed the southern part of the island. Its origin is obscure, some ascribing it to Gortyn, the son of Rhadamanthus, and others to Taurus, who carried off Europa. In process of time, however, it eclipsed all the other cities of Crete, especially after the island was reduced by the Romans. Of its ancient splendour and magnificence we may form some judgment from its ruins, which are still visible about six miles from mount Ida; though many of them have been carried away by the Turks. In ancient times it was famous for the temples of Apollo, Diana, and Jupiter Hecatombræus, so called because Menelaus there sacrificed to Jupiter 100 oxen, when he received information of Helena's flight. Its walls were washed by the river Lethe. Theophrastus, Varro, and Pliny speak of a plane tree near Gortyna, which never shed its old leaves till new ones sprouted forth.

GORTYNIA, a town of Greece, in the northern part of Macedonia.

GORUAH, in *Geography*, a town of Hindoostan, in Bahar; 62 miles W.S.W. of Bahar.

GORY, a town of Georgia, in the province of Carduel, on the Kur; 45 miles W. of Tettis. N. lat. 41° 55'. E. long. 44° 30'.

GORZE, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Metz;

7 miles S.W. of Metz. N. lat. 49° 3'. E. long. 6° 4'. The place contains 1535, and the canton 14,278 inhabitants, on a territory of 220 kilometres, in 31 communes.

GORZEGNO, a town of France, in the department of the Stura, on the Bormida; 13 miles S.E. of Alba. N. lat. 44° 38'. E. long. 8° 17'.

GORZKE, a town of the principality of Magdeburg; 34 miles E. of Magdeburg.

GOSAYPOUR, a town of Hindoostan, in Allahabad; 13 miles N.W. of Jionpour.

GOSCHGOSCHUENK, a town of America, in the Delaware, consisting of three villages situated on the banks of the Ohio. Its name signifies "the habitation of owls," from the number of those birds that resort hither.

GOSCHUTZ, a town of Silesia, in the principality of Oels; 25 miles N.N.E. of Breslaw. N. lat. 51° 23'. E. long. 17° 30'.

GOSSELINI, JULIAN, in *Biography*, an Italian writer, was born at Rome in 1525, where he pursued his maturer studies in the house of the cardinal de Santa Fiora. When he was seventeen years of age he was taken into the service of Ferdinand Gonzaga, then viceroy of Sicily. He accompanied that nobleman to Milan in 1546, and became his secretary, and was afterwards taken to the court of Spain, where he obtained the esteem and favour of Philip II. Under the duke of Albuquerque he was imprisoned on a charge of conspiracy against the life of Giambatista Monti. He vindicated his own cause, was released, and admitted to public employment. He died in 1587, leaving behind him several works, that obtained for him high reputation: of these the principal are, "The Life of Ferdinand Gonzaga," "Three Conspiracies, &c." "Rime," or a collection of poems, several times reprinted. "Discourses." "Letters," &c. Bayle.

GOSFIELD, in *Geography*, a township of Essex county, in Upper Canada, situated upon lake Erie.

GOSHAWK, in *Ornithology*, the English name of the *FALCO palumbarius*; which see.

GOSHEN, in *Ancient Geography*, a territory of Egypt, situated between the Red sea and the Nile, upon the borders of Canaan, not far from On or Hieropolis, which Joseph obtained of Pharaoh for the residence of his father Jacob and family. This was a fertile spot of ground, and fit for cattle: and, therefore, as Josephus tells us, Pharaoh kept his own in that district. It was also separate from Egypt, and therefore fittest for Jacob and his family, which would be out of all danger of interfering with the Egyptians.

GOSHEN, in *Geography*, a township of America, in the county of Hampshire, and state of Massachusetts, between Cummington and Conway; 14 miles N. of Northampton; incorporated in 1781, and containing 724 inhabitants.—Also, a township in Vermont, lying partly in Addison county, and partly in Caledonia, adjoining to Salisbury on the west.—Also, a township in Cheller county, Pennsylvania, containing 966 inhabitants.—Also, a town in Litchfield county, Connecticut, famous for the production of excellent cheese, containing 1,493 inhabitants: 7 miles N.W. of Litchfield.—Also, the most considerable town in Orange county, New York; about 58 miles N. of New York city. Its situation is pleasant, and it contains about 60 or 70 compact houses, an academy, court-house, gaol, and Presbyterian church. The township contains 2563 inhabitants.—Also, a place in London county, Virginia, where is a post-office; 37 miles from Washington.—Also, a town in Kennebeck county, Maine, containing 270 inhabitants.

GOSTEN *Cr.ck.* a river of New Jersey, which runs into Delaware bay. N. lat. 39° 10'. W. long. 74° 54'.

GOSHIGOS-

GOSHOSBINK, a Moravian settlement in Pennsylvania, situated on Alleghany river, about 15 miles above fort Franklin.

GOSIR, a town of Arabia, in Hadramaut, near the coast; 75 miles S.W. of Keschim.

GOSLING, a town of Aultria; 12 miles S.E. of Bavarian Waidhoven.

GOSLINGS, the name given to young geese.

GOSPEL, a history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.

The word is Saxon, and of the same import with the Latin term *evangelium*, or the Greek *ευαγγελιον*, which signifies *glad tidings*, or *good news*; the history of our Saviour being the best history ever published to mankind. This history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John, who from thence are called Evangelists. (See each of these articles.) The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

We shall here subjoin the titles of some of the principal of these apocryphal gospels, as we find them in Jones's Canon, and Lardner's Works, with remarks that will serve to enable us to distinguish them from our four gospels, the authenticity of which is evinced under other articles in this work. (See BIBLE, CANON, and TESTAMENT.) Several of these spurious gospels are mentioned in the decree, ascribed to pope Gelasius, in the council of Rome, A. D. 494, which pronounced them to be apocryphal. The gospel of "Andrew the Apostle," is only mentioned in this decree. No fragments of it are extant, nor are there any testimonies concerning it. The gospel of "Apelles" is not mentioned by any writer before Jerom, who places it among the apocryphal pieces of the New Testament. Apelles was a disciple of Marcion, flourished about the year of Christ 180, and is supposed to have formed this gospel out of the true and genuine gospels for the use of his followers at the close of the second century. The gospel, "according to the twelve apostles," is mentioned by Origen, Ambrose, and Jerom, but they unanimously concur in rejecting it, and in expressly asserting that the church receives only four gospels. Jerom supposes this to have been the same with the gospel according to the Nazarenes. The gospel "according to St. Barnabas" is not noticed by any of the Christian writers of the first four centuries; nor do there seem to be any fragments extant, that unquestionably belong to it. Mr. Jones apprehends that this was merely some interpolated corrupted gospel of St. Matthew. The gospel of "Bartholomew" is mentioned by Jerom as apocryphal, and Jones, for reasons which he alleges, inclines to think, that it was the same with the gospel of St. Matthew, used by the Hebrews or Nazarenes. M. Daille is of opinion that it was forged but a very little time before Gelasius. The gospel of "Basilides" is named by Origen, Ambrose, and Jerom, among the apocryphal books of the New Testament; but no fragments of it remain. The gospel of "Cerinthus" is mentioned only by Epiphanius in connection with an exposition of the first words of St. Luke's gospel, as many other Christian writers notice the apocryphal books; and it seems probable, from the similarity of the opinions adopted by Cerinthus and the Ebionites, that the gospel of Cerinthus and his followers was no other than the Ebionite or Nazarene gospel, i. e. the gospel of St. Matthew corrupted and interpolated, in Hebrew. The gospel "according to the Egyptians," was one of the most celebrated apocryphal books, and supposed even by several modern critics to have been a faithful compo-

sure of some Catholic Christians in Egypt, before either of the four canonical gospels now received. The first Christian writer who cites it is Clemens Alexandrinus, who, however, rejects it, though some have supposed that a passage in the second epistle of Clemens Romanus to the Corinthians is taken from this gospel. It is mentioned by Origen, Jerom, and Epiphanius among apocryphal books. Many modern writers, as Erasmus, Grotius, Grabe, Mills, suppose, that it is referred to in the introduction to St. Luke's gospel, and therefore that it was prior to his; and Dupin and F. Simon think, that though it is not of the same authority with the four canonical gospels, it ought not to be rejected. Mr. Jones is of opinion, that it was composed by some very early heretics to support their doctrines of celibacy and abstemiousness, and very probably by those of Egypt; and Dr. Lardner thinks that it was not written before the third century. The gospel of the "Ebionites" was either altogether, or very nearly, the gospel of the Nazarenes. The gospel of the "Encratites" has been mentioned by Fabricius and some others, but there is reason for doubting whether any gospel was ever called by this name. The gospel of "Eve" has been mentioned by several modern writers, but only by Epiphanius among the ancients; it was, without doubt, a forgery of the Gnostics. The gospel of the "Hebrews" was the same with that of the Nazarenes. The gospels of "Hesychius" were some interpolated copies of our received gospels. The gospel of "Judas Icarion" is mentioned by Irenæus and Epiphanius as peculiar to one of the most monstrous and inconsistent sects that ever assumed the Christian name. The false gospels of "Lucianus," who was a famous critic and martyr under Dioclesian, were, like those last-mentioned, corrupted, interpolated copies of our present gospels. The gospel of "Matthias," of which there are now no remains, is mentioned by several of the most celebrated writers among the ancients, viz. Origen, Eusebius, Ambrose, and Jerom; but they all represent it as apocryphal. The gospel of "Marcion" is taken notice of by Tertullian and Epiphanius, but it appears to have been one of our own gospels, mutilated and altered; probably that of St. Luke, from which he took away entirely the two first chapters, and many other parts, inserting many things of his own, with a view to favour the opinions he had adopted. The gospel of the "Nazarenes" or "Hebrews" is the most famous of all the ancient gospels. Some have supposed that St. Paul refers to this gospel, Gal. i. 6. It is cited by Ignatius, as some have supposed, by Clemens Alexandrinus, by Origen, by Eusebius, by Epiphanius, by Jerom; and it is mentioned by Bede, Sixtus Senensis, Baronius, Casaubon, Grotius, F. Simon, Dupin, Grabe, Toland, Nye, Richard Mill, Fabricius, Mangey, and other modern writers. However it is alleged, that this gospel was never received by any primitive writer as canonical, nor was it cited or appealed to, as of any authority, by any one writer of the first four centuries; and moreover that it was composed out of St. Matthew's and the other authentic gospels, with additions of some other things received by oral tradition. It is allowed, that it was an early composition, and Mr. Jones says, that it was undoubtedly extant in the beginning of the second century, and seems to have been made by some converted Jews, to favour their notion of blending judaism and christianity together. "As many mistakes," says Dr. Lardner, "have been entertained about the 'gospel according to the Hebrews,' it may not be unreasonable to observe here, that probably it was an Hebrew translation of St. Matthew's original Greek gospel, with additions from the other gospels; to which possibly might be added some few particulars received by tradition from the early Jewish believers."

believers." (See EBIONITES and NAZARENES) This excellent writer elsewhere observes, it is not necessary for us to suppose, that the ancient fathers who mention other gospels, thought, "that all, if any of those gospels, were written before St. Luke's, or that he spoke of them; for Basilides and Apelles could not write gospels before the second century: and they might suppose, that several, if not all the others, mentioned by them, were written after St. Luke's. The meaning of what these ancient writers say is, that the church receives four gospels only. There were many others. But to them may be applied the words of St. Luke; they only took in hand, or attempted. They did not perform, as Matthew, and Mark, and Luke, and John did. And they might express themselves in that manner concerning gospels written after St. Luke's, as well as before it."

The gospel of "Peter" has been taken notice of by many of the ancient writers, as Serapion, Tertullian, Origen, Eusebius, and Jerom. Some have supposed, that this was the gospel of St. Mark, who was the companion of Peter, and wrote the gospel now extant under his name. But there is reason for believing that the gospel of Peter was different from that of St. Mark. It is not very certain by whom it was forged. Dr. Grabe, and after him, Dr. Mill, suppose it to have been made by Leucius, whom they reckon to have been a heretic of the second century; but Leucius did not live till the latter end of the third, or the beginning of the fourth century; whereas this gospel appears to have been extant in the second century, as we may infer from the account of it by Serapion, who was bishop of Antioch in the 11th year of the emperor Commodus, *i. e.* A.D. 190. Mr. Jones apprehends, that this gospel was composed by those ancient heretics in the second century, called *Docetæ* (see that article); and he conjectures that the gospel of Basilides above-mentioned, was either wholly, or in a great measure, the same with this apocryphal gospel under the name of Peter. The gospel of "Perfection" was one of the numerous forgeries of the Gnostics, who pretended to a greater perfection in knowledge and virtue than all others, and hence took their name. (See GNOSTICS.) The gospel of "Philip" was another forgery of the same persons. The gospel of "Scythianus" was composed by him who was the source and author of the Manichean heresy. The gospel of "Tatian" was no other but a harmony of four gospels, or a sort of epitome of the whole history contained in our four gospels. The gospel of "Thaddæus" is merely mentioned in the decree of pope Gelasius. The gospel of "Thomas," or the gospel of the "Infancy of our Saviour," is mentioned by Origen, Eusebius, Cyril, Ambrose, Athanasius, and Jerom, and is unquestionably apocryphal; though this is different from the gospel of Thomas, one of the followers of Manes, the head of the Manichees, for Origen, who mentions the former, lived a considerable time before the Manichean heresy was divulged. The gospel of "Truth" was a forgery of the Valentinians in the second century. This is supposed by some to be the same with the gospel of "Valentinus," but others are of opinion that he had a gospel of his own, different from that called the gospel of Truth used by his followers. For further particulars we refer to Jones's Canon and Lardner's Works.

GOSPINI, in *Geography*, a town of the island of Sardinia; 24 miles S. of Oristagni.

GOSPORT, is a sea-port town of Hampshire, England. In the time of king Henry VIII., when Leland visited this part of the island, Gosport was only a poor village inhabited by fishermen, but it has gradually become a town of considerable extent and importance; and of late years has been

regularly fortified on the land side by a line of bastions, redoubts, counterescarpes, &c. that extends from Weovil to Stoke, or more properly, Alverstoke lake. Within the works on the Weovil side, are the king's brewery and cooperage, with an immense range of storehouses for wine, malt, hops, &c. This place communicates with the sea by means of a large basin and canal, with extensive quays, where vessels of considerable burthen can take in their stores. Many small sloops belonging to Weovil are employed in the conveyance of wine, beer, and water, to the ships in the harbour. On the Weovil side are also the new barracks, an extensive range of buildings, with every convenience for a great number of soldiers. Gosport, considered as a sea-port, is handsomely built, and the police well regulated. The town is a chapelry to the neighbouring village of Alverstoke: the chapel is a spacious edifice, standing in a large well-planted cemetery, to the south of the town; the interior is neat, and disposed into a middle and two side aisles. The work-house for the poor is a large, airy, and commodious building. Here are also several charity-schools; and some alms-houses for distressed widows. The markets are held three days weekly, and are much frequented: fish and vegetables are sold in great abundance; the latter being brought, not only from a considerable distance inland, but also from the Isle of Wight. Two fairs are held annually. Several breweries are established; and a very extensive iron foundery, where numerous articles are manufactured for government. Gosport is 78 miles distant from London: the population of the parish of Alverstoke, including the inhabitants of this town, was returned, under the act of 1801, at 11,295; the number of houses being 1906. The connection between Gosport and Portsmouth is preserved by numerous ferry-boats that ply across the harbour, which in this place is about three quarters of a mile in width.

At a small distance south of Gosport, is the Royal Hospital of Hasler, built between the years 1746 and 1762, for the reception of sick and wounded seamen, on the earnest recommendation of the late earl of Sandwich. It is situated within 400 yards of the extremity of the point of land which bounds the west side of the entrance to Portsmouth harbour; and consists of an extensive front, and two wings, each comprising two distinct ranges of buildings. In this hospital upwards of 2000 patients can be accommodated; the regular expence of the establishment in salaries, &c. is above 5000*l.* annually.

Nearly a mile south-west from Hasler hospital is Fort Monkton, a modern and regular fortification, exceedingly strong, and defended by thirty-two pieces of heavy ordnance; to the westward, ranges a strong redoubt; and this, together with the fort, effectually secures this part of the coast. On the shore, to the eastward, a high and massive stone wall has been erected, to preserve the land from the ravages of the sea.

Near the extremity of the neck of land which terminates the entrance of the harbour on the east side, is the Black house, a very strong fort, defended by a formidable battery. *Beauties of England and Wales, vol. vi.*

GOSPORT, formerly called *Appledore*, a fishing town of America, on Star Island, belonging to Rockingham county, New Hampshire, containing 85 inhabitants; about 12 miles E. S. E. of Piscataqua harbour.

GOSS, in *Rural Economy*, a term occasionally applied to the common woad in different places, and which is sometimes written *gorse*. See FURZE.

GOSSAINGUNGE, in *Geography*, a town of Hindoostan, in Oude; 15 miles S. E. of Lucknow.

GOSSAMER is the name of a fine filmy substance, like cobwebs,

cobwebs, which is seen to float in the air, in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSAMPINUS, a name given by Pliny and the ancients to a tree growing in the East Indies, which produced a sort of cotton, the threads of which were too short to be spun or carded; so that it served only for the stuffings of beds and the like, for which it was very proper, being very light and soft. It was in some esteem in medicine also, to recal the heat and spirits into parts to which it was applied. It is called by Piso *arbor lanigera*, the wool-tree, and had its ancient name from the words *gossypium*, cotton, and *pinus*, the pine-tree, being somewhat like the pine in external appearance, yet bearing a sort of cotton.

GOSSE-ABDIAH, in *Geography*, a town of Nubia, on the Tacazé; 90 miles S. of Jalac.

GOSSEC, M. in *Biography*, a voluminous French musical composer of the old school, almost the only lineal descendant of Lulli and Rameau. He had force, fire, and knowledge; but his style was not that of the present day, either in Italy or Germany, nor could his friend, M. La-borde, persuade us, that "true genius is in need of no school or model. In whatever nation a man of genius may be born, he will make himself known, and not march with less firmness, though without a guide, in the road to glory. Celebrated schools cannot give genius, that is the boon of nature, and nature wants no school." *Essais sur la Mus.*

Unluckily, nature alone has never made an artist. A good painter, poet, or musician, can never be made without education, study, and models. Ingenious works have been produced by dint of genius, but never faultless. The awkwardness of self teaching will always appear; and taste, elegance, facility, grace, and often learning, will be wanting to render them perfect.

GOSSEINS, in *Geography*, a town of Thibet, on the Dewah. N. lat. 30° 30'. E. long. 81° 24'.

GOSSELIES, a town of France, in the department of Jemmapes, and chief place of a canton, in the district of Charleroy. The place contains 2872, and the canton 12,894 inhabitants, on a territory of 100 kilometres, in 17 communes.

GOSSIPIUM. See **GOSSYPIMUM**.

GOSSLAR, in *Geography*, a town of the kingdom of Westphalia, on the Gose, which runs near this place into the Oekar. It was a free and imperial town, having on one side the bishopric of Hildesheim, and on the other the principality of Wolfenbuttle. It was founded in the year 922, by Henry the Fowler, and part of it re-built after being destroyed by fire in 1728. It has four parish churches, two chapels, and two Lutheran convents. Its principal trade arises from the mines of iron and lead in the Rammel mountain near it; 30 miles S. of Brunswick. N. lat. 51° 55'. E. long. 10° 26'.

GOSSUM, a swelling of the thyroid gland. See **BRONCHOCELE**.

GOSSWEINSTEIN, or **GOSSMANSTEIN**, in *Geography*, a town of the bishopric of Bamberg, on the Putlach, 20 miles E. S. E. of Bamberg. N. lat. 49° 45'. E. long. 11° 10'.

GOSSYPIMUM, in *Botany*, the Cotton plant. The name is supposed by the learned to be of Egyptian origin, and if so, is akin to *Cotnemesgiar*, or *Gotnemesgiar*, the evident source of our word Cotton, which is given as the Egyptian appellation of the plant in Alpinus, de Plantis

Ægypti, 71. Pliny makes it a Latin word, though the more common name he says is Xylon; the Greek *ξύλον*.—Linn. Gen. 355. Schreb. 468. Willd. Sp. Pl. v. 3 803. Cavan. Diss. fasc. 6. 309. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 453. Juss. 274. Lamarck. Illustr. t. 586. Gærtn. t. 134. (Xylon; Tourn. t. 27.)—Class and order, *Monadelphia Polyandria*. Nat. Ord. *Columnifera*, Linn. *Malvaceæ*, Juss.

Gen. Ch. Cal. Perianth double: the outer of one leaf, three-cleft, flattish, largest: inner of one leaf, cup-shaped, with five blunt notches. *Cor.* Petals five, inversely heart-shaped, flat, spreading, attached to the tube of the stamens by their base. *Stam.* Filaments numerous, connected in their lower part into a tube, separate and lax above, inserted into the corolla; anthers kidney-shaped. *Pist.* Germen superior, roundish; style columnar, as long as the stamens; stigmas three or four, oblong, thickish. *Peric.* Capsule roundish, pointed, with three or four cells and as many valves, with contrary partitions. *Seeds* numerous, oval, fringed and enveloped with long wool.

Ess. Ch. Calyx double; the outer three-cleft. Capsule with three or four cells. Seeds enveloped in wool.

The species of Cotton, like those of all plants cultivated from the most remote antiquity, in various countries, for economical purposes, are extremely difficult to define, and obscured by numerous varieties.

Linnaeus in Sp. Pl. ed. 1, defines three species only,

1. *G. herbaceum*. Camer. Epit. 203. Cavan. t. 164. f. 2, supposed to be a native of the Levant, East Indies, and Africa, and generally cultivated in those countries for its produce.—Leaves five-lobed, pointed, with one gland beneath. Stem herbaceous, nearly smooth.—This is annual, with a bushy, branched, often zig-zag stem, smooth or only slightly downy. *Leaves* cut half-way down into three principal, and two smaller lateral, pointed rounded lobes. The mid-rib bears one gland at its back, about half an inch from the stalk. *Flowers* yellow, purple at the base. *Capsule* the size of a walnut, enveloped in the calyx like a filbert.

2. *G. barbadense*, taken up from Plukenet, t. 188. f. 1. Leaves three-lobed, entire, with three glands beneath.—Supposed to be a native of Barbadoes. It is at least one of those cultivated in the West Indies. The plant is in all its parts larger than the foregoing; lobes of the *leaves* not near so deep.

3. *G. arboreum*. Cavan. t. 165. Pluk. t. 188. f. 3. (Cudu-pariti; Rheede Hort. Mal. v. 1. 55. t. 31.)—Leaves palmate, five-lobed; lobes lanceolate. Stem shrubby.—Native of the East Indies in a sandy soil. The woody perennial stem, and deep-cut long-lobed leaves, whose mid-rib bears one gland, distinguish this. The flowers are reddish. The cotton is used in manufactures. Willdenow erroneously quotes Alpinus here.

His *Cotnemesgiar* is in the Plant. Ægypt. t. 71, not his Exot. t. 38, and does not agree with the East Indian plant.

To these is added in Sp. Pl. ed. 2. 975,

4. *G. hirsutum*. Cavan. t. 167. Leaves with three or five acute lobes. Stem branched, hairy.—The synonym of Tournefort is wrong.—This is said to come from America. It appears to us a hairy variety of the first, for the gland on the mid-rib, which Linnaeus thought an exclusive mark of *hirsutum*, is found in both.

What Linnaeus intended by *G. religiosum*, Syst. Nat. ed. 12. v. 2. 462, is rather doubtful. He defines it—"Leaves three-lobed, acute, with one gland beneath. Branches dotted with black."—We have an East Indian plant which answers to this definition, but it does not exactly agree

agree with what he has marked *religiosum* in his own herbarium, which appears to us *barbadense*; though it may be what he had in his garden.

With the *latifolium* of Murray, Comm. Gott. for 1776. t. 1, we are unacquainted—Cavanilles figures and describes several more species, especially *G. vitifolium*, t. 166, a noble plant, from Commerçon's herbarium, gathered in the Mauritius.—Willdenow, adopting these, reckons ten species in all, but the synonyms of the whole genus require revision.

GOSTADT, JOTTSTADT, or *Josephstadt*, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 23 miles S. of Chemnitz. N. lat. 50° 26'. E. long. 13° 2'.

GOSTIN, a town of the duchy of Warlaw; 48 miles N.N.W. of Rawa.

GOSYTULLA, a town of Bengal; 22 miles E. of Kishenagar.

GOTARA, a town of Hindoostan, in Bahar; 57 miles S.S.W. of Patna.

GOTERON, a valley of Switzerland, in the canton of Friburgh, on the N.W. of the town of Friburgh, near the bridge leading to Bern, takes its name from the Goteron, a small rivulet; it is extremely narrow, and above two miles in length, and is bounded on each side by overhanging rocks of sandstone. Vernet, the celebrated landscape painter, studied these rocks with great attention, and frequently declared that, excepting those of Tivoli, he never saw any whose varying tints had a more pleasing and harmonious effect. The valley contains several mills, an iron foundery, where the ore brought from Franche Comté is forged, and a manufacture of linen and cotton, established by some merchants of Neuchatel, under the protection and encouragement of government.

GOTH, STEPHEN, in *Biography*, archbishop of Upsal, in Sweden, in the 16th century, concurred in the measures adopted by king John, to restore and re-establish popery in that kingdom. With this view he sanctioned a new liturgy, which, under the pretence of bringing the Lutheran church nearer to the simplicity of the earlier ages of the gospel, artfully assimilated the doctrines and ceremonies of worship to those of Rome, with the omission of some particular forms and expressions which would have too plainly disclosed the object in view. This liturgy was ordered to be used in all the churches. The king's brother Charles, and the clergy within his jurisdiction, were alarmed at this attempt, and they so effectually roused the jealousy and excited the fears of the people, and of the states, that after repeated efforts to carry his point, which introduced great confusion into the kingdom, and had nearly produced a civil war, the king was obliged to relinquish his scheme, and the liturgy was suppressed. It has long since become an object of curiosity among collectors, and is entitled "Liturgia Suecane Ecclésiæ cum præfatione et notis Laurentii Upsaliensis Episcopi," 1576. Univer. Hist.

GOTHA, in *Geography*, a principality of Germany, in the circle of Upper Saxony, bounded on the N. by the electorate of Saxony, on the E. by the duchy of Weimar, on the S. by the county of Henneberg, and on the W. by the principality of Eisenach. The duchy contains 12 towns, and more than 200 churches: it abounds in grain and fruit, and the southern division contains part of the forest of Thuringia, and some mine works. The state consists of three classes, *viz.* counts, nobility, and some barons, convoked by the prince. The reigning duke maintains a guard of 1600 men, two regiments, each of which is composed of 800 men, and a corps of artillery. The chief rivers are the Leine and the Neisse.

The capital of the principality of the same name is seated

on an eminence near the Leine, which supplies the town with water, conveyed by stone-canals, and is among the best and handsomest towns in Thuringia. It has an hospital for the soldiers, two schools for their children, and barracks, in which the military art is taught: it has likewise a foundery for cannon, balls, &c. two churches, a good academy, a house of correction, an hospital for widows, and another for orphans. The inhabitants carry on a considerable trade in wool and woollen manufactures, and beer; and they derive benefit, not only from the agriculture of the vicinity, but from the passengers that traverse through it from Leipsick to Upper Germany. The residence of the duke, called Friedenstein, stands on a hill above the town, and contains an armoury, a valuable library, a museum of natural curiosities, and an excellent cabinet of medals; 13 miles S.W. of Erfurt. N. lat. 50° 57'. E. long. 10° 40'.

GOTHA, a river of Sweden, which issues from the southern extremity of the lake Wenner, near Wennerborg, and after a course of 70 miles, falls into the sea near Gotheborg. In most places this river flows with a gentle current and in a narrow channel, and is navigable only in some parts of its course for small craft of 20 tons burden. If it could be rendered navigable through its whole course, the Wenner lake might be joined with the German ocean; but as numerous shoals and cataracts intervene, the communication has been attempted by the Carlgraf canal, the canal of Trollhætta, and the sluices of Akerström and Edet. About 10 miles from Gotheborg the river Gotha divides into three branches: two unite again after encircling a small rocky island, crowned with the fort of Bolus, formerly deemed impregnable; the stream formed by the union of the two branches is called the Northern river, and falls into the sea after a course of 10 miles. The third branch retains the original name of Gotha; and the space included between the Northern river and the Gotha is named the island of Hisingen.

GOTHARD, ST., a town of Hungary, near which the Turks were defeated by the Christians, in the year 1664; 21 miles W. of St. Croit.

GOTHARD, ST. a chain of mountains of Switzerland, in the canton of Uri, the summit of which rises above the sea 9075 feet, though some have estimated its height to be much greater. The particular parts of this chain are called by different names; of which the principal are the Salla, Profa, and Surecha, to the east; the Feudo, the Patina, and the Locendro, to the west; to the north, the Ursino; and to the south, the ridge of naked and piked rocks of the Val-Maggia. Of these, the Feudo is the highest. There are six pastures on the neighbouring heights, on which are fed 200 cows, 150 goats, and 30 horses. The river Tesino has three principal sources in the chain of St. Gothard: the first is a spring near the foot of the Profa, the second is the lake of La Salla, in another part of the eastern chain, and the third is furnished by the snows of mount Feudo. These three sources uniting with another branch, that flows from the Furca, through the valley of Bedneto, form one great current, which takes its course towards the south, enters the lake of Locerno, and traversing part of the Milanese, falls into the Po. The source of the Reufs is the lake of Locendro, an oblong piece of water, about three miles in circumference, stretching between the mountains of Patina and Locendro, and almost entirely supplied by the numerous glaciers which crown the summit of the Locendro. The waters issuing from this lake rush down the valley of St. Gothard, and joining in the vale of Ursinen, the two branches which come from the Furca on one side, and from the Grison mountains on the other, flow towards the north into the lake of Lu-

cern, and from thence throws itself into the Aar. The valley of St. Gothard is exceedingly dreary. It does not contain a single shed, nor produce a single tree; and the sides of the mountains are barely sprinkled with short herbage.

Mount St. Gothard affords one of the best Alpine passages from Germany and Switzerland to Italy. The Romans were acquainted only with that over the Great Bernhard and Septimer. The Gothard was called by them sometimes Adula, sometimes the *High* and *Leventine Alps*. The present road over this mountain begins at the village Hospital, in the Urfern valley, and terminates on the south side, at Airolo: its breadth is from ten to twelve feet, and it is covered with large pieces of granite.

The first attempt of passing over the Gothard in a travelling carriage, was successfully made in the month of July, 1775, by the late Mr. Greville, the gentleman to whose early exertion in collecting and in employing persons well qualified to assist him, we owe the extensive assemblage of minerals lately purchased by government for the British museum.

Though, in the high Gothard valley, the temperature is seldom below 19° of Reaumur, yet, on the N. side of the mountain, the climate is sufficiently rough to make the growth of trees cease at the height of 4566 feet. Among a vast number of plants common to the Alps in general, we find here, as peculiar to mount Gothard, the *Viola minima*, and *Campanula patula*.

But most interesting is this mountain in regard to its mineral substances, and its geognostic structure in general: for, respecting the former, it may be said, that there is scarcely any where a tract of country known, that, within the same extent of space, affords so considerable a variety of them. This is not the place for enumerating all these fossils; we should, however, not omit mentioning, that the *tremolite*, which has received its name from the valley of Tremola, is, according to Ebel, not found there, but deeper down the mountain, in the Leventine valley. See TREMOLITE.

The St. Gothard consists entirely of primitive rocks, which, however, display great variety in their mixture. On the N. side veined granite, gneiss, mica-slate; in the plain of the rocky valley, where the Hospitium stands, granite of large grain, traversed by beds of veined granite and mica-slate; from the summit downwards, on the S. side, massive granite of large and small grain alternately, veined granite, mica-slate; in the Tremola valley, on the Fiado and Soreseia, hornblende-slate commences, mixed in some places with fine granular quartz, in others with feldspar, and lower down with fine reddish-brown, dodecahedral garnets; over which beautiful rock the road winds, through the Piostella forest, down to Airolo. On the N. side, in the Urfern valley, among the just mentioned rocks, runs pot-stone on the S.S.E. part of the valley, and on the N.N.W. primitive lime-stone and clay-slate; while the S. side in the Leventine, Canaria, and Piora valleys, exhibits primitive lime-stone and gypsum.

All rocks of the Gothard are disposed in strata, having a direction from E.N.E. to W.S.W., and from N.E. to S.W. which is best observed between Hospital and Airolo, where the road makes a transversal section, almost through the whole of the central chain. The regularity of the stratification of the granite is most striking in the neighbourhood of the Rudant bridge: the strata are from three to four inches thick, and have their direction from N.E. to S.W. Likewise, on the Prosa and Fiado, and southward from Hospital down the valley of Tremola, the primitive lime-stone and gypsum, which pass on the S. side of the mountain through the Leventine, Canaria, and Piora valleys, and the lime-stone, clay-slate, and pot-stone, seen on its N. side,

in the Urfern valley, are the continuations of the same formations that range through the whole of the Pays de Vaud.

The ridges of mountains constituting the Gothard are exceedingly broken, and bear the marks of causes the most destructive; nor is it improbable that they were infinitely higher in ancient times, and that, at the period of the Romans, they were not unaptly called the *Highest Alps*. The upper rocky valley, where the Hospitium is situated, is covered with numberless pieces of rocks, which are all precipitated from the surrounding peaks. The great proportion of a small grained granite, among the rocks of the Gothard, are the probable causes of this extraordinary devastation. The upper, nearly circular, rocky valley, was in former times completely shut on all sides: the remains of the rocks that formerly filled the chasms are still distinctly seen on the N. side, near the bridge over the Rudant, where the Reufs forms a beautiful fall; and on the S. side, below the Hospitium, the rocks approach each other so closely, that the violent action which produced the present chasms is sufficiently evident. Before that revolution happened, it is highly probable that this considerable valley formed a deep lake; nor is it less so, that the Urfern-valley, before the Devil's mountain was broken through, and the upper Leventine valley, before the Platifer, near Dazeo Grande, was rent asunder, represented deep seas of considerable extent.

GOTHEBORG, a town of Sweden, in West Gothland, distinguished by a commodious port, and standing near the scite of Lodefe, a town built by Gustavus Vasa, which, being endowed with singular privileges, soon became the great emporium for the trade of the western provinces. Charles IX., when duke of Gothland, having, in 1604, laid the foundations of a new town in the island of Hisingen, not far from Lodefe, called it Gotheborg, in honour of his duchy. On his accession to the throne, he erected in his new town a trading company; drew thither many foreigners, particularly the Dutch, to whom he allowed an exemption from all duties of export and import during twenty years; established a corps of English and Scots troops, and granted to the Calvinists the free exercise of their religion, the first place in Sweden where this toleration was permitted. By these means Gotheborg soon became a flourishing port, and, next to Stockholm, the most commercial town in Sweden. In 1611 it was reduced to ashes by the Danes, and afterwards rebuilt in the reign of Gustavus Adolphus on the present scite, and obtained a confirmation of its ancient rights, with a grant of several new privileges.

Gotheborg is built in a singular situation. At a small distance from the sea is a marshy plain, not more than half a mile in breadth, watered by the rivers Gotha and Moldal, and almost inclosed with high ridges of bare and rugged rocks. Gotheborg stands partly on the ridges, and partly in the plain, and is divided into the upper and lower town. The latter is entirely level, intersected by several canals, and the houses are constructed on piles: the upper part hangs on the declivities, and rows of buildings rise one above the other like the seats of an amphitheatre. The whole is regularly fortified; and the circumference is near three miles, exclusive of the suburbs, called "Haga," which lie towards the harbour. The streets are uniformly straight; some few of the houses are of brick, but most of them are constructed of wood, painted red. The harbour, formed by two chairs of rocks, is about a quarter of a mile in breadth; and the entrance is defended by the fort of New Elfsborg, which stands on a small rocky island, and contains a garrison of 250 men.

A royal society of sciences and literature has been lately established

established in this town, on the plan of that of Upsal. The acts, written in the Swedish tongue, and printed in 8vo. contain disquisitions on various subjects, in the several branches of science, natural history, antiquities, history, and polite letters. The population amounts to 20,000 persons, in consequence of an increase, occasioned by the extension of its commerce, particularly on account of the East India company, and the success of the herring fishery. The East India company was established in 1731, and on account of the ice, which closes the port of Stockholm, in the gulf of Bothnia, at the proper season of the departure of ships for the East Indies, the company carries on its commerce from Gotheborg, whose harbour, lying in the German ocean, is more open. In 1740, the herrings, which had not hitherto usually approached the western shore of Sweden, flocking in shoals, the inhabitants of Gotheborg established a fishery, which has been very lucrative. The fishery begins in November, and though it continues scarcely three weeks, it supplies the fishermen of Gotheborg with not less than 600,000 barrels. Of these, 200,000 are salted, and train-oil is drawn from the remainder; fifteen barrels of herrings yielding one of oil, which is principally exported to Holland and Spain. One barrel of salt, procured from Spain, cures three barrels of herrings: the average exportation of salted herrings may be estimated at 150,000 barrels, and the inland consumption of Sweden at 50,000. An English consul and factory reside at Gotheborg; and a chapel, with a regular chaplain, is appropriated for their use. The fortifications of Gotheborg are so weak, that in the year 1788 it must have fallen into the hands of the Danes, if foreign powers had not interfered. N. lat. 57° 40'. E. long. 11° 44'. Coxe's Travels in Sweden.

GOTHIC, or **GOTICK**, something that has a relation to the Goths, an ancient people, originally inhabiting that part of Sweden called Gothland; whence they spread themselves over Greece, Dalmatia, Bulgaria, Italy, Spain, &c. See **GOTHIS**.

Gothic Architecture, a term of reproach to denote one or more kinds of architecture which prevailed during the middle ages. It seems to have been invented by the restorers of the Grecian orders in Italy, about the middle of the 16th century, to signify every preceding species of European architecture not conformable to them, and it was imported in the same sense into England by Mr. Evelyn and sir Christopher Wren, though the latter appears sometimes to confine the term to the pointed style, in which particular he is followed by the greater part of late writers. Mr. Evelyn, quoted by sir Christopher Wren, in his "Parentalia," says: "Gothic architecture is a congeries of heavy, dark, melancholy, monkish piles." In the same sense, sir Christopher himself, speaking generally of what he terms Gothic architecture, calls it "Mountains of stone; vast, gigantic buildings, but not worthy the name of architecture. This we now call the Gothic manner: so the Italians called what was not after the Roman style." In opposition to the idea which this eminent architect here gives of the architecture in question, he, in another part of his Parentalia, describes the inventors of it as "setting up slender and mis-shapen pillars, or rather bundles of staves and other incongruous props, to support ponderous arched roofs without entablature." In conformity with this latter notion of sir Christopher, Mr. Rions, a professional writer, says: "Modern Gothic is distinguished by the lightness of its work, the excessive boldness of its elevations and of its sections, by the delicacy, profusion, and extravagant fancy of its ornaments." The same confusion of language, if not of ideas, prevails amongst the admirers of the Gothic style, so called, as

amongst the declared foes of it. The late poet laureat, Thomas Warton, who has written a great deal on the subject, and who had planned a "History of Gothic Architecture," speaking of Salisbury cathedral, expressly denies that it is in the Gothic style, while two other celebrated writers in the same line, the Rev. James Bannham and Capt. Grofs, as positively affirm that this cathedral is "entirely in the Gothic style." The perplexity and uncertainty of an ordinary reader must necessarily be increased by the different senses in which the terms, ancient architecture, modern architecture, Saxon architecture, Norman architecture, and English architecture, are now used by different writers. To clear up this confusion, and to present distinct and clear ideas on these much agitated subjects, it seems best to treat them in an historical manner.

It is demonstrable that the regular orders of Grecian architecture were upon the decline throughout the Roman empire after the reign of the Cæsars, and still more so after that of Constantine the Great. A century later the Ostrogoths over-ran and subdued Italy, the Visigoths, Spain, the Huns, Germany, the Vandals, the Roman provinces of Africa, the Franks, France, and the Saxons, Britain. These several barbarians destroyed innumerable monuments of architecture as well as of the other arts, but they none of them introduced a style of building different from that which they found practised in the conquered countries. They did not instruct the ancient inhabitants to build in a new manner; on the contrary, they learnt of them so much of the art as they actually acquired. But the art itself being vastly degraded in the fifth and sixth centuries, and those warlike hordes not being very apt scholars, wonder their first structures were executed in a rude and heavy style. Still nothing is more groundless than to speak of Gothic architecture in the manner of Mr. Evelyn and sir Christopher Wren, as of a style of building invented or introduced by the Goths. The fact is, the heavy circular manner of building which prevailed throughout Christendom, from the fall of the Roman empire, in the fifth century, down to the twelfth century, was the Roman, or, what is the same thing, the Grecian style, incorrectly and rudely executed. Amongst us it is called the Saxon style, because it prevailed during what is called the Saxon period or dynasty in South Britain; but the first teachers and the models of it were both of them strictly Roman.

On the first introduction of Christianity amongst our Saxon ancestors, at the conclusion of the sixth century, they consecrated many of the existing Pagan temples to the Christian worship, according to the instructions which they received to this effect from pope Gregory the Great, and they ran up other temporary oratories of wood or wattles, as we learn from Bede, and other original historians. Very soon, however, the same Roman missionaries, who converted them, taught them to build churches of stone after the Roman manner; for this denomination of it, *the Roman manner*, (*more Romano*,) is always mentioned by the aforesaid historians. The first archbishop of the Northumbrians, Paulinus, who was a Roman monk, appears to have been the chief architect amongst the English Saxons at the beginning of the seventh century. He built churches of stone at York, Lincoln, and other places. His next successor but one, Wilfrid, was an Englishman, who not only equalled but greatly surpassed his master in architecture. For the churches which he built at Rippon and at Hexham were long celebrated for being the finest buildings of their kind north of the Alps: but then it is expressly recorded, both of him, and his rival in architecture, Benedict Biscop, abbot and founder of the church and monastery of Wearmouth;

GOTHIC ARCHITECTURE.

mouth, that they made different journeys to Rome, and studied the architecture of the church of St. Peter's and other churches there, and that they even hired workmen from thence to execute their works in England. Thus it evidently appears, that the style of architecture, which is called the Saxon style, was not the invention of our ancestors, but was imported from Italy in the seventh century; and it is equally evident, from various monuments, that the Italians in this and the subsequent ages built in the same heavy manner, and made use of the same members and ornaments, that the English Saxons did. Still the architecture of our ancestors, previously to the conquest, though very heavy and rude, has been too much depreciated by many English writers. The Rev. Mr. Bentham, in his "History of the Church of Ely," or rather the poet Gray, who drew up the architectural part of that work, refutes Somner, Staveley, and other authors, who deny that the Saxon builders made use of stone for their buildings, or knew how to turn an arch; but then this very writer fails to do them the justice due to them, where he signifies that they were unacquainted with the use of towers, bells, and transepts, previously to the tenth century. It would have been strange if they had not imported these amongst other ecclesiastical inventions from Italy during the preceding centuries; but we have otherwise sufficient proofs that they had adopted each of them long before the tenth century.

During a great part of the ninth and tenth centuries, England and France were as much harassed by invasions of the Northern barbarians, as their former inhabitants, the Gauls and Britons, had been in the fifth century, by the ancestors of the now civilized Saxons and French. These turbulent invaders, who were indifferently called Danes or Normans, were guilty of much greater devastation upon the existing religious monuments, at least, than the Goths and Vandals had committed; because the latter were Christians, though Arians, when they over-ran the civilized world; whereas the Danes and Normans, when they invaded England and France, were persecuting Pagans. So great was the dread of their violence throughout the last mentioned country, that the following petition was there added to the litany: "From the fury of the Normans, O Lord deliver us." In fact, the Almighty was pleased to deliver first France and then England, from the scourge which had so long and so sorely afflicted them; but in a very different manner from what the Christian inhabitants expected. Instead of witnessing the extermination or subjugation of their barbarous enemies, they saw them bend their necks to the yoke of Christ, and become models of piety and morality to themselves and the other Christian nations. Such at least was the case with the Northern men, who settled in that part of France, which from them has since been called Normandy. A lasting peace and tranquillity being, through this happy event, restored to the French provinces, its princes and nobles began to rebuild their demolished churches, and to erect others with incredible diligence. But no people shewed so much zeal in this undertaking as the newly converted Normans. The reader will be convinced of this, when he is given to understand that William the Conqueror, during the few years that he reigned in Normandy, previously to his invasion of England, built two noble churches and abbeys, and his nobles, not fewer than thirty-eight, each of them vying with the rest, to make his building the most magnificent and splendid. Such were the Normans, the bravest, most industrious, and most religious people, and the most addicted, in particular, to ecclesiastical architecture of all Christian people, when William, their prince, with the tower of his nobles, his army, and his ecclesiastics, came to settle in England soon after the middle of the eleventh century. It is to be observed, that the most celebrated schools of

literature and the arts, and more particularly of architecture in Europe, at this period, were the abbeys of Bec and Caen in Normandy, the former of which produced those three great architects, Lanfranc and Anselm, successively archbishops of Canterbury, and Gundulph, bishop of Rochester. But indeed all the Norman prelates and abbots appear to have been able architects; for there was hardly a cathedral or abbey church in England which was not rebuilt by one or other of them, in the course of thirty or forty years after the conquest. The characters which they aimed at in these structures were evidently the sublime and beautiful. To produce the former effect, they built their churches as long and as lofty as possible; to produce the latter effect, they not only built in a much more neat and perfect manner than the Saxons had done, but also they made use of certain new invented ornaments in their structures. Of these the most ostensible and ordinary was the arcade or series of arches which, in one or other of its various forms, is to be met with in all the existing Norman churches. From the continued efforts of these indefatigable and ingenious architects, to make their churches as awful and as beautiful as possible, before the middle of the twelfth century, a new style of building was produced, called "the Pointed Style." It certainly appeared, for the first time, either in England or in France; nevertheless, the first ascertained instance of it which has hitherto been produced, claims the honour of the invention for this country. But before we proceed to give a more particular account of the rise and progress of this singular style of building, it will be proper to detail the various other systems which have been published respecting it.

It has been seen above, that Mr. Evelyn and sir Christopher Wren describe the architecture of the middle ages, in general, whether circular or pointed, under the opprobrious term of Gothic, as being the real invention of the Goths and other barbarians. The former of these writers, as quoted with applause by the latter, says, in his "Parentalia:" "The Goths and Vandals having demolished the Greek and Roman architecture, introduced, in its stead, a certain fantastical and licentious manner of building, which we have since called modern Gothic, of the greatest industry and expensive carving, full of fret and lamentable imagery, sparing neither pains nor cost." We see that the writer here speaks of the light pointed ornamental style of our ancestors no less clearly than he does in another passage, quoted above, of the plain heavy circular style, called the Saxon; and that he supposes the former no less than the latter to have been really introduced into the countries, which had formed the Roman empire, by the Goths and Vandals, who subdued them. How little reason there is for ascribing the Saxon style to these barbarians has been shewn above; and, with respect to the pointed style, it is sufficient to observe that this appeared in no part of Christendom before the twelfth century; whereas the Goths and Vandals committed whatever depredations on the monuments of Roman art, which they did commit, in the fifth century, and that their power was every where crushed, and their very name extinguished in the course of the sixth century, except, indeed, in Spain, where the name of Gothic remained attached to the reigning family, till the beginning of the eighth century and no longer. So groundless and absurd, in every respect, is the term Gothic, as applied to pointed architecture!

At the same time that sir Christopher commends the system of his friend Mr. Evelyn, he himself departs from it, since he prefers the word *Saracenic* to denote the pointed style. "What we now vulgarly call the Gothic," he says, "ought properly and truly to be named Saracenic architecture, refined by the Christians, which first of all began in the East, after

GOTHIC ARCHITECTURE.

the fall of the Greek empire. The holy war gave the Christians who had been there an idea of the Saracen works, which were afterwards imitated by them in the West."

This system concerning the pointed style, namely, that it originated with the Saracens, has, out of mere respect to the name of its author, Sir Christopher Wren, been followed by bishop Lowth, in his life of Wykeham, by Rious, by War-ton, by Grose, and, in short, by the generality of modern writers who have had occasion to enter upon the subject. In refutation, however, of this system, we have to remark that the first, or Grand Crusade, in which the conqueror's son, Robert, and many other Normans and Englishmen embarked, making part of above a million of persons, who were engaged in it, began in 1096, and terminated by the capture of Jerusalem in 1099. Now it is certain from history that the cathedrals of Exeter, Rochester, and Chichester, with many abbey churches, were built wholly in the circular style after the last-mentioned year. Amongst these the instance which is most to the present purpose is that of Rochester cathedral, which was built by that greatest architect of his age, Gundulph, formerly a monk of Bec abbey, then bishop of Rochester, as well as the castle of that city, the chapel in the white tower of London, &c. without the least mixture of the pointed style. The reason of this is, because Gundulph had travelled through the East on a pilgrimage to Jerusalem, a little before the crusade took place, when he had an opportunity of surveying the churches and other buildings of those countries at his leisure. Again, it has been remarked by Grose, Benthain, and other writers on the subject, that in all the descriptions and drawings of buildings in the Holy Land and other parts of the East, given us by Pocock, Norden, Shaw, Le Bruyn, &c. there is but one church, namely, that of St. John d'Acre, in the proper pointed style (which church the writer of this article has discovered to have been built by William, an Englishman, at the time when our Richard I. made himself master of that city); and that very rarely such a thing as a pointed arch is represented as existing in those countries. It is true a late writer, the Rev. Mr. Whittington, in his "Survey of the Ecclesiastical Antiquities of France," has proposed to discover from these and other drawings pointed architecture in every part of the East, from the Euxine sea to Egypt; but then it appears that he calls the mis-shapen obelisks and minarets of the Mahomedan mosques pointed architecture. He has another argument for his assertion, namely, that "it is improbable the dark ages of the West should have given a model of architecture to the East." If there is any force in this argument, it would follow that the musical scale of bells, optical glasses, the mariner's compass, gun-powder, and printing were discovered in the East instead of the West, contrary to the known fact.

Mr. Murphy, to whom the admirers of pointed architecture are indebted for his elegant views of the church of Batalha in Portugal, conjectures that this style was borrowed from the pyramids, and that of course Egypt was its native soil. But in almost every country and age men have built their habitations with sloping roofs to carry off the falling rain; hence they must have seen the figure of a triangle at the gable ends of them, no less than the Egyptians did in their pyramids. Denon's, Meyer's, and other views of ancient buildings in Egypt, are by no means favourable to Mr. Murphy's system. There is indeed an ancient hall in the castle of Cairo, called Joseph's Hall, which is a great deal in the pointed manner, and which is supposed by the vulgar to have been built by the patriarch of that name; but Niebuhr and lord Valentia give sufficient reason to believe that it was

built by Saladin, the enemy of our Richard I, whose true name was Joseph. In fact, it is in the style of that period. According to this supposition, we are warranted in believing that this hall was the workmanship of Christian prisoners, or fugitives, after the third crusade. Mr. Murphy's theory is equally destitute of historical grounds and moral probability.

Bishop Warburton, in his "Notes on Pope's Epistles," endeavours to unite together two of the above-mentioned refuted systems, that which derives pointed architecture from the Northern Goths, and that which brings it from the Eastern Saracens, at the same time that he assigns the western peninsula of Europe for the real place of its birth. The following is an abridgment of his account "When the Goths had conquered Spain, and the religion of the old (Christian) inhabitants had inflamed their piety, they struck out a new species of architecture unknown to Greece and Rome. For this northern people having been accustomed, during the gloom of Paganism, to worship the Deity in groves, when their new religion required covered edifices, they ingeniously projected to make them resemble groves; at once indulging their old prejudices, and providing for their present conveniences by a cool receptacle in a sultry climate, with the assistance of Saracen architects, whose exotic style of building suited their purpose." All this is a mere reverie. The Goths and Vandals entered Spain in the year 409. They did not, however, acquire there a new religion from the old inhabitants, for they were already Christian; and habituated to the use of churches. On the other hand, the Moorish Saracens did not enter Spain till three hundred years afterwards, namely, till the year 712, when having cooped up the Christians in the mountains of Asturias, there continued ever afterwards the most relentless warfare between the two people. It is impossible to conceive more monstrous ideas than that the Christian Goths should have brought with them into Spain a partiality for the Pagan worship which they had practised in the forests of Germany, and that they should have retained it for the space of three hundred years afterwards, till they had the means of employing their implacable enemies, the Mahomedan Moors, to build Christian churches for their use; and that when this was effected, they should have kept the secret of pointed architecture to themselves for the space of 400 years longer! Were all this possible, or were it a fact that this style had been imported into our country from any other, where it had been practised for a considerable time before, it would have made its appearance amongst us all at once, with its several striking characters; contrary to what we actually see was the fact. After all, if the aisle of an ancient cathedral resembles an avenue of trees in some respects, it differs from it in many others, which are obvious to the sight.

Having followed different guides, north, east, and west, in search of the original pointed architecture, we have latterly been invited by an ingenious artist to accompany him to the south, namely, into Italy, the cradle of modern arts, with a promise that he will there point out to us much earlier specimens of this style than are to be met with in this northern climate. In the year 1805 Mr. Smirke jun, then returned from Italy, laid before the Society of Antiquaries a certain drawing, since engraved in the "Archæologia," vol. xv, of the dressings of a window belonging to the cathedral of Messina, in the richest style of the third pointed order, being such as we have no example of in this country before the middle of the 15th century. These dressings he would have us believe are oval with the cathedral aisle, which was built by the Norman chief, Roger, earl of Sicily,

GOTHIC ARCHITECTURE.

ly, in the eleventh century. He presented another drawing, published by the society as aforesaid, which appeared to be much more for his purpose, because of the known dates of the original. This drawing represents a portion of the outside of the baptistery of the cathedral church at Pisa, which baptistery was certainly built by Diotisalvi in 1152. The drawing exhibits what we should call Roman and Saxon work, with intermixed crocketed pediments and pinnacles, such as we were unacquainted with for more than a hundred years afterwards. Lastly, this gentleman shewed a view of the cloister of Campo Santo, adjoining the last mentioned cathedral, built in 1278. Here we see the richest tracery mullions under semi-circular arches, the whole of which he considered as being the same original work. These specimens gained many converts to his system, that of Italy being the parent country of pointed architecture.

But there is no error which we have so much to guard against in studying architectural antiquity as the confounding of subsequent alterations with the original work. There are few adepts in this science who would not start at the first sight of Mr. Smirke's drawings, and who would not pronounce the works they represent as an incongruous mixture of the architecture of different ages; but it was reserved for sir Henry Englefield's profound knowledge of the subject and critical acumen to detect and exhibit in detail the pointed enrichments with which later architects had decorated the plain circular works of their predecessors. To the justice of this learned antiquary's remarks the accurate history of the cathedral of Pisa, written by Martini a canon of that church, bears ample testimony. In a word, the very specimens which Mr. Smirke has produced in favour of Italy's claim to the invention of pointed architecture, as well as all the other buildings, tombs, and altars at Rome, and in every other part of Italy, demonstrate its great inferiority both in date and in execution, to England, France, and Germany, with respect to this particular style.

Allied, in one respect to the system of bishop Warburton, is that of sir James Hall, bart, who, in "An Essay on Gothic Architecture," now published, endeavours to shew that the pointed style was borrowed from the idea of upright posts surrounded with others, the heads of which are to meet like those of trees in an avenue. But the utmost that the ingenious baronet proves is that basket-work may be made to resemble pointed architecture, not that pointed architecture was borrowed from existing models of basket-work. Lord Orford, heretofore sir Horace Walpole, in his "Observations on English Architecture," says, that the architecture in question was copied from shrine-work; just as if the making of boxes preceded the building of houses! After all, this is only placing the tortoise under the elephant; for where did artists learn to fashion their shrines in the pointed style! Lastly, Mr. Payne Knight derives this style from all the three parts of the world, heretofore known, Europe, Asia and Africa, where he decides, in his "Principles of Taste," that "the style of architecture which we call cathedral or monastic, is manifestly a corruption of the sacred architecture of the Greeks or Romans, by a mixture of the Moorish or Saracenic, which is formed out of a combination of the Egyptian, Persian, and Hindoo."

But why should we wander into every remote corner of the world, and even into the regions of fancy in search of an invention which belongs to our own climate? And for what purpose should we take so much pains to prove a plant to be an imported exotic which we have seen sprouting up, and attaining its full growth in our own garden? Let us now go back to the point from which we started in pursuit of va-

rious false systems. We have seen above that the greatest people, without dispute, of the eleventh and twelfth centuries, namely, the Normans, the conquerors of England, France, Italy, Sicily, and various regions in the East, were at the same time a most industrious and ingenious people, and possessed of the most ardent passion for ecclesiastical architecture of any people we read of, and that they vied with each other in the grandeur and beauty of their respective structures. To produce the effect of grandeur, as it has been before observed, they gave the greatest possible length and height to their churches; for that of beauty they devised several architectural ornaments; the most common of which was the arcade or series of small round arches, which appear on some part or other of all their churches built in this country subsequent to their conquest of it, and which sometimes cover the whole of them over; as we see on the outside of St. Botolph's priory, and St. Oyth's abbey in Essex, and in the basement story of the inside of Durham cathedral. These arcades the architects diversified in a great variety of ways, as may be seen upon the tower of St. Augustine's monastery in Canterbury, built by the Norman abbot Scoltandus in 1080. One of the varieties consisted in making the circular arches intersect each other. The portion thus intersected formed a new kind of arch, more graceful in its appearance, and far better calculated to give an idea of height than the round one, which, however, had hitherto been adopted by all nations, whether Egyptians, Greeks, Romans, or Saxons. In fact, every one must be sensible that a pyramid or obelisk, from its aspiring form, appears to be taller than a semi-circular arch, the diameter of which is equal in height to it. These plain and intersecting arcades were sometimes irregularly intermixed, as in Carilepho's and Flambarð's work on the north side of Durham cathedral; and sometimes placed in alternate rows, as in that of Remigius on the façade of his church at Lincoln. The pointed arch thus formed appeared first in mere *basso relievo*, as in the above mentioned instances, amongst several others; but soon it was likewise seen in *alto relievo* over niches and recesses, in the walls of churches, as in the remains of archbishop Lanfranc's work in Canterbury cathedral, and in the abbey churches of Glanbury and Rumsy. It is probable that some of the first, if not quite the first open arches in the pointed style now existing, are the twenty windows in the intersected portions of such crossing arches in the choir of St. Cross near Winchester, made by that great encourager of the arts, and particularly of architecture, bishop Henry de Blois, king Stephen's brother. The date of this work is 1132, according to Godwin, Grose, and others, or else 1130, according to bishop Lowth, who had examined the records of this foundation, and Rudborne, the monk of Winchester, in his "Historia Major Wintoniensis." Most probably the choir was begun in the former year, and finished in the latter. As the prelate proceeded in his work, from the choir to the transept and tower of his church, he made several other pointed arches without any intersecting circles over them, notwithstanding the greater part of his work, as still appears, was the circular Saxon. In 1138, as we are assured by the above-mentioned monk of Winchester, and another monk who wrote the "Annales Wintoniensis," bishop De Blois rebuilt his episcopal mansion of Farnham in Surrey, where his successors still ordinarily reside. Now in the ancient part of this building, we see at the present day pointed arches resting upon circular Saxon columns, just as we do at St. Cross; and no architectural critic, with these documents before him, will hesitate

GOTHIC ARCHITECTURE.

tate a moment in pronouncing them part of the work in question, executed by De Blois in 1138. As the same prelate restored the abbatial church at Rumsley, where his niece Mary was a nun, and as he himself had been abbot of Glastonbury, before he was bishop of Winchester, we may safely attribute the pointed arches, intermixed with the circular ones in these two structures, to his direction, some time in the latter end of the reign of his cousin Henry I.

After all, it would be rash to pronounce absolutely that bishop De Blois of Winchester was the author of pointed architecture, since we have convincing evidence, that churches were built by other architects about this period, in the same mixed style of pointed and circular work. We must, however, incidentally observe, that before the conclusion of this twelfth century, the circular style was entirely laid aside, as well with respect to columns as to arches. We have evidence, for example, in the annals both of St. Wurburg's abbey Chester, and of Peterborough abbey, quoted by Dugdale, that Bildwas abbey in Shropshire, where the seven pointed arches of the nave, surmounted by small circular arches, in the upper story, are still seen, was founded either in 1136 or 1139; probably it was begun in the former year, and finished in the latter. We might argue in the same manner from the dates and actual state of Kirkstall abbey, Lantony abbey, and several other ancient structures. If we may give implicit credit to the testimony and the plates of captain Grose, the Scotch architects were not long in adopting the style of their English neighbours. It is remarkable that the ecclesiastical buildings erected by David king of Scotland, and his nobles, before he came into England in order to command the armies of his niece, the empress Maud, were purely in the Saxon style; whereas those founded there, after that event, present the same mixture of circular and pointed architecture which prevailed at that period in England.

A late writer, the Rev. Mr. Whittington, whose professed object it was to transfer the credit of the discovery in question from the Norman English and English to the French, which credit the latter seem disposed, from traditional accounts, to attribute to our countrymen, has asserted that examples of pointed arches, of a more ancient date than any existing in England, are to be met with at the abbey church of St. Denis near Paris, which church was finished in 1144. It appears, however, that this writer was unacquainted with the historical evidence on which the above-mentioned early instances of the pointed arch in England rest, and that he was even at a loss to determine which of the works at St. Denis really belonged to the period he has assigned. If we examine the pointed windows of this abbey, exhibiting different transactions of the first crusade in Montfaucon's "Monarchie Françoise," which windows are said by this great antiquary to have been executed by abbot Suger in 1140, we shall not find the appearance of a pointed arch in any one of them. It may be added, that in the famous tapestry of Bayeux, representing the conquest of England, and said to have been wrought by the conqueror's mother, there is no appearance either of a pointed, or so much as of an intersected arch, in the several churches, shrines, and other architectural works there displayed. In a word, throughout the whole of Montfaucon's plates, we every where find the French pointed architecture much inferior to that of a corresponding date in our own country.

To return to the subject of intersecting arches: we observe these sometimes to consist of plain semicircles crossing each other, as on the outside of the south transept of Wal-

kelyn's work at Winchester, and on the north transept of Warlewast's work at Exeter, forming in the intersections simple pointed arches; and sometimes we remark that the intersections rest upon pillars, each of them being surmounted with a capital, or at least with an abacus, as on the north transept of Durham, and the west front of Lichfield cathedrals. In the latter case, we have the appearance of pointed arches with lateral points, or cusps within the heads of them, as sir James Hall has very aptly named them. This addition to the pointed arch was occasionally used in the first period or order of pointed architecture, but afterwards it became universal. The addition of another cusp on each side of the pointed arch turned its trefoil head into a cross-foil. In like manner, four of these cusps being placed at equal distances within that circle or "L'Œil de Bœuf," which the Roman and Saxon architects had been in the habit of placing in the tympanum of their pediments, turned it into an elegant quatrefoil or cross. By means of additional cusps, and circles within circles, the Catherine wheel, or Marygold window, as it is called in England, or "La Rose du Portail," as the French term it, was easily produced. In all the works executed during the middle and latter part of the twelfth century, a confused and heterogeneous mixture of styles is every where discernible, as might be expected where circular fashion began to be left off, and the pointed one to be used instead of it.

In a general way, the arches were altered before the columns. Hence nothing is so common as to find in the structures erected between 1140 and 1180, arches of the sharpest points, resting on circular Saxon pillars of the greatest circumference. It could not, however, long escape the observation of our indefatigable architects, that such heavy supporters ill accorded with the lightness of the aspiring arch. Accordingly, towards the latter end of this twelfth century, in some instances the circular Saxon column began to be shaped like the Arabic numerical figure 8, so as to retain its former strength, and to appear gracefully slender; and where columns were made use of more for decoration than for strength, as for example to support ornamental arcades, or the cornices of windows or doors, very thin detached columns were employed, and those for the most part made of Parbeck or Petworth marble. We have a striking and most interesting example of these and other improvements which took place in the pointed style, towards the latter part of the twelfth century, in the east end of Canterbury cathedral. Persons who cannot see the original, will find it accurately represented in Mr. Carter's treasury of original specimens, called "The Ancient Architecture of England." This portion of our Metropolitan church was rebuilt, after an accidental fire had destroyed the upper part, and weakened the remainder of it, between the years 1175 and 1180. As we have the incomparable advantage of possessing a circumstantial account of this building, and of the differences between it and the former structure, raised a hundred years before by archbishop Lanfranc, which account is drawn up by the intelligent monk Gervase of Canterbury, who was an eye-witness of what he relates, we shall subjoin some of the most material parts of it; he tells us then, that the pillars of the new choir were of the same form and thickness with those of the old choir, but that they were twelve feet longer; that the former capitals were plain, while the latter were delicately carved; that there were no marble columns in Lanfranc's work, but that there was an incredible number of them in the work of the two Williams; that the stones which formed the ancient arches were cut with an axe, but those of new arches with

GOTHIC ARCHITECTURE.

a chuffel; that the vaulting of the side aisles of the choir was plain, whilst that of the new choir was groined and fixed with key-stones; that the former choir had a flat ceiling ornamentally pointed; but that the succeeding choir was elegantly vaulted with hard stone for its ribs, and light toph stone for the interlicies; finally, that there was only one *triforium*, or gallery, round the ancient choir, whilst there were two such in the modern choir. The east end of this venerable cathedral, as it is seen at the present day, and as it is represented by Mr. Carter, exactly corresponds in these and in other particulars with this description of it, given 600 years ago. It is all in the first order of the pointed style, except the main pillars, which are (to the eye) round, with a sort of Corinthian capital, and except the arches springing from these pillars, which are also circular as far as the *concha absidis* or altar end, these being pointed, as likewise with the exception of certain blockings and mouldings, where the Saxon billet ornament is still seen.

The improved architecture of this, the most dignified church in the island, could not fail of being adopted in our other churches, when there was occasion for rebuilding or repairing them. Lincoln cathedral seems to have led the way in this particular about the year 1195, under the direction of its bishop St. Hugh, who was not less renowned for his skill in architecture than for the sanctity of his life. This prelate undertook to rebuild the whole of his vast cathedral, and he was so intent upon the work, that, as Matthew Paris tells us, he carried mortar and stones on his own shoulders for the use of the masons. The building was so far advanced at the time of his death, which happened in the year 1200, that he is considered and called its founder, though his work was not finished till about fifty years afterwards, in the episcopacy of Robert Grossetete. Excepting the west front, which is almost all the work of the Norman prelate Remigius, and the towers, the groining, the screens, and certain other decorations added in the fourteenth century, the whole vast pile of St. Mary's church and Chapter-house at Lincoln is in the simple style of the first or lancet order of pointed architecture; but awful and beautiful beyond the conception of those who have not seen it, and greatly superior to any church of the same order and period to be found in France. In 1202, the rich and powerful bishop Godfrey de Lucy, amongst his other great works, began to rebuild the eastern part of his cathedral at Winchester, which he executed in the style of the Metropolitan choir, but without the least mixture of the Saxon. His extensive work is still to be seen there, consisting of long narrow sharp-pointed windows and other arches, detached pillars of Purbec marble, quatre-foil mouldings, and light groining of simple intersecting ribs. And, whereas, it became very usual, for the sake of gracefulness and also of use, where they were used as windows, to place two of these narrow arches close together under another pointed arch of greater width, in consequence of which a vacant space occurred between their heads; a trefoil, quatrefoil, or cinquefoil was frequently introduced, with the happiest effect, to fill up this space. In 1227 archbishop Walter de Grey began to rebuild the northern Metropolitan church of York in the prevailing style, and he actually finished the fourth cross aisle as it is now seen. The same kind of work was going on at this time at Worcester, Salisbury, and other cathedral and abbey churches. The last-mentioned church, which was an entire new foundation, begun by bishop De Poore in 1220, and finished by bishop Bridport in 1258, exhibits, in its front and other parts, the double lancet arch, with the intermediate quatrefoil rose, and all the other cha-

acters described above. There being occasion, however, to place three lancet arches together in the windows of the upper story, the head of the middle one was gracefully raised above the other two, an improvement which was soon adopted in many other churches. A still more striking improvement which took place, if not at Salisbury for the first time, at least about the time of its completion, was the elevation of the cornice, pediment, or canopy which had hitherto adhered, or at least had been very near to the architrave of the arch. This was now raised, like the two sides of a triangle, to a considerable height above it. The jambs of the pediment were at first rather short, not reaching, by any means, so low as the springing of the arch, and generally resting on some small flower or other slight ornament. The point of the canopy always terminated in a trefoil or other graceful ornament, but was not, as yet, adorned with crockets or foliage down the jambs. Bishop De Poore, being translated to Durham, began to ornament the east end of his present cathedral in the style which he had introduced into the one he had left. Whilst the work at Salisbury was drawing towards a conclusion, that at Westminster abbey was beginning, namely, in the year 1245. The north transept, and part of the adjoining nave of the church, remain in almost the same state they were left in by their founder Henry III. The windows of the last-mentioned portion of the abbey, together with the corresponding aisle, are larger and better proportioned than any which had hitherto been seen in this island. Here also we meet with the cinquefoil rose between the heads of the two lights; while the exterior windows of the triforium or gallery consist entirely of a triple cinquefoil under a pointed arch. These two models for the upper part of church windows were long followed. On the other hand, the arches and windows of the transept, being placed in a regular order, and very near to each other, presented an appearance of those large mullioned windows which, in the succeeding period of this style, came into fashion. In this part also of the abbey church, namely, the inside of the transept, we begin to meet with good statuary.

During the reign of Henry's son, Edward I., which began in 1272, the architecture of this country, through the ingenuity and industry of its artists, acquired a new character, and may be said to have grown into a new order of the pointed style. The first and distinguishing feature of this was the general adoption of the well proportioned and well turned aspiring arch. The arches which had hitherto been constructed, though sometimes accidentally perfect, were, for the most part, too acute. But the arches built at the latter end of the thirteenth century generally approached to the perfect proportion. This proportion, according to the best judges, is when an equilateral triangle can be inscribed within the crown and impost of the arch. The arches also were gracefully turned. Besides all this, they were now invariably ornamented in their heads with cusps, or as to form trefoils, cinquefoils, or septfoils. In like manner the pediments or canopies over the arches were universally purfed, that is to say, adorned with the representation of foliage called crockets, from the corbel on which they rested up to the rich flower or other elaborate finial in which they terminated. These corbels or brackets now corresponded in height with the springing of the arch, and mostly exhibited built of the founders or other benefactors of the establishment. Pinnacles, which hitherto had been both very simple and very rare, were, in this improved order, placed at the sides of almost every arch, and on the top of almost every buttress, being invariably purfed and surmounted with rich finials. A pinnacle of a proportionable

GOTHIC ARCHITECTURE.

size being placed on a tower, instead of a buttress, became a broach or spire. Accordingly the use of spires became almost general in the fourteenth century. We even read of a new built tower being pulled down, because it was unequal to bear the weight of this grand ornament, when a new one was built, which, with its spire, was as high as the church was long. In the same spirit of ornamental grandeur, the buttresses, supporting the upper part of the nave, instead of being concealed in the roofs of the side aisles, were brought into view with suitable decorations, and made to stretch over the tops of those aisles, in what are called flying buttresses. The window no longer consisted of an arch divided by a simple mullion, and surmounted with a single or a triple rose, but was henceforward, in all grand churches, portioned out by mullions into three, four, five, six, and sometimes into nine different bays or days, as the separate lights in a window were then called; and these again were frequently subdivided by one or more transoms running across them. Their heads also were varied by tracery work into a variety of architectural designs, and sometimes, as at the west end of York, into the form of a beautiful flower. The plain niches of the thirteenth century became, in the fourteenth, gorgeous tabernacles, in which as much architectural skill was often displayed as in the whole church to which they belonged. These tabernacles, as well as various other parts of the sacred edifice, were filled with statues, which frequently shewed equal spirit in the design and art in the execution. Finally, the ribs supporting the groined ceiling were no longer simple intersecting arches; but they branched out into tracery work, still richer and more elegant than that in the grand windows of this period; and wherever the ribs met, they were tied together by an architectural knot or boss, which generally exhibited some instructive device. It must not be forgotten, that during the latter part of this period, the pediments which before had been straight, began to humour the sweep of the arch, by which means they became less high and more graceful.

We have instances of these improvements, or rather of this new order of the pointed style, in the three remaining architectural crosses, erected by Edward I. those of Northampton, Geddington, and Waltham, to the memory of his queen Eleanor, who died in 1290; likewise in the magnificent tomb of his brother Edmund Crouchback in Westminster abbey, who departed this life in 1296. But the most complete specimen of the whole detail of these improvements is York Minster, the nave of which, as it stands, was built between the years 1290 and 1330, and the choir some thirty years after the latter period. If any similar structure in the same style, but upon a smaller scale, could, in its time, have vied with this in beauty and grandeur, it was St. Stephen's chapel, Westminster, now the house of commons, which Edward III. began to erect in 1348. Of the inimitable beauties of the latter erection, only a few scattered vestiges remain, to shew the architectural antiquary what it was in its glory. There are few, if any, of our cathedrals and remaining abbey churches which were not rebuilt or restored in some considerable part or other of them, according to this improved order. Before 1321, bishop Langton had added the Lady chapel to his cathedral of Litchfield, and had groined the nave and choir, and had erected the magnificent western façade. About the same time the greater part of the nave of Westminster abbey church was rebuilt. Between the years 1327 and 1340, Exeter cathedral was groined, and its heavy Norman arches and pillars were changed into light and graceful pointed arches and cluster-columns, by its munificent prelate Grandison. During the

pontificate of archbishop Courtenay, which began in 1381, and that of his successor Arundel, the nave of Canterbury cathedral was rebuilt. During the same period that eminent prelate and architect, William of Wykeham, was employed in performing the same difficult transmutation of the nave of Winchester cathedral, which had been performed in that of Exeter. The circular columns and arches were not taken down, as has been generally supposed, but the former were eased and the latter reduced to a joint. This may be ascertained by an attentive examination of the work within the roofs of those structures; and without this trouble, by simply looking at the nave of Gloucester, St. Albans, or Ruffey great church, where the operation here described will appear to have been performed, on two or three of the circular pillars and arches at the west end, and to have been left off with respect to the other pillars and arches. The taste for these improvements descended even to country parish churches, few of which did not sooner or later exchange their ancient windows, at least, for those of the pointed style.

But human arts, like the human body, when they have attained to the perfection of their state, tend towards their decline. This was the case with that singular invention, pointed architecture. Its rise, progress, and decline, occupy little more in the chronology of the world than four centuries. As its characteristic perfection consisted in the due elevation of the arch, so its decline commenced by an undue depression of it. This new style, or third order of pointed architecture, took place in the latter part of the fifteenth century, and is to be seen in the royal chapels of St. George, Windsor, of King's college, Cambridge, and of Henry VII., Westminster. It cannot be denied, that the builders of these splendid and jolly admired structures displayed more art and more professional science than even their predecessors had done; but then they displayed this at the expence of the style itself, which they cultivated, and of the awful and devout impressions which this style was invented to excite. The spectator was now amazed to see huge masses of stone, called pendent capitals, each one of more than a ton weight, hanging in the air, which, instead of supporting the vast groins they were fixed in, were supported by them; the consequence of this, however, was to bring the flat arches of the ceiling still nearer to the eye, so that their curvature was henceforward discernible at their springing rather than at their point. Finally, ingenuity was at this period much more affected than awfulness: hence those royal chapels, and several mortuary ones built in Winchester, Peterborough, and our other grand churches, during the time of the two last Henries, are seen covered over with tracery, and loaded in their groins and friezes with busts, armorial bearings, and rebuses, beyond all due proportion, so that, however elegant the design, and exquisite the execution of them generally is, a judicious spectator, after admiring them, fails not to prefer to them the chaste grandeur of York Minster, or even the unadorned majesty of Salisbury cathedral. The church-windows of this period were so multiplied and enlarged, as to become what a late writer, Mr. Whittington, professes to admire "all window," but which they certainly could not become without great detriment to the character of awfulness in the church itself. The same depression of the pointed arch took place on the outside as in the inside of the buildings of this period. Instead of the tapering pinnacles and lofty spires which had hitherto adorned the towers of churches, these structures were now generally covered with round cupolas, and the portals, instead of being surmounted with crocketed pediments and graceful pinnacles,

GOTHIC ARCHITECTURE.

were generally enclosed within square architraves, the chief ornaments of which were seen in the spandrels. All this, however, is to be understood with some exceptions. For example, bishop Oliver King erected his church at Bath, about the year 1500, in a very simple fashion of pointed architecture, and bishop Fox repaired the presbytery and chancel of Winchester cathedral with a chaste and tasteful elegance.

But the downfall of pointed architecture in this kingdom became inevitable from various causes, chiefly, however, from the loss of its characters of majesty and awfulness, the necessary consequence of the depression of its sublime and graceful arch. The destruction of it was complete at the beginning of the reign of Edward VI., from which period, till the introduction of the pure Grecian style in the reign of Charles I., a real Gothic, or at least a truly barbaric style took place, consisting of a confused medley of all the known styles and orders of styles, intermixed with globes, triangles, pyramids, obelisks, frets, and other whimsical and ugly devices, as may still be seen in the sepulchral and other monuments of the period in question.

From what has been said, it appears that the term Gothic architecture is an improper one, as applied to any species of architecture whatsoever; that the mode of building which prevailed amongst our ancestors before the conquest, called the Saxon style, consisting of round pillars with rude capitals and bases, and of circular arches, was strictly Roman, being copied, even to its minute ornaments, from coeval originals at Rome, and having been first taught and practised in this island by Roman masters; that this style was succeeded, before the middle of the twelfth century, by a style of architecture perfectly new, the essential character of which is the pointed arch, from which, by a natural process, the slender cluster column, the aspiring cornice or pediment, the crocketed pinnacle and lofty spire, with the other ornaments mentioned above, actually grew; that this style was not borrowed from Northern Goths, nor Eastern Saracens, nor Western Moors, nor Southern Italians (for in this style the Italians themselves were but novices, and not very apt ones), but that it was discovered in this climate, most probably by the English Normans, the greatest people of the 12th age, and the fondest of ecclesiastical architecture that ever existed; that the style was improved by the joint efforts of the Normans, English, and French, at a time when our kings were masters of the fairest provinces of France, and brought to its perfection, chiefly by the ingenuity and industry of the English, during a period in which England was in prosperity by her conquests, and France in desolation from her defeats; that there are three distinct orders in this style, the members and proportions of which can be distinctly pointed out by professional men, (such as the author of the "Ancient Architecture of England") with almost as much accuracy as those of the five Grecian orders; on which subject it may be observed, that these Grecian orders were practised long before their members and proportions were accurately laid down, that the characteristic of the first order is the acute arch, and that the period of its duration may, in a general way, be said to have lasted from the middle of the twelfth to the end of the thirteenth century: of this order, Lincoln, Beverley, and Salisbury churches are examples; that the chief characteristic of the second order, is the perfect or equilateral arch, the reign of which was from the end of the thirteenth, till after the middle of the fifteenth century, to which order York Minster, and the naves of Winchester and Canterbury cathedrals belong; and that finally, the characteristic of the third order is the obtuse

arch, which grew into fashion about the last-mentioned period, and lasted to the downfall of pointed architecture itself in the middle of the sixteenth century. The finest specimens of this, doubtless, are the above-mentioned royal chapel. With respect to the proper denomination of this style, some of the learned, as well as the vulgar in general, still call it the Gothic, others the Saracenic, a third class, the Norman, a fourth, the English, and a fifth, the pointed. From the whole of what has been said above, it will be readily concluded, that the present writer conceives the last of these terms to be the best adapted to the style, as being the most strictly descriptive of its characteristic quality.

This article is the abridgment of a much longer treatise on pointed architecture, which is shortly expected to appear from the press of Mr. Taylor's Architectural Library; in which treatise many historical documents in support of the present system, and certain plates to illustrate it, will be seen. M.

GOTHIC Bible. See BIBLE, and ARGENTÆUS *Codex*.

GOTHIC Character, or Writing, is a character or manner of writing, which, in the main, is the same with the Roman, only that it is very full of angles, turns, and bendings, especially at the beginning and ending of each letter.

The manuscripts in Gothic characters are not very ancient. Ulphilas, bishop of the Goths, was the first inventor of the Gothic characters, or the first who composed the Gothic alphabet, in imitation of the Greek, and the first that translated the bible into the Gothic tongue.

The letters used in the Gothic gospels are twenty-five in number, and formed, with slight variations, from the capitals of the Greek and Latin alphabet.

As these characters, in which the *Codex ARGENTÆUS*, or Gothic version of the bible, was written by Ulphilas, their inventor, were derived partly from the Greek and partly from the Latin, Michaelis (Introd. to the N. T.) thinks it natural to ascribe the said version not to the Franks or Germans, but to the Goths, who lived on the borders of the Danube; or in Wallachia, where they at that time resided, the Latin was spoken, and their nearest neighbours were the Greeks. A mixed alphabet, such as that which is found in the *Codex Argentæus*, is such as might reasonably be expected. Some of the words in this version are still used in the Lesser Tartary, the ancient seat of the Goths; e. g. *swilan*, "to die," from *swalt*, "death," a word that is quoted by Busbeck, from the language of the Crim Tartars. In this version, many words are adopted immediately from the Greek; viz. *ατα*, *atta*, father; *αμς*, *mus*, the shoulder, where even the *s* is retained from the Greek termination, &c. Hence it is inferred, that the dialect, in which such words occur, was that of a nation that lived in the neighbourhood of the Greeks. This version has also Slavonian words, such as *fan*, a master, which prove it to have been written in the dialect of a nation that bordered on Sarmatia. The same may be said of many Latin words: such as *anacumbjan*, accumbere, to sit at table, *militondans*, militantes, foldiers, *agba*, water, &c. This argument is the more decisive, when we consider, that the Goths, in the time of Ulphilas (see his biographical article,) lived in Wallachia, a country in which Roman colonies had been planted, and where a corrupt Latin is spoken at this very day. Ulphilas himself lived in Wallachia, and had it in his power at least to make use of Latin letters, as well as those of the Greeks, with whom he had continual intercourse. See *GOTHIC Language*.

The Runic characters are also frequently called Gothic characters. See Mabillon, *De Re Diplom.* lib. i. cap. 2.

But

GOTHIC LANGUAGE.

But they who take the Gothic characters to be the same with the Runic, are mistaken; as is shewn by Ol. Wormius, Junius in his preface to the Gospels written in Gothic letters, and Dr. Hicks on the Runic Tongue.

GOTHIC *Column* is any round pillar in a Gothic building, either too thick or too small for its height.

There are some found even twenty diameters high, without either diminution or swelling.

GOTHIC *Language*, the language of the Goths. This language, as the acknowledged parent of the English, is of considerable importance; while its remote antiquity, the scantiness of its records, and the circumstance of its having been studied only by few among the learned, have rendered it a matter of great uncertainty as to its character and origin. The questions respecting its antiquity and genius are resolvable into those in regard to the people who used it. Monf. Mallet, in his "Northern Antiquities," supposes that the ancient Gauls and Germans, the Britons and the Saxons, were all originally one and the same people: and thus he makes the Gothic the same with the Celtic tongue. This opinion, which was first taken up by Cluverius in his "German Antiquities," has been since adopted by Keysser in his "Northern and Celtic Antiquities," and Pelloutier in his "History of the Celts," and maintained by them with uncommon erudition. According to these writers, the ancient and original inhabitants of Europe consisted only of two distinct races of men, *viz.* the Celts and Sarmatians; and from one or other of these, but chiefly from the former, all the ancient nations of Europe are descended. The Sarmatians, or Sauromatae, were the ancestors of all the Slavonian tribes, *viz.* the Poles, Russians, Bohemians, Wallachians, &c. who continue to this day a distinct and separate people, extremely different in their character, manners, laws, and language from the other race, which was that of the Celts; from whom, as they suppose, were descended the old inhabitants of Gaul, Germany, Scandinavia, Britain, and Spain, who were all included by the ancients under the general name of Hyperboreans, Seythians, and Celts, being all originally of one race and nation, and having all the same common language, religion, laws, customs, and manners.

This opinion, though supported with an uncommon display of deep erudition and a great variety of specious arguments, is controverted by the late learned and ingenious Dr. Percy, in a preface to Monf. Mallet's Northern Antiquities, which he has translated and enriched with notes. This profound antiquarian, in opposition to the French writers, states that ancient Germany, Scandinavia, Gaul, and Britain, were not inhabited by the descendants of one single race; but, on the contrary, divided between two very different people; the one of whom he calls with most of the Roman authors Celtic, who were the ancestors of the Gauls, Britons, and Irish; the other Gothic or Teutonic, from whom the Germans, Belgians, Saxons, and Scandinavians derived their origin; and that these were *ab origine* two distinct people, very unlike in their manners, customs, religion, and laws.

The Gothic, then, is radically different from the Celtic according to Dr. Percy, who, on the authority of Hicks, as stated in the preface to his "Institutiones Grammaticæ Anglo-Saxonicæ," gives the following genealogy of the two languages. Gothic is the parent of 1. Old Saxon, or Anglo-Saxon; 2. Francic or Franco-Theotisc; 3. Cimbric, or Old Icelandic. From the first, *viz.* the Anglo-Saxon, are again derived English, Broad Scotch, Belgic, or Low Dutch, and Frisic. From the Francic, are derived German, or High Dutch, German of Swabia, and Swiss; while the Cimbric, in

its turn, gave birth to the Icelandic, Norwegian or Norse, Danish, and Swedish. On the other hand, the Celtic is represented by the same writer as the parent of the ancient Gaulish, the ancient British, (ramified into the Cornish, Armorican, or Bas-Bretagne, and Welsh,) and the ancient Irish, which was subdivided into Manks, or language of the Isle of Man, into Erse, or Highland Scotch, and Irish. To the old original mother tongue of all the Gothic dialects, it has been usual to give the name of Teutonic, not so much as Dr. Percy asserts from its being the language of Tuisto, the great father and deity of the German tribes, as from the Teutones, the people who used it: the same probably with the Cimbric, or as the Greeks called them Κίμυρροι, who inhabited the northern regions, and more particularly the Danish islands. Now, in opposition to this writer, we are free to affirm, there is no ground for believing that this mother tongue, whether called Gothic or Teutonic, was in its primæval form different from the Celtic. And this proposition we shall endeavour to make manifest from the very specimens by which Dr. Percy has attempted to shew their essential difference. But before we enter on this question, it is necessary to remark, that learned men, in their enquiries concerning the origin of nations, have not sufficiently attended to the consideration which we learn from the Mosaic history, that all nations originated in a common family, and at first spoke a common language. Let us suppose that some members or descendants of this family, (as we read of Gomer,) emigrated from Asia to Europe. If they settled in Greece, they introduced with them the primæval customs, and language, though somewhat corrupted no doubt from its original purity. Others, actuated by the same spirit of emigration, would soon follow; and, if more powerful, would dislodge their predecessors, who had no other resource but to seek new habitations in remoter regions.

As these wanderers multiplied, they advanced, till, in the course of years, all the countries on the north and west, as well as on the east of Europe, were completely peopled. But this population of course could not take place before they had been divided into independent tribes, and distinguished by correspondent difference in dialects and manners. But still a very great resemblance must have as yet been visible among them in both these respects, however separated from each other: for in the earlier periods of society, language, though widely used, must long have continued the same, with little variations, it being corrupted and diversified into distinct tongues only by the progress of civilization, by the refinements of literature, by improvements in art and in government, and by those political convulsions which the love of conquest, inspired by conscious superiority in those arts, produces. All the nations of Europe, therefore, in the ruder and more early ages, may be considered as using only the same great primordial speech, grown indeed into distinct branches, and assuming in one country the appearance of being independent of, and unconnected with those used in other countries. Now, if we suppose that the Celts were the first emigrants from Asia, who, pervading Europe, settled in Gaul, Old Spain, Britain and Ireland; while their brethren, under the names of Cæta (Goths), Seythæ, Cimbræ, &c. directing their course to the North, occupied Thrace, Scandinavia and other northern territories; it would follow, that these tribes, however remote, used at first either the same language, or languages which had a close affinity from their relation to the common primæval tongue. Nor would there be material difference in this conclusion, though we should suppose, with many learned men, that the inhabitants of the North of Europe came, not from the East but from

GOTHIC LANGUAGE.

the North of Asia, as they must still have been descendants of the same primitive family, which, according to Moses, peopled the world. Thus the Celtic and the Gothic or Teutonic must have been, in their origin, the same or sister tongues.

But further, while the ancient Celts and Goths continued in the darkness for which they became proverbial, the inhabitants of Greece rapidly improved in laws and the arts of life. In this improved state, Greece became, in regard to the less favoured inhabitants of the North and West, what Asia had hitherto been in respect to Greece; a fresh source of civilization and letters. Its language, growing more copious and refined with the people, diffused itself with the blessings of knowledge and society, which their example or instruction imparted to the Northern and Western inhabitants of Europe. Thus Greek, with the arts of Greece imported into Italy, gave birth to the Latin tongue; and this at a later period necessarily affected the Celtic language, in consequence of the victories which the Roman arms achieved in Gaul and in Britain. This revolution greatly widened the line of distinction which for ages had been extending between the Celtic and the Gothic tongues; the former being assimilated to the Latin, the latter to the Greek, by a copious influx of new terms. It were indeed matter of great curiosity if some records of the Celtic and Gothic tongues had been preserved before they were yet modified by the ascendant languages of Greece and Rome; but no such records unfortunately have survived the wrecks of time. And we can judge of the ancient Celtic only from the Welsh, its acknowledged daughter; while we are left to form our judgment of the primæval Gothic from the remnants of a version of the New Testament, effected by Ulphilas, into the dialect used by the Goths in Mœsia, and hence called Mæso-Gothic.

Having made this preface to shew that the Celtic and Gothic had one common basis, viz. the primordial tongue imported from Asia, we proceed to prove, as far as we are able from their respective offspring, that they had in common many Asiatic words, and were modified by a great portion of Latin and Greek terms: and that from these two causes they essentially resembled each other. The Lord's prayer is thus rendered in the ancient Gothic of Ulphilas.

Literal translation :

<p>1 Atta unfar thu in himin nan</p> <p>2 Veihnai namo thein</p> <p>3 Quimai thiudinassus thei- nas</p> <p>4 Vairthai Vilga theins fue in himina, gah ana air- thai</p> <p>5 Hlaif unferana thana fei- ntinan gif uns himnidaga</p> <p>6 Gah alet uns thatei seu- lans sigaima, sua fue gah veis aletam tham seulam unferan</p> <p>7 Gah ni bringais uns in frailubngai</p> <p>8 Ak lausei uns afthamma ubilin, Amen.</p>	<p>1 Father our thou in hea- ven</p> <p>2 Be sanctified thy name</p> <p>3 Come thy kingdom</p> <p>4 Be done thy will so in heaven, also on earth</p> <p>5 Give us this day the bread eternal</p> <p>6 And forgive us that we are debtors, as also we forgive those our debt- ors</p> <p>7 And bring us not into temptation</p> <p>8 But deliver us from evil, Amen.</p>
---	---

The following is a specimen of the Celtic, as existing in the Welsh tongue :

<p>1 Ein Taad, yr hwn wyt yn y Nefoeth</p> <p>2 Santeiddier dy enw</p> <p>3 Deved dy deyrnas</p> <p>4 Bydded dy Ewyllys ar y ddaiar megis y mae yn y nevoeth</p> <p>5 Dyro i ni heddyw ein bara beynyddiol</p> <p>6 A madde i ni ein Dy- ledion fel y maddeuwn ni ein dyledwyr</p> <p>7 Ag nac arwain ni i brofedigaeth</p> <p>8 Eithr gwared ni rhag drwg, Amen.</p>	<p>1 Ourfather, the one who art in heaven</p> <p>2 Be hallowed thy name</p> <p>3 Come thy kingdom</p> <p>4 Be thy will on the earth as it is in the heaven</p> <p>5 Give to us this day our daily bread</p> <p>6 And remit to us our debts as that we remit to our debtors</p> <p>7 And lead us not into trial</p> <p>8 But deliver us from evil, Amen.</p>
---	---

We propose next to lay before our readers a brief analysis of these two specimens, which it is presumed will shew that the two languages in question have much nearer resemblance to each other, than Dr. Percy, or any person who has not a thorough knowledge of both, could possibly imagine. The Hebrew אָדָּא, *ad*, pronounced with an initial and closing vowel, is *adda*, and signifies *beloved*, and this is the source of the Gothic *atta*, and the Greek ἀττα, with the utmost propriety applied to a parent as the dearest object of love. The same word in Hebrew is written אָדָּא, *doad*, and is no other than the Celtic *taad*, under a difference of character. In the Cornish it is *tae*, in the Frisic *haita*, in the Lapland *atki*, and the old Cantabrian or Biscayan *aita*, *father*. Unfar is the Greek ἰμ-
ταρ, thus strangely corrupted, ἰμταρ, *untar*, *unfar*; and hence the English *our*. In the same manner, ἰμταρ has degenerated into *uns*, *uns*, *us*. The Celtic *ni* is the Hebrew and Arabic pronoun نِي, *ani*, which, founded with only the closing vowel, is *ni*, *us*, and with only the initial *ein*, *our*. The Gothic *in* and the Welsh *yn* have originated in the Greek ἐν, or the Latin *in*; but it is observable that both these languages use this preposition as it is used in Latin, when followed by an accusative noun in the sense of *into*, *unto*, or *to*: thus *in fraislubngai*, into temptation; *inni*, or *i ni*, to us. The Welsh language is remarkable for the attention paid to harmony in the arrangement of its terms. To produce this effect the termination of a preceding word, in order to coalesce with the succeeding one, is somewhat changed, and thus made to unite both into one. Thus *rhawn* is *yr hwn*, *the one*, where *r* or *rb* (aspirated after the manner of the Greek ρ) is prefixed to *awn*, the Latin *anus*, or the Anglo-Saxon *an*. *Wyt*, moreover, is a coalition of *wy ty*, *art thou*, or *thou art*; *wy* being the substantive Greek verb εἶ or εἶμι, whence the Goths derived their *im*, and the English *an*. The Greek χουαυρ, *tempest* or *clouds*, by softening the guttural into an aspirate, of which we shall presently give some more examples, has in the Gothic degenerated into *himin*, the place where the tempests or clouds reside, namely, the *sky* or *heaven*. In the Franco-Theotifc the same word is *himil*, and in the Cimbric *himal*. It exists also in the Celtic; but there it has retained its original sound and sense, under the form of *cwmwyl*, *a cloud*. It is singular that the same association of ideas, founded on the nature of things, has transferred the Greek νεφος, or the Latin *nubes*, to signify in Welsh *heaven*, under the shape of *neof* or *nefoedd*.

2. *Veihnai* is the verb of *veiba* or *veibs*, *holy*, which is but the Greek ἁγιος, with the labial σ substituted for the aspirate, as the old Latins have done in numerous instances, some of which we shall presently produce. On the other hand, *santiddier* is *sanctus*, converted by the Welsh into a verb; while

GOTHIC LANGUAGE.

dy is the same with the Gothic *thu*, and no other than the Latin *tu*, or the Æolic *tu*, or the English *thou*. The Gothic *thein*, it is obvious, has given birth to the English form of *thine*. *Namo*, whence our *name*, retains the Persian character of *naam*, though perhaps it is more immediately derived from *nomen*, and is a kindred noun with the Welch *enw*, which probably degenerated from *enwaz*, by dropping the last syllable.

3. The Arabic **قَامَ**, *quam*, *legs*, has given birth to the Gothic *quiman*, *to use the legs*, i. e. to come, and to the Anglo-Saxon *guman*, and our *com*. The same word has been imported into the Celtic in the shape of *cammu*, signifying *to hop* or *step*. The same word exists in the Shanferit, *gumun*, *to go*. The corresponding Welsh *deved* or *dywad*, is the Greek **ταξ**, **ταξω**, or **ταω**, *to stretch to an object*, which last descended from the Arabic **أَتَى**, *ata*, by dropping the initial vowel. The same verb exists in Welsh, under the different figure of *thorwy* or *thorwys*, and is no other than the English *to w*, *to conduct*. The Gothic *thiudinaffus*, *a kingdom*, seems originally to have meant *the emperor of a subdued nation*, from the Greek **βασίς**; and **αυξ**, or **αυσσα**, as the offspring of the former exists in this tongue *thiuda*, *gens*, *populus*. On the other hand, the Welsh *deyrnas* is the Greek **θρονος**, corrupted, by the transposition of *r*, into *thornos* or *dyrnas*. Our English *thron* conforms to the original in sound and sense. In the Anglo-Saxon the corresponding word is *ryc*, which still exists in such English compositions, as *bishopric*, i. e. the dominion of a bishop. In the Great Indian language above-mentioned, this term subsists under the character of *reyh*, meaning *wealth*, and which is nearly the same in sound and sense with the Anglo-Saxon *ryc*, or our *rich*, and the Latin *res*, *property*.

4. As *light* or *air* is the chief medium of existence, the Hebrew term **אָוַר**, *awar*, gave birth to the Latin *eram*, *ero*, and the Gothic *wair* or *wairthan*, *to be*, *to become*. The Welsh *hydded*, which exists also in the form of *byw*, and which is the same with the Greek **βίω**, and the Latin *vivo*, descended from the Persian *bodan*, *to be*. *Wilga* is **βίω**, or **βίω**, with *ga* annexed, by an analogy common in the Gothic tongue. The Welch *wollys*, or with *e* prefixed, *ewylls*, has flowed from the same source; and under the former of these forms is nearly allied to the English *will*. *Sue* is our *so*, or the Greek **σ**; reversed, a fate very common with monosyllables in the ancient languages. *Gab* came from **καί**, and *ana* from **ανα**, which, in composition, means *up*, and has given birth to the Gothic sense of *upon*. *Airibai* is the Arabic **أَرَادَ**, *arets*; while the Welsh *dair*, or as it is otherwise written, *tyr*, originated in *terra*. The Hebrew **אָבַר**, *aber*, the parent of **αβρ** in Greek, of *aber* in German, *eser* in Gothic, and *over* in English, has contracted in Celtic into *ar*, in the sense of *upon*.

5. The Arabic **لَحْمٌ**, *lahm*, *food*, is the origin of the Gothic *blais*, and the English *loaf*. *Thana*, or *than*, is the accusative article **του**. *Sintinein* is formed from the noun *smith*, *vicissitude*, *change*, which is no other than the Hebrew **שָׁנָה** or **שָׁנָה**, *smith*, that change or period of time called a year: hence *sintinein* came to signify *continual*, or *perpetual*. Our Lord, we believe, by the clause **του αειτου του επιουσιου**, meant not, as it is generally rendered, *daily bread*; but the bread belonging to us, and essential to us as immortal beings, namely, the bread of the soul. (See "Mr. Jones's Illustrations of the four Gospels," p. 123.) In this sense the clause was understood by the early commentators, and by the Gothic translator, who has rendered it *blais thana sintinein*, the eternal bread. In Hebrew, Arabic, and Persian, **כַּף**, *kaph*, denotes the palm of the hand; hence it

came to signify the action of the hand, which consists either in imparting or receiving. In the former sense it gave birth to the Gothic *gif*, and in the latter to the Latin *castio*. *Hinnidaga* means *this day*; *hinma*, or as we write it, *him*, being the personal pronoun used definitively, and *diga*, or *daeg*, according to the Anglo-Saxon, being the Latin *dies*; *him day for this day*, which is more common in the plural form among the vulgar *them days*.

The Welch *dyro*, in the same verse, is the Greek **δωρο**, *a gift*, converted into a verb. *Heddyw* is a disguised form of *hadie*, which last is only a contraction of *hoc die*, *this day*. *Bana* is a word which exists in all languages. Its origin is the Hebrew **פָּרָה**, *pharah*, *fruit*; and hence **παρος** in Greek, *far*, and *pario* in Latin, *brodth* in Cimbric, *brat* in Francic, *brodt* in German, *branta* in Norse, *bread* in English, *brad* in Danish, and *brar* in Frisic. *Bryahyddiel*, rendered *daily*, appears to be composed of *brye*, *a top* or *summit*, and *yddiol*, the Latin *dies* adjectived, and means a top of each day, or a head of each day, i. e. daily. The word is also used *beyngyddial*, *beyn* being a corruption of *pen*, a head. The Welsh are fond of this expression, and have a phrase, *poeb dyb ar y pen*, each day on his head, meaning every day in succession.

6. *Aflet uns*, i. e. *of-let*, or *let off*, *dismiss to us*. *Thatci* is a corruption of the Greek **ταυτε**, *this* or *that thing*, and is thus the parent of the English *that*: hence the reasonableness of the explanation which the celebrated Mr. Tooke has given of such phrases—*remit to us that thing*, viz. *sculans sculans*, we are debtors. *Sculans* were persons under command, under obligation or debt, from the Greek **σουλαν**, *to labour*: hence appears to have been derived our *scullion*, a mean domestic servant. In ancient times labourers usually paid their rents in kind from the products of their fields: hence, in Greek, the tenant was called **χειροφιδετης**. On the same principle, in Gothic, the word signifying *to labour*, came to signify *to owe*, or *to be in debt*. *Siguma* is only the Latin *sinus* corrupted by the insertion of *ga*, a particle of frequent use in Gothic. The Welch *a mathe*, or as it may be written, *ammaddeu*, is a composite of *ag madde*, and *renit*, the first being the Latin conjunction *ac*, the second the Greek **αριστη**, the same with **αριστη**, *to dismiss* or *remit*. *Dyledion*, the plural of *dyled*, is the Latin *debita*, things to be erased, or to be cancelled by being paid, i. e. debts. The noun *wor*, or the plural *wyr*, which in this tongue is so often added to the name of a thing, is but the Latin *vir*—*dyledawyr*, *debtmen* or *debtors*.

7. The Goths and Anglo-Saxons corrupted **λαβειν** into *leoran* and *bringan*, and hence our *to bear*, and *to bring*—*ni bringai*, do not bring us. The Latin *ne* in Gothic is *ni*, in Anglo-Saxon and English *no*, in Welsh *na* or *neg*. *Fraistubngai* is the corresponding noun of *frasisan*, *to tempt*, and therefore primarily meant *pressure*, *straightness*. The Welch *arwain* is the French *rene* with the vowel *a* prefixed, and is the same with our *rein*: its proper sense is to lead a horse with a bridle. The French, in deriving words from the Latin, generally reject the guttural in the middle or at the end; and on this principle the root of *rene* is *regno*, *to rule*, *direct*. *Profeligantib* strictly denotes *experience*, and its origin is the Latin *prelo*, which last is itself taken from the Greek **παρε**, *pasture*, or the corresponding verb **παρε**, *to taste* or *chew*.

8. The Gothic *ak* is the Latin *ac*, though used by the latter in a conjunctive, by the former in a disjunctive sense—*lut*. The root is **αυξ**, or the thence derived *auges*, whence the Gothic *augan*: and *ak*, conformably to the form of this

GOTHIC LANGUAGE.

last verb, is also written *auð* in the sense of *nam, enim*. The corresponding Welsh word is *eitbr*, derived from *επειρος, another*. The explanation of it is this—lead us not into trial; another thing, *i. e.* do another thing, namely, deliver us from evil: on this principle the conjunction *αλλα, but*, originated in *αλλο*. *Laufen*, which has given birth to various words in Anglo-Saxon and in English, and among the number to *loose, lose, lease, release, let*, is apparently the offspring of the Hebrew *לָזַן, luz, decedo, recedo: to deliver* from evil is but to cause to recede from evil, and thus *laufen* corresponds in sense as well as in sound to the original. A loose character is a character freed or loosened from the rules of sobriety and justice, and this deviation from rectitude is implied in the original *לָזַן*; while the compound *release* comes close to the Gothic signification of *lausan*, to deliver. The Welsh which answers to this is *gwared*, and is no other than the Latin *gero*, (properly pronounced *guero*.) *to manage, to carry*. The Arabic *فَرَعَ, pharâ*, is the origin of our word *free*, its primary sense. Being thence applied to men, it came to signify those who were the heads of families, or who went before them: hence it was used to convey the more general and abstract ideas of precedence or beginning; in this sense it is the origin of *πρῶτος* in Greek, *præ* in Latin, *fra* or *fram* in Gothic, *ifra* in Cimbric. In the Anglo-Saxon *m* is annexed, and hence our word *from*, though the Scotch use it in the original purity of *frac*. The corresponding Welsh *rhag*, which means *far, distance*, has retained with great exactness the sound and sense of *רָחַק, rbak*, its Hebrew original. The Gothic *ubil*, German *ubel*, Anglo-Saxon *ifle*, and English *evil*, is the Persian and Arabic *بَلِي, bala*, with a vowel prefixed. The Persian *tarik*, is the parent of the English *dark*: and as darkness was the symbol of *evil*, or of the supposed demon which created it, the Celts received it to express *evil* under the form of *drwg*: and it is remarkable that the same word with *alpha privativum* is used by the Greeks to denote a contrary sense—*απειροματος, not dark, ingenuous, sincere, true*. In the same language *παρανομος* means an *impostor*, which the lexicographers, misled by mere similitude of sound, have erroneously referred to *παρυσια, to eat*.

From this analysis, which we hope is worthy the attention of the learned, we shall draw a few conclusions respecting the Gothic tongue. First, it appears to resemble the Celtic, in having a common Asiatic basis, and in containing a copious influx of Greek and Latin words. As the two languages were not essentially different, there is no foundation for supposing, with Dr. Percy, that the Celts and the Goths were originally distinct races of men. And here we cannot help specifying a feature in these tongues, which, in a remarkable manner, bespeaks their original identity, or their immediate descent from a common parent.

The Gothic, with its offspring the Anglo-Saxon and the German, uses the particle *ga* or *ge* prefixed to words, and especially to verbs. The Gothic sometimes inserts *g* in the middle of words, and frequently before the infinitive termination of verbs: *αξῆτω, or augere, is wabhsan, and χλευσειν, to deride, blabgan, to laugh*. In consequence of this analogy, words borrowed from Greek and Latin are remarkably disguised, and they must be stripped of this peculiarity before they can be traced to their true origin. The Celtic, if we may judge from the Welsh, was distinguished by the same characteristic feature: thus, the Latin *vir* is *gwor; vinum, gwyn; vagus, gwag*, &c. On this principle *εμεις, like, as*, in Welch is *meis*, which bears the sense of the original. The identity or similitude of the two languages will account for the Goths and Celts being called by the common name

of Cimmerians or Cimbri, which the true Britons, the undoubted descendants of the Celts, still inherit under the name of Cymri.

Sir W. Jones, in his sixth discourse delivered to the society at Calcutta on the antiquities of Asia, has the following passage well worthy of our attention, as tending to confirm, in a remarkable manner, the result of the preceding inquiry. The passage is this: “It has been proved by clear evidence and plain reasoning, that a powerful monarchy was established in Iran long before the Assyrian government; that it was in truth a Hindoo monarchy, though, if any chuse to call it Cuscan, Casdean, or Scythian, we shall not enter into a debate on mere names; that it subsisted many centuries, and that its history has been ingrafted on that of the Hindoos, who founded the monarchies of Ayodhya and Indraprestha; that the language of the first Persian empire was the mother of the Sanscrit, and, consequently, of the Zend and Parsi, as well as of Greek, Latin, and Gothic; that the language of the Assyrians was the parent of Chaldaic and Pahlavi, and that the primary Tartarian language also had been current in the same empire; although, as the Tartars had no books, or even letters, we cannot, with certainty, trace their unpolished and variable idioms. We discover, therefore, in Persia, at the earliest dawn of history, the three distinct races of men, whom we described on former occasions as possessors of India, Arabia, and Tartary; and whether they were collected in Iran from distant regions, or diverged from it, as from a common centre, we shall easily determine from the following considerations. Let us observe, in the first place, the central position of Iran, which is bounded by Arabia, by Tartary, and by India; whilst Arabia lies contiguous to Iran only, but is remote from Tartary, and divided even from the skirts of India by a considerable gulf. No country, therefore, but Persia seems likely to have sent forth its colonies to all the kingdoms of Asia: the Brahmans could never have migrated from India to Iran, because they are expressly forbidden by their oldest existing laws to leave the region, which they inhabit at this day; the Arabs have not even a tradition of an emigration into Persia before Mohammed: nor had they, indeed, any inducement to quit their beautiful and extensive domains; and as to the Tartars, we have no trace in history of their departure from their plains and forests till the invasion of the Medes, who, according to etymologists, were the sons of Madai, and even they were conducted by princes of an Assyrian family. The three races, therefore, whom we have already mentioned, (and more than three we have not yet found,) migrated from Iran, as from their common country: and thus the Saxon Chronicle, I presume on good authority, brings the first inhabitants of Britain from Armenia; while a late very learned writer concludes, after all his laborious researches, that the Goths or Scythians came from Persia; and another contends, with great force, that both the Irish and Old Britons proceeded severally from the borders of the Caspian; a coincidence of conclusions from different media, by persons wholly unconnected, which could scarce have happened, if they were not grounded on solid principles. We may, therefore, hold this proposition firmly established, that Iran or Persia, in its largest sense, was the centre of population, of knowledge, of languages, and of arts; which, instead of travelling westward only, as it has been fancifully supposed, or eastward, as with equal reason might have been asserted, expanded in all directions to all the regions of the world.” Here we see it stated, as the result of Sir William Jones’s inquiry, that the Goths, the Irish, and the Old Britons, or the Celtae, were originally the same people,

and

GOTHLAND, a country of Sweden, bounded on the N. by Sweden Proper, on the E. and S. by the Baltic, and on the W. by the Sound, the German ocean, and Norway. This country is inhabited by a people, who derived their origin from the Getæ, or Tartars of the Crimea. The Goths had kings of their own, till the year 1132, when they were united to Sweden. The country is pleasant and fertile, consisting of pasture and arable land; and abounding in lakes and rivers plentifully stored with fish, and also with forests and mines. It contains 48 towns, and is divided into East, West, and South Gothland.

East Gothland is bounded on the N. by the provinces of Nericia or Nerike, and Sudermanland, on the E. by the Baltic, on the S. by Smoland or Smaland, and on the W. by the Wetter lake, which separates it from West Gothland. It is about 80 miles long, and 70 broad. It produces wheat, rye, barley, oats, pease, &c. in such abundance as to supply the neighbouring provinces. It has likewise many fine orchards, with meadows, pastures, lakes, and rivers abounding with fish, extensive forests, iron-mines and founderies, and quarries of stone and marble. The inhabitants are occupied in husbandry, hunting, and fishing, and also in some places in the mines. The chief towns of this province are Nordkiöping, Söderkiöping, Linköping, and Wadstena; which see respectively.

South Gothland is divided into three provinces, viz. Skonen or Skone, Halland, and Blekingen, which have at sundry times changed their masters, till at length Charles Gustavus annexed them for perpetuity to the Swedish dominions, by the treaty of Roschild, in the year 1658.

West Gothland is bounded on the N. by Warmeland, on the E. by Nericia, the Wetter lake, and Smaland, on the S. by Smaland and Halland, and on the W. by the Scagerrack. It is about 115 miles long, and 15 broad; like East Gothland it was under the administration of its own kings and laws. The soil produces corn, vegetables, and fruit; and affords excellent pastures, which enable the occupiers to supply other provinces with butter and cheese. The rivers, lakes, and sea-coast abound with fish; and in several places are erected iron-forges, alum-works, paper mills. The inhabitants are chiefly employed in agriculture and fishing. The chief towns are Gotheborg, Wenneborg, Lidkiöping, and Falköping; which see respectively.

GOTHLAND, or *Gottland*, an island belonging to Sweden, situated in the Baltic, between N. lat. 56° 54' and 57° 56', and E. long. 18° 6' and 19° 6'; about 70 miles long and 25 in its greatest breadth. It was formerly an independent kingdom, but is now subject to the supreme court of justice at Stockholm. Its situation has gained for it the appropriate denomination of the "Eye of the Baltic." The soil is fertile, and affords fine woods of oak and pine, and good pastures; and its breed of sheep is accounted excellent. It has large quarries of stone, which is exported to Stockholm and other places, and some curious species of stone morals, carnelians, agates, and beautiful petrifications. It furnishes likewise good lime-stones, tar, and deal-boards. Although it is not infested with bears or wolves, it abounds with foxes, deer, and hares. The inhabitants gain their subsistence by tilling the ground, grazing, fishing, working in the quarries, burning lime, and other sorts of mechanic trades, and navigation. The peasants are in a state of absolute dependence on the burghers, who supply them with necessaries, and with money for paying their taxes, and to whom they surrender the whole produce of their industry, without stipulating any price. This island was at first sub-

ject to the crown of Sweden, and afterwards to the Danes for near two centuries, till the year 1645, when by the treaty of Bromsebro, it was restored to Sweden. The capital of the island is Wisby, on the western coast.

GOTHS, a people, who came originally, according to Jornandes (Rer. Get.) who abridges the Gothic history of the learned Cassiodorus, comprised in 12 books, from the vast island, or rather peninsula, called Scandinavia, and including the present Sweden, Norway, Lapland, and Finmark. The learned Grotius, and after him Sheringham, and most of the northern writers, maintain by arguments, which, as many conceive, have not been refuted, but which are not convincing to others, that the Cimbrians (see CIMBRI), Getes (see GETÆ), and Goths, were the same nation; that Scandinavia was first peopled by them; and that from thence they detached colonies into the islands in the Baltic, the Chersonesus, and the adjacent places, yet destitute of inhabitants. Many vestiges, which cannot be ascribed to the arts of popular vanity, attest the ancient residence of the Goths in the countries beyond the Baltic. From the time of the geographer Ptolemy, the southern part of Sweden seems to have continued in the possession of the less enterprising remnant of the nation, and a large territory is even at present divided into East and West Gothland. (See GOTHLAND.) The time when the Goths first settled in Scandinavia, and the period at which they first peopled with their colonies the islands, the Chersonesus, and the neighbouring places, have not been ascertained. Some have said, that their first settlement was conducted by Eric, contemporary with Sarah, grandfather of Abraham. However this be, the peopling of the islands in the Baltic sea, of the Chersonesus, and of the adjacent places on the continent, is called by the Northern writers, the *first* emigration of the Goths or Getes. The attempt to cross the Baltic was natural and easy. The inhabitants of Sweden (as we learn from Tacitus) were masters of a sufficient number of large vessels with oars; and the distance is little more than 100 miles from Carlscroon to the nearest ports of Pomerania and Prussia. At least as early as the Christian era, and as late as the age of the Antonines, the Goths were established towards the mouth of the Vistula, and in that fertile province, where the commercial cities of Thorn, Elbing, Königsberg, and Dantzick were long afterwards founded. Westward of the Goths, the numerous tribes of the Vandals were spread along the banks of the Oder, and the sea-coast of Pomerania and Mecklenburg. A striking resemblance of manners, complexion, religion, and language, seemed to indicate that the Vandals and Goths were originally one great people. (See VANDALS.) In the age of the Antonines the Goths were still seated in Prussia. About the reign of Alexander Severus, they made frequent and destructive inroads into the Roman province of Dacia. In this interval, therefore, of about seventy years, we must place the *second* emigration of the Goths, from the Baltic to the Euxine. To what cause this was owing is matter of mere conjecture. Perhaps a pestilence or a famine, a victory or a defeat, an oracle of the gods, or the eloquence of a daring leader, were sufficient to impel the Gothic arms on the milder climates of the south. Besides the influence of a martial religion, the number and spirit of the Goths were equal to the most hazardous adventures. The use of round bucklers and short swords rendered them formidable in a close engagement; the manly obedience which they yielded to hereditary kings gave uncommon union and stability to their councils; and the renowned Amala, the hero of that age, and the tenth ancestor of Theodoric, king of Italy, enforced, by the ascendant of personal merit, the prerogative

of his birth, which he derived from the *anfes*, or demigods of the Gothic nation.

Whatever was the motive of their migration, they took their route eastward, entered Scythia, advanced to the Cimmerian Bosphorus, and, driving out the Cimmerians, settled in the neighbourhood of the Mæotic lake. Thence, in process of time, they sent out numerous colonies into Thrace, Dacia, Mæsia, or Italy, and lastly into the countries bordering on the Euxine sea, forcing every where the ancient inhabitants to abandon their native abodes. Such is the account given by Jornandes, and Ablavius, a celebrated writer among the Goths, who lived long before him. In the vicinity of the Mæotic lake, they had, it is said, Filimir for their king, who was a warlike prince; in Thrace, Mæsia, and Dacia, Xamolxis, a great philosopher: and in the countries on the Euxine sea, princes of the illustrious families of the Balthe and the Amali, the Visigoths being subject to the former, and the Ostrogoths to the latter. In all these countries they were the same people, though subject to different princes, and known by various appellations. As for the denominations of Westrogoths, softened by the Latins into that of Visigoths, and Ostrogoths, they were distinguished by those names before they left Scandinavia, being called Westrogoths and Ostrogoths, or western and eastern Goths, from their situation to the west and east, the former inhabiting that part of Scandinavia which borders on Denmark, and the latter the more eastern parts, near the Baltic. The information we derive from Jornandes concerning the various migrations and settlements of the Goths is conformable to the accounts that are given by the ancient Greek and Latin authors with respect to the different colonies and settlements of the Getes. That the Goths and Getes were the same people, is supposed by all the writers who flourished in or near the times in which both empires were overrun by them. Those authors, without doubt well acquainted with their origin, call them sometimes Goths, sometimes Getes, and sometimes Scythians; and several authors tell us, that the Getes and Goths had been long known to the Romans, and also to the Greeks by the former names, but not by the latter, till their incursions into the empire.

When the Goths greatly increased in Scythia, they resolved to seek new settlements; and accordingly, pursuing their route eastward, and travelling through several countries, they returned at length into Germany. Their leader in this migration was the celebrated Woden or Odin, of whom many strange things are related. It is said by the northern writers, that he was king of the Asgardians, supposed to be the same people with the Aspurians mentioned by Ptolemy and Strabo. Asgardia and Aspuria are said to be a common name of their city, situated, according to Strabo, near Bosphorus Cimmerius; and Aspuria was the metropolis of a country which Strabo calls Asia; hence Woden and his followers are styled by the ancient Gothic writers Ase, Asiani, and Asiæ. The kings of Aspuria are represented as being masters of all that part of Scythia that lay west of mount Imaus, and which the Latins called "Scythia intra Imaum," or Scythia within mount Imaus. Of this Asgardia or Aspuria, Woden is said to have been king; and hence he emigrated with a great multitude of his followers in quest of new settlements; or, as some say, with the great design of forming in Sweden, considered as the inaccessible retreat of freedom, a religion and a people, which, in some remote age, might be subservient to his purposes; when his invincible Goths, armed with martial fanaticism, should issue in numerous swarms from the vicinity of the Polar circle to chastise the oppressors of mankind. Having passed through different countries, and perform-

ed a variety of exploits, he at length arrived in Sweden, where he was allowed to settle, and where he reigned till his death. His name became so famous that the northern nations ranked him among the gods, and worshipped him with divine honours. He is supposed to have brought with him out of Asia the Runic characters (see Runic), and to have taught the northern nations the art of poetry; whence he is styled the father of the Scaldi or Scaldri. See SCALDS.

That the Goths, under the conduct of Woden, came from Scythia into the northern parts of Germany, is a received opinion among the northern writers, and, as they allege, confirmed by an immemorial tradition, by the ancient chronicles of those countries, and by many monuments and inscriptions in Runic characters, some of which are still to be seen in Sweden, Denmark, and the neighbouring islands. That there were such migrations can hardly be questioned, since we find the same names common to the inhabitants of Scandia and Asiatic Scythia, and likewise the same language, as Grotius, and after him Sheringham, have shewn. The ancient language of the Goths is now spoken by the Tartars of Precop, whence, and from other collateral circumstances, it has been concluded that the Scandian Goths and Asiatic Scythians had one and the same original. As to the time of this migration of Scythians under Woden into the northern parts of Germany, those who maintain it have not been able to determine. Some refer it to a period about 24 years B. C.; for at that time, they say, Pompey laid waste Syria, and great part of Asia, and menaced the north with ferocity. After all, this wonderful expedition of Woden or Odin is admitted with great hesitation, or indeed scarcely admitted at all by many, into authentic history. According to the obvious sense of the Edda (see EDDA), and the interpretation of the most skilful critics, Algard, instead of denoting a real city of the Asiatic Sarmatia, is the fictitious appellation of the mystic abode of the gods, the Olympus of Scandinavia; from whence the prophet was supposed to descend, when he announced his new religion to the Gothic nations, who were already seated in the southern parts of Sweden.

Before we proceed with our brief abstract of the history of the Goths, we shall give some account of their character, customs, laws, and religion, before they embraced Christianity. With regard to their general disposition and character, they were celebrated for their hospitality and kindness to strangers; and it is said that they derived their name from their being eminently good; the name of Goth being derived, according to Grotius and other writers, from the German word *got.n*, signifying *good*. They encouraged, says Dio, the study of philosophy more than any other barbarous or foreign nation, and often selected their kings from among their philosophers. Polygamy was not only allowed, but encouraged, and every one was respected according to the number of his wives, and of course his children. Adultery with them was a capital crime, and invariably punished with death. This severity, and likewise polygamy, prevailed among them, when they were known to the Greeks and Romans only by the name of Getes, as appears from the poet Menander, who was himself a Gete, and from Horace (l. iii. od. 24.) who bestows great encomiums on the virtue and chastity of their women. Of their laws we shall have occasion to speak in the sequel of this article. Their government was monarchical. Their religion seems to have been the same with that of the ancient inhabitants of Scandinavia and Saxony; which see respectively. Till the end of the eleventh century, a celebrated temple subsisted at Upsal, the most considerable town of the Swedes and Goths. This temple was enriched with the gold which the Scandinavians had acquired

in their piratical adventures, and sanctified by the uncouth representations of the three principal deities, the god of war, the goddess of generation, and the god of thunder. In the general festival that was solemnized every ninth year, nine animals of every species (without excepting the human) were sacrificed, and their bleeding bodies suspended in the sacred grove adjacent to the temple. The only traces that now subsist of this barbaric superstition are contained in the *Edda*; which see. See also ODIN.

Caracalla was the first Roman emperor who quarrelled with the Goths, and marched against them into that part of Dacia, north of the Danube, of which they had taken possession; but the advantages which he seems to have gained over them in a few skirmishes were very inconsiderable. It appears, that the Romans were alarmed at an early period by the progress of this warlike nation; for in the reign of Alexander, which began in 222, considerable sums of money were sent to them from Rome, in order to prevent their disturbing the peace of the empire. Notwithstanding these bribes, as soon as they heard of the assassination of the emperor Maximin, who was of Gothic extraction, they resolved to revenge it, and accordingly entering Mœsia, they totally laid waste that province. Not long after they made themselves masters of Thrace, from which they were driven by Gordian. Under Philip, his successor, they committed dreadful ravages both in Thrace and Mœsia. Soon after their retreat from the siege of Marcianopolis, the capital of the second Mœsia, and after having compelled the inhabitants to ransom their lives and property, they passed the Danube a second time, under the command of their king, Cniva, with a more considerable force; and having obliged Darius the son of the Roman emperor, to save himself by flight, they were opposed by the emperor himself. Darius, having compelled them to raise the siege of Nicopolis, they retired towards Philippopolis, took it by storm, and massacred, as is said, 100,000 persons in the sack of that city. The time, however, which was consumed in this tedious siege, enabled Darius to revive the courage, restore the discipline, and recruit the number of his troops, after the defeat they had sustained in their pursuit of the Goths. Thus recruited, the emperor exerted his utmost vigilance to oppose either the progress or the retreat of the barbarians. The Goths were now, on every side, surrounded and pursued by the Roman arms; and exhausted by the long siege of Philippopolis, they would gladly have purchased, by the surrender of all their booty and prisoners, the permission of an undisturbed retreat. The emperor, confident of victory, refused to listen to any terms of accommodation; and the high-spirited barbarians preferred death to slavery. The two armies, therefore, prepared for an engagement. The conflict was severe; two lines of the Gothic army were thrown into disorder; and the third only remained entire, prepared to dispute the passage of a morass, which was imprudently attempted by the Roman troops. Here the fortune of the day assumed a new aspect. In this morass the Roman army, borne down by the weight of their armour, after an ineffectual struggle, was irrecoverably lost; nor could the body of the emperor ever be found. Upon the election of Gallus A. D. 251, the first object of his attention was to deliver the Illyrian provinces from the intolerable weight of the victorious Goths. He offered them every inducement in his power to withdraw their forces; and he even promised to pay them annually a large sum of gold, on condition they should never afterwards infect the Roman territories by their incursions. This tribute, however, though granted at the expence of the honour of the Romans, was insufficient to secure their permanent repose.

New swarms of barbarians, encouraged by the success, and conceiving themselves not bound by the obligation of their brethren, spread devastation through the Illyrian provinces, and terror as far as the gates of Rome. In this period of alarm and distress, Æmilianus, governor of Pannonia and Mœsia, rallied the scattered forces of the empire; and the barbarians were unexpectedly attacked, routed, chased, and pursued beyond the Danube. Under the reigns of Valerian and Gallienus, the frontier of the last-mentioned river was perpetually infested by the inroads of the Germans and Sarmatians; but it was defended by the Romans with more than usual firmness and success. Nevertheless, the great stream of the Gothic hostilities was diverted into a very different channel. The Goths, in their new settlement of the Ukraine, soon became masters of the northern coast of the Euxine; to the south of that inland sea were situated the wealthy provinces of Asia Minor, which possessed all that could attract, and nothing that could resist, a barbarian conqueror. The little kingdom of Bosphorus, whose capital was situated on the straits, through which the Mæotis communicates itself to the Euxine, was composed of degenerate Greeks, and half-civilized barbarians. In this small kingdom, domestic factions, and the fears, or interest, of obscure usurpers, who seized on the vacant throne, admitted the Goths into the heart of Bosphorus.

Here they acquired a naval force sufficient to transport their troops to the coast of Asia. For this purpose, they constructed a sort of flat-bottomed boats, called "Canaræ," framed of timber only, without any iron, and occasionally covered with a shelving roof, on the appearance of a tempest. With this kind of fleet, they first appeared before Pityus, at the utmost limit of the Roman provinces, with a convenient port, and fortified with a strong wall. Their first attack was repulsed; but, renewing their attempts, they destroyed this city. Then circling round the eastern extremity of the Euxine sea, their navigation from Pityus to Trebisond was a course of about 300 miles. This city was large and populous, defended by a double inclosure of walls, and had its usual garrison strengthened by a reinforcement of 10,000 men. But this numerous garrison was dissolved in riot and luxury, and thus rendered carelessly guarding their impregnable fortifications. The Goths, availing themselves of the supine negligence of the besieged, erected a lofty pile of fascines, ascended the walls in the silence of the night, entered the defenceless city, sword in hand, massacred the inhabitants, destroyed the temples and splendid edifices, and gained an immense booty. With the rich spoils of the city they filled a great fleet of ships, which they found in the port, and, satisfied with the success of their first naval expedition, returned in triumph to their new establishments in the kingdom of the Bosphorus. In their second naval expedition, possessed of greater powers both of men and ships, they took a new course, followed the western coast of the Euxine, passed before the wide mouths of the Borythenes, the Nieker, and the Danube; and increasing their fleet by a great number of fishing barks, they approached the narrow outlet through which the Euxine sea pours its waters into the Mediterranean. In this expedition they plundered the cities of Bithynia, Chalcedon, Nice, Prusa, Apamea, Cius, and Nicomedia. From the recent attack of Prusa, the Goths advanced within 18 miles of Cyzicus; but their progress was stopped by the small river Rhyndacus, which issues from the lake Apolloniates, and which was then swelled into a broad and rapid stream. Their retreat to the maritime city of Heraclea, where their fleet was probably stationed, was attended by a long train of waggons, laden with the spoils of Bithynia,

and was marked by the flames of Nice and Nicomedia, which they wantonly burnt. The third naval expedition of the Goths consisted of 500 sail of transports, containing about 15,000 warriors. They now steered their destructive course from the Cimærian to the Thracian Bosphorus; and were carried to the lake of the Propontis. Their landing on the little island of Cyzicus was followed by the ruin of that ancient and noble city. They thence issued through the narrow passage of the Hellespont, and pursued their winding navigation amidst the numerous islands scattered over the Archipelago, or Ægean sea. At length the Gothic fleet anchored in the port of Piræus, five miles from Athens, ravaged Greece, and caused the rage of war, both by land and sea, to spread from the eastern point of Sunium, to the western coast of Epirus, advancing within sight of Italy. The indolent Gallenus was roused; the emperor appeared in arms; and his presence contributed to check the ardour of the enemy. Some of the numerous Gothic host broke into Mœsia, for the purpose of forcing their way over the Danube to their settlements in the Ukraine. Others returned on board their vessels, and re-tracing their course through the Hellespont and the Bosphorus, and finding themselves secure within the basin of the Euxine, landed at Anchialus, in Thrace, near the foot of mount Hæmus, and refreshed themselves by the use of those pleasant and salutary hot-baths. Amidst their devastations, we may select the destruction of the famous temple of Diana at Ephesus, which they burnt in their third naval invasion. It is also said, that they threatened to destroy all the libraries of Athens, but were prevented from executing their menace by the profound observation of one of their chiefs, that as long as the Greeks were addicted to the study of books, they would never apply themselves to the exercise of arms. Under the reign of Claudius, A. D. 269, the Goths collected an armament more formidable than any that had yet issued from the Euxine. On the banks of the Niester they constructed a fleet of 2000, or even of 6000 vessels, which, in their passage through the Bosphorus, encountered various disasters. However, they made several descents on the coasts, both of Europe and Asia. But discontent and division arose in the fleet, and some of their chiefs deserted them, and sailed away towards Crete and Cyprus: the main body, nevertheless, pursued their course, anchored at the foot of mount Athos, and assaulted the city of Thessalonica. Their attacks were soon interrupted by the rapid approach of Claudius. The Goths, eager for a general engagement, relinquished the siege of Thessalonica; and with this view, leaving their navy at the foot of mount Athos, traversed the hills of Macedonia. Claudius was distressed, but at the same time firm and determined. The event exceeded even his own expectations, as well as those of the world; and having gained signal victories, and delivered the empire from this host of barbarians, he was distinguished by posterity under the glorious appellation of the Gothic Claudius. The decisive battle was fought near Naïssus, a city of Dardania. The war was afterwards diffused over the provinces of Mœsia, Thrace, and Macedonia, and the superior talents of the emperor generally ensured the success of his arms. The Goths suffered to such a degree, that a select body of their youth was received among the Imperial troops, the remainder was sold into servitude, and the female captives were so numerous, that every soldier appropriated to himself two or three women. To complete the disasters of the Goths, their fleet was either taken or sunk, so that their retreat was thus intercepted. Aurelian, the successor of Claudius, distinguished himself during the Gothic war, and, at last, put an end to

it by a lasting and beneficial treaty. The Goths were engaged to supply the armies of Rome with a body of 2000 auxiliaries, consisting entirely of cavalry, and, in return, stipulated an undisturbed retreat, with a regular market as far as the Danube, provided by the emperor's care, but at their own expence. But the most important condition of peace was understood rather than expressed in the treaty. Aurelian withdrew the Roman forces from Dacia, and tacitly relinquished that great province to the Goths and Vandals. This proved, in the event, a wise measure; for, after Dacia became an independent state, it seemed as the firmest barrier of the empire against the invasions of the savages of the North.

About the year 273, the second of the reign of Probus, the Goths entered Thrace, and advanced as far as Illyricum, laying waste the country with fire and sword; but as soon as they heard that the emperor was marching against them, they retreated and left their booty behind them. In Illyricum, Probus was met by deputies from the Gothic nations, suing for peace, and submitting to his power. No further mention is made of the Goths till the year 289, at which time Dioclesian is said to have gained a complete victory over them. From this victory Dioclesian assumed the name of "Sarmaticus," as appears from several ancient coins and inscriptions. From this year to the 15th of Constantine, the Goths gave no disturbance to the empire, being engaged in wars with the neighbouring nations. As soon as the Goths were disengaged from other wars, they invaded the Roman empire; but they were overcome by Constantine in several battles, fought at Campana, in Pannonia, and at Margus and Bononia, in Upper Mœsia. The emperor determined to chastise as well as to repulse the insolent barbarians who had dared to attack the territories of Rome, passed the Danube, and penetrated into the inmost recesses of Dacia; and when he had inflicted a severe revenge, condescended to give peace to the suppliant Goths, on condition that as often as they were required, they should supply his army with a body of 40,000 soldiers. In the year 331, a war broke out between the Goths and Sarmatians; on which occasion the latter had recourse to Constantine, who was glad to embrace an opportunity of humbling that ferocious nation. In the first action the barbarians gained the advantage; but the event of a second and more successful action, in April 332, retrieved the honour of the Roman name. Near 100,000 of the enemy were either put to the sword, or perished after the battle with hunger and cold; and this defeat was so signal, as to oblige Alaric, king of the Goths, to sue for peace, and to deliver hostages to the emperor, one of whom was his own son. The Goths not only continued quiet, but served the Romans with great fidelity, during the remaining part of Constantine's reign; and in the reigns of Constantian, Julian, Trajan, and Valentinian I. But in the first of Valens, they made inroads into Thrace, and laid waste that province. The emperor purchased their retreat for a sum of money. In the following year news was brought him to Bithynia, that the Goths were again ready to break into Thrace. When Procopius revolted, and assumed the title of emperor, the Goths espoused his cause, and sent a body of troops to his assistance; but before their arrival, he was defeated and put to death. They, however, continued in the territories of the empire, committing great ravages in Thrace and Mœsia. Valens sent a strong detachment against them, and their retreat being cut off, they were obliged to lay down their arms, and yield themselves prisoners. After hostilities which lasted three years from 366 to 369, the barbarians submitted, and thus appeased the resentment of Valens. After the ratification of the treaty, Valens returned in triumph to Constantinople,

stantinople, and the Goths remained in a state of tranquillity about six years; till they were violently impelled against the Roman empire by an innumerable host of Scythians, who appeared to issue from the frozen regions of the North. In the year 375 the Huns invaded the territories of the Goths, and spread among them such a general consternation, that they fled for refuge to the Roman dominions. Valens listened to their supplications, and granted them protection. The liberality of the emperor, however, was accompanied with too harsh and rigorous conditions. Before they passed the Danube, they were required to deliver their arms; and it was insisted that their children should be taken from them, and dispersed through the provinces of Asia; where they might be civilized by the arts of education, and serve as hostages to secure the fidelity of their parents. A probable testimony has fixed the number of the Gothic warriors at 200,000 men; and if we can venture to add the just proportion of women, of children, and of slaves, the whole mass of people which composed this formidable emigration must have amounted to near a million of persons, of both sexes and of all ages. The Goths, justly provoked at the cruel treatment they met with from the Roman officers, who were to supply them with provisions, had scarcely entered Thrace, under the conditions imposed upon them, when they began to mutiny and plunder the country. This occasioned a long and bloody war between them and the Romans. They were joined by the Huns, Alani, Taisfaks, and other swarms of their countrymen. In the battle of Hadrianople, A. D. 378, the Roman cavalry fled; and the infantry was abandoned, surrounded, and cut in pieces; and though the Goths were obliged to raise the siege of Hadrianople, the tide of the Gothic inundation rolled from the walls of this city to the suburbs of Constantinople; and the Roman provinces were ravaged by the barbarians. At this time a suspicion prevailed, that the Goths of Asia had formed a secret and dangerous conspiracy against the public safety. An order was promulgated that, on a fixed day, the Gothic youth should assemble in the capital cities of their respective provinces; and as a report was industriously circulated, that they were summoned to receive a liberal gift of land and money, the pleasing hope allayed the fury of their resentment, and perhaps suspended the motions of the conspiracy. On the appointed day, the unarmed crowd of the Gothic youth assembled in the square, or forum; the streets and avenues were occupied by the Roman troops; and the roofs of the houses were covered with archers and slingers. At the same time in all the cities of the East, the signal was given of indiscriminate slaughter; and the provinces of Asia were delivered by the cruel prudence of Julius, who was master-general of the troops, from a domestic enemy, who, in a few months, might have carried fire and sword from the Hellespont to the Euphrates. At length the Goths submitted to Theodosius I., and were allowed by him to settle in Thrace and Mesia, which two provinces had been almost depopulated by the frequent incursions of the neighbouring barbarians, and the late destructive war. A numerous colony of the Visigoths was settled in Thrace; the remains of the Ostrogoths were planted in Phrygia and Lydia; their immediate wants were supplied by a distribution of corn and cattle; and their future industry was encouraged by an exemption from tribute for a certain number of years. Hopes were entertained that the manners of the barbarians would in time be polished, and that their posterity would be insensibly blended with the body of the Roman people. Notwithstanding these flattering expectations, it was apparent to every discerning eye, that the Goths would long remain the enemies, and might soon become the

conquerors of the Roman empire. As the impatient Goths could only be restrained by the firm and temperate character of Theodosius, the public safety seemed to depend on the life and abilities of a single man. He died in the month of January A. D. 395, and before the end of the winter of the same year, the Gothic nation was in arms. The interruption, or at least the diminution, of the subsidy which the Goths had received from the prudent liberality of Theodosius, was the specious pretence of their revolt. Instead of being impelled by the blind and headstrong passions of their chiefs, they were now directed by the bold and artful genius of Alaric. In the year 396 Alaric marches into Greece; and he hastened to occupy the city of Athens, and the important harbour of the Piræus. Corinth, Argos, and Sparta yielded without resistance to the arms of the Goths. From Thermopylæ to Sparta, the leader of the Goths pursued his victorious march, without encountering any mortal antagonists; and the Christian faith, which he had devoutly embraced, taught him to despise the imaginary deities of Rome and Athens. In 397 Stilicho, the general of the West, advanced to chastise the invaders of Greece. The skill and perseverance of the Roman at length prevailed: and the Goths, after sustaining a considerable loss by disease and desertion, gradually retreated to the lofty mountains of Phœloe, near the sources of the Peneus, and on the frontiers of Elis; a sacred country, which had formerly been exempted from the calamities of war. Their camp was immediately besieged; and reduced to great distress by thirst and hunger. A strong line of circumvallation was formed to prevent their escape. Alaric was secret, prudent, and rapid in his operations: he immediately negotiated a treaty with the ministers of Constantinople; and Stilicho was compelled to retire from the dominions of Arcadius; and he respected, in the enemy of Rome, the honourable character of the ally and servant of the emperor of the East. Alaric is declared master-general of the Eastern Illyricum; and the use to which he applied his new command distinguishes the firm and judicious character of his policy. He issues his orders to the four magazines of offensive and defensive arms, Margus, Ratiaria, Naïffus, and Thessalonica, to provide his troops with an extraordinary supply of shields, helmets, swords, and spears. With the unanimous consent of the barbarian chieftains, the master-general of Illyricum was elevated, according to ancient custom, on a shield, and solemnly proclaimed king of the Visigoths. Thus armed with double power, and seated on the verge of the two empires, he amused the two emperors Arcadius and Honorius, till he declared and executed his resolution of invading the dominions of the West. He was tempted by the fame, the beauty, and the wealth of Italy, which he had twice visited; and he secretly aspired to plant the Gothic standard on the walls of Rome, and to enrich his army with the accumulated spoils of three hundred triumphs. Alaric loses no time in executing his purpose of invading Italy, and advances, against much opposition, towards the capital of the empire. It was in the year 400 that he first entered Italy, making dreadful ravages in his progress. His march, probably from Thessalonica, through the warlike and hostile country of Pannonia, as far as the foot of the Julian Alps; his passage of those mountains, which were strongly guarded by troops and entrenchments; the siege of Aquilina, and the conquest of the provinces of Istria and Venetia, appear to have employed a considerable time. In the year 403, Alaric approached Milan, and the emperor Honorius, dreading his arrival, fled to Ravenna. Stilicho, however, prepared to march against the enemy, whom he found encamped at Pollentia, on the Tanaro, in Piedmont. While the

Christian Goths were devoutly celebrating Easter, they were attacked by Stilicho, and after a very severe engagement, they retreated from the field of battle, after the total defeat of the infantry, with their cavalry entire, under the command of Alaric, who possessed a mind, that was invincible and superior to misfortune, and that derived new resources from adversity. The Gothic sovereign, wishing to distinguish his retreat by some illustrious exploit, attacked Verona, but in the battle that ensued he suffered a defeat no less disastrous than that at Pollentia. In the year 408 Alaric marched again towards Rome; with bold and rapid marches he passed the Alps and the Po; hastily pillaged the cities of Aquileia, Altinum, Concordia, and Cremona; increased his forces by the accession of 30,000 auxiliaries; and, without meeting a single enemy in the field, advanced as far as the edge of the morass, which protected the impregnable residence of the emperor of the West. He soon after pitched his camp under the walls of Rome. A ransom having been offered and accepted, he raised the siege A. D. 409. Alaric's next attack was directed against the port of Ostia, one of the boldest and most stupendous works of Roman magnificence; and as soon as he was in possession of this important place, he summoned the city to surrender at discretion; but he contented himself with superseding Honorius, and bestowing the purple on Attalus, prefect of the city. Attalus was soon after degraded, and his degradation was followed by the third siege and sack of Rome, Aug. 24, A. D. 410. At the hour of midnight the Salarian gate was silently opened, and the inhabitants were awakened by the tremendous sound of the Gothic trumpet. Eleven hundred and sixty-three years after the foundation of Rome, the Imperial city, which had subdued and civilized so considerable a part of mankind, was delivered to the licentious fury of the tribes of Germany and Scythia. After six days' pillage and desolation, the victorious Goths evacuated Rome, and their intrepid leader advanced into Campania, and having ravaged that and the neighbouring provinces of Lucania, Samnium, Apulia, and Calabria, he approached the straits of Sicily, with a design to pass over into that island, and thence into Africa; but he was seized in the neighbourhood of Rhegium with a fit of illness, of which he died in a few days. (See ALARIC.) He was succeeded in the Gothic throne by his brother-in-law Ataulphus, or Adolphus, who concluded a peace with the empire, and marched into Gaul A. D. 412. Being driven out of Gaul A. D. 415, he retired to Spain, where he was soon after assassinated. Jingeric, his successor on the Gothic throne, shared the same fate. After his death the free choice of the nation bestowed the Gothic sceptre on Vallia or Wallia, who concluded a peace with the Romans, and commenced a sanguinary, but successful war with the barbarians, who had settled in Spain. His victorious Goths, A. D. 419, forty-three years after they had passed the Danube, were established, according to the faith of treaties, in the possession of the second Aquitain, a maritime province between the Garonne and the Loire, under the civil and ecclesiastical jurisdiction of Bourdeaux. The Gothic limits were afterwards enlarged by the additional grant of some neighbouring dioceses; and the successors of Alaric fixed their royal residence at Thouloufe. Thus, about the same time, in the last year of the reign of Honorius, the Goths, the Burgundians, and the Franks, obtained a permanent seat and dominion in the provinces of Gaul. Vallia was succeeded by Theodoric, who first made war with the Romans, and gained several places in Gaul belonging to them, and afterwards concluded a peace with them. The Goths continued quiet in the countries that had been allotted them in Gaul for the space of ten years, or till the

year 436, when, the Romans being engaged in a war with the Burgundians, Theodoric availed himself of that opportunity to enlarge his dominions. At length the Gothic king made peace with the Romans; and in the year 453 engaged by an alliance with them to assist them against the Huns, who had entered Gaul. Theodoric, his son and successor, breaks with the Romans; but his brother Theodoric, who next occupied the Gothic throne, and who was eminently distinguished by his talents and attainments, cultivated the friendship of the Romans, and contributed by his martial exploits to the support of the Roman empire. Theodoric entered Spain with a large army of Goths and Burgundians; and having almost reduced the Suevians in Galicia, A. D. 457, he passed from thence into Lusitania, and reduced several places. Upon his return to Gaul, he took several cities belonging to the Romans, but was at length checked in his career and defeated by Ægidia, commander in chief of the Roman forces in that country. In Spain the Goths were more successful than they were in Gaul, and became masters of the greater part of the country. Under Euric, who ascended the throne A. D. 466, the Goths drove the Romans out of Spain; and all the provinces, except Galicia, and part of Lusitania, which were subject to the Suevians, acknowledged him for their king, who residing at Thouloufe, governed them by his lieutenants. Euric, having also made himself master of the best part of Gaul, comprising the whole tract between the Rhone and the Loire, and of the greater part of Spain, was still desirous of reducing the remaining parts of both countries, when his death at Arles, A. D. 484, put a stop to his great designs. Euric is said to have been the first who gave written laws to the Goths, for till his reign they had been governed by customs only; and for this purpose he employed Leo, his prime minister, one of the most learned men, and best civilians of that period. These laws were called the "Theodorician" laws; and were introduced by Euric upon the people of Gaul and Spain, who had been long accustomed to the Roman laws; but Alaric, his son and successor, restored the Roman laws to their former authority, and caused them to be observed throughout his dominions. About this period the kingdom of the Visigoths in Gaul terminated; and they, being driven from thence, fixed their royal seat at Toledo, in Spain. (See VISIGOTHS.) For the history of the Ostrogoths; see OSTROGOTHS. Under Theodoric, who, A. D. 493, caused himself to be proclaimed by his Goths king of Italy, and was acknowledged as such by the emperor Anastasius, the successor of Zeno, Theodoric secured his new kingdom by alliances with neighbouring powers; he quartered all his Goths in the castles and strong holds, with their officers who were to command them in time of war, and govern them in time of peace; he retained the Roman laws, the same form of government, the same distribution of provinces, the same magistrates and dignities; and, besides, according to the custom of the Goths, he appointed for each city inferior judges, distinguished by the title of counts, who were to administer justice, and decide all disputes; and in this respect the polity of the Goths, as Grotius observes, far excelled that of the Romans. Thus Italy, from the dominion of the Romans, fell under that of the Goths, almost without any perceptible change. See THEODORIC.

At subsequent periods attempts were made to recover the country from subjection to their government; particularly in the reign of Justinian. Under the weak reign of Theodatus, the Gothic king of Italy, Belisarius invaded Italy, entered Rome A. D. 536, and reduced Naples A. D. 537. He defended Rome against the whole army of the Goths,

Goths, who besieged it A. D. 537, and continued it above a year till their final departure. During this siege, which was raised in March, A. D. 538, one-third of their enormous host was destroyed in frequent and bloody combats under the walls of the city, and the evils of famine and pestilence were aggravated by their own licentiousness, and the unfriendly disposition of the country. Vitiger, their king, retired for shelter within the walls and morasses of Ravenna. At length Belisarius besieged the city, and took it in the latter end of the year 539. The submission of the capital was imitated in the towns and villages of Italy; and the independent Goths who remained in arms at Pavia and Verona, were ambitious only to become the subjects of Belisarius. But his inflexible loyalty rejected, except as the substitute of Justinian, their oaths of allegiance. In the year 540, the Goths revolted, and Totila, the nephew of their late king, undertook the restoration of the kingdom of Italy. His first movements were rapid and successful; and after reducing by force, or treaty, the towns of inferior note in the midland provinces of Italy, Totila proceeded, A. D. 546, to encompass Rome, and to starve its inhabitants. Famine had relaxed the strength and discipline of the garrison, and Rome was taken by the Goths in December, A. D. 546. After the departure of Totila, it was recovered by Belisarius in February, A. D. 547. (See BELISARIUS.) When Totila returned to avenge the injury and disgrace, the Goths were thrice repulsed; they lost the flower of their troops; the royal standard had almost fallen into the hands of the enemy, and the fame of Totila sunk, as it had risen, with the fortune of his arms. Rome was again taken by the Goths, A. D. 549. Justinian made great preparations for the Gothic war, the conduct of which was committed to Narfes, who defeated Totila in a bloody engagement, July, A. D. 552, and Totila himself was struck through the body with a lance. Narfes then proceeded to the conquest of Rome; and Justinian once more received the keys of the imperial city, which, under his reign, had been *five* times taken and recovered. The last king of the Goths was Teias, who was unanimously chosen to succeed and revenge their departed hero, March, A. D. 553. Sixty days were consumed in distant and fruitless combats, between the Gothic and Roman armies, but at length, after an engagement of many hours, Teias fell, and his head, exalted on a spear, proclaimed to the nations, that the Gothic kingdom was no more. After a reign of 60 years, the throne of the Gothic kings was filled by the exarchs of Ravenna (see EXARCH); and the remains of the Gothic nation evacuated the country or mingled with the people. (Anc. Un. Hist. vol. xvii. Gibbon's Hist. vol. vii. passim.)

The Goths spread themselves very widely in their various migrations, and formed part of the population of the several nations of Europe. In England the Celtic population was succeeded by the Gothic, and about two-thirds of England were possessed by the Belgic Goths. (See BELGÆ and ENGLAND.) About the time that the Belgæ seized on the south of England, it appears that a hundred Gothic tribes passed to the south of Ireland. (See IRELAND.) In France, or Gaul, the Goths, or warlike German tribes, under the denomination of Belgæ, seized on a third part of the country into which they introduced the Gothic language and manners. (See BELGÆ and GAUL.) The original population of the Netherlands was Celtic; but it was afterwards supplanted by the Belgæ. (See BELGÆ and NETHERLANDS.) In Germany, the Scythians or Goths, proceeding either from Scandinavia, or, as others say, from their original seats on the Euxine, expelled the Cimbri and Fins, and these, intermixed with the German nations, destroyed the Roman

empire in the west. (See GERMANY, and the preceding part of this article.) Prussia appears to have been peopled by the Peucini and Ællii, Gothic tribes bordering on the Venedi, who were Slavonians. (See PRUSSIA.) The Vandals, who conquered Spain in the fifth century, were subdued by the Visigoths under Euric, who found the modern kingdom of Spain. (See SPAIN.) The original population of Turkey in Europe chiefly sprung from the ancient Scythians on the Euxine, the progenitors of the Dacians, Thracians, &c. and even of the Greeks. The regions of Turkey in Asia were peopled by Scythic nations, intermixed with a few Assyrians from the south. (See TURKEY.) The Batavi of Holland were the most northern people of Belgic Gaul, and without doubt a German or Gothic progeny. (See BATAVI, GAUL and HOLLAND.) The Cimbri or northern Celts, who originally peopled Denmark, were expelled by the Goths, if they were not, as some conceive, tribes of the same nation; and the Fins or Laps of Norway, which, with Sweden, constitutes the ancient Scandinavia, were driven to the northern extremities by the Gothic invasion. (See DENMARK, NORWAY, SCANDINAVIA, and SWEDEN.) The Helvetians, or original Swifs, are supposed by some writers to have been Celts; but others, with greater probability, consider them as a Gothic race, or very ancient colony of Germans.

It has been a general opinion, strenuously maintained by Cluverius and Pelloutier, and adopted by Mallet in his "Northern Antiquities," that the Gothic and Celtic nations were the same; but the ingenious English translator of Mr. Mallet's "Northern Antiquities" has produced a variety of testimonies from ancient authors, to prove that the Celtic and Teutonic or Gothic nations were, *ab origine*, distinct, and that they differed considerably in person, manners, laws, religion, and language. The former were the ancestors of the Gauls, Britons, and Irish; and the Germans, Saxons, and Scandinavians derived their origin from the latter. The Celtic tribes were probably the first that travelled westward; and the Goths, or Getæ of the ancients, who emigrated at different times from the eastern countries after them, might borrow some of their opinions and practices, which will account for the resemblance that has been observed between them, without admitting that they were descended from them, or that they should be considered as the same people. In the same way we may account for those relics both of Celtic and Gothic superstitions, which are discernible in Gaul and Britain, and many other countries, the inhabitants of which derive their descent equally from the Celts and Goths, who were at different times masters of these kingdoms, and whose descendants are now blended together; thus, the first inhabitants of Gaul and Britain being of Celtic race, followed the Druidical superstition. The ancient Germans, Scandinavians, &c. being of Gothic race, professed that system of polytheism which was afterwards delivered in the Edda; and the Franks and Saxons, who afterwards settled in Gaul and Britain, being of Gothic race, introduced the polytheism of their own nation, which was in general the same that prevailed among all the other Gothic or Teutonic people. See, however, the article *GOTHIC language*, where the original identity of the Celts and Goths is maintained partly by general reasoning, and partly by etymological investigation.

GOTLUNDA, in *Geography*, a town of Sweden, in Nericia; nine miles N. N. E. of Orebro.

GOTOMB, a town of Poland, in the palatinate of Lublia; 28 miles N. W. of Lublin.

GO-TON, a town of China, in the province of Se-tchuen; 48 miles N. W. of Ou-mong.

GOTSEELA, a town of Bengal; 48 miles W. of Midnapour.

GOTTA, or GOTTO *Ilands*, a cluster of small Japanese islands. N. lat. $30^{\circ} 40'$. E. long. $131^{\circ} 40'$.

GOTTAUL, a town of Bengal; 33 miles S. of Burdwar. N. lat. $22^{\circ} 42'$. E. long. $88^{\circ} 5'$.

GOTTESBERG, a town of Silesia, in the principality of Schweidnitz, near which are two mines, one of gold, not now worked, and another of coals. The manufacture of this town consists of knit worsted stockings. It contains two churches; 12 miles S. W. of Schweidnitz. N. lat. $50^{\circ} 35'$. E. long. $15^{\circ} 54'$.

GOTTESGAB, a town of Bohemia, in the circle of Saatz. N. lat. $30^{\circ} 22'$. E. long. $12^{\circ} 54'$.

GOTTI, VINCENT-LEWIS, in *Biography*, was born at Bologna in the year 1664. At sixteen years of age he embraced the ecclesiastical life among the Dominican monks, and when he had completed his course of philosophy at Bologna, he was sent to study theology for four years at Salamanca in Spain. Upon his return to Italy in 1688, he was appointed professor of philosophy in the university of Bologna; and soon recommended himself by his talents and virtues to the polls of prior and provincial of his order. In 1728, pope Benedict XIII. raised him to the dignity of the purple; and three years afterwards appointed him member of the congregation for examining bishops. So highly was he esteemed, that in the last conclave, which was held during his time, he had the suffrages of a great number of the college for his being raised to the papal throne. He died at Rome in 1742, in his 79th year. His works, which are much valued by the Catholics, particularly by those in Italy, display considerable erudition and abilities. Of these the principal are "De vera Christi Ecclesia," in three volumes; "Theologia Scholastico-dogmatica, juxta Mentem divi Thomæ Aquinatis, &c." in six volumes 4to.; "Colloquia Theologica-polemica, in tres classes distributa, &c." 4to.; "De Eligenda inter Diffidentes Christianos Sententia," written in answer to a piece with the same title, by the celebrated John le Clerc; and an elaborate work in defence of the truth of the Christian religion against Atheists, Idolaters, Mahometans, Jews, &c. in 12 volumes. He was employed at the time of his death in writing "A Commentary on the book of Genesis." Moreri.

GOTTIGNIES, GILES-FRANCIS, was born at Brussels in the year 1630, and entered into the order of the Jesuits at Mechlin in 1653, whence he was sent to Rome, to pursue his theological studies; here he spent the rest of his life employed in teaching the mathematics, and writing different works in that science. He died in 1689, when he was about sixty years of age. He was a considerable mathematician: a great lover of pure geometry, and had a distaste to the algebraic method of resolving problems; his works are very numerous, and have been highly commended for perspicuity and precision. They relate to arithmetic and geometry; to the various parts of astronomy, and other branches of speculative and practical mathematics. Moreri.

GOTTINGEN, or GOETTINGEN, in *Geography*, a town of the kingdom of Westphalia, and principal place of a district, named from it, is situated in a spacious, pleasant, fertile valley, on a canal, branching from the river Leine, and dividing the town into the New town and Marsch. The number of houses is about 1000, containing about 8000 persons; the streets are large and paved; it has five parish churches, and one for Calvinists; the Roman Catholics perform their religious service in a private house. The town is governed by a provost, named by the sovereign, burgo-masters, and a synod chosen by the regency, assisted by a council. The university of Göttingen claims peculiar notice; it was founded

in 1734 by George II, king of England, and consecrated on the 17th of September 1737, and by the attention of its first curator, baron Munchausen, it has risen to distinguished reputation. It has a splendid church, with its own pastor; and it is accommodated with a stately edifice of stone, the ground-floor of which serves as a hall for public lectures, and the upper apartments are appropriated to the library, council-chamber, and other necessary purposes. Its library is very large and valuable, and it is called the "Bulowean," from a collection of about 10,000 volumes, with which it originated, bequeathed by baron Bulow for public use, and granted by his heirs to the university. A royal society of sciences, founded in 1751, and a royal German society, form part of the university. It has likewise a fine observatory, erected on a tower on the ramparts, with a physic garden, anatomical theatre, &c. The territory belonging to the town is very considerable; 22 miles N. E. of Cassel. N. lat. $51^{\circ} 31'$. E. long. $9^{\circ} 52'$.

GOTTO, a country of Africa, situated to the south of Jimbali and Tombuctoo, and the river Niger or Joliba, about 15° N. lat., and from 0 to 2° E. long. It was formerly divided into several petty states, under their own chiefs, but it is now under the government of a king. Its chief town is called Mooffeeddo, from the name of their first monarch.

GOTTOLENGO, a town of Italy, in the department of the Mela; 15 miles S. of Brescia.

GOTTORP. See SLESWIC.

GOTTSCHÉE, a town of Middle Carniola; 20 miles S. S. E. of Laybach. N. lat. $45^{\circ} 53'$. E. long. $14^{\circ} 48'$.

GOTZEL, a town of Bavaria; 36 miles E. of Ratisbon.

GOVAN, a town of Scotland, in Lanarkshire; the population of which, in 1801, was 6701, of which 1314 were employed in trade and manufactures; four miles W. of Glasgow.

GOVANDORE, a bay on the coast of Chili.

GOVANIA, in *Botany*, was named by Jacquin in honour of Anthony Gouan, a physician and celebrated botanist of Montpellier, where he has long filled the botanical chair, and, as far as we know, is still living, though at a very advanced age. He was the friend and correspondent of Linnæus, and is the author of a *Flora Mompeliaca*, arranged according to what he himself calls a hybrid system, the outlines being on the principles of Tournefort, the subordinate sections taken from the Linnæan sexual system. This work appeared in 1765. He had previously, in 1762, published a *Hortus Mompeliensis* according to the last-mentioned system. Each work forms an octavo volume. They are chiefly remarkable for the secondary generic characters, taken from the habit, subjoined to the essential ones which are founded on the fructification. Professor Gouan published also a folio volume of *Observationes Botanicae*, with plates, illustrative of the plants of his neighbourhood: as well as a quarto in Latin and French on the methodical arrangement, and generic characters at length, of fishes.—Jacq. Amer. 263. Linn. Gen. 547. Schreb. 33. Mart. Mill. Dict. v. 2. Juss. 381. Lamarck. Illustr. t. 845.—Class and order, *Polygonia Mompeliaca*, or rather *Pentandria Mompeliensis*, Nat. Ord. *Dumosea*, Linn. *Rhamni*, Juss.

Gen. Ch. Cal. Perianth of one leaf, superior, funnel-shaped, five-cleft; tube permanent; segments of the limb ovate, acute, spreading, deciduous. Cor. Petals five, opposite to the stamens, hood-shaped, elastic. Stam. filaments five, awl-shaped, the length of the segments of the calyx, and alternate with them, inserted into the tube; anthers roundish, incumbent, sheltered by the petals. *Pist.* Germen inferior, roundish; style awl-shaped, divided half-way down

down into three segments; stigmas obtuse. *Peric.* Capsule with three angles, separable into three parts, of one cell each, not bursting. *Seeds* solitary, ovate, compressed, polished.—There are some male flowers, furnished with a style, but destitute of germen and stigma.

Eff. Ch. Calyx five-cleft. Petals five, hooded, covering the anthers. Style three-cleft. Capsule inferior, separating into three single-seeded parts.—Some flowers male.

Jacquin originally described two species, of which Linnæus adopted but one. Lamarek has added three more, all in our possession, to which we are enabled to furnish three non-descript species, making eight in all.

1. *G. domingensis*. Linn. Sp. Pl. 1663. Lamarek Dict. v. 3, 4. (*G. glabra*; Jacq. Amer. 264. t. 179. f. 40. *Lupulus fylvestris americana*, &c. Pluk. t. 201. f. 4.)—Leaves ovate, pointed, ferrated, nearly smooth. Wings of the fruit dilated, kidney-shaped.—Native of woods in Hispaniola and the Bahama islands. A climbing much branched *shrub*, the young branches downy, ending in long simple spiral tendrils. *Leaves* alternate, on short hairy stalks, ovate, a little unequal, an inch and half long, bluntly ferrated, furnished with a blunt entire point, and with several straight parallel veins directed forward. The young leaves are rather downy, old ones nearly smooth. *Stipulas* small, half arrow-shaped. *Flowers* in long terminal clusters, small, greenish and unornamental. *Capsules* of a light spongy texture, their central part as big as a small pea, the wings thrice as long, spreading, pale brown, smooth and somewhat polished. *Seeds* hard, of a shining brown.

2. *G. tomentosa*. Jacq. Amer. 263; Linn. MSS. in Sp. Pl. (*G. crenata*; Lamarek Dict. v. 3, 5?)—"Leaves ovate, crenate, downy."—Native of woods in Hispaniola, climbing to the tops of lofty trees. *Jacquin*. Of this we have seen no specimen. *Jacquin* says the *leaves* are four inches long. *Seeds* black and shining. Lamarek supposes his plant to be the same on account of the great size of its leaves, and he says it is distinguished from all others by their crenatures. *Jacquin* describes his as slightly crenate.

3. *G. cyclocarpa*.—Leaves elliptic-oblong, pointed, obsoletely ferrated, roughish, naked on both sides. Wings of the fruit narrow, orbicular.—Native, we believe, of the West Indies. The very young *shoots* and *leaves* only are silky and ferruginous. The full-grown *leaves* are near three inches long and one broad, somewhat ovate, either almost entire, or furnished with shallow distant ferratures, and a short entire blunt point; they are green and quite naked on both sides, but harsh to the touch on the upper surface. Veins distant. *Footstalks*, *flowerstalks*, and *stipulas* hairy. *Flowers* somewhat silky. *Fruit* orbicular at each side, each wing forming a hemisphere, and not being much dilated.

4. *G. denticulata*.—Leaves ovate, pale and downy beneath, entire, with a finely-toothed point.—Gathered by the late Mr. Christopher Smith in the island of Honimoo, East Indies.—The *leaves* are about an inch and half long, with straight veins, connected by numerous minute reticulations, and are remarkable for the numerous little sharp teeth which border their upper part and terminal point, while the rest of their margin is entire. Their upper side is roughish to the touch, but green and naked; while the lower is hoary with very dense short down, the veins only being naked. *Stipulas* small and deciduous. A simple curled *tendril* terminates each lateral branch, as in all the foregoing. *Flowers* in axillary downy clusters, with lanceolate deciduous bractæas. The *fruit* we have not seen.

5. *G. mauritiana*. Lamarek Dict. v. 35.—Leaves ovate, pointed, variously ferrated, downy on both sides.—Native of the heights called the *Gol*, in the desert, of the île de

Bourbon, where it was gathered by Commerfon, and sent to the botanic garden at Paris. The *leaves* are the size of the last, but green and clothed with silky down on both sides. Their figure is ovate, rarely somewhat cordate, often unequal, sharp-pointed, their margin singularly variable, being sometimes nearly entire, having only scattered shallow ferratures, sometimes very deeply and doubly ferrated, not unlike the Roman nettle, *Urtica filulifera*. *Stipulas* ovate, acute, clothed with shining reddish silky hairs, as well as the young twigs and tendrils. The *fructification* is wanting in our specimens. Lamarek says the *capsules* have rounded thin and membranous wings.

6. *G. tiliaefolia*. Lamarek Dict. v. 3, 5. (*G. Stadtmani*; Willem. Herb. Maurit. 58?)—Leaves heart-shaped, bluntly pointed, smooth on both sides, bluntly and slightly ferrated. Native of the île de Bourbon, near *la Villbague*. Commerfon. The *stem* is much branched and divaricated, smooth, except the very young shoots. *Leaves* an inch or inch and half long, and nearly as broad, heart-shaped, with shallow ferratures and a short blunt point. They are light green and naked on both sides, smooth above; minutely chagrined beneath. *Stipulas* glandular. *Flower-stalks* rusty and downy. The *tendrils* become very thick and strong by age.

7. *G. integrifolia*. Lamarek Dict. v. 3, 5.—Leaves ovate, bluish, entire, smooth on both sides. *Stipulas* awl-shaped. Long cultivated in the Paris garden, but its native country is not remembered. We have a specimen from thence, destitute of *flowers* and *fruit*, yet we readily agree with Lamarek that there can be no doubt respecting its genus. The habit, stem, tendrils, folded young leaves, and their pale parallel veins, all indicate a *Gouania*, for no genus can be more natural than this. The *leaves* are usually about an inch long, exactly ovate, (not oval) without any elongated point, though tipped with a gland; their margin quite entire, their midrib sometimes slightly hairy at the back. *Stipulas* awl-shaped, deciduous. *Footstalks* hairy only while young.

8. *G. smilacina*.—Leaves heart-shaped, minutely ferrated, acute, somewhat hairy. *Stipulas* awl-shaped. *Flower-stalks* umbellated, scarcely so long as the leaves. Brought by the late sir G. L. Staunton, Bart. we believe from the Brasils. The zig-zag *branches*, with small heart-shaped *leaves*, and numerous axillary umbels of *flowers*, give it the aspect of a *Smilax*. The *tendrils* grow from the first joint of each branch, and are elegantly spiral; rusty and hairy, like the *flower-stalks* and *calyx*. The principal *leaves* are usually about an inch long, green on both sides, their ribs and veins always very hairy, their surface more or less so. *Stipulas* awl-shaped, hairy. S.

GOUAREC, in *Geography*, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Loudeac; 24 miles S.W. of St. Brieuc. The place contains 678, and the canton 6,993 inhabitants, on a territory of 207½ kilometres, in 5 communes.

GOUD, or GAUD. See WELD.

GOUDA, or TERGOUW, in *Geography*, a city of Holland, seated on a branch of the Rhine, called Iffel, where it receives the Gouw, from which it derives its name. The great church of this town is one of the largest and handsomest in the country, and is particularly famous for its painted glass windows, which were executed principally by Theodore and Walter Crabeth of this town, and which are carefully preserved. The town is advantageously situated, on account of the sluices and canals, which are running streams, and its convenient port on the Iffel. It has five gates, and is so circumstanced by reason of the sluices, which may inundate the adjacent country, the breadth and depth of its ditches,

and the strong fortifications on the banks of the Ifsel, that it cannot easily be besieged. Its chief trade consists in cordage, cheese, and tobacco-pipes; and it has a regular communication by boats with Amsterdam, the Hague, Rotterdam, Utrecht, &c; 22 miles S. of Amsterdam. N. lat. 52° 1'. E. long. 4° 36'.

GOUDHURST, a post-town of England, in the county of Kent, containing 1782 inhabitants; 11 miles S. of Maidstone, and 44 S.E. of London.

GOUDOZ, a town of Asiatic Turkey, in Natolia; 72 miles E.N.E. of Kiutaja.

GOUDIMEL, CLAUDE, in *Biography*, one of the early and most celebrated composers of music to the metrical French translations of the psalms for the use of the Calvinists. He was a native of Franche-Comté, who seems to have lost his life at Lyons, on the day of the massacre of Paris, for having set to music the psalms of Clement Marot. Goudimel has been much celebrated by the Calvinists in France for this music, which was never used in the church of Geneva, and by the Catholics in Italy for instructing Palestrina in the art of composition, though it is doubtful whether this great harmonist and Goudimel had ever the least acquaintance or intercourse together. He set the "Chansons Spirituelles" of the celebrated Marc-Ant. De Muret, in four parts, which were printed at Paris, 1555. We may suppose Goudimel, at this time, to have been a Catholic, as the learned Muret is never ranked among heretics by French biographers. Ten years after, when he set the psalms of Clement Marot, this version was still regarded with less horror by the Catholics than in later times; for the music which Goudimel had set to it was printed at Paris by Adrian Le Roy, and Robert Ballard, with a privilege, 1565. It was reprinted in Holland, in 1607, for the use of the Calvinists, but seems to have been too difficult; for we are told by the editor of the psalms of Claude Le Jeune, which were printed at Leyden, 1633, and dedicated to the States-General, that, "in publishing the psalms in parts, he had preferred the music of Claude Le Jeune to that of Goudimel; for as the counterpoint was simply note for note, the most ignorant in music, if possessed of a voice, and acquainted with the psalm-tune, might join in the performance of any one of them; which is impracticable in the compositions of Goudimel, many of whose psalms being composed in fugue, can only be performed by persons well skilled in music.

The works of Goudimel, who was certainly the greatest musician in France, during the reign of Charles IX., are become so scarce, that his name and reputation are preserved by Protestant historians, more in pity of his misfortunes, than by any knowledge of their excellence. With respect to his having been the master of Palestrina, that point will be discussed elsewhere.

The earliest mention of Goudimel, as a composer, that we have been able to discover, is in a work entitled "Liber quartus Ecclesiasticarum Cantionum quatuor vocum vulgo Motetæ vocant," printed at Antwerp, by Susato, 1554, eighteen years before his death. On scoring several of these motetæ, we found the harmony pure and correct, but constructed entirely on the principles of the ecclesiastical tones: probably before he became a disciple of Calvin. The title of all his compositions may be seen in Draudius, *Bibl. Classicæ and Bibl. Exot.* (See FRANC, CLAUDE LE JEUNE, and PALESTRINA.) The motets of Goudimel, in four parts, resemble in gravity of style, simplicity in the subjects of fugue, and purity of harmony, the ecclesiastical compositions of our venerable countryman Bird.

VOL. XVI.

GOODSWAARTE, in *Geography*, a small island at the mouth of the Meuse, S. of the island of Putten.

GOUEGA, a town of Africa, in Whidah; 10 miles W.S.W. of Sabi.

GOVENDING, a town of Bengal; 32 miles E. of Calcutta.

GOVERDAN, a town of Hindoostan, in Mawat; 10 miles E.S.E. of Dig.—Also, a town in Oude, near the Dewah; 20 miles N. of Azingur.

GOVERDUNPOUR, a town of Hindoostan; 44 miles N. of Allahabad.

GOVERNUNGURRY, a town of Hindoostan, in Canara; 14 miles S.E. of Onore.

GOVERNMENT, a quality or office which gives a man power or right to command or rule over a place, a city, a province, a kingdom, or the like, either supremely or by deputation.

Government is either *general* and supreme, as that of a whole kingdom, empire, sovereign state, &c. or *particular* and subordinate; which, again, is subdivided into *civil*, *military*, and *ecclesiastical*.

Our cities, corporations, and boroughs, are usually governed by mayors, with aldermen and common-councilmen.

GOVERNMENT is also used for the country, city, or place to which the power of governing or commanding is extended.

GOVERNMENT, again, is used for the manner or form of governing, *i. e.* for the police of a country, state, &c.

In this sense the various forms of government have generally received their denominations from the number of persons to whom the supreme power has been entrusted. If it be in one person, it is called a *monarchy*, especially if the chief magistrate lies under considerable restrictions, or governs by fixed and established laws; whereas, if this single person lie under fewer restraints, or directs every thing by his own will and caprice, the government is called *despotic*. If the supreme power be lodged in a limited number of persons, the government is called an *oligarchy*, or *aristocracy*; and if all the citizens have an equal vote in making laws, and appointing magistrates, or the supreme power is lodged in the whole body of the people, it is called a *democracy* or *republic*. See these several articles.

Civil government and society originate in the wants and fears of individuals, who, being naturally free, equal, and independent, associate together, either by express or tacit consent, for the mutual preservation of their lives, liberties, and estates, on this fundamental principle, that the whole should protect all its parts, and that every part should pay obedience to the will of the whole. However the several forms of government, that now subsist, actually begun, there is and must be in all of them a supreme, irresistible, absolute, uncontrolled authority, in which the *jura summi imperii*, or the rights of sovereignty, reside; and this authority is placed in those hands, wherein, according to the opinion of the founders of such respective states, either expressly given, or collected from their tacit approbation, the qualities requisite for supremacy, *viz.* wisdom, goodness, and power, are the most likely to be found.

Individuals unite for mutual protection and benefit; and, therefore, the legislative and executive authority of government, originally derived from themselves, should be invariably directed to no other end but their safety and welfare; and that form of government is most eligible, which is best adapted to these purposes. Cicero declares himself of opinion, in his fragments *De Rep. lib. ii.* "esse optimam con-

GOVERNMENT.

titutam rempublicam, quæ ex tribus generibus illis, regali, optimo et populari, sit modice confusa.' Of this kind is the British constitution, which lodges the executive power of the laws in a single person, and the legislative in three distinct powers, entirely independent of each other; *viz.* the king; the lords spiritual and temporal, forming an aristocratical assembly; and the house of commons, freely chosen by the people, which renders it a kind of democracy; and each branch of this aggregate body, actuated by different views, and attentive to different interests, is armed with a negative power, sufficient to repel any innovation which it shall think inexpedient or dangerous. Nothing can endanger or hurt the constitutional government of Britain, but destroying the equilibrium of power between one branch of the legislature and the rest: for if ever it should happen that the independence of any one of the three should be lost, or that it should become subservient to the views of the other two, there would soon be an end of our constitution: the legislature would be changed from that which was originally set up by the general consent and fundamental act of the society; and such a change, however effected, is, according to Mr. Locke, at once an entire dissolution of the bands of government, and the people are thereby reduced to a state of anarchy, with liberty to constitute to themselves a new legislative power. Locke on Government, book ii. chap. 19. Blackst. Com. vol. i. Introd.

Another excellent writer gives a different account of the origin of civil government from that which has been above stated. Accordingly, he observes, that government, at first, was either patriarchal or military; *that* of a parent over his family, or of a commander over his fellow-warriors. Paternal authority, and the order of domestic life, says Dr. Paley, (Moral Philosophy, vol. ii.) supplied the foundation of civil government. The condition of human infancy prepares men for society, by combining individuals into small communities, and by placing them from the beginning under direction and controul. A family contains the rudiments of an empire. The authority of one over many, and the disposition to govern and to be governed, are in this way incidental to the very nature, and coeval, no doubt, with the existence, of the human species. Besides, a parent would retain a considerable part of his authority after his children were grown up, and had formed families of their own. This is the second stage in the progress of dominion. The first was that of a parent over his young children; this that of an ancestor presiding over his adult descendants. The association, thus formed, would naturally be continued after the death of the original progenitor; and the members of it, accustomed to the benefits resulting from it, might be induced to supply his place by a formal choice of a successor, or they might voluntarily, and almost imperceptibly, transfer their obedience to one of the family, which had claimed their respect and confidence, or, again, they might receive with due deference a successor, appointed by the first ancestor. Thus we have a tribe or clan, incorporated under one chief, and fulfilling the purposes of civil union, without any other or more regular convention, constitution, or form of government than what has now been described. Two or three of these clans would frequently, by marriage, conquest, mutual defence, common distress, or some other accidental circumstances, be united into a society of larger extent. Another source of personal authority, which might extend, or supersede, the patriarchal, is that which results from military arrangement. A popular and successful leader, in every action of aggression or defence, would gain a powerful and permanent influence among his followers. This advan-

tage, added to the authority of the patriarchal chief, or favoured by any previous distinction of ancestry, would enable the person who possessed it to acquire the almost absolute direction of the affairs of the community; more especially if he took care to associate to himself proper auxiliaries, and to gratify or remove those who opposed his pretensions.

The causes which have contributed to introduce hereditary dominion, are principally the influence of association, which communicates to the son a portion of the respect that was paid to the virtues or station of the father, the mutual jealousy of other competitors, the greater envy with which all behold the exaltation of an equal, than the continuance of an acknowledged superiority, and the number of adherents left by a reigning prince, who preserve their own importance, merely by supporting the succession of his children, and the apprehension of calamities that are incidental to contested elections. The ancient state of society in most countries, says our author, and the modern condition of some uncivilized parts of the world, exhibit that appearance, which this account of the original of civil government would lead us to expect. The earliest histories of Palestine, Greece, Italy, Gaul, and Britain, inform us that these countries were occupied by many small independent nations, resembling those which are now found among the savage inhabitants of North America, and upon the coast of Africa. This theory, it is added, affords a presumption, that the earliest governments were monarchies, because the government of families, and of armies, from which, according to the preceding statement, civil government derived its institution, and probably its form, is universally monarchical.

Our readers will observe that this theory is very different from sir Robert Filmer's patriarchal scheme, now, indeed, almost forgotten and scarcely deserving to be recorded; the refutation of which constitutes the first part of the admirable Locke's Treatise on Government. According to this scheme, all government is absolute monarchy, which the author founds on this previous principle, that no man is born free. The absolute sovereignty of Adam was the result of a divine appointment and donation, and this sovereignty has been regularly conveyed by a divine hereditary right to all succeeding monarchs. The notion, that kings reign by a *divine right*, independently of the designation of the people, and not accountable to them for the exercise of their power, absurd as it will now very generally be thought, was, however, for a long time not only admitted, but prevalent even in this country. It is strongly inculcated in the Homilies of our established church, and was strenuously maintained by several of its respectable divines. Dr. Tillotson, enlightened and excellent as he was in other respects, could not, in the middle part of his life, emancipate himself from the idea, that it was sinful to resist government, as is evident from his letter to lord Russell. That power originates with the people was condemned as an abominable tenet by the famous Oxford decree of 1683; but this is a topic on which it is needless to enlarge.

In the most popular forms of government, says Dr. Paley, the physical strength resides in the governed; and it therefore becomes an inquiry of considerable importance, among politicians, what motives induce the many to submit to the few. In the discussion of this question our author distributes the subjects of a state into three different classes, *viz.* 1. Those who obey from prejudice, or who are determined by an opinion of *right* in their governors, which opinion is founded upon *prescription*: this prescriptive title, in hereditary monarchies, is corroborated, and its influence considerably augmented, by an accession of religious sentiments, and by that sacredness

GOVERNMENT.

facredness which men are apt to ascribe to the persons of princes. 2. Those who obey from reason, by a consideration of the necessity of some government or other, and of the certain mischief of civil commotions. 3. Those who obey from self-interest, and who are kept in order by a variety of considerations that immediately affect themselves.

Concerning the moral obligation of submission to civil government, those who adopt the principles of Mr. Locke, and many other political writers, allege a compact between the citizen and the state, as the ground of the relation between them; and this compact binding the parties, like private contracts, resolves the duty of submission into the universal obligation of fidelity in the performance of promises. This compact is either, 1. *Express*, on the part of the primitive founders of the state, who are supposed to have met together for the declared purpose of settling the terms of their political union, and a future constitution of government. The whole body is supposed to have unanimously consented to be bound by the resolutions of the majority; and that majority is supposed to have fixed certain fundamental regulations, and thus to have constituted, either in one person, or in an assembly, a *standing legislature*, to which, under these pre-established restrictions, the government of the state was thenceforward committed, and whose laws the several members of the convention were, by their first undertaking, thus personally engaged to obey.—This transaction is sometimes called the “*Social compact*,” and these supposed original regulations compose what are meant by the “*constitution*,” the “*fundamental laws of the constitution* ;” and form, on one side, the “*inherent indefeasible prerogative of the crown*,” and, on the other, the unalienable “*birth-right*” of the subject; *i. e.* a *tacit* or *implied* compact by all succeeding members of the state, who, by accepting its protection, consent to be bound by its laws. “*This account of the subject*,” says Dr. Paley, “*although specious, and patronized by names the most respectable, appears to labour under the following objections; that it is founded upon a supposition false in fact; and leading to dangerous consequences.*” No such social compact was ever really made, nor any such original convention of the people ever actually held, or could be held in any country, antecedent to the existence of civil government in that country. It is to suppose it possible to call savages out of caves and deserts, to deliberate and vote upon topics, which the experience, and studies, and refinements of civil life, alone suggest: therefore no government in the universe began from this original. At a *Revolution* some imitation of a social compact may have taken place. The establishment of the United States of North America bears the nearest resemblance of it. Should it be said, that the original compact is not proposed as a fact, but as a fiction, for the commodious explication of the mutual rights and duties of sovereigns and subjects; to this representation it may be replied, that the original compact, if it be not a fact, is nothing; it can confer no actual authority upon laws or magistrates, nor afford any foundation to rights, which are supposed to be real and existing. But in the books, and also in the apprehension of those who deduce our civil rights and obligations *à priori*, the original convention is appealed to, and treated of, as a reality.

Moreover, it is alleged, that the theory of government, which affirms the existence and the obligation of a social compact, leads to conclusions unfavourable to the improvement, and to the peace, of human society. Upon this theory it may be presumed that many points, called “*fundamentals*” of the constitution, were settled by a convention of the people, anterior to the establishment of the subsisting

legislature, and which the legislature has no right to alter, or interfere with. This circumstance affords a dangerous pretence for disputing the authority of the laws. Hence arose the doubt, which so much agitated the minds of men in the reign of Charles II., whether an act of parliament could of right alter or limit the succession of the crown. Besides, if it be by virtue of a compact that the subject owes obedience to civil government, he ought to abide by the power of government which he finds established, however absurd or inconvenient it may be. Moreover, every violation of the compact on the part of the governor releases the subject from his allegiance, and dissolves the government.

Dr. Paley, rejecting the intervention of a compact, as unfounded in its principle, and dangerous in the application, assigns for the only ground of the subject's obligation, “*the will of God as collected from expediency.*” Accordingly the author reasons in the following manner. It is the will of God that the happiness of human life be promoted; civil society conduces to that end; civil societies cannot be upheld, unless in each, the interest of the whole society be binding upon every part and member of it; and this step of the argument conducts us to the conclusion, namely, that so long as the interest of the whole society requires it, that is, so long as the established government cannot be resisted or changed without public inconvenience, it is the will of God (which *will* universally determines our duty) that the established government be obeyed; and no longer. This principle being admitted, the justice of every particular case of resistance is reduced to a computation of the quantity of the danger and grievance on the one side, and of the probability and expence of redressing it on the other. If it be asked, who shall judge of this? the answer is, “*Every man for himself.*” In contentions between the sovereign and the subject, the parties acknowledge no common arbitrator; and it would be absurd to refer the decision to *those* whose conduct has provoked the question, and whose own interest, authority, and fate, are immediately concerned in it. From the substitution of “*public expediency*” into the place of all implied compacts, promises, or conventions whatsoever, our author infers, 1. That it may be as much a duty at one time to resist government as to obey it, *viz.* when more advantage will in our opinion accrue to the community from resistance, than mischief. 2. That the lawfulness of resistance, or the lawfulness of a revolt, does not depend alone upon the grievance which is sustained or found, but also upon the probable expence and event of the contest. Hence those who concerted the revolution in England were justifiable in their counsels. 3. That irregularity in the first foundation of a state, or subsequent violence, fraud, or injustice in getting possession of the supreme power, are not sufficient reasons for resistance, after the government is once peaceably settled. 4. That resistance is not justified by every invasion of the subject's rights, or liberty, or of the constitution; by every breach of promise, or of oath; by every stretch of prerogative, abuse of power, or neglect of duty on the part of the chief magistrate; unless these crimes draw after them public consequences of sufficient magnitude to outweigh the evils of civil disturbance. 5. That no usage, law, or authority whatever, is so binding, that it need or ought to be continued, when it may be changed with advantage to the community. 6. As all civil obligation is referred into expediency, what, it may be asked, is the difference between the obligation of an Englishman and a Frenchman, or why is a Frenchman bound in conscience to bear any thing from his king, which an Englishman would

not be bound to bear, since the obligation of both is founded in the same reason? Although their conditions may differ, their *rights* should seem to be equal; and yet we are accustomed to speak of the rights as well as the happiness of a free people, compared with what belong to the subjects of absolute monarchies; and how, it may be reasonably inquired, can this comparison be explained, unless we refer to a difference in the compacts by which they are respectively bound? In order to obviate this difficulty, it is allowed that a Frenchman is in conscience bound to endure many things from his prince, to which an Englishman would not be bound to submit for the following reasons; *viz.* because the same act of the prince is not the same grievance where it is agreeable to the constitution, and where it infringes it; and because redress in the two cases is not equally attainable. The duty of obedience is defined by different boundaries, and the point of justifiable resistance is placed at different parts of the *scale* of suffering—all which is sufficiently intelligible without a social compact. 7. The interest of the whole society is binding upon every part of it. If we appeal to the Christian scriptures with regard to the duty of civil obedience or the *extent* of our civil rights and obligations, Christianity hath left us where she found us; she has neither altered, nor ascertained it. The two passages to which writers have generally referred in their investigation of this subject are Romans xiii. 1—7, and 1 Peter ii. 13—18. In order to comprehend the proper import of the instructions contained in these passages, there are two questions relating to the subject of civil obedience, which should be considered, *viz.* whether to obey government be a moral duty and obligation upon the conscience at all, and how far, and to what cases, that obedience ought to extend? These passages, it may be observed, inculcate the *duty*; but they do not describe the *extent* of it. The due consideration of this distinction is sufficient to vindicate these passages of scripture from any explanation of them that shall favour an unlimited passive obedience. But admitting what many commentators have stated, that an opinion was privately cherished by the first Christians, which led them to conceive, that their conversion to Christianity entitled them to new immunities, to an exemption as of *right* (however they might give way to necessity) from the authority of the Roman sovereign, we are furnished with a still more apt and satisfactory interpretation of the Apostle's words. The two passages apply with great propriety to the refutation of this error. Little need be added in explanation of particular clauses. St. Paul has said, "whosoever resisteth the power, resisteth the ordinance of God." This phrase, "the ordinance of God," is by many so interpreted as to authorize the most exalted and superstitious ideas of the regal character. But surely such interpreters have sacrificed truth to adulation. For, in the first place, the expression, as used by St. Paul, is just as applicable to one kind of government, and to one kind of succession, as to another,—to the elective magistrates of a pure republic, as to an absolute hereditary monarch. In the next place, it is not affirmed of the supreme magistrate exclusively, that *he* is the ordinance of God; the title, whatever it imports, belongs to every inferior officer of the state as much as to the highest. The divine right of *kings* is, like the divine right of *constables*, in the law of the land, or even actual and quiet possession of their office; a right ratified, we humbly presume, by the divine approbation, so long as obedience to their authority appears to be necessary or conducive to the common welfare. Princes are ordained of God by virtue only of that general decree, by which he assents, and adds the

sanction of his will, to every law of society, which promotes his own purpose, the communication of human happiness: according to which idea of their origin and constitution, and without any repugnancy to the words of St. Paul, they are by St. Peter denominated the "*ordinance of man.*" Paley, *ubi supra*. See KING, LAW, LIBERTY, MONARCHY, PARLIAMENT, PASSIVE obedience, &c.

GOVERNMENT, in *Grammar*, is understood of that construction of nouns and verbs, wherein they require some alteration to be made in others joined or constructed with them.

Construction is divided into two parts; that of *concord*, and that of government, called also *regimen*. See CONCORD and REGIMEN.

GOVERNOLIO, in *Geography*, a town of Italy, in the department of the Mincio; 12 miles S. E. of Mantua.

GOVERNOR, an officer vested by a king, or sovereign prince, with the command and administration of a province, place, &c.

A governor represents the king; and not only commands the garrison, troops, &c. but the citizens, &c. A governor of a fortified place was anciently required to hold out three attacks, before he surrendered.

GOVERNOR is also frequently used for a president or superintendent.

Thus we say, the governor of the bank; the governor and directors of the South Sea company; the governor of an hospital, &c.

GOVERY, in *Geography*, a town of Hindoostan, in the circle of Rajamundry; 10 miles W. N.W. of Rajamundry.

GOUF. See GOLF.

GOUFRE, in *Geography*, a town of Canada, in the river St. Lawrence; 50 miles E. of Quebec.

GOUGANE-BANRA, a lake of Ireland, in the county of Cork, not far from Inchigeel. The river Lee rises in a mountain above this lake, through which it flows. It was formerly the residence of St. Fin-Bar, and is visited by great numbers of pilgrims, whilst its romantic beauties attract a few travellers, notwithstanding the ruggedness of the road.

GOUGE, WILLIAM, in *Biography*, who flourished in the former part of the seventeenth century, was born in the parish of Bow, in the year 1575. He was educated partly at St. Paul's school, and partly at Eton, and, in 1595, he was elected to King's college, Cambridge. Here, in due time, he performed with much applause all the exercises required by the statutes, and took his degrees. In 1607, he was admitted into orders, and in the following year obtained the rectory of Blackfriars, London. In this situation he continued during the remainder of his life, discharging the pastoral functions with great diligence and fidelity, and setting before his parishioners an example worthy of imitation. The zeal with which he performed the duties of his office, led him to establish a weekly lecture, which was frequented not only by his own people but by many of the London clergy, the members of the Inns of Court, and the more respectable and serious citizens. In 1628, he was admitted to the degree of doctor of divinity, and about the same period he became one of the trustees of the society that had united for the purpose of buying up impropriations, to bestow them on such unpatronized clergymen as were distinguished for piety and other ministerial qualifications, which occasioned his being prosecuted in the star-chamber. In 1653, he was nominated one of the assembly of divines, and was held in such reputation by that body, that he was often called to fill the moderator's chair

during his absence. He was selected as a proper person to write notes on the bible, and took, for his share of the work, from the beginning of the first book of Kings to that of Job. He died in the year 1653, soon after he had completed his 78th year. He had, for several years, been esteemed the father of the London ministers. In his deportment, he was modest, humble, and affable; he had a pious and benevolent spirit, and continued to preach as long as he had strength to walk into the pulpit. Besides the "Annotations" already referred to, Dr. Gouge published many other theological pieces, as "A Commentary on the Epistle to the Hebrews;" "An Exposition of the Lord's Prayer;" "The whole Armour of God," &c.

GOUGE, THOMAS, son of the preceding, was born at Bow, in the year 1605; and having, in his academical course, followed the steps of his father, he was first chosen fellow of his college, and afterwards presented with a living at Coldsden, near Croydon, in Surrey, where he continued but a short time; and, in 1638, he undertook the more important charge of St. Sepulchre's parish, London. During a period of twenty-four years he discharged the duties of his profession with the most exemplary zeal. Besides preaching twice every Sunday, and often on week days, he visited his flock, catechised their children, enquired into and relieved the wants of the poor, and devised plans for their employment. He is said to have given the hint which produced the humane and benevolent institutions of Mr. Firmin, which have been referred to in the memoir of that excellent citizen. When the act of Uniformity took place, he was too conscientious to sacrifice his principles on the shrine of power, and was ejected from his living. His time was now zealously devoted to acts of beneficence and charity. He employed his own fortune, which was considerable, in relieving the wants of his poorer brethren, who, on account of their non-conformity, were deprived of their means of subsistence; and he was a successful applicant to the rich, from whom he received large sums, which were applied to that humane purpose. In the year 1671, he set about a plan for introducing knowledge and religion into the different parts of Wales, which at that period were in the most deplorable darkness. He established schools in different towns where the poor were willing that their children should be taught the elements of learning, and he undertook to pay all the expences which were incurred in the outset of the business. By degrees these schools amounted to between three and four hundred, and they were all annually visited by Mr. Gouge, when he carefully enquired into the progress made by the young people, before whom he occasionally preached in a style adapted to their age and circumstances in life, until he was obliged to desist by prosecutions carried on against him in the ecclesiastical courts. With the assistance of his friends, whose purses were ever open at his command, he printed eight thousand copies of the bible in the Welsh language, a thousand of these were distributed freely among those who could not afford to purchase them, and the rest were sent to the cities and chief towns in the principality, to be sold at reasonable rates. He procured likewise the church catechism, and other practical pieces, to be printed in the Welsh language, and distributed among the poor. To these and such like charitable undertakings did Mr. Gouge devote his time, his talents, and his fortune, when precluded by the intolerance of the laws from officiating in the capacity of a preacher. He was accustomed to say with pleasure, "that he had two livings which he would not exchange for two of the greatest in England." These were Wales, where he travelled every year to diffuse the principles of

knowledge, piety, and charity: and Christ's Hospital, where he catechised and instructed the children in the fundamental principles of religion. He died suddenly in 1681, in the seventy-seventh year of his age. His death was regarded as a public loss. A funeral sermon was preached on the occasion by Dr. Tillotson, afterwards archbishop of Canterbury; who, at the conclusion of an animated eulogium on his piety and virtue, observes, that "all things considered, there have not, since the primitive times of Christianity, been many among the sons of men, to whom that glorious character of the son of God might be better applied, than "he went about doing good." And Mr. Baxter, in his Narrative of his own Life and Times, says of Mr. Gouge, "I never heard any one person, of whatever rank, fort, or sect soever, speak one word to his dishonour, or name any fault that they charged on his life or doctrine; no, not the prelatists themselves, save only that he conformed not to their impositions; and that he did so much good with so much industry." This eminent Christian divine published a few practical pieces, of which the following may be mentioned; "The Principles of Religion Explained:" "A Word to Sinners:" "Christian Directions to walk with God:" "The surest and safest Way of Thriving, viz. by Charity to the Poor;" "The Young Man's Guide through the Wilderness of this World." Gen. Biog. Neal's Hist. of the Puritans.

GOUGE, an instrument used by divers artificers; being a sort of round, hollow chisel; serving to cut holes, channels, grooves, &c. in wood, stone, &c.

GOUGEON, JOHN, in *Biography*, a French sculptor and architect in the reigns of Francis I. and his successors, is reckoned the first who introduced a true taste for sculpture in France, and freed it from the barbarism of former times. He was employed in many of the public works with which Paris began to be decorated in the reign of Francis I. Of these the most considerable is the fountain of the Nymphs, called the Innocents, finished in the year 1550. Among the other remains of his workmanship is a tribune in the hall des Cent-Suisses, at the Louvre, enriched with sculptures, and supported by four gigantic Caryatides. He was an able medalist, and struck several pieces for Catharine de Medicis, which are sought by the curious. He generally worked in small, and there are no detached figures or groups by his hand. His reliefs are executed with taste, his drapery is light and elegant, his figures graceful and flexible, but their attitudes somewhat forced. He was a Huguenot, and was shot as he was working on a scaffold, on the infamous St. Bartholomew's day, 1570. Gen. Biog.

GOUGH'S ISLAND, in *Geography*, a small island in the Southern Atlantic ocean, discovered by captain Gough in 1715. It is very high land, in S. lat. 40° 15'. W. long. 81° 57'. Some doubt being entertained with respect to its true longitude, it was recommended to M. de la Perouse to ascertain its true position, as it lies in the way of ships going directly to India, or China, early in the season, without touching at the Cape.

GOULET, CLAUDE PETER, in *Biography*, was born at Paris in 1697. His father, a taylor by trade, in vain opposed his inclination for a studious life. He was educated among the Jesuits, and, having taken orders, became a canon of the church of St. Jacques de l'Hôpital in Paris. He was an associate of several academies in France, and was generally esteemed for his learning, and also on account of the mildness of his temper and the purity of his morals. He died in 1767, and had collected a library of ten thousand well chosen volumes, which was the basis of his numerous works. Of these, the following may be mentioned, "Vies des

des Saints," in two vols. 4to. "Supplement to Moreri's Dictionary," two vols. folio. "Bibliothèque des Ecrivains Ecclesiastiques," three vols. 8vo. "Discours sur le Renouveau des Etudes depuis le xiv Siècle." "De l'Etat des Sciences en France depuis la Mort de Charlemagne jusqu'à celle du Roi Robert." This dissertation obtained for the author the prize of the Academy of Belles Lettres, and he was complimented by a deputation from that body, desiring permission to nominate him to the vacant place of the deceased abbé Vertot. Goujet was likewise author of "Bibliothèque Française, ou Histoire de la Littérature Française," 18 volumes 12mo. which is reckoned his most valuable work. Moreri.

GOUJIN, in *Geography*, a town of Portugal, in the province of Beira; 12 miles S.W. of St. Joao de Pefqueira.

GOVINPOUR, a town of Hindoostan, in Bahar; 26 miles S. of Bahar.—Also, a town of Bengal; 10 miles W. of Nuldingah.

GOULAMCONDA, a town of Hindoostan, in the Myfore; 9 miles S. of Gooty.

GOULART, SIMON, in *Biography*, a French Protestant divine, was born at Senlis in 1543. He began his studies late in life, but by persevering industry, he made a great proficiency in the learned languages, and was chosen pastor of the church of which Calvin had been minister. Here he discharged the duties of his office with much diligence and success, till within a few years of his death, which took place in 1628, when he was about 85 years of age. He edited many works, performing at the same time the business of a commentator. Among these were the "Works of Plutarch;" "St. Cyprian's Works;" "Seneca's Works," &c. He made a collection of "Remarkable Histories" in 2 vols. 8vo., and wrote several pieces relating to the history of his own times. The most interesting and curious of the latter description is his "Collection of the most memorable events which occurred during the League, with notes and original documents," in six vols. 4to. Many of his pieces were anonymous, but to these he usually affixed the initials S. G. S. signifying "Simon Goulart Senlisien." He had such an extensive acquaintance with the literature of his time, and knew so well to whom different publications, that were printed without the writer's name, were to be attributed, that Henry III. of France, being desirous of knowing who was the author of a piece published under the assumed name of Stephanus Junius Brutus, and intended to propagate republican doctrines, sent a person to Geneva to enquire into the matter of Goulart, but the latter refused to communicate the fact, for fear of exposing the author to serious injury. Moreri Bayle.

GOULDSBOROUGH HARBOUR, in *Geography*, a harbour of the United States of America, in the district of Main. N. lat. 44° 25'. W. long. 67° 53'.

GOULERGAUT, a town of Thibet; 28 miles S. of Deuprag.

GOULOUR, a town of Hindoostan, in the circar of Sanore; 18 miles N. of Sanore.

GOULSTON, THEODORE, in *Biography*, was the son of William, rector of Wymondham, and was born in Northamptonshire. He became probationer fellow of Merton college, Oxford, in 1596: and, after applying himself to the study of physic in this university, he practised for a time with considerable reputation at Wymondham and its neighbourhood. At length, after taking his doctor's degree in 1610, he removed to London, and became a fellow of the College of Physicians, and afterwards censor. He resided in the parish of St. Martin's, near Ludgate, and was in

great esteem, as well for classical learning and theology, as for the practice of his profession. He died in the year 1632; and by an article in his will testified such regard to the interests of medicine, as entitles him to grateful commemoration. This was a bequest of 200 pounds, to purchase a rent charge for the maintenance of an annual pathological lecture within the College of Physicians, to be read by one of the four youngest doctors of the College. The public has been indebted on several occasions to this institution for ingenious dissertations, delivered as Gullstonian Lectures; as those of Dr. Musgrave; Dr. Fordyce's Treatise on Digestion; &c.

Dr. Goullton published the following works. "Versio Latina et Paraphrasis in Aristotelis Rhetoricam." Lond. 1619, &c. "Aristotelis de Poetica Liber, Latine conversus et Analytica Methodo illustratus." Lond. 1623. And after his death, his intimate friend Thomas Gataker, B. D. published his "Versio, variz Lectioes et Annotationes Criticaz in opuscula varia Galeni." Lond. 1640. Aikin, Biograph. Mem. of Med.

GOUMEL, in *Geography*, a town of Africa, and capital of the country of the Foulahs, and residence of the Siratik. N. lat. 16° 16'. W. long. 11° 32'.

GOUNDA, a town of Hindoostan, in Oude; 32 miles E.N.E. of Manickpour.

GOUPIA, in *Botany*. See GLOSSOPETALUM.

GOUPIL, JAMES, in *Biography*, a physician of the sixteenth century, was born in the province of Poitou. He acquired a considerable knowledge of the ancient languages, and afterwards directed his studies to medicine, in the schools of Paris, where he graduated in 1547. His talents attracted the attention of the court, and he was appointed by Henry II. to the professorship of medicine in the royal college, in 1555, a vacancy being occasioned by the death of Sylvius. He is principally known as an editor and annotator of the writings of Dioscorides, Alexander Trallian, Aetnarius, and some other Greek writers: and he was engaged in the same labour, in respect to some of the writings of Hippocrates, when his studies were terminated by death, in 1568. Eloy.

GOUR, called also *Lucknoui*, in *Geography*, the ancient capital of Bengal, supposed to be the "Gangia Regia" of Ptolemy, which stood on the left bank of the Ganges, about 25 miles below Rajemul. N. lat. 24° 53'. E. long. 88° 14'. It was the capital of Bengal 730 years B. C. and was repaired and beautified by Achar, A. D. 1575, who gave it the name of "Jennuteabad," which name part of the circar in which it was situated still bears. It was deserted, as it is said, on account of the insalubrity of its air. Taking the extent of the ruins of Gour at the most reasonable calculation, it is not less than 15 miles in length, along the old bank of the Ganges, and from two to three in breadth. Several villages stand on part of its site; the remainder is either covered with thick forests, the habitations of tygers and other beasts of prey, or become arable land, whose soil is chiefly composed of brick-dust. The principal ruins are a mosque lined with black marble, elaborately wrought; and two gates of the citadel, which are grand and lofty. The bricks, which continue to be an article of merchandize, are of a peculiarly solid and durable texture.

GOURA, or GURA, a town of the duchy of Warfaw, on the Vistula; 12 miles from Warfaw.

GOVRA, a town of Persia, in the province of Irak; 35 miles E. of Isfahan.

GOURAY, a cape on the E. coast of the island of Jersey; 4 miles E. of St. Helier.—Also, a town of France,

in the department of the North Coasts; 8 miles S. of Lamballe.

GOURD, in *Botany*. See CUCURBITA.

GOURD, *Bitter*. See COLOCYNTHIS.

GOURD, *Indian tree*. See CRESCENTIA.

GOURD, *Sour*. See BAOBAB.

GOURD-worm, the English name of a species of worm found in the intestines of several animals. It has this name from its resembling the seed of the gourd in figure.

GOURDON, in *Geography*, a town of France, in the department of the Lot, and principal place of a district, 16 miles N. of Cahors. N. lat. $46^{\circ} 44'$. E. long. $1^{\circ} 28'$. The place contains 3703, and the canton 12,115 inhabitants, on a territory of 150 kilometres, in 15 communes.

GOURDY, *Legs of Horses*. See GREASE.

GOUREY, in *Geography*, a town of Hindoostan, in Oude; 10 miles N. W. of Lucknow.

GOURGONG, a town of Hindoostan, in Allahabad; 10 miles N. of Corah.

GOURGOUTY, a town of Hindoostan, in Golconda; 36 miles W. S. W. of Rachore.

GOURIN, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of Pontivy; 26 miles W. N. W. of Pontivy. The place contains 3674, and the canton 11,819 inhabitants, on a territory of $242\frac{1}{2}$ kilometres, in five communes.

GOURMA, a town of Abyssinia, on the coast of the Red sea. N. lat. $14^{\circ} 52'$.

GOURMUNGUL, a town of Hindoostan, in Golconda; 12 miles S. W. of Malkar.

GOURMELEN, ETIENNE, in *Biography*, was a native of Brittany, and was sent at an early age to Paris, where he studied surgery, and afterwards medicine; in the latter of which he took the degree of doctor in the year 1559, and was elected dean of the faculty in November, 1574. Surgery, however, continued to be the favourite object of his attention, and he was appointed by Henry III. professor of surgery in the Royal College in the year 1588. But he did not long fill his chair, for he died in 1594. His writings, which were valuable in their day, have now lost their interest, in consequence of the great improvements of modern surgery: they consist of a "Synopsis Chirurgie," printed in 1566, and afterwards translated into French;—a Latin translation of Hippocrates "De Alimento," with a commentary;—and a treatise, entitled "Chirurgie Artis ex Hippocratis et Veterum decretis ad rationis normam redacta, Libri tres," 1580. Eloy. Dict. Hist.

GOURNAI, LE JARS DE, MARY, was born at Paris in 1506. She was, while very young, deprived of her father, and acquired an adoptive one in the celebrated Michael Montagne, who became the object of her enthusiastic admiration. After the death of Montagne she became heiress of his writings, and published an edition of his "Essays," dedicated to cardinal Richelieu. She had well improved the lessons of youth, and was intimately acquainted with the learned languages. She maintained a correspondence with many of the most eminent literary characters of the age, by some of whom she was honoured with the title of the "Tenth Muse;" by others she was denominated the "French Syren;" it is not, however, improbable, that the uncommonness of female learning at that time in France, rather than the intrinsic merit of her writings, excited admiration. In her own language she wrote a stiff and awkward style, and her taste in reading was usually turned to the compilations and commentaries of past ages. She passed her life in celibacy, contented with a small pension from the court, and much

esteemed by her particular friends, some of whom were persons of high rank. She died at Paris in 1645, in her 79th year, and was honoured with many epitaphs from literary characters. Her works were collected in a quarto volume, under the title of "Les Avis ou les presens de M^{lle} Demoiselle de Gournai." Her temper was apt to be violent, and she was very resentful of real or supposed injuries; by these means she made herself many enemies, who attacked her in their writings, in which neither her person, nor the defects in her character were spared. Bayle. Moreri.

GOURNAY, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Neufchatel, 24 miles E. of Rouen. N. lat. $49^{\circ} 29'$. E. long. $1^{\circ} 47'$. The place contains 3545, and the canton 11,301 inhabitants, on a territory of 180 kilometres, in 19 communes.

GOURNEI, a town of Egypt, on the site of the ancient Thebes.

GOUROCK. See GREENOCK.

GOURRI, a town of Abyssinia; 35 miles S. W. of Affab.

GOURVILLE, JOHN HERALD DE, in *Biography*, born at Rochefoucauld in 1625, was taken by the celebrated duke of that title into his service as valet de chambre, but in a short time he became his confidential friend. He was patronized by the great Condé, and was employed by the superintendant Fouquet, in public business. So well did he approve himself to his employers for political talents and integrity that he was proposed to the king as successor to Colbert in the ministry. He died in 1705, leaving behind him "Memoirs of his Life from 1642 to 1698," in two volumes 12mo. These memoirs are written with frankness and simplicity, in a lively, though incorrect style, and they contain many curious and well authenticated anecdotes of the ministers and principal persons of his time, of which, it is said, Voltaire made much use. Moreri.

GOURY PASHUM, in *Natural History*, a name given by the people of the East Indies to a kind of orpiment of a deep yellow colour, veined with red in several places, and in some with white. It is found principally at the bottoms of mountains. They calcine it several times, and afterwards give it internally after intermitting fevers, and use it externally in ointments for the itch.

GOUSSET, JAMES, in *Biography*, was born at Blois in the year 1635. He was educated for the ministry, and was chosen pastor of the Protestant church at Poitiers in the year 1662. He was thrice invited to undertake the professorship of divinity at Saumur, but refused to quit his flock till compelled to become a fugitive from the kingdom, in consequence of the revocation of the edict of Nantz. On this occasion he took refuge in Holland, and afterwards was settled, as French minister, at Groningen, where he likewise exercised the offices of professor of divinity, and of the Hebrew language in the university of that city. He died there in 1704, in his sixty-ninth year. His principal works were "Dissertations in Controversy with the Jews," 1699. "Commentarii Linguae Hebraicae," 1702, which form a valuable Hebrew dictionary, of which the best edition was published at Leipzig in 1743. "Dissertationes in Epistolam Pauli ad Hebraeos," &c. 1712. At his death he left behind him numerous MSS., among which are commentaries upon the whole of the sacred scriptures. Moreri.

GOUST, GOUT, a French term, for what the Italians call *gusto*, and we *taste*.

GOUT, in *Medicine*, a disease principally characterized by inflammatory attacks of the joints, more especially of the feet,

foot, which return at intervals, and are connected with derangement of the digestive organs. The term, however, includes such a variety of morbid affections, in its extended sense, that it is not easy to give a concise definition of it; and we must have recourse to a more ample description of those affections, in order to convey a just notion of its signification.

The ancient physicians included all the varieties of inflammation, that are liable to occur in the joints, under the general term, *Arthritis*, (from *ἄρθρον*, a joint, with the termination *itis*, denoting inflammation,) for the distinctions, made by modern physicians, between the two modifications of inflammation in the joints, now denominated *gout* and *rheumatism*, had not then been attended to. The term *Arthritis*, however, was used both as a generic and specific term, and signified, not only inflammation of the joints generally, but the ordinary form of gout by way of excellence. But the Greeks also gave specific names to the varieties of arthritis, according to the particular joints which the disease occupied: thus, for the ordinary form of gout in the foot the term *πυδύρα*, *podagra*, was employed, which also became a generic title; for gout in the hand, the word *χειρῶνα*, *chiragra*; and for gout in the knee, *γονύρα*, *gonagra*; and so on. Among the species of arthritis was also included the *ischias*, *sciatica*, or *hip-gout*, which is now deemed a species of rheumatism. These terms the Romans adopted; and they are still retained in medical language. Our vernacular term *gout*, which came to us probably through the French, *la goutte*, originated in the dark ages among the humoral pathologists, who considered the disease as arising from the slow deposition of a morbid humour, *guttatim*, as it were, upon the joints; hence, the name *gutta*, or *drop*, was applied to the disease. This term, according to Du Cange, was used by Radulfus, a Dominican of the 13th century, who writes, "cum *gutta*, quam *podagram* vel *arthriticam* vocant, frequenter vexaretur." *Musgrave de Arthritide*.

In consequence of the various forms which gout assumes, physicians have divided it under two heads, *regular* and *irregular* gout, or, as some have termed it, *tonic* and *atonic* gout; the former occurring in the earlier periods of life, while the strength or tone of the system remains unbroken; the latter, after a certain degree of weakness, or atony of the constitution, has been produced by the frequent attacks of the disease, advanced age, or other causes. We shall first describe the symptoms by which these forms of the disease are characterized, and afterwards state the causes and method of treatment, together with the speculations of pathologists, respecting the nature of the disease, beginning with an account of the paroxysm of

Regular Gout.—It is an inflammatory affection of the joints of the foot, which constitutes what is called a fit or paroxysm of the regular gout. This sometimes comes on suddenly without any warning of its approach; but it is generally preceded by several symptoms, especially by those of indigestion, as heart-burn, flatulence, and heaviness after meals, with eructations of acid or bitter matters, and some degree of languor and torpor of the body; but immediately before the fit the appetite is sometimes unusually sharp. There is also often an unusual coldness of the feet and legs for a few days preceding the fit, with the cessation of the perspiration about the former; a frequent numbness, alternating with a sense of prickling, along the whole of the lower extremities; occasional cramps of the muscles of the legs; and an unusual turgescence of the veins, are occasionally observed.

The attack is sometimes felt in the evening, but more

commonly about two or three o'clock in the morning; when the patient is awakened from a quiet sleep by a pain affecting one foot, generally the ball or first joint of the great toe, but sometimes the other parts of the foot, or the ankle. This pain is accompanied with more or less of chilliness and shivering, which, as the pain increases, gradually cease, and are succeeded by a hot stage of pyrexia, or symptomatic fever, which continues during the same time as the pain. The pain becomes by degrees more and more violent: at first it is attended with a sensation, as if warm water were poured upon the membranes affected, and is said to resemble the pain of a dislocated joint; as it becomes severe it is sometimes described as resembling the pain of a tension, or laceration of the ligaments, sometimes as like that from the gnawing of a dog, and sometimes as a feeling of weight and constriction of the membranes of the part, which becomes so exquisitely tender, as not to endure the weight of the bed-clothes, nor even the shaking of the room from a person walking briskly in it. Hence, great restlessness of the whole body, and especially of the part affected, always accompanies the fit; the patient constantly changing his posture, with a view to ease the pain, which, nevertheless, continues severe all the following day, until mid-night, after which it gradually remits; and about two or three in the morning, that is, after twenty-four hours from the first attack, it commonly ceases almost entirely; and this freedom, with the breaking out of a free perspiration, allows the patient to fall asleep. On waking, he finds the pain slight, and the part affected with some redness and swelling.

When a paroxysm has thus come on, although the violent pain, after the period of twenty-four hours, be considerably diminished, yet the patient is not entirely without pain. For some days he has a return every evening of pain and fever, which continue, with more or less violence, till morning. After continuing in this manner for several days, the disease sometimes goes off entirely, not to return till after a long interval; and in such cases it generally leaves the person in very perfect health, enjoying greater ease and alacrity in the functions both of body and mind, than he had for a long time before experienced.

It often happens, however, that the disease does not thus speedily quit the patient, especially when he has previously suffered considerably from its attacks. For, instead of ceasing altogether after a few days, it seizes the other foot in the same manner as it did the former, both in respect to the vehemence and duration of the pain. Most commonly the foot first affected becomes quite easy, in such a case, and even as strong and healthy as if it had not been diseased; but sometimes both feet are affected together, and with equal violence. When this happens, the succeeding exacerbations, as Sydenham remarks, are less regular both as to the time of coming on, and as to their continuance; but the pain always increases in the evening and remits in the morning; and what is called a fit of the gout, which goes off sooner or later, according to the age and constitution of the patient, is made up of a number of these little fits. For when this disease lasts two or three months, it is not to be esteemed one continued fit, but rather a series or assemblage of small fits, the last of which proves milder and shorter, until the whole is terminated. In strong constitutions, and such as have the gout seldom, the attack is commonly finished in fourteen days; but in those of advanced life, or who have frequent returns of the disease, these series of fits will continue for two months; and in such persons as are more debilitated, either by age or the long continuance of the disorder, it will not

go off till the summer advances, (beginning, as is most common, in January, or early in February,) which seems to drive it away.

When the fit is going off, a violent itching seizes the foot, especially between the toes, and the cuticle peels off. The appetite and strength return sooner or later, according to the greater or less severity of the preceding fit, and the interval of health between the paroxysms is generally nearly in the same ratio; *i. e.* longer in proportion to the greater violence of the last fit. At the beginning of the disease, Dr. Cullen observes, the returns of it are sometimes only once in three or four years; but after some time the intervals become shorter, and the attacks become annual: afterwards they come twice each year, and at length recur several times during the whole course of autumn, winter, and spring; and as it happens that, when the fits are frequent, the paroxysms become also longer, so, in the advanced state of the disease, the patient is hardly ever tolerably free from it, except, perhaps, for two or three months in summer.

Before the disease becomes thus inveterate, however, it has gradually assumed other appearances, and attacked other parts of the body. At first it commonly affects one foot only; but afterwards every paroxysm affects both feet, the one after the other, and then both together; and its changes of place, as it continues to recur, are not only from one foot to the other, but also from the feet into other joints, as the hands, wrists, elbows, knees, &c.; so that there is scarcely a joint in the body that is not, on one occasion or other, affected. It sometimes seizes on two different joints at the same time; but more commonly it is severe in a single joint only, and passes successively from one joint to another; so that the patient's affliction is often protracted for a long time. The pains, indeed, are commonly less violent, in this state of the disease, than they were at first; but, in addition to them, loss of appetite, sickness, and other symptoms of the atonic gout, now afflict him. Besides, in the intervals between the first paroxysms of the disorder, the joints which had been affected were entirely restored to their former suppleness and strength, and were free from pain or uneasiness, and all the functions of life were well performed. But in this protracted condition of the disease, the joints remain not only weak and stiff, after the termination of the fit, but they become at length so contracted and disabled, that although the patient can stand, and perhaps walk a little, yet it is very slowly, and with great lameness and difficulty, so that he is scarcely able to move from room to room; and sometimes the joints lose their motion altogether.

In many persons, though not in all, when the disease has frequently recurred, this immobility of the joints is farther increased by the formation of concretions, of a chalky appearance, upon the outside of them, and for the most part immediately under the skin. The secretion or deposition of this matter is characteristic of the disease, being the consequence of gouty inflammation alone. It seems to be deposited at first in a fluid form, but afterwards becomes dry and firm; in which state the concretions have the appearance of a friable earthy substance, and have been called *CHALK-stones* (which see). From the investigations of Dr. Wollaston, however, and other modern chemists, it has been ascertained that they contain no calcareous or earthy matter, but consist of a neutral salt, formed by the combination of the lithic or uric acid, with the fixed alkali, soda,—constituting a lithate or urate of soda. These concretions form principally about the joints of the toes and fingers, in little no-

dules, which Sydenham compares to crab's eyes; but sometimes they appear about the larger joints, as the elbow and knee, occasioning a whitish swelling almost as large as an egg, which becomes gradually inflamed and red. Mr. Watson has related an example of a very extensive deposition of urate of soda, in a gouty man, who was a martyr to the disease. Chalk-stones not only enveloped the joints of his great toes, formed tumours upon his legs, and, being mixed with the synovia of the large joints, rendered this fluid as thick as cream; but "the joints of the fingers were swelled and knotty, every knot being a lump of chalk; and I was told," he adds, "that when he played at cards, he used frequently to score up the game with his knuckles." (See Medical Communications, vol. i. art. 3.—See also Parkinson's Obs. on the Nature and Cure of Gout, p. 5.)

Such is the progress of gout, as it affects the joints, and while it may, therefore, be called *regular* gout. Sydenham, indeed, and some other writers, confine the appellation of *regular* to gout in the feet only; and consider it as *irregular*, when it attacks the hands or other joints. But Dr. Cullen, Warner, and the physicians of the present day, in general, agree in calling the disease, when it consists only of an inflammatory affection of the joints, the *regular* gout: "and," Dr. Cullen observed, "whatever symptoms we can perceive to be connected with, or to depend upon, the disposition which produces that inflammatory affection, but without its taking place, or being present at the same time, we name the *irregular* gout." First Lines, § 518.

Irregular gout, anomalous, internal or atonic gout, as it has been also called, consists of various symptoms of disorder in the internal organs of the body, which do not differ from the symptoms affecting the same organs under other circumstances; it is, therefore, suspected that these symptoms are of gouty origin, when they occur in persons bearing the marks of a gouty diathesis or disposition: and especially when, in such habits, either a manifest tendency to the inflammatory affection of the joints has formerly appeared, or when the symptoms alluded to are intermixed with, and are relieved by, some degree of the inflammatory affection. The morbid symptoms which appear, in such cases, and are considered as signs of *atonic* gout, are principally affections of the stomach; such as loss of appetite, indigestion, and its various concomitants of sickness, nausea, vomiting, flatulency, acid eructations, and pains in the region of the stomach. These symptoms are frequently accompanied with pains and cramps in the upper extremities of the body, which are relieved by the discharge of wind from the stomach. Together with these affections of the stomach, costiveness also commonly occurs; but sometimes a looseness with colic pains. These affections of the alimentary canal are often attended with all the symptoms of hypochondriasis; as dejection of mind, a constant and anxious attention to the slightest feelings, an imaginary aggravation of these, and an apprehension of danger from them. In the same atonic gout, the viscera of the thorax are also sometimes affected, and palpitations, faintings, and asthma occur. And the head also is often disordered, with pains, giddiness, somnolency, and even apoplectic and paralytic affections. (Cullen. See also Musgrave "De Arthritide Anomala," where these various modifications of irregular gout are described at length; and Warner's "Full and Plain Account of the Gout," where his observations are translated, pp. 70—90, second edit.)

We may here remark, in passing, that many errors have probably been committed, in considering almost every species of indisposition, that occurs in gouty habits, as arising

from the gouty diathesis. We remember to have heard this point strenuously insisted upon by the able professor of physic, in the university of Edinburgh, Dr. Gregory. Many of the symptoms above enumerated are obviously connected with the impaired functions of the stomach, and occur in dyspepsia, or indigestion, in habits not gouty; such are the various hypochondriac sensations; the palpitations of the heart, often arising from over-distension of the stomach with flatus, by which the heart is mechanically pressed upwards: the cramps in different parts of the body, which are often relieved by a discharge of wind from the stomach; the difficulty of breathing, often occasioned by great distension of the stomach, which impedes the descent of the diaphragm; and the head-ache, giddiness, &c. which are daily observed to be connected with impaired digestion. On the other hand, inflammatory disorders of the lungs and other viscera, congestions in the head, inducing head-ache, somnolency, vertigo, &c., and ultimately various degrees of paralytic and apoplectic disease, not essentially different, in any respect, from the same affections in habits not tainted with gout, have probably been suffered to go on, and to prove fatal, under a notion that they were gouty, and the proper remedies have been therefore neglected.

The *irregular gout* occurs in a less equivocal form, when the inflammatory state of the joints has come on in the usual manner, but when, without arising to the ordinary degree, or at least without continuing for the usual time, and receding gradually, as is common, the pain and inflammation suddenly and entirely cease, while some internal part becomes disordered. This has been called the *retrocedent* or *repelled gout*. When the gout is thus retrocedent, the same internal parts are attacked, and the same disorders produced, as in the irregular or atonic gout, where no previous imperfect attack upon the joints had shewn itself. The stomach is for the most part commonly affected, whence violent pain, sickness, vomiting, anxiety, &c.: the heart and lungs are also occasionally attacked; and sometimes the occurrence of apoplexy, palsy, or delirium, mark the head as the seat of the retrocedent disease.

Another variety of irregular gout has been denominated *misplaced gout*; namely, when, instead of the joints of the extremities, the stomach, brain, lungs, intestines, kidneys, or bladder, become affected with symptoms of inflammation, which give way upon the appearance of the inflammation in the extremities, when that takes place. This inflammation of the internal organs, however, is indicated by the same symptoms which accompany inflammation of the same parts, arising under other circumstances, and in constitutions not gouty: and it has probably been sometimes supposed to be of gouty origin, when it arose from the ordinary causes. Dr. Cullen affirms, that he never met with any instances of misplaced gout in his practice, and that no case has been distinctly made out by medical writers, except that of pulmonary inflammation. But he had known two varieties of internal disease alternate with external gouty inflammation; *viz.* the one an affection of the neck of the bladder, producing pain, strangury, and catarrhus vesicæ; the other an affection of the rectum, sometimes marked by pain alone in that part, and sometimes by hæmorrhoidal swellings.

Such are the phenomena, by which the various forms of regular and irregular gout are chiefly characterized. The next object of our inquiry will be the

Causes of Gout.—Among the *predisposing* causes of gout, an original peculiarity of constitution, often transmitted from the parent to the offspring, appears to be the most common; in other words, the disease is said to be *hereditary*. This position, indeed, has been controverted, especially by Dr.

Cadogan (see his *Diff. on the Gout*, and all Chronic Diseases, p. 7.); but the discussion has turned upon a mere dispute about words. For it is admitted, on all hands, that the *predisposition* of the constitution to be affected by gout is transmitted from father to son, like other peculiarities of habit; like the family-likeness, for instance, in features, in voice, complexion, &c. It is true, indeed, as Dr. Cadogan contends, that some persons acquire this gouty disposition, who have it not by hereditary transmission; and, on the other hand, that the hereditary predisposition may be counteracted by various causes, but particularly by certain modes of life, so that the disease itself shall never appear. Yet it is equally true, that the same occasional causes, which will excite the disease in those who are hereditarily predisposed to it, will not produce it in others, although applied in greater force; and, therefore, the existence of an original constitutional predisposition must necessarily be inferred. The middle and advanced periods of life are also more disposed to gout, than the early periods: thus it does not commonly attack men until after the age of thirty-five, and generally not till a still later period. When the gout does appear, in more early life, of which there are instances, it seems to be in those in whom the hereditary disposition is very strong, and to whom the exciting causes have been applied in a considerable degree. Hippocrates remarks, that eunuchs are not liable to be affected by gout, nor boys previous to venery: but the intimation included in the remark is probably unfounded; since, with respect to the latter, the disease, as we have already stated, is almost peculiar to an advanced period of life; and the eunuchs, who, in the time of Hippocrates, were chiefly Persian slaves, were doubtless confined to the strict discipline and the frugal and temperate life, which the rigorous laws enjoined to all, and therefore not exposed to the most active causes of gout. For Galen, in his commentary upon this observation of Hippocrates, observes that, in his time, the remark was no longer true, "owing to too much indulgence on their part in an indolent, as well as intemperate mode of life:" and the remark is confirmed by modern experience. (Van Swieten. loc. cit.)

It has been fully ascertained, indeed, that the principal source of the gouty habit consists of high feeding and indolence conjoined. Sydenham (who, upon the subject of gout, stands unrivalled in accuracy of observation, and the model of all succeeding writers, many of whom have done little more than copy his history of it) begins his account of the disease with these remarks. "The gout generally attacks those elderly persons who have spent the greater part of their lives in ease and indulgence, both in the use of high feeding and of wine, or other spirituous and fermented liquors; and who, in consequence of the sluggishness of advanced life, have ceased from all those exercises to which they were accustomed in their youth. The gout, however," he adds, "does not always wait till an advanced age; it sometimes attacks those who are in the prime of life. But these persons have unfortunately received the seeds of the disease from their parents; or, if not, they have indulged in premature and excessive venery, or left off entirely those exercises which they had previously used with great activity, and have been besides most indulgent to the appetite, and drank to excess of vinous and spirituous liquors, afterwards suddenly turning to those that are thin and cold." (Sydenham, *Tractatus de Podagra*.) These facts have been long known. There is a Greek epigram literally signifying, "of limb-relaxing Bacchus and limb-relaxing Venus is born a daughter, the limb-relaxing Gout." And a similar observation is contained in the adage, "Bacchus pater, Venus mater, et Ira obstetrix Arthritidis." While this fact is confirmed,

confirmed, on the one hand, by the testimony of ages in the affirmative, it is corroborated also, on the other hand, by observation in the negative. Dr. Cullen remarks that gout seldom attacks those who are employed in bodily labour, or who live much upon vegetable aliment, or those who make no use of wine or other fermented liquors. Indeed, the gout is said to be altogether unknown where these liquors are not used, as among the common people of Turkey. Among the lower orders of people, even in this country, the disease is very rare, and still more rare in Scotland and Ireland, where animal food and strong ale and beer are less used. Van Swieten observes, that some people who, from comfortable circumstances, have been reduced to labour for their subsistence, and to exchange a luxurious table and indolence for a spare diet and activity, have lost their gout. He mentions particularly the instance of a certain priest, who enjoyed a rich living, and had been an old and constant sufferer from the gout; but happening to be taken by the pirates of Barbary, he was kept constantly at work in the galleys for the space of two years: "which had this good effect, that afterwards, when he was ransomed from captivity, having lost all his troublesome and monstrous fatness, he never once had a fit, though he lived several years after the event." (Van Swieten, Comment. ad Aph. 1255.) Several anecdotes of a similar nature are related by the industrious Schenckius. (Obs. Med. Rarior. lib. v. p. 657. edit. 1644.) In a word, much exercise, which will often counteract the influence of intemperance, will, when combined with temperance, counteract even the hereditary disposition to the disease.

The effect of full living and indolence, in producing the gouty diathesis, is also manifest from the form and temperament of the persons in whom it occurs. These are especially men of robust and large bodies with large heads, and of full and corpulent habits. They have commonly also a coarser skin; and if, with the ancients, we might denote the temperaments of men by certain terms, we should say that the gout especially assails men of a *cholero-sanguine* temperament, and seldom attacks the purely sanguine or melancholic. Women are not very liable to the gout, probably from their less intemperate mode of life, in general, than that of men: but those females whom it attacks are generally of robust and full habits. It is said not to occur in them commonly till after the cessation of menstruation; which perhaps only implies that it is a disease of advanced life. For as Dr. Cullen justly remarks, "it often happens to such (the robust) long before the menstrual evacuation has ceased," and he had "found it occurring in several females, whose menstrual evacuations were more abundant than usual." (First Lines, § 494.) A fact, which we may explain, with Dr. Gregory, by observing, that those women who indulge much in vinous and fermented liquors, are more liable to menorrhagia than others.

It is obvious, then, that the experience of all ages concurs in assigning intemperance and indolence as the principal sources of that habit of body, in which the gout is liable to occur. This habit, or predisposition, seems to be sufficient, in many cases, to produce the disease itself, or at least to require the application of slight and imperceptible exciting causes to bring it forth. The disease, indeed, depends so much upon predisposition, that it is difficult to assign the occasional causes; the same agents appear to be sometimes the generators of a predisposition to it only, and at other times actually to excite the disease.

The *exciting causes* which often suddenly bring on a fit of the gout, in those who are predisposed to it, are, in the first place, those circumstances which induce a sudden debility, especially of the stomach. The concurrence of *indigestion*,

and the local inflammation in gout, is one of the characteristics of the disease; and, as we have already stated, the latter is usually preceded for some time by the former. Hence whatever suddenly depresses the digestive power, is liable to induce the local and constitutional disease. Thus a paroxysm of gout has frequently been excited by an occasional excess in the use of wine or spirits; by overloading the stomach with food, or by eating such as is not easily digestible in its nature; by the copious use of vegetable acids or accefcient matter, especially by weak accefcient wines, punch, &c.; all of which tend to debilitate the digestive organs either directly or indirectly. In the same way, excess of venery, which powerfully influences the stomach, (Van Swieten, Aph. 586, and 1255,) has often brought on a fit. This seems to have been universally understood by the ancients. We have already noticed the observation of Hippocrates; and Aëcius, in recounting the general causes of gout, says, these are, "abounding crudities, frequent drunkenness, and, above all, an immoderate use of venery." (Sermon xii. Cap. 6.) Sydenham and Van Swieten add their testimony to the fact. Intense study, night-watching, excessive anxiety and attention to business, all of which greatly depress the power of the body in general, and of the stomach in particular, destroying the appetite, and producing a sense of uneasiness, sinking, or weight about the region of the stomach, are likewise enumerated among the occasional causes of the gouty paroxysm. The same is true with respect to the violent emotions and passions of the mind, more particularly of anger. "Ira obiletrix arthritidis" is part of the adage above quoted: and the three causes of gout, insisted on by Dr. Cadogan, are intemperance, indolence, and *vexation*. The influence of violent mental emotions on the functions of the body is, indeed, very manifest, and more especially on the function of digestion; the disturbance of which, we have already observed, is exceedingly instrumental in the production of gout. "The first immediate effect of violent grief or vexation," says Dr. Cadogan, "is to take off the action of the stomach entirely. Let us suppose a man in the best health, the highest good humour and spirits, as well as good stomach, sitting down to dinner with his friends, receives suddenly some very afflicting news. Instantly his appetite is gone, and he can neither eat nor swallow a morsel. Let the same thing happen after he has made a hearty cheerful meal, as suddenly the action of his stomach, the whole power of digestion is cut off totally, as if it were become paralytic, and what he has eaten lies a most oppressive load. Perhaps as the excess of weakness is often convulsion, it may be rejected by a violent vomit, or do greater mischief: for which reason such strokes of distress are less hurtful received upon an empty than a full stomach." &c. (Loc. cit. p. 55.) The gouty habit, indeed, is often an irritable habit; and Sydenham observes, that a fit of gout may be called a fit of anger. (See also Van Swieten. § 1258.)

Among other exciting causes of gout, the sudden ceasing from the customary exercises or labour is commonly mentioned, and its principal effect is probably upon the function of digestion, which is so much under the influence of exercise. Indolence, in general, as contributing to induce the gouty disposition, is well understood: and the sudden cessation of activity, like all other sudden changes, is apt to produce a sudden accession of the paroxysm, in those who are predisposed to the disease. In a similar manner, a sudden change in the mode of living, the opposite to excess, namely, from high feeding to a very spare and abstemious diet, is liable to induce the paroxysm of gout. That such a sudden abstraction of the powerful stimulus of a copious supply of food and strong liquors, must necessarily induce a considerable

direct debility in the organs of digestion, is well understood by those who are acquainted with the laws of stimulants on the animal body. (See DEBILITY and EXCITABILITY.) This fact, however, although sometimes adduced as an argument against the advantages of an abstemious regimen, in preventing the gout, affords no such legitimate inference. It is too obvious, indeed, to require an elaborate discussion, that all extremes, hastily adopted, are liable to derange the animal economy; and that habit alone can render extreme moderation invariably beneficial, on the one hand, and enable us to bear excess with a considerable degree of impunity on the other. Another mode of debilitating the system, which sometimes brings the paroxysm of gout, is excessive evacuation of any kind; such as by hæmorrhage, brisk purging, vomiting, &c.; especially in aged persons, whose constitutions are already much broken down by the disease.

Sudden vicissitudes of weather, especially when connected with moisture, as from mild to cold, or from severe cold to damp and mild weather, often excite the gout; hence, Sydenham remarked, that the most frequent occurrence of the gouty paroxysm takes place in the latter end of January, or the beginning of February. The fit may be produced either by the local application of cold and moisture to the feet, or by a general exposure to it; for such exposure, which in most people will occasion rheumatism, a catarrh, or a sore throat, will, in a gouty subject, excite a fit of the gout. In like manner, bruises and sprains of the leg or foot, or mere over-exercise of the muscles and ligaments of those parts, as in long walking, will sometimes bring on a paroxysm.

There is another alleged cause of the gout, which it would not now be necessary to mention, were it not noticed by Boerhaave, Van Swieten, and others, *viz.* contagion. Van Swieten considers the disease as analogous to dysentery and other maladies, which, although originating from very obvious causes, nevertheless propagate themselves afterwards by contagion. But the stories, by which this doctrine is supported, are somewhat ridiculous; such as this, that a dog lying at his master's feet during a paroxysm of the gout, suddenly ran howling and barking round the room, expressing the pain which he had caught from his master, whose torture at the same time became greatly alleviated, &c. (Swieten Com. ad § 1255.)

Of the Diagnosis.—The attack of the *regular* gout is readily distinguishable from the only disease which resembles it, *viz.* acute rheumatism, if all the symptoms are taken into consideration. In the first place, gout is commonly a disease of advanced life; acute rheumatism is most frequent from the age of 18 to 30. Nor does rheumatism, like the gout, seize the feet in preference to the other joints, or remain for a considerable time in the same joint; but at the first attack it often attacks every joint of the body in succession, and sometimes continues for several months. The colour of the skin of the part affected in rheumatism, if it be changed, is only slightly red, whereas it becomes of a deep bright red in the gout. The pain in the rheumatism is not extremely acute, while the part is at rest, but becomes violent when it is moved only; which is not the case in the gout. And the symptoms of indigestion and disordered stomach, which precede the paroxysm of the gout, together with the marks of distinction just mentioned, will serve particularly to determine the nature of the paroxysm. It must be admitted, however, there are instances of the combination of the symptoms of the two diseases, which renders it difficult to decide to which of them the individual examples belong. (Heberden, Comment. de Morb. p. 58.)

Again, the symptoms which the *irregular* gout presents, are extremely numerous and proteiform, appearing frequently as dyspepsia, hysteria, hypochondriasis, asthma, palpitation, syncope, vertigo, apoplexy, paralysis, &c. according to the original or acquired tendency of the constitution to those diseases. Hence the discrimination between these modifications of gout, and the disease which it mimics, is occasionally very difficult.

Of the nature or proximate cause of Gout.—This is a part of the subject upon which, if we were to confine ourselves to the communication of actual and useful knowledge, we should be altogether silent, or say but a few words. The observation, indeed, will apply to many other diseases, as well as to gout; but as gout is an affection almost exclusively occurring in the higher classes of society, among the wealthy and intelligent, it has claimed a more general attention, and become the object of more general discussion. It is greatly to be lamented, however, that the most mistaken notions have prevailed, from the earliest times, in regard to the nature and extent of the insight, which we are capable of obtaining, into the operations of the animal economy, and to the means by which we can obtain it. Instead of confining themselves to the observation of the phenomena of health and disease, faithfully recording these phenomena, and arranging them according to their most obvious analogies, physicians have been busy in searching after their hidden causes; and, fancying a resemblance between the most dissimilar things, have successively called to aid the analogies of every human science, as it advanced in cultivation, to explain the phenomena of animal life. The ancient doctrines of numbers and elements, and their qualities, and the modern discoveries and suppositions of the chemical, mathematical, and mechanical philosophers, have in turn been assumed as affording the most perfect elucidation of the operations of the living body; and, as they have, of course, been in turn exploded, we need not recur to any other argument in proof of their want of foundation. By these remarks we wish only to shew the futility of reasoning on the subject of proximate causes of disease, which, as we are and must remain entirely ignorant of the proximate cause of health and life, must be equally inscrutable. “Nam quæ demum causæ,” as Celsus justly observes, “vel secundam valetudinem præsent, vel morbos excitent, &c. ne sapientiarum quidem professores scientia comprehendunt, sed conjecturâ prosequuntur.” (De Med. Præf. lib. i.) The inquiry respecting the proximate cause of diseases is as futile as the speculations of the Cartesians to explain the essence of gravitation, and have as little to do with the advancement of true medical science, as the hypothesis of an ether assisted Newton in his observations and calculations respecting the phenomena of that agent.

If these observations should not be sufficiently intelligible to the general reader, a brief enumeration of the hypotheses, which have been invented by medical writers, in order to explain the essential nature of gout, will probably be sufficient to prove the absurdity of such attempts. Most of the Greek and Roman physicians, with the exception of the methodists, considered the presence of a corrupted humour in the small vessels as the essential cause of gout. Hippocrates believed this humour to consist of bile and phlegm, which flowed upon the joints. Galen followed him in supposing the defluxion upon the joints to be chiefly pituitous or phlegm, or bile mixed with phlegm. Paulus Ægineta attributed the disease to a redundancy of blood, black bile, and phlegm. Trallian and Cassius imagined, that it arose from the blood itself being forced into the joints; and Orisbanus affirmed that the blood in gouty people was viscid, resembling

resembling melted glass, which remaining in the joints, produced the cretaceous matter. Aretæus, one of the most able of the Greek writers, is the only one who passes over the essential cause of the disease, a knowledge of which he assigns to the gods alone; the evident causes, he says, are apparent to man. Themison, Cælius Aurelianus, and the methodic sect, attributed gout to relaxation or stricture of the parts; some, however, imputed it to the one state, and others to the opposite. The Arabians followed closely in the path of their masters, and taught that one or other of the humours was predominant, or that they were variously combined, in cases of gout. So luminous and instructive were the doctrines of the ancients!

In the dawn of modern science, the humours were almost banished by the hypotheses of the chemists; but although we hear little more of bile, phlegm, and melancholy, or black bile, all disease was nevertheless attributed to a morbid or peccant matter, and salts, earth, or tartar, were deemed the immediate cause of gout and other maladies; and Paracelsus, Van Helmont, and others, are very abusive of the ancients for promulgating so many absurd doctrines! When the mathematical and mechanical physicians arose, they took up the hypothetical doctrines of their predecessors, and reasoned concerning the action of these supposititious humours, salts, &c. upon mechanical principles; the chemical doctrines predominated, however, over the ancient humours. Thus, to use the words of Dr. Warner, "according to Sydenham the arthritic matter consists of the putrefying heat and acrimony of indigested juices: Boerhaave gives it the appellation of an acrimony or over-toughness of the liquid which waters the nervous parts: Liller makes it to be a crude and viscid serum become ichorous and corrosive: Bennet defines it an acrimony that is invariably of the putrid, volatile alkaline nature: Quincy says that it consists of rigid particles, such as approach near to the saline, of the nature of tartar, and not much unlike that which forms itself into concretions in the urinary passages: Cheyne in one place calls it tartarous, urinous, or other salts: Ingram will have it to be a coagulation made by a mixture of saline particles with the oil of the adipose membrane. As every one of these writers makes the gouty matter to be an acrimony taken in with our aliment, which they call either putrid, viscid, corrosive, saline, urinous, or tartarous, so Dr. James, whose name needs no addition, disagreeing with them all, hath judged this acrimony to be earthy." (See Warner on the Gout, p. 91.—See also a sensible and learned dissertation on this topic, in "An Historical, Critical, and Practical Treatise of the Gout, by Thomas Thomson, M.D. Lond. 1742.) But such hypotheses did not die with Dr. James; for in a treatise on the gout, published in 1805, we find the following statement: "The proximate cause of gout appears to be, a peculiar saline acrimony existing in the blood, in such a proportion, as to irritate and excite to morbid action, the minute terminations of the arteries, in certain parts of the body." (See Observations on the Nature and Cure of Gout, &c. by James Parkinson,) a statement, which is equally indefinite, hypothetical, and practically useless, with those that have preceded it.

On reviewing these opinions of men, who have been deservedly esteemed the ornament of their profession, some readers may express their surprise that such an extraordinary difference should be found among them, and that so much error (for of opposite opinions one half at least must be wrong) should exist in the science. But the only rational ground for wonder is, that so many men of sound understanding should have employed themselves in inquiries beyond the reach of their faculties, and should have imagined that,

in framing hypothetical suppositions, they had acquired any actual knowledge, or had advanced one step in the practical improvement of their art. If a number of philosophers were engaged in investigating the nature of light and heat, and should not only execute a series of experiments on the reflection, refraction, and divisibility of the one, and on the properties of expansion, inflammation, vaporization, &c. of bodies, which belong to the other; but should likewise think it necessary to form conjectures relative to the nature and qualities of the sun, which is the source or proximate cause of both; these conjectures, like the medical hypotheses just quoted, however they might amuse us, would add not a tittle to our knowledge, nor would the want of them be any diminution of our information, or of our practical powers.

The great source of these hypotheses, respecting the existence of a morbid humour in the gouty habit, is, no doubt, the appearance of a palpable matter, of a peculiar nature, in the joints diseased. This chalk-like matter, however, will be found to afford no ground for such a conclusion, if the circumstances are duly examined. In the first place, the production of this morbid matter may be the effect of the disease; and that it is so, is apparent from its not occurring in all cases of gout, and from its seldom or never accompanying the first attacks of the disease, but only appearing after repeated paroxysms. Nor have we any direct evidence, from experiment or observation, of the smallest difference in the blood or other humours of gouty people, from those of other persons. On the other hand, we know that the vessels in particular parts acquire the power of secreting or otherwise producing new fluids, when inflammation is induced. Thus a blow in a fleshy or membranous part shall occasion inflammation, and a considerable quantity of pus shall afterwards be accumulated or discharged, as in a common abscess: yet no one supposes that this pus was contained in the mass of the circulating blood, any more than he supposes that urine and bile are contained in that mass, and not elaborated by the kidneys and liver. The appearance of the chalky matter, or urate of soda, in the parts attacked by gouty inflammation, is therefore to be considered as the result of that inflammation, and not as its cause. If the general mass of blood were contaminated with this morbid matter, or any peculiar acrimony tending to produce it, why is it never deposited on the viscera and other internal parts? yet no such deposition was ever observed: those parts remain invariably free from it in the most inveterate forms of the gout, and the appearance of chalk-stones is confined exclusively to the membranous and ligamentous parts which exhibit inflammation externally. In the next place, the frequent and sudden translation of the disease from one part to another is not consistent with the supposition of its dependence on the presence of a morbid matter: but analogous changes or *metastases* of other inflammations, in which no peculiar matter is produced, are exceedingly common. Besides, up in the supposition of such a translation of morbid matter, its operation should be similar on every part: whereas it seems to be very different, being stimulant and exciting inflammation in the joints, but sedative and destroying the tone or energy of the stomach. Farther, as Dr. Cullen justly observes, "the supposition of a morbid matter is quite superfluous; for it explains nothing, without supposing that matter to produce a change in the state of the moving powers; and a change in the state of the moving powers, produced by other causes, explains every circumstance, without the supposition of a morbid matter: and to this purpose it may be observed, that many of the causes exciting gout do not operate upon the state

of the fluids, but directly and solely upon that of the moving powers." Dr. Cullen likewise remarks, that the supposition of a morbid humour being the cause of gout has been hitherto useless, since it has not suggested any successful method of cure: but, on the contrary, that particular suppositions have often corrupted the practice, and have frequently led from those views, which might be useful, and from that practice which experience had approved. (First Lines, pt. 530.)

Having failed to explain the phenomena of the disease, on the supposition of a morbid condition of the fluids of the body; we might take up the doctrine of the *nervous* pathologists, and attempt an explanation of the symptoms, upon the notion of a derangement of the living solid, or moving fibre, as Dr. Cullen has done. (Loc. cit. §. 533—6.) But it is sufficient to peruse the account given by that celebrated physician, to be convinced that it is a mere repetition of the phenomena of the different varieties of the disease, couched in a new phraseology; and therefore that it is practically as useless as that which he controverts. It cannot be questioned, we apprehend, in the present state of our physiological knowledge, that the prime agents in the operations of the living body, whether in health or disease, are the solid, irritable, and moving parts; and that by these the fluids or humours are chiefly elaborated and modified: but it is likewise obvious, that the solids derive their powers from certain conditions of the circulating fluids, which are varied by respiration, nutrition, &c. Therefore the disputes between those, who confine the origin of gout to the one or other part of the system exclusively, must be deemed frivolous. Our knowledge is necessarily limited to the phenomena of the disease, and the order in which they occur, and to the effects of physical agents upon them, as taught us by observation and experiment. "Nulla tamen adhuc obscurior quaestio est," says Dr. Heberden, "quam quæ versatur de hujus morbi causis, effectibusque, et remediis." (Comment. de Morb. Cap. 9.) But we cannot doubt that these numerous hypotheses, which have at once diverted the minds of physicians from the labour of observation, and have perverted their views of facts, have rendered the subject more obscure than it would otherwise probably have been.

Before we come to the method of treatment, there is another question to be noticed, upon which much discussion has taken place, and which has perhaps been popularly solved with considerable incorrectness: we mean the question, whether regular fits of the gout are salutary; *i. e.* whether they altogether remove or prevent other complaints. The affirmative is generally maintained: and this opinion has arisen partly from observation, and partly from the hypothesis, that a paroxysm of gout consists in an effort of the constitution, by which the morbid matter is thrown off through the part affected. In a number of instances, beyond a doubt, the various symptoms of indigestion, whether affecting the stomach and bowels only, or the lungs and heart by vicinity, and the head by sympathy, are relieved or altogether carried off by the complete fit. Perhaps Dr. Heberden is scarcely correct, when he considers this relief as either, in a great measure imaginary, like that which many invalids invariably obtain from a change of their physician, or from a new medicine; or as not more frequent than similar relief from slight indisposition after other violent diseases: he appeals, however, to an ample experience in support of his opinion. He thus writes: (we translate from the Latin edition) "There are some countries in which the itch is a very frequent disease, and there this eruption is deemed salutary. Even an ague was formerly considered by

the majority of physicians as a wholesome affection, and is still so considered by some persons; its occurrence was therefore a subject of congratulation both with the patients and their friends, and every precaution was taken not to get rid of it too soon. But these notions are almost exploded in this country; and if we shall discover a remedy equally effectual for the gout, as those with which we cure the diseases just mentioned, we shall at length learn with what perfect safety and advantage the gout may likewise be eradicated."—"I confess," he adds, "that I have seen some persons who rejoiced on the first attack of the gout, as if it assured to them all future happiness, and who, dreaming only of the most perfect health to come, easily persuaded themselves that this first fit had been wonderfully beneficial. This is a common disposition with mankind, as often as they have recourse to new physicians, or to remedies not before tried. But, passing by such persons, let us inquire the opinion of those, who have suffered under long and frequent paroxysms, and who are better acquainted with the disease. Of a very great number of patients whom I have seen, and whose cases I have committed to writing, more than twice as many, to say the least, have found no relief whatever from their previous complaints, in consequence of the regular fit, or have even suffered an increase of them, as have seemed to derive any benefit: and, in my opinion, the evils which were attributed to the disease, more certainly originated from that source, than the supposed advantages. Occasionally, indeed, we find that other complaints have ceased on the supervention of the gout; but the same thing also happens after acute fevers, after palsy, asthma, small-pox, and insanity, of all which I have witnessed many examples; yet no one will call these diseases salutary. On the other hand, gout frequently occurs to persons affected with vertigo, asthma, indigestion, and melancholy; where, so far from alleviating these disorders, it produces a considerable aggravation of their symptoms. Besides, in some patients, all these complaints constantly accompany the paroxysm of gout, and continue during the whole of its course." (Loc. cit. p. 36.)

At all events, if we look at the life of the gouty in general, we find ultimately but little ground for congratulation. In some, it is true, the disease occurs at distant intervals, and soon goes off, and therefore occasions very little, if any, obvious injury. Even epilepsy itself, when its attacks are rare, does not prevent the patient from reaching old age. But this is far from being the case frequently with either disease. In many persons whom the gout attacks, the health suffers from the time of the first fit, and gradually grows worse, until it is greatly broken, or fails altogether. It may possibly be doubted, in such cases, whether the gout caused these evils; but we are very certain that it has not been the remedy for them, nor in any way salutary.

We may justly wonder, therefore, with Dr. Heberden, how it has come to pass, that the gout is held in so much honour in England; unless it be that it is a disease, which several great men have suffered, and which chiefly attacks those happy personages who enjoy leisure and affluence, and all the good things of life. Louis XIV. of France happened to labour under a fistula in the anus, and the surgeons of that time were constantly called in by his fashionable subjects to administer relief to imaginary fistulae; which royal disease they persuaded themselves had attacked them: and it is probable, as Dr. Heberden suggests, that had there existed any medicated waters in France, capable of producing fistula, they would have been visited with the same anxiety with which our countrymen hasten to those of Bath, in the hope of returning with the gout.

Of the Cure.—Perhaps this may be deemed an improper term for the treatment of a disease, which, on the one hand, has been affirmed to be incurable by medicine, and called the opprobrium of physicians; and, on the other, has been considered so salutary, that it ought not to be cured, and could not be cured without the most imminent danger to the patient. Nay, farther, as much trouble has been taken to produce and excite the gout, as to relieve or cure it; and all the evils which arthritides suffer, are not supposed to arise from a superabundance of gout, but because they have not had enough. It would be only justice, however, as the intelligent writer just quoted remarks, to the art of physic, no longer to call the disease its opprobrium, until the patients lay aside their prejudices and fears, and have a disposition to be cured. “*Utinam,*” he adds, “*tam in promptu esset invenire, quam tutum adhibere, podagræ remedium.*” (Comment. p. 43.)

The treatment, it is obvious, must be necessarily very different according to the different forms of the disease, the different periods of life, and the state of strength of the patient, &c. We shall first speak of the practice necessary to be pursued in the regular gout; which will resolve itself into the treatment requisite during the fit, and that which is proper during the interval.

Treatment of the Regular Fit.—All active measures, during the occurrence of a regular paroxysm of gout, have been prescribed by writers in general since the days of Sydenham. This physician remarked, that the more violent the pain and inflammation, the shorter in general will be the fit, the recovery most perfect, and the interval between this and the succeeding paroxysm the longer. If this opinion were admitted as just, it would suggest the prohibition of any remedies which might moderate the inflammation. But against this doctrine another hypothesis has been advanced by Dr. Cullen, which is at least equally plausible, and better supported by analogy, if not by fact: namely, that the violence of the inflammation may weaken the tone of the parts, and while it renders them less liable to similar violent attacks, and the consequent more perfect recovery, may, by that very debility, invite a return of the disease. On the whole, the indications of practice generally pursued at present, are to moderate the violence of the inflammation and febrile action, when it is severe, without applying any active remedies to the foot itself. After enumerating the various external applications, such as poultices, fomentations, blisters, sinapisms, camphor, and stimulating substances, which have been occasionally recommended, Dr. Cullen concludes, that from any of them there is danger of rendering the gout retrocedent; “and that therefore the common practice of committing the person to patience and flannel alone, is established upon the best foundation.” As there is no danger from the fit of gout, when regular, in a constitution not much broken, this method may be pursued with a certain degree of impunity: but it cannot be questioned, that the loads of *flannels*, which are sometimes used, often augment the necessity for a supply of *patience*, by increasing the inflammation and pain in the foot. It is true, that the parts thus swelled and painful, are more acutely sensible to cold, as well as to other impressions, than in health; but no covering beyond what is sufficient to prevent a troublesome sensation of cold, if that should occur, can be necessary. (Heberden.) All poultices, fomentations, and warm bathing during the inflammatory stage are pernicious.

It is more than probable, that considerable errors have been committed, upon the hypothetical notion of keeping the gout in the extremities, at least in the younger subjects of gout, by deviations from the antiphlogistic regimen. In

such subjects vinous and fermented liquors should be altogether abstained from during the fit; and the diet should consist of light aqueous and vegetable matters, or thin animal broths: the bowels should be kept open by laxative medicines, and the skin moist by diaphoretics of the neutral salts. This is at least a palliative system, and the prejudices of men in general are averse to any more active interference with the disease. But in case the inflammation is extremely violent, in young and hale men, Sydenham, Cullen, Huxham, and other able authorities, concur in recommending the employment of blood-letting from the arm. This, however, they do not recommend to be often repeated, on account of the debility which may ensue; and as the part affected is not an organ important to life, and the inflammation so purely local, there does not appear to be any good reason for recurring to this remedy, except in cases of extraordinary violence, in very plethoric habits, in which the symptomatic fever itself might prove hurtful. Local blood-letting, by means of leeches applied to the foot itself, promises more advantage, and experience itself has proved the efficacy and safety of the practice. (See Cullen, First Lines, par. 563—Mufgrave de Arthrit. regulari, cap. 8. § 4.) Cupping and scarifying the neighbouring parts have also been found beneficial.—(Mufgrave.)

We are persuaded that hypothesis has had much more influence than observation and experience, in exciting the general fears about interfering with the progress of the gouty inflammation, and of the danger of its being driven to some internal part by such interference. When it was believed, that a quantity of morbid matter existed in the inflamed part, it was inferred, of course, that it could only be removed by expulsion or by repulsion, in which last case it must fall upon some other organ. We know very well, that the same hypothesis, and the same fears prevailed no long time ago with respect to cooling the skin in fevers, and especially in eruptive fevers, such as scarlet fever and small-pox. “The perspiration will be checked,” said the theorist, “if you allow the skin to be cooled, and the *peculiar matter* must therefore be thrown back upon the bowels, or the lungs, or the brain, and the effect may be fatal.” But ample, and unvarying experience has now demonstrated, not only that such danger was altogether imaginary, but that washing the skin with cold water, even under the full eruption of scarlatina, and in the eruptive fever of small-pox, affords the most grateful relief to the patient, and is the most effectual moderator of his disease. (See COLD, effects of as a remedy.) Nor is a considerable experience of the safety and efficacy of a similar practice, in subduing the inflammation of gout, wanting. The great Dr. Harvey himself, whose name is immortalized by the discovery of the circulation of the blood, was in the habit of immersing his foot in cold water, as soon as he perceived the approach of the gout, and thus removed the disorder: he lived to the age of eighty. Van Swieten mentions an officer of infantry, who was induced to rub his gouty feet with snow, and afterwards, emboldened by success, walked a little way barefoot upon the snow, and returned quite free from pain: the interval before another fit was also lengthened by this practice. Similar observations were likewise made by the ancients. Aëtius informs us, that he had seen a person labouring under what he calls a bilious gout, “who obtained extraordinary relief from immersing and keeping his feet some time in cold water.” And it is an aphorism of Hippocrates, that “cold water, copiously poured upon swellings of the joints, painful ulcers, *gouty disorders*, and convulsed limbs, lessens and removes the pain.” (Aph. 25. sec. 5.—See also Heberden Comment. p. 45.—Van Swieten, Com. ad Aph. 1273.) But the most extensive evidence

of the efficacy of this practice, in curing the paroxysm of gout, has been adduced by Dr. Kinglake, (see a Dissertation on Gout, &c. Lond. 1804,) who brought forward about thirty cases, in which the application of cold water to the inflamed part, during the gouty paroxysm, was invariably and speedily successful in relieving the pain and removing the disease, without any untoward circumstance ensuing. Dr. Kinglake maintains, that the inflammation of gout is to be treated upon the same principles as other local inflammations, and yields to the same treatment. That this proposition is correct, while the constitution remains unbroken, we fully believe; but to what extent the principle will hold, in those whose system is greatly debilitated and decayed, as well by age as by frequent and protracted disease, remains as yet undetermined by experience. With the diminished strength of the patient, the paroxysms become diminished in violence, and active remedies are, therefore, the less required; but from what we have detailed above, it appears at least highly probable that, in the first attacks of gout, the application of cold, judiciously employed, so as to remove the morbid heat and no longer, would always be safe, and would contribute as well to shorten the paroxysm, as to diminish the suffering of the patient, and to preserve the joints from the injury, which protracted inflammation and morbid effusions necessarily occasion.

The operation of *purgatives*, which is known to be essentially useful in other inflammations, has been considered as beneficial in the gout by some physicians, but has more commonly been altogether forbidden. Sydenham expresses himself very strongly in prohibition of purging, at any period of the fit, or even in the interval of health. Had he expressed his conviction upon this point simply as the result of experience, we should have been disposed to bow to his authority; but his theory appears to have had at least an equal share in producing this conviction; and unfortunately this theory involves the most gross contradiction. In the beginning of the paroxysm, we are told that there is great danger lest purgatives should stop the inflammation of the foot, "by throwing back into the mass of blood that *peccant matter*, which nature was protruding to the extreme parts." (Tractat. de Podagra.) But after the termination of the fit, there is extreme danger, "lest a new paroxysm in the foot, equally severe with the former, should be produced by a purgative." (Ibid.) So that this theory blows hot and cold, like the fable in the fable; and these dangerous purgatives draw the *peccant matter* out of the foot, when it happens to be in, and are the most effectual means of throwing it into the foot after it has been driven out not only from the foot, but from the whole body (according to the hypothesis) by nature!

Sydenham, however, lived long enough to retract, in part, his opinion respecting the injurious influence of purgatives in the gout, especially if the milder ones are used, and an anodyne given after the operation. (Dissert. de Mictu Sanguineo, &c. 1686.) Van Swieten observes, "many physicians are of opinion, that part of the gouty matter may be carried off by purgatives, and the fit rendered much more mild, especially if it be occasioned from errors in diet;" and he quotes Hoffmann, who recommends gentle purgatives in all cases of local pain, and has mentioned an instance in his own person of the most striking benefit derived from a purgative taken immediately before the fit of gout. An instance has been related to us, in which the gout was completely banished, during a space of nearly twenty years, by the use of a brisk purgative, taken when the first symptoms of the fit began to appear; the medicine employed in this instance consisted principally of scammony,

in the dose of about fifteen grains. We have seen this medicine used in a few cases, with some relief, in smaller doses, and without any untoward consequences. That purgatives, as well as cold applications, may be resorted to with advantage in the beginning of the paroxysm of gout wherever the constitution is unimpaired, we consider as tolerably well established on the grounds of observation; although we do not doubt that many of the cases of repelled gout, which have been attributed to such causes, may have really occurred, under circumstances of broken and feeble constitution, or of peculiar idiosyncrasy. But the accidents arising from a careless or injudicious abuse of any practice, afford no just argument against the rational and cautious use of it.

We apprehend, however, that many disorders have been very erroneously attributed to repulsion of the gout, which might be more correctly explained upon other grounds. For every inflammatory disease that occurred, even at the distance of several months from the cessation of the fit, has been considered as the result of the premature cure of the gout: whereas, it is next to impossible that so long an interval could have taken place between the cause and its effect; and, on the other hand, as gout is most frequent in plethoric habits, which are also most liable to inflammatory diseases, the occurrence of pleurisy or apoplexy, in such cases, is doubtless to be attributed to the plethora, and not to the previous gout. Dr. Cullen mentioned that he had known about twenty persons die suddenly, more than half of whom were of gouty habits.

The violence of the pain, in the paroxysm of gout, would naturally suggest the use of opiates: but experience has shewn that opium, in any form, when administered in the beginning of any inflammatory disease, with which much heat of skin and great febrile excitement are connected, generally fails to give relief; on the contrary, that it tends to increase the heat, fever, and restlessness, and, with them, the pain likewise. When, however, the violence of the paroxysm is somewhat abated, yet continues to return, so as to occasion painful and restless nights, opiates may then be given with safety and with advantage, especially in the case of persons advanced in life, and who have been often affected with the disease. The hypothetical objection to the use of opiates, that they tend "to lock up the morbid matter," is altogether groundless. Dr. Warner speaks with delight of the soothing influence of opium in the fits of gout, which he suffered in the latter periods of his life. (P. 133—136.)

Hitherto we have seen that the practice, generally pursued in the paroxysm of gout, is merely palliative; an actual cure being deemed a desideratum by most persons, and a thing improper to be attempted by others. Of late, however, a medicine has been introduced into this country from France, which is said to possess a specific power over the gouty paroxysm, which it removes "*cito, tuto, et jucundé.*" The composition of this medicine is at present unknown, but it has been ascertained that it is a vegetable matter, and it is said by the inventor to be a plant heretofore not used in medicine. It is called *eau medicinale d'Huffon*. It has appeared, in many instances in which it has been employed in this country, and that in persons of the first rank and character, to possess the power of removing the paroxysm of gout in the course of twenty-four hours, leaving the patient in a state of good health, and in possession of the same use of his limbs which he enjoyed before the fit. It is said that, in general, it increases the various excretions considerably, if taken in the full dose, producing several loose motions from the bowels, a free perspiration, and an increased discharge

charge of urine. But the influence of the medicine on the gouty paroxysm is not attributed to these evacuations; since, in some instances, in which a smaller dose was taken, a similar relief to the gout was procured, without any increase of the excretions. No untoward circumstance whatever has yet occurred, in consequence of the speedy removal of the paroxysm: but farther experience will be requisite to enable us to form a satisfactory estimate of its properties. (See an Account of the Eau Medicinale d'Huffon, by Edwin G. Jones. M. D. Lond. 1810)

Treatment in the Interval.—Whatever method is adopted in the treatment of the fit of gout, whether it be merely palliative, or so active as to shorten the attack, the constitution retains its predisposition, and is equally liable to suffer a return of the disease. It is not yet ascertained, we believe, whether the fits, when warded off by the *eau medicinale*, do not recur more frequently. It is the treatment of the patient in the interval of health, by which alone the disease can be cured, *i. e.* the paroxysms prevented from returning, and the gouty diathesis eradicated. How this is to be effected, we cannot learn from a view of the proximate cause, or essential nature of the disease; for upon this point we have no actual knowledge: but, as we possess some knowledge of the exciting causes of the disease, or of the circumstances which generate or foster the predisposition to its attacks; so, by removing these, we may hope to prevent the production of that predisposition, or to diminish it, if not to remove it altogether. Now, we have seen that intemperance and indolence are the parents of the gouty diathesis, where it is not hereditary, and are the chief agents in exciting it to activity, where it is. The inference, then, is obvious: by *temperance and activity*, and not by medicine, the return of the gouty paroxysms is principally to be prevented.

There is, perhaps, no subject, on which Englishmen in general entertain so many unfounded prejudices, or listen to argument with so little attention or conviction, as that of *temperance*. It is conceived that physicians, in inculcating the advantages of it, only talk idly about it, in the way of their profession; and that what is called good living, when not carried to actual debauch, is favourable to the support and health of the body. It is, indeed, so universally the practice, in this country, to indulge an artificial appetite, beyond the actual wants of nature, that temperance is a thing, as Dr. Cadogan observes, of which an Englishman can acquire no idea at home. It is, however, altogether comparative with respect to individual constitution; for some persons will become plethoric to a morbid degree, upon diet which is barely sufficient to support life in others. Perhaps Dr. Cadogan's test is correct. "As long as a man eats and drinks no more than his stomach calls for," (*i. e.* when unexcited by variety of dishes, by sauces and condiments, or by interposing liquor of any kind) "and will bear without the least pain, distention, eructation, or uneasiness of any kind, &c. he may be said to live in a very prudent well-regulated state of temperance, that will probably preserve him in health and spirits to great old age." (On the Gout, p. 31)

We know too well, however, the general want of power or inclination to resist the pleasures of the table, with that degree of perseverance and to the requisite extent, to expect that many cures of the gout will be effected in this way; but this we may assert, that the only instances of the eradication of the disease, which are known, have been accomplished by rigid and persevering temperance. Dr. James Gregory, the present professor of medicine in the uni-

versity of Edinburgh, is a remarkable example of the perfect cure of the gout by such means. Born of gouty parents, he was attacked severely when young, and suffered several paroxysms, which, after being banished by abstemious living, recurred on a short indulgence on revisiting Oxford; but he has since that time entirely kept the foe at a distance for about thirty years, by extreme temperance and much exercise, and is now hale and strong, though advanced several years beyond the age at which his father died, broken down by the gout. This he repeats annually to his pupils with no small exultation. His diet has been chiefly broth, or a sparing quantity of plain animal food, with little or no wine. Dr. Cadogan affords another instance of the benefit of rigid temperance in his own person, "having not only got rid of the gout," he says, "of which I had four severe fits in my younger days, but also emerged from the lowest ebb of life, that a man could possibly be reduced to by colic, jaundice, and a complication of complaints, and recovered to perfect health, which I have now uninterruptedly enjoyed above 70 years." (Loc. cit. p. 83.) Dr. Heberden likewise observes, that although complete cures of the gout are extremely rare, yet he has seen more than one instance in which, by a total abstinence from animal food and wine, the patients were restored from a state of extreme debility and misery, to such a degree of health and strength, as rendered their life no longer useless to others, nor painful to themselves. *Comm. p. 44.*

It can scarcely be doubted, indeed, that a complete cure of the disease might, by a rigid plan of life, be accomplished in most cases, when the patients are not above the age of 30 or 35 years, even if they should already have experienced two or three paroxysms. In older habits, where the disease is of longer standing, a complete cure cannot be so confidently anticipated; but experience has shewn that the severity and the consequent evils of the disease may be effectually mitigated by temperance, even under such circumstances. It is a most dangerous and mistaken notion that the gout is to be encouraged; for its tendency is to increase in frequency, and in duration, to cripple the limbs, and to render the body liable to a variety of disorders, which tend to render life both shorter and more miserable than it would otherwise be.

The fear of the pernicious consequences of rigid temperance is an unfounded prejudice, very prevalent in this country; but if there be any danger, it can only originate in general from the suddenness with which an extreme change is made. We have seen, in the case of the *mill* of Bilericay, however, what a small quantity of nutriment is absolutely requisite for the wants of the constitution, and how beneficial even an extreme change of diet sometimes proves. (See *COMPULSION*.)

The next point of management in the interval, which, together with temperance, conduces to the prevention of the recurrence of gout, is *exercise*. This tends to obviate plethora, on the one hand, by promoting the circulation and all the secretions, and to strengthen the stomach, on the other hand, and promote the function of digestion; and plethora and indigestion, as we have already stated, commonly precede the gouty paroxysm, and are connected with the gouty diathesis. By those who cannot walk, which is the best mode of exercise for the gouty, riding on horseback, or even in a carriage, should be substituted. Even friction, where these modes of exercise cannot be resorted to, may be an useful succedaneum. Dr. Cadogan's directions on this head are worthy of attention. If the patient "can neither walk nor ride at all, he must by degrees be brought to do

both by the assistance of others, which may be given him in the following manner: let a handy active servant or two be employed to rub him all over, as he lies in bed, with flannels, or flannel gloves, fumigated with gums and spices, which will contribute greatly to brace and strengthen his nerves and fibres, and move his blood without any fatigue to himself. This may take up from five to ten minutes at first, but must be repeated five or six times a day, supposing him totally unable to help himself. But if he can walk a hundred yards only, it will forward him greatly to walk those hundred yards every two hours; and if he can bear a carriage, let him go out in it every day, till he begins to be tired. The first day or two all this may disturb and fatigue him a little; but if he has patience to persevere to the fourth, I dare promise him some amendment and increase of strength; which he must employ, as young merchants do a little money, to get a little more. Thus he must go on rubbing, walking, and riding a little more and more every day, stopping always on the first sensation of weariness to rest a little, till he be able to walk two or three miles at a stretch, or ride ten without any weariness at all." He must ever remember, however, that the habit of body is only to be corrected by habitual measures; and perseverance, therefore, must be his motto in regard to exercise, not less than with respect to temperance. But it must be observed, in general, that the exercise should not be violent; for if violent, it cannot be long continued, and must always endanger the production of atony and debility in proportion to the degree of violence. "It must be moderate," to use the words of Dr. Cullen, "but at the same time constant, and continued through life."

It has been supposed by some persons, that an abstemious and active mode of life for a limited time, as for instance, an abstinence from animal food and fermented liquors, and a diet of milk and farinaceous matters alone, for the space of one year, might be sufficient for a radical cure of the gout. Such an opinion was expressed by Celsus, who says that "some, by cleansing themselves thoroughly by drinking asses' milk, have for ever banished the disease; and others, by abstaining, during a whole year, from wine, mulse, and venery, have obtained a security from it for the remainder of their lives." (De Medicina, lib. iv. cap. 22.) In a few cases, this plan may possibly have succeeded; but it is well known that many persons, who, by entering on an abstemious course, had been delivered from the gout, have, on returning to their former mode of living, had the disease return with at least equal violence.

While an abstemious regimen, combined with exercise, will tend to correct the gouty habit, if steadily pursued; it will be at the same time advisable to avoid as much as possible some of those circumstances, which we have mentioned above as among the frequent exciting causes of the disease; more especially when the gouty habit has become established by a repetition of the fits, or is hereditary in its origin. In such cases, the measures, which we have proposed, are not easily pursued to the requisite extent, and are commonly attempted even with reluctance: men, therefore, have been very desirous to find a medicine which might answer the purpose, without requiring a restraint on their manner of living. Of this desire numerous empirics and self-interested pretenders have taken advantage, and have been induced either to amuse the gouty with inert medicines, or have rashly employed those of the most pernicious tendency. It is unnecessary for us to inquire into the nature of those alleged *specific* nostrums, which, after being for some time in vogue, were neglected or exploded, as their inutility or injurious qualities were thus acknowledged. But after premising that

we are much disposed, with Dr. Cullen and others, to believe the impossibility of curing the gouty habit by medicines, we shall notice one or two known medicines, which have been in vogue no long time ago. If the gouty constitution is created by a series of high-feeding and indolence, how is it to be expected that medicine can change that constitution, especially while the cause continues to operate?

The *Portland powder* is a medicine which obtained considerable reputation, as a cure for the gout, about the middle of the last century. This powder derived its name from the duke of Portland, who received so much relief from it, that he ordered the formula to be printed, and delivered to all who should ask for it. It was brought from Switzerland by a friend of the duke's. The powder consists of the roots of aristolochia rotunda and gentian, and of the tops and leaves of germander, ground-pine, and centaury, well dried and powdered, equal weights. This powder was ordered to be taken for a year or two, at first in the dose of a drachm daily, but afterwards in smaller quantities. (See Medical Obs. and Inquir. vol. i. art. 14.) In the work just referred to, Dr. Clephane has shewn that a similar composition was used by the ancients for the cure of gout. Such a formula is given by Galen, in his treatise De Antidotis, lib. ii. cap. 17., which he says he had used himself. Cælius Aurelianus speaks of similar medicines, under the denomination of *annalia medicamina*, from their being taken for the space of a year. Aëtius gives, among other gout medicines, an "antidotus podagrica ex duobus centaureæ generibus," which differs from the Portland powder in one ingredient only. But several of the ancients considered the long uninterrupted use of these medicines as dangerous; and assure us that they are extremely hurtful in the hot and bilious, and are only proper in cold and phlegmatic constitutions. The Portland powder has fallen into neglect, under a notion that it was ultimately prejudicial. "In every instance," says Dr. Cullen, "which I have known of its exhibition for the length of time prescribed, the persons who had taken it were indeed afterwards free from any inflammatory affection of the joints: but they were affected with many symptoms of the atonic gout; and all, soon after finishing their course of medicine, have been attacked with apoplexy, asthma, or dropsy, which proved fatal." (First Lines, par. 557.) Dr. Heberden, however, is of opinion, that the popular prejudices against this medicine at present are as far beyond the truth, as they formerly were in its favour. (Comment. p. 48.) He attributed to it considerable powers of alleviating the disease, by strengthening the stomach and supporting the function of digestion; and believes that many of the evils (which, because they followed its exhibition, were imputed to its operation,) were in reality the consequences of the disease, and not of the remedy. That those cases, however, of apoplexy, &c., which, it is admitted, occur in gouty habits, would be probably accelerated, if not occasioned, by the use of a stomachic powder, while the full diet was continued, appears to be extremely probable: for the plethora must have been increased in proportion to the artificial increase of the digestive powers. We should, therefore, be disposed to conclude, that the constant use of such a medicine must be pernicious, unless it were combined with temperance in eating and drinking; and that, with such a regimen, it would in all probability be highly beneficial, if taken whenever the symptoms of indigestion should appear.

Another class of remedies has been employed in the interval between the paroxysms of gout, and in many instances with considerable alleviation to the disease, rendering the

the fits milder, and the intervals between them longer: we allude to the *antacids*; such as the alkalis, and absorbent earths. The nature of the chalky matter, produced in inveterate gout, which is an acid, and denominated lithic or uric acid, (being the same which is found in the urine and urinary concretions,) has led to the theory, that this acid, or its elements, is the morbid humour of the gouty; and therefore naturally suggested the idea of using alkaline medicines as remedies for the disease. And as æcescent drinks are found to increase the gouty diathesis, and to increase the disordered state of the digestive organs; so alkaline medicines have been found to relieve the symptoms of indigestion, and at the same time to lessen the disposition to gout. Thus the caustic alkalis have been found beneficial; but not more so, we believe, than the mild or carbonated alkalis, especially potash; and the absorbent or alkaline earths have likewise afforded relief, and sometimes speedily removed some of the urgent symptoms of disordered stomach; especially the preparations of chalk, lime-water, and magnesia. The magnesia is perhaps one of the best medicines of this sort for the gouty, as it not only corrects the acidity of the stomach, but at the same time is laxative to the bowels, and thus contributes to obviate plethora. When these antacids do not sufficiently open the bowels, or do not prevent coliciveness, a little rhubarb, aloes, or some other aromatic purgative should be conjoined with them. It appears, from some experiments made by Mr. Home and Mr. Brande, and recently published in the *Philosophical Transactions*, (Part I. for 1810) that magnesia has a much more powerful influence in preventing the formation of the uric acid, in the urine, than any of the alkalis; it is probable, therefore, that it may be more beneficial in the gout. As a warm laxative the tincture of guaiacum was much recommended, and as it combines a stimulant with an evacuant property, it may be serviceable in some constitutions.

Cure of the irregular Gout.—We have already remarked, that false theory has led to much false alarm, and doubtless to many mistakes in practice, especially relative to the atonic gout; all the various symptoms of dyspepsia, and hypochondriasis being often supposed to be gouty, when no actual gout had ever appeared. Hence fomentations, blisters, rubefacients, and other local stimulants to the extremities, the Bath waters, hot pediluvia, &c. have been employed to bring on the gout in the feet, instead of relying on the remedies which might restore the functions of the digestive organs. The Bath waters are certainly to be recommended in those cases, as they are possessed of considerable powers in restoring the healthful condition of the stomach, especially when it has been disordered by irregular and intemperate living; and of relieving those wandering pains, which are deemed gouty, but which, as Dr. Heberden observes, are the common accompaniments of declining years and a broken constitution.

In these cases of atonic or wandering gout, as it is called, all the means usually employed to strengthen the habit in general, and the stomach in particular, are to be resorted to. Moderate, but frequent and regular exercise on horseback, or walking, must be pursued; the diet should be a little more generous, and some wine may be necessary; but both food and drink of the æcescent kind must be shunned, and if wine, of whatever sort, should be found to increase the acidity of the stomach, spirits much diluted with water should be substituted. At the same time, for the purpose of supporting the tone of the stomach, preparations of iron, the Peruvian bark, bitters, and aromatics in moderation may be resorted to; and laxatives, employed only so as to prevent costiveness, must be taken. The propriety of frequent gentle

vomits, where the indigestion is troublesome, is more than problematical; for, while they give a temporary relief, by removing a load of undigested food, they tend to debilitate the organ, and thus to increase the evil which they were intended to remove. At the same time, all the causes of debility formerly mentioned, must be shunned, and exposure to cold especially must be carefully avoided: the most certain means of doing this is by repairing to a warm climate during the winter season.

Cure of misplaced or retrocedent Gout.—These, like the atonic gout, are in a considerable degree the bugbears of medical speculation, more especially the misplaced gout; they do, we believe, occasionally occur in cases of old and inveterate gout, but certainly much more rarely than is generally believed. This opinion Dr. Heberden states from his own experience (Comment. p. 41.—See also "Letters on the Cause and Treatment of Gout," by Dr. Robert Hamilton, Lynn, 1809.) The last mentioned physician, who had employed bleeding and other antiphlogistic remedies, both upon himself and several of his friends for eighteen years, never saw any thing like a retrocession of gout; and Dr. Cuilen never saw an instance of misplaced gout.

When the gout has disappeared in the extremities, the stomach and bowels are sometimes attacked with most acute pain, which is of a spasmodic nature, and to be relieved only by strong diffusive stimulants, and opium in full doses. Opiates are doubtless the most effectual antispasmodics; but their operation will be aided by combining with them the ethers, volatile alkali, the free use of strong wines, and aromatics, given warm, or ardent spirits, if these are not effectual. Camphor, musk, asafoetida, and other strong smelling substances, may be employed as adjuvants, especially in less violent cases. External heat to the region of the stomach, hot pediluvia, or the warm bath, will contribute by their stimulant powers to overcome the spasm and pain. If the stomach is known to be loaded, as by a previous repast, its contents may be evacuated upwards, by draughts of warm water, with wine, or of chamomile tea, or downwards by means of some of the cathartic tinctures, as of nutta, or rhubarb.

As those persons, who are subject to paroxysms of the gout, are generally plethoric in their habits, so they are liable to inflammatory diseases: and it cannot be doubted, that ordinary attacks of inflammation of the lungs, of palsy, and apoplexy, have been deemed gouty, and have proved fatal from the omission of blood-letting. When the symptoms of pleurisy, or peripneumony, or the acute pain of head, vertigo, somnolency, threatening apoplexy, or the actual symptoms of apoplexy and palsy occur; we ought not to delay the exhibition of the usual remedies for those diseases, or be induced to be sparing in the use of the lancet, because we apprehend a gouty diathesis; for death may be produced in a few minutes. And, as Dr. Heberden justly observes, "where the danger is imminent, from the violence of the symptoms, and we are doubtful whether they be gouty or inflammatory, we incur much greater risk by omitting blood-letting in a disease arising from inflammation, than by drawing blood in a disease arising from gout." Indeed these very physicians, who condemn bleeding and other evacuations in gout, in the extremities, gravely prescribe the prompt administration of these remedies, when the lungs, head, or other viscera are attacked with it. In a word, when the internal viscera are affected with unequivocal symptoms of inflammation, the same treatment by local and general evacuation, blistering, &c. must be resorted to, as in all other cases of inflammation, regard being had at the same time (an observation, indeed, which applies to the practice of medicine

universally) to the peculiar circumstances of the patient's age, strength, and constitution.

GOUT-wort, in *Botany*. See *ANGELICA*.

GOUTIER, **GÔTRE**, or *Gôitre*, terms in *Surgery*, applied to a chronic enlargement of the thyroid gland. See *BRONCHOCLE* and *GOITRE*.

GOUTY-LAND, in *Agriculture*, a term used by the farmers to denote a hollow fuzzy black earth, with little springs, that have no free outlet, and therefore swell and elevate the surface in many places.

GOUEVA, in *Geography*, a town of Portugal, in Estremadura; 20 miles S.E. of Viseu.

GOUX DE LA BOULAYE, **FRANÇOIS LE**, in *Biography*, a celebrated traveller, was born in the province of Anjou about the year 1610. Little is known of his early life, but that he felt a strong propensity for rambling into foreign countries: he employed ten years successively in traversing various parts of the globe. He seems to have been willing to become all things to all men, in order to obtain his wishes in safety. In Africa and many parts of Asia he passed for a Mahometan, and in Europe he was a good Catholic. On his return, he published an account of his travels, under the title of "Les Voyages des Observations de François de la Boulaye le Goux, en divers Pays, d'Europe, d'Asie, et d'Afrique, jusqu'à l'Année 1650." This work was published in 4to. and illustrated and adorned with engravings. The style is incorrect, but the facts, as far as they are borne out with truth, are said to be very curious. He was so much altered in his person during his absence from France, that his mother even, either could not, or would not recognize him, and he was obliged to institute a law-suit to establish his rights as heir in the family. In 1668 he was appointed ambassador to the Porte and the great mogul, by Lewis XIV. who was very desirous of renewing his commerce with the East. Le Boulaye died in Persia of a fever before he had executed this mission. Moreri.

GOUYE, **THOMAS**, was born at Dieppe in the year 1650. He was brought up among the Jesuits, and was at an early period distinguished by an ardent love for mathematical and scientific pursuits. In 1699 he was elected a member of the Royal Academy of Sciences at Paris, of which body he became an assiduous attendant, and was highly esteemed for the useful contributions which he made to their memoirs. He died at Paris in 1725, leaving behind him, as memorials of his learning and industry, "Physical and Mathematical Observations tending to the Improvement of Astronomy and Geography, sent from Siam to the Academy of Sciences at Paris, by the Jesuit Missionaries, with Reflections and Notes, in two volumes." The first volume was published in 1688, the second in 1692, and both have been inserted in the seventh volume of the collections of the Academy. Moreri.

GOW, in *Geography*, a town of Hindoostan, in Bahar; 40 miles S.S.W. of Bahar. N. lat. 25. E. long. 84. 48'.

GOWER, **JOHN**, in *Biography*, an ancient English poet of the fourteenth century, is said to have been descended from a family at Stitenham in Yorkshire. He had the best education which the times afforded, and at a proper age became a member of the society of the Inner Temple, where he attained to a high degree of respectability in the profession of the law, and where he became acquainted with Chaucer. Some writers affirm that, in the course of his professional duties he was appointed chief justice of the court of Common Pleas, though others think the judge was another person of the same name who was a contemporary with the poet. Gower attached himself to the duke of Gloucester, uncle to

Richard II., and was much noticed by the king himself, at whose desire he wrote his principal work. He had, however, a pliable mind, and could turn his pen to different interests; for on the accession of Henry IV. he not only wrote in adulatory terms to the new king, but even reflected on the mis-government of the one who had been deposed, and who had been his patron. His circumstances were such as to put him beyond the fear of want, for he appears to have been a liberal contributor to the rebuilding of the church of St. Mary Overy in Southwark. During the first year of Henry's reign, our poet had the misfortune to be deprived of his sight, an affliction which he did not long survive. He died in the year 1402, at a very advanced age. Gower, says his biographer, is entitled to a place among English writers only relatively to the time in which he flourished; for though well furnished with learning, and a successful cultivator of his native language, he has not the least pretensions to genius or invention. He is characterized by his friend Chaucer, as the "moral Gower;" he was uniformly grave, even upon topics that might inspire vivacity. He was author of three volumes, entitled "Speculum Meditantis;" "Vox Clamantis;" and "Confessio Amantis." Of these, the first is a moral tract, and relates to conjugal duties; the second is a metrical chronicle concerning the insurrection of the people under Richard II., in Latin elegiac verse: the third, or "Lover's Confessions," relates to the morals and metaphysics of love. This is the only one that has been printed, and it was among the earliest products of the English press, by Caxton in 1483. It seems, says Mr. Warton, to have been his object to crowd all his erudition into this elaborate performance. The most interesting part of the work is a variety of stories adduced as moral examples, and taken from authors most in vogue, ancient and modern. The language is perspicuous, and the versification frequently harmonious. Biog. Brit. Warton.

GOWER, in *Geography*, a district of Wales, in the south-western extremity of Glamorganshire, below the town of Swansea, and bounded by the Irish sea and the Bristol channel.

GOWER, *Cape*, a cape on the E. coast of China, lying in the track from the southward to the gulf of Peking. A reef of rocks runs out from a neck of land near this cape, which appeared to have a compact harbour. The entrance to it was between the cape and the reef just mentioned. When the persons concerned in the embassy to China passed this cape, a considerable number of vessels were decried in the harbour, and a pretty large town behind it. N. lat. 36° 57'. E. long. 122° 15'.

GOWER'S Island, a small, flat, low island, in the Pacific ocean, so called by captain Carteret, who passed it in August 1767; he found no anchorage, and could only obtain a few cocoa-nuts in exchange for nails; the inhabitants resembled those of Egmont isle. S. lat. 7° 56'. E. long. 158° 56'.

GOWER'S Harbour, a bay on the S. W. coast of New Ireland; 5 miles N. of cape St. George. M. Bougainville calls this "Praslin Bay," and by Dampier it is called "St. George's bay." S. lat. 4° 50'. E. long. 150° 48'.

GOWGAT, a town of Hindoostan; 12 miles W. of Agra.

GOWGATCHY, a town of Bengal; 12 miles N. of Calcutta.

GOWN, **ROBE**, a long upper garment, worn by lawyers, divines, and other graduates, who are hence called *gentlemen of the gown*, or *gown-men*.

The gown is an ample sort of garment, worn over the ordinary

ordinary clothes, hanging down to the feet. It is fashioned differently for ecclesiastics, and for laymen.

At Rome, they give the name virile gown, *togas viriles*, to a plain kind of gown, which their youth assumed when arrived at puberty. This they particularly denominated *prætexta*.

In some universities, physicians wear the scarlet gown. In the Sorbonne, the doctors are always in gowns and caps. Beadles, &c. wear gowns of two colours.

Among the French officers, &c. they distinguish those of the short gown, or robe; which are such as have not been regularly examined. They have also barbers of the short gown, who are such as are obliged to practise in an inferior way to surgeons, or those of the long robe.

Gown is also taken, in the general, for the civil magistrature, or the profession opposite to that of arms.

In this sense it was that Cicero said, "Cedant arma togæ."

GOWRAH, in *Geography*, a town of Bengal; 27 miles S. S. E. of Doesa.—Also, a town of Hindoostan; 5 miles N. E. of Benares.

GOWRAN, a poet town of Ireland, in the county of Kilkenny. It is a place at present of no importance, but was a borough before the Union, and there are some ruins which seem to intimate its former importance. It is 52 miles S. from Dublin.

GOWREY, a town of Hindoostan, in Oude; 53 miles W. of Kairabad.

GOWRY-BIRD, in *Ornithology*, a name given by Edwards to the *Loxia punctuloria*.

GOWRYPOUR, in *Geography*, a town of Bengal; 26 miles S. E. of Dacca.

GOWT, in *Engineering*, or go-out, is a name applied to the sea sluice, or valves used in embankments next the sea or tidal rivers, for letting out the land-waters when the tide is out, and preventing the ingress of salt-water. Some of the gowts in the fens of Lincolnshire and Cambridgeshire are very large works, and cost immense sums of money.

GÓY, in *Geography*. See ANGOL.

GOYANES, a town of Spain, in Galicia, on the sea-coast; 25 miles S. W. of Santiago. N. lat. 42° 32'. W. long. 8° 50'.

GOYAS, GOJAS, or Goyaz, a town and government of Brazil, extending from 42 to 54° W. long. and from 6° 30' to 19° S. lat. the inhabitants of which are estimated at 8930 whites, 29,630 Indians, and 34,100 negroes, who are employed in searching for gold in the mines, which were discovered in the year 1726.

GOYAVA, a town on the W. coast of the island of Grenada. N. lat. 12° 13'. W. long. 61° 31'.

GOYAVES, a town of the island of Guadaloupe, giving name to a bay in which it is situated.

GOYEN, JOHN VAN, in *Biography*, a painter, born at Leyden in 1596, who studied successfully the practice of landscape-painting under several masters, and having an uncommon readiness and skillfulness of hand, he produced a great many works of a light agreeable kind; with much character of nature, but no great relish of art; which, in their time, however, were very highly esteemed and widely spread over Europe.

Views of the scenes on the banks of the canals and rivers of the Low Countries were his favourite studies; sometimes he emerged to the sea shore, or sunk into the interior of the country, and sketched the villages that presented themselves to his taste in the one, or the harbours, &c. of the other; but all are touched by the same kind of pencilling, and

generally in the same hue of colour, when he came to work them up into pictures. Certainly, they have much merit of a peculiar kind, such as lightness in the handling, and freedom in their effect; but frequently they are rapid and flimsy, and by no means justify the high value and reputation affixed to them. It is said that the grey tone, too frequently found in his pictures, arose from the use he made of Haerlem blue, which is apt to fade into that tint, and therefore no longer in use. It may be so; but that grey is not the predominant defect in his pictures: it is the evident haste with which they are wrought, and their consequent imperfection of imitation, that induces us thus to condemn what the world have too long estimated in a high ratio, which ought only be given to works completed with the skill and purity of taste of a Caracci or a Claude. He died in 1656, aged 60.

GOZ, or GOZEN, in *Geography*, a sea-port town of Morocco, on the coast of the Atlantic, in the vicinity of Mogodor.

GOZO, an island of the Mediterranean, situated N. W. of Malta, and at a little distance from it. This island is about 25 miles in circumference, rather fertile, and containing about 3000 inhabitants.

Gozo, or *Gasla*, a small island in the Mediterranean, about 27 miles from the S. W. coast of Cardia; anciently "Clauda," near which St. Paul sailed in his voyage to Rome. Some biblical writers suppose that the Gozo near the isle of Malta is the Claudia of the Book of Acts. It is occupied by about 30 families; who have a Greek church, and is occasionally visited by vessels for a supply of water and provisions. At a small distance to the west is a very little island called "Pulo Gozo," or Little Goz. N. lat. 34° 48'. E. long. 23° 46'. See CLALDA.

GOZZANO, a town of Italy, in the department of the Gogna; 18 miles N. of Novara.

GOZZOLI, Benozzo, in *Biography*, one of the early practitioners of the art of painting on its revival. He was a Florentine, and disciple of Fra. Angelico; but subsequently imitated with very great success the style of Masaccio, his contemporary. Vasari speaks of him with great esteem under the name of Benozzo, and relates histories of his many productions at Florence, Volterra, Rome, and Pisa; at which latter place are his most conspicuous labours, both in history and portraits, which indeed at that time were usually introduced in historical pictures. At Pisa he died in 1478, aged 78, and a monument, with a Latin epitaph, is placed near his principal work in the Campo-Santo; a monument of his powers, and the esteem in which they were held.

GRAAF, REINIER DE, an excellent physician, was born at Schoonhove, a town in Holland, where his father was an eminent architect, on the 30th of July, 1641. He studied physic at Leyden, where he made great progress, and at the age of 22, published his treatise "De Succo Pancreatico," which gained him considerable reputation. In 1665, he went to France, and received the degree of M. D. at Angers; but he returned to Holland in the following year, and settled at Delft, where his great success in practice excited the envy of his professional brethren. He married in 1672, and died in August, 1673, when he was only 32 years of age. He published three dissertations relative to the organs of generation in both sexes, upon which he had a controversy with Swammerdam. His works were published in 8vo. at Leyden, in 1677 and 1705; they were also translated into Flemish, and published at Amsterdam in 1686. Hutchinson, *Biog. Med. Eloy.*

GRAAF REYNET, in *Geography*, a district of southern Africa,

Africa, in the colony of the Cape of Good Hope, extending to the eastern extremity of the colony. On the E. it is divided from the Kaffers by the Great Fish river, the Turka, the Bambarberg, and the Zuureberg; on the W. from the districts of Zwelendam and Stellenbosch by the Camtoos river, the Gamka or Lion's river, and Nieuwveld mountains; on the N. from the Bosjesman Hottentots by Plettenberg Landmark, the great Table mountain, and the Karreeberg; and on the S. it is terminated by the sea-coast; the whole length and breadth of this district may be about 250 by 160 miles, making an area of 40,000 square miles, which is peopled by about 700 families, each family commanding about 57 square miles of territory. Great part of it has been occasionally abandoned on account of the incursions of the Kaffers and Bosjesmans. The inhabitants are a sort of Nomades, who would long ago have penetrated with their flocks and herds far beyond the present boundaries of the colony, if they had not been resisted by the Kaffers. The boors of this district are graziers; and it is entirely composed of loan-farms, which were grants made to the original settlers of certain portions of land to be held on reasonable yearly leases, on condition of paying to government an annual rent of 24 rix-dollars. Barrow's Travels in S. Africa, vol. ii.

GRAAT, or GRAET BARENT, in *Biography*, an historical painter, whose name is remembered principally upon account of his close imitation of the works of Bamberccio, and of his having founded an academy at Amsterdam, where he was born, to which the best artists of his time resorted to study after living models; by which means much improvement was obtained, and spread among those who cultivated taste and science in the arts. He died in 1709, aged 81.

GRAB, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 17 miles W. N. W. of Leitmeritz.

GRABATARI, GRABBATARI, in *Church Antiquity*, such persons as deferred the receiving of baptism till the hour of death; or who did not receive it till they were dangerously ill, and out of hopes of life: from an opinion, that baptism absolutely washed away all former sins.

The word is formed of *grabatum*, *bed*; and that from the Greek *κατακλιω*, a *hanging bed*, of *κατακλιω*, *I suspend*: such as was the bed of slaves, poor people, Cynic philosophers, &c. who are enemies of luxury and ease.

GRABAU, in *Geography*, a town of the duchy of Warfaw; 12 miles S. of Kalish.

GRABAW, a town of Austrian Poland, in the palatinate of Belz; 28 miles N. N. W. of Belz.

GRABE, JOHN ERNEST, in *Biography*, a learned divine, and editor of the Alexandrian manuscript, in the Royal Library at London, was born at Koningsberg, in Prussia, in the year 1666. Here he received his education, and in due time took his degree of M. A. applying himself with all diligence to the study of divinity, and the perusal of the fathers. He had been brought up in the Lutheran principles, but having imbibed some notions inconsistent with the commonly received faith, respecting the uninterrupted succession of bishops being essential to the existence of the true church, he was summoned before his superiors and imprisoned. Upon his release, after a few months, he chose rather to quit the church than abandon his opinion, and determined to become a member of the Catholic religion. He delivered, in a memorial to the electoral college at Sambia, in Prussia, in 1695, containing the reasons for his change, and then left Koningsberg, that he might be at liberty to carry his plan into execution, in some place where he should be beyond the reach of the

Prussian jurisdiction. While he was on the road to Erfurt, through which he meant to pass to a Catholic country, the elector of Brandenburg sent three treatises to him in answer to his memorial, by three Prussian divines, written by order of the elector. This great attention of his sovereign claimed the respect of Grabe, who not only read them with care, but felt desirous of discussing the question more closely before he formed his ultimate determination of abandoning the religion in which he had been educated. He accordingly wrote to one of the persons that had answered his memorial, intimating a strong wish to return to Berlin, that he might enjoy the benefit of a conference with him. This privilege was obtained for him; M. Grabe returned and was soon prevailed on to relinquish his purpose of joining the papal communion, but still he maintained the obnoxious tenet for which he had suffered imprisonment. Finding him immovable on this point, his friend advised him to remove to England, where, said he, "you will find the outward and uninterrupted succession which you want: take then your route thither: this step will cause less uneasiness to your friends, and, at the same time, equally satisfy your scruples." He gladly complied with the advice, and was strongly recommended to king William, who immediately granted him a pension of 100*l.* per ann. to enable him to pursue his studies. From this time he considered England as his country, because he conceived that its ecclesiastical constitution approached nearer on the whole, than that of any other, to the primitive pattern. He shewed his gratitude for the liberal patronage which he received by the publication of several learned works. Having formed a design of printing some curious and scarce pieces of the fathers, in defence of his own opinions, he obtained access to the university of Oxford, to examine the treasures of the Bodleian library, and, in 1698, he published "Spicilegium S. S. Patrum, &c." vol. 1. 8vo.; and in the following year, the second volume of the same work appeared. Shortly after this, he was ordained a deacon of the church of England, and was appointed chaplain of Christ-church, Oxford. This promotion he accepted, in order that he might be entitled to the emoluments without being required to discharge the duties of the appointment, for he had refused, on his ordination, to receive the sacrament, on account of the omission of the prayer in the communion service, mentioning the sacrifice, before the elements were distributed, which had been inserted in the first common-prayer book of king Edward VI., and he ever afterwards continued a non-conformist in this particular. In the same year in which he took orders, Mr. Grabe published "S. Justinii Philosophi et Martyris Apologia Prima pro Christianis, &c." illustrated with the notes of several learned men, and additional remarks of his own; and in 1702 he published "S. Irenaei Episcopi Lugdunensis contra omnes Haereses Libri quinque, &c." with prolegomena and notes. On the accession of queen Anne to the throne, Mr. Grabe's pension was continued, and her majesty was advised to employ him in printing the Alexandrian MS. in the royal library, of the Septuagint translation of the Old Testament. The queen took the opportunity of informing him of the appointment herself, and at the same time made him a handsome present as an encouragement to his exertions. In 1705, he published proposals for printing that work by subscription, setting forth the superior value of this copy to the Vatican MS.; he also gave three specimens, containing so many different methods for the projected edition, in the final choice of which he was to be determined by the learned world. As a testimony of their approbation of the design, the university of Oxford presented

mented him with the degree of doctor of divinity. His proposals met with a very favourable reception on the continent as well as in England, and he received a handsome present from his own sovereign, the king of Prussia, and liberal subscriptions from the principal nobility, clergy, and gentry of all parts. In 1707, he gave to the public his first volume, under the title of "Vetus Testamentum juxta Septuaginta Interpretes; tom. I continens Octateuchum." This volume contains the Pentateuch, and the three following books. In the expectation of an accession of additional MSS. he deferred the second and third volumes, and published the fourth volume in the year 1709. This contained the book of Psalms, of Job, of the three books of Solomon, &c; and in the following year he published a Latin dissertation, giving a particular account of the reasons why he had departed from the usual order of publication, and of the helps which he expected to receive in order to perfect his plan. These were, a Syriac MS. of the historical books of the Old Testament, with Origen's remarks upon them, and two MSS. one belonging to cardinal Chigi, and the other to the college of Lewis XIV. When he received these MSS. and had collated them, he prepared a volume of annotations on the whole work, and collected materials for the Prolegomena. The time which these objects took, caused a material delay in the publication of the second and third volumes, which did not, in fact, appear till after the author's death. This event took place in 1712, when he was only in the forty-fifth year of his age. He had previously to this published "An Essay upon the Arabic MSS. in the Bodleian library, and that ancient book, called the Doctrine of the Apostles, which is said to be extant in them, wherein Mr. Whiston's mistakes about both are plainly proved." The third volume of his great work was published in 1719, and the fourth in 1720. On his death-bed he was attended by Dr. Smalridge, by whose means he desired that the public might be informed that he died in the faith and communion of the church of England, though he considered its constitution to be defective in some points, in which he thought the nonjuring clergy adhered more closely to the apostolical doctrine and discipline. Of his talents there were different opinions, but of his industry and learning no one could harbour a doubt. Dr. Thirlby says, in the dedication of his edition of Justin's Apology, "he was a good man, and not unlearned, and well versed in the writings of the fathers. But he was no critic, nor could be one, since he was not furnished with genius or judgment, or, to speak the truth, with learning sufficient for the purpose." In this opinion Le Clerc coincides, and adds, that his books gained him the character of a laborious person rather than that of a great critic. He was the author of many other works besides those which have been mentioned, and was editor of an elegant edition of bishop Bull's works: he likewise assisted in preparing for the press archdeacon Gregory's edition of the New Testament in Greek; and he left behind him many MSS. some of which have been published. *Biog. Brit.*

GRABEN, in *Geography*, a town of Croatia; 12 miles S. of Varasdin.

GRABO, a town of Sweden, in East Gothland; 11 miles S.E. Linkioping.

GRABON, a town of the duchy of Mecklenburg, on the Elbe; 80 miles N.W. of Berlin. N. lat. 53° 23'. E. long. 11° 44'.

GRABUSA, an island of the Mediterranean, near the N.W. coast of the island of Candy, confirmed to the Turks

by the peace of Carlowitz, and generally garrisoned with 1000 men. N. lat. 35° 40'. E. long. 23° 33'.

GRABUT, in *Biography*, an obscure French musical composer, whose name is not to be found in the annals of the art. He was brought into England to flatter the partiality of Charles II. for the music of France; and employed by Dryden to set his political opera of "Albion and Albanus," though Purcell had already given indisputable proofs of his superior genius, and was rapidly rising into fame and national favour.

This drama, written under the auspices of king Charles II., was rehearsed several times, as the author informs us in his preface, before his majesty, "who had publicly declared, more than once, that the compositions and choruses were more just and more beautiful than any he had heard in England." We believe this prince was not very skilful in music, nor very sensible to the charms of any species of it but that of France, of the gayest kind; however, royal approbation is flattering and extensive in its influence. Unfortunately for the poet and musician, his majesty died before it was brought on the stage; and when it did appear, the success seems not to have been very considerable. Upon a perusal of this drama, it seems hardly possible, so near a revolution, that it should have escaped condemnation upon party principles; as, under obvious allegories, Dryden has lashed the city of London, democracy, fanaticism, and whatever he thought obnoxious to the spirit of the government at that period. Had Orpheus himself not only composed the poem and the music, but performed the principal part, his powers would have been too feeble to charm such unwilling hearers."

GRACAY, in *Geography*, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges; 9 miles S.W. of Vierzan. The place contains 2204, and the canton 5459 inhabitants, on a territory of 145 kilometres, in 9 communes.

GRACCHURIS, an ancient town of Hispania Tarraconensis, mentioned by Livy, Antonine, and Ptolemy, and said to be built by the proconsul Titus Gacchus Sempronius, after having conquered the Celtiberians. Others suppose that it existed before Sempronius, under the name of "Illurcis," and that he only repaired it. It is now called Arreda.

GRACCHUS, TIBERIUS SEMPRONIUS, in *Biography*, a person very memorable in the history of Rome, was the son of a father of the same name, a distinguished commander, and excellent citizen, who, from the Plebeian ranks, arrived at distinguished honours, and the highest offices in the state, having been master of the horse to the dictator, Junius, after the celebrated battle of Cannæ, afterwards consul, and, at length, to complete his glory, he was slain while fighting for his country. The mother of the subject of this article was Cornelia, daughter of Scipio Africanus, whose character has been illustrated in the proper place. Tiberius received every advantage of education that the pious affection of a wise parent could bestow, and his natural disposition seconded the efforts of his instructors. He was modest, and remarkably mild in his temper; and became, at a very early age, distinguished for eloquence, sobriety, and political knowledge; and his reputation was sealed by an admission into the venerable college of augurs. It is mentioned, as a proof of the high character which he sustained, that Claudius Appius, one of the most illustrious persons in Rome, and president of the senate, offered him, spontaneously, his daughter in marriage, which he thankfully accepted. When Appius informed his wife what he had done, she replied, "Why so suddenly, you might have taken

GRACCHUS.

taken time, even if Tiberius Gracchus were the man." In conformity with the Roman custom, Tiberius passed his youth in military service; first in Africa, under his brother-in-law, the younger Scipio, where he obtained great credit in the army, being equally beloved by those above and those below him. He was made *questor*, in the Numantian war, to the consul C. Hostilius Mancinus. This was in the year B. C. 137: the campaign was unfortunate, and the Roman general was under the necessity of negotiating a treaty of peace with the enemy. The Numantines, who had been betrayed in a former treaty by the Romans, refused to negotiate, unless it were with Tiberius Gracchus, with whose character for probity and strict honour they were well acquainted. This being admitted, a peace was immediately concluded. The treaty, though as favourable as, from circumstances, could be expected, was received by the Romans with great indignation: they determined to annul it, and to deliver those, who had been instrumental in making it, into the hands of the Numantines. The consul was accordingly given up to them, naked and in chains, and it is probable that Tiberius Gracchus would have shared the same fate had not a powerful interest been exerted in his favour. A sense of the injulice of the senate on this occasion, and resentment of the dishonour they had thrown upon his treaty, was supposed to be a principal cause of the subsequent hostilities in which he engaged against that body. The condition of the Romans, at this period, afforded a good opportunity for the exertions of patriotism; for the great mass of the lower classes of citizens were in a state of abject poverty. Lælius the Wise, the friend of Scipio, had attempted to introduce some remedy for this evil, but the serious opposition of men in power had deterred him from the execution of his plan. Tiberius Gracchus resolved to take up the cause. He was accordingly elected a tribune of the people, and proposed a revival of the Licinian law, with certain modifications, which greatly softened its operation. (See AGRARIAN LAW.) It offered a full compensation out of the treasury for all the land above the 500 acres allowed, which any one might be obliged to resign to the public, and permitted every child of a family to hold 250 acres above the 500 held in the father's name. This proposal was received, as it might be expected, by the superior orders, whose rights and properties were to be affected by it: they were determined to stand by one another in resisting the innovation. On the other hand, Gracchus lost no time in rousing the people to a knowledge and assertion of their claims as men and members of society. His speeches were addressed to their interests and their feelings: his arguments were specious and highly dangerous to the peace of those whose wealth was become the object of popular discussion. In one of his harangues, he exclaimed, "The wild beasts have their caves and dens, but the brave men who shed their blood in the cause of their country have nothing free but the air and the light. It is a mere mockery when their generals exhort them to fight for their sepulchres and household gods, when, perhaps, not a man among them is possessed of a domestic altar, or sepulchre, of his ancestors. The private men bleed and die to secure the luxuries of the great, and they are denominated the masters of the world, while they are not owners of a foot of ground." At length, after much tumult in the state, the Agrarian law was passed, and Appius Claudius, Tiberius Gracchus, and his younger brother Caius, were appointed commissioners to carry its provisions into execution. In his progress in the business he was embarrassed with many obstacles, and, on his part, he took measures effectually to thwart the purposes of

the great; and, by new laws which he got enacted, he rendered the property of all the old families insecure. The difficulties which occurred in carrying the new law into effect were suspended by the death of Attalus, king of Pergamus, who made the Roman people his heirs. Gracchus procured a law for the distribution of his treasures among the poorer citizens, and for the disposal of the revenues of Pergamus, not by the senate, but by the assembly of the people. These measures gave him a great degree of influence among the citizens, and he conceived the design of securing the powers of which he felt himself possessed, by raising his father-in-law to the consulate, his brother to the tribuneship, and continuing to himself the same office another year. He also planned other regulations for abridging the authority of the patricians, and throwing more weight into the popular scale. The day of election was approaching, and the senators resolved to make a stand against the innovations which he proposed, and a conspiracy was openly formed to take away the life of Tiberius Gracchus. Of this he was informed by a friendly senator, as he was proceeding to the capitol. He, nevertheless, advanced, and his party prepared to repel force by force. In the uproar, he attempted to speak, but his voice could not be heard. He made signs to his friends, by raising his hand to his head, to shew that his life was in danger. This signal was instantly interpreted by his enemies as a demand of the regal crown, and Scipio Nasica, the inveterate enemy of Gracchus, cried out "Since we are betrayed by our consul, let those who love the republic follow me." A general contest now commenced. The adherents of Gracchus were quickly dispersed, and himself was dispatched with a thousand blows. Not less than 300 persons were slain in this commotion, and the bodies of the dead, even that of Gracchus himself, were ignominiously thrown into the Tiber. Several of his friends were afterwards banished, and not a few put to death, without the form even of trial, and the senate passed an act of indemnity for all those who were concerned in the massacre. The people, however, indignant against his enemies, drove Nasica from Italy, and would never permit him to return. With respect to Tiberius Gracchus, his character has been celebrated either as that of a martyr to liberty, or as a victim to lawless ambition, according to the different principles of those who have commented on his actions. Many have thrown on his memory reflections as unmanly as they are severe. It seems to be acknowledged on all hands that he possessed great talents, and was esteemed for his private worth. That he was a man of ambition none will deny, and it may be that a love of popularity suggested the great measures which he proposed; nevertheless, the historian may be safely followed, who says, that he was actuated by the best intentions, but that he prosecuted his design with too much violence.

GRACCHUS CAIUS, brother to Tiberius, but his junior by nine years, enjoyed the same advantages of education with his brother, which he so well improved as to become one of the ablest orators of his time. Cicero says of him, that he knows not if he had his equal in eloquence, and recommends his compositions, though unfinished, to the study of youth. After the tragical end of his brother, Caius passed some time in retirement, cultivating his rhetorical talents, and secretly preparing to act his part on the theatre of the public. In the year 126 B. C. he accompanied the consul Aurelius Orestes to Sardinia as his *questor*, and obtained great applause, as well for his humanity and temperance, as for a strict attention to the duties of his office. The senate shewed evident signs of jealousy on account of the

the popularity which he acquired, and retained him as pro-questor in Sardinia in order to keep him at a distance from the Roman forum. Perceiving their intentions, he ventured, in defiance of their orders, to quit the island without leave of his commander, and suddenly made his appearance at Rome. He was called to account for this breach of military discipline, but was readily acquitted. Soon after he became a candidate for the tribuneship, and such was the zeal of the people in his favour, that the Campus Martius was not able to contain the multitude who flocked from the Italian towns to support his election, and many gave their votes from the tops of the adjacent houses. Caius had not forgotten the enemies of Tiberius, and would have pursued them to their destruction, but was probably dissuaded from it by his mother. His speeches were calculated to revive the indignation of the people against the senators for their conduct towards Tiberius, and he proposed and carried motions for confirming his brother's laws, and the passing of others still more obnoxious to the patricians. He was appointed commissioner for the division of lands among the poor citizens and allies, and in his progress through Italy he employed his talents and wealth in repairing roads, building bridges, and in other works equally useful and important. He established public granaries in Rome, from which the citizens were to have their monthly distributions of corn at a low price, the expenses of which were to be defrayed by duties laid on goods imported into the dominions of the late king Attalus. By these, and other acts of a like kind, he so ingratiated himself with the people, that he was chosen a second time tribune. Triumphant in his success, he proposed a law for transferring from the senators to the knights the cognizance of all private causes. When he had obtained his purpose he exclaimed, "at length I have humbled the senate." He now felt himself the arbiter of the republic, and treated the patricians with contempt. This behaviour hastened his ruin. There is a point, beyond which the most successful man, whatever be his pretensions, cannot go with safety. Caius had transgressed this boundary, and his enemies were perpetually on the watch for opportunities to check his power, and to introduce rivals who might, by the appearance of more liberality, depreciate his reputation and influence in the state. During his absence in Africa his enemies were ever on the alert to injure his fair fame, and to ascribe unworthy and base motives to all that he did or proposed to do; and in the tumult which accompanied the discussion of some of his laws after his return, he fled to the temple of Diana, and, unwilling to sacrifice either himself or his adherents to popular fury, he proposed terms of accommodation. These were rejected by the arts of Opimius the consul, and a price was instantly set upon the heads of Gracchus and his friend Fulvius. A formal battle ensued, in which multitudes were slain on both sides, and the populace without hesitation deserted their friends: Fulvius concealed himself, but, being discovered, was instantly killed. Gracchus, having solemnly imprecated upon the heads of the Roman people perpetual slavery for the base desertion of the cause, left the city and passed across the bridge named Sublicius. His retreat was favoured by two faithful friends, who defended the bridge till they fell covered with wounds. In the mean time Gracchus reached a grove sacred to the furies, where it is said a slave, by his order, first dispatched him, and then put an end to his own life. Others have, however, given a different account of the matter; they say that he was overtaken by his enemies, and by them slain. His head was cut off and sold to the consul for its weight in gold. The body was thrown into the Tyber, but afterwards being taken from the water it was delivered to his afflicted mother

for burial. This catastrophe, in which three thousand persons perished, happened in the year 121 B.C., and the senate immediately proceeded to abolish all the laws of the Gracchi. Their names, however, were still fondly cherished by the people, statues were erected to their memory, and the places in which they were killed were consecrated, by religious rites, to their manes. Caius has been generally considered as less pure in his intentions, and less moderate in his plans, than Tiberius. From the evidence of history it should seem, that the disturbance of the public tranquillity was rather owing to his opposers than to him; "so that," says the historian, "instead of calling the tumults of that period the 'sedition of the Gracchi,' we should rather call them the sedition of the senate against the Gracchi, since the efforts of the latter were made in vindication of a law, to which the senate had assented, and as the designs of the former were supported by an armed power from the country that had never before interfered in the business of legislation, and the introduction of which gave a most irrecoverable blow to the constitution. Caius in his person was graceful, his action was strong and impressive, his voice of great compass and melodious when the vehemence of his pleading did not raise it to too high a key; to correct this defect he was accustomed to place a judicious person behind him with a pitch-pipe, by which he was enabled to regulate his tone. In temper he was warmer than Tiberius, nor was he distinguished by sobriety of manners, though in this respect he might be advantageously compared to the Roman youth in general. Plutarch. Univer. Hist.

GRACE, GRATIA, χάρις, in *Theology*, denotes in general any gift or favour, which God *freely* bestows upon mankind; whether such gift pertains to the present or future life: but as those which relate to the improvement of their temper, and their fitness for final happiness, were favours of the greatest importance, this term is by way of eminence applied to them. The proper signification of the word *grace* is favour;—favour in such a sense as denotes mercy and goodness in a superior, either remitting somewhat of his own right, or conferring somewhat beneficial upon others, *freely* and without any obligation of debt. And because this may be done in various modes and in a great diversity of instances, hence the word *grace* in scripture is accordingly applied in a corresponding diversity of significations. Sometimes it signifies those extraordinary gifts and favours of the Holy Ghost, by which the apostles were enabled to demonstrate the truth of their commission, to preach their doctrines with authority, to convince gainers with evidence, and to govern the churches by a proper distribution of different trusts and offices. The gifts or powers, by which the apostles were enabled to do all these things with extraordinary efficacy and success, are therefore called *grace*, because they are not at all natural acquisitions but free gifts of God; distributed to every one, not according to the will of man, but at such times, and in such proportions, and to such persons, and for such purposes as God himself pleased. See Rom. i. 5. Ephes. iv. 7. 11.

In other passages, the same word is used to signify that extraordinary assistance and support which God has been pleased sometimes to afford to his servants under extraordinary difficulties and trials; and this is called *grace*, because it is considered as given particularly and gratuitously upon extraordinary occasions over and above the general supports arising from the considerations of reason, and from the promises and motives of the gospel in general. See 2 Cor. xii. 9.

A third sense, in which the word *grace* sometimes occurs in the New Testament, is to express such moral virtues as are the effects of men's being influenced by the spiritual

motives of the gospel, and the practice of which preserves men in the favour of God, and recommends them to his gracious acceptance. (See Ephes. iv. 29. 2 Pet. iii. 18. 2 Cor. viii. 1. 6.) Moral virtues are plainly for this reason distinguished by the denomination of grace, because they proceed from and are founded on a regard to God in general, and in particular to his will revealed under the gracious dispensation of the gospel of Christ.

Another signification of the word grace in Scripture is to express the merciful acceptance of repentance and amendment, by which God is pleased, not out of any obligation of justice, but in gracious goodness, to restore men to favour. In this sense Paul says (1 Cor. xv. 9.) "By the *grace* of God I am what I am:" so John, i. 17., the doctrine of Christ is styled "*grace and truth.*" The Apostles' preaching is by St. Luke (Acts, xiv. 3.) called "*the word,*" or declaration "*of God's grace:*" so when St. Paul declares (Rom. iii. 24.) that repenting sinners are "*justified freely by grace,*" and blames those "*who continue in sin, that grace may abound.*" The word *grace* in all these passages signifies that merciful and compassionate disposition of the divine nature, by which God freely remits of his right of punishment, and receives penitent sinners, upon more gracious terms, and to greater degree of his favour, than he was bound to do by any obligations of justice.

Hence it is, that the gospel itself, as being the great and standing declaration of God's mercy and goodness towards men, shewn forth in the free pardon and forgiveness of sin upon the gracious terms of repentance and amendment, is in the New Testament very frequently meant by the phrase, "*the grace of God.*" (Clarke's Sermon. vol. ii. p. 265—275. 8vo. fol. ed. vol. i. p. 180, &c.) Bishop Pearce (Comm. vol. ii. p. 259.) renders *χαρις* in 1 Cor. x. 30. thanksgiving, and not *grace*, as it is in our version; and he observes that this sense of the word *χαρις* is too frequent in St. Paul's writings to require a proof of it. He adds that *ευχαριστω* in the latter part of the verse confirms this sense.

Some divines define *grace* to be any degree of divine influence on the mind, inclining it to believe in Christ, and to practise virtue; and those divine influences, which are not effectual in producing saving faith and sincere obedience, they call *common grace*, in contradistinction to *special grace*, the operation of which is completely efficient and saving; and those influences which introduce *special grace*, though they do not actually amount to it, are with respect to that introduction sometimes called *preparatory*. It is disputed among theologians whether *special grace*, which they suppose is never on the whole finally rejected, so as to fail of working faith in those who are the happy objects of it, be in the nature of its operations upon the human mind *irresistible* or not; and it is also questioned, whether *common grace* be *sufficient*. Whether the mind be entirely *passive* in the first moment of its conversion, or whether there be any co-operation of our own together with the influences of divine *grace* upon the heart, is a question, which has been also very much disputed amongst divines of a particular description; and another question, no less the subject of controversy, is similar to the former, and that is, whether the work of regeneration and conversion be accomplished in an *instant*. But we should far exceed our prescribed limits if we were to state the arguments *pro* and *con* on questions of this nature.

GRACE, in *Law*, is sometimes used for a faculty, licence, or dispensation; but this seemeth to be only in a case where the matter proceedeth, as it were, *ex gratia*, of grace and favour; and not where the licence or dispensation is granted of course or of necessity.

GRACE is also a term in the formula of all patents, &c. which begin, George, by the grace of God, king of Great Britain, &c. The Romish bishops frequently began their mandates in the like manner: such a one, by the grace of God, and the holy see, bishop of, &c.

The English archbishops say, by divine grace, or divine providence. See ARCHBISHOP.

All sovereigns use the phrase *grace of God*; as emperors, kings, princes, &c. Anciently dukes, counts, and even lords, talked in the same style. In the new collection of Father Martene we meet with a mere seigneur, or lord, qualified by the grace of God seigneur de Combourn. Louis XI. forbade the duke of Brittany to style himself by the grace of God.

GRACE is also a title of dignity, attributed to princes of inferior rank, and who are not qualified for that of highness.

In former times the kings of England were addressed under the title of *grace*, as they are now under that of majesty. See KING.

Our English dukes and archbishops are still addressed under the title of *grace*. But that title is most frequent in Upper Germany, and particularly Austria, where it is borne by the barons, as being inferior to that of excellence.

GRACE is also applied to persons, and various kinds of performances, to denote a quality, or rather the result of a combination of qualities, which attracts peculiar notice, and affords peculiar pleasure.

GRACE is also used for a short prayer offered before and after meat. This practice is very ancient, and has very generally obtained both in the heathen and Christian world: and hence *grace-cup* is used by some of our poets for the cup or health drank after grace.

GRACE, in the arts of *Painting* and *Sculpture*, is used to signify a peculiar quality which heightens the effect that beauty of form is calculated to produce, and renders it still more engaging.

We have already, in the article *BEAUTY*, slightly touched upon this subject, and there mentioned the origin of the term among the Greeks; who gave to the Charites or Graces, whom they deified, the presidency over whatever was amiable and engaging in the actions or sentiments of mankind. By the undiguised nakedness in which they always represented these goddesses, to whom they gave the names of Aglaia, Thalia, and Euphrosyne: they allegorized the pure sincerity and simplicity in which acts of kindness should always be wrought. By the union of these persons, which are gently holding each other by the hands, or with their arms round each other's necks, they marked the union of spirit which dictates acts of benevolence and social intercourse; and by devoting them to the service of Venus, exemplified the necessity of uniting the virtues of humanity to the beauties of person, in order to become truly engaging.

This allegory of the ancient Greeks leads us to the just conception of the meaning of the word *grace* when applied to the arts. Whatever can lend to beauty, increase of interest upon the beholder, is entitled to be called *graceful*, or at least elegant. (See *ELEGANCE*, in *Painting*.) As the heart of man, when inclined to good, is to his mental, so is *grace* to his personal accomplishments; that, which gives the most delightful gratification to those with whom he associates. Without it, art is nothing, compared with the values it acquires by its presence. Independent of all which constitutes mere beauty of form, it is absolutely necessary to give it its full force, its greatest effect, *viz.* that which

beauty acquires by motion, wherein alone grace is visible.

Poets as well as painters and sculptors acknowledge the value of this quality : and the best have constantly applied it to the objects of their adulation when moving. Milton says of Eve, "Grace was in all her steps." Ariosto adds it to perfect the beauties of his Alcina; when he says,

"Avea in ogni parte un lascio tefe
O parli, o rida, o canti, o passo mova."

The graces, lurking about the mouth and the eyes of a beautiful person when in motion, are the most constant theme of poets, and as constantly the source of emulation to the painter and sculptor to imitate; and when the artist has by his ingenuity discovered and represented truly those minute variations of form which take place both in figure and features, when the mind is excited by some amiable emotion; he has obtained the ultimatum of his art; no power can go beyond it. Apelles, the ancient Greek artist of most repute, declared of his contemporaries, that their several works possessed every beauty but the perfection which grace alone can give: in this he found himself unrivalled. Ancient sculpture is fraught with it; their figures, whether in action or repose, possess it; and when we say that it may be found in figures reposing, we do not militate against the sentiment that action is the basis of grace; a previous motion being supposed to have taken place, to produce the graceful position. No figure, standing, sitting, or lying down, can be graceful, however beautiful it may be, whose parts or members are presented altogether straight and full to the eye. Without some varying turn being given to the head, the body, the arms, or the legs, it will be in vain to look for grace; and it is their being arrested in the action they may assume, at the most agreeable and expressive point of view, which gives the consummation of this invaluable quality to them. Then, if fixed for ever, they will be for ever graceful; and the delight which the contemplation of their mere beauty of form and proportion conveyed, will be heightened to the summit of that gratification which art is enabled to afford.

Wherein then lies this source of perfection? How, with certainty, may we express it in our works? is the hitherto unanswered query of the artist; or answered but in part and unsatisfactorily. All writers on painting have touched upon grace, and some have attempted to give information of the principles whereon it rests. Lamozzo, in his Trattato della Pittura says, that Michael Angelo gave the following precept to Marcus de Sirena, his pupil. "That he should always make a figure pyramidal, serpent-like, and multiplied by one, two, three!" In which precept (Lamozzo continues) in mine opinion the whole mystery of the art consisteth. For the greatest grace and life a picture can have, is, that it express motion. Now there is no form so fit to express *motion as that of flame of fire.*" This text is again repeated by Du Fresnoy, and thus has Dryden translated the passage; "Large flowing gliding out-lines, which are in waves, give not only a grace to the part, but to the whole body, as we see in the Antinous, and in many other of the antique figures. A fine figure, and its parts, ought always to have a *serpent-like and flaming form*; naturally, those sorts of lines have I know not what of life and seeming motion in them; which very much resemble the activity of the flame and of the serpent."

On these two remarks our own industrious and skilful Hogarth has built a system, which, if it be not altogether compleat, has yet much sagacity and utility in it, and which he has given to the world in his Analysis of Beauty. He therein adopts the serpentine line, (which he illustrates by

supposing a wire drawn spirally round a cone from its base to its apex), as the basis of grace, with much apparent truth: and he is most certainly supported by all those fine works wherein gracefulness is acknowledged to reside. The Torso of the Belvidere, the Venus de Medicis, the Apollo Belvidere, the Laocoon, who, in the midst of the violent anguish he suffers, still possesses grace. All these, and indeed all others, which have any pretensions of the like kind, have the serpentine line for the base of their composition, in a greater or less degree. Who shall laugh at a system upheld by such authority! Walpole attempts to ridicule it, as well as others, because Hogarth was not equal to put it in practice. The futility of such an argument needs no illustration. To conceive a thing in the imagination, and not be able to exemplify it by practice, is by no means an uncommon occurrence among artists, or among men; yet the propriety of the conception may be unquestionable, taken on general grounds. Hogarth's mistake appears to have been, having fixed the boundary of grace; having given what he calls the *precise line* of it; whereas, all the antique figures mentioned above are graceful, while each varies from the other in the quantum of curve which its action consists of. Hence arises, that he so narrowed the sphere wherein grace was observable, which in nature is found to be so widely extended, that, without just consideration, his ingenuity was regarded as the ravings of eccentricity; whilst no good arguments were adduced to disprove the general principle, which appears to us to be just. How to employ it, is another question. And here we fear no rules will suffice to guide the practitioner in art. As we said of elegance, we repeat of grace: he that is endowed by nature with a power to feel its beauties, and display its effects, may, by cultivation, improve his original stock; but he that requires to be taught what grace is, will, in vain, seek to obtain the power of painting it; if he ever arrives at the knowledge of it, or the power of seeing it, in nature or in art. A constant observation upon the actions, in figure and feature, of those who are by nature graceful, is the best school in which to study it, and the readiest mode to discover wherein it lies.

Grace is not, or rather ought not, to be confined to the figures in a composition. Every part of the picture should have a conjunctive effect to produce grace in the whole. Contrast of form will aid the beauty of the principal parts, but that contrast should never force itself into notice, the artifice would then become apparent, and the eye would not be led to the beautiful parts, but, on the contrary, be detained from them. The painter therefore who has conceived a graceful figure, should either paint it singly, or be careful so to support it, by proper accompanying lines and objects, that its beauty be not lost in the mass, and its effect overpowered by other forms of less value becoming obtrusive to the observer. And great care should be taken to prevent every attempt to produce grace in the action of figures, from degenerating into affectation. Where that begins, grace ends: and detestation or ridicule, instead of admiration, becomes the meed of the artist! No vice in art is so odious as affectation! If the best executed work imaginable be unhappily tinged with it, few minds of an elegant or graceful turn of feeling will bear to dwell upon it. Those artists who allow their minds to be impressed with the passion or sensation they wish to convey in their figures, and thence conceive the action of them, are not so liable to fall into this error, as those whose ideas are more intent on making an agreeable picture, and think of the actions, before they have considered the passions of their figures. Raphael is an instance of the former; Correggio and Parmigiano,

giano, great and graceful as they frequently were, nevertheless belong too often to the latter class, and even their extraordinary brilliancy of talent does not secure them from just censure when that is the case.

The best examples of grace are to be found in ancient sculpture and paintings, and in the works of Raphael. Some few of the works of Correggio, of Parmigiano, and of Guido Rheni, possess it, perhaps, more refined than Raphael's; but they are so near the extreme boundary wherein real unaffected grace resides, that they are dangerous exemplars to a student. A confirmed artist may observe them to advantage.

Sir Joshua Reynolds possessed it largely, and perhaps we ought to have added his name to Raphael's. But yet he is not always pure: a little too much of the Correggiefque is admitted in some of his fancy pictures; and particularly in the expressions of the features.

GRACE, *Act of*, properly denotes an act of amnesty, or oblivion, for the pardon of all offenders who are qualified, or come within the conditions of it.

The term is also sometimes extended to an act made for relief of insolvent debtors in the several prisons; by setting those who are qualified, at liberty from their debts and confinement.

GRACE, *Covenant of*. See COVENANT.

GRACE Cup, so called because the beverage contained in it was circulated amongst the community, or other company, at a particular time, and by a special favour. It was also called *Poculum Charitatis*, or the *Cup of Charity*, as being intended to indicate and promote brotherly love. At other times it was termed the *Wassel Cup* or *Bowl*, because each one of the company, in drinking out of it, drank health to his next neighbour in the old terms, *Was heil*. William of Malmesbury, describing the customs of Glastonbury abbey soon after the conquest, says, that on such and such particular days, the monks had "Medonem in justis et vinum in charitatem." Mead in their cans, and wine in the grace cup. A large cup or bowl of this nature was always heretofore placed on the table of princes, &c. as well as of abbots. In the eleventh volume of the *Archæologia* there is an engraving of a grace cup, which formerly belonged to Glastonbury abbey, and a dissertation upon it by Dr. Milner. The inside of this cup, which holds two quarts, is furnished with eight pegs, at equal distances, one below the other, in conformity with Edgar's law, to repress excess in drinking. This measurement allowed of half a pint to each person.

GRACE, *Days of*. See DAY, in *Law and Commerce*.

GRACE, *Herb of*. See RUE.

GRACES, GRATIE, in the *Canon Law*, are the same with what we otherwise call *provisions*; which see.

GRACES, *Expectative, Gratia Expectativa*. See EXPECTATIVE.

GRACES, *Gratia, Charities*, in the *Heathen Theology*, were fabulous deities, three in number, who attended on Venus.

Their names are Aglaia or Eglé, Thalia, and Euphrosyne; *i. e.* shining, flourishing, and gay; and they were supposed by some to be the daughters of Jupiter and Eurynome, the daughter of Oceanus, and by others to be the daughters of Bacchus and Venus. Vossius de *Idol* lib. xiii. cap. 15. Homer (*Iliad*, lib. xiv.) changes the name of one of the graces, and calls her Palithée, and he is followed by Statius. (*Theb.* lib. ii.)

Some will have the graces to have been four, and make them the same with the *Horæ*, *Hours*, or rather with the four seasons of the year. See HOURS.

The Lacedæmonians admitted only two of them, whom

they worshipped under the names of Clito and Phaenné. The Athenians allowed the same number, but denominated them Auxo and Hegemone.

A marble in the king of Prussia's cabinet represents the three graces in the usual manner, with a fourth, seated, and covered with a large veil, with the words underneath, *AD SORORES IIII*. Yet Mons. Beger will by no means allow the graces to have been four: the company there present, he understands to be the three graces, and Venus, who was their sister, as being daughter of Jupiter and Dione.

They are always supposed to have hold of each other's hands, and never parted. Thus Horace, (*lib. iii. od. 21.*) describes them:

"Segnesque nodum solvere gratiæ,"

They were also represented in the attitude of persons dancing; whence Horace says (*lib. i. od. 4.*):

"Alterno terram quatunt pede."

They were commonly thought to be young virgins. In the earlier ages they were represented only by mere stones, that were not cut; but they afterwards were represented under human figures, at first clad in gauze. But the custom of giving them drapery was laid aside; and they were painted naked to shew that the Graces borrow nothing from art, and that they have no other beauties than what are natural.

Yet, in the first ages, they were not represented naked, as appears from Pausanias, *lib. vi.* and *lib. ix.* who describes their temple and statues. They were of wood, all but their head, feet, and hands, which were white marble. Their robe or gown was gilt; one of them held in her hand a rose, another a die, and the third a sprig of myrtle.

They had temples, as we learn from Pausanias, at Elis, Delphos, Perga, Perinthus, Byzantium, and in several other places of Greece and Thrace. The temples consecrated to Cupid were also consecrated to the Graces: and it was also customary to give them a place in those of Mercury, in order to teach men, that even the god of eloquence needed their assistance. Indeed some authors reckoned the goddesses of persuasion in the number of the Graces, thus intimating, that the great secret of persuasion is to please. The Muses and the Graces had commonly but one temple; and Pindar invokes the Graces almost as often as he does the Muses. Festivals were appropriated to their honour through the whole course of the year, but the spring was chiefly consecrated to them as well as to Venus. Greece abounded with monuments sacred to these goddesses; and their figures were to be seen in most cities, done by the greatest masters. They were also represented on many medals. The favours which these goddesses were thought to dispense to mankind, were not only a good grace, gaiety, and equality of temper, but also liberality, eloquence, and wisdom, as Pindar informs us; but the most noble of all the prerogatives of the Graces was, that they presided over all kindnesses and gratitude; inasmuch that, in almost all languages, their names are used to express both gratitude and favours.

GRACES. There is a good article for Fr. music, by M. Framery, under the term *Agrémens*, *New Encycl. Meth.* p. 54: in this he candidly acknowledges all the defects ascribed to Fr. singing by Rousseau and Burney. See AGRÉMENS, RIFORMANTI, SHAKE, BEAT, TRILL, and *Musical CHARACTERS*.

GRACIAN, BALTHASAR, in *Biography*, an eminent Spanish writer, was born in 1603. He entered among the Jesuits at the age of sixteen, and became a teacher in their society,

Society, of the belles-lettres, of philosophy, and of theology. He likewise exercised the duties of a preacher, and was at length rector of the Jesuits' college of Tarragona, where he died in the year 1658. He was a much esteemed author, and most of his works have been translated into French and other foreign languages. The principal of these are "The Hero;" "Reflections on the political Conduct of Ferdinand the Catholic;" "A Treatise on the different Kinds of witty Conceptions." A work treating of the errors to which man is liable, and a collection of meditations on taking the holy communion. Moreri.

GRACIAS A' DIOS, in *Geography*, a town of Mexico, in the province of Honduras, and audience of Guatemala, situated at the mouth of a river, which communicates with the bay of Honduras. It has some gold mines in its neighbourhood. N. lat. $14^{\circ} 30'$. W. long. $90^{\circ} 6'$.—Also, a cape on the N. coast discovered by Columbus. N. lat. 15° . E. long. $132^{\circ} 50'$.—Also, a cape, called "False Cape Gracias a' Dios," on the coast of Nicaragua, 63 miles from the other. N. lat. $13^{\circ} 36'$.

GRACILIS, in *Anatomy*, a muscle of the leg, thus called from its slender shape.

It arises partly tendinous, and partly fleshy, from the os pubis internally, between the first and second heads of the triceps; and in its descent on the inside of the thigh, grows narrow, and becomes tendinous, a little below the sartorius, and is thus inserted into the tibia. It assists in bringing the thigh and leg inwards.

GRACILIS *Rectus*, a name given by Riolan to one of the muscles of the leg, called by Winslow the *rectus cruris anterior*, and by Cowper the *rectus femoris*. Albinus calls it the *rectus cruris*.

GRACULA, in *Ornithology*, a genus of the order Picæ, having the bill convex and acute at the edges, the base rather naked; tongue entire, sharpish, and fleshy; and the feet formed for walking. The genus *gracula* corresponds with the mainate of Brisson, from whom it appears to have been adopted by Linnæus under the former term. Some of the species of this natural tribe were known to Ray, who refers them to the crows; and also to Willughby, who considers them as of the stare or starling kind. The species of *gracula*, described in the Gmelian *Systema Naturæ*, amount to twelve; and this number is increased to fourteen in the work entitled "Index Ornithologicus" of Dr. Latham, by the addition of the new species *iderops*, and the introduction of the Linnæan *Paradisæa tristis*, which latter the last mentioned writer has deemed it requisite to remove to this place. As a secondary to the essential or generic character above described, it may be proper to observe that the birds of this kind have the bill thick, and compressed at the sides; the nostrils small, at the base of the bill and sometimes situated near the edge; the toes three forward and one behind, the middle toe connected at the base to the outer one, and the claws hooked and sharp. Their principal food consists of fruits and insects.

Species.

RELIGIOSA. Violet-black; spot on the wing white; band on the hind head naked and yellow. Gmel. Linn. *Mainatus*, Briss. *Sturnus indicus Bontii*, Ray. *Bontius's Indian stare*, Will. *Le Mainate*, Buff. *Minor grakle*, Albin.

The length of this bird is ten inches and a half, its bulk equal to that of the black-bird: the bill an inch and a half long, of an orange colour tipped with yellow; the legs tawny or orange; feathers of the head, except the middle

ones, very short and silky; and the naked band reaching nearly to the nape. This species is found in many parts of India, and not unfrequently in a tame or domesticated state, being naturally of a familiar disposition, and capable of being taught to whistle, sing, and imitate the articulations of the human voice with greater precision than any of the parrot tribe. In the islands of Sumatra and Java it is called by the natives *hill-mayna*, and in China, whither it is imported from the latter place, its common name is Tecong. Several supposed varieties of this bird are described by writers, the most remarkable of which is that called the greater minor grakle, le grand mainate of Brisson; this entirely corresponds with the ordinary kind, except in size, which it materially exceeds, being in this respect not inferior to the jackdaw; it inhabits the island of Hainan, in Asia.

CALVA.—Sub-cinereous, with the head naked each side. Linn. *Merula calva Philippinensis*, Briss. *Merle chauve des Philippines*, Buff. *Goulin*, ib. *Iting*, *Tabadura*, vel *Gulin*, &c. Phil. Transf. *Bald grakle*, Lath.

Size of the black-bird, with the head and cheeks bare of feathers and flesh-coloured, except a narrow list of short brown feathers, extending from the base of the bill to the back of the head; the naked part becoming of a deep red when the bird is irritated: the general colour above is silvery-ash, beneath grey-brown, bill and legs brown. These birds build their nest in the hollows of trees, especially preferring those of the cocoa-nut: it is represented as a noisy chattering bird, of voracious appetite, and as living principally on fruit. Found in the Philippine islands.

FÆTIDA. Black; exterior part of the quill-feathers blueish; band round the neck naked. Linn.

Native of America, in size resembling the magpie: the head with erect, short, silky feathers; nostrils oval and naked; tongue sharp; and tail even at the tip.

BARITA. Somewhat grey; shoulders blue; quill-feathers at the outer edge green. Linn. *Monedula tota nigra*, Ray. *Boat-tailed grakle*, Lath.

Size of the cuckoo: the bill shortish, rather black, paler beneath and naked at the base; the plumage black, inclining to grey, and glossed with purple; tail rounded, concave when folded, and becoming flat on being expanded; legs and claws black. The species inhabits the Antilly islands and North America. It feeds on insects and fruits.

CRITATELLA. Black, the first quill-feathers at the base, and tail-feathers at the tip white; bill yellow. Gmel. *Merula sinensis cristata*, Briss. *Merle huppé de la Chine*, Buff. *Chinese starling or black-bird*, Edwards.

A species rather larger than the black-bird; the plumage inclining to blue, with a crest of feathers on the head which it can raise and depress at pleasure; greater quill-feathers from the base to the middle white, the remaining part deep blue; tail-feathers, except the two in the middle, tipped with white; legs dull yellow. The crested grakle sings and talks like the species *religiosa*, but with inferior distinctness; and is frequently kept in cages in China, which country it inhabits in a wild state; its principal food is rice, worms, and insects.

SAULARIS. Blueish-black; belly, spot on the wings, and lateral tail-feathers white. Gmel. *Lanius bengalensis niger*, Briss. *Pie griefche noir de Bengale*, Buff. *Bengal magpie or dial-bird*, Albin. *Dial grakle*.

Native of Bengal. Size of the Missel thrush, with the head, neck, breast, back, rump and upper tail-coverts black; belly, sides, thighs, and under tail-coverts white; tail even at the end, black above, and white beneath. The female differs in being black instead of brown on the fore-

part of the neck and breast, and in the white being more obscure.

QUISCALA. Violet, black; tail rounded. Linn. *Picus jamaicensis*, Briss. *Cornix purpurea*, Klein. *Fur-zea*, Kalm. *Izanal*, Ray. *Black-bird, or maize-thief*, Kalm. Tr. *Purple grackle*, Arct. Zool.

Native of Mexico, and the warmer parts of America, and the West Indies; sings finely, builds on trees, is destructive to plantations, but useful in destroying the noxious insects that infest them. The flesh is black and unfavourable. Its size is about that of the black-bird, the male a little exceeding the female in bulk; the bill and legs are black; tail long and cuneated, and with the wings purple; the female entirely dusky.

ATTIUS. Greenish-blue; belly rusty; legs blood-red, Linn. *Corvus Ægyptius*, Hasselq. *Egyptian grackle*, Lath.

Size of a lark; and is supposed by Hasselquist to feed on insects, the remains of centipedes and scorpions being found in the stomach. The bill is black; neck with a longitudinal rusty line each side, and the claws black.

LONGIROSTRA. Brown, beneath ochre-yellow; head and neck black; band round the neck naked and wrinkled; area of the wings white; tail cuneated, black, and at the tip white. Pallas, &c.

Native of South America; length eight inches. This appears to be the same species as that described by Sonnini under the name of merle des Savannes.

STURNINA. Hoary; spot on the crown and back between the wings violet-black; tail and wings with a tinge of green, the latter with a double white stripe. Pallas.

Inhabits the Ozier banks of Dauria; the nest and eggs resemble those of the thrush; the plumage of the female is dirty ash, with the back brown; and the wings and tail deep black.

ICTEROPS. Black; band on the wings and body beneath white; the region of the eyes naked and wrinkled. Lath. *Le mainate a face jaune*, Vieill. *Yellow faced grackle*.

Length seven inches and a half; bill compressed; nostrils oval; legs yellow and wrinkled. Native of New Holland.

CAYANENSIS. Striated; above tawny, beneath yellowish; head and chin varied with tawny and white; tail wedged, sharp and with the wings tawny. Gmel. *Climbing grackle*.

Inhabits the interior parts of Guiana; is about ten inches in length, and remarkable for climbing trees; the bill is black, about two inches long, and a little curved; the legs are also black.

CARUNCULATA. Cinereous; tail and quill-feathers black; crown and chin with warty excrescences. Gmel.

Length six inches; and supposed to inhabit the Cape of Good Hope.

MELANOCEPHALA. Head black, front white; back, tail, and wing-coverts blueish-ash, the last with a transverse white streak near the extremity. Don. *Gracula melanocephala*, Lath. *Le mainate a tête noire*, Vieill. *Black-headed grackle*.

A species recently discovered in New South Wales; its height is about eight inches; the bill yellow, a little bent, and formed at the base like that of the *Turdus*, or thrush tribe; the tail three inches long; the legs very long in proportion, of a pale yellow ochre-colour, and armed with strong blackish claws.

VRIDIS. Dull green; throat above brown and blackish varied; under parts of the plumage whitish, with some blackish streaks; wings blackish, edged with white; tail blackish, with white tip. Don. *Gracula viridis*, Lath. *Le mainate vert*, Vieill. *Green grackle*.

Lately found; the species inhabits New Holland, and

appears to be very rare; the bill is strong, somewhat inclining at the base, and the colour of horn; the legs blackish.

CYANOTIS. Space about the eyes bare of feathers and bright blue; head black, with a white cross on the hind part; upper part of the neck, body, scapulars, wing-coverts, and tail yellowish-green; breast lead-colour; plumage beneath white. Don. *Gracula cyanotis*, Lath. *Le mainate a oreilles bleues*, Vieill. *Blue eared grackle*.

Length twelve inches and a half; bill black; legs blue black, with very hooked black claws. Native of New South Wales.

PICATA. Greater part of the head, the neck; transverse band on the breast, back, border of the wings, and tail above nearly to the tip black; throat, breast, wing-coverts, body beneath, and under surface of the tail-feathers white. Don. *Gracula picata*, Lath. *Le mainate pie*, Vieill. *Pie grackle*.

Rather larger than the black-headed grackle, and like that species inhabits the regions of Australasia; the general colour black and white, the former partially glossed with purple; bill yellow, and corresponding in form with that of the black-headed grackle; and the legs lead colour.

GRACULUS, the *Shagge*, a species of *Pelecanus*; which see.—Also, a species of *Corvus*; which see.

GRADATION, the act of ascending, step by step, to any pitch or eminence: from the Latin *gradus*, *degree*, *step*.

GRADATION, in *Architecture*, signifies an artful disposition of parts, rising, as it were, by steps or degrees, after the manner of an amphitheatre: so that those placed before do no disservice, but rather service, to those behind.

The painters also use the word gradation for an insensible change of colour, by the diminution of the tints and shades. See below.

GRADATION, in *Chemistry*, is a kind of process belonging to metals. It consists in gradually raising, or exalting them to a higher degree of purity and goodness, so as to increase their weight, colour, consistence, &c.

GRADATION, in *Logic*, is an argumentation, consisting of four or more propositions, so disposed as that the attribute of the first is the subject of the second; and the attribute of the second is the subject of the third, and so on, till the last attribute come to be predicated of the subject of the first proposition. As in Porphyry's tree; man is an animal; an animal is a living thing; a living thing is a body; a body is a substance: therefore man is a substance.

An argument of this kind is liable to many fallacies; both from the ambiguity of words and things; *e. gr.* Peter is a man; man is an animal; animal is a genus; genus is an universal; therefore Peter is an universal.

GRADATION, in *Painting*, relates both to chiaro-scuro and to colour; that is, all the different degrees in which light and dark, and colour may be modified, are comprehended in it.

An object receding from the light, and gradually losing it, becomes at its farthest extremity obscurely defined. A coloured body, pure or bright in tint, under the same circumstances, gradually diminishes in clearness of hue throughout its receding parts, and becomes dull and dark. By fixing the scale of gradation in both these particulars, effects of great force or great simplicity may be produced. The scale of descent being made rapid, great force will ensue, from the strong oppositions it promotes; and the reverse will take place when the degrees of descent are prolonged, and less contrast thereby effected. The nature of the sub-

ject, and the situation of the figures with regard to light, must's be the artist's guide in this matter.

The *gradation of colour* includes not only what is mentioned above, *viz.* the different degrees of purity, or brilliancy of the same colour, but also the approximations of each colour to its neighbour, necessary to produce harmony; and also the art of gradually losing the local colour in obscurity, and yet maintaining the character of it in the object: which is extremely difficult and of great importance in the art of painting.

GRADATION, in *Rhetoric*, is when a series of considerations or proofs is brought rising by degrees, and improving each on the other. See **CLIMAX**.

Such is that in Cicero to Herennius: "Africano industria virtutem, virtus gloriæ, gloria æmulos comparavit."

GRADI, *Italian*, degrees. Every ecclesiastical mode, and every key in secular music, has its *gradus*, its scale; no note of which can be changed by an accidental *flat*, *sharp*, or *natural*, without changing the key. As in the key of F major with one flat at the clef, annul that flat by a natural, and the key is changed to C, add another flat and it modulates into B b.

GRADISCA, or **GRADISCH**, in *Geography*, a town of Germany, and capital of a small county, annexed with Goritz to the dominions of Austria, seated on the Lizonzo, built in the year 1473 to stop the incursions of the Turks, additionally fortified in 1764, and erected into a bishopric in 1784; taken by the French in 1797:—5 miles S. of Goritz. N. lat. 46° 2'. E. long. 13° 27'.—Also, a town of Slavonia, on the river Save, near the borders of Croatia, well peopled and fortified; 132 miles W. of Belgrade. N. lat. 45° 10'. E. long. 17° 50'.

GRADISELLO, a town of Italy, in the department of the Adda and Ogliã; 8 miles S. of Breno.

GRADISTA, a town of European Turkey, in Bulgaria, on the borders of Servia; 40 miles S. of Viddin.

GRADISZTE, a town of Walachia; 48 miles N.E. of Galacz. N. lat. 45° 23'. E. long. 27° 19'.

GRADITZ, a town of Bohemia, in the circle of Koniggratz; burnt by Zisca; 12 miles N. of Koniggratz.

GRADO, a small island in the gulf of Venice, near the coast of Friuli, with a town which was the first see of the Venetian patriarch. N. lat. 45°. E. long. 13° 17'.

GRADUAL, **GRADUALE**, was anciently a church-book, containing divers prayers, rehearsed, or sung, after the epistle: called in some of our ancient writers *gradile*, *graduale*, *graille*, &c.

After reading the epistle, the chantor ascended the ambo with his gradual, and rehearsed the prayers, &c. therein; being answered by the choir; whence the name gradual, on account of the steps or degrees of the ambo.

The gradual or graille, which the provincial constitutions of archbishop Winchelsea, made at Merton, A. D. 1305, required to be in every church, was a book containing all that was to be sung by the choir at high mass; the tracts, sequences, hallelujahs; the creed, offertory; trifagium, and also the office for sprinkling the holy water. "Gradale sic dictum, à gradalibus in tali libro contentis."

It is sometimes taken for a mass-book, or part of it, instituted by pope Celestine, anno 430. See stat. 37 Hen. VI. cap. 32.

In the Romish church, gradual is an appellation still given to a verse which they sing after an epistle, and which

was anciently rehearsed on the steps of the altar: though Ugutio gives us another account, and says it took its denomination gradual because sung in the gradual ascent from note to note. Magri speaks differently still, and will have it to have taken its name because sung while the deacon went up the stairs to the pulpit, to sing the Gospel.

GRADUAL, *Gradualis*, is also applied to the fifteen psalms, sung among the Hebrews, on the fifteen steps of the temple. Others are rather of opinion that they were thus denominated because the singers raised their voice by degrees, from the first to the last.

Cardinal Bona, in his treatise of Divine Psalmody, says, the fifteen gradual psalms are intended to represent to the mind, that we only arrive at the perfection of goodness, or holiness, by degrees. He goes on to lay down the fifteen degrees of virtue, corresponding to the fifteen psalms; five of them are for beginners; five for proficients; and the rest for the perfect.

GRADUATE; a person who has the degrees of any faculty: a graduate in physic, in divinity, in music, &c. See **DEGREE**, **DOCTOR**, &c.

This privilege of graduates is no older than the fifteenth century: it being observed, that men of learning were much neglected by the collators, and patrons of churches; complaint, therefore, was made to the council of Basil, where this decree was made; which was afterwards confirmed by the Pragmatic Sanction, and again by the Concordat.

GRADUATION of Astronomical Instruments, is the dividing of a circle, or of some aliquot part thereof, into degrees and its sub-divisions, on the limb of any instrument that is used for measuring angles with a great degree of accuracy. (See the article **DEGREE**.) When the instrument to be graduated is of a portable size, admitting of only a small radius of curvature for the limb that is to be divided, the operation is very readily as well as accurately performed by an engine, such as Ramsden's or Troughton's, the former of which we have described under the article *ENGINE for dividing Circles*, &c. but when the radius of the instrument is too large to admit of division by an engine, the task of graduating, by the determination and adoption of original dividing points or lines, requires no ordinary portion of skill, manual dexterity, and perseverance to be united. Before the establishment of the Royal Observatory at Greenwich, the art of graduating was in a rude state, but a desire to have this institution furnished with superior instruments of observation has stimulated the different astronomers royal, successively, to encourage the talents of superior artists from time to time, till at length such perfection is attained, that little more can now be hoped for in the improvement of our best English instruments. The history of the art of graduating astronomical instruments, and the gradual development of the most convenient and most accurate modes of proceeding, together with the difficulties to be surmounted in the various stages of progress towards perfection, will be best explained by a concise detail of each successive method of dividing, that has been practised, agreeably to the order of time; and by remarks arising out of each detail, as they most naturally occur.

We know not sufficient of the astrolabes of Hipparchus and Ptolemy to enable us to give any satisfactory account of the nature and accuracy of their divisions and sub-divisions, though it is probable that the graduated circles on them contained each 360°, agreeably to the Egyptian mode of dividing the circle. Neither can we give a very perfect description

scription of the manner in which Copernicus, long afterwards, had his astrolabe and meridian quadrant graduated, though we have shewn under our article CIRCLE that his parallactical instrument, with which his altitudes were chiefly taken, had its limb divided by equal divisions that were the subtenses of $3' 49'' 137$ each.

Tycho Brahe's instruments had the advantage of a long radius, which rendered any inequalities that might occur in his divisions of less value than they would have been in instruments of short radii; the smallest sub-divisions into which he professed to mark his spaces were $10'$ each, and the single minutes and portions of a minute, even to $15''$ and $10''$, were indicated by triangular diagonals; but with what degree of precision the sub-divisions were effected, and what dependence could be placed on his diagonals, as to accuracy, at this distance of time, it is not an easy matter to ascertain: it is recorded, however, that the operation of graduating his instruments was performed by his own manual labour.

And what we have here said of the instruments of Tycho Brahe, is equally true of the *machina celestis* of Hevelius; whatever accuracy his apparatus possessed, was the result of his own persevering industry, but we are not aware that his method of proceeding had been particularly detailed.

In Dr. Hook's *Animadversions on the Machina Caelestis* of Hevelius, 1674, this very ingenious mechanist has published an account of his method of racking the exterior edge of the limb of his quadrant, as performed by Tompion, which method, he says, "does not at all depend upon the care and diligence of the instrument-maker, in dividing, graving, or numbering the divisions, for the same screw makes it from end to end." But, as Smeaton has very properly observed, this inventive contriver has not given his reader any precautions or particular directions how the perfection of the screw is to be ensured, or how the notches of the rack work are to be rendered perfectly equal among themselves, notwithstanding the unequal densities, and hardness of different portions of the metal so racked. The difficulties alluded to here, were acknowledged by the duc de Chaulnes, in a memoir of the Royal Academy of Sciences at Paris, published in the year 1765. The doctor called the account of his method, "an explication of the new way of dividing," and as an original invention, it may probably be called his own, though the want of a perfect screw, with intervals exactly proportioned to the effective radius of his quadrant, was a source of error, that posterior contrivances were required to remedy. See ENGINE (by Ramsden) for cutting the screws of the circular dividing engine.

The use of Dr. Hook's screw for racking the limb of an astronomical instrument was not, however, abandoned, without a fair trial of its accuracy in reading the quantity of the angles so measured; for Flamsteed, (or Flamsteed,) on his appointment to the Royal Observatory in 1676, employed Tompion to construct him a sextant of six feet nine and a quarter inches radius, at the expence of Jonas Moore, with an endless screw of seventeen threads per inch, acting on the racked edge of the limb, and with telescopic sights, which had not been before used: the result of this trial was, that some shake took place in the notches, that were worn by the screw, and frequently an error of a whole minute in reading an observation was unavoidably produced thereby. To remedy this evil, in the following year degree spaces, with diagonal divisions to read to the accuracy of $10''$, were added as a check on the measures of the screw, and a column, to contain the check angle by diagonal lines, was filled up from the 11th of September of the year 1677. These additions, it appears, from the *Prolegomena* of the *Historia Caelestis*, were inserted by Flamsteed himself, and a comparison of the screw with

the diagonals proved that an error of as much as *one minute* was frequently the result of the reading by the screw. In an observation of the moon, taken on the 9th of June 1687, Smeaton says, that on looking over the observations, he detected an error of $55''$, which, upon a radius of six feet nine inches, he calculates amounts to more than $\frac{1}{50}$ th part of an inch. The screw, however, was useful for giving a regular slow motion to the telescopic sights, and though its use, as an accurate measure of a large arc, was soon abandoned in astronomical instruments, it has been retained as an excellent mode of producing a slow motion, by the aid of a tapped clamping piece, and has been applied with great success to the limb of a dividing engine, which, being a complete circle, admits of equalization of the contiguous notches, by a long continued simultaneous action of several threads of a very perfect screw, carried many times all round the circle, when the exact situations of distant notches have been ensured by the checks afforded by accurate divisions, previously made on its plane.

Notwithstanding what we have above said of the imperfect measurement of an angle by the screw, it was not relinquished without another trial in Flamsteed's time, by Abraham Sharp, his amanuensis, to whose skill and dexterity in manual operations of a mechanical nature both Flamsteed and Smeaton have borne ample testimony; the latter of whom says, "I look upon Mr. Sharp to have been the first person that cut accurate and delicate divisions upon astronomical instruments." The instrument at which Sharp laboured, and to which he applied the screw in conjunction with the diagonals of the divided spaces, in 1689, was the *mural arc* at Greenwich, of which the radius is six feet seven inches and a half. "But yet," says Smeaton, in his paper on this subject, read November 17, 1785, at the Royal Society's room, "whoever compares the different parts of the table for conversion of the revolutions, and parts of the screw belonging to the mural arc into degrees, minutes, and seconds, with each other, at the same distance from the zenith on different sides, and with their halves, quarters, &c. will find as notable a disagreement of the screw-work from the hand-divisions, as had appeared before in the work of Mr. Tompion; and hence we may conclude, that the method of Dr. Hook, being executed by two such masterly hands as Tompion and Sharp, and found defective, is in reality not to be depended on in nice matters."

This inference of Smeaton obviously implies, that what he calls the *hand-divisions* of the mural arc, are more accurate than the readings by the screw alone; but, as he has given no other test of the accuracy of these hand-divisions, nor has explained by what process they were inserted, the more legitimate inference would have been, that either the screw, or the hand-divisions may be faulty, or both may be so in their respective degrees. It is to be regretted that Sharp, who was a mathematician as well as a mechanist, has not published the method he adopted of marking out and cutting his dividing lines, which is more immediately the subject of our present article. Had he made his hand-divisions first, and checked his notches, made by the screw, thereby, as Ramsden did with his engine afterwards, his measures by the screw would have been more perfect, though the centre-work might have been liable to be galled by too much pressure of the screw against the notched edge of the instrument, when frequently used.

Nearly about the time that the mural arc was fixed at Greenwich, Olaus Roemer, the Danish astronomer, supplied his domestic observatory with an instrument that had divisions and telescopic sights moving in the meridian, by means of a long axis, common to both the divided arc and telescope, which

GRADUATION.

which therefore admitted of better adjustment for the vertical motion than the mural arc was capable of; and which may be considered as the first *transit instrument* that properly deserves such a name. In dividing his arc, Mr. Roemer disregarded the total length, with respect to an exact number of degrees, and looked more particularly to the equality of the divisions, which were convertible into degrees and minutes, by a table calculated for this purpose. The method he made choice of, for rendering his divisions equal, was to begin at one end of his arc, and to proceed by stepping, and by marking the dividing points with a proper pressure at each step, till the whole arc was finished: for this purpose he did not depend on a pair of dividers, however strong their legs, but two fine pointed pieces of strong tempered steel were tied, or otherwise fixed together in such a way, that the distance between the two points was $\frac{1}{4}$ th or $\frac{1}{5}$ th of an inch, and the radius of the arc to be divided was so proportioned, from $2\frac{1}{2}$ to 3 feet, that this distance made a space very nearly equal to $10'$; whether exactly so, or not, did not signify, as the difference was allowed for by the calculated table, when an angle had been read by the divided spaces as numbered. It is easy to conceive that this mode of measuring an angle would be as accurate as any other, after the due allowance was made, provided the spaces were perfectly equal to each other; but the theory of this method is more perfect than the practice; for none of the mixed metals is so perfectly uniform in its density, and so free from hard particles, occasionally met with by the stepping points, as to ensure the perfect equality of the divided spaces, however carefully the stepping points are pressed in a vertical direction; the smallest deviation on making the first impression becomes greater by pressure, and an attempt to rectify any erroneous points can never be depended upon: but, what is worse, every individual deviation from perfect equality is charged on the whole arc, which therefore will be either longer or shorter than the true length, by the aggregate of all the positive, or negative quantities, that predominate in the inequalities of the individual spaces thus divided; and the longer the arc is from the first point, when any angle is measured, the greater is the error of the measurement in all probability, because the greater is the probable aggregate of the deviations from perfect equality in the spaces. The total arc thus divided was about 75° ; but as Roemer applied no correction to the errors of the distant divisions of this arc, no dependence could be placed on the result of the readings, even when converted into degrees and minutes by his table, which supposed the arc perfectly divided.

The next ingenious artist who distinguished himself in the art of graduating astronomical instruments, was the celebrated Graham. At the appointment of Dr. Halley to the Royal Observatory of Greenwich, Flamsteed's instruments were removed by his executors, and in the year 1725, Graham undertook the construction of a new mural quadrant, which remains as a standing proof of his skill, to this day, in the said observatory. This artist availed himself of every contrivance that had been practised by his predecessors, and invented such a strong, and, at the same time, light method of constructing the frame-work of the iron quadrant, constructed by Jonathan Sisson, as evinced his superior knowledge of mechanics, as well as Sisson's precision in the workmanship. The diagonals were now rejected, as being incapable of being read by a fiducial edge with requisite exactness, and the vernier scale was substituted as much preferable in this respect, and the beam-compass, with equal advantage, was substituted for the ruler and dividing knife, which were liable to considerable parallax, notwithstanding

the greatest precaution taken in drawing the dividing lines, or in marking the dividing points. The screw for slow motion was also used for dividing the vernier scale in a proper way, after its value was ascertained; and its perfection was ensured, with respect to the due inclination of its threads all round, as well as to the equality of their spaces: and lastly, in order that the advantage of *continual bisection* might be introduced as a *check* on the degree spaces, the quadrant was divided in 96 spaces, with sub-divisions, in a separate arc: and the readings from the 96th arc were a constant test of the readings by the 90, when converted into degrees and minutes by calculation, or by a table used for that purpose.

As it is not our intention to describe here the structure of Graham's quadrant, but merely to describe his method of graduating the limb of brass, which was laid over the iron frame, we shall satisfy ourselves by stating that two separate arches were struck by a beam-compass, secured from bending by several bracing pieces; the respective radii of which were 96.85, and 95.8 inches. The inner arch was divided into exact degrees, and twelfth parts of a degree, or $5'$ spaces; but the outer one was divided, as we have said, into 96 equal parts, and each of these again sub-divided into 16 equal parts, so that the sub-divisions were 10 each other as 1080 : 1536, or in smaller number, as 25 : 32. To convey to the reader an idea how the arcs were divided, suppose the quadrant to be represented by *fig. 1.* of *Plate XVIII.* of *Astronomical Instruments*, and that the occult line *a b d* be required to be divided into degrees by points inserted thereon, as centres for cutting the dividing lines from; the known property of the circle, that the chord of sixty degrees is always equal to the radius, afforded the means of laying down the total arc of 90 in the first place; thus, from the point *a*, or zero of the arc, the point *b* was marked by measurement of the same points of the beam-compass unaltered, that struck the occult line; and this arc of 60° was bisected at *c* by an extent nearly equal to the chord of 30 from the points *a* and *b* respectively; the extent, however, being a trifle less than the chord of 30 , the two sweeps did not intersect each other, but approached so nearly together, that the small space between the sweeping lines was bisected by a point put in by hand, by the assistance of a magnifying eye-glass: the distance of this point *c* from *a* or from *b* being the chord of 30° , was laid along the limb from *b* to *d*, the extreme point of the whole arc of 90 , and when this operation was so carefully performed, that the arcs *a c*, *c b*, and *b d* were precisely of the same length, when compared with each other, the total arc might safely be depended on, as being of its true dimensions. During this nice operation, it was presumed, that the length of the dividing beam had not altered by any variation of temperature. The next step was to bisect each of those three arcs of 30 into six of 15 each, in the same manner as *a b*, the arc of 60 , was bisected into *a c* and *c b*: but the arcs of 15 were not divisible into a lower number than three parts of each 5 ; in order to tripartite each arc of 15 , a separate arc was used, as an arc of trial, described by the original radius unaltered, and $\frac{1}{3}$ 15 were transferred to it, and divided by trial till one-third of it was ascertained to measure exactly the distance between the two points of the compass; this distance was then laid off each way from each of the afore said points of the arcs of 15 , and the second space of each being found equal to their contiguous first and third spaces thus measured, the whole arc was sub-divided into 18 equal arcs of 5° each: in the same manner, a fifth part of one of the arcs of 5 , first transferred upon another part of the arc of trial, was ascertained by repeated adjustments and examinations, and then inserted within the divisions of the

GRADUATION.

divided arc, by turning the points over twice each way, from every point already laid down, and then the middle space of each five being found equal to the extreme as well as contiguous spaces respectively, the whole arc was subdivided into points of one degree of distance from each other. But to ensure a perfect equality among these spaces required great steadiness of hand, as well as observation of the eye, and caution, to preserve the regulated distances of the points, unaltered during the operation. Of course, the marking point was required to be fine, and at the same time well tempered, as well as strong enough to bear pressure, which pressure was also necessary to be made in a perpendicular direction on the face of the limb. The sub-divisions of the degree spaces into 12 parts of 5' each, were done first by trisection, and then by bisection, or *vice versa*, in the manner we have already described; and the delicacy of these operations, on so small a scale, required extraordinary attention and care to ensure perfect equality among the smallest sub-divisions, which were now in a state to be transferred by lines tending to the centre of the arc to be graduated. This was an operation that could not be done well by the straight edge of a rule, and a marking point, or dividing knife that would be liable to deviate a little, notwithstanding the greatest care; here another, but smaller beam-compass was substituted for the ruler, probably for the first time, for the purpose of transferring the graduated points from the occult arc into the arc to be graduated, in the following manner; suppose the points *g* and *e* to be intended to be transferred; because the lines to be cut, as the dividing lines, are required to be in a direction tending directly towards the centre *o* of the concentric arcs, described on the limb; the distance of the cutting point, from the stationary point of the compass, was taken of such a length, that the cutting point crossed the arc to be cut at right angles, or, in other words, the beam was so situated, as to become a tangent to the arc to be cut; therefore the distance of the two points of the beam was regulated by the distance of the occult line of dots *e*, *b*, *d*, from the arc to be graduated by the straight lines, or rather by the curved lines, which in fact were substituted, and which passed without sensible error for straight lines, when the tangent line in question was long. From the point or dot *g*, the curve *b k* was drawn, and from the dot *e* the curve *f i*; but in such a way that a small portion only of each, that lies between the circular lines, was cut on the face of the instrument. In the same manner all the other dots were successively transferred, while each representative of the numerals 5, 10, 15, &c. were made longer than their intermediate lines of division, and the sub-dividing lines were again still shorter. The vernier carried by the telescope, when nicely and accurately divided, would detect any inaccuracy in the sub-divisions thus transferred, by the aid of a magnifier properly adjusted.

The arc of 96 divisions, with their sub-divisions, was not, properly speaking, graduated, but divided and sub-divided into portions of smaller value than degrees, and 5' spaces; but as the number chosen is divisible continually by the number two, it was completed by continual bisections, which method therefore requires no further explanation. We are told by Dr. Smith (in his Optics) that these two arcs were never found to differ from each other more than 5" or 6' on any part of the limb, but that when there is such difference, the preference ought to be given to the bisected arc of 96 divisions.

To prove that the spaces obtained by the lines of transfer are equal to those between the corresponding dots or points, let *e f* and *g h* be joined, also *o f*, *o b*, *o e*, and *o g*; and the triangles *e o f*, *g o b*, will be every way similar, and equal to each other; therefore, if the common angle *e o b* be taken

away from the equal angles *e o f*, *g o b*, the angles *e o g* and *f o b*, that remain, will also be equal to each other.

It does not appear that Graham took any measures to guard against, or even to detect the errors that his method of dividing is liable to, from variations of temperature in his quadrant and beam, during the time that the operation is going on, and from the corresponding variations of length in the metals, according to their respective expansibilities; nor is it quite certain that he was aware of the probable extent of such errors, seeing he constructed the frame-work of his instruments of iron, and had his circle to be divided of brass. In Dr. Bradley's zenith sector made by Graham, Dr. Maskelyne has caused an iron limb to be substituted for the original brass one, and has had the points of division inserted on studs of gold, to avoid the errors that arose from the unequal expansibility of the different metals.

We might here mention Mr. H. Hindley's plan of dividing a circle by a toothed circular plate and endless screw in form of an engine, about the year 1740, but that we think his method of dividing and drilling the holes of his plate, by bending a straight slender bar of brass into a circle, and transferring the holes therefrom, cannot be depended on where much accuracy is required in the divisions of a circle. It was originally intended, and is much better calculated, for dividing and cutting the notches between the teeth of a wheel; but the reader may see the plan described, and some improvements on it proposed by Smeaton, in his paper already mentioned, as contained in the Philosophical Transactions of London, in the year 1785.

Jeremiah, the son of Jonathan Sisson, was of Graham's school of dividing, and did nearly as much justice to the method he adopted, as Graham himself, probably; and his nice care, and persevering assiduity, have classed him among the first dividers of his time; but we are not aware that he was the inventor of any original contrivance, except, perhaps, that he applied a triple index to some of his instruments, one of which had the vernier, and each of the others had a single line or stroke drawn at one-third of a circle from each other, and from zero of the vernier, which might act as a check on the eccentricity of the circle, as well as on the inequality of its divisions; though it does not appear certain that this was the original intention, as the three props of his vernier-bar in his theodolites required it to be triple; but in his circular indexes one stroke only was made, and that opposite the vernier: the importance of a triple vernier has not been noticed particularly by any one, previously to the time of Mr. Ed. Troughton's introduction of the triple vernier into his circular instruments. Mr. Ludlam, however, says, that Sisson very early rejected the method of trisection, and that of stepping too. "Having (by means of the radius and bisections only) divided his quadrant into three arches of 30 each, he set off in each of these arches the chord of 21' 20", or 256 times five minutes. This chord was taken off a scale of equal parts, and was checked by the chord of 8' 40", both chords together filling up the arch of 30°. The arch of 21' 20" was divided by continual bisections into arches of five minutes each." This description, says Mr. Ludlam, in a note to page 4, of his Introduction and Notes on Mr. Bird's method of dividing, was given by Jeremiah Sisson, in a private letter dated May 20, 1766; and according to the same letter it appears also, that Sisson placed the fixed or central point of his compass in a blank tangential line, as hereafter described by Bird, during the operation of transferring the divided points into linear divisions; but as Bird has in the year 1767 published these processes as originally his own, and as he worked for the Sissons previously to 1766, we are disposed to consider Bird, and not

either

GRADUATION.

either of the Siffons, as the real contriver of the methods here adverted to. Siffon (the younger) rejected the arc of 96, as being only a help to a bad divider; but Bird used to retort on him, by saying, that good dividing was not afraid of such a test of its accuracy.

It is the characteristic of a great genius in mechanics, not to tread too closely in the steps of his predecessors, but, availing himself of any hints that may have been presented to him, to mark out a more direct and even path for himself, that shall throw in his way fewer obstacles to impede his progress. This was the case with Mr. Bird, who, having been brought up a cloth-weaver in the county of Durham, and having noticed some very coarse divisions on the face of a clock that fell in his way, immediately set about dividing one himself, in a much neater manner, and was so pleased with his success, that in the year 1740 he came to London, and was in business for himself as an instrument-maker, only five years afterwards. After having made himself acquainted with the methods at that time in use of dividing a circle, he saw that no one had guarded against the errors produced by the effects of variable temperature on the beam of the compass, as well as on the metal of the scales and circles to be divided; he also saw that bisection of an arc had so much advantage over trisection, or quinquesection, that he abandoned the latter modes of dividing altogether, and was the first probably to compute chord-lines, to be taken from a good *vernier* (what he calls *nonius*) scale, by the beam-compass, in order to determine such points in an arc of 90°, as may enable a division by continual bisection to be adopted, and at the same time such as may be laid down without loss of time, or, in other words, without sensible change of atmospheric temperature.

We cannot better describe Mr. Bird's method of dividing astronomical instruments than by using his own words. "The requisites," says he, "for the performance of this work are as follow: A scale of equal parts, by which the radius may be measured to 0.001 of an inch must be provided. My scale is 90 inches long, each inch divided into 10, contiguous to which are nonius (*vernier*) divisions, *viz.* 10.1 inches divided into 100 equal parts, shewing 0.001 of an inch, and by the assistance of a magnifying glass, of one inch focal length, a third of 0.001 may be taken off by estimation.

"Provide fine beam-compasses, to which magnifying glasses of not more than one inch focal length should be applied. Let the longest beam be sufficient to draw the arcs, and measure the radius; the 2d to measure the chord of 42° 40'; the 3d to measure the chord of 30°; the 4th, 10 20'; the 5th, 4° 40'; and if a sixth, to measure 15°, be made use of, so much the better.

"The radius of the arc of 90° at the points is equal to 95.938 inches, from which the following numbers were computed, *viz.* 49.6615 inches = chord of 30°; 25.0448 inches = chord of 15°; 17.279047 inches = chord of 10° 20'; 7.81186 inches = chord of 4° 40'; and 69.80318 inches = chord of 42° 40'. Having drawn the several arcs, between which the divisions were to be cut, the radius and the lengths of the above chords were taken by the beam-compasses, which, together with the scale, were laid upon the quadrant, where they remained till the next morning; during which time the door of the room was kept locked. Before sun-rise I re-measured the radius, which required some correction; the beam being of white fir, and the scale of brass, which probably contracted, while the beam remained unaltered; the other beam-compasses also required correction. Now the quadrant and scale being of the same temperature, the faint arc *b d* (*fig.* 2. of

Plate XVIII. of *Astronomical Instruments*.) was struck, and with a very fine prick-punch (*pointil*) the point *a* was made; with the same beam-compass unaltered I laid off from *a* to *e* the chord of 60°, making also a fine point: with the chord of 30° *a e* was bisected in *c*. Now one point of the beam-compasses containing 60' was fixed in *c*, and with the other was marked the point *r* or 90°: next, with the beam-compasses containing 15°, was bisected *er* in *n* or 75°; from *n* was laid off the chord of 10° 20'; and from *r*, 4° 40'; which two last chords joined exactly in *g*, being the point of 85° 20': now each degree being to be divided into 12 parts, or every 5', therefore, $85 \times 12 + 4 = 1024$, a number divisible by continual bisections. The last chord computed was 42° 40', with which *a g* was bisected in *o*; *a o* and *o g* were bisected by trials: but, whoever undertakes to divide a large quadrant, will do well to compute also the chord of 21° 20'; but for this chord any of the beam-compasses already provided, which will take in the length, may be used. The point *g*, being formed as above, I proceeded, by continual bisections, till I had the number required, *viz.* 1024. To fill up the space between *g* and *r*, containing 56 divisions, the chord of 64 divisions was laid off from *g* towards *d*, and divided like the rest by continual bisections; as was also from *a* towards *b*. The points 30°, 60°, 75°, and 90°, fell in without any sensible inequality."

So much will suffice for giving a general idea of Bird's proceedings, in *dividing* his astronomical instruments; but his method of transferring the divided points into dividing lines was equally original, and guarded also against errors that might arise from the handling of the beam during the operation, by variable temperature; before, however, we proceed to detail this process, it may be proper to observe, that the points made on the faint circle were inserted by a *pointil*, or piece of steel-wire, with a conical point made fast into a piece of cylindrical brass rounded at the upper end: the steel part was $\frac{1}{15}$ th of an inch thick, and $\frac{3}{4}$ ths of an inch long, and the brass part 2½ long, and $\frac{1}{4}$ th of an inch in diameter. The angle of the steel conical point was from 20° to 25°, and the point somewhat above a spring temper, so that the point made in the circle did not exceed 0.001 of an inch; as it was sharpened on an oil-stone while turning round, and while drawn in a direction outwards from the point itself, the surface partook of the nature of a conical shape when gently pressed on, as it revolved in the point of bisection, which point, by reason of the four angular burrs made by the intersecting lines, could be felt as well as seen. The points of the beam-compasses were never made to approach nearer to each other than two or three inches, but at the ends of the arcs spring dividers, with conical points, were substituted to measure small arcs. Another precaution was, that in all bisections, the place to be pointed was laid off from left to right, and then from right to left, from the respective central points.

As the maxim, "that an arc may be bisected, but not practically trisected or quinquesectioned with certainty," was the maxim adopted by Bird, when he introduced the use of his scale for measuring the chords, so the maxim, "that a right line cannot be cut on brass, so as accurately to pass through two given points, but that a circle may be described from any centre, to pass accurately through a given point," was taken up by him when he adopted the beam-compass, as Graham and Siffon had done, for cutting the small portions of a circle, instead of perfectly straight lines, as boundaries of the divisions. His plan of doing this, however, was new, as may be seen from his own words.

"The next step," says he, "is to cut the linear divisions

GRADUATION.

from the points : the best instrument for this purpose is the beam-compass, having both its points conical and very sharp. Draw a tangent to the arc bd , suppose at e , it will intersect the arc xy in g , this will be the distance between the points of the beam-compass to cut the divisions (nearly) at right angles to the arc bd . Lodge that point of the beam-compass next your right hand, in the point r ; let the other fall freely into the arc xy ; press gently with your finger upon the screw-head that fastens the socket (and that is convex), and with the point towards the right hand cut the divisions. In this manner you must proceed with the rest."

The intention of transferring the central or resting point of the compass into a blank tangential line, instead of suffering the said point to rest in the respective points made in the faint arc, is, that in the former case should any alteration take place in the length of the beam, during the operation of cutting, no error is charged on the divisions cut, but the alteration is compensated by the distance of the newly made point in the tangential line from the cutting point; that is, each division is charged only with such a minute error, if any, as arises from temperature during the act of cutting a single stroke, and if one of the points should break, another may be replaced without inconvenience; whereas, by the method of Graham, a broken point produces considerable difficulty; and the whole error arising from temperature, during the whole process of cutting all the divisions, is charged not only on the total arc, but likewise in a certain undivided degree on each of the whole divisions. This idea of getting quit of the effects of temperature is ingenious, but has been objected to as liable to the ill effects of stepping in a certain degree, inasmuch as that a hard particle, lying under the point of rest, may cause a little deviation in the distance, before the stroke is cut. This objection, however, was not allowed to be realized by Bird, who no doubt must have obviated it by some other plan, had he found any real inconvenience arising from it. Great care, notwithstanding, must have been taken in setting down, and pressing on the point at rest, in a perpendicular direction. Another objection applied to Mr. Bird's scale, from which the chord-lines were measured, inasmuch as the scale itself might be erroneous in some places, and would impart its errors to the arcs measured from the computed chords taken therefrom.

Besides the arc of 90° , the mural arc by Bird had an arc of 96 divisions, like Graham's, divided by continual bisections, till each of the 96 divisions had 16 sub-divisions, as a check on the accuracy of the arc of degrees; but subsequent dividers of astronomical instruments have found this superfluous, as being in the opinion of others, as well as of Jeremiah Sisson, a check only on bad dividing, and as rendering the reduction of observations troublesome, when made thereby.

The vernier was retained by Bird as the best method he knew of sub-dividing the 5' spaces into quantities of 30" each, which was the smallest angle he professed to measure; and to effect his purpose he made ten divisions on his vernier equal to eleven on the limb of the instrument, first by computing the chord of thirty-two parts, and then by taking ten out of those parts, when bisected, as the proper divisions for the vernier; these, being made in points, were also transferred by a tangential line into linear divisions by the beam-compass, as before described; but great care was taken, that the stroke zero on the vernier was drawn from the quadrant's centre, precisely parallel to the line of collimation of the telescope. Mr. Ludlam says, that the cutting-point which Sisson used was flat in the knife-edge form, but that Bird's was a triangular prism, with a slope ground down to

a point at one of the angles; which formed the cutting-point.

At the request of the commissioners of the Board of Longitude, Mr. Bird, in the year 1767, published his method of dividing in a quarto pamphlet, for which they rewarded him with 500*l.* besides 60*l.* for his plates, after having bound him to instruct an apprentice of seven years in the art of constructing and dividing astronomical instruments.

Mr. Smeaton is of opinion that Bird's method of dividing may be improved in one respect, and expresses himself on the subject thus:

"I must here observe that I apprehend no quadrant, that has ever undergone a severe examination, has been found to form a perfect arch of 90° , nor is it at all necessary it should; the perfect equality of the divisions throughout the whole is the first and primary consideration; as the proportion of error, when ascertained by proper observations, can be as easily and readily applied when the whole error of the right-angle is fifteen seconds, as when it is but five. In this view, from the radius taken, I would compute the chord of $16'$ only. If I had an excellent plain scale, I would use it, because I should expect the deviation from the right angle to be less than if taken from a scale of more moderate accuracy; but if not, the equality of the divisions would not be affected, though taken from any common diagonal scale. This chord, so prepared, I would lay off five times in succession, from the primary point of 0 given, which would complete $80'$; I would then bisect each of those arches of $16'$, as prescribed by Mr. Bird, and laying off one of them beyond the 80th, would give the 88th degree, proceeding then by bisection, till I came to an arch of $2'$, laying that off from the 88th degree, would give the point of 90° . Proceeding still by bisection, till I had reduced the degrees into quarters of $15'$ each, I would there stop, as from experience I know that when divisions are over close, the accuracy of them, even by bisections, cannot be so well attained, as where they are moderately large. If a space of $\frac{1}{4}$ this of an inch, which is a quarter of a degree, upon an eight feet radius, is thought too large an interval to draw the index over by the micrometer screw, this may be shortened by placing another line, at the distance of one-third of a division on each side of the index line, in which case the screw will never have to move the index plate more than one-third of a division, or $5'$, and the perfect equality of those side lines from the index line may be obtained, and adjusted to $5'$ precisely, by putting each of the side lines upon a little plate, capable of adjustment to its true distance from the middle one, by an adjusting screw. The above hint is not confined to the chord of $16'$, which prohibits the sub-division going lower than $15'$; for if it be required to have divisions equivalent to $5'$ upon the limb itself, then I would compute the chord of $21' 20''$ only; and laying it off four times from the primary point, the last would mark out the division $85^\circ 20'$, pointed out by Mr. Bird, supplying the remainder to a quadrant from the bisected divisions as they arise, and not by the application of other computed chords." Mr. Smeaton, sensible, however, that this method of laying $16'$ five times over, or $21^\circ 20'$ four times over, may be objected to, as liable to the errors of *stepping*, arising from Roemer's method, afterwards proposes to lay down the chord of $64'$, or of $85^\circ 20'$, from computation all at once, and then to bisect, and complete the quadrant from the bisected divisions, which Mr. Bird himself prescribed as a good method for Hadley's sextants and octants. But these plans are now superseded for instruments of small radius by the dividing engine, which performs the work with great expedition, as well as accuracy, and the original methods of dividing the circle are only useful for the larger

GRADUATION.

larger instruments, and for the finishing of the dividing engines themselves.

In the year after Mr. Bird had published an account of his method of dividing astronomical instruments, the duc de Chaulnes printed in French a folio work, entitled "Nouvelle methode pour diviser les Instrumens de Mathematique et d'Astronomie," and also a work proper to be bound with the former, called "Description d'un Microscope et de differens Micrometres destinés a mesurer des parties circulaires ou droites avec la plus grande precision." The former of these pamphlets contains 15 plates, and the latter six, which exhibit plans and drawings in different points of view, of all the apparatus, both in pieces and together; these are not necessary to be copied by us, but we will describe them as far as they fall within our present purpose. This new method of dividing is performed by the assistance of compound microscopes, with cross hairs in the focus of the eye-glasses of each, to be fixed to the circle to be divided in any given situation, and of moveable pieces of brass with fine dividing lines marked thereon, which may be so fixed with wax, as to be adjustable to the point of intersection in the focus of any of the microscopes, and when duly adjusted, a sliding point-trail, moving in a complex frame of brass, cuts the line, on the circle to be divided, that shall correspond to the point of the circle where the adjustable division is fixed; though the line cut is not in the same part of the circle. As this method may be considered as the ground-work of Ramsden's method of dividing a large circle, and has not, that we know of, been translated into our language, we will give the substance of that part of the work which more immediately relates to our present subject, without following the author through all his minute details. The circle, which the duc de Chaulnes proposes to divide by his original method, is the table of his dividing engine, but as it is equally applicable to any circle that may be fixed concentrically on it, we will suppose it an astronomical circle for altitudes or azimuths that is to be divided by his method. In the first place, he proposes to have from 30 to 40 thin pieces of smooth brass about one-third of an inch long, and one-sixth broad, having each a fine stroke drawn across, perpendicular to the long sides and just deep enough to be seen; and secondly, three compound microscopes are to be provided, one to be fixed diametrically opposite the point-trail, or cutting point, that is carried in and out, *i. e.* towards and from the centre of the circle by an adjustable frame, and the other two are adjustable to any given points along the plane of the circle to be divided. When the circular lines are struck on, the adjustable microscopes, which we will call A and B, are placed as opposite to each other, in a diametrical line, as can be guessed, or roughly measured by any of the ordinary means, and a moveable division on a piece of brass already described, is put by means of wax under each of the two microscopes, and moved by hand, till the lines, which must be in a radial direction, fall respectively under the centres or intersecting points of the fields of view; these microscopes, it must be understood, are fixed, not on the table which bears the circle, and which is made so as to revolve on a long vertical axis, but on a fixed or stationary surrounding frame, that is unconnected with the table itself, when the table is at liberty to revolve; suppose now the table and circle on it to be carried half round, while the microscopes remain fixed, in such a way that the moveable division which was under the microscope A, falls under the centre of microscope B; in this situation, if the opposite division falls under the centre of A, the circle is truly bisected; but as this is not likely to be the case at the first trial, the quantity that is over or short must be adjusted, one

half by the moveable division, and the other by the microscope, and the operation of reversing must be repeated, and the rectifications made, till the circle is found to be truly bisected, both backwards and forwards, by the coincidence of the divisions with the intersected points in each focus of the microscopes. The two microscopes A and B may now be removed, and the third or fixed microscope must be made fast over one of these two dividing strokes, after the point-trail has been brought precisely to occupy the place of the other, in which situation the point-trail and the fixed microscope will stand so diametrically opposite each other, that whenever an adjustable line is brought to bisect the field of view of this microscope, the point-trail will be ready to cut a line on the opposite side of the circle, and whenever a set of adjustable divisions are properly placed, by the wax, on one semi-circle, the lines in the other semi-circle, directly opposite these respectively, can be permanently cut, before the moveable pieces are taken off, and afterwards the said lines so cut may be brought successively under the fixed microscope, in order that their opposites, where the moveable pieces were stuck on, may, in like manner, be cut; so that one-half of the circle will be sufficient to be divided and sub-divided by the adjustable pieces, seeing that each of its divisions and sub-divisions, brought in succession under the fixed microscope, may be instantly transferred by the point-trail, into the opposite semi-circle, and also these in their turn transferred back again. Let us now see how the semi-circle is divided and sub-divided by means of the two microscopes A and the fixed one, B being no longer wanted; the first operation is the trisection of it into arcs of each 60°; for this purpose, while the point-trail remains at T, (*fig. 3. of Plate XVIII.*) one of the points cut, *viz.* at 180°, and the fixed microscope rests at Z, or zero, *i. e.* the first point of the circle, to be figured 0 or 360; two moveable pieces are stuck on at C and D respectively, so as to trisect the semi-circle Z B T very nearly, and the microscope A is placed directly over C, so as to view its stroke or line at the point of intersection in the focus of the eye-glass; there it is made fast for the present; the line C is now brought under the fixed microscope at zero, by making the circle revolve, and suffered to remain; the piece D has its stroke put under the microscope A, as before was the case with piece C, now at zero; the circle is again made to revolve till the stroke of D is under the fixed microscope at zero; in this situation the point T, or 180°, will have been brought forward 120°, or 60° twice over, provided the pieces C and D were truly placed, and in this case an eye, looking into the microscope A, will see this dividing line bisect the field of view; but as this is not likely to happen at the first trial, the microscope must be moved one third of the error now shewn, and each of the pieces C and D another third, accordingly as the portions of the semi-circles Z C, C D, and D T taken together, are found to be more or less than an exact semi-circle. The operation we have here described is repeated again and again, till the three equidistant arcs amount to an exact semi-circle; after which they are rendered permanent, by strokes made successively on the opposite semi-circle, at the points *c* and *d*, which trisect the semi-circle T A Z, when the adjustable strokes C and D are in succession exactly fixed in the centre of the field of view of the fixed microscope. The distance between the two microscopes, which is here 60°, is called the *opening* of the microscopes, which are considered as the two points of a pair of dividers, and the arc between them is therefore denominated accordingly.

The next step is to bisect the arcs of 60° each, into two of 30°, by an opening of 30°; to do this one moveable piece, stuck at the middle of each arc of 60°, will be requisite, and
the

the two halves, to the right and left of each piece, may be examined and adjusted till the bisections are complete, and in a state to be transferred into the opposite semi-circle; for instance, suppose the arc of 60° from Z to C to be bisected, put a moveable stroke at 30° , more or less, and place the microscope A over it; make the table and circle revolve till this stroke 30° falls under the fixed microscope; in that situation, the stroke 60° ought to bisect the field of view of microscope A, and whatever the deviation may be, plus or minus, it must be adjusted by trial, partly by moving the microscope A, and partly by moving the piece with the stroke on at 30° , when brought back again under the microscope A. In the same way, any other bisection may be made within the possible opening of the microscopes. Again, the arcs of 30° are trisected, as before described, into arcs of 10° , which are all transferred into the opposite semi-circle in succession.

With respect to the division of the arcs into smaller quantities than those of 10° , where the microscopes approach too near together to admit of the necessary adjustments, an ingenious mode of sub-dividing is adopted by a property of the number 9, thus; having all the arcs of 10° round the semi-circle laid down, the points 90° and 180° are of course among them, and as these are divisible by 9, an opening of nine degrees is taken by trial, which repeated ten times, by means of the moveable strokes, will reach from 0 to 90° , when properly adjusted; besides the 10° , 20° , 30° , &c. there will now be 9° , 18° , 27° , &c. up to 90° , and also 99° , 108° , 117° , &c. up to 180° , and the differences or spaces left between the divisions obtained from 10° , and those from 9° repeated, will be respectively 1° , 2° , 3° , &c. up to 9° ; now, if the points 9° , 18° , 27° , &c. which numbers decrease by unity in the units place, be made in succession points of commencement, for the arc of 10° to be repeated from, they will from 9° produce 19° , 29° , 39° , &c.; from 18° they will give 28° , 38° , 48° , &c.; and from 27° they will give 37° , 47° , 57° , &c. and so of the rest, till all the single degrees are put on by the arc of 10° thus applied from the points derived from 9° and its multiples. The work is performed thus: make the opening of the microscopes again 10, by fixing the one called A at the tenth degree when zero is at the fixed one, then turn the table and superincumbent circle to be divided till the stroke 9° comes to zero, then a moveable piece stuck properly under A will be 19° ; bring this to the fixed microscope, and the place for 29° will be had for the next stroke, under A again; and in like manner every individual degree may be marked in succession, by taking those ending with 8, after those ending with 9 have been gone through; and after that, those ending with 7, with 6, with 5, &c. till all the numerals are included. If the circle is large enough to admit of division to 5° by the opening of the microscopes, the numbers 4 and 5 may be substituted with advantage for 9 and 10, and then the opening may be 20° for inserting them, instead of 10° , as in the mode we have described. When half degrees are required to be inserted 15° may be bisected, and the line obtained will be in the middle between 7° and 8° , from which stroke, with an opening of 15° , all the other half degrees may be marked as before, by the aid of the adjustable marks to be transferred afterwards into the opposite semi-circle, and all the strokes in that semi-circle may then be transferred back again permanently, so as to complete the circle.

The use of the numerals nine and ten, or of the four and five, is evidently borrowed from Clavius the Jesuit, whose problem for thus dividing a right line, or arc of a circle, was published in 1611.

Another method of sub-dividing the circle, when marked

into degrees, as above described, is also proposed as being less tedious, and capable of carrying the sub-divisions to a lower denomination; thus, a socket is made to fit the arbor of the revolving table that carries the circle to be divided, so tight, that it will revolve with the said arbor, or without it, as the case may be: to this socket a telescope is fixed with a vertical hair in the focus of its eye-glass, that may bisect any distant mark to which it may be directed, then a long ruler, of six or seven feet in length, is divided, for instance, into twelve equal parts, so that it may be read distinctly; the distance of this ruler is so adjusted from the telescope, that when placed at right angles to the line of collimation, it may just subtend *one degree*, which may be first calculated nearly, and then adjusted by trial, till the run of the telescope over the twelve marks of the ruler be exactly corresponding to the run of one degree of the circle under one of the microscopes. In this situation of things, the divisions of the ruler, as seen through the telescope, are, with great care and steadiness, transferred in succession, not to one of the degree spaces itself on the circle, but to a pattern-piece of brass, which may be afterwards fixed with screws under the object lens of the fixed microscope, so as to be applied in succession to each separate degree, as the circle is made to revolve, during the operation of transferring these five minute spaces, to the opposite parts of the circle, by means of the pointil. In strictness, the ruler, viewed through the telescope, ought to be a portion of a circle; but the arc and the chord of one degree are so nearly alike, that one may be substituted for the other, without sensible error. When small circles, or parts of a circle, were proposed by the duc de Chaulnes to be divided, they were fixed on the revolving arbor of the table, and the microscopes and cutting point were so arranged, that the divisions of a large divided circle were transferred to the small one in succession, and the whole apparatus, so arranged, constituted an *engine* for dividing; but the work could not be performed with such expedition as with our modern engines, where stops are substituted for the microscopes, and where the *touch* has greatly the advantage over the *fight*. With respect to the accuracy of the work performed by the duc de Chaulnes, we are greatly inclined to believe, that the sliding mechanism of the cutting-point would not secure the strokes from having a devious direction sometimes, arising from the necessary liberty that the sliding parts must have had to admit of free motion, unless, indeed, the parts of action were fitted with extreme nicety.

Lastly, the vernier scale was retained by the author before us, as the best sub-divider of the $5'$ spaces, or other small divisions; but he has not conceived it necessary to describe, in detail, how he proportioned it to the divisions of his circle, though it is easy to conceive how this may be done by the help of microscopes and the cutting-point. Our remark on this original method of dividing is, that it shews great ingenuity; but we conceive, that making an equality in the divided and sub-divided arcs will not always ensure perfection in the *angular measures*, because the axis of motion may be out of the centre of the divided circle, and the eccentricity will neither be detected by this method, nor allowed for in the divisions and sub-divisions, unless, indeed, two or three equidistant verniers were used for taking an average of the readings from different sides of the circle. It is somewhat remarkable that the same thought that introduced the microscopes for measuring the arcs to be divided, did not substitute them for the vernier, in reading off small quantities of a sub-division when an instrument was finished; which practice was left for Mr. Ramsden afterwards to adopt. The second semi-circle, being only the copy of a

GRADUATION.

copy, renders this method of dividing less worthy of imitation, as an original method, than it would have been if the imperfections of the first portion of the circle had not been necessarily transferred to the other, and from that back again. In short, we think the wax-work might have been better employed.

The elder Troughton (John) whose dividing was acknowledged to be equal to that of any of his predecessors, or contemporaries, used the beam-compasses, like Bird, but rejected the computation of chords, and the measures taken from scales, as being liable to uncertainty in determining the primary points from which the bisections were to proceed. After having described his circle, or rather quadrantal arc to be divided, he determined the point $60'$ with the radius, as Graham and Bird had previously done, and, having bisected it at $30'$, set off $30'$ in addition to the $60'$ to complete the arc of $90'$; he then bisected till he had arcs of $15'$, and again till he had $7' 30'$ in each division: the two marks nearest to $90'$ were now $82' 30'$, and $86' 15'$; but the point $85' 20'$, or limit of the largest bifunctional arc, lay between these two, and could not be obtained by further bisections; the space between the two marks in question was therefore trisected, and the more forward of the two new points was $85'$: again, the space between this mark of $85'$, and that of $86' 15'$, was trisected; from which came $85' 25'$, as denoted by the more backward of the two new marks; and lastly, a fifth part of one of the sub-divided arcs was set backwards from $85' 25'$, to $85' 20'$, the point from which the 1024 divisions were inserted from 0 entirely by bisections. The quadrantal arc was then completed from the sub-divisions thus obtained. It may be necessary, however, to observe, that the marks at first made by the radius, bisections, trisections, &c. were none of them permitted to be permanent, being of no further use than to ascertain the individual point $85' 20'$, from which the subsequent bisections were to commence. This method is considered as being preferable to Bird's method of computing the chords and using the scale, inasmuch as it does not depend on secondary or auxiliary means of ascertaining the primary point in the bifunctional arc. It has uniformity of means to recommend it in preference to those mixed methods that depend partly on computation, and partly on the extended radius.

The method of dividing a large circle, commonly known by the appellation of *Ramsden's method*, or the method of *coaxing*, consists of Bird's method, and of that proposed by the duc de Chaulnes united: the circle is first divided by the beam-compasses into primary points; and the true situation of each of these points is ascertained by opposite microscopes, as the work proceeds, and is rectified accordingly, by pushing the points forward or backward a trifle, till they are in their true places. This method, now generally practised by all the best dividers, except the present Mr. Troughton, has not, that we know of, been very particularly described, with references to drawings, &c. though it is capable of considerable accuracy in the hands of a good workman, who has perseverance enough to do justice to it. The great number of points that will require to be rectified, will, notwithstanding the utmost precaution, render the work irregular in its appearance, and a circular line must necessarily pass through the centre of all the points or conical holes, to render them concentric; besides, the bifunctional arcs deform the conical shape of the points, by passing through them, and the subsequent erasures must leave an unevenness in the metal that cannot but offend a nice eye. Sir George Shuckburgh, in his paper on the equatorial, calls

the points that have been enlarged by rectification, and burnished level again, "doubtful or bad points;" and these bear a considerable proportion to the whole. "It would," says Mr. Troughton, "be a great improvement of this method to divide the whole by hand at once, and afterwards to correct the whole; for a dot, forced to its place, as above, will seldom allow the compass-point to rest in the centre of its apparent area; therefore, other dots made from those will scarcely ever be found in their true places. This improvement also prevents the corrected dots from being injured or moved by the future application of the compasses, no such application being necessary."

The circle that is divided by this method is placed horizontally to have its first points made, after it has had its circle described from a revolution on its own axis, and then it is placed vertically in a frame, in which it revolves, and which carries the microscopes with micrometers, that sub-divide, and read to the accuracy of one second, in order that the semi-circles, taken from any given opposite points, may have their equality ascertained, or their deviation therefrom determined previously to final rectification. In these operations great attention is paid to the temperature of all the metallic parts employed in the work.

Mr. Ed. Troughton has deviated from the beaten track of his predecessors, and made a road for himself, (probably before Ramsden's plan was adopted,) that he has trodden with great success, and which he has fully described in a paper of the Philosophical Transactions of the year 1809, which gained him Copley's medal. The reason that caused him to think for himself on this subject, as he has done successfully on many others, seems to have been this: "With as steady a hand, and as good an eye," says he, "as young men generally have, I was much disappointed at finding, that after having made two points, neat and small to my liking, I could not bisect the distance between them without enlarging, displacing, or deforming them with the points of the compasses."

This discovery led to the abandonment of the beam-compasses and spring-dividers, and, the art of turning appearing to have approached the nearest to perfection of any of the mechanical arts, a *roller* was thought of, which by its revolutions might sub-divide the circumference of a circle rolled over, after the ratio of their respective diameters was ascertained and properly adjusted. When this speculation was first attempted to be realized, some circumstances occurred which could not be certainly inferred from reasoning, *a priori*, from known data, but of which a perfect knowledge was necessary for the consummation of the project; in the first place, it was found on trial, that however smooth the surfaces of the circle and roller were made, there was no *slippery* action, as might have been expected, but the points of contact acted with each other in an apparatus like that hereafter to be described, as the teeth of wheel-work of indefinitely small dimensions; the certainty of this kind of action was an indispensable condition; secondly, notwithstanding this stability in the motion of the roller, it was found to measure different portions of the metallic circle with different degrees of accuracy, some of the measures being a trifle plus, and others minus, with respect to the truth: this want of accuracy, which, as we have said, did not depend on any sliding of the roller, was expected to take place previously, in a certain undefined degree, by reason of the unequal density of hammered materials, and of their consequent unequal *porosity*; but thirdly, though there was found to be a deviation from true measurement in individual

GRADUATION.

dual portions of the circle, yet, when the roller was properly adjusted to measure the whole circle without a remainder, it was found to possess the desirable property of accommodating itself to the same track again, as often as the circuit was repeated, and consequently of arriving at the point zero again without the least sensible deviation. This circumstance, which may be considered as a phenomenon in mechanics, reproduced the hope of success, which the want of perfect regularity in measuring the intermediate portions of the circle was calculated to discourage: and a remedy, hereafter described, was successfully employed to equalize the measurements, nay, so exactly was the course of the roller found to be identically the same in every part of its circuit, that, when duly adjusted for diameter, the deviation at any individual point, from the first measure, would not exceed a *second*. This uniformity in the mode of the roller's travelling furnished the means of correcting its own inaccuracies of measurement, seeing that these inaccuracies, once ascertained, always remained the same at the same points of the circle, provided that zero of the roller started from zero of the circle, at the commencement of its first circuit. We cannot convey an adequate conception of the mechanical application of a roller to the division and sub-division of a circular instrument, without a reference to drawings of the apparatus actually used; nor can we describe that apparatus better than in the words of the author himself. The instrument, of which he has described the graduation, is a four feet meridian circle, at present the property of Stephen Groombridge, esq. of Blackheath.

“The surface of the circle, which is to receive the divisions,” says Mr. Troughton, “as well as its inner and outer edges, but especially the latter, should be turned in the most exact and careful manner; the reason for which will be better understood when we come to describe the mode of applying the roller: and as no projection can be admitted beyond the limb, if the telescope, as is generally the case, be longer than the diameter, those parts which extend further must be so applied, that they may be removed during the operation of dividing.” *Plates XIX. and XX of Astronomical Instruments* exhibit the principal parts of the apparatus; *fig. 1.* shews the plan, and *fig. 4.* the elevation of the revolving parts of the mechanism, in both of which the same letters of reference are affixed to corresponding parts, and both are drawn to a scale of half dimensions. A A is a part of the circle, the surface of which is seen in the plan, and the edge in the elevation. B B B is the main plate of the apparatus, resting with its four feet *a, a, a, a,* upon the surface of the arc; these feet, being screws, may be adjusted so as to take equal shares of the weight, and then are fastened by nuts below the plates, as shewn in *fig. 4.* C C and D D are two similar plates, each attached to the main plate, one above, and the other below, by four pillars; and in them are centered the ends of the axis of the roller E. F and G are two friction wheels, the latter firmly fastened to B, but the former is fixed in an adjustable frame, by means of which adjustment these wheels and the roller E may be made to press, the former on the interior, and the latter on the exterior edge of the circle, with an equal and convenient force; namely, by the bending of the pillars of the secondary frame, and of the axis of the roller. At the extremities of the axis of the roller, and attached to the middle of the plates C and D, are two bridges, having a screw in each, by means of which an adjustment is procured for raising or lowering the roller respecting the edge of the circle, whereby the former having its diameter at the upper edge about .001 of an inch greater than at the lower edge,

on account of its being a little conical, may easily be brought to the position where it will measure the proper portion of the circle.

Much experience and thought upon the subject have taught me, that the roller should be equal to one-sixteenth part of the circle to be divided, or that it should revolve once in $22^{\circ} 30'$, and that the roller itself should be divided into sixteen parts, no matter whether with absolute truth, for accuracy is not at all essential here. Each of such divisions of the roller will correspond with an angle of $1^{\circ} 24' 22''.5$, or $\frac{1}{16}$ th part of the circle. This number of principal divisions was chosen, on account of its being capable of continual bisections, but they do not fall in with the ultimate divisions of the circle, which are intended to be equal to $5'$ each.

The next thing to be considered is, how to make the roller measure the circle. As two microscopes are here necessary, and those which I use are very simple, I will in this place give a description of them. *Fig. 3.* is a section of the full size, and sufficiently explains their construction, and the position of the glasses; but the micrometer part, and manner of mounting it, are better shewn at H in *figs. 1* and *4.* The micrometer part consists of an oblong square frame, which is folded into a slit, cut at right angles in the main tube; another similar piece, nicely fitted into the former, and having a small motion at right angles to the axis of the microscope, has at one end a cylindrical guide-pin, and at the other a micrometer screw; a spring of steel wire is also applied, as seen in the section, to prevent play, by keeping the head of the micrometer in close contact with the fixed frame. This head is divided into one hundred parts, which are numbered each way to fifty; the use of which will be shewn hereafter. A fine wire is stretched across the moveable frame, for the purpose of bisecting fine dots. Two of these microscopes are necessary; also a third, which needs not have the divided head, and which must have in the moveable frame two wires crossing each other at an angle of about 30° ; this microscope is shewn at I, *fig. 1.* In the two first micrometers a division of the head is of the value of about 0.2, and the power and distinctness such, that when great care is taken, a much greater error than to the amount of one of these divisions cannot well be committed in setting the wire across the image of a well-made dot. The double eye-glass has a motion by hand, for producing distinct vision of the wire; and distinct vision of the dots is procured by a similar adjustment of the whole microscope. The first step towards fixing the roller is to compute its diameter according to the measure of the circle, and to reduce it agreeably thereto, care being taken to leave it a small quantity too large. The second step is, after having brought the roller into its place in the plate B B, to make a mark upon the surface of the circle, near the edge, and a similar one upon the roller, exactly opposite each other; then carry the apparatus forward with a steady hand, until the roller has made sixteen revolutions; if now the mark upon the roller, by having over-reached the one upon the circle, shews it to be much too large, take it out of the frame, and reduce it by turning accordingly: when, by repeating this, it is found to be very near, it may be turned about .001 of an inch smaller on the lower edge, and so far its preparation is completed. The third and last step is the use and adaptation of the two microscopes; one of these must take its position at H in *fig. 1.* viewing a small well-defined dot made for the purpose on the circle; the other, not represented in the figure, must also be fixed to the main plate of *fig. 1.* as near to the former as possible, but viewing one of the divisions on the roller with a due attention to each microscope, it will now be seen to the

GRADUATION.

the greatest exactness, when, by raising or depressing the roller, its commensurate diameter is found.

Fig. 5. is a representation of the apparatus for transferring the divisions of the roller to the circle. It consists of two slender bars, which, being seen edgewise in the figure, have only the appearance of narrow lines; but looked at from above, they resemble the letter A. They are fastened to the main frame, as at W and Z, by short pillars, having also the off leg of the angle secured in the same manner; Y is a fine conical steel point for making the dots, and X is a feeler, whereby the point Y may be pressed down with an uniform force, which force may be adjusted, by bending the end of the bar just above the point, so as to make the dots of the proper size. The point Y yields most readily to a perpendicular action, but is amply secured against any eccentric or lateral deviation.

The apparatus so far described, is complete for laying the foundation, *i. e.* for making 256 primary dots; no matter whether with perfect truth or not, as was said respecting the divisions of the roller; precision in either is not to be expected, nor wished; but it is of some importance that they should be all of the same size, concentric, small, and round. They should occupy a position very near the extreme border of the circle, as well to give the greatest radius possible, as that there should be room for the stationary microscope, and other mechanism to be described hereafter.

It must be noticed that there is a clamp and adjusting screw attached to the main plate of *fig. 1.*, but as it differs in no respect from the usual contrivances for quick and slow motion (see CIRCLE), it has been judged unnecessary to lumber the drawing with it.

Now the roller having been adjusted, with one microscope H upon its proper dot on the circle, and the other microscope at the first division on the roller, place the apparatus of *fig. 5.* so that the dotting point Y may stand directly over the place which is designed for the beginning of the divisions. In this position of things, let the feeler X be pressed down, until its lower end comes in contact with the circle; this will carry down the point, and make the first impression, or primary dot, upon the circle; unclamp the apparatus, and carry it forwards by hand, until another division of the roller comes near the wire of the microscope; then clamp it, and with the screw-motion make the coincidence complete; where again press upon the feeler for the second dot; proceed in this manner until the whole round is completed.

From these 256 erroneous divisions, by a certain course of examination, and by computation, to ascertain their absolute and individual errors, and to form these errors into convenient tables, is the next part of the process, and makes a very important branch of my method of dividing.

The apparatus must now be taken off, and the circle mounted in the same manner, that it will be in the observatory. The two microscopes, which have divided heads, must also be firmly fixed to the support of the instrument, on opposite sides, and then wires brought to bisect the first dot, and the one which should be 180° distant. Now the microscopes remaining fixed, turn the circle half round, or until the first microscope coincides with the opposite dot; and if the other microscope be exactly at the other dot, it is obvious that these dots are 180° apart, or in the true diameter of the circle; and, if they disagree, it is obvious that half the quantity by which they disagree, as measured by the divisions of the micrometer head, is the error of the opposite division; for the quantity measured is that by which the greater portion of the circle exceeds the less. It is convenient to note these errors + or -, as the dots are found too

forward or too backward, according to the numbering of the degrees; and for the purpose of distinguishing the + and - errors, the heads, as mentioned before, are numbered backwards and forwards to fifty. One of the microscopes remaining as before, remove the other to a position at right angles; and, considering for the present both the former dots to be true, examine the others by them; *i. e.* as before, try by the micrometer how many divisions of the head the greater half of the semi-circle exceeds the less, and note half the quantity + or - as before, and do the same for the other semi-circle. One of the micrometers must now be set at an angle of 45° with the other, and half the differences of the two parts of each of the four quadrants registered with their respective signs. When the circle is a vertical one, as in the present instance, it is much the best to proceed so far in the examination with it in that position, for fear of any general bending or spring of the figure; but for the examination of smaller arcs than 45°, it will be perfectly safe and more convenient to have it horizontal; because the dividing apparatus will then carry the micrometers, several perforations being made in the plate B for the limb to be seen through at proper intervals. The micrometers must now be placed at a distance of 22 30', and the half differences of the parts of all the arcs of 45° measured and noted as before; thus descending by bisections to 11° 15', 5 37' 30", and 2° 48' 45". Half this last quantity is too small to allow the micrometers to be brought near enough; but it will have the desired effect if they are placed at that quantity and its half, *i. e.* + 13 7".5, in which case the examination, instead of being made at the next, will take place at the next division but one, to that which is the subject of trial. During the whole of the time that the examination is made, all the dots, except the one under examination, are for the present supposed to be in their true places; and the only thing in this most important part of the business, from first to last, is to ascertain with the utmost care, in divisions of the micrometer head, how much one of the parts of the interval under examination exceeds the other, and carefully to tabulate the half of their difference.

I will suppose that every one who attempts to divide a large astronomical instrument, will have it engraved first. Dividing is a most delicate operation, and every coarse one should precede it. Besides its being numbered is particularly useful to distinguish one dot from another; thus in the two annexed tables of errors, the side columns give significant names to every dot in terms of its value to the nearest tenth of a degree, and the mistaking of one for another is rendered nearly impossible.

The foregoing examination furnishes materials for the construction of the table of half differences, or apparent errors. The first line of this table consists of two varieties; *i. e.* the micrometers were at 180° distance for obtaining the numbers which fill the columns of the first and third quadrants; and at 90° for those of the second and fourth quadrants. The third variety makes one line, and was obtained with a distance of 45°; the fourth consists of two lines, with a distance of 22 30'; the fifth of four lines, with a distance of 11 15'; the sixth of eight lines, with a distance of 5 37' 30"; the seventh of sixteen lines, with a distance of 2 48' 45"; and the eighth and last variety, being the remainder of the table, consists of thirty-two lines, and was obtained with a distance of 4° 13' 7".5.

The table of apparent errors or half differences, just explained, furnishes data for computing the table of real errors. The rule is this; let *a* be the real error of the preceding dot, and *b* that of the following one, and *c* the apparent

GRADUATION.

error, taken from the table of half differences, of the dot under investigation; then is $\frac{a+b}{2} + c =$ its real error.

But as this simple expression may not be so generally understood by workmen as I would wish, it may be necessary to say the same thing less concisely. If the real errors of the preceding and following dots are both + or both -, take half their sum, and prefix thereto their common sign; but if one of them is + and the other -, take half their difference, prefixing the sign of the greater quantity: again, if the apparent error of the dot under investigation has the same sign of the quantity found above, give to their sum the common sign for the real error; but if their signs are contrary, give to their difference the sign of the greater for the real error. I add a few examples.

Example 1.

For the first point of the second quadrant.

Real error of the first point of the first quadrant	0.0
Real error of the first point of the third quadrant	- 6.9
Half sum or difference	- 3.4
Apparent error of the dot under trial	+ 12.2
Real error	+ 8.8

Example 2.

For the point 45° of the second quadrant.

Real error of the first point of the quadrant	+ 8.8
Real error of the last point of the quadrant	- 6.9
Half difference	+ 0.9
Apparent error of the dot under trial	- 8.9
Real error	- 8.0

Example 3.

Point 88°.6, or last point of the third quadrant.

Real error of the point 84°.4 of the third quadrant	- 21.0
Real error of the point 2°.8 of the fourth quadrant	- 2.9
Half sum	- 11.9
Apparent error of the dot under trial	- 4.0
Real error	- 15.9

Example 4.

Point 88°.6, or last of the fourth quadrant.

Real error of the point 84°.4 of the fourth quadrant	- 21.6
Real error of the point 2°.8 of the first quadrant	- 10.2
Half sum	- 15.9
Apparent error of the dot under trial	+ 9.5
Real error	- 6.4

It is convenient, in the formation of the table of real errors, that they should be inserted in the order of the numbering of the degrees on their respective quadrants; although their computation necessarily took place in the order in which the examination was carried on, or according to the arrangement in the table of apparent errors. The first dot of the first quadrant having been assumed to be in its true place, the first of the third quadrant will err by just half the difference found by the examination; therefore these are alike in both tables. The real error of the first dot of the second quadrant comes out in the first example; that of the fourth was found in like manner, and completes the first line. It is convenient to put the error of the division 90° of each quadrant at the bottom of each column, although it is the same as the point 0° on the following quadrant. The line

of 45° is next filled up; the second example shews this; but there is no occasion to dwell longer upon this explanation, for every one, who is at all fit for such pursuits, will think what has already been said fully sufficient for his purpose. However, I will just mention that there can be no danger in the formation of this table, of taking from a wrong line the real errors which are to be the criterion for finding that of the one under trial; because they are in the line next to it; the others which intervene in the full table not being yet inserted. The last course of all is, however, an exception; for, as the examining microscopes could not be brought near enough to bisect the angle 2° 48' 45", recourse was had to that quantity and its half; on which account the examination is prosecuted by using errors at two lines distance, as is shewn in the two last examples.

When the table of real errors is constructed, the other table, although it is of no further use, should not be thrown away; for, if any material mistake has been committed, it will be discovered as the operation of dividing is carried on; and in that case the table of apparent errors must be had recourse to, indeed not a figure should be destroyed until the work is done. Respecting the angular value of the numbers in these tables, it may be worth mentioning, that it is not of the least importance; 100 of them being comprised in one revolution of the micrometer screw; and in the instance before me, 56 of them made no more than a second, it is not pretended that one of these parts was seen beyond a doubt being scarcely $\frac{1}{325}$ of an inch, much less the tenths, as exhibited in the tables; but as they were visible upon the micrometer heads, it was judged best to take them into the account.

Having now completed the two first sections of my method of dividing; namely, the first which consists of making 256 small round dots; and the second in finding the errors of those dots, and forming them into a table; I come now to the third and last part, which consists in using the erroneous dots in comparison with the calculated errors, so as ultimately to make from them the true divisions.

It will here be necessary to complete the description of the remaining part of the apparatus. And first a little instrument which I denominate a sub-dividing sector presents itself to notice. From all that has hitherto been said, it must have been supposed that the roller itself will point out, upon the limb of the instrument to be divided, spaces corresponding to others previously divided upon itself, as was done in setting off the 256 points; but, to obviate the difficulty of dividing the roller with sufficient exactness, recourse was had to this sector; which also serves the equally important purpose of reducing the bisecting points to the usual division of the circle. This sector is represented in full dimensions by *fig. 2*; it is formed of thin brass, and centered upon the axis at A, in contact with the upper surface of the roller; it is capable of being moved round by hand; but by its friction upon the axis, and its pressure upon the roller, it is sufficiently prevented from being disturbed by accident. An internal frame BB, to which the arc CC is attached, moves freely in the outer one, and by a spring D is pushed outwards, while the screw E, whose point touches the frame B, confines the arc to its proper radius. The arc of this sector is of about four times greater radius than the roller, and upon it are divided the spaces, which must be transferred to the instrument, as represented on a magnified scale by *fig. 6*. Now the angle of one of the spaces of the circle will be measured by sixteen times its angular value upon the sectorial arc, or 22° 30'; but this does not represent

GRADUATION.

sent any number of equal parts upon the instrument, whose sub-divisions are to be $5'$ each; for $\frac{1^\circ 24' 22''.5}{5}$ is exactly $16\frac{1}{2}$, therefore so many divisions are exactly equal to a mean space between the dots, whose errors have been tabulated. Let therefore the arc of the sector be divided into 16 spaces, of $1^\circ 20'$ each, and let a similar space at each end be subdivided into eight parts of $10'$ each, as in *fig. 6*; we shall then have a scale, which furnishes the means for making the true divisions, and an intermediate examination at every bisectional point.

I have always divided the sector from the engine, because that is the readiest method, and inferior to none in point of accuracy, where the radius is very short; but as it is more liable than any other to central error, the adjustment of the arc by the screw E becomes necessary; by that adjustment also any undue run in the action of the roller may be reduced to an insensible quantity.

When the utmost degree of accuracy is required, I give the preference to dividing by lines, because they are made with a less forcible effort than dots are, and also, because if any small defect in the texture of the metal causes the cutter to deviate, it will, after passing the defective part, proceed again in its proper course, and a partial crookedness in the line will be the only consequence: whereas a dot, under similar circumstances, would be altogether displaced. But, on the contrary, where accuracy has been out of the question, and only neatness required, I have used dots; and I have done so, because I know that when a dot, and the wire which is to bisect it, are in due proportion to each other, the wire covering about two-thirds of the dot, the nicest comparison possible may be obtained. It may be further observed, that division by lines is complete in itself; whereas that by dots requires lines to distinguish their value.

On the upper side of *fig. 1*. is represented the apparatus for cutting the divisions. It consists of three pieces, J, K, L, jointed together, so as to give to the cutter an easy motion for drawing lines directly radiating from the centre, but inflexible with respect to lateral pressure; *d, d*, are its handles. The cutting point is hidden below the microscope H; it is of a conical form, and were it used as a dotting point, it would make a puncture of an elliptic shape, whose longer diameter would point towards the centre. This beautiful contrivance, now well known, we owe to the ingenuity of the late Mr. Hindley of York; it was borrowed by Mr. Ramsden, (see ENGINE for *dividing*.) and applied with the best effect to his dividing engine.

Previously to cutting the divisions, the parts now described must be adjusted. The cutting apparatus must be placed with the dividing point exactly at the place where the first line is intended to be drawn, and clamped, so that the adjusting screw may be able to run it through a whole interval. The microscope H must be firmly fixed by its two pillars *b, b*, to the main frame, with its micrometer head at zero; and with its only wire in the line of the radius, bisecting the first of the 256 dots. And it should be observed that the cutting frame and this must not vary respecting each other, during the time that the divisions are cut; for any motion that took place in either would go undiminished to the

account of error. The microscope I is also fastened to the main frame, but it is only required to keep its position unvaried, while the divisions of the sector pass once under its notice, for it must have its wires adjusted afresh to these divisions at every distinct course. The microscope I has two wires, crossing each other at an angle of about 45° ; and these are to be placed so as to make equal angles with the divisions of the sector, which are not dots but lines. The sectorial arc must also be adjusted to its proper radius by the screw E, *fig. 2. i. e.* while the main frame has been carried along the circle through a mean interval shewn by H, the sector must have moved through exactly $16\frac{1}{2}$ of its divisions, as indicated by I.

Things being in this position, after having given the parts time to settle, and having also sufficiently proved the permanence of the micrometer H, and the cutting frame, with respect to each other, the first division may be made; then, by means of the screw for slow motion, carry the apparatus forward, until the next line upon the sector comes to the cross wires of I; you then cut another division, and thus proceed until the 16th division is cut = $1^\circ 20'$: now the apparatus wants to be carried further, to the amount of $\frac{1}{4}$ ths of a division, before an interval is complete, but at this last point no division is to be made; we are here only to compare the division on the sector with the corresponding dot upon the instrument: this interval, however, upon the circle will not be exactly measured by the corresponding line of the sector, which has been adjusted to the mean interval, for the situation of the dot $1^\circ 4'$ is too far back, as appears by the table of real errors, by -4.8 divisions of the micrometer head. The range of the screw for slow motion must now be restored, the cross wires of H set back to -4.8 divisions, and the sector moved back by hand, but not to the division 0, where it began before; for, as it left off in the first interval at $\frac{1}{4}$ ths of a division, it has to go forwards $\frac{1}{4}$ th more before it will arrive at the spot where the 17th division of the instrument $1^\circ 25'$ is to be made, so that in this second course it must begin at $\frac{1}{4}$ th short of 0: go through this interval as before, making a division upon the circle at every one of the sixteen great divisions of the sector; and I should now reach the third dot, allowing for a tabular error of -10.2 , when the division $\frac{1}{2}$ ths of the sector reaches the cross wires of I. It would be tedious to lead the reader through all the variety of the sector, which consists of eight courses; and it may be sufficient to observe, that at the commencement of every course, it must be put back to the same fraction of a division which terminated its former one; and that the wire of the micrometer H must always be set to the tabular error belonging to every dot, when we end one interval and begin another. The eight courses of the sector will have carried us through $\frac{1}{2}$ d part of the circle $11^\circ 15'$, and during this time the roller will have proceeded through half a revolution: for its close contact with the limb of the circle does not allow it to return with the sector when the latter is set back at every course. Having in this manner proceeded from one interval to another, through the whole circle, the micrometer at last will be found with its wire at zero, on the dot from which it set out; and the sector, with its 16th division, coinciding with the wires of its microscope."

GRADUATION.

We might have quoted several other parts of Mr. Troughton's paper for the advantage of the reader, but instead thereof, we recommend the perusal of the whole to such persons as are interested in this subject, and shall conclude our account of the present method of dividing by remarking, that it requires not more than one-fourth of the time that Bird's method does, and not much more than one-twelfth that Ramsden's demands, and is applicable to a quadrant or sextant, &c.; that it may be performed by night, by the aid of an appropriate lamp, as well as by day; that the work is, as it were, magnified by the sector; that any erroneous action of the roller, when verified at every interval, does not extend its influence to any distant divisions; that the divisions of the sector very conveniently convert the 256 points into degrees and parts of a degree, while the micrometer head allows for their errors of position; that all tools liable to vary their dimensions by change of temperature are here abandoned; and lastly, that *vision* alone is employed in ascertaining the measures of the arcs divided; on which account this method is called *dividing by the eye*; which appellation, indeed, might have been given to the *duc de Chaulnes's* method; a method which, we understand, Mr. Troughton was not acquainted with till lately, and from which it will be perceived his differs very essentially. We have no hesitation in asserting, that this far excels every other method of graduating large circles that we are acquainted with.

Soon after Mr. Troughton's paper was read at the Royal Society's room, the late Henry Cavendish, esq. F. R. S., whose death is an irreparable loss to the scientific world, contrived a new method of using the beam-compass, with a view of avoiding the difficulties of pointing the exact middle of a small space between two scratches, and of using that point again without altering its conical figure. As these difficulties had led to Mr. Troughton's new contrivances, Mr. Cavendish presumed that a removal of them would render the beam-compass unobjectionable; and that future dividers might continue the use of an instrument which long habit has rendered familiar. The method proposed, but which probably has not been adopted, if tried at all, is, to unite a microscope that has got a micrometer, with the beam-compass, in such a way, that no dots may be necessary at all in dividing or sub-dividing any arc of a circle, but that bisection, trifsection, and quinquesection, may all be performed by *vision* before the dividing strokes are made on the circle to be divided; we say *circle*, because this method is not intended to apply to a quadrant, or any other aliquot part of a circle. We will endeavour to explain the method now before us as concisely as possible. Let C C C, in *fig. 4.* of *Plate XVIII.* of *Astronomical Instruments*, be the circle to be divided, in which we will retain the original letters of reference, and B B B a frame resting on its plane so steadily as to be without shake, but notwithstanding to have the power of sliding smoothly round the circumference to any given point, to which it may be adjusted by a slow motion, and there clamped; let $d\delta$ be a beam-compass, having its cutting point adjustable near δ , and let m be a microscope with two parallel hairs, one fixed, and the other moveable by the micrometer, made so as to slide along the beam of the compass into any required situation. Let a point d on the frame be so chosen, that the line $d m \delta$ may lie in the direction of the chord of half the arc to be bisected, when bisection is used, in which case the whole length from d to δ must be very nearly equal to the whole chord of the said arc, and then both the centre of the field of view of m , and also the point δ , will fall in the circle to be divided. It is not said how the fixed or central point d is

to be supported, and kept perfectly steady, but as its distance from the centre of the circle must necessarily depend on the length of the chord $d\delta$, it is proposed that the piece of metal that constitutes the support should be adjustable by a sliding motion of some sort, and that the beam near δ should rest on a prop to guard the cutting point, when demitted low enough to make a stroke. Suppose now F and f to be the extreme points of an arc to be bisected somewhere near ϕ ; after having placed the microscope at or near the middle of the beam, with respect to the two points d and δ , and fixed the point on the resting place of d , slide the frame till the fixed hair in the center, which must be exactly perpendicular to the line d in δ , intersects the circle at F ; then, lowering the point δ from its prop, make a faint scratch; in the next place turn the beam-compass a little raised at the end δ , round its centre d , till it is found over the circle, at the other side at D , where it must rest on a prop for a time; slide now the frame forwards, and adjust till the fixed hair cuts the point f , and there fix it; the second scratch must now be made, which will be over, or short of the first, accordingly as the microscope has been beyond or short of the middle of the distance $d\delta$. It is not proposed to make a dot between these two strokes, but to bisect the space between with the hair, by the eye, or, if necessary, by the moveable hair of the micrometer, after it has measured the whole of this space; the bisecting line being now the true place of ϕ , which we suppose brought back to the microscope at m , this intersection is the extreme point of the bisecting arc $F\phi$ or $f\phi$, which must be bisected successively in like manner, when the point α has been adjusted. When the arcs become small, a crooked point is proposed to be used at δ , that it may not be in the way of the microscope; or otherwise, if that plan will not succeed, to adopt what he calls Mr. Troughton's method of bisecting an odd number of contiguous divisions, which was also done, as we have seen, by the *duc de Chaulnes* and others. In cutting the lines of division, the microscope and point δ are proposed to be very near together, and, if possible, so near at one side of one another, that the stroke cut may coincide with the fixed hair, when the beam has an angular motion given, as a check on the stability of the microscope; and lastly, the point d must be so taken that the line $d\delta$ may now be a tangent to the circle at the cutting point.

If the whole circle could be graduated by continual bisection, this account is all that would be necessary for explaining the method of dividing here proposed, but, as trifsection and quinquesection are necessarily introduced, either before or after bisection, where the computation of chords is rejected, we must give also an account of these processes, which we believe are original. Suppose the arc $a\alpha$, in *fig. 5.* to be proposed for quinquesection, the equal measures af , fe , ed , db , and ba , are laid down in succession, by bringing a to the microscope, and making f nearly one-fifth of the whole, then by bringing up f to the microscope, and marking e , &c. in the same way, beginning at α , the points β , δ , ϵ , and ϕ , are made with the same extent, which it appears was with too small an opening. Now the true point of the first quinquesection from α will be between α and β , and distant from β just one-fifth of the differential space βb , and the second point will be two-fifths of δd from δ , and so on for the rest; therefore, in cutting the dividing strokes, the micrometer must measure the whole differential space, and then allow for the due proportion, after which it must be brought into the place of the fixed hair, to bisect the scratch before covered by it, and then the dividing line may be cut: in the same way allowance may be made for $\frac{2}{5}$ ths of the small space δd , before a second dividing stroke is made;

or,

GRADUATION.

or, which gives less trouble, when the first quinquesection line is truly laid down, it may be transferred forward by using the fixed hair with it first, and then with the second, while the third is cutting, and so forth till they are all measured and cut in succession from the first measure repeated. This method is, however, acknowledged to be liable to the double error that may arise, first, from placing the intermediate point, and again, of sub-dividing from it. A third method for quinquesections or trisections is lastly proposed, but is considered inferior to the former plans, and therefore may be passed over in silence.

We must confess there is something specious in the theory of Mr. Cavendish's proposed method of dividing, but our opinion, that it would not answer well in practice, has been confirmed by the assertion of a practical artist, whose judgment in this art we estimate much more highly than our own. Supposing the point *d* on the frame not to be altered in shape or position by the large sweeps of the beam from right to left, and *vice versa*, alternately, nor yet the point injured, there must necessarily be a change of position in the hands of the operator, as well as in his whole body, at every backward and forward change of the beam, to the right and left, which circumstance will be not only unfavourable to expedition, but also to accuracy; in fact, the operator must be both right-handed and left-handed to succeed with an alternation of operations that require the greatest nicety of management, and in which the hands, the eye, and the diversified attitudes of the body, have all an equal share, and where a false stroke once made cannot be well rectified. The bisected arcs will not be more affected by change of temperature probably than by Bird's method, but the quinquesectioned arcs may be sensibly affected, as some time must necessarily be taken up in ascertaining the measures by vision, while the operator breathes on the beam during the inspection of the microscope, and is also handling it in two places during the whole time of obtaining the line points, or rather lines, in question.

Soon after Mr. Cavendish's paper on the manner of dividing astronomical instruments had been read before the members of the Royal Society, the Rev. William Lax, A.M. F.R.S., Lowndes's professor of astronomy in the university of Cambridge, addressed a paper to the astronomer royal, which was also read and printed in part 2. of the year 1809, immediately after Mr. Cavendish's paper. This paper, as well as Mr. Cavendish's, was probably brought forward in consequence of Troughton's paper, printed in part 1. of the same year.

The method of examination made use of by professor Lax may be familiarly explained thus, without entering into any mathematical formulae to mark the value of particular expressions, that might puzzle the ordinary reader: two microscopes were adapted by frame-work, so as to be capable of adjustment to any given points of the circle to be examined, and one of them, having a micrometer attached to it, was capable of measuring minute differences between a given arc of 90° , 60° , or 45° , &c. and any of the following multiples of that arc taken in succession; consequently, if all the said differences marked + or -, as the case might be, balanced one another exactly, when the whole circle was gone through, the measure of the first arc was a standard measure, or the exact fraction of the whole that it ought to be; if not, a proportional part of the balance of errors would belong to it, and must be allowed for accordingly. It is not necessary to be more minute in explaining the principle of examination before us, as it is of no use in graduating a circle, but is only intended as a correction on bad graduation, like

the French repeating principle, to which it bears some analogy. The author's idea of ascertaining the fractional value of each division in his instrument successively, which he calculates will cost him an expenditure of 98 hours, is founded on an opinion that astronomical instruments in general do not possess that degree of accuracy in their divisions that the makers of them affirm; but he does not appear to be aware that as rigid an examination as his own is practised by all the best instrument-makers in the final adjustment of the divisions, and that too by means of micrometrical microscopes; so that, if a posterior examination is found necessary, it must, generally speaking, be necessary in consequence of some change of figure that the instrument has undergone from carriage, accident, or temperature; in any of which cases the professor's mode of examination will be very desirable. But any one who proposes to take the trouble of making a table of all the positive and negative errors in the divisions of an indifferent instrument, will do well to have the whole of the original paper before him at the time, by which every step in the process will be pointed out as it is wanted. Without meaning to discourage any attempt of this nature, for the proposal of which astronomers are much indebted to the learned professor, we profess a belief that three or four readings of any individual observation by as many microscopes properly arranged round the divided circle, in stationary situations, will answer every purpose of accuracy, and correct all the usual sources of error that exist at the time of making the observation; for when any table of errors is completed with the greatest care, it ought only to apply to observations made while the instrument remains in the same predicament as it was when the table was constructed. Mr. Troughton, who is engaged with the construction of his six-foot circle for the Royal Observatory, intends, we understand, to adopt the use of four microscopic readings, two opposite each other, which will correct for eccentricity simply considered, and two at 120° distance from one of the former ones, which will check the bifunctional dividing, and correct the inaccuracies of division, if any, as well as the effects of any change of figure in the circle by unequal temperature, in the room where it may be used. This proposal, coming from so skilful and experienced an artist as Mr. Troughton, we consider as a strong argument in favour of our opinion, which we expressed in favour of three readings in our article CIRCLE, before the paper in question was published, or known to us.

"I find," says Mr. Lax, "that I can read off, to a certainty, within less than three-fourths of a second, and hence I conclude that I could examine the divisions of my circle (of one foot radius) without being liable to a greater error than 9.63 seconds." This is stated on calculation to be the extreme limit; which, according to the doctrine of chances, can very seldom happen, but if one-half of this error is likely to happen in any one division of the whole circle, as read off by the microscopes, the result will be, that the errors of the table may be as great as those of a well-divided instrument, supposing it to preserve its figure unaltered after examination. In another part of the paper before us, the author says, "we may likewise observe that by this examination we shall not only be secured against the errors of division, but against those which arise from bad centering, and from the imperfect figure of the circle, and which in general are of too great a magnitude to be neglected." From this observation we must necessarily conclude, that the distance between the microscope and micrometer, used in measuring, was not the measure of the included arc, but of the angular quantity at the centre opposite that arc: for it must be evident, that, in case the axis of motion is not precisely the centre

GRADUATION.

of the divided circle, the *arc*, simply considered, will not be the true measure of the *angle*; seeing one side of the circle will be farther from the centre than the other. For instance, if we suppose the line that passes from zero to the centre of the divided circle, should also pass through the centre of motion, placed a small quantity out of the centre of the graduated circle, in this case the angles subtended by the first and fourth quadrantal arcs will be greater than those subtended by the second and third; but if the line from 90° to the centre of motion should pass through the centre of the divided circle, then the angles subtended by the first and second quadrantal arcs will be greater than those subtended by the third and fourth. When, however, the microscopes have a cross hair, as well as a radial one, the length of the *radius* as well as of the *arc* may be measured, and consequently the true quantity of the subtended angle.

The great similarity between the duc de Chaulne's method of dividing a circle, and of professor Lax's method of examining one when divided, cannot but strike the reader; they both use microscopes, one with a micrometer attached, and both take multiples of the arc under consideration; but one corrects the errors by adjustment during the act of dividing, and the other calculates and tabulates them for subsequent corrections.

Neither will the likenesses pass unnoticed between the apparatus employed by Mr. Lax, and that for the purpose of examining standard measures, described by sir Geo. Shuckburgh (*Phil. Trans.* 1798); but Mr. Troughton, we know, acquits the learned professor of borrowing any thing from him.

In the spring of 1810, Mr. James Allan, of Blewitt's Buildings, Fetter Lane, London, received the gold medal from the Society of Arts, at the Adelphi, for a new method of equalizing the teeth on the edge of an engine plate for dividing sextants, &c, which would have been described most properly under the article *ENGINE*, but as it was not then made known, we will take some notice of it in this place, though the Society's account is not yet published. The professed improvement of Mr. Allan's method of racking, consists in its enabling a bad divider of a circle to correct his divisions, by what he calls a *self-correcting* process. The contrivance is this: the usual wheel or circular plate that is racked, has a brass rim of about two inches breadth, and of the same diameter and thickness as the wheel, rabbeted over it, so as to appear a part of the same wheel; four steady pins, at the exact distance of a quadrant from each other, keep the rim in its place by the aid of several equidistant screws, and the rim will therefore admit of four positions on the wheel. When the wheel and rim together have been faintly racked in the usual way (see *ENGINE* by *Ramsden*) one of the other positions is given to the rim, suppose the opposite one, and then the operation of racking by the screw is resumed; when the teeth are a little formed, another position is given to the rim, and the racking resumed as before to a certain extent, and, after several changes have been gone through, it is presumed that the teeth become nearly equalized, and are exactly equal to one another at the conclusion. How far this will be precisely the case we will not pretend to assert. We conceive it to be a very nice operation to drill four holes in the wheel and rim so exactly equidistant and concentric, that a reversed position shall not affect their relative fittings, and if there is the least deviation in this respect, it will be charged as an error on the divisions. The screws also profess to be placed so as to admit of reversing in position,

and unless the steady pins fill their holes completely, these pins will, in all probability, be drawn aside by the fixing screws in some of the positions. If the wheel is truly racked in the first instance by a careful divider, and the steady pins placed with precision, the reversing of the rim will not disturb the coincidence of the two rows of teeth all round, which is the thing ultimately desired; but if the original division was bad, and had both negative and positive deviations from true division, in different parts of the circle, then we have a doubt whether the rim will produce the desired effect of equalizing them: a good screw will of itself equalize contiguous teeth, when fifteen teeth or upwards are acted on at the same time; but it will not equalize distant teeth, which the rim professes to do. In order, however, to answer the purpose of a *self-corrector*, the rim must be competent to meet all cases of bad division that are liable to occur; let us suppose, in the first place, that whenever large teeth are made by the divider on one side of the wheel, teeth corresponding in smallness are to be met with at the opposite side, in this case, which is the most favourable to the operation of the rim, the errors being opposed to each other, by an opposite position of the rim, will correct each other, provided they are of similar quantity, and the rim will produce its desired effect; but, secondly, if equal errors happen to be in the same direction they will not be corrected at all; and, thirdly, if unequal errors be in the same direction, they will be corrected by only half their difference; nay, arcs of the wheel, that are true at first, will, we conceive, be vitiated, unless they fall in with arcs of the rim that are also true. How far a change of temperature will affect this long process we will not affirm; but we hesitate not to give it as our opinion, that an upper plate, or wheel, revolving on the same centre as the wheel itself, would be less liable to central error than the rim with steady pins, however carefully fixed; for steady pins could not then cause any sensible eccentricity in fixing at the different positions.

It would have been desirable if Mr. Allan had given, with his account of the racking, his method of making a perfect screw, which is essential in a dividing engine. We lately had an opportunity of examining one of his engine-divided reflecting circles, and found, however, the opposite verniers very well corresponding with each other all round the circumference.

GRADUATION of a Circle geometrically. After the description we have given in our preceding article of the various practical methods of graduating astronomical instruments, it may, perhaps, seem superfluous to give a further account of the methods that geometers have proposed for graduating a circle theoretically; but which have been of little or no use in the practical division of circles, or circular arcs, on instruments. It is not sufficient for the purpose of the instrument-maker, that a problem be true merely, but that the means necessary for its adoption in practice be not subject to the introduction of error. The ancient geometry implies the possibility of making a straight line in practice through two given points, which cannot be effected with certainty by a ruler and pointed tool, however carefully applied, while the modern geometry of Mascheroni, the Italian, rejects the use of lines altogether, and substitutes the compasses only in the division of a circle. We will gratify the curiosity of the reader with a few specimens of each method in succession.

In Adam's geometrical and graphical essays are the following problems, which imply the practicability of drawing a straight line through two given points.

GRADUATION.

PROBLEM I.

“To cut off from any given arc of a circle a third, a fifth, a seventh, &c. odd parts, and thence to divide that arc into any number of equal parts.”

Example 1.—To divide the arc AKB into three equal parts, CA being the radius, and C the centre of the arc. Bisection AB , *fig. 1.* of *Plate XXI.* of *Astronomical Instruments*, in K , draw the two radii CK , CB , and the chord AB ; produce AB at pleasure, and make $BL = AB$; bisection AC at G ; then a rule on G and L will cut CB in E , and BE will be $\frac{1}{3}$, and CE $\frac{2}{3}$ of the radius CB ; on CB with CE , describe the arc Eed ; lastly, set off the extent Ee or De from B to a , and from a to b , and the arc AKB will be divided into three equal parts.

Corollary.—Hence, having a sextant, quadrant, &c. accurately divided, $\frac{1}{2}$ the chord of any arc set off upon any other arc of $\frac{1}{2}$ that radius will cut off an arc similar to the first, and containing the same number of degrees. Also, $\frac{1}{3}d$, $\frac{1}{4}th$, $\frac{1}{5}th$, &c. of a larger chord will constantly cut similar arcs on a circle whose radius is $\frac{1}{3}d$, $\frac{1}{4}th$, $\frac{1}{5}th$, &c. of the radius of the first arc.

Example 2.—Let it be required to divide the arc AKB , of the same figure, into five equal parts, or to find $\frac{1}{5}th$ of the arc AB .

Having bisected the given arc AB in K , and drawn the three radii CA , CK , CB , with radius CI describe the arc INM , which will be bisected in n by the line CK ; then take the extent In , or its equal Ma , and set it off twice from A to B ; that is, first from A to a , and then from a to o , and oB will be $\frac{1}{5}th$ of the arc AB . Again, set off the same extent from B to m , and from m to c , and the arc AB will be accurately divided into five equal parts.

Example 3.—To divide the given arc AB into seven equal parts. AB being bisected as before, and the radii CA , CK , CB , drawn, find (by a problem referred to) the seventh part PB of the radius CB , and with the radius CP describe the arc PrN ; then set off the extent Pr twice from A to 3 , and from 3 to 6 , and $6B$ will be the seventh part of the given arc AB ; the compasses being kept to the same opening Pr , set it from B to 4 , and from 4 to 1 ; then the extent $A1$ will bisect 13 into 2 , and 46 into 5 ; and thus divide the given arc into seven equal parts.

It is obvious, that this method of dividing any portion of a circle, into an odd number of equal parts, is subject to three sources of error in practice; 1st, the variation of the compass from expansion; 2d, the uncertainty of getting the exact points of intersection where the angles are acute; and 3dly, the probable deviation of the points in stepping; to say nothing of the errors arising from drawing the right lines, which would, in all probability, exceed all the other errors put together, even before they are doubled and trebled, &c. by stepping.

PROBLEM II.

“To divide a given arc of a circle into any number of equal parts by the help of a pair of beam, or other compasses, the distance of whose points shall not be nearer to each other than the given chord,” (by Clavius).

Let AB , *fig. 2.* of *Plate XXI.* be the given circular arc to be divided into a number of equal parts. Produce the arc at pleasure; then take the extent AB , and set it off, on the prolonged arc, as many times as the given small arc is to be divided into smaller parts, namely, to the points

$C, D, E, F,$ and G . Divide now the whole line AG into as many equal parts as are required in AB , as GH, HI, IK, KL, LA , each of which contains the given line, and one of those parts into which the given line is to be divided. For AG is to AL , as AF to AB ; in other words, AL is contained five times in AG , as AB is in AF ; therefore, since AG contains AF , and $\frac{1}{5}th$ of AB , BL is $\frac{4}{5}th$ also of AB . Then, as GH contains AB , plus FH , which is $\frac{1}{5}th$ of AB , FI will be the $\frac{6}{5}ths$ of AB , DK $\frac{7}{5}ths$, and CI $\frac{8}{5}ths$. Therefore, if we set off the interval GH from F and H , we obtain two parts between F and I ; the same interval, or extent, set off from these two points near I , gives three parts between D and K ; when set off from the points from D to K , it gives four parts in CL ; and the next transfer will, from those points, give five parts from B to A ; so that, lastly, the same extent will give back again the remaining divisions in succession from those between B and C .

This method is liable to some of the same sources of error as the preceding method, when compasses alone are depended on; but it is useful, according to the *duc de Chaulne's* mode of proceeding, and may be serviceable in Ramsden's method of dividing, where the points are rectified by opposite microscopes. In all probability the vernier scale owes its origin to this problem of Clavius, which problem may be variously diversified, to prevent the necessity of small extents; but whenever small spaces are marked out on an arc by a differential plan of this sort, it is requisite that the extent begun with should not alter during the whole process, and also that the points, once marked, should be capable of being resumed with certainty at the subsequent transfer. When, however, an error is made in any divided space by a hard particle, or otherwise, this error will recur at every multiple of the extent measured therefrom.

This problem of Clavius, it will be remarked, implies the given arc AB to be measured, or otherwise known previously to the proposed sub-division.

When an entire circle is proposed to be divided into degrees, the radius, which is equal to the chord of 60° , affords the means of making six equal arcs; and these arcs may be sub-divided to arcs of 15° each by bisection only; but to reduce the equal arcs to a still lower denomination, recourse must be had to either trisection, quinquefsection, computation of the chords, or the differential method originally proposed by Clavius, all which have been already described.

The method of dividing a circle, proposed by *L. Mafcheroni*, is translated into French by *A. M. Carette*, 1798, and is contained in the second book of his “*Geometrie du Compas.*” This method rejects not only the drawing of lines, but all measurement from scales, and bisections of an arc by trial, as well as trisections, quinquefsections, &c. but admits of stepping, and supposes the extent of a pair of compasses, once taken, to be afterwards invariable. The radius of the circle is the basis of all the other extents, which are very few in number, considering the various divisions that may be made therewith, and three points determined, one without and two within the circle, afford the means of taking all the measurements, instead of a scale; consequently, any circle divided by this method must necessarily have its plane extended considerably beyond and within the circular space to be divided, which is seldom the case in a large instrument, where a ring or rim is attached to radial bars, to form a wheel for the body of the instrument, which construction contributes equally to strength and lightness; a

GRADUATION.

flat sheet of metal, which the present method of dividing requires, is seldom, if ever, adopted in the construction of an instrument of considerable radius. The second book of the "Geometry of the Compass," which has not yet been translated into English, and which therefore may not be known to many of our readers, contains ten problems on the division of the circumference of a circle, and one on the manner of bisecting an arc by a new process, that makes no superfluous marks, and requires no second trial: these problems are accompanied by demonstrations and corollaries, that would enlarge our article too much, were we to translate them entirely, but we will give so much of the substance of these problems, as will enable the reader to comprehend the nature and extent of the division in question, which we apprehend will be deemed more curious than useful. The ten problems divide the circle into the following parts, according to the order in which they here succeed one another, *viz.* 4, 8, 12, 24, 48, 5, 10, 120, 20, and 240. Let *fig. 3*, of *Plate XXI.* be a diagram for illustrating the four first divisions or problems. Let one beam, or other kind of compass, describe the circle with the extent *BA* from the centre *A*, and let this compass have its extent preserved unaltered, to represent the radius, and be called the first compass; with this extent and beginning at *B*, as zero, turn over to *C, D, E, d, e*, and back to *B* again: now if this is accurately done, *BAE* will bisect the circle, *BDd* will trisect it, and the six original points will divide it into six arcs of 60° each; take now *BD*, the chord of 120° in the second compass, and preserve this extent unaltered; from zero *B* and its opposite point *E*, bisect the point *a* out of the circle, with this extent; then will the distance *aA*, taken in a third compass, and kept unaltered, be the chord *BF* of 90° ; also of the arc *EF*, of *Ef*, and of *fB*; the circle is now divided into four quadrants at the points *B, F, E*, and *f*. To obtain an eighth part of the circumference, set *A B*, by the compass *N^o 1*, from the point *a*, out of the circle, to *G* and *H* in the arc on each side; then the semi-circle is divided into four, and the points *g* and *h*, in the other semi-circle, may be transferred from *G* to *g*, and from *H* to *h*, with the compass *N 3*, or chord of 90° , and the whole circle will now be divided into eight equal arcs by the points *B, G, F, H, E, h, f, g*.

To gain twelve equal arcs of the circle, with *N^o 1*, or extent equal to radius, from *F* as the first point turn over to *N*, and *n*, in succession one way, and to *O* and *o* in succession the other; and the whole circle will be divided into twelve equal arcs by the points *B, N, C, F, D, O, E, o, d, f, c, n*. To double this number of equal arcs, begin at *G* with the same extent of radius, and step to *L* and *M* one way, and to *k* and *i* the other; also from *H* with the same extent step to *I* and *K* one way, and to *m* and *l* the other way, which points will bisect the former twelve arcs, and make the whole 24. Hitherto we have had occasion for no other point but *a* for determining the 24 arcs, and it is somewhat remarkable, that the three extents ascertained thereby, *viz.* the radius, the chord of 90° , and the chord of 120° , are to each other in the simple ratio of the square roots of 1, 2, and 3 respectively. In order to sub-divide, without trial, the 24 arcs into 48, another point *e* within the circle is necessary; with a fourth compass take the extent *aN*, and find the point *e* by intersection from *B* and its opposite point *E*; then *N 1*, or radius, will cut the circumference from this point *e* into the points μ and ν ; so shall *K \mu*, μN , *M \nu*, and νO be each equal to the 48th part of the whole circumference. To divide the circumference into five equal parts, a third point *b* within the circle, and in the same diameter with *e*, but at the opposite side of the centre, will be

necessary: to avoid confusion from further sub-division, we will take another *fig. (4)* with similar letters of reference as the preceding one. With *N^o 3*, or extent *aA* of 90° , intersect at the point *b* from the points *N* and *O*, then with a fifth extent *Bb* set off from *B* to *Q*, and the arc *BQ* will be the fifth part of the circumference. To bisect these five large arcs, take the sixth extent *Ab* and set it from *B* to *P*, which will be equal to the arc *PQ*, and, consequently, will be a tenth part of the circumference. Again, without any further operation, the small arc *QI*, already marked, will be the 120th part of the circumference; and to obtain $\frac{1}{240}$ th part of the same, in the quadrant *BVf*, the fifth extent *Bb*, set off from *f* to *V*, will leave the arc *BV* equal to this quantity. And lastly, to procure 240 equal arcs, take the extent *e\pi*, and set it over from ϵ to β , and from β to δ , so shall the arc *P\delta* be the $\frac{1}{240}$ th part of the circumference; but to subdivide all the circumference by the small arc *P\delta* of $1^\circ 30'$, the arc *NG* of 15° must first be divided into five parts of 3° each, without quinquesection; thus, with the extent *Ab = BP*, step from *B* to the points *P, Q, R, S*, and it will fall next in *E* already marked; then with *Ab*, as before, begin at *L* and put in the points *q* and *p* successively; also from *I* put in π ; and from *O* put in ϕ , by stepping the points ϵ, ν , and δ ; thus shall the points p, P, π and ϕ sub-divide the arc *NG* into five equal arcs, and $\delta\pi$ will be found equal *P\delta*, or $\frac{1}{240}$ th part of the whole. After having obtained these five sub-divisions of 3° and $1^\circ 30'$, the first may be transferred, with the extent *NG* for instance, into other arcs of 15° in succession, beginning with *GC* first, and using the points *N, p, P*, &c. as they occur, till the whole is gone through, after which the small arcs thus transferred may be bisected by an extent δN , going a second time over the same points in succession as before. Thus will the whole circumference be sub-divided into 240 parts of each $1^\circ 30'$.

The eleventh or last problem on this subject, is to divide any arc *BC* (*fig. 5*) into two equal parts in *G*. To do this; with radius *AB*, which has described the arc *BC* to be divided, and from the centres *B* and *C*, the two extremities of the arc, let the arcs *AD* and *AE* be described; let *AD* and *AE* be each made equal to *BC*; then from the points *D* and *E*, as centres, and with radius *DC* or *EB*, find by intersection the point *F*; lastly, with the radius *AF*, and from the centres *D* and *E*, let the point *G* be intersected, which will fall in the circumference, if the operation is truly performed, and will also bisect the arc *BC* as was required.

By the help of the three remarkable points *a, e*, and *b*, in our *fig. 4*, the author of the *Geometry of the Compass*, has laid down in his twelfth and last book a dozen equations, some one of which may be applied to determine, by approximation, almost any small arc of a circle that shall cut off a given quantity. It would be tedious to enter here minutely into his various calculations, but, for the sake of amusing the reader, we will select the solutions of a few problems, without the annexed demonstrations, which would enlarge our article too much.

PROBLEM I.

To find the arc of one degree without the error of half a second.

Solution.—Let the arc *Bz*, below *B*, be $55^\circ 30'$, (in the circle which has been divided into 240 parts of each $1^\circ 30'$;) take the distance *bx'*, and from the point *e*, as a centre, describe an arc to cut the circumference in some point *Z'*, and the arc *BZ'*, above *B*, will be $52^\circ 59' \frac{1}{2} \frac{1}{3}$, or 53° within about $25''$; then in the divisions between *B* and *F* is the

Division

division 54° , or $\frac{1}{2}^\circ$ of the whole circle; there will therefore be $54^\circ - 53^\circ = 1^\circ$ by approximation within the required degree of accuracy.

Solution 2.—Let the arc BZ be taken = $10^\circ 30'$, (by the divisions existing) from the centre a , and with the distance bZ as radius, cross the circumference in the said point $Z' = 29^\circ 29' \frac{2}{3} \frac{1}{2}$, or $29^\circ 30'$ without an error of half a second; then look for $28^\circ 30'$ in the existing divisions, viz. $\frac{1}{2}^\circ$ of the circle, and the difference will be very nearly as before = 1° . This solution is less accurate than the former by about $4''$; the error being $29''$.

PROBLEM II.

To find an arc of $15'$ without an error of $1''$.

Solution.—Take the arc $Bz = 12^\circ$ below B, the distance cz will be the chord of $87^\circ 15'$; with a radius of this extent, and from B, as a centre, cut the arc BF above, in the point Z' , and the arc BZ' will be $87^\circ 15'$; but among the existing divisions of the arc is 87° , or $\frac{2}{3}^\circ$ of the circumference; therefore, the difference of the two arcs is $= 15'$.

PROBLEM III.

To find an arc of $10'$ without an error of $10''$.

Solution.—Take the arc Bz downward = $49^\circ 30'$, and the distance bz will be the chord of $38^\circ 50'$, without an error of $10''$; then, the division 39° , or $\frac{1}{2}^\circ$, being found already, their difference on the circumference taken from B upwards, will be an arc of $10'$.

PROBLEM IV.

To find an arc of $6'$ within $13''$.

Solution.—Take the chord of 45° from B to G above, and from the point b cut the circumference at z , which will be at $40^\circ 6'$, downwards from B, without an error of $13''$, but 40° counted downwards already exists, therefore the small arc between is $6'$.

PROBLEM V.

To find an arc of $1'$ within $22''$.

Solution.—Let Bz downwards be = 27° ; from the point c as a centre with radius bz , cut the circumference above at Z ; and the arc BZ will be $29^\circ 59'$, with an excess of $22''$; therefore, the arc BN being $30'$, the arc ZN will be $1'$ within $22''$.

By such means as these an arc of $9'$ within $7''$ is determined; also, an arc of $20''$ within $1''$; an arc of $15''$ within $10''$; an arc of $12''$ within $1''$; an arc of $10''$ within $1''$; and an arc of $5''$ within $2''$; but these last arcs are so minute in all ordinary circles, that we omit the solutions, as being of no utility.

We have hitherto supposed the circle divided into 360° with their sub-divisions, but the French have proposed a centesimal division of the circle to be substituted, where each quadrant has 100° instead of 90° , making 400° in the whole circle, with each degree sub-divided by hundreds, &c. This mode of dividing has been exemplified by L. Mascheroni, in his *Geometry of the Compass*; and Mr. Troughton has described the method of graduating a circle in this way by his method, if it should ever prevail in England; but, as there appears to be no advantage to the divider in affording divisions lower than 25° , and as our tables of logarithms, as well as astronomical tables, are adapted to the existing mode of dividing the circle, we are unwilling to lend our

aid to the introduction of useless innovations, by entering more minutely into the subject.

L. Mascheroni is the Italian geometrician, we are informed, who taught Bonaparte some problems, when in one of his campaigns in Italy, with one of which he puzzled the French mathematicians, and gained the reputation of being an adept in mathematics.

GRADUATION, in *Mineralogy*. When a mineral is discovered which is intermediate between other known species, and in different specimens, or parts of the same specimen, approaches very near to such known minerals, it is said to *graduate*, pass into, pass over to, or make transitions to, such minerals. Frequently, the strata of the earth graduate thus into each other, so that it is extremely difficult to define where one stratum ends and another of very different properties begins: these graduations are not uncommon between some lime-stone strata and the chert beds in them. More frequently, each stratum is separated by a thin layer or way-board of pulverulent matter, which occasions the strata to part freely; and often, in such cases, the parts of the strata in contact with these way-boards differ nothing from the general mass of each stratum, or there is no graduation between one stratum and the next in succession.

GRADUATION of saline Liquors, in *Chemistry*, is a method of concentrating weak saline solutions, by pouring them through a heap of faggots, and exposing them in this divided state to a free current of air. See **MURIATE of Soda**.

GRADUS GEMONIC. See **GEMONIÆ**.

GRÆA, Γεζία, a name used by the old Greek writers for the wrinkled pellicle which arises upon milk in the boiling.

It was also used in a figurative sense for the wrinkles in the skin of old people.

GRÆCIA, GREECE, in *Ancient Geography*, a country of considerable extent, forming, as it were, the boundary or frontier between Europe and Asia, and comprehending a great number of different states and kingdoms. We have various opinions as to the etymology of the appellations Græci and Græcia. The most prevalent opinion traces the origin of these terms to Graicus or Græcus, the father, as some say, but, according to others, the son of Thesalus, who gave its name to Thesaly. Salmatius supposes the name Græcus to be derived from Ragau or Rau, the son of Peleg, the fourth in descent from Shem, the son of Noah, by the transposition of a letter in order to soften the sound. Pezron deduces it from Graia, signifying in Celtic *ancient*, and applicable to the Grecians by way of contradistinction to more modern people. But it has been objected to this etymology, that the Pelasgi and Hellenes were a more ancient people than the Greeks. M. de Gebelin supposes the origin of the appellation to have been the word *rha*, or *rhe*, denoting vast or immense, in reference to the sea which terminated the Adriatic gulf, on the borders of which the Greeks migrated southwards, whence he forms *Ræicus*, signifying this sea, and by prefixing the guttural G to the lingual R, *Græicus*. The Greeks were also called Achæans, Hellenes, and Pelasgi. The first of these appellations is supposed to have been derived from Achæus, the son of Xuthus, the son of Hellen, and father of Ion; the second from Hellen, just mentioned, the son of Deucalion, and father of Dorus, from whom sprung the Dorians; and the third, from a pretended founder Pelasgus, who, taking possession of the Peloponnesus, occasioned its being denominated Pelasgia. Grotius, Salmatius, and Stillingfleet,

names of considerable authority in disquisitions of this nature, suppose that the descendants of Peleg, the fourth in descent from them, the son of Noah, whom they suppose to have been the father of the Scythians, were the first who peopled Greece; and that they only softened the name of Peleg, or Phaleg, their progenitor, and called them Pelasgians. But Bochart (in his "Phaleg") shews, that both Phaleg and Ragau, and their descendants, remained in the confines of Media and Armenia; and that the Scythians were the descendants of Magog, and not of Phaleg or Ragau. Some have asserted that the most ancient name of all is that of Iones, which the Greeks themselves derive from Xuthus, grandson to Deucalion. Josephus affirms (Ant. l. i. c. 7.) that their original is of much older date; and that Javan, the son of Japhet, and grandson of Noah, and his descendants, were the first who peopled these countries; and in proof of this position the learned Bochart has alleged several strong presumptive arguments. He first adduces the authority of Josephus, just cited; he then appeals to the name of the patriarch, יָוֶן, which, without the points, sounds more properly Ion than Javan; he next alleges the authority of Moses, who says (Gen. x. 5.) that "by these" (the sons of Japhet) "were the isles of the Gentiles divided;" which, according to the genius of the Hebrew, mean, not islands properly so called, but all maritime countries, at any distance from Palestine, especially those which are along the Mediterranean; and he also refers to the prophets (Is. cap. ult. v. 19. Dan. viii. 21. x. 20) who call Græcia by the name יָוֶן, Ion, or Javan, and hence the Jews have always called the Greek tongue יוֹנִית, Javanith. To these arguments he adds that the clear remains of Elisha, Javan's eldest son, are still to be found in that of Elis, one of the ancient kingdoms of the Peloponnesus.

GRÆCIA, or *Ancient Greece, Geography of.* Exclusively of the provinces of Epirus and Macedonia, which long remained barbarous and uncultivated, the continental possessions of the Greeks (says Dr. Gillies,) were nearly equal to Scotland in extent. In its length, comprehended between the 36th and 41st degrees of N. latitude, the whole country is almost equally divided by two opposite gulfs, compressing between them a mountainous neck of land, to the breadth of only five miles, into the peninsula of Peloponnesus, and the territory extending northwards, from the extremity of the Corinthian isthmus to the southern frontier of Macedonia. The Peloponnesus, 160 miles in length, and scarcely 100 in breadth, is every where intersected by mountains, particularly the towering ridges of Zarex and Taygetus. During the flourishing ages of Greece, this small peninsula contained seven independent communities of un-

equal power and fame, which ranked in the following order: the comparatively large, and highly diversified, territory of Laconia; the fruitful vale of Argos; the extensive coast of Achaia; the narrow but commercial isthmus of Corinth; the central and mountainous region of Arcadia; together with the more level countries of Elis and Messenia, which are throughout better adapted to tillage, than any other provinces of the Peloponnesus. The Grecian possessions beyond the isthmus of Corinth were more considerable, extending above 200 miles from east to west, and 150 from north to south. They were naturally divided by the long and intricate ridges of Olympus, Pindus, Oeta, and Ossa, into nine separate provinces; which, during the celebrated ages of Grecian freedom, were occupied by nine independent republics. They comprehended the extensive and fertile plains of Thessaly and Bœotia, both of which were, in early times, much exposed to inundations, and the latter, abounding in subterranean caverns, was peculiarly subject to earthquakes; the less fertile, but more secure territory of Attica; the western provinces of Ætolia and Acarnania, encompassed on one side by dangerous seas, and confined on the other by almost impassable mountains; and the four small rocky districts of Phocis, Doris, Locris, and Megara.

These names and divisions (says the above cited historian) which remained to the latest times, are pretty accurately marked by Homer, whose poems continued, through succeeding ages, to be the approved standard and legal code, to which neighbouring communities appealed, in adjusting their disputed boundaries. This qualification, however, must be admitted with two exceptions. During the Trojan war, the extensive province of Thessaly sent forth above a fourth part of the whole Grecian strength, and was divided among many warlike leaders. But when commerce, navigation, and the mechanic arts, enriched and adorned the middle and southern divisions of Greece, the northern district of Thessaly lost its ancient pre-eminence. The other exception arose from the extensive power of the house of Pelops, which had, by fortunate marriages and rich successions, acquired dominion over the northern and eastern parts of the Peloponnesus, formerly containing several independent principalities, and, after the misfortunes of Agamemnon and his family, again divided into the immortal republics of Sparta, Argos, Corinth, and Achaia. The following table will exhibit at one view the principal states of Greece, with some of their towns and rivers, referring to each article for a further account, and observing that we have admitted into it Macedonia, though it was not properly a province of Greece till after the reign of Philip, or rather that of Alexander, and also Epirus and Illyria.

	To the East.	{ <i>Thera, Naxia, Paros, Delos, Myconus, Tenos, Andros, Ceos,</i> <i>EUBÆA, Scyros, Thafos.</i>	

The ancient authors who are to be consulted with regard to the different periods of the geography of Greece, are Homer, for the more remote times, in his account of the forces collected for the siege and capture of Troy; Strabo, who avails himself of ample materials to which he had access; Pausanias, who details the results of his own travels and observations; and Ptolemy, who furnishes an useful nomenclature of the states and chief towns, with their longitudes and latitudes.

GRÆCIA, or *Ancient Greece*, *hisl.ry of*. The traditions of the Greeks (says the learned historian, Dr. Gillies,) agree with the authentic records of sacred history in representing the countries afterwards known by the names of Thrace, Macedon, and Greece, as peopled at an earlier period than any other portion of the western world. The southern corner of Europe, comprehended between the 36th and 41st degrees of latitude, bordering upon Epirus and Macedonia towards the north, and on other sides furrounded by the sea, was inhabited, above 18 centuries before the Christian era, by many small tribes of hunters and shepherds, among whom the Pelasgi and the Hellenes were the most numerous and powerful. The barbarous Pelasgi venerated Inachus, as their founder; and, for a similar reason, the more humane Hellenes respected Deucalion. From his son Hellen, they derived their general appellation, which originally denoted a small tribe in Thessaly, and from Dorus, Eolus, and Ion, his more remote descendants, they were discriminated by the names of Dorians, Eolians, and Ionians. The Dorians took possession of that mountainous district of Greece, afterwards called Doris; the Ionians, whose name was gradually lost in the more illustrious appellation of Athenians, settled in the less barren parts of Attica; and the Eolians peopled Elis and Arcadia, the western and inland regions of the Peloponnesus. Notwithstanding many partial emigrations, these three original divisions of the Hellenes generally entertained an affection for the establishments which had been preferred by the wisdom or caprice of their respective ancestors; a circumstance which remarkably distinguished the Hellenic from the Pelasgic race. While the former discovered a degree of attachment to their native land, seldom found in barbarians, who live by hunting or pasturage, the latter, disdainig fixed habitations, wandered in large bodies over Greece, or transported themselves into the neighbouring islands; and the most considerable portion of them gradually removing to the coasts of Italy and Thrace, those that remained melted away into the Doric and Ionic tribes. At the distance of 12 centuries, obscure traces of the Pelasgi occurred in several Grecian cities; a district of Thessaly always retained their name; and their colonies continued, in the fifth century B. C., to inhabit the southern coast of Italy, and the shores of the Hellespont; and in those widely separated countries, their ancient affinity was recognized in the uniformity of their rude dialect and barbarous manners, extremely dissimilar to the customs and language of their Grecian neighbours. Such is the account of the first settlers in Greece, given by Dr. Gillies on the cited authorities of Herodotus, Dionysius Halicarn., Pausanias, Thucydides, Diodorus Siculus, and Strabo. Modern authors, however, have entertained different opinions on this subject. Some have supposed that the Pelasgi succeeded the Hellenes, and others have considered them as the same people under different denominations. According to M. de Gebelin, Moses, the Jewish legislator, has given us the primitive origin of the Greeks. In tracing the genealogy of the descendants of Noah he says that Japhet, one of the sons of Noah, had seven sons: that the fourth was called Ion, and that he was the father of Elifa, Tharsis or Thra-

sis, Ketim, and Dodanim; this Ion was the father of the Greeks, and M. de Gebelin labours to find among the Greeks four nations formed by his four sons. With this view, he says, that Pelasgia comprehended the whole territory between the Danube and the sea of Peloponnesus; and here we may discover, as he conceives, the respective situation of each of Ion's four sons. Thrace acknowledges Tharsis or Tharsis for its founder; Ketim possessed the country of the Getæ, N. of Macedonia, and Macedonia itself; Dodanim had the country that lay between Macedonia and the Peloponnesus, inhabited by the Dorians; and Elifa designated the inhabitants of the Peloponnesus. This author, in no small degree indulging his imagination, and yet exercising a very considerable degree of ingenuity and attention to facts, observes, that the history of Deucalion is the foundation of the Greek chronology and history: this Deucalion is distinguished by his deluge, his ark, and his being the father of the Greeks or Hellenes. All these circumstances afford a presumption that Deucalion and Noah were the same person. He also says, that the fable of the Argonauts and their voyage to Colehis is a copy of the navigation of Noah. Phryxus, or the "man saved," in the Grecian mythology, is Noah. He discovers also other coincidences, which lead him to conclude, not only that Noah and Deucalion, but that Ion and Hellen, the reputed father of the Greeks, were the same persons; and that the Hellenes and Pelasgi were the same people. According to this writer, the Pelasgi were the sole possessors of the whole country which extended itself from the banks of the Danube, to the sea of the Peloponnesus; they peopled Thrace, Getia, Macedonia, Illyria, Epirus, Thessaly, the Phocide, Attica, and the Peloponnesus; they sent colonies to the isle of Crete, to Etruria, and to the south of Italy; and others crossed the Danube, and were denominated Dacians and Getæ. Greece was in this state, says M. de Gebelin, when some colonies of strangers arrived on its coasts, as Cecrops at Athens, Danaus at Argos, and Cadmus in Bœotia. These, he says, came not from Egypt, but from Phœnicia, a neighbouring country. The first inhabitants of Greece, whence-soever they came, were, in a very considerable degree, like the ancestors of other people, barbarous and savage; and the Hellenes, whose manners were mild and gentle, contributed in some measure to civilize them; but their efforts produced effect very slowly. At length, however, the happy position of their country, forming a kind of frontier between Europe and Asia, and divided only by a narrow sea from Egypt and Syria, and not far remote from those eastern regions which were anciently most populous and flourishing, invited strangers first to visit, and afterwards to dwell among them. The Greeks were not insensible of their obligations to strangers for the most important discoveries, not only in religion, but in agriculture and the arts; but as they advanced to superiority in arts and arms, above surrounding nations, they vainly fancied that their infancy was reared by the gods: and to the gods they transferred the merit of many useful inventions, that had been communicated to them or their progenitors by their ancient visitants: and it must be acknowledged, that the worship of several divinities was introduced at the same time, and by the same persons, who made known to them the arts most subservient to the purposes of human life.

From the middle of the 16th to the middle of the 14th century, B. C. an inundation of Egyptians, Phœnicians, and Phrygians overflowed the Hellenic coasts. The principal colonies were conducted by Cecrops and Danaus, Egyptians, who respectively settled in Athens and Argos; Cadmus, a Phœnician, who founded Thebes in Bœotia; and Pe-

Tops, a Phrygian, whose descendants, by intermarriages with those of Danaus, king of Argos, and Tyndareus, king of Lacedæmon, or Sparta, acquired in the person of Agamemnon for powerful an ascendant in the Peloponnesus. The family of Deucalion still reigned in Theffaly; but Thebes, Athens, Argos, and Sparta, which were long regarded as the principal cities of Greece, thus fell under the dominion of four foreign lines of princes, whose exploits, and glory, and misfortunes are immortalized by the first and noblest productions of Grecian genius; such are the works of Homer and Pindar, and of the Greek tragedians.

The invaders of Greece introduced many important and useful improvements. They brought into that country the knowledge of the Phœnician alphabet; they assisted them in the operations of agriculture; they multiplied the rites of religion; discovered to them several uses of the metals; and, in return, adopted the Grecian language, and generally conformed to the Grecian customs and institutions. By the Phœnicians they were taught and encouraged to brave the dangers of the sea, and to maintain a commercial intercourse with each other, as well as with foreign nations. Their country, indeed, was peculiarly advantageous for this purpose; three sides of it being washed by the sea, and being surrounded by numerous islands, and abounding in excellent harbours. Greece, however, was slow in availing itself of the advantages it enjoyed; and in making improvements in commerce, as well as in agriculture, and other useful arts. Many circumstances concurred to retard its improvement. The inhabitants of different parts of the country were unconnected on account of the creeks and rivers, as well as the mountains and promontories, that rendered Greece different from any other part of Europe. The Grecian states were small; each city was at war with its neighbour, and want of union and mutual concurrence prevented their advancement in science and the arts. Besides, their coasts were ravaged by pirates, and the metals, instead of being formed into useful implements of agriculture, were converted into instruments of destruction, partly for hostility and partly for self-defence; and the inland country was invaded by Thracians, Amazons, and other northern savages. But these irruptions and ravages of the barbarians occasioned the institution of the Amphictyonic council, which restored some degree of present tranquillity to Greece, and laid the foundation of its future grandeur. This council produced, after a considerable interval of time, *viz.* in the year 1263 B. C. the Argonautic expedition, an undertaking which was attended with a beneficial effect on the manners and character of the Greeks. (See ARGONAUTIC.) In the progress of the Greeks towards civilization, they perceived the advantages of political confederacy, before they became sensible of the benefits of civil union; and accordingly a federal association between different communities was formed before the members of any one state had been sufficiently united in the system of domestic policy. In order to cement such disorderly communities by laws and governments, they had recourse to the wise institutions and examples of the Cretans, which are represented not only as the most ancient, but as the best regulations that ever were established in any portion of the Grecian territory. (See CRETÆ.) Theseus communicated the Cretan improvements to the Athenians; from Athens they were diffused through Attica, and in process of time through the neighbouring provinces of Greece; insomuch, that at the commencement of the Trojan war, in 1193 B. C. all the Grecian states had adopted one uniform system of government, uniting the independent spirit of European freedom with the respectful veneration of Egyptian and Asiatic superstition.

Of the mythology and manners of the Greeks in the heroic ages, as well as their geography and history, Homer, whilst he has indulged his fancy, has given us an accurate delineation; and such as was conformable to the system of opinions and belief which prevailed among his countrymen. The religion, or mythology of the Greeks, was adapted to the melioration of their condition, and to the improvement of civil society. Unlike that of the rude inhabitants of ancient Germany, among whom the offices of priest and king were administered by different persons, the sceptre, which denoted the connection of civil power with sacred protection, was conferred, among the Greeks, on those who, while they continued the humble ministers of the gods, were appointed to be the chief, but accountable guardians of the people. The same voice (says Dr. Gillies), that summoned the warriors to arms, or that decided, in time of peace, their domestic connections, conducted the order of their religious worship, and presided in the prayers and hymns addressed to the divinity. These prayers and hymns, together with the important rite of sacrifice (which was likewise performed by royal hands), formed the ceremonial part of the Grecian religion. The *moral* was far more extensive, including the principal offices of life, and the noblest virtues of the mind. The useful quality of courage was peculiarly acceptable to the stern god of war; but the virtues of charity and hospitality were still more pleasing to the more amiable divinities. To this purpose Homer says (Od. xiv. 56.) "all strangers and beggars come from Jove." The submission of subjects to their prince, the duty of a prince to preserve inviolate the rights of his subjects (Il. xvi. 385.), the obedience of children to their parents, the respect of the young for the aged, the sacred laws of truth, justice, honour, and decency, were inculcated and maintained by the awful authority of religion. Even the most ordinary transactions of private life were consecrated by the piety of the Greeks. They ventured not to undertake a voyage, or a journey, without soliciting the propitious aid of their heavenly protectors. Every meal (and they had three in a day, *viz.* *αεισιος, δειπνος, λεγετο*), was accompanied with a sacrifice and libation. The common forms of politeness, the customary duties of civility, were not decided by the varying tastes of individuals, but defined by the precise voice of the gods. The laws of religion were guarded and enforced by corresponding functions. The dreaded vengeance of imaginary powers was established in the Grecian creed; and it appears from the writings of Homer throughout, that every important event, prosperous or adverse, which happened either to individuals or to nations, appeared to the Greeks, as the reward of their religion and virtue, or the punishment of their irreligion and vice. The principles above stated are confirmed not only by the writings of Homer and Hesiod, but by almost every page of Herodotus, of Pindar, as well as of the Greek tragedians and historians.

The origin of the gods of Greece has afforded a subject of elaborate discussion; and many learned writers have traced it to Palestine, Egypt, and other nations, whence the first settlers or future emigrants sprung. By the dim light of etymology and tradition (says the ingenious historian of Greece), and the deceitful glare of legend and fable, inquisitive men have endeavoured to trace the corrupted streams of Pagan worship to the pure fountain of the Jewish dispensation; and it must be acknowledged, that the general doctrine of providence, the rebellion in heaven, the state of innocence, the fall of man, atonement by sacrifice, and a future state of retribution, for which the present life is only preparatory, are tenets, all, or some of which, are found in

the traditions of all nations, Greeks and Barbarians. (See Hesiod, Oper. and Di. v. 110, 165. Theog. v. 220. 725.) But our author observes, that the majesty of Jehovah is very feebly represented by the united power of Homer's divinities; and that the mythology of the Greeks is of such a peculiar texture, that, whencesoever originally derived, it must have undergone a particular modification in the Grecian soil; nor (he says) is it easy to concur with the opinion of writers who bring it immediately from Egypt, Chaldæa, or Lesser Asia, when we consider that there is not the smallest vestige in Homer of the judicial astrology which prevailed so much in the two first countries, (Diod. Sic. l. ii. Exod. ch. vi. Plin. l. xxv), or of the worshipping of idols, which almost universally prevailed in the last. (Old Testament, passim.) Dr. Gillies traces the origin of the Grecian faith and worship in the natural passions of the human heart, the hopes, the fears, the wants, the misery of man, which have in all ages rendered him a prey to the terrors of superstition.

The great pillar of superstition, raised by the anxious passions of men, was fortified in Greece by a peculiar sensibility of character, which exerts itself in the ardour of social affection, and strengthens, by a thousand associations, their belief of invisible and intelligent powers. The nature, the characters, and the occupations of the gods, were suggested by the lively feelings of an ardent, rather than by the regular invention of a cultivated mind. These celestial beings were subject to the blind passions which govern unhappy mortals: their wants, and their desires, were similar to those of man. But what was wanting in the dignity and perfection, was supplied by the number of the gods. Homer only describes the principal and reigning divinities; but Hesiod, who gives the genealogical history of this fanciful hierarchy, makes the whole number amount to 30,000. Every virtue had its protector, every quality of extensive power in human life had its patron, and every grove, mountain, and river its favourite inhabitants. (See GODS.) The religious creed of the Greeks, composed of materials, in great measure created by fancy, formed by poetry into beauty, and improved into use by policy, became the happiest antidote against the furious resentment, the savage cruelty, and the fierce spirit of wild independence, which usually characterizes the manners of barbarians. Upon the whole, the ancient and venerable superstition of the Greeks was distinguished above most other false religions, by the uncommon merit of doing much good, without seemingly occasioning any considerable harm to society. The Grecian tenets, while they inculcated profound respect to the gods, had no tendency to break the spirit or to repress the courage of their warlike votaries. In order to avert the calamities threatened by the anger of their divinities, they did not recur to the infliction of tortures on themselves, but they repaired the wrongs which they had committed against their fellow-citizens, or compensated, by new attentions, for the neglect shewn to the ceremonies of their national worship. In their estimation, the doing of injury to men, and the omission of prayer to the gods, were the principal causes of the divine displeasure, which they were anxious to avert by a diligent practice of moral duties. The dangerous power of oracles, the abused privileges of asylums, the wild raptures of prophetic enthusiasm, the abominable ceremonies of the Bacchanalia, and the horrid practice of human sacrifices, all which are circumstances that cover with deserved infamy the latter periods of Paganism, were unknown to the good sense and purity of the heroic ages; nor is there to be discovered the smallest vestige of any of these wild or wicked inventions, either in the writings of Homer, or of his cotemporary Hesiod. Their religious sys-

tem communicated its beneficial influence to the civil and military institutions of the Greeks, to the laws of nations, as well as to the regulations of internal policy, and to the various duties of domestic as well as of social life.

In examining the political states of the Greeks, during the heroic age, we shall find that they deserve the title of republics, rather than that of monarchies. The soldiers of any warlike tribe fought and conquered, in their attack of a more fertile territory than their own woods and mountains, not for their leaders, but for themselves: and the land acquired by their united valour was considered as a common property. No distinction was known among them, but that which was occasioned by the difference of personal merit and abilities. This difference raised a chief or leader to the head of each society; and his superior usefulness in this station, was rewarded by the gratitude of his tribe with a valuable portion of ground, separated from the common property. (Il. xii. 310.) This person, who commanded in the field, became the arbiter and judge of their civil differences, and he was invested with the honourable office of presiding in their religious solemnities. These important functions of priest, judge, and general, conferred on the best and bravest in each particular tribe, were conferred, upon the union of several tribes into one state or nation, on the best and bravest of all the different leaders. The various states of Greece formed a general confederacy, in which the council of princes regulated the resolutions of the monarch, and the voice of the assembly ruled that of the council; and so likewise in each particular kingdom, the decisions of the senate prevailed over the will of the prince, and the acknowledged majesty of the people controuled the decisions of the senate. The same distribution of power took place in every particular village.

The civil rights of the Greeks were maintained by the same simplicity which regulated the political system. As the price of submitting to the restraints of society, a man was secured in the enjoyment of his life and property: his moveables were equally divided, at his death, among his descendants; and the unnatural right of primogeniture, which, in order to enrich the eldest son, reduces the rest of the family to want and misery, was altogether unknown to the equal spirit of the Grecian institutions. Causes respecting property were decided by the first magistrate, or by judges of delegated authority. The prosecution of murderers belonged to the relations of the deceased, who might accept a compensation in money for the loss which the family had sustained; but in defect of this composition, all the members of the tribe concurred with the aggrieved, in either punishing the murderer by death, or compelling him to leave the society.

The history of the heroic ages of Greece presents the most interesting picture of conjugal love, parental affection, and filial duty. The institution of marriage was ascribed to the gods; and it was celebrated with all the pomp of religious festivity. Adultery was held in the greatest detestation, and always mentioned with the same horror as murder. The guilty person might purchase immunity, but more frequently escaped death by voluntary banishment. It has been erroneously said, that, in ancient Greece, wives, as well as concubines, were the slaves of their husbands, and that they were purchased by them. The attention of women was chiefly confined to domestic care and occupations, which did not require any great degree of strength, courage, or wisdom. Weaving and embroidery, which were employments of females, were practised by ladies of the highest rank, and even by queens; and they were also entrusted

crused with the education of their children. They were permitted to join in the celebration of religious rites and ceremonies, and many of them were consecrated to the service of particular divinities.

War, being the principal employment of the Greeks in the heroic ages, they supplied by courage what they wanted in skill. They marched to the field in a deep phalanx, rushed impetuously to the attack, and bravely closed with their enemies. Their principal weapon was the spear; and when the use of this failed, they drew their swords, and rushed impetuously on the foe. The Greeks had also bows, slings, and darts; which were chiefly used in their military pastimes. Their defensive armour was complete: a light helmet, adorned with plumes, covered the head and face, a fine corslet defended the breast, greaves of brass descended to the feet, and an ample shield, loosely attached to the shoulders, turned in all directions, and opposed its firm resistance to every hostile assault. Their close compact combats served to excite the most furious passions, and to embitter national animosity by personal hatred and revenge. Before any war could be undertaken, it was necessary to dispatch ambassadors, who explained the injury that had been done, demanded satisfaction, and if this were refused, denounced the resolution of their community to prosecute its claim by force of arms. After the commencement of war, the characters of heralds were equally respected by friends and foes; and they travelled in safety through the midst of embattled hosts. The use of poisoned weapons was forbidden, under pain of the divine displeasure. The will of the gods required that life should be spared, when a sufficient ransom was promised; and when a treaty of peace was concluded, without any ratification but the honour of the contracting parties, the perfidious wretches who betrayed the sanctity of their engagements were devoted, amidst libations and sacrifices, to the fury of the terrible goddesses. (*Iliad*, iii.)

From the practice of war we may now turn our attention to the arts of peace. Pasturage and agriculture supplied the Greeks with food and clothing; but their implements for preparing these articles were very imperfect. The principal produce of their fields was barley, which supplied the ordinary food of men as well as horses. Mills were unknown, and the grain was bruised between two large stones with the hand. They cultivated the olive, but knew not how to extract the oil; and though their soil was favourable to the grape, the juice was obtained by a tedious and operose process, which rendered wine scarce and dear. Of the mechanic arts, weaving was best understood; and the hatchet, wimble, plane, and level, are the tools mentioned by Homer, who seems to have been unacquainted with the saw, the square, and the compass. Homer does not mention the orders of architecture; and pillars are the only ornaments assigned to the edifices which he describes. The roofs of the houses, consisting of two floors, and surrounded by a wall, were flat. The invention of enamelled metals had been cultivated with peculiar success; and though painting, properly so called, was rude and unformed during the age of Homer, the genius of the divine poet has described the rudiments of his kindred art with such graces as would adorn its most refined state of perfection. Music was much practised among the early Greeks. (See *Music of the Greeks*.) The sciences were in a low and imperfect state. For arithmetic they had little occasion; by means of their astronomy they were enabled to observe the constellations which directed the adventurous course of the mariner; but their navigation was so imperfect, that they seldom abandoned the coasts. The only stars mentioned by Homer are the

Great and Little Bear, the Pleiades, the Hyades, Orion, and the Dog-star. Of their games, we give an account under GAMES and GYMNASTICS. As to their general character, we shall transcribe two or three paragraphs from the first volume of Dr. Gillies's *History of Ancient Greece*, to which we have been indebted in the compilation of this article. "The Greeks," says Dr. G., "had advanced beyond that uniform insipidity of deportment, that fullness of manners, and that hardened insensibility of heart, which universally characterizes the savage state. They still possessed, however, that patient intrepidity, that noble spirit of independence, that ardent attachment to their friends, and that generous contempt of pain, danger, and death, which render the description of the wild tribes of America so interesting to a philosophic mind. Of two principal enjoyments of life, study and conversation, they were little acquainted, indeed, with the consolations and pleasures of the first, the want of which was compensated by the sincerity, the confidence, the charms of the second. Their social affections were less comprehensive in their objects, but more powerful in their effects than those of polished nations. A generous chief rushes to certain death to revenge the cause of his friend; yet refuses to the prayers of an aged parent the melancholy consolation of interring the remains of his favourite son, till the corresponding image of his own father strikes his mind, and at once melts him to pity. (*Iliad*, xxiv.) The imaginary wants and artificial passions which are so necessary to urge the hand of industry, and to vary the pursuits of men, in improved commercial societies, were supplied to the Greeks by that excessive sensibility, which interested them so deeply in the affairs of their community, their tribe, their family, and their friends, and which connected them by the feelings of gratitude even with the inanimate objects of nature. As they were not acquainted with the same diversity of employments, so neither were they fatigued with the same giddy round of dissipated pleasures which augment the splendid misery of later times. Though ignorant of innumerable acts which adorn the present age, they had discovered one of inestimable value, to render the great duties of life its most entertaining amusement. It will not, perhaps, be easy to point out a nation who united a more complete subordination to established authority with a higher sense of personal independence, and a more respectful regard to the dictates of religion with a more ardent spirit of martial enterprise. The generous quality of their political establishments, and their fancied intercourse with the gods, conspired to raise them to a certain elevation of character which will be for ever remembered and admired. This character was rendered permanent in Sparta, by the famous laws commonly ascribed to the invention of Lycurgus, but which will appear (under that article) to have been "almost exact copies of the customs and institutions that universally prevailed in Greece during the heroic ages." The character of the Greeks in subsequent periods will appear in the account of the several states, provinces, or kingdoms, which they occupied.

The general history of Greece may be divided into four periods, marked by as many memorable epochs. The *first* extends to the siege of Troy in the year 1184 B.C.; the era of its commencement is not precisely ascertained; but if we date it with the foundation of the kingdom of Sicily by Ægeides in the year 2089 B.C., it lasted 905 years. This was properly the infancy of Greece; and comprehends the establishment of the kingdoms of Sicily, of Argos, 1859 B.C., of Athens, 1556 B.C., of Troy, 1546 B.C., of Thebes, 1493 B.C., of Mycenæ, 1344 B.C.; the deluge of Ogyges, 1764 B.C. and that of Deucalion, 1503 B.C.;

the murder committed by the daughters of Danaus on their husbands, 1485 B.C.; the introduction of the Phœnician letters into Greece, 1493 B.C.; the legislation of Minos in Crete, 1406 B.C.; the Argonautic expedition, 1263 B.C.; the exploits of Theseus, 1234 B.C.; the war of the seven heroes against Thebes, 1225 B.C., &c. &c.

The *second* period begins with the siege of Troy, and terminates with the battle of Marathon, 490 B.C., including about 694 years. In the year 1104 B.C., 80 years after the taking of Troy, the Heraclidæ, or descendants of Hercules, conducted the Dorians to the eastern coast of Peloponnesus, and having landed their followers without opposition, assailed the defenceless territories, to which they had long laid claim, comprehending the whole peninsula, except the central province of Arcadia, and the maritime district of Achaia. The five other provinces were conquered at the same time, though by different means. Laconia was betrayed to the invaders; Argos acknowledged their authority; Corinth, Elis, and Messenia submitted to their arms. The revolution was complete, and effected with little bloodshed; but not without great oppression of the ancient inhabitants, many of whom emigrated, and many were reduced to slavery. The Heraclidæ divided their new acquisitions by lot. Upon the division of Peloponnesus the kingdom of Lacedæmon commenced, 1102 B.C. In the year 1096 B.C., or 88 years after the taking of Troy, the Eolians, having traversed the northern parts of Græcia in quest of new settlements, crossed the Hellespont, and established themselves along the shore of the ancient kingdom of Priam. They gradually diffused their colonies from Cyzicus on the Propontis to the mouth of the river Hermus; which delightful country, together with the isle of Lesbos, from this time received the name of Eolis or Eolia, denoting that its inhabitants belonged to the Eolian branch of the Hellenic race. In the year 1070 B.C. royalty terminated in Athens upon the death of Codrus, and the Athenians were afterwards governed by Archons. In the year 1044 B.C., 60 years after the return of the Heraclidæ, the Ionians, blended with other emigrants, having seized the central and most beautiful part of the Asiatic coast, gradually diffused their colonies from the banks of the Hermus to the promontory of Posidion, and afterwards took possession of Chios and Samos; and all these countries were united in the year above-mentioned by the name of Ionia, intimating that the Ionians composed the most numerous division of the colony. (See IONIA) The Doric migration took place in the year B.C. 944 (See DORIS)

During the heroic ages we have seen, in the preceding part of this article, that the authority of kings was founded on religion, supported by gratitude, and confirmed by utility. While they approved themselves worthy ministers of heaven, they were entitled to due and hereditary honours; but they were bound to respect the rights, the sentiments, and even the prejudices of their subjects. But at length, incited by ambition and avarice, they transgressed the prescribed limits, and trampled on those laws which their predecessors had held sacred. The minute division of property, which had taken place, not only in Peloponnesus, but in the northern provinces of Greece, rendered the nobles and people more sensible of their encroachments, and induced them to resist their oppressors. The more independent and illustrious citizens, who from the earliest times had been accustomed to come armed to the council or assembly, communicated their grievances, and adopted proper means for removing them. Miltas, the fourth Argive prince in succession to Temenus, to whom Argos fell on the Heraclidan distribution, was con-

demned to death for usurping absolute power. In Attica monarchy more honourably expired; it perished still more disgracefully in Arcadia; but was gradually abolished in every province of Greece, except Sparta, from the southern extremity of Peloponnesus to the northern frontier of Thesaly. The consequence of the abolition of monarchy was the introduction of accumulated evils. These, however, were removed, or at least alleviated, by the authority of the Amphictyonic council, and by that of the oracles, particularly that of Delphi. This latter oracle confirmed by its awful sanction the Olympic games and Spartan laws, which had been respectively established, the former by Iphitus, and the latter by Lycurgus in the same year, viz. 884 B.C.; and which served to the safety of their respective territories, though in different ways; the Olympic games by rendering Elis the most pacific, and the laws of Lycurgus by making Sparta the most warlike, of all the Grecian communities. Greece, even under its kings, was divided into many independent states; and under the republican form of government it was still more subdivided; and hence wars became more frequent, and battles more bloody and more obstinate. But the long and spirited contest between the Lacedæmonians and Messenians was the only war of that age which produced permanent effects. Of Laconia and Messenia we shall give an account under their respective articles. We shall here observe, that they were both governed by kings of the family of Hercules, and inhabited by subjects of the Doric race, and yet this kind of mutual affinity and connection was not sufficient to counteract other causes, which produced hostilities among them. Urged by reciprocal provocations which we cannot here detail, the Spartans invade the Messian frontier and attack the small town of Amphica; and thus in the year 743 B.C. began the first war between the Messenians and Lacedæmonians, which lasted 19 years, and terminated with the surrender of Ithome, their capital, to the Lacedæmonians, and the dispersion of its inhabitants. In the year 685 B.C. the Messenians prepare to revolt, and a second war commences, which continued 14 years, and ended with the capture of Ira, or Eira, by the Lacedæmonians, after a siege of 11 years. The conquest of Messenia rendered Sparta the most considerable power in Greece, as its subjects occupied two-fifths of the Peloponnesus. In the year B.C. 600 commenced the first "Sacred War," occasioned by an injury committed against the oracle of Delphi, and undertaken by order of the Amphictyons, and terminated by the total destruction of the cities accused of sacrilegious outrage. On occasion of the happy termination of this war the Pythian games were re-established 591 B.C. The battle of Marathon, which closes this second period of the Grecian history, terminated, after a very severe contest, in the total defeat of the Persians, and triumph of the Athenians under their commander Miltiades.

The *third* period of the history of Greece comprehends an interval of 167 years, that elapsed between the battle of Marathon and the death of Alexander, 323 B.C. The Athenians, in compliance with the advice of Themistocles, augment their navy; and under his command they defeat the fleets of Ægina and Corcyra. Themistocles, instead of allowing the Athenians to indulge themselves in security after the advantages they had gained, exhorted them to be always ready for action. In consequence of this judicious counsel, they were enabled to oppose the immense armaments of Xerxes. The Athenian fleet proved the safe-guard of Greece, and prevented a country, from which the knowledge of laws, learning, and civility was destined to flow over Europe, from becoming a province of the Persian empire, and being confounded with the mass of barbarous nations. Xerxes was provided
