The lesser hours, are *prime*, *terce*, *sixth*, and *none*. They are called *hours*, or *canonical hours*, as being to be rehearsed at certain hours prescribed by the canons of that church, in commemoration of the mysteries accomplished at these hours. These hours were anciently also called *course*, *curfus*. F. Mabillon has a dissertation on them, entitled *de Curfu Gallicano*.

The first constitution enjoining the observation of the canonical hours, is of the ninth century, being found in a capitular of Heito, bishop of Brazil, directed to his curates, importing, that the priests shall never be absent at the canonical hours, either by day or night.

Hours, *Prayers of forty*, are public prayers continued for

the space of three days successively, and without intermission before the holy sacrament, to obtain the assistance of heaven on some important occasion.

In these days, care is taken, that the holy sacrament be exposed forty hours, *viz.* thirteen or fourteen hours each day.

Hour-circles, or **HORARY CIRCLES**, in *Astronomy*, &c. are great circles, meeting in the poles of the world, and crossing the equinoctial at right angles; the same as meridians.

They are supposed to be drawn through every fifteenth degree of the equinoctial and equator, and on both globes are supplied by the meridian hour-circle and index. See **GLOBE**.

The planes of the hour-circles are perpendicular to the plane of the equinoctial, which they divide into twenty-four equal parts.

Hour-glass, a popular kind of chronometer or clepsydra, serving to measure the flux of time, by the descent or running of sand out of one glass vessel into another.

The best hour-glasses are those, which, instead of sand, have egg-shells well dried in the oven, then beaten fine and sifted.

Hour-glasses are much used at sea for reckoning, &c.

There is also a sort of hour-glasses, which depend on the flux of water, or some other liquid, more properly called *clepsydra*. See **CLEPSYDRA**.

Hour-lines, on a *Dial*, are lines which arise from the intersections of the plane of the dial, with the several planes of the hour-circles of the sphere, and therefore must be all right lines. See **DIAL**.

Hour-scale, a divided line on the edge of Collins's quadrant, being only of tangents of forty-five degrees each, set together in the middle. Its use, together with the lines of latitude, is to draw the hour-lines of dials that have centres, by means of an equilateral triangle, drawn on the dial-planes. See **DIALLING lines**, and **SCALE**.

HOURA, in *Geography*, a small island near the W. coast of Scotland. N. lat. $57^{\circ} 56'$. W. long. $5^{\circ} 16'$.

HOURIS, in *Modern History*, is a name given by the Mahometans to those females that are designed for the faithful in paradise. These are not the same with whom they have lived on earth, but formed for this purpose, with singular beauty and undecaying charms.

HOURSACK, in *Geography*, a town of Persian Armenia; 150 miles E.N.E. of Erivan.

HOUSAGE, a fee which a carrier, or other person, pays for laying up goods in a house.

HOUSANABUD, in *Geography*, a town of Hindoostan, in Bahar.

HOUSANGUNGE, a town of Hindoostan, in Oude; 40 miles N. of Manickpour.

HOUSATONICK, or **HOOSTONNUC**, signifying in the Indian language “over the mountain,” a river of Connecticut, which has two sources; one in Laneborough, the other in Windsor, both in Berkshire county, Massachusetts. These branches unite in Pittsfield, and the river, after passing through a number of towns, discharges itself into Long Island Sound, between Stratford and Milford, in Connecticut. It is navigable about 12 miles to Derby. Between Salisbury and Canaan, this river forms a cataract 150 yards wide, and 60 feet in perpendicular fall. Several useful mills and iron works are erected on the falls of this river.

HOUSE, a habitation, or a building constructed for sheltering a man's person and goods from the inclemencies of the weather, and the injuries of ill disposed persons. Houses differ in magnitude, being of two or three, and four stories,

stories, in the materials of which they consist, as wood, brick, or stone, and in the purposes for which they are designed, as a manor-house, farm-house, cottage, &c.

Ancient Rome consisted of forty-eight thousand houses, all insulated or detached from one another.

For the number of houses, and of inhabitants to a house in England, &c. see the article *EXPECTATION of Life*. See also each county and town, under its respective appellation.

A pleasure house, or country house, is that built for occasional residence, and for the pleasure and benefit of retirement, air, &c. This is the *villa* of the ancient Romans; and what in Spain and Portugal they call *quinta*; in Provence, *casine*; in some other parts of France, *closerie*; in Italy, *vigna*.

The citizens of Paris have also their *maisons de bouteilles*, *bottle houses*, to retire to, and entertain their friends; which in Latin might be called *micæ*; the emperor Domitian having a house built for the like purpose, mentioned under this name by Martial, lib. ii. ep. 59.

It is a thing principally to be aimed at, in the site or situation of a country house, or seat, that it have wood and water near it.

It is far better to have a house defended by trees than hills; for trees yield a cooling, refreshing, sweet, and healthy air and shade, during the heat of the summer, and very much break the cold winds and tempests from every point in the winter. The hills, according to their situation, defend only from some certain winds; and if they are on the north-side of the house, as they defend from the cold air in the winter, so they also deprive you of the cool refreshing breezes, which are commonly blown from thence in the summer. And if the hills are situate on the south side, they then prove also very inconvenient.

A house should not be too low seated, since this precludes the convenience of cellars. If you cannot avoid building on low grounds, set the first floor above the ground the higher, to supply what you want to sink in your cellar in the ground; for in such low and moist grounds, it conduces much to the dryness and healthiness of the air to have cellars under the house, so that the floors be good and ciled underneath. Houses built too high, in places obvious to the winds, and not well defended by hills or trees, require more materials to build them, and more also of reparations to maintain them; and they are not so commodious to the inhabitants as the lower-built houses, which may be built at a much easier rate, and also as complete and beautiful as the other.

In buildings or houses not above two stories with the ground-room, and not exceeding twenty feet to the raison-place, and upon a good foundation, the length of two bricks, or eighteen inches for the heading course, will be sufficient for the ground-work of any common structure, and six or seven courses above the earth to a water-table, where the thickness of the walls is abated, or taken in, on either side the thickness of a brick, namely, two inches and a quarter.

For large and high houses, or buildings, of three, four, or five stories with the garrets, the walls of such edifices ought to be from the foundation to the first water-table three heading courses of brick, or twenty-eight inches at least; and at every story a water-table, or taking in on the inside for the summers, girders, and joints, to rest upon, laid into the middle, or one quarter of the wall at least, for the better bond. But as for the innermost or partition wall, a half brick will be sufficiently thick; and for the upper stories, nine inches, or a brick length, will suffice.

The parts, proportions, &c. of the houses in London, are regulated by statute. See *BUILDING*, and article *FIRE-cocks*.

Every man has a right to air and light in his own house; and therefore if any thing of an infectious smell be laid near the house of another, or his lights be stopped up and darkened by buildings, &c. they are nuisances punishable by our laws; but no action lies for merely obstructing the opening of a prospect. If a man's house be attacked with intent to kill, and the owner or his servants kill the thieves in defending him and his house, this is not felony, and incurs no forfeiture. One man may compel another to repair his house in several cases, by the writ *de dono reparanda*. The doors of a house may not be broke open on arrears, except in cases of treason or felony, &c. The riotously pulling down of a house is felony excluded clergy. Stealing lead, or iron bars, or rails fixed to houses, &c. is felony punishable by transportation, by 4 Geo. cap. 32. The hundred is liable to damages by the burning of houses. 9 Geo. cap. 32. See *ARSON*, *BURGLARY*, &c.

HOUSE-cricket, in *Entomology*. See *GRYLLUS domestica*.

HOUSE, Hot. See *HOT-house* and *STOVE*.

HOUSE, Green. See *GREEN-HOUSE*.

HOUSE, Ice. See *ICE*.

HOUSE-lamb, in *Rural Economy*, a name given to that sort of lamb which has been reared and fattened in the house. See *LAMB-fuckling*.

HOUSE, Summer, a little edifice erected at the corner of a garden, and contrived so as to let air in on all sides; or to exclude it, as you find proper.

HOUSE, Town, or Hall, is a place where the officers and magistrates of a town or city hold their meetings, for the due administration of their laws and policy. See *HALL* and *GUILD*.

HOUSE, Work. See *WORK-house* and *BRIDEWELL*. See also the article *RASPIHYS*.

HOUSE of Correction. Justices of the peace in sessions are to make orders for erecting or enlarging houses of correction, and for the maintenance and government of the same, and for the punishment of offenders committed thither; on presentment of the grand jury, or of a justice on his own view or knowledge, that such houses are wanted. (7 Jac. I. c. 4. 17 Geo. II. c. 5. 14 Geo. II. c. 33. 22 Geo. III. c. 64. 24 Geo. III. sess. 2. c. 55.) In every county of England there shall be a house or houses of correction, built at the charge of the county, with all conveniences for the setting of people to work. The expence of building, repairing, and purchasing land, &c. for houses of correction, and maintaining them, shall be defrayed by order of the justices in sessions, by the monies raised in the same manner as the general county-rate; and when the amount thereof shall exceed one-half of the amount of the ordinary annual assessment for the same, (computed at a medium for the last five preceding years), they may borrow on mortgage of the said rates, any sum not less than 50*l.* nor more than 100*l.* each, ordering the interest to be paid off yearly, and so much of the principal sum as shall at least be equal to the interest, until the whole shall be discharged; provided that the whole money borrowed be fully paid within 14 years from the time of borrowing the same. (17 Geo. II. c. 5. 22 Geo. III. c. 64. 24 Geo. III. sess. 2. c. 55.) The justices at their quarter sessions shall nominate one or more justices, within their respective districts as visitors and inspectors, who shall report to the next quarter sessions. And the justices in sessions are to appoint governors or masters of such houses of correction, and their salaries, &c. which are to be paid quarterly out of the county rate. They may also allow such

governors some proportion of the profits earned by the prisoners. The salaries shall be fixed with a reference to the quantity of work done. (22 Geo. III. c. 64. 31 Geo. III. c. 46.) These governors are to set the persons sent on work, and to punish offenders (except by whipping); and in case of repetition of offences to report to the visiting justices, who shall order such offenders to be punished, either by moderate whipping, repeated whippings, or close confinement for any term not exceeding one month. Governors are to yield a true account every quarter-sessions of persons committed to their custodies; and if they suffer any to escape, the justices may fine them.

The justices, at some general or quarter-sessions, at which five justices, at the least, shall be present, may make such rules and orders for receiving, separating, classing, dieting, clothing, maintaining, employing, reforming, governing, managing, treating, and watching offenders during their confinement in penitentiary houses, according to 19 Geo. III. c. 47. (See *PENITENTIARY Houses*, and *TRANSPORTATION*.) Such rules and orders are to be submitted to the judges of assize, &c. 31 Geo. III. c. 46. If persons ordered to hard labour shall escape, or be assisted in escaping, or rescued, every such offence shall be punished in the same manner as the like offence would be punished by 19 Geo. III. c. 74. concerning penitentiary houses. Separate apartments shall be provided by 22 Geo. III. c. 64. By the same act, the governor or keeper of every house of correction shall employ persons, not committed to hard labour, in some work that is not severe, and allow them half their earnings, to be paid at the time of their discharge. The justices in sessions may also appoint, at pleasure, a minister of the church of England, residing near the house of correction, to perform divine service there every Sunday, and appoint him a salary not exceeding 20*l.* a-year. No governor or assistant shall sell, or be licensed to sell, or have any benefit from the sale of any wine, ale, beer, spirituous or other liquors; nor shall such liquors be brought into the house of correction, to be drank there, unless for a medical purpose, by a written direction, under the hand of the apothecary or surgeon attending such house, under a penalty of 10*l.* The master shall deliver to the justices, at every general quarter-sessions, a written account of the persons in custody, with the offence of each, time of commitment, distinguishing the age and sex of those committed to hard labour, the business in which they have been employed, and the behaviour of each during confinement.

The house of correction is for the employing and punishing of idle and disorderly persons, parents of bastard children, beggars, servants running away, trespassers, rogues, vagabonds, &c. Poor persons refusing to work, are there to be whipped, and set to work and labour; and any person who lives extravagantly, having no visible way to support himself, may be sent to the house of correction, and set to work there, and may be kept there, until he gives the justice satisfaction in respect to his living, but not to be whipped. A person ought to be convicted of vagrancy, &c. before he is ordered to be whipped.

Whereas doubts may arise where authority is given to any justice or justices, to commit offenders to the house of correction, for offences cognizable before them out of sessions, how long offenders may be there detained, and in what manner treated, when the time and manner of their punishment is not by law expressly limited; it is enacted by 17 Geo. II. c. 5. that when any offender shall be committed as aforesaid, by virtue of any law in being, or to be made, and the time and manner of their punishment are not expressly limited, the said justice or justices shall commit such offenders to the

house of correction, there to be kept to hard labour until the next general or quarter-sessions, and until discharged by due course of law: and two justices (of whom the justice who committed him to be one) may discharge the said offender before the sessions if they see cause: and if he shall not be so discharged, the said sessions may either discharge him or continue him further, not exceeding three months. A table of rules and orders for the government of houses of correction, is ordered to be fixed in some conspicuous part of such houses by 22 Geo. III. c. 64, of which the following is a copy:

“ Rules, orders, and regulations to be observed and enforced at every house of correction provided and established, or to be provided and established, under the authority of the acts of the 7th year of the reign of his late majesty king James I. the 17th of king George II. and the 22d of king George III.

“ 1. That the several persons who shall be committed to the house of correction to be kept to hard labour, shall be employed (unless prevented by ill health) every day during their confinement (except Sundays, Christmas day, and Good-Friday), for so many hours as the day-light in the different seasons of the year will admit, not exceeding twelve hours, being allowed thereout to rest half an hour at breakfast, an hour at dinner, and half an hour at supper, and that the intervals shall be noticed by the ringing of a bell.

“ 2. That the governor of each house of correction shall adapt the various employments, which shall be directed by the justices at their quarter-sessions, to each person in such manner as shall be best suited to his or her strength and ability, regard being had to age and sex.

“ 3. That the males and females shall be employed, and shall also eat and be lodged in separate apartments, and shall have no intercourse or communication with each other.

“ 4. That every person so committed shall be sustained with bread, and any coarse but wholesome food and water; but persons under the care of the physician, surgeon, or apothecary, shall be sustained with such food and liquor as he shall direct.

“ 5. That the governor, and such other persons (if any) as shall be employed by the justices to assist the governor, shall be very watchful and attentive in seeing that the persons so committed are constantly employed during the hours of work; and if any person shall be found remiss or negligent in performing what is required to be done by such person to the best of his or her power and ability, or shall wilfully waste, spoil, or damage the goods committed to his or her care, the governor shall punish every such person in the manner hereafter directed.

“ 6. That if any person so committed shall refuse to obey the orders given by the governor, or shall be guilty of profane cursing or swearing; or of any indecent behaviour or expression; or of any assault, quarrel, or abusive words, to or with any other person: he or she shall be punished for the same in the manner hereafter directed.

“ 7. That the governor shall have power to punish the several offenders for the offences herein before described, by closer confinement; and shall enter in a book, to be kept by him for the inspection of the justices at the quarter-sessions, and the visiting justice or justices, the name of every person who shall be so punished by him, expressing the offence, and the duration of the punishment inflicted.”

Bridewell is a prison for correction in London, and offenders may be sent thither. See *BRIDEWELL* and *HOSPITAL*.

HOUSE is also used for a convent or monastery.

Regular priests give the name houses to the places they

reside in, and not that of convents or monasteries, which properly belong to simple friars. Thus we say the Jesuits' house, and the Barnabites or Theatins' house.

The Jesuits have both professed houses, and colleges for novices, which they call *houses of probation*.

They have also *houses of retreat* for spiritual exercises, where they receive secular persons and ecclesiastics disposed to practise the same with them for eight or ten days.

HOUSE is also used for one of the estates of the kingdom assembled in parliament.

Thus we say, the house of lords, the house of commons, &c. See COMMONS, PARLIAMENT, and PEERS.

HOUSE is also used for a noble family; or a race of illustrious persons issued from the same stock. See GENEALOGY.

In this sense we say, the house or family of the Stuarts, the house of Bourbon, the house of Hanover, of Austria, of Lorrain, of Savoy, &c.

HOUSE, in *Astrology*, a dodecatemory, or 12th part of the heavens.

The division of the heavens into houses is founded on this, that the stars and planets, when found herein, are supposed to have certain influences, either good or evil, upon sublunary bodies; and to each house is assigned its particular virtue or influence; upon the consideration whereof they draw horoscopes. See HOROSCOPE.

This division is made by six great circles, called *circles of position*, which cut each other in the common intersection of the meridian and horizon, in the ordinary way of domifying, which is that of Regiomontanus: for the ancients had three other ways.

These circles divide the equator into 12 equal parts, of 30 degrees each, without any regard to the zodiac. The horizon and meridian are two circles of the celestial houses, which divide the heavens into four equal parts, each whereof comprehends three houses. There are six above the horizon, and as many below it; and six eastern and six western houses.

The scheme or figure of the heavens consists of 12 triangles, which are likewise called houses; wherein are laid down the stars, signs, and planets, comprised within the respective spaces of the circles of position.

Each planet has two certain houses, whereing they say it exerts itself with peculiar vigour. Leo is the sun's house, and Cancer that of the moon; Capricorn is Saturn's, &c.

Some call the houses dodecatemories; but that name is more immediately appropriated to the twelve signs or divisions of the zodiac. See DODECATEMORY.

The Astrological houses have their particular names according to their qualities. The first is the *house of life*, being the ascendant, and containing five degrees above the horizon, the rest beneath it; the second is the *house of riches*; the third, the *house of brothers*; the fourth, in the lowest part of heaven, the *house of relations*, and the angle of the earth; the fifth, the *house of children*; the sixth, the *house of health*; the seventh, the *house of marriage*, and the angle of the west; the eighth, the *house of death*, and upper gate; the ninth, the *house of piety*; the tenth, the *house of offices*; the eleventh, the *house of friends*; and the twelfth, the *house of enemies*.

It is popularly, and as it were poetically, said, that the sun had 12 houses, by which are meant the 12 signs, though in reality it has only one sign, *viz.* Leo: besides, the division of houses is accommodated to the equator, and not the zodiac.

They begin numbering the houses with the ascendant, and pass them to the *inimæ cœli*; so that the vertical point makes the beginning of the tenth.

HOUSES, *Differences of*, in *Heraldry*. See DIFFERENCES.

HOUSE-bote, *Estovers*, in *Law*; or an allowance of timber out of the lord's wood, for the repair and upholding a house or tenement.

Some make house-bote two-fold, *viz.* *Estoverium edificandi & ardendi*. See ESTOVERS.

HOUSE-breaking, or *House-robbing*, the robbing or plundering a man in some part of his house, or his booth, or stall, in a fair or market; the owner, or his wife, children, or servants, being within the same.

This was made felony by stat. 23 Hen. VIII. and 3 Ed. VI. but it is since also made felony, though none be within the house, 26 Eliz. See BURGLARY and LARCENY.

HOUSE-burning. See ARSON.

HOUSE-coal, in *Mining*, is applied to such sort of coals, as are adapted, and in general used as firing by the inhabitants of coal districts, called also *fire-coal*, to distinguish them from lime-coal, engine-coal, steek, &c. which are refuse, or sinking-coal, used chiefly for burning lime, working steam-engines, &c.

HOUSE-island, in *Geography*, one of the Shetland islands, about seven miles long and one broad. N. lat. 60° 4'. W. long. 1° 35'.

HOUSE painter. See PAINTING.

HOUSE of Recovery, a hospital for the reception of persons labouring under infectious fever, or typhus, with a view not only to the cure of the disease, but to the suppression of the contagion.

This very important institution, of which many examples are now to be found in England and Ireland, is of very recent date; the first house of the kind having been established at Manchester in the year 1796, when this appellation was adopted, as being less alarming to the feelings of the poor, and of the public in general, than that of *fever-house*. For the original suggestion of such establishments, and for the satisfactory documents in proof of the safety and advantages which they afford, deduced from a long and philosophical investigation of the nature of contagion, the country is indebted to Dr. Haygarth. The principles on which he recommended the plan, had been inferred by so cautious an induction from observation and experiment, that every instance of the practical application of them has served but to corroborate their truth.

It is well known to those who have attended to the history of epidemic diseases, that the various contagious fevers, which have been denominated the plague, putrid, spotted, and malignant fevers, have, together with the small-pox, measles, and scarlet fever, been the principal scourges of mankind, since history has afforded us any accurate records on the subject; and that the ravages of pestilence in general have been confined to the crowded population of large camps, towns, and cities. (See EPIDEMIC.) With the origin of the small-pox, measles, and scarlet-fever, we are altogether unacquainted; they seem to be propagated only by a specific contagion, generated in the bodies of those who labour under the diseases. But the origin of the other fevers above specified has been traced, we apprehend, with a clearness that admits of no doubt, to the effluvia generated from the accumulated filth, and the uncleanly persons and habitations, abounding in large and populous cities. (See HEALTH, *Public*.) And although it has been shewn, that the frequency and extensive range of these pestilential fevers have been curtailed, and some of them actually annihilated, by the system of public and private cleanliness and ventilation adopted in modern times; yet until the abodes of poverty can be rendered airy and cleanly, (a consummation scarcely to be hoped for,) contagion will continue to be generated under certain circumstances, and will necessarily

HOUSE OF RECOVERY.

necessarily tend to propagate itself to an indefinite extent. And such, in fact, has been the actual state of the case, in all large and crowded towns, until within a very few years. The inhabitants of the cellars and garrets in the dirty alleys and lanes in Manchester, Liverpool, London, Dublin, &c. &c. have been found to suffer severely from the generation of infectious fever in their apartments, or from the ready propagation of it, whenever introduced.

From the nature of the accommodation of the poor in their lodging-houses, from their inability to preserve cleanliness, and from the constant intercourse between the inhabitants of the different apartments of these houses, not only is contagious fever generated; it is also readily propagated, and it becomes an irremovable inmate, as it were, of the houses. "When a fever either arises in, or is introduced into the house of a poor person, every circumstance favouring its progress, it generally attacks the family in succession: their clothes, and the woollen and cotton part of their furniture become infected, retain the infection tenaciously, and are capable of communicating the disease for a long time. These they can neither afford to purify or destroy. Thus their dwellings and persons continually breathe contagion; and where this is the situation, not of one family only, but of a great number, it is hardly possible to prevent a communication of the disease to the families of the rich, among whom it would never have been produced." (Ferriar's Med. Hist. and Reflect. vol. i. p. 243.) The same author, speaking of the situation of some of these habitations of the poor in Manchester, observes, "In those houses a very dangerous fever constantly subsists, and has subsisted for a considerable number of years. I have known nine patients confined in fevers at the same time in one of these houses, and crammed into three small dirty rooms, without the regular attendance of any friend or even of a nurse. Four of these poor creatures died, absolutely from want of the common offices of humanity, and neglect in the administration of their medicines. As soon as one dies, or is driven out of his cell, he is replaced by another, who soon feels, in his turn, the consequences of breathing infected air. In most of these places lodgers are received; the consequence is a perpetual succession of fever patients among them." That these representations are faithfully correct, those who have had an opportunity of visiting the sick poor in this metropolis can evince. We have seen the inhabitants of the same house attacked, several successive times, by the influence of their own contagion. Even the convalescents, from their confinement in the midst of infection, have frequent relapses, so that the disease would sometimes continue on the same spot for several months together.

It must be obvious, that these nests of contagion are constant sources of danger to the public, and that diseases may be communicated even to distant quarters of the town, by the sale of clothes, impregnated with it in its most active form (see Dr. Willan on Scarlatina), and by the public coaches, &c. And it must be not less clear, that the mere removal of a few infected individuals to the public hospitals, is altogether inadequate to strike at the root of the evil, although it may preserve the lives of some of the individuals thus removed. A striking illustration of these points is afforded in a case mentioned by the late Dr. T. A. Murray. He was called upon to visit a poor man in a close alley leading from Shoe-lane, who was ill of typhus-fever. This patient occupied a back room, on the ground floor, together with his wife and five female children, the eldest of whom was sixteen years of age, the youngest two. There was but one bedstead in the room, but some bedding lay on the floor, between this and the fire-place; it was lighted by one

window, which, from its construction, could not be opened. The room, the bedding, and the persons of the inhabitants were all filthy and offensive in the highest degree. It appeared, however, that the mother had been first attacked, in consequence, as she supposed, of having visited a person who died of the fever in one of the upper apartments. She had immediately obtained admission into an hospital, and remained there until she thought herself able to return to her family; though still retaining in her clothes, or person, enough of the contagion to infect them. Soon after her return her husband was attacked by the fever; then the second and third of her daughters; afterwards the eldest and the two youngest. Medicine, as might have been foretold, was of very little service in such a situation. The father of the family died on the fourth day after he was visited. The children continued to linger under the disease, when this report was made. The eldest of them was conveyed to a hospital in a hackney coach, having, until the time of her removal, lain by the side of her father, on that part of the infected bed which the dead body of their father had previously occupied. See Remarks on the Situation of the Poor in the Metropolis, as contributing to the Progress of Contagious Diseases, by Dr. Murray, published by the Society for bettering the Condition of the Poor, in 1801. p. 27.

On contemplating scenes like this, and considering the danger thence resulting to the public, and the misery inflicted on the families of the poor, we cannot but highly approve the nature of an institution, which has for its object at once the removal of the patients from such pestilential habitations (by means which secure the public), to a *House of Recovery*, and also the purification of the infected apartments, and the destruction of the contagion, in the clothes and furniture, and whatever else may be imbued with it. Such are the purposes accomplished by the institution of Houses of Recovery; and we shall briefly state the grounds upon which such establishments were proposed, the methods in which they have been executed, and the happy results which have accrued from them.

The first suggestion of the advantages of the establishment in question was made by Dr. Haygarth, at Chester, about the year 1772, from a consideration of the nature of contagion, and of the mode and limits of its propagation. His own observations, supported by those of Sir John Pringle, Dr. Lind, and others, had taught him that contagious effluvia are particularly active in close and unventilated apartments; but that, in the open air, or when diluted by the free admission of fresh air into the infected room, they become comparatively inert and harmless, and might be breathed for a long time with perfect impunity; and that even the concentrated infection of a close room might be respired for a short time without producing fever, especially at a little distance from the person deceased. It had been shewn too, by Dr. O'Ryan's experiments at Montpellier, that the contagion of small-pox was limited in its operation to the distance of a few feet from the person infected; and by Dr. Russell, Dr. Mertens, &c. that even the contagion of the plague was harmless at a similar distance, particularly in the air of well ventilated places. (See CONTAGION, where the evidence of these statements is adduced.) In short, Dr. Haygarth was irresistibly led to the conclusion, that contagion is not communicated to any distance through the air, and that, in a well ventilated and clean apartment in a house or hospital, persons affected with contagious fever might be received, without any risk to the occupants of other apartments in the same building, much less to the inhabitants of neighbouring or even adjoining houses. In consequence of these well-founded opinions, a

HOUSE OF RECOVERY.

Fever-ward was opened in the infirmary at Chester, in the year 1773, with the most beneficial effects; *i. e.* two wards were set apart for the reception of patients labouring under typhus-fever, and were continued open without any injury to the other wards of that hospital, or to the neighbourhood, but with a great diminution of contagious fever in the town.

For, in the mean time, the attention of the officers of the infirmary was directed to the apartments from which the sick had been removed; the furniture, clothes, &c. which had been about the persons of the patients, were purified, by washing, fumigation, &c. and the rooms cleaned and white-washed. The patients, after their recovery in the fever-wards, were sent home to their families in clean garments; being thus rendered secure from the chance of re-infection on their arrival, and incapable of communicating it to their inmates.

The success of this establishment led to the opening of fever-wards in the infirmary at Liverpool, under the direction of the late Dr. Currie, where the experiment was attended with the same success. The inhabitants of Manchester, from the pressing representations of Dr. Ferriar, were induced to form a separate establishment, as already stated, in 1795; and similar houses have been instituted in several of the large towns both in England and Ireland, especially at Dublin, Waterford, Cork, &c. in London, Leeds, and other places; in all of which the principles of Dr. Haygarth have been invariably confirmed, and the most substantial benefits conferred upon the inhabitants.

Regulations of a House of Recovery.—The following are the principal regulations adopted in the management of the House of Recovery, in Gray's-inn-lane Road, London, which was opened in 1802, under the patronage of the Society for bettering the Condition of the Poor; they are chiefly taken from those of the establishment at Manchester. See Dr. Ferriar, *loc. cit.* vol. iii. p. 66.

1. The admission of patients is left entirely to the physician, who, as soon he has ascertained the state of the person recommended, gives an order for that purpose; whence no time is lost by searching for the recommendation of governors, or by stated periods of admission, as in the ordinary hospitals.

2. A sedan chair, or covered litter, provided with a moveable lining, is kept at the house, in which all persons are carried thither at the expence of the institution; so that no public carriages can be thus infected.

3. All patients on admission have their infectious clothes changed for clean linen, and are washed with lukewarm water. The clothes brought into the house with them are properly purified and aired. During their continuance in the house, all linen and bed-clothes, on being removed from the bodies of the patients, are immediately immersed in cold water, and all discharges are removed from the wards without delay.

4. The floors of the wards are washed daily near the beds, and twice a week generally; and fumigations with nitre and sulphuric acid are frequently employed; the walls are white-washed once every three months with quick-lime, fresh slaked in water, and while it continues bubbling and hot. The bedsteads are of iron, without curtains, and the beds stuffed with straw for the convenience of being frequently changed.

5. The fumigation, just mentioned, the efficacy of which in destroying contagion, has been satisfactorily proved by M. Morveau, Dr. Johnstone, and Dr. C. Smyth (see FUMIGATION), is employed in the apartments which the patients have left; their walls are white-washed with hot lime, where that operation is deemed necessary; and such articles of clothing as are not capable of being purified are de-

stroyed, and replaced at the expence of the institution. (See the Reports of the Institution for the Cure and Prevention of Contagious Fever in the Metropolis. Ferriar, *Med. Hist. and Refl.* vol. iii. p. 66.)

The advantages of such institutions have become almost immediately apparent wherever they have been adopted. Great apprehensions were at first entertained (founded entirely on popular prejudices and mistakes in regard to the nature of contagion), that the neighbouring dwelling-houses might be infected through the air, where a house of recovery was established. But it was soon perceived that no such infection took place; but, on the contrary, that the neighbourhood of the houses (at Manchester for instance), was the first part of the town to be purified from the contagion which it heretofore cherished. This apprehension was also strongly expressed in London, where the House of Recovery was originally a private dwelling-house, standing *in a row*, and of course *contiguous* to dwelling-houses on both sides. But the experience of nine years has completely removed all the fears of the adjoining inhabitants.

In respect to the establishment at Manchester, it is stated that "the beneficial effects of the House of Recovery are almost beyond belief; the facts are, however, established by authentic documents. The number of fever patients in the pile of buildings *in the neighbourhood of the House of Recovery*, for the two preceding years and eight months, were 1256, something more than an average of *four hundred* a year; those in the same district, from July 1796 (a period commencing two months after the establishment of the House of Recovery), to July 1797, being twelve months, were only *twenty-six*."

Again, "in January 1796 (before the establishment of the House of Recovery), the whole number of home-patients visited by the physicians of the Manchetter Infirmary was 206, of which 226 were cases of fever; in January 1797, the number of their home-patients was 161, and of these only 57 were cases of fever." See Reports of the Society for bettering the Condition of the Poor.

Both at Manchester and at Dublin (where the number of fevers is much greater, and the establishment upon a more extensive scale), the diminution of fevers has been so great, as to enable those institutions to comprehend a much wider district than in the outset. In London, many of the alleys and courts near Gray's-inn-lane, Saffron-hill, and other crowded districts, in which contagious fever was generally existing, have been, for several years, since the purifying measures of the House of Recovery were put in execution, altogether free from fever.

Dr. Ferriar remarks, while enumerating the benefits derived from these institutions, "I can also perceive, that a salutary impression has been made upon the minds of the poor respecting the utility of cleanliness in their houses. The idea of fever comprehends, among them, that of ruin to their circumstances, and desertion by their neighbours; it may, therefore, be expected, that they will catch at every means within their reach to avoid so dreadful an evil." (*Loc. cit.*)

Notwithstanding the ample and demonstrative evidence which now exists of the advantages and perfect security with respect to the public, of these institutions, the prejudiced and erroneous notions of the communication of contagion, through the air, continue to prevail with great numbers of persons, and to prevent the establishment of fever-wards and houses of recovery. Those who wish for satisfactory proofs upon this subject, may consult Dr. Haygarth's Letter to Dr. Currie on the Prevention of contagious Fevers: Dr. Currie's Reports on the Effects of Water: Dr. Ferriar's *Med. Hist. and Reflections*, vol. ii. and iii.: the Reports of the Houses

of Recovery of Dublin, London, &c.; and of the Society for bettering the Condition of the Poor. And in the collection of papers (2 vols.) published by Dr Clarke of Newcastle, may be found the almost unanimous opinions upon the safety of such establishments, from a multitude of the most able and respectable physicians and surgeons in the island.

HOUSE-TAX. See WINDOW.

HOUSE-WATER, in *Mining*, is used where steam-engines are employed on mines, or collieries, for the water which is necessary for condensing, which often is obtained at very considerable expence, particularly in deep lead mines, in rocky districts, where the water that is pumped from the bottom of the mine can otherwise be discharged into a fough at a great distance below the surface; in such situations, the high-pressure engines of Trevethick, which want no condensing water, have been found very serviceable. At Yatefloop mine, near Wincles, in Derbyshire, they some years ago erected a large steam-engine under ground, on this fough, to avoid the lifting of house-water.

HOUSE-WIFE'S CLOTH, is a middle sort of linen cloth between fine and coarse, fit for family uses.

HOUSED-IN, in *Ship Building*. The seaman say of a ship, which, after the breadth of her bearing is brought in too narrow to her upper-works, that she is housed-in, or pinched too much.

HOUSED is also applied to the situation of the great guns of a ship, when they are secured at sea by their tackles and breechings.

HOUSE'E, in the *Manege*. See HOUSING.

HOUSELEEK, in *Botany*. See SEMPERVIVUM.

HOUSELEEK, *Lesser*. See SEDUM.

HOUSELEEK, *Small Annual*. See TILLÆA.

HOUSELEEK, *Water, of Egypt*. See PISTIA.

HOUSHOLD, the family or domestics of a prince, or private person.

The principal officers of the king's household are the lord steward, lord chamberlain, groom of the stole, master of the great wardrobe, and master of the horse.

The civil government of the king's house belongs chiefly to the lord steward of the household, who has an annual salary of 1460*l.* He has authority over all officers and servants of the king's house, except those of the chapel, chamber, and stable, who are under the jurisdiction of the lord chamberlain, master of the horse, and dean of the chapel, and he is the judge of all crimes committed within the court, or the verge. See COURT.

Under the lord steward are a treasurer of the household, whose place is 1200*l.* a-year; comptroller, with the same salary; paymaster, with 500*l.* a-year; master of the household, at 500*l.* a-year; clerks of the household, assistant clerks, clerks comptrollers, &c.; the officers and servants belonging to the almonry, the marshalsea, the verge, the kitchen, gardener, purveyors, &c.

The next principal officer of his majesty's household is the lord chamberlain, whose salary is 1200*l.* a-year; in whose department are the vice-chamberlain, with a salary of 1159*l.* 8*s.* 4*d.* a-year; secretary and clerks, superintendant of payments, groom of the stole, with an annual appointment of 2000*l.*; lords of the bed-chamber, grooms of the bed-chamber, gentlemen of the privy-chamber, master of the ceremonies with assistant and marshal, gentlemen ushers of the privy-chamber, gentlemen ushers who are daily waiters, to whom belongs black rod, assistant gentleman usher, grooms of the privy-chamber, gentlemen ushers who are quarterly waiters in ordinary, pages of the back stairs, pages of the bed-chamber, master of the robes with groom and clerks, wardrobe-keepers, serjeants at arms,

&c. the band of music, the medical department, house-keepers, tradesmen, artists, rangers and troopers of the forests, surveyors general of the king's woods, &c. chief justices in Eyre, officers of the royal chapels, chaplains in ordinary, ten priests in ordinary, sixteen gentlemen of the chapel-royal; preachers at the king's chapel, Whitehall, organists, &c. subordinate to the master of the horse, whose salary is 1266*l.* 13*s.* 4*d.* the clerk-martial and first equerry; the equeries, pages of honour, clerk of the stables, equerry of the crown stable, and yeomen riders. To the king's hunt belong the master of the stag-hounds, whose annual appointment is 2000*l.* a-year; the huntsman, six yeomen prickers, and grand falconer, whose yearly salary is 1200*l.* The military department of the king's household consists of the yeomen of the king's guards, the honourable band of gentlemen-pensioners, and the troops of the household, comprehending the horse and foot guards, &c.

HOUSHOLD DAYS, are four solemn festivals in the year, when the king, after divine service, offers a benefact of gold to God on the altar. See BESANT.

The household days are Christmas, Easter, Whitsunday, and All Saints.

The household days are a part of the twelve collar and offering days.

HOUSING, in *Agriculture*, a term denoting the twisting or running together of hop-binds above the tops of the poles; by which means great injury is done to the crops.

It is likewise employed to signify the practice of putting of different sorts of live-stock into sheds or other covered buildings, in order to protect them during the severity of the winter season.

HOUSING, or *Houfée*, a cover laid over the saddle of a horse, in order to save it from the weather, dirt, &c.

The word is formed of the French *houffe*, which signifies the same thing; though it anciently denoted a kind of hood worn by country people.

The cavaliers appeared with their embroidered housings.

HOUSING, *Bool*, is a piece of stuff fastened to the hinder part of the saddle that covers a horse's croup; either for the sake of ornament to hide the horse's leanness, or to save the clothes of the rider from being daubed and soiled by the sweat of the horse.

HOUSING, *Shoe*, is a piece of cloth bordered with a fringe, oftentimes put round the saddle to cover the croup, and hang down to the lower part of the belly, to save the stockings of those who ride without boots.

HOUSING, among *Bricklayers*, a term used for a brick which is warped, or is cast crooked or hollow in burning; in such a case, they say it is housing.

HOUSING, or *Houfe-line*, in *Sea Language*, denotes a small line formed of three fine strands or twills of hemp, smaller than rope-yarn. It is chiefly used to seize blocks into their strops, to bind the corners of the sails, or to fasten the bottom of a sail to its bolt-rope, &c.

HOUSSA, in *Geography*, a country of Africa, lying N. and S. of the Niger, or Neel-Abeed, and placed in major Rennell's map of Africa S. of the Great Desert, or Sahara, and between Tombuctoo on the W. and Tocruar on the E., in N. lat. from about 15° to 17° 30', and E. long. from about 3° to 5°. The inhabitants, according to the account which Mr. Horneman received of them, are negroes, but not quite black; they are distinguished from their neighbours by an interesting countenance, and are represented as the most intelligent people in the interior of Africa; their stature is less disagreeable than that of the negroes, and they are much addicted to pleasure, dancing, and singing. Their disposition is beneyolent and mild. They are described as indutrious

dustrious and skilful in the culture of the natural productions of their country, and in this respect they excel the Fezzaners, who obtain their clothes and household implements from them. Their music, compared with that of the Europeans, is imperfect, but the Houffian women possess musical powers sufficient to produce tears from their husbands, and to inflame their courage to the greatest fury against their enemies. The capital of this country is Houffa, situated, in Rennell's map, in N. lat. 16° 30'. E. long. 4° 30'. It lies at a small distance N. from Neel-Abeed. Mr. Park was informed by a^l thereof, whom he met with at Benown, and who had travelled through a number of kingdoms, that he had visited Houffa, and that it was the largest town he had ever seen. Mr. Park was also informed by others, that of the chief towns of Jenné, Tombuctoo, and Houffa, situated on or near the banks of the Niger, the last was the most considerable, and that the least of them was much larger than Sego. He was further told, that caravans frequently arrive both at Tombuctoo and Houffa, from the countries on the Mediterranean, travelling across the Desert by the way of Fezzan, with European goods and other merchandize.

HOUSTONIA, in *Botany*, named by Gronovius and Linnæus, after Dr. William Houston, F.R.S. who resided several years in the West Indies, and visited the Spanish main, from whence he sent various seeds to Miller and other botanists of that time, between the years 1728 and 1732, besides making several curious observations upon *Contragyna*, *Jalap*, and other medicinal plants. He died in Jamaica in 1733. Some engravings, by his own hand, of the parts of fructification of various new genera of plants, in the manner of Plumier, came into Miller's hands, who sent an impression of them, in 1736, to Linnæus. Most of these plates were purchased, with Miller's herbarium and papers, by sir Joseph Banks, who printed and liberally distributed an edition of them, with the Latin descriptions and remarks of the author, under the title of *Reliquiæ Houstonianæ*, in quarto, in 1781. A few of the plates were re-engraved, after impressions of some that had been lost.—Linn. Gen. 51. Schreb. 68. Willd. Sp. Pl. v. 1. 583. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 235. Juss. 197. Lamarek. Illustr. t. 79. Gærtn. t. 49.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Stellata*, Linn. *Rubiacea*, Juss.

Gen. Ch. *Cal.* Perianth half superior, of four small, upright, permanent teeth. *Cor.* of one petal, funnel-shaped; tube much longer than the calyx, cylindrical, slightly dilated at the top; limb in four deep, roundish or elliptical, spreading segments. *Stam.* Filaments four, in the neck of the tube, very small; anthers simple. *Pist.* Germen half inferior, roundish, two-lobed, compressed; style simple, shorter than the tube; stigma cloven, acute. *Peric.* Capsule in the bottom of the calyx, surrounded by its teeth, roundish, didymous, bursting at the top transversely, of two cells, and two valves which are contrary to the partition. *Seeds* few, small, ovate, attached to the partition.

Obs. Linnæus appears, as Gærtner remarks, to have mistaken the receptacle covered with seeds for one single seed, owing probably to the unripe state in which he saw it.

Ess. Ch. Corolla of one petal, funnel-shaped. Capsule of two cells, half superior. Seeds several, roundish.

1. *H. cærulea*. Linn. Sp. Pl. 152. Curt. Mag. t. 370. (*Lychnidis*, aut potius *Allines*, cognata *difermos*; Pluk. Phyt. t. 97. f. 9.)—Radical leaves ovate. Stipulas abrupt. Stem repeatedly branched. Flower-stalks elongated, single-flowered.—Native of Virginia and other parts of North America. It was brought to Kew in 1785, from the west

coast of that country, by Mr. Meuzies, to whom botany is so much indebted for various discoveries in that quarter, the South seas, and New Holland. The roots are fibrous and perennial. Stems numerous, erect, four or five inches high, and sometimes much more, repeatedly branched, square, smooth, slender, leafy, many-flowered. Leaves from half an inch to an inch long, entire, smooth, rough-edged, rather acute; the radical ones obovate or spatulate, stalked; stem-leaves opposite, much narrower, elliptic-lanceolate, sessile. Stipulas very short and broad. Flowers of a brilliant pale blue, or almost white, with a yellow eye, jasmine-like and very pretty, but scentless, produced all summer long. Each grows on a very long, simple, naked, lateral or terminal, smooth stalk. The two-lobed *germen*, and still more the *capsule*, rises above the entire part of the calyx; though its lower half be immersed in the base of the latter, all plants of this natural order having, strictly speaking, an inferior *germen*. Mr. Curtis says this species is quite hardy in England, best cultivated in a pot, with plenty of moisture, and easily increased by parting its roots. If paid the least attention to, it flowers perpetually, spring, summer, and autumn. We have no where seen it so fine as at Kew.

2. *H. longifolia*. Willd. n. 2. Gærtn. v. 1. 226.—Leaves lanceolate, tapering at each end. Stipulas ovate, pointed, often cloven. Flowers corymbose.—Native of North America. Gathered near Lancaster in Pennsylvania, by the Rev. Dr. Muhlenberg. This has more the habit of a *Galium*. It seems perennial. The stem is from three to five inches high, square, smooth, leafy, but little branched. Leaves linear-lanceolate, tapering at each end, about an inch long, smooth, somewhat revolute. Stipulas pale, ovate or triangular, acute; the lower ones undivided; the upper in two, three, or more segments. Flower-stalks axillary and terminal, forming a leafy corymbus. Teeth of the calyx very long; its base short. Limb of the corolla not much spreading.

This species was confounded by Linnæus and some of his correspondents with the following, from which it differs greatly in the narrowness of its leaves. Our Pennsylvanian specimen seems a fellow one to what Willdenow described.

3. *H. purpurea*. Linn. Sp. Pl. 152.—Leaves ovate, roughish; the lower ones heart-shaped. Stipulas ovate, pointed. Flowers corymbose.—Native of Virginia; said to have been introduced to the Kew garden, where it flowers most part of the summer, by Mr. Masson, in 1800. The plant is roughish in many parts. Stem much branched, forked. Leaves an inch or more in length, and half an inch broad, ovate or heart-shaped. Stipulas much as in *H. longifolia*. Inflorescence also similar, but the stalks are rough, more numerous and more divided. Calyx and corolla shaped as in the last.

That beautiful plant the *Bouvardia triphylla* of Salis. Parad. t. 88; Hort. Kew. ed. 2. v. 1. 245; which is *Houstonia coccinea* of Andr. Repos. t. 106, and has been referred to *Ixora* by Jacquin and Cavanilles, was long mistaken by our cultivators for *Houstonia purpurea*, and was once contended by some to be an *Hamelia*. We may now hope it will rest in peace; yet the ignorant, who have learned to call it by a wrong name, will perhaps not easily adopt a new one. So important is it for those who direct the public information, to be circumspect before they decide, and never to alter but with sufficient reasons.

HOUT or Wood bay, in *Geography*, a bay on the S. coast of Africa, N.N.W. from the Cape of Good Hope. S. lat. 34° 5'. E. long. 18° 19'. This bay is contiguous to Chapman's bay; the latter communicating, by a declivity of the mountains, about 2700 yards in length, with Vis or Fish

bay close to Simon's bay; and the former, by another defile, with the great road leading from cape Town to Simon's bay. Hout bay affords safe and convenient anchorage for eight or ten ships; and has a rivulet of fresh water falling into it from the back part of Table mountain; but the getting out of the bay is supposed to be very difficult and precarious, on account of the eddy winds from the surrounding mountains when they are moderate in the offing, or from the south-easterly winds setting into the entrance, as well as from the constant westerly swell and wind prevailing from that quarter in the winter season. Hout bay is now defended with a battery and a block-house.

HOU-TCHEOU, a city of China, of the first rank, in the province of Tche-kiang, situated on a lake from which it takes its name. The quantity of silk manufactured here is almost incredible; and it is also the chief place in China for making writing pencils. Its district contains seven cities, one of which is of the second, and six of the third class. N. lat. $30^{\circ} 52'$. E. long. $119^{\circ} 32'$.

HOUTEVILLE, CLAUDE FRANCIS, in *Biography*, was born at Paris in 1688. He became a member and secretary of the French academy, and secretary to cardinal Dubois, whose friendship obtained for him the abbey of St. Vincent du Bourg-sur-mer, in the diocese of Bourdeaux. This was in the year 1723, and in the same year he was admitted a member of the French academy. He died in 1742, aged 54. His principal work is entitled "The Truth of the Christian Religion proved by Facts," three vols. 4to.

HOUTTUYNIA, in *Botany*, received its name in compliment to Dr. Houttuyn, of Amsterdam, a collector and merchant of natural curiosities, one of the people who subscribed towards the expence of sending Thunberg to Japan, by which he enriched both his collection and his purse, in the true spirit of a Dutch virtuoso and patron. Thunb. Jap. 12. Act. Holm. ann. 1783. 149. t. 5. Murray in Linn. Syst. Veg. ed. 14. 519. Schreb. 614. Willd. Sp. Pl. v. 2. 290. Mart. Mill. Dict. v. 2. Juss. 25. Lamarck. Illustr. t. 739.—Class and order, *Heptandria Trigynia*. Nat. Ord. *Piperitæ*. Linn. *Aroidæ*. Juss.

Gen. Ch. *Cal.* Spatha of four ovate, concave, obtuse, coloured, spreading leaves; spadix about as long as the spathe, oblong, covered with flowers; perianth none. *Cor.* none. *Stam.* Filaments generally seven, short, equal; anthers vertical, ovate, two-lobed. *Pist.* Germen roundish, somewhat triangular; styles three, awl-shaped, short; stigmas recurved, acute, downy on the upper side.—*Fruit* unknown.

Eff. Ch. Spatha of four leaves. Spadix covered with flowers. Corolla none.

1. *H. cordata*. Thunb. Jap. 234. t. 26. *Doku Dami*, or *Sjunjak*, of the Japanese. Found by Thunberg, very abundantly, in ditches by the way sides, and about towns, between Miaco and Jedo in Japan, flowering in May and June. The *root* is fibrous and annual. *Stem* herbaceous, erect, from a span to a foot high, simple, or slightly branched, rather zigzag, furrowed, leafy, scarcely downy; its lower joints throwing out numerous whorled fibres. *Leaves* alternate, stalked, heart-shaped, broad, pointed, entire, veiny, smooth, finely dotted; paler beneath. *Stipulas* broad, sheathing, united to the footstalks and clasping the stem. *Flowers* few, stalked, solitary, opposite to some of the upper leaf-stalks. Leaves of the *involucrum* white, rather above half an inch long. *Flowers* purplish, with yellow anthers.

One of professor Thunberg's own specimens, (indeed no other botanist, as far as we know, has gathered the plant,)

shews very plainly the three recurved stigmas, with the styles, in each flower, and has enabled us to correct the character and classification of the genus. The *Houttuynia* seems to occupy in Japan the place of our *Sagittaria*, to which its flowers bear a not very remote resemblance, however different in botanical characters. The leaves look somewhat like those of *Aristolochia Clematidis*.

HOW, in *Agriculture*, a term which frequently denotes a small round hillock, or small hill of the artificial kind.

How, in *Geography*, a town of Poland, in the palatinate of Lenciez; 32 miles N.E. of Lenciez.

HOWAN SOUND, a strait of the sea, between the islands of Egilsha and Rowfa, two of the Orkney islands.

HOWARD, THOMAS, in *Biography*, earl of Surrey, and duke of Norfolk, an eminent commander in the reign of Henry VIII., was born in 1473. He was brought up to arms, and soon after the accession of Henry was decorated with the knighthood of the garter. He served with his brother sir Edward, against sir Andrew Barton, a Scotch free-booter, or pirate, who perished in the action. When his brother, sir Edward, was killed in an action near Brest, in 1513, he was appointed to the office in his stead, and in the capacity of high admiral he effectually cleared the channel of French cruizers. The victory of Flodden-field, in which the king of Scotland was slain, was chiefly owing to his valour and good conduct. For this his father was restored to the title of duke of Norfolk, and the title of earl of Surrey was conferred on him. In 1521 he was sent to Ireland as lord-lieutenant, chiefly for this purpose, it was thought, of having him out of the way during the proceedings against his father-in-law, the duke of Buckingham. Here he was very instrumental in suppressing the rebellion, and having served there two years, he returned, and had the command of the fleet against France. By the death of his father, he succeeded to the title and estates as duke of Norfolk. Notwithstanding his great services, Henry, at the close of his tyrannical life and reign, caused the duke to be sent to the Tower on a charge of high treason, and his son to be beheaded in his presence. The death of the king saved the duke's life. (See HENRY VIII.) He was, however, detained prisoner during the whole of the reign of Edward VI., but one of the first acts of Mary, after her accession to the throne, was to liberate this faithful servant of her late father. He was, after this, the principal instrument in suppressing the rebellion excited by sir Thomas Wyatt. He died in August 1554, having passed his eightieth year. Hume's Hist.

HOWARD, HENRY, earl of Surrey, son of the preceding, a nobleman of considerable accomplishments, and one of the early English poets, was born about the year 1520. In his youth, he resided at Windsor as companion to the young duke of Richmond, natural son to Henry VIII., whom he afterwards accompanied to Wolfey's new college at Oxford. He then made the tour of Europe, under the impression of a romantic passion for the daughter of the earl of Kildare, whom he characterizes with the epithet of "Fair Geraldine." In the spirit of chivalry, he published at Florence a general challenge at tilting to all persons who should dispute the supremacy of her beauty. He came off victorious, and as a reward, was presented with a shield by the grand duke of Tuscany. On his return to England, about 1541, he was decorated with the order of the garter. In 1542 he acted as lieutenant-general in the army with which his father invaded Scotland. He accompanied the king in his expedition to France in 1544, and was field-marshal of the army before Boulogne. After serving his country with great valour, he fell

fell a victim to the jealousy of Henry VIII., who pretended to suspect him of a design to marry his daughter Mary. He and his father, as we have already seen, were sent to the Tower, and the son was beheaded on Tower-hill, in the year 1547, leaving behind him two sons and three daughters. His sonnets are printed in Anderson's collection of British Poets. His eldest son, Thomas, was the duke of Norfolk, who was so conspicuous in the reign of Elizabeth for his negotiations with Mary, queen of Scots, terminating in his ruin. The earl of Surrey translated the second and fourth books of Virgil's *Æneid*, which were published in 1557. According to Warton, "Surrey, for justness of thought, correctness of style, and purity of expression, may justly be pronounced the first English classical poet."

HOWARD, CHARLES, lord Effingham, and earl of Nottingham, a distinguished naval commander, was born in 1536; he was son of lord William of Effingham, and grandson to Thomas, second duke of Norfolk. In his youth he served in several expeditions under his father, then lord-admiral, and, in 1559, he was sent as ambassador to France, and after his return he was elected knight of the shire for Surrey. In 1568 he was appointed general of the horse. The same year he displayed great valour in the north, against the rebels commanded by the earls of Northumberland and Westmoreland. The following year he had the command of a squadron, with which he escorted, from Zealand to Spain, Anne of Austria, daughter of the emperor Maximilian, who was betrothed to Philip of Spain. In 1572 he succeeded his father as lord Effingham, and not long after was made knight of the garter. He had, as we have seen in some preceding articles, the important command of the English fleet when the Spanish Armada entered the channel, and by his great skill and prudence contributed principally to its destruction. For this important service he was created earl of Nottingham, and enjoyed the queen's confidence to her death. (See ELIZABETH.) In the rebellion excited by the earl of Essex, lord Nottingham commanded the force which invested Essex-house, and brought him to submission. At the coronation of king James, the earl officiated as lord high-steward, and he was soon after appointed ambassador to the court of Spain. His last service in the capacity of admiral, was the conveying to Flushing of the princess Elizabeth, married in 1613 to the elector palatine. After his return, he lost the king's favour, and resigned the post to the duke of Buckingham. He died in 1614. *Biog. Brit.* - Hume.

HOWARD, *fr* ROBERT, an English writer, was the son of Thomas, earl of Berkshire, and educated at Magdalen college, Oxford. He suffered considerable losses during the civil wars, but at the Restoration he was knighted, and made auditor of the exchequer. He was a zealous friend of the Revolution, and died about the year 1700. As an author, he wrote several plays: the *History of the Reigns of Edward and Richard II.*; the *History of Religion*, 1694.

HOWARD, JOHN, born at Hackney, or Enfield, in 1727, was son of a carpet-warehouseman, and upholsterer in London. The father died during the infancy of his son, who was left in the hands of guardians, by whom he was apprenticed to a grocer. He did not serve his time out, but bought his indentures, and indulged his curiosity in a tour to France and Italy. Upon his return, he fell into a weakly state of health, which, with his attachment to reading and the study of nature, induced him to withdraw into privacy in the country. From a motive of gratitude, he married the person with whom he lodged, and who had carefully attended him, though she was sickly, and twice his age, and even remonstrated against the inequality of such an union. He passed three years with her in conjugal harmony, and upon her death, in 1756, set out

upon another tour to the continent. In this, his leading object was to view the ruins of Lisbon, lately desolated by an earthquake. He was defeated in his plan by the capture of the vessel in which he sailed, and by being carried a prisoner into France. The sufferings which he underwent, and to which he was witness in others, made a deep impression on his mind; this was probably the principal cause of the philanthropical exertions which afterwards employed so large a portion of his life. Upon his liberation, he laid the state of his fellow-sufferers before the commissioners of the sick and wounded, who received his information with gratitude. In 1758 he married the eldest daughter of Mr. Serjeant Leeds, of Croxton, Cambridgeshire. His principal residence for some years was at Cardington, near Bedford, where he put in practice those schemes for the good of his poor neighbours and tenants, in which he ever took delight. He built upon his estate a number of very neat and comfortable cottages, to each of which he annexed a little ground for a garden. These he peopled with sober and industrious tenants, over whose welfare he watched with the vigilance of a parent. In 1765 his domestic happiness was irreparably injured by the death of his wife, soon after she had borne him her only child. The care of his son and his usual benevolent occupations continued to employ him till the year 1773, when he was selected to serve the office of high-sheriff for the county of Bedford. In the course of his official duties he found that a multitude of abuses prevailed, which he knew not how to remedy; he determined, however, to obtain every possible information on the subject. He began by visiting most of the county gaols in England; and on a second journey he extended his researches into town-prisons and houses of correction, and so diligently did he pursue his object, that he was enabled, in the month of March 1774, to lay before the house of commons a large mass of information, for which he received the public thanks, and on the credit of his testimony, two bills were passed during the same session of parliament, one, "For the Relief of acquitted Prisoners in Matters of Fees:" the other, "For preserving the Health of Prisoners." The heads of these bills, with the several regulations contained in them, Mr. Howard procured to be printed, and sent to every keeper of a gaol throughout England. He now felt the high importance of the business in which he had engaged, and resolved to devote himself and his fortune to the improvement of this part of civil polity. With this view he made two tours on the continent, travelled into Scotland and Ireland, and the fruit of his researches was given to the public in 1777, under the title of "The State of the Prisons in England and Wales, with Preliminary Observations, and an Account of some Foreign Prisons." As soon as this work appeared, the world was astonished at the mass of valuable materials accumulated by a private, unaided individual, through a course of prodigious labour, and at the constant hazard of his life, in consequence of the infectious diseases prevalent in the scenes of his enquiries. He was, from this moment, looked on as one of the extraordinary characters of the age, raised up by providence for the purpose of meliorating the condition of that wretched part of the community for whom he interested himself. He was anxious to correct their vices, which he thought would be best effected by gentle but strict discipline, accompanied with all the comforts of which their wretched situation was susceptible. His zeal was seconded by the exertions of parliament, and a bill was brought in for the establishment of houses of correction, according to his ideas. He now made another tour on the continent, and took a still more accurate view of all the prisons in every part of England, Wales, Scotland, and Ireland, including in his observations whatever related

related to hospitals. He every where noted down the structure and regulations of these several kinds of buildings, and procured plans and draughts where he thought they might suggest something useful for imitation. These researches furnished him with materials for an appendix to his former work, which was printed in the year 1780. About this period he accepted the office of one of the three supervisors appointed for establishing penitentiary houses. He made it a condition of his acceptance that Dr. Fothergill should be one of his associates, but the death of the doctor, and some difference of opinion concerning the situation of the first of these buildings, caused him, in 1781, to resign his office, but it was only to resume his far greater exertions in the same noble cause. He travelled through the whole of the northern kingdoms of Europe, and revisited the prisons of his own country: he seemed resolved to take no repose while any thing remained in which he thought his farther labours might serve the interests of humanity. The progress of contagion, in prisons and hospitals, had led him to consider all the means used for checking it, and he expected to find these practised in their fullest extent in the prevention of the plague; he therefore resolved to examine all the lazarettos in Europe. Personal risk never, in his estimation, stood in the way of duty: he did not hesitate to expose himself to all the dangers which attended so near an approach to the most alarming pestilence. He set out in 1785, unaccompanied by a servant, not thinking it justifiable to expose any human being to the dangers which, for the public good, he was willing to undergo. He took his way by the south of France, through Italy, to Malta, Zante, Smyrna, and Constantinople. From the last named city he returned to Smyrna, where he knew the plague then prevailed, for the express purpose of going to Venice with a "Foul Bill," as it is called, that he might be subjected to all the rigour of a quarantine in a lazaretto, in order that he might practically know its rules. Such an enterprising and heroic conduct in the great cause of humanity excited the attention of almost every thinking individual of Europe. On his return by Vienna, the emperor Joseph expressed a desire of seeing him: the interview passed as between an enlightened sovereign desirous of information, and a plain independent gentleman, above the awe of rank or the vanity of being noticed. During his absence on this journey, a subscription was entered into for the purpose of erecting a statue, and it was soon filled with names of the first distinction. As soon as he heard of the scheme, he expressed such a decided aversion from what he denominated being "dragged out in public," that it was reluctantly abandoned. On his return he revisited once more the prisons, bridewells, hospitals, and prison-hulks of his own country, which occupied his attention during the course of two years. The year 1789 was chiefly devoted by him to the methodizing and printing the important matter which he had collected since his last publication. This appeared in a quarto volume, entitled "An Account of the principal Lazarettos in Europe, with various Papers relative to the Plague, &c." At the close of this publication he declared his intention of again quitting his native country, for the purpose of revisiting Russia and Turkey, and extending his travels in the East. He quitted England in the summer of 1789, and proceeded through Germany, to Peterburg and Moscow; at all places the prisons and hospitals were thrown open to him, as if the governments of the earth were ready to second his humane and benevolent designs, and hailed his presence as that of a general censor of that part of the police, whose authority was recognized in every civilized country. He next proceeded to the new Russian settlements on the Black sea, and took his station at the town of Cherfon.

At this place a fever of a most malignant kind prevailed; among the victims of which was a young lady whom he had been requested to visit, being supposed to possess medical skill of a superior kind in those cases. From her he probably received the contagion which carried him off on the 20th of January 1790, about the age of sixty-three. He was buried in the neighbourhood of Cherfon, and all honours were paid to his memory by prince Potemkin and other men in office. For a more full and very interesting account of this gentleman, who has been frequently characterized, and justly so, as "The noblest of all the Howards;" the reader is referred to Dr. Aikin's "View of the Character and public Services of the late John Howard, esq. L.L. D. F. R. S." 1792. Dr. Aikin expresses himself in the following terms in the General Biography: "The bare recital of what Mr. Howard did in the cause of humanity, is sufficient to place him among the greatest benefactors of mankind, as well as the most extraordinary private characters recorded in biography. He was, indeed, singularly calculated for the task which he undertook. Accustomed to the most rigorous temperance, so as to discard from his diet animal food and fermented liquors, he found no difficulty in living in the poorest countries. In all other respects his mind was equally master of his body, and he incurred hardships of every kind without repugnance. In temper he was calm and reposeful, but firm and resolute; proof against every allurements or intimidation that might divert him from his purpose. Economical in private expences, he knew no bounds in his expenditure on objects of public utility, and regarded money only as an instrument of beneficence. In honour, integrity, and attachment to principles, he was not surpassed by any human being. His talents were rather of the useful than the shining kind, but peculiarly adapted for that collection of facts and observations in which he employed himself. The testimony of public respect which he refused when living, has been conferred upon his memory, and his monumental statue was one of the first of those by which the cathedral of St. Paul's has been made a receptacle of national worthies."

We cannot close this article without subjoining the eloquent eulogium pronounced upon Mr. Howard, by Mr. Burke in his "Speech at Bristol, previous to the election in 1780." Having occasion to mention him, he adds, "I cannot name this gentleman without remarking, that his labours and writings have done much to open the eyes and hearts of mankind. He has visited all Europe,—not to survey the sumptuousness of palaces, or the stateliness of temples; not to make accurate measurements of the remains of ancient grandeur, nor to form a scale of the curiosity of modern art; not to collect medals, or collate manuscripts;—but to dive into the depths of dungeons; to plunge into the infection of hospitals; to survey the mansions of sorrow and pain; to take the gage and dimensions of misery, depression, and contempt; to remember the forgotten, to attend to the neglected, to visit the forsaken, and to compare and collate the distresses of all men in all countries. His plan is original; and it is as full of genius as it is of humanity. It was a voyage of discovery; a circumnavigation of charity. Already the benefit of his labour is felt more or less in every country; I hope he will anticipate his final reward, by seeing all its effects fully realized in his own. He will receive not by retail, but in gross, the reward of those who visit the prisoner; and he has so forestalled and monopolized this branch of charity, that there will be, I trust, little room to merit by such acts of benevolence hereafter."

HOWARD, SAMUEL, brought up in the king's chapel,
took

took his degree of doctor of music at Cambridge at the time of the installation of the duke of Grafton as chancellor of that university. Dr. Howard had studied much under Dr. Pepusch at the Charter-house, and was well acquainted with the mechanical rules of counterpoint. His overture in the "Amorous Goddess," a happy imitation of Handel's overture in "Alcina," particularly the musette and minuet, was long very popular in the theatres and public gardens. But his ballads, which were long the delight of natural and inexperienced lovers of music, had the merit of facility; for this honest Englishman preferred the style of his own country to that of any other so much, that he never staggered in his belief of its being the best in the world, by listening to foreign artists or their productions, for whom and for which he had an invincible aversion.

He began to flourish about the year 1740, and from that time till Arne's Vauxhall songs were published under the title of "Lyric Harmony," they were the most natural and pleasing which our country could boast.

After the decease of Michael Christian Festing, Dr. Howard took the lead in managing the affairs of the musical fund; but not with equal address and intelligence.

He was a dull, vulgar, and unpleasant man; and by overrating his own importance, and reigning paramount over his equals, he rendered the monthly meetings disagreeable, and cooled the zeal of many well-wishers to the society.

He long laboured under a dropsy, yet walked about with legs of an enormous size, during several years. But it was not this disorder which put an end to his existence, at last, but repeated paralytic strokes. He died about the year 1783.

HOWARD'S POINT, in *Geography*, a cape on the N. W. coast of the island of Egmont, or New Guernsey. S. lat. $10^{\circ} 42'$. E. long. $164^{\circ} 18'$.

HOWARD, a township of America, in the county of Suffolk, Upper Canada, W. of Oxford; watered on the N. by the Thames and on the S. by lake Erie.

HOWASSE, a town of Hindoostan, in Malwa; 10 miles N.E. of Tandla.

HOWDEN, anciently called *Hoveden*, a market town in the division of Howdenshire, in the East Riding of the county of York, England, is 20 miles S.E. of the city of York, 25 W. of Hull, and 184 N. of London. In the year 1801 the town contained 325 houses and 1552 inhabitants. In the reign of Edward the Confessor this town, with the church and lands around it, belonged to the monastery of Peterborough. William the Conqueror, however, seized them, and gave the whole to the bishop of Durham: in consequence of which the bishop built a palace here. And some of them made it their principal residence. The following prelates died here: Hugh Pudsey in 1195; Walter de Kirkham in 1260; and Walter de Skirlaw in 1405. Leland describes the bishop's palace as built partly of timber and partly of brick and stone. What remains is now converted into a farm house, near which are the ruins of several large buildings, and a long range of granaries. King Henry III. granted the bishops the following privileges attached to this manor: the goods of all persons who committed felo-de-se; of wrecks cast on the shores of the Ouse; of tollage and lastage; of having a clerk of the market; and a coroner, &c. This town has been much improved lately, in the erection of new buildings, paving the streets, and in other respects. In the market place is a large edifice called the Moot-hall; in which is the council house, a place for keeping courts. The bishops of Durham are required by ancient custom to maintain a bull-ring in the market place, and to provide ropes for securing the bulls when baited. In the

year 1751 a large work-house was built here by subscription. The Domesday survey notices a church at the place; but the present building is of different eras. The tower was built by bishop Skirlaw about the year 1390, and the same prelate also erected a chapter-house on the south side of the choir. This church is collegiate, and is built in a cruciform shape, with a nave, transepts at the eastern end, or chancel, and tower in the centre. It displays some interesting specimens of ancient ecclesiastical architecture. It is much to be regretted that the inhabitants have suffered the elegant chapter-house to fall in ruins: and the chancel part is also in a shameful dilapidated state. Here are a weekly market on Saturdays, and five annual fairs, one of which, commencing on the 25th of September, ending on the 3d of October, is considered the greatest mart for horses in England. In the parish are two chapels of ease, one at Barmley, and the other at Laxton. A chapel for Methodists, and another for Independents, are established here. This place gave birth to Roger of Hoveden, who was monk of the abbey. Savage's History of Howden Church, 12mo. 1797, and Hutchinson's History, &c. of Durham.

HOWE, JOHN, in *Biography*, a learned English non-conformist divine, was born at Loughborough, in Leicestershire, in the year 1630. His father, who was minister of the place, being ejected by archbishop Laud, on account of connecting himself with the Puritans, removed with his son to Ireland, where they continued, till the rebellion in that country obliged them to return to England, when they settled in Lancashire. The son received a good classical education, and was sent at an early age to Christ's college, Cambridge. He continued at Cambridge till he took his degree of B. A., and then removed to Oxford, where he was appointed bible-clerk of Brazen-Nose college in 1643. In this situation he so distinguished himself in learning and piety, that he was elected fellow of Magdalen college. In 1652 or 3, he became a preacher, and was ordained at the church of Winwick, Lancashire, after which he was chosen minister of Great Torrington in Devonshire, where he discharged the functions of his office in the most exemplary manner. Having occasion to take a journey to London, he went as a hearer to the chapel at Whitehall. Cromwell was present, and, struck with his demeanor and person, sent a messenger to inform him that he wished to speak with him when the service was over. In the course of the interview he desired him to preach before him the following Sunday: he requested to be excused: the protector would not be denied, and even undertook to write to his congregation, a sufficient apology for his absence from them longer than he intended. This led to the appointment of Mr. Howe to the office of his domestic chaplain, and he accordingly removed with his family to Whitehall. He was soon appointed lecturer of St. Margaret's church, Westminster, where he was much admired and followed as a preacher. In this situation of importance and influence Mr. Howe embraced every occasion that offered of promoting the interests of religion and learning, and was always ready to do kind offices to men of merit among the royalists. He was so zealous in behalf of the interests of others, that Cromwell once asked him if he never meant to think of himself; "I wonder," says he, "when the time is to come, that you will move for any thing for yourself, or your family." To some of the peculiar notions of Cromwell Mr. Howe could not assent, and in one particular instance he thought it right to preach against them in his presence, because he believed they might lead to practical ill consequences. The friends of the preacher were alarmed for him, and one of them predicted, that he would find it difficult,

difficult, if not impossible, to regain his favour. "I have," said the worthy man, "discharged my conscience, and the event must be left to God." From this period the friendship of Cromwell was less ardent, and his manners cool and reserved, but he never mentioned the subject to him. Upon the death of Oliver, he was continued by his son Richard in the same situation, as domestic chaplain at Whitehall, and upon the deposition of Richard, he returned to his people at Torrington. In 1662, he was ejected from his living under the act of Uniformity; but after he had been silenced by the law, he continued to preach occasionally in the private houses of his friends and acquaintance, till a process was taken out against him. He was summoned before the bishop of Exeter, who did what he could, as a friend, to persuade him to conform, but when he found that his admonitions were in vain, the prelate dismissed him with strong assurances of his continued regard. In 1671, Mr. Howe removed to Ireland, to become chaplain to lord Massarene, who lived at Antrim, by whom he was received and treated with great respect and attention. On account of his learning, and true Christian temper, he acquired the particular friendship of the bishop of Antrim, who, together with his metropolitan, gave him leave to preach in the parish church every Sunday in the afternoon, without submitting to the terms of conformity. In the year 1685, the Dissenters being cruelly persecuted in every corner of the kingdom, Mr. Howe accepted of an invitation from lord Wharton to accompany him on his travels into foreign countries. During these travels he had the satisfaction of seeing most parts of Europe, and of conversing freely, not only with a number of learned Papists, but several eminent Protestant divines, both Lutherans and Calvinists. In 1686, he settled at Utrecht, where he took his turn in preaching at the English church in the city, and assisted the English students in the university, by his instruction and advice in the prosecution of their studies. Here he became acquainted with several eminent persons of his own country, and among others with Dr. Burnet, afterwards bishop of Salisbury, with whom he was accustomed to speak freely upon a variety of topics. In a conversation they once had respecting non-conformity, Dr. Burnet told him that it would not last long; but that when Mr. Baxter, Dr. Bates, and himself (Mr. Howe) were laid in their graves, it would sink and come to nothing. Mr. Howe said it could not be so, because it did not depend on persons but principles, which, when adopted on grounds approved of after serious and sincere enquiry, would not be laid aside by men of conscience. While he continued in Holland, Mr. Howe was admitted to frequent audiences by the prince of Orange, afterwards king William III. of England, who always maintained a sincere respect for him. Mr. Howe returned home in 1687 upon king James's declaration for liberty of conscience, but scarcely was he quietly settled when he was called on by his brethren to consider what was to be done in that crisis, and he without hesitation gave his opinion against the king's dispensing power. After the Revolution he discharged the duties of his pastoral office with unwearied diligence, labouring most zealously to promote the interests of real practical religion, and to diffuse a spirit of candour, charity, and mutual forbearance, among his dissenting brethren. He died in 1705, when he had nearly completed his seventy-fifth year. Mr. Howe was a person of distinguished piety and virtue, of eminent intellectual endowments, and of extensive learning. According to Cranger, "He was one of the most learned and polite writers among the Dissenters. His reading in divinity was very extensive: he was a good Orientalist, and understood several of the modern languages."

His works are numerous and truly excellent; the whole have been collected and printed in two volumes folio, 1724, with a life of the author prefixed, to which the reader is referred for more particulars than can be given in this article. Perhaps the principal of his pieces are "The Blessedness of the Righteous laid open," and "The Living Temple: or a designed Improvement of that Notion that a good Man is the Temple of God." Biog. Brit. Neal's History of the Puritans.

HOWE, RICHARD, *Earl*, born in 1725, was the second son of lord viscount Howe. He was educated at Eton, which he left when he was only fourteen years of age, to enter the service of his country on board the *Severn*, commanded by the honourable captain Legge, which made a part of commodore Anson's squadron destined for the fourth seas. At twenty years of age he was appointed to the command of a sloop of war; in this he beat off two large French frigates after a gallant action, for which he was made post-captain. He was now appointed to a frigate, and afterwards made captain of admiral Knowles's own ship of eighty guns in Jamaica, with which, at the peace in 1748, he returned to England. On the renewal of the war he was appointed to the *Dunkirk* of sixty guns, making part of admiral Boscawen's squadron, and he captured, off Newfoundland, the *Alcide* French man-of-war of sixty-four guns. In 1757, he served under admiral Hawke, and in the following year was appointed commodore of a squadron, with which he destroyed a number of ships and magazines at St. Malo. Prince Edward, afterwards duke of York, served on board his ship, and on the sixth of August, of the same year, he took Cherbourg, and destroyed the bastion. About this time, by the death of his brother, he became lord Howe, and shortly after had a considerable share in the victory over the French fleet commanded by Conflans. When admiral Hawke presented him to the king, his majesty said, "your life, my lord, has been one continued series of services to your country." On the return of peace he was appointed a lord of the admiralty, and afterwards treasurer of the navy. In 1770 he was promoted to the rank of rear-admiral of the blue and commander-in-chief in the Mediterranean. In 1775 he rose in succession to vice-admiral of the blue: at this time, lord Hawke gave the following seaman-like testimony to his merit in the house of lords, "I advised his majesty," said he, "to make the promotion, I have tried my lord Howe on important occasions: he never asked me how he was to execute any service, but always went and performed it." In the contest with America, it was the policy of ministers to employ, in high commands, officers whose public principles had led them to be favourers of popular rights, and the opposers of coercive measures. Among these none stood higher than lord Howe, and his brother the general. These, by embarking in the cause, were probably actuated with the persuasion that they could settle the differences without having recourse to the sword. Lord Howe went out with limited instructions, and every attempt at pacific measures proved to be in vain. He was now obliged, by his naval character, to follow such a plan as would do honour to his profession. When the French joined the American cause, lord Howe had an opportunity of exhibiting his great talents as a commander; in 1778, through the inattention of the administration, he was left with a force very inferior to that of the enemy, and the English fleet was brought into a situation of much danger, but by the skilful exertion of his lordship, the French thought it prudent to sail away, without putting their strength to a trial. The enemy's fleet now invetted Rhode Island, but by the manœuvres of lord Howe its plans were again defeated. Disgusted, probably, with the cause in which he never cordially

dially

dially embarked, and detesting the principles of an administration who were desirous of destroying the rights of their countrymen across the Atlantic, lord Howe resigned in 1778, and remained unemployed till 1782, when, upon the change of administration, he was advanced to the rank of admiral of the blue, created a viscount of Great Britain, and appointed to the command of a fleet fitted out for the relief of Gibraltar, which he performed in the teeth of the combined fleets of France and Spain, who shunned an action, though far superior in force and numbers. At the conclusion of the war he was made first lord of the admiralty, an office which he held with a short intermission by a change of administration, till 1788, when he was created an English earl. In 1793, when the war with France broke out, his lordship, at the king's particular desire, accepted the command of the channel fleet, and on the glorious 1st of June, as it is now called, he obtained a most decisive victory over the French Fleet, took seven men of war, and rendered the others incapable of farther opposition. On the part of the British not a ship was destroyed, or taken, or even much injured, and this vast success was obtained with the loss of but few men, though the slaughter among the enemy's crews was very great. The gratitude and enthusiasm of the nation was proportioned to the importance of the service, and the 1st of June is consigned, by the epithet already noticed, to futurity, among the most splendid days of our national calendar. In 1795 lord Howe was appointed general of the marines, and in 1797 he resigned his naval command, and was decorated with the order of the garter. His lordship died in 1799, at the age of seventy-three, having served his country with the highest reputation for a long period of almost threecore years. Lord Howe was ever distinguished by cool and steady valour, sound judgment, and consummate seamanship. Month. Mag. Gent. Mag.

HOWE, *The*, in *Geography*, a small island in the English channel, near the N.W. coast of the island of Guernsey.

HOWE'S *Foreland*, the northern point of a peninsula on the N.E. coast of Kerguelen's land. S. lat. 48° 48'. E. long. 69° 28'.

HOWE'S *Island*, an island in the South Pacific ocean. S. lat. 31° 36'. W. long. 159° 4'.

HOWE'S *Island*, an island in the South Pacific ocean, discovered by Captain Wallis in 1767, on which a few cocconut trees were growing. It is about ten miles long and four broad. S. lat. 16° 46'. W. long. 154° 8'. Captain Cook observed it in his passage from Ulhetea to the Friendly isles, in 1774, and found it to be a low reef-island of a circular form, about four leagues in compass, composed of several small patches connected by breakers, the largest lying on the N.E. part. It appeared to have no inhabitants.

HOWE'S, or *Lord Howe's Island*, one of the cluster, called Queen Charlotte's islands, separated from Egmont island by a passage extending about 11 leagues, and about four miles broad. Lord Howe's island lies in S. lat. 11° 10'. E. long. 164° 43'; and Cape Byron, the N. E. point of Egmont island, in S. lat. 10° 40'. E. long. 164° 49'. Both these islands appear to be fertile, and have a pleasant appearance, being covered with tall trees of a beautiful verdure. The inhabitants of Egmont island are extremely nimble, vigorous, and active, and seem to be almost as well qualified to live in the water as upon the land, as they were in and out of their canoes almost every minute.

HOWE'S *Sound*, a bay or inlet in the gulf of Georgia. The entrance is in N. lat. 49° 23'. E. long. 237°.

HOWELL, JAMES, in *Biography* born in Carmarthen-shire about 1596, was educated at Jesus college, Oxford,

and at the close of his studies he came to London to seek employment, being unable, through straightened circumstances, to remain at the university the usual period. Through the interest of sir Robert Mansel he was appointed steward to a patent glass manufactory, it being requisite to send an agent abroad to procure the best materials and workmen. He left England in 1619, and visited many commercial towns in Holland, Flanders, France, Spain, and Italy. In this journey he laid in a large stock of knowledge of men and things, and obtained an acquaintance with modern languages very unusual at that period. His love of literature did not prevent him from performing his duty to his employers. He negotiated a supply of the best barilla, at a cheap rate, from Alicaut, and engaged some able workmen at Venice and other places. He returned to London in the winter 1621; in the following year he went to Spain, and during his absence was chosen fellow of Jesus college. In 1624 he had acquired such reputation that he was made secretary to lord Scrope, president of the North, and in 1627 was chosen member of parliament for Richmond, Yorkshire. In 1630 he accompanied Robert, earl of Leiceiter, who was appointed ambassador extraordinary to the court of Denmark, in quality of his secretary, and displayed his oratorical talents in Latin speeches before the king of Denmark and some German princes. He was afterwards employed in state affairs, and in 1640 became clerk of the council; but in 1643 his papers were seized by order of parliament, and he was committed to the Fleet, where he supported himself by his pen. His writings were numerous, but chiefly of a temporary kind. He is chiefly known as an author by *A Collection of Letters*, in one volume, octavo, containing much of the history of the times. In the reign of Charles I. he was esteemed a royalist, but his remarks upon the fatal catastrophe which terminated that inglorious reign shew that he felt nothing for the fate of the monarch. He flattered Cromwell, and by his bending temper he was made historiographer to Charles II. He died in 1666, and the following inscription is to be seen on his tomb in the Temple church: "Jacobus Howell, Cambro-Britannus, Regius Historiographus (in Anglia primus); qui post varias peregrinationes tandem naturæ cursum peregit, fatur annorum et famæ, domi forisque: huc usque erraticus, his fixus. Biog. Brit.

HOWILEMUR, in *Geography*, a town of Persia, in the province of Ghilan; 90 miles N.W. of Reshd.

HOWITZERS, in *Artillery*, are a kind of mortars, invented by the Germans about the year 1593 or 1594, which are mounted upon carriages like travelling gun-carriages, and have their trunnions placed nearly in the middle. The construction of howitzers is as various as that of mortars, excepting the chambers, which are all cylindrical. They are distinguished by the diameter of the bore, *e. g.* a ten inch howitzer is that, the diameter of which is 10 inches. Howitzers are capable of doing great execution, by firing shells and grapes of shots, in a siege where the distance is small, and in the field, if they were placed in the flanks or between the battalions. They are also more easily carried from one place to another than mortars. For the dimensions of different howitzers, and remarks on their construction, the reader may consult the article CANNON.

HOWKER, or HOOKER, a vessel much used by the Dutch; built something like a pink, but rigged and masted like a hoy.

Howkers carry from 50 to 200 ton; and with a small number of hands will go to the East Indies. They are commonly navigated with two masts, *viz.* a main-mast and a mizzen.

wizen-mast. They tack soon and short, will sail well, and lie near the wind, and live almost in any sea.

HOWLE, in *Ship-Building*. When the foot-hooks of a ship are scarfed into the ground-timbers, and bolted, and then the plank laid on them up to the orlop, the carpenters say, they begin to make the ship howle.

HOWSTACK, in *Geography*, one of the smaller Shetland islands, near the E. coast of Mainland. N. lat. $60^{\circ} 23'$. W. long. $1^{\circ} 10'$.

HOWTH, a peninsula on the W. coast of Ireland, which stretches to the eastward, on the north of Dublin bay. The hill of Howth is an important guide to the mariner, and a light-house has been erected on it in a conspicuous situation. As, however, the bay of Dublin is often difficult of access, and as the bar is a great impediment to the sailing of the packets at a fixed hour, the attention of government has been directed to the forming of an harbour on the north side of the peninsula of Howth; and a very fine pier is now (1811) erecting for this purpose under the direction of able engineers. It is expected that this new harbour will not only answer as a much better station for the packet-boats, but will also contribute to improve the trade of Dublin. The pier commences nearly under the small town of Howth, and extends towards Ireland's eye. The point of Howth is in N. lat. $53^{\circ} 21'$. W. long. $6^{\circ} 3'$.

Howth, a small port-town of the county of Dublin, province of Leinster, Ireland, on the northern side of the peninsula noticed in the last article. It is seven miles from Dublin.

HOXTER, a town of Westphalia, belonging to the abbey of Corvey, three miles N.W. of it, but given to the king of Prussia in 1802.

HOY, one of the larger Orkney islands, about 11 miles long and more than three broad, separated from Pomona by a channel about a mile and a half wide. Round the coast are several bays, in which there is good fishing. The principal places are Hoy and Southwall. N. lat. $58^{\circ} 43'$. W. long. $3^{\circ} 7'$.

Hoy, a small vessel or bark, usually rigged like a sloop, and employed for carrying passengers and luggage from one place to another, particularly on the sea-coast. In Holland the hoy has two masts; in England it has but one, when the main-mast is sometimes extended by a boom, and sometimes without it.

Hoy Head, in *Geography*, a cape on the W. coast of the island of Hoy. N. lat. $58^{\circ} 48'$. W. long. $3^{\circ} 12'$.

HOYA, in *Botany*, named by Mr. Brown in honour of Mr. Thomas Hoy, F.L.S. an experienced botanist, and able cultivator. Brown Tr. of the Wernerian Society, v. 1. 26. Aselep. 15. Prodr. Nov. Holl. v. 1. 459.—Class and order, *Pentandria Digynia*. Nat. Ord. *Gentortæ*, Linn. *Apocinee*, Juss.

Eff. Ch. Corolla wheel-shaped, five-cleft. Crown of the stamens in five depressed fleshy leaves, whose inner angle extends into a tooth over each anther. Anthers terminated by a membrane; masses of pollen attached by their base, converging, compressed. Stigma pointless. Follicles smooth. Seeds comose.

A genus of twining or decumbent shrubs, with opposite leaves, and many-flowered umbels standing between the foot-stalks. Two species only are defined by Mr. Brown, though he suspects the first of them may prove, when properly examined, to comprehend several hitherto confounded.

1. *H. carnosa*. (*Aselepias carnosa*; Linn. Suppl. 170. Willd Sp. Pl. v. 1. 1264. Sims in Curt. Mag. t. 788. Sm. Exot. Bot. v. 2. 21. t. 70. *Stapelia chinensis*; Lour. Cochinch. 205.)—Leaves elliptic-oblong, fleshy. Corolla

downy. Leaflets of the crown furrowed underneath.—Native of various parts of Asia, as well as of New Holland, within the tropics. The late Hon. Mrs. Barrington received the living plant from the straits of Sunda, and it flowered in her stove for several successive seasons, from May to July. The whole shrub is succulent and smooth. Stem climbing, round, downy above. Leaves two or three inches long, slightly revolute, pale beneath, on thick stalks. Flowers extremely beautiful and singular, in large globose umbels, smelling like a mixture of honey and the Ieruvian Heliotrope. They are blush-coloured, with a purple centre; their corolla downy; the star-like crown smooth and polished, like porcelain.

2. *H. viridiflora*. (*Aselepias volubilis*; Linn. Suppl. 170. Watta-kaka-codi; Rheede Malab. v. 9. 25. t. 15.)—Leaves ovate, pointed, membranous, smooth, as well as the corolla. Crown without furrows. *Brown*. Native of woods in Ceylon. *Koelig*. Smooth in all its parts. Leaves ovate or heart-shaped. Flowers green, without scent.

HOYA, in *Geography*, a principality of Germany, bounded on the N. by the county of Delmenhorst, the territory of Bremen, and the Weser, on the E. by the principalities of Lüneberg and Calenberg, on the south by the principality of Minden, and on the W. by the county of Diepholz; about 32 miles long and 29 broad. In this district the heaths are large and the soil is sandy; nevertheless it contains some good pastures and arable lands, producing wheat, rye, barley, oats, flax, and buck-wheat. On the sides of the rivers are good meadows. The chief rivers are the Weser and the Aller. The inhabitants are partly employed in agriculture and breeding of cattle, and rearing of bees, and partly in manufacturing linen, woollen, stockings, &c. Most of the peasants are bondsmen. The country comprehends 54 parishes, in which Lutheranism is professed. Hoya was annexed to the dominions of the elector of Hanover in 1705; a small part excepted, which belonged to Hesse-Cassel. It contains 17 small towns, besides the capital of the same name, situated on the Weser. N. lat. $52^{\circ} 51'$. E. long. $9^{\circ} 12'$.

HOYA, *La*, a town of Mexico, in the province of New Biscay; 90 miles N.W. of Parral.

HOYACHU, in *Botany*, the name given by the Chinese to the acacia tree. They make great use of this tree in arts and medicine. They have a way of striking a fine yellow upon paper with its flowers; and they give the seeds in several diseases, in some of which, as in the dysentery and hæmorrhages, they are of great service. But, beside these, they make an odd medicine of them, which they take with great readiness for purposes it can never answer. They pick out the seeds carefully from the pods, as soon as ripe; they put these into a flat vessel, and cover them with ox's gall; this is to be set for a hundred days to dry, in a place where the sun does not come; after this, one of these seeds is to be swallowed every day before the first meal; and, by continuing this a proper time, they say the eye-sight, if lost, is restored, and their gray hairs become black. *Observ. sur les Coutumes de l'Asie*, p. 240.

HOYER, in *Geography*, a town of Denmark, in the duchy of Sleswick, with a harbour for small vessels, situated on the coast of the North sea, celebrated for its oyster fishery; 6 miles W. of Tondern.

HOYERSWERDA, a town of Lusatia, on the river Elsten; 34 miles N.N.E. of Dresden. N. lat. $51^{\circ} 26'$. E. long. $14^{\circ} 16'$.

HOYLAND, a town of Norway, in the diocese of Drontheim; 92 miles N.N.E. of Drontheim.

HOYLE LOUGH, one of the many large lakes in the county

county of Westmeath, province of Leinster, Ireland, and remarkable for the circumstance of two rivers flowing in opposite directions from it. This lake is about 3 miles N. from Mullingar.

HOZA, a town of Lithuania, in the palatinate of Troki; 8 miles N. of Grodno.

HOZARDARA, a mountain of Persia, in the province of Irak; 21 miles S. of Ispahan.

HOZIER, PETER D', *Seigneur DE LA GARDE*, in Provence, a gentleman distinguished by his genealogical and historical researches, was born at Marfeilles in 1592. He received a good education, and then entered into the army under the count de Crequi, the genealogy of whose family he drew up. His success in this attempt caused him to be employed by several other noble families in a similar service. To favour his pursuits, he obtained, in 1620, a place among the gentlemen of the king's household. He was raised to other posts of honour, and in 1628 the order of St. Michael was conferred on him by Lewis XIII. He was, immediately after this, pensioned by the court, expressly for the purpose of affording him leisure for his curious researches concerning the illustrious families of the kingdom, of which, by his long labours, he had acquired a particular knowledge. In 1642, he was made maitre-d'hôtel to his majesty, and in 1654 was raised to the dignity of counsellor of state. He died at Paris in 1660. He was author of "A History of Brittany," in folio, and a number of genealogies, some of which were printed, and others left in MS. His private character was highly estimable; and so good was his memory, that he was able to answer at once any question concerning arms, contracts, affinities, dates, &c. relative to all the families which had been the subjects of his enquiries, so that it was said jokingly, "that he must needs have been present at all the marriages and baptisms in the universe." He left a son Charles-René d', who succeeded him in the office of judge of arms, and was honoured by the duke of Savoy with the knighthood of St. Maurice. He died at Paris in 1732, and had been distinguished by his knowledge of heraldry. He had written several works by order of Lewis XIV., particularly "Le Nobiliaire de Champagne." The nephew of this gentleman, Lewis Peter d'Hozier, was also his successor in office: he died in 1767. During the period of his administration appeared "L'Armorial ou Registres de la Noblesse de France," in ten vols., folio. Moreri.

HOZING of DOGS, the cutting out the balls of their feet. See EXPEDITATION.

HOZOW, in *Geography*, a town of Poland, in the palatinate of Kiev; 30 miles S.W. of Bialacerkiev.

HRADEK, a town of Bohemia, in the circle of Koniggratz; 12 miles S.E. of Koniggratz.

HRADISCH, or HRADISTA, a town of Moravia, capital of a circle of the same name, seated on an island in the river Moraw, famous for its excellent wine and fruit; 30 miles S. of Olmutz. N. lat. 49° 5'. E. long. 17° 24'.

HRADITZ, a town of Bohemia, in the circle of Rakonitz; 15 miles S.W. of Rakonitz.

HRASGRAD, a town of European Turkey, in Bulgaria; 32 miles S. of Ruscek.

HREBNIA, a town of Lithuania, in the palatinate of Minsk; 16 miles S.S.E. of Minsk.

HRESK, a town of Lithuania, in the palatinate of Novogrodek; 10 miles N.N.E. of Sluck.

HROZOW, a town of Lithuania, in the palatinate of Novogrodek; 18 miles N. of Sluck.

HUA. See FAIFO.

Vol. XVIII.

HUACRE-CHUCO, a town of Peru, in the audience of Lima, and jurisdiction of Guamalies.

HUAHEINE, or HUAHENE, one of the Society islands, in the South Pacific ocean, situated in S. lat. 16° 43', W. long. 150° 52', first discovered by Cook in 1769, and visited again in 1777, when he left Omai, after his visit to England, in possession of a house and land, which he took care to provide for him. This island is distant from Otaheite about 31 leagues, in the direction of N. 58° W., and is about seven leagues in compass. Its surface is hilly and uneven, and it has a safe and commodious harbour, called by the natives "Owalle," or "Owharre," lying on the W. side, under the northernmost high land, and within the north end of the reef, which passes along that side of the island. This harbour may be entered by two inlets or openings through the reef, about 1½ mile distant from each other: the southernmost being the widest, and having on the south side of it a very small sandy island. The productions of this island are much the same with those of Otaheite, but about a month forwarder. Of the cocoa-nuts the inhabitants make a food which they called "Poe," by mixing them with yams; they scrape both fine, and having incorporated the powder, they put it into a wooden trough, with a number of hot stones, by which they make a kind of oily hasty-pudding, which the English sailors liked very well, especially when fried. The inhabitants are nearly the same with those of Otaheite, with regard to person, dress, language, and other circumstances pertaining to their disposition and character. They are, however, of a larger size, and of a stouter structure. Mr. (sir Joseph) Banks measured one of these men, and found him to be six feet three inches and a half high; but they are invincibly lazy. The women were fairer than those of Otaheite, and in general more handsome. Persons of both sexes seemed to be less timid and less curious. Although they were not strictly honest, yet it is acknowledged, to their honour, that when they understood that one of their number had been detected in the act of stealing, they manifested strong signs of disapprobation, and prescribed a good beating for the thief, which was immediately administered. In this island they observed a kind of chest or ark, the lid of which was nicely sewed on, and thatched very neatly with palm-nut leaves, it was fixed upon two poles, and supported on little arches of wood neatly carved; the poles served to remove it from one place to another. In one part of it was a square hole, in the middle of which was a ring, touching the sides, and leaving the angles open, so as to form a round hole within a square one. See ARK.

HUALE, a town of Arabia, in the province of Hadjar, on the W. coast of the Persian gulf. N. lat. 25° 49'. E. long. 50°.

HVALSOE, a small island on the North sea, near the coast of Norway. N. lat. 69° 40'.

HUANACO, in *Zoology*, a Peruvian animal of the camel tribe. See CAMELUS *Huanacus*.

HUARTE, JOHN, in *Biography*, a native of French Navarre, who was distinguished in the seventeenth century by a Spanish work of great merit, entitled, "A Trial of the Wits, or a Treatise on the different Kinds of Genius among Men, with Rules and Directions, shewing to what Kind of Study any Person is best adapted." The book has been translated into English. Moreri.

HUBAIAN, in *Geography*, a town of Persia, in the province of Farsistan; 50 miles E. of Baiza.

HUBALD, HUCBALD, or HUGBALD, in *Biography*, a monk of St. Amand, in Flanders, who preceded Guido more than one hundred years, was contemporary with Remi, and author of a treatise on music, which is still subsisting in

the king of France's library, under the title of "Enchiridion Musica," No. 7202, transcribed in the eleventh century. In this work there is a kind of gammut, or expedient for delineating the several founds of the scale, in a way wholly different from his predecessors; but the method of Guido not only superseeded this, but, by degrees, effaced the knowledge and remembrance of every other that had been adopted in the different countries and convents of Europe. However, the awkward attempts at fingering in consonance, which appear in this tract, are curious, and clearly prove that Guido neither invented, nor, rude as it was before his time, much contributed to the improvement of this art.

Hubald places the whole force of his *diaphonics*, or harmony, upon fourths and fifths.

The good monk says, if to these two parts two more are added in the octave, the harmony will be complete: and then writes, after his manner, the same fragment of melody over again, with a very small change at the end in the accompaniment, which he calls *organum*; which see. It is easy for a professed musician to divine what a strange effect such a combination of founds would have. At length, however, growing still more daring in his experiments, in the eighteenth chapter the question is, "How much higher the principal melody may go than the *organum*," and the ingenious monk determines the point by allowing that while one voice remains in the same tone, the other may wander about at its pleasure. The succession of four 3ds in the next example, renders it more like music of this world, in point of harmony, than any of the rest. And, indeed, a very few alterations in the under part would make the whole fragment supportable to modern ears.

Hubald, the respectable author of these curious specimens of crude harmony, was not only a musician but a poet; and an idea may be formed of his patience and perseverance, if not of his genius, from a circumstance related by Sigebert, the author of his life, by which it appears that he vanquished a much greater difficulty in poetry than the lippogrammists of antiquity ever attempted: for they only communicated a single letter of the alphabet from a whole poem: but this determined monk composed three hundred verses in praise of *balneis*, which he addressed to the emperor Charles the Bald, and in which he obliged the letter C to take the lead in every word, as the initial of his patron's name and infirmity, as thus:

"Carmina Clarifonæ Calvis Cantate Camœnæ."

These examples will sufficiently indicate the infant state of counterpoint previous to the time of Guido, and enable the reader to judge whether it was much improved by his discoveries.

Hubald died in 930, at the age of ninety. See COUNTERPOINT.

HUBARA, or HOUBARA of *Buffon*, in *Ornithology*, the ruffed bustard of Latham. See OTIS.

HUBARLIK, in *Geography*, a town of Prussian Lithuania; 25 miles E. of Bialacerkiev.

HUBBARDSTON, a township of America, in Worcester county, Massachusetts, incorporated in 1767; containing 1113 inhabitants; 60 miles W. of Boston.

HÜBBER, a small island in the Baltic, between the island of Ufedom and the continent. N. lat. 54° 38'. E. long. 13° 40'.

HUBBERTON, a township in Rutland county, Vermont, containing 642 inhabitants; 50 miles N. of Bennington.

HUBELI, a town of Hindoostan, in the country of Sanore; 20 miles N.W. of Sanore. N. lat. 25° 53'. E. long. 75° 24'.

HUBER, JOHN-JAMES, in *Biography*, a celebrated anatomist, was born at Basle in 1707. He was a pupil of the great Haller at Berne in 1730; after which he studied at Strasburgh, and in 1733 took the degree of M.D. at his native place. He visited Paris in 1735, and in the same year was appointed physician to the court of Baden Dourlach. At the request of his preceptor, Haller, who had removed to Göttingen he examined the Graubund mountains in Switzerland, and transmitted to him his collection of plants found in that district, previous to the publication of Haller's work on the botany of Switzerland. The author acknowledged the services of Huber in his preface, and invited him to Göttingen, in 1738, to be dissector. He speedily rose to considerable reputation, being made extraordinary professor of anatomy in that city in 1739; professor in the Caroline college at Cassel, with the rank of court-physician, in 1742; and counsellor of state and body-physician to the prince, in 1748; which office he continued to fill during thirty years, and died in 1778. He had the honour of being elected, without his knowledge, into the most celebrated of the learned societies of Europe. The chief objects of his research were the structure and ramifications of the spinal marrow, and the nerves originating from it; the supposed influence which the imagination of the mother has over the child; and the cause of miscarriages. His principal works are entitled, "Commentatio de Medulla Spinali. speciatim de Nervis ab ea provenientibus," cum icon. Göett. 1741, 4to. "Commentatio de Vaginæ Uteri structura rugosa, necnon de Hymene," 1742, 4to. He published a letter in the *Philos. Transactions*, vol. 46. "De cadavere aperto in quo non existit vesica fellea, et de Sterno gibboso." *Gen. Biog.*

HUBERT, MATTHEW, was born of humble parents, at Chatillon, on the Maine, in the year 1640. He was educated for the church, and was admitted into holy orders as soon as he had attained the proper age. His eloquence as a preacher caused him to be noticed, and followed by vast crowds. His popularity did not produce in his mind any ill effects: he was distinguished for piety, humility, and a general kindness and suavity of manners. He was not ashamed, at the highest pitch of his popularity, of his low origin, or of the obligations he had been under to his friends. Meeting once, in company, with a person of distinction, who observed to him that he recognized in Hubert an old fellow-student; he replied, with emotions of pure and unfeigned gratitude, "That is a circumstance which I can never forget, for you had the goodness not only to furnish me with books, but to bestow on me a part of your clothes." He died in 1717 at the age of 77. Six volumes of his sermons were published by father Monteuil in 1725, which were, at one time, as much read in the closet, as they had been admired from the pulpit. Moreri.

HUBERT, *St.*, anciently *Andainum*, or *Andagium*, in *Geography*, an ancient town of France, in the department of the Forêts, situated in the forest of Ardennes, on the small river Homme. It took its name from an abbey of Benedictines, where the remains of St. Hubert were deposited in 825, in compliance with the decree of a council, held at Aix-la-Chapelle; 25 miles N.W. of Arlon. N. lat. 50° 1'. E. long. 5° 27'.

HUBERT, *St.*, *Order of*, an order of knighthood, instituted in the duchy of Juliers, by Gerard V., duke of Juliers, in memory of a victory gained by him over Arnold of Egmont, on St. Hubert's day, in the year 1447. In 1709 it was revived by John-William, elector-palatine of the Rhine. The reigning elector-palatine is grand master. It was also used at Wurtemberg, where the reigning duke of Wurtemberg

temberg was grand master. The collar of the order is a chain of gold, to which is pendent a cross pattée, set with jewels, from the angles of which issue rays of gold; on the centre is a medallion of gold enamelled, with a portrait of St. Hubert, kneeling before a crucifix, placed between the horns of a stag standing in a wood, all proper. The knights also wear, on the left side of their coat, a circle surrounded with rays, embroidered in gold; and in the middle of it, on a red ground, some German words, signifying "Keep firm in the Faith." At all times, except festival days, they wear the cross tied to a red ribbon, which passes scarf-wise from the left shoulder to the right thigh.

HUBKOW, in *Geography*, a town of Poland, in Volhynia; 64 miles N.W. of Zytomiers.

HUBNER, JOHN, in *Biography*, a German historian and geographer, born in 1668, was celebrated likewise as an instructor of youth, and became rector of the school of Hamburg. He died in 1732, and is known to posterity by several useful compendiums in history, geography, &c., which have been translated into several languages. His chief works are, "Bibliotheca Historica Hamburgensis;" "Museum Geographicum." Moreri.

HUBS, in *Rural Economy*, a term applied in some districts to the names of wheels of certain kinds.

HUCAMYBUFF, in *Agriculture*, a term applied in some places to such coarse tufty grass as remains after eating down the more luxuriant pasture lands by live stock, and which is afterwards mown and made into rough sort of hay. This sort of work is in other districts often denominated *hobbing*. It is often pronounced *hogamybuff* by the farmers.

HU-CHOU-LO-TCHUAN, in *Geography*, a town of Corea; 600 miles E.N.E. of Peking. N. lat. $42^{\circ} 27'$. E. long. $128^{\circ} 51'$.

HUCH, or **HUCHO**, in *Ichthyology*. See *SALMO Hucho*.

HUCKABACK, in *Commerce*, is a kind of linen, on which the figures are raised.

HUCKESWAGEN, in *Geography*, a town of the duchy of Berg; 24 miles E.S.E. of Dusseldorp.

HUCKLE BONE, the hip-bone. See *COXÆ Offa*.

HUCQUELIERS, in *Geography*, a town of France, in the department of the straits of Calais, and chief place of a canton, in the district of Montreuil; nine miles N.E. of it. The place contains 710, and the canton 11,967 inhabitants, on a territory of $242\frac{1}{2}$ kilometres, in 24 communes.

HUCKSTER, one that sells provisions or small wares by retail.

HUD SHEAF, in *Agriculture*, the name by which the sheaf that covers the top of the haddock is frequently known. See **HUDDER**.

HUDEDE, JOHN, in *Biography*, a burgomaster of Amsterdam, who flourished in the seventeenth century, and died in 1704, was eminent in his character of a magistrate, and possessed a commanding genius for mathematical studies. Much was expected from his talents as a man of science, but he was diverted from the pursuit by state affairs. He was nevertheless the author of several excellent little pieces "On the Reduction of Equations;" "De Maximis et Minimis," and his "Commentary on the Geometry of Descartes," &c. Moreri.

HUDELGUR, in *Geography*, a town of Hindoostan, in Orissa; 15 miles N. of Boad.

HUDDER, in *Agriculture*, a name given, in many counties, to the sheaf by which the haddock is covered and protected at top from the effects of rain, &c.

HUDDERSFIELD, or **HUTHERSFIELD**, in *Geogra-*

phy, a market-town and parish in the West Riding of Yorkshire, England, is a large improving place, noted for being the centre of a manufacturing district. The parish consists of the following hamlets, or townships; Quarby with Lindley, Longwood, Golcarr, and part of Scamandan, Slaughtwaite, and Marsden, all of which are chiefly occupied by persons engaged in different branches of the woollen manufacture. The goods made here consist chiefly of narrow plain cloths, both fine and coarse, with some broad cloths, elastics, beaverettes, kerseymeres, &c. For the display and sale of these, a commodious building, of a circular form, called the Cloth-hall, was erected here, in 1765, by sir John Ramsden, who possesses nearly the whole of the land on which the town is built, and also a great many houses. The building consists of two stories, and is divided into two courts. All the windows open to these areas. A market is held here every Tuesday, which commences early in the morning, and is closed at half past twelve o'clock at noon. The resort of manufacturers, wool-staplers, &c. to this mart, is very numerous, many of whom come from Leeds, Halifax, Wakefield, and other places in the vicinity. Besides the market here are three annual fairs. The police of the town is under a constable and his deputy, who are annually chosen, or rather appointed, by the Ramsden family at their court-leet held at Almonsbury. Huddersfield is 14 miles west of Wakefield, and 188 from London. In the year 1800 it contained 1398 houses, and 7268 inhabitants. In the vicinity of the town are the following seats: Whitley-hall, belonging to the Beaumont family; Kirklees-hall, the property of sir George Armytage, bart.; Fixly-hall, the seat of Thomas Thornhill, esq.; and Millsbridge, belonging to W. Radcliffe, esq. West of Almonsbury is an eminence called Castle-hill, on the summit of which is an ancient entrenchment, supposed by some topographers to have been the Roman Cambodunum; but Mr. Watson, in his History of Halifax, attributes it to the Saxons, and thinks, that Slack, to the north of Huddersfield, was the scite of that station. The Roman road from Manchester, Mancunium, to York, Eboracum, passed near Almonsbury, and the name, and contiguity to the Roman road, are against Mr. Watson's conjectures.

HUDDERSFIELD Canal, is an inland navigation in Yorkshire and Lancashire, begun in pursuance of acts of parliament passed in the years 1793 and 1800, of which we gave an account in our article **CANAL**, and have here only to add, that the locks are 72 feet long and nine feet wide, and generally rise about ten feet: there is a tunnel of about 200 yards long, S.E. of Scout Mill, near Ashton-under-line: an aqueduct of cast-iron, 50 or 60 feet long, having a stone bridge of one arch by its side for the towing-path: these were erected in 1801 and 1802. At Wright's Mill the canal crosses the Tame, to its western side, just after it has entered Yorkshire, on a two-arch stone aqueduct. The canal has been now a long time completed, and is used, from its western end, about eight miles to Woolroyd, and from its eastern end to Diglee in Sadleworth; and at this time, the great tunnel $3\frac{1}{4}$ miles long and 250 yards beneath Pule hill on the grand ridge, is, we believe, very nearly finished. The bridges on this canal have been imprudently constructed, many of them, even under the public roads, without towing-paths under them, and must be taken down and widened. On the 29th of November, 1810, a second accident happened to the reservoirs of this canal, when the Driggle reservoir on Stanedge, containing 28 acres, burst, and inundated the vallies below.

HUD-SJERA, a town of Arabia Felix, in the province of Yemen; 36 miles W.N.W. of Sana.

HUDSON.

HUDSON, HENRY, in *Biography*, a distinguished naval commander, of whom nothing is known till about the year 1607. At this period he was sent out on an expedition, by some London merchants, in a small vessel for exploring a north-east passage to Japan and China. This daring adventurer set sail on the 1st of May with a crew of only ten men and a boy, besides himself, and proceeded beyond the 80th degree of latitude in the North sea, when, being stopped by the ice, they returned and arrived at England in the following September. In a second voyage he landed at Nova Zembla, but proceeded no farther east, and returned in August. In 1609 he was fitted out for a third voyage by some merchants of the Dutch-East-India-company, and after another unsuccessful attempt to the eastward he steered for the American coast, and went down as far as Chesapeake-bay. His crew, dissatisfied with their want of success, prevented him from endeavouring to find a westerly passage through Davis's strait, and he returned in November. In a fourth voyage he came, June 4th 1610, within sight of Greenland, and proceeding westward, he reached, in sixty degrees of latitude, the mouth of the strait bearing his name. Through this he advanced along the coast of Labrador, to which he gave the name of Nova Britannia, till it issued in the vast bay which perpetuates the memory of Hudson. At first he thought he had discovered the long sought passage to the north-west, but experience taught him that it was only a bay, and he resolved to winter in it. They found provisions during the winter season, but at the approach of spring they were reduced to the utmost difficulties. The commander forgot his own sufferings in the hope of making new discoveries, but his crew, not having the same motives for patience and perseverance, began to mutiny, and he threatened to set them on shore. They, on the other hand, willing to anticipate the execution of his purpose, seized Mr. Hudson, his son, and seven others, who were most attached to him, and putting them on shore at the west end of the straits, left them to perish by the waves, or other hardships. Such was the end of Henry Hudson, a man illustrious in the annals of naval discovery.

HUDSON, JOHN, was born in 1662 at Widehope, near Cocker-mouth, where he received the early part of his education, and at the age of fourteen he was admitted into Queen's college, Oxford. In 1684 he took his degree of M.A. and then removed to University college, of which, in two years after, he was chosen fellow. In 1701 he was elected head-keeper of the Bodleian library, against the competition of the learned Wallis, afterwards Arabic professor. He now took his degree of D.D., and in 1712 he was made principal of St. Mary-hall. He employed the advantages of his situation in editing several of the most valuable authors of antiquity. Of these the following may be mentioned, "Velleius Paterculus;" "Thucydides;" "Geographiæ Veteris Scriptores Græci Minores;" "Dionysius Halicarnassus;" and "Longinus." The editions of Dr. Hudson are valued for their elegance and correctness. He never possessed any ecclesiastical preferment, and died at St. Mary-hall in Nov. 1719. *Biog. Brit.*

HUDSON, THOMAS, a portrait painter, who enjoyed for many years the principal repute and practice of the profession in London, after Richardson, under whom he studied, and Jervas were gone. Yet, though confessedly the best of his time, it is but small praise to say so of him; he will be longer remembered as the master of an illustrious pupil who soon eclipsed him, when he began to appear before the public, and who yet remains unrivalled, sir Joshua Reynolds.

Hudson certainly improved upon the taste of the artists

who immediately preceded him, and who had fallen in succession from Kneller, into the utmost imbecility of practice as well as feeling in the art. For a while his success was interrupted by Vanloo and Liotard, but the English gentry in general were faithful to their compatriot, and were content with his honest similitudes, with fair tied wigs, velvet coats and white fatten waistcoats, duly gilt and embroidered.

When Reynolds began to practise and gain fame, Hudson was advanced in years, and having acquired an independency of fortune, he retired and left the field to his youthful rival, after having finished his most capital performance, the family piece of Charles duke of Marlborough.

He went to reside at a beautiful villa which he built at Twickenham, where he died in 1779, at the age of 78. He was twice married, first to the daughter of his master Richardson, and afterwards, towards the close of his life, to a Mrs. Fiennes, a gentlewoman of good fortune, to whom he bequeathed his villa, with an excellent collection of cabinet pictures and drawings by the old masters.

HUDSON, WILLIAM, one of the earliest Linnæan botanists in England, was born in Westmoreland, about the year 1730. He served his apprenticeship to an apothecary in Panton street, Haymarket, to whose business he succeeded, and with whose widow and daughters he continued to reside. His acquaintance with the amiable and learned Mr. Benjamin Stillingfleet, greatly advanced his taste and information in natural history. This gentleman directed his attention to the writings of Linnæus, and gave his mind that correct and scientific turn, which caused him to take the lead as a classical English botanist, and induced him to become the author of the *Flora Anglica*, published in 1762, in one volume octavo. The plan of this book was, taking Ray's *Synopsis* as a ground-work, to dispose his plants in order, according to the Linnæan system and nomenclature, with such additions of new species, or of new places of growth, as the author or his friends were able to furnish. The synonyms of the most valuable authors, since the time of Ray or Dillenius, were superadded, as well as descriptions of new or rare plants; and even new specific characters, wherever the English specimens did not well answer to the definitions in Linnæus. Some few generic alterations were also hazarded; but for the most part the Linnæan definitions in this department were relied on. Many synonyms also were copied from Linnæus or other writers, as appears by errors of the press retained in the transcribing. Of this too common fault we have had occasion to take notice on some other occasions, but we by no means intend to assert that Mr. Hudson consulted none of the authors he quoted. On the contrary, we believe such blind transcription was more rarely practised by him than by many other writers. The particular places of growth of the rarer species were given in Ray's manner, in English, though the rest of the book was Latin. The elegant preface was written by Mr. Stillingfleet, and probably the concise, but not less elegant, dedication to the late duke of Northumberland, "*artium, tum utilium, tum elegantiorum, judici et patrono.*"

This publication gave Mr. Hudson a considerable rank as a botanist, not only in his own country, but on the continent, and derived no small advantage from a comparison with Dr. Hill's attempt of the same kind. He had indeed previously, in the course of his medical practice, formed some valuable connexions, which were cemented by botanical taste, and he found leisure, from time to time, to visit several friends in the course of his botanical expeditions, especially in Devonshire. His correspondence with Linnæus, Haller, and others, as well as amongst his countrymen, was frequent

frequent and very useful to him in the course of his studies, which were extended not only to botany in all its cryptographic minutiae, but, with great ardour also, to insects, shells, and other branches of British zoology. He was elected a fellow of the Royal Society Nov. 5th, and admitted Nov. 12th 1761. He took the lead very much in the affairs of the Apothecaries' company, and was their botanical demonstrator in the Chelsea garden for many years.

Mr. Hudson, having never married, continued to reside in Panton street with the last-surviving daughter of his friend and master, an amiable and valuable woman, married to Mr. Hole; nor did he remit in his attention to science or business. There the writer of the present narrative often visited him, and experienced his kind, though somewhat reserved, communications and favour. His *Flora* being grown very scarce, inasmuch that a copy had been sold for near twenty times its original price, he published, in 1778, a new edition, in two volumes, with many additions, and various alterations. Some of the latter, respecting the species or varieties of grasses, have been thought less advantageous than the rest. On the whole, however, this edition was worthy of its author, and of the advanced state of the science. The *Flora Scotica* of his contemporary Mr. Lightfoot, a man of more popular manners and style, will not bear a comparison with it for authenticity or originality, however pleasing and estimable for the graces it bestows on even the driest parts of the science.

The merits of the subject of this article were of a higher order. In his social intercourse he courted not the many, but was warmly attached to a few. His moral character was without a stain, and his mind was established on the soundest principles. His tranquillity received a dreadful shock in the winter of 1783, when his house, and the greater part of his literary treasures, were destroyed by a sudden fire, caused, as it was believed, by the villainy of a confidential servant, who knew of a considerable sum in money which his master had received a day or two before. No traces of the gold were found amongst the ruins. The servant, after a treacherous application for assistance, on the pretence of being totally destitute, disappeared. The property had, by accident, been for a short time only, uninsured, and the loss was therefore considerable, in a pecuniary point of view, to a man whose resources were not extensive. He bore the whole like a philosopher and a Christian, giving up his practice, and retiring, with Mr. and Mrs. Hole, to a more economical residence in Jermyn street, where he died May 23d 1793, Mrs. Hole surviving him but a few months.

The accident of the fire entirely defeated a project Mr. Hudson had for many years kept in view, of publishing a *Fauna Britannica*, on the plan of his *Flora*, for which he had long been collecting materials. His taste for his favourite pursuit remained to the last, unimpaired and unembittered by these disappointments. He became a fellow of the Linnæan Society early in 1791, liberally contributing to its infant funds, and attending the meetings as often as his now declining health would allow. His lungs had for many years been in an ulcerated state, and he laboured under frequent imposthumes in that part; but a succession of paralytic attacks appear to have been the more immediate cause of his dissolution. His resigned and placid exit was conformable to the tenour of his life. His remains were interred at the adjoining church of St. James's. "May the writer of this leave no more errors behind him, as an author, or as a man!" S.

HUDSON City, in *Geography*, a port of entry and post-town of America, in the county of Columbia, and state of

New York, on the E. side of Hudson river; 132 miles N. of New York city. This town was begun in 1783, on a spot, accessible by vessels of any size; and was laid out in squares, formed by spacious streets, crossing one another at right angles. Each square contains 30 lots, and each lot is 50 feet in front and 120 feet in depth. From the period of its commencement, the increase of this town has been wonderfully rapid; in two years 150 dwelling houses were erected, with shops, barns, warehouses, and other buildings, a covered rope-walk, and one of the best distilleries in America; and the number of inhabitants collected in this short interval of time amounted to 1500. Since the year 1786, a printing-office has been established, several public buildings have been erected, with dwelling-houses, stores, &c. The town is abundantly supplied with water, conveyed by pipes to their cellars, from a spring at the distance of two miles. To the southward is a large bay, and it commands extensive views from the eminence on which it is situated. The river is a mile wide, and forms towards the north a number of creeks and bays. From the S.E. to the S.W. the city is screened by hills, and the distant prospect is terminated by a chain of stupendous mountains, called the "Kaats' hill." Here is a bank, called the "bank of Columbia, whose capital may not exceed 160,000 dollars, composed of 400 shares, at 400 dollars each. This city is governed by a mayor, recorder, four aldermen, four assistants, and other officers. The number of inhabitants in Hudson township is 3664. N. lat. 42° 14'.

HUDSON, a flourishing town in Trumbull county, and state of Ohio, about 35 miles W. of Warren, containing about 200 inhabitants.

HUDSON'S Bay, an inland sea, so called from the voyager Hudson, who in 1610 discovered the straits which bear his name, and this inland sea, approaching the Baltic in size, which has, however, been denominated Hudson's bay. Hudson's sea may be considered as extending from W. long. 70°, to long. 115°, or 45° of longitude, which, allowing the degree only 30 miles, will be 1350 geographical miles in length, and its medial breadth about 350. The entrance of this bay from the ocean, after leaving to the N. cape Farewell and Davis's straits, is between Resolution isles on the N., and Button's isles on the Labrador coast, to the S., forming the eastern extremity of the straits distinguished by the name of the discoverer. The shores are generally rocky and precipitous; with some large beaches; the isles of Salisbury, Nottingham, and Digges, are also very lofty and naked. The depth of water in the middle of the bay is 140 fathoms. From cape Churchill to the S. end of the bay are regular soundings; near the shore shallow with a muddy or sandy bottom. To the N. of Churchill, the soundings are irregular, the bottom rocky, and in some parts the rocks appear above the surface at low water. From Moose river, or the bottom of the bay, to Cape Churchill, the land is flat, marshy, and wooded with pines, birch, larch, and willows. From cape Churchill to Wager's water, the coasts are all high and rocky to the sea, and destitute of wood, except the mouths of Pockerekelko and Seal rivers. The hills on their back are naked, nor are there any traces of trees for a great distance inland. The mouths of all the rivers are filled with shoals, except that of Churchill, in which the largest ships may lie; but 10 miles higher, the channel is obstructed with sand-banks; and all the rivers, as far as they have been navigated, abound with rapids and cataracts, from 10 to 60 feet perpendicular. As far inland as the Hudson-bay Company have settlements, which is 600 miles to the W., at a place called "Hudson House," N. lat. 53°. W. long. 106° 27', is flat country. The climate

is almost always wintry, the hot weather in June, though violent, being of short duration. The snows begin to fall in October, and continue to fall at intervals during the winter; the ice on the rivers is eight feet thick. Port wine freezes in a solid mass, and brandy coagulates. The ice begins to disappear in May, and hot weather commences about the middle of June. Mock suns and halos are frequent and brilliant; the night is enlivened with the Aurora Borealis; and the stars appear with a fiery redness. Thunder, though not frequent, is very violent. The sea does not abound with fish, but it furnishes the common whale, and the beluga or white whale is taken in considerable numbers in June, when the rivers on the south have discharged their ice. Large sturgeons are also caught near Albany. Shell fish are very rare, common muscles excepted, which are frequent. Multitudes of birds retire to this remote country, as well as to Labrador and Newfoundland, from places most remotely south, perhaps from the Antilles; and some even of the most delicate little species. Most of them, with numbers of aquatic fowls, are seen returning southward, with their young broods to more favourable climates. The savages partly regulate their months by the appearance of birds. All the grouse kind, ravens, cinereous crows, titmouse, and Lapland finch, brave the severest winter; and several of the falcons and owls seek shelter in the woods. The rein deer pass in vast herds towards the N. in October, seeking the extreme cold. The male polar bears rove out at sea, on the floating ice, most of the winter, and till June: the females lie concealed in the woods, or beneath the banks of rivers till March, when they come out with their twin cubs, and bend their course to the sea in search of their consorts. The large tract of territory on the south of this sea is the property of the Hudson's Bay company, who derive their chief profits from furs. This sea has been repeatedly explored for a N.W. passage to no purpose. Chesterfield inlet, (see CHESTERFIELD,) stretches far to the W., and terminates in a magnificent lake of fresh water, communicating with this sea by a broad river; the adjacent land being level, rich in pasture, and abounding with deer. It is probably believed, that the Hudson sea on the N.E. opens into the Arctic ocean, where the perpetual ice presents an insurmountable barrier to commercial adventurers. The gulf, or sea of Davis, may be considered as part of the sea of Hudson, and probably joins the Arctic ocean.

The regions around Hudson's bay and that of Labrador have been sometimes called *New Britain* (which see). The parts on the W. of Hudson's bay have also been called New North and South Wales; while that on the E. is styled East Main. In the S., James's bay stretches inland about 300 miles by about 500 in breadth; and the most valuable settlements are in that vicinity, as Albany fort, Moose fort, and East Main factory. Further to the S. and on the confines of Upper Canada, are Brunswick house, Frederick house, and some others, belonging, probably, to the N.W. company. In the N., Severn house is at the mouth of a large river, which seems to flow from the lake of Winnipic. York fort stands on Nelson's river: and still further to the N. is Churchill fort, which seems to be the farthest settlement in that direction. To the W. the Hudson's Bay company had extended little further than Hudson's house; while the superior spirit of the N.W. company, established in 1784, has nearly approached the Pacific. The boundary between the Hudson's Bay company and Canada is understood to follow the ridge that gives source to the rivers flowing N. and S. as far as lake Annipeg, so that lat. 49° is said to form the limit. The most important rivers in this country are, the Nelson, or Saskatchewan, and the Severn: the comparative course of

the latter scarcely exceeding 400 British miles, but of great breadth and depth. In the S. the Albany, Moose, Abnib, and Harricana, are the most considerable; but all the rivers are impeded with falls and shoals. In the sea of Hudson are several high islands. Pennant's Arctic Zoology. Pinckerton's Geog. vol. iii.

HUDSON'S Bay Company. See COMPANY, and the preceding article.

HUDSON'S House, a factory belonging to the Hudson's Bay company in North America, on the W side of the Saskatchewan river. N. lat. 53. W. long. 106 27.

HUDSON'S Point, a cape of the island of Antigua, on the S.E. coast. N. lat. 17 12'. W. long. 61 23'.

HUDSON'S River, one of the largest and finest rivers in the United States of America, which rises in a mountainous country of New York, between the lakes Ontario and Champlain, and after pursuing a south-easterly course within six or eight miles of lake George, then a straight course E. and afterwards S. 12 or 15 W., discharges itself into York bay. The whole length is about 250 miles; from Albany to lake George the course is 65 miles, which is navigable only for batteaux, and has two portages, occasioned by falls, of half a mile each. The passage through the highlands, of 16 or 18 miles, affords a wild romantic scene. The bed of this river, which is deep and smooth to a surprising distance through a hilly, rocky country, and even through ridges of some of the highest mountains in the United States, must have been produced by some signal convulsion of nature. The tide flows a few miles above Albany, which is 160 miles from New York. The river is navigable for floops of 80 tons to Albany, and for ships to Hudson city. About 60 miles above New York the water becomes fresh. This river is stored with a variety of fish; and it affords singular advantages for carrying on the fur-trade with Canada, by means of the lakes: and its conveniences for internal commerce are very great.—Also, a river broad but short, emptying itself into Chesapeake bay, in Dorchester county, Maryland. Hill's Point, N.E. of it, closes the broad mouth of this river.

HUDSON'S Straits, or *Frobisher's Mistaken Strait,* the narrow sea between the Atlantic ocean and Hudson's bay, N. of Labrador. See HUDSON'S Bay.

HUDSON'S Bay Porcupine, in Zoology. See HYSTRIX *Dorsata*.

HUDSONIA, in Botany, named by Linnæus in honour of his friend and correspondent Mr. William Hudson, author of the *Flora Anglica*.—Linn. Mant. 11. Schreb. 322. Willd. Sp. Pl. v. 2. 858. Mart. Mill. Dict. v. 2. Juss. 162. Lamarck. Illustr. t. 401.—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Ericis affinis*, Juss. *Hyperica*, Bergius.

Gen. Ch. Cal. Perianth inferior, in three deep, lanceolate, obtuse, rather concave segments. Cor. Petals five, sessile, ovate-oblong, obtuse, shorter than the calyx. Stam. Filaments 15 or 18, capillary, the length of the corolla; anthers roundish. Pist. Germen superior, ovate; style thread-shaped, the length of the stamens; stigma simple. Peric. Capsule cylindrical, half as long as the calyx, of one cell and three valves. Seeds three, rounded on one side, angular on the other.

Ess. Ch. Petals five. Calyx in three deep parallel segments. Stamens fifteen. Capsule superior, of one cell and three valves. Seeds three.

Obs. The characters are corrected from the description of Bergius, which escaped the notice of Schreber; who merely copied the *Maniffa*, in which there is said to be no corolla.

1. *H. ericoides*. Linn. Mant. 74. Willd. Hort. Berol. v. 1. t. 15. Bergius in Act. Holm. for 1778. 19. t. 1; not 18. t. 2, as in Willdenow. (*Ericæformis suffrutex virginianus, floribus exiguis, vasculo feminali oblongo trifariam diviso*; Pluk. Mant. 68.)—The only known species, a native of Virginia and other parts of North America, yet Michaux has it not. We saw it alive and in flower at Kew in the spring of 1809. The stem is shrubby, procumbent, round, with very numerous, ascending, compound leafy branches, greatly resembling a heath. Leaves scattered, small, needle-like, close-pressed, somewhat imbricated, acute, hairy, especially on the younger shoots. Flowers lateral, on slender, hairy, solitary, simple stalks longer than the leaves. Calyx externally downy, internally yellow. Petals and stamens of a uniform lemon-colour, much resembling some small *Hypericum*.

HUE, in *Painting*, signifies any degree of strength or vividness in a colour, from its greatest or deepest power to the weakest intimation of it.

HUE-AND-CRY, in *Law*, derived from the French *huer* and *crier*, which both signify *to shout, or cry aloud*, denotes the pursuit of one who has committed felony, &c. on the highway.

If a party robbed, or any in the company of one murdered or robbed, come to the constable of the next town, and require him to raise hue-and-cry, or to pursue the offender, describing him, and shewing, as near as he can, which way he is gone, the constable is forthwith to call for aid from the parish to seek the felon; and if he is not found there, he is to give the next constable warning, till he be apprehended, or at least pursued to the sea-side.

The Normans had a pursuit with a cry after offenders, not unlike this; which they called *clamor de baro*. See CLAMOR.

Hue is also used alone, ann. 1 Edw. I. stat. 2. In ancient records it is called *butefsum* & *clamor*, which properly signify a pursuit by horn and by voice.

This process of pursuing is mentioned by statute Westm. 1. 3 Edw. I. cap. 9. and 4 Edw. I. *de officio coronatoris*. But the principal statute relative to this matter is that of Winchester, 13 Edw. I. cap. 1. & 4 which directs, that from thenceforth every county shall be so well kept, that immediately upon robberies and felonies committed, fresh pursuit shall be made from town to town, and from county to county; and the hue-and-cry shall be raised upon the felons, and they who keep the town shall follow with hue-and-cry, with all the town and towns near; and so hue-and-cry shall be made from town to town, until they be taken and delivered to the sheriff. And that such hue-and-cry may more effectually be made, the hundred is bound by the same statute, cap. 3, to answer for all robberies therein committed, unless they take the felon, which is the foundation of an action against the hundred, in case of any loss by robbery. By stat. 27 Eliz. cap. 13. no hue-and-cry is sufficient, unless made with both horsemen and footmen. And by stat. 8 Geo. II. cap. 16. the constable or like officer refusing or neglecting to make hue-and-cry, forfeits 5*l.* and the whole vill or district is still in strictness liable to be amerced, according to the law of Alfred, if any felony be committed therein, and the felon escape. Hue-and-cry may be raised either by precept of a justice of the peace, or by a peace-officer, or by any private man that knows of a felony. (2 Hal. P. C. 100—104.) But if a man maliciously or wantonly raises a hue-and-cry, without cause, he shall be severely punished as a disturber of the public peace. 1 Hawk.

P. C. 75. Blackst. Comm. vol. iv. p. 290, &c. See HIGHWAYMEN.

In supplement to this ancient establishment, Sir John Fielding's plan was instituted for the discovery of offenders, after they have escaped the fresh pursuit upon hue-and-cry, by sending immediate notice to a certain known office in London, from whence are issued weekly accounts to every part of the kingdom, describing the offence and the offenders with as much accuracy as the case will admit. By these means many notorious offenders have been apprehended, and much stolen property hath been recovered.

HUELAMO, in *Geography*, a town of Spain, in New Castile; 22 miles N.N.E. of Cuenca.

HUELBA, or HUELVA, a town of Spain, in the province of Seville, situated on the coast of the Atlantic; three miles W. of Moguer. N. lat. 37° 13'. W. long. 7° 1'.

HUELGOAT, LE, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Chateaulin; nine miles N.W. of Carhaix. The place contains 766, and the canton 9496 inhabitants, on a territory of 305 kilometres, in seven communes.

HUELMA, a town of Spain, in Grenada; 13 miles S.W. of Grenada.

HUERNIA, in *Botany*, so called by Mr. R. Brown, "in memory of Justus Huernius, one of the earliest collectors of Cape plants, and from whose drawings the first account of *Stapelia* was taken," from which genus the present is separated.—Brown. Afleph. 11.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contorta*, Linn. *Apocinea*, Juss.

Ess. Ch. Corolla bell-shaped, its limb in ten segments, the intermediate ones very small and tooth-like. Column of fructification concealed. Crown of the stamens double; the outer in five cloven segments; inner of five undivided awl-shaped leaves, gibbous at their base, alternate with the segments of the outer. Anthers simple at their summit; masses of pollen erect, attached by their base, cartilaginous and pellucid at one edge. Stigma pointless. Follicles nearly cylindrical, smooth. Seeds comose.

The plants which compose this genus have the remarkable fleshy, angular, and toothed habit of *Stapelia*, and the whole of the third section of that genus in Willd. Sp. Pl. v. 1. 1293, (with a ten-toothed corolla,) is thought to belong to *Huernia*. Mr. Brown has however examined only the *campanulata*, Masson. Stapel. t. 6; *venusta*, t. 3; and *gutata*, t. 4. They are all natives of the south of Africa. The flowers of these three are all pale yellow, richly dotted with red or dark purple. The *reticulata*, t. 2, which has every appearance of being of the same genus, bears a splendid crimson corolla, reticulated with yellow lines.—As far as habit is concerned, we cannot but think this genus artificial, the crown of the stamens in *Stapelia*, and its nearest allies, being somewhat liable to aberration of character.

HUERS. See BALKERS and *Pilchard* FISHERY.

HUERS, the name given to certain fountains in Iceland, which form jets d'eau of scalding water 94 feet high and 30 feet in diameter. They arise from cylindrical tubes of unknown depth; near the surface they expand into apertures of a funnel-shape, and the mouths spread into a large extent of stalaetical matter, formed of successive scaly concentric undulations. The occurrence of this phenomenon is foretold by noises roaring like the cataract of Niagara. These huers are not confined to the land; they also rise in the sea, and form scalding fountains amidst the waves.

HUESCA, a town of Spain, in the province of Aragon,

gon, situated on the Isuela, the see of a bishop, suffragan of Saragossa, containing four parishes, five convents, and an university founded in 1354. In the seventh century, this town was the capital of a small Moorish kingdom; but in 1096 it was recovered by the Christians; 27 miles N.N.E. of Saragossa. N. lat. 42° 7'. W. long. 0° 27'.

HUESCAR, a town of Spain, in Granada, containing two parishes and four convents; seven miles W.N.W. of Carthagena.

HUET, PETER DANIEL, in *Biography*, a learned French prelate, was born at Caen in 1630. Owing to the death of his parents, his education devolved upon an aunt who placed him, while young, in the Jesuits' college at Caen, where he was distinguished by assiduity and an amiable disposition. He cultivated with much success not only polite literature, but mathematics, philosophy, jurisprudence, and the Hebrew language. In connection with the latter study, he cultivated the acquaintance of the learned Bochart, the Calvinist minister of Caen, but to avoid suspicion, their conferences were first held in secret. When he attained to the age of manhood he visited Paris, and began to indulge his passion for books, by purchasing as many as his finances would admit of. In 1652 he accompanied Bochart in a journey to Sweden, whither that learned man had been invited by queen Christina. He was tired of the country before the approach of winter; and leaving Bochart there, he returned through Holland, where he passed some time in visiting the universities and men of learning. On his arrival at Paris, a controversy arose between him and Bochart, concerning Origen's commentary on St. Matthew's gospel, which put an end to their friendship. In 1661, Huet published his first work, entitled "De Interpretatione," the object of which was to confine, within due limits, the licence of translators, especially those of the scriptures. He instituted, about this period, an academy of physics at Caen, the members of which assembled weekly at his house, where they read memoirs, and conducted experimental enquiries. This institution was patronized by the minister Colbert, through whose influence the royal munificence was extended, not only to the society, but also to its founder, and Huet was put on the list of learned men upon whom pensions were regularly conferred. In 1670, when Bossuet was appointed preceptor to the dauphin, Huet was called to the office of sub-preceptor. In this post, one of his employments was to superintend that edition of the classics which is commonly known here as the Delphin edition. In 1674 he was elected a member of the French academy, in 1676 priests' orders, which he had hitherto deferred taking, were given him, and in 1678 he was presented to the abbey of Aunay in Normandy, a place, the beauties of which he has celebrated in verse, and which became his favourite residence. He was presented, in 1685, to the bishopric of Soissons, but owing to the disputes then existing between France and Rome, he never obtained his bulls, nor took possession of his see, and which he readily exchanged in 1689 for that of Avranches, which was his native province. To this see he was not consecrated till 1692, and in 1699 finding the burthen of the situation too great for his comfort, he begged permission to resign his bishopric, and was presented by the king, as a pecuniary compensation, with the abbacy of Fontenai near Caen. Here he became the victim of several law suits, and at length made his retreat from the world and its vexations into the house of the Jesuits at Paris, to which he bequeathed his library. Here he remained absorbed in his studies, and in intercourse with a few learned men, till his death in January 1721, at the great age

of ninety-one. Huet was the author of many learned works, and may be regarded as one of the most distinguished literary scholars of the age in which he flourished. Of his various publications the following have been translated into English. "On the Origin of Romances;" "On the Situation of the Terrestrial Paradise;" "History of the Commerce and Navigation of the Ancients;" and "On the Weakness of the Human Understanding." Moreri.

HUETA, in *Geography*. See GUETA.

HUF, a town of European Turkey, in Moldavia, on the Pruth; 50 miles S.S.E. of Jassi. N. lat. 46° 34'. E. long. 46° 19'.

HUG, or *Cornish* HUG, a term used in wrestling, when one has an adversary on his breast, and holds him fast there.

HUGH, in *Biography*, abbot of Flavigny, who flourished in the beginning of the twelfth century, celebrated for his talents as an ecclesiastical historian, descended from an illustrious family, was born in the year 1065. He embraced the monastic life in the abbey of St. Vannes at Verdun, but when the members of that community were dispersed, he, together with the other monks, took refuge at the monastery of Flavigny, in the diocese of Autun. Here he acquired so much esteem and respect, that, upon the death of the abbot, in 1097, he was elected to that dignity, though he was not more than thirty-two years of age. He was author of "Chronicon Verdunense," which is divided into two parts, the first contains an ecclesiastical history from the birth of Christ to the close of the tenth century, and the second a continuation of the same from 1002 to 1102. This second part furnishes us with much valuable information concerning the ecclesiastical affairs of France in the eleventh century. It was drawn out of obscurity by father Labbè, who calls it an inestimable treasure, and printed it in the first volume of his "Bibliotheca nova Manuscriptorum," from a supposed autograph of the author, found in the Jesuits' college at Paris. Moreri.

HUGH of Fleury, a learned French monk, who flourished about the year 1120, and embraced the ecclesiastical life in the abbey of Fleury. He was author of "Chronicon Libris VI. ad Ivonem Carnotensem," commencing with the reign of Ninus, king of the Assyrians, and terminating with the death of the emperor Lewis the Pious, in the year 840; and also of a short, but well digested chronicle, from the beginning of the world to the reign of Lewis the Pious. Hugh was author likewise of "Lib. II. de regia Potestate, et sacerdotali Dignitate, ad Henricum Angliæ Regem," which is thought by some critics to be the most valuable of his works. Moreri.

HUGH of St. Victor, was born near Ypres, in Flanders, about the year 1097. When he was eighteen years of age, he entered into the congregation of the canons regular of St. Augustine, at the monastery of St. Victor, in Paris, where he spent the remainder of his life, and rose to the office of prior. In 1130 he was appointed to the theological chair, which he filled with so much reputation, that he was commonly called a "second Augustine." He died in 1140, when only in the 44th year of his age. His works were collected and published in three volumes folio. They have been several times reprinted.

HUGH of St. Charus, or St. Theodoric, a French monk, and cardinal in the thirteenth century, was born in the vicinity of Vienne, in Dauphine. In 1225 he entered into the Dominican order of preaching friars, of which he was soon appointed provincial. He was afterwards created doctor by the faculty of the Sorbonne, and was sent by pope Gregory

gory IX. on a mission to Constantinople, to attempt to bring about an union between the eastern and western churches. In 1245 he was created a cardinal by pope Innocent IV. under the title of St. Sabina, who also employed him in many important and difficult negotiations. He died at Orvieto in the year 1263. He was author of many very useful works, but the most celebrated is the "Concordance of the Bible," of which he was the inventor, and in drawing up which, he employed many monks of his order. This work was printed at Cologne in 1684, and is entitled "Concordantia major Latinorum Bibliorum pro omnibus vocibus declinabilibus in tota S. scriptura repertis." Moreri.

HUGH Capet. See CAPET.

HUGHES, JOHN, in *Biography*, an English poet, was born, in 1677, at Marlborough. He was educated in London, was a student in the academy of Mr. Thomas Rowe, and was a contemporary of Dr. Watts, Mr. Say, and some others who arrived at eminence. Mr. Hughes attached himself to polite literature, and was a practitioner in the fine arts. He obtained a place in the office of ordnance, and was secretary to various commissions, for purchasing lands for the use of the Royal docks. His employments under government, and his political principles, induced him to exercise his poetic talents upon public topics. He published "A Poem on the Treaty of Ryfwick;" "The Court of Neptune;" "A Poem on the Return of King William from Holland;" and a pindaric ode, entitled "Of the House of Nassau." His sentiments and poetry rendered him acceptable to the Whig party, and connected him with Addison, Steele, and other persons of distinction. He became one of the writers in the *Tatler*, *Spectator*, and *Guardian*. His taste for music introduced him to the acquaintance of several eminent composers, and led him to write many pieces for musical accompaniment. In 1715 he published, by subscription, an edition of Spencer, by which he gained great credit as an elegant critic. In 1717 he obtained the patronage of lord chancellor Cowper, who gave him the place of secretary to the commissions of the peace. His want of health interrupted the enjoyment of his good fortune. Under much bodily labour he composed his tragedy of "The Siege of Damascus," which was brought on the stage in February 17th, 1719-20, on which night the author finished his earthly career, at the age of forty-three. He was a man generally beloved and respected: his temper was amiable, his morals were pure, and his integrity was unimpeachable. His tragedy is the principal piece of his composition. In 1735 a complete collection of his poems and dramatic pieces was published with an account of his life in two volumes, 12mo. by his brother-in-law, William Duncombe, esq. The younger brother, Jabez Hughes, published a translation from Claudian of the Rape of Proserpine: and the story of Sextus and Erietho from Lucan; also Suetonius's Lives of the Cæsars, and some of Cervantes novels. Another John Hughes, fellow of St. John's college, Cambridge, published, in 1712, an edition of Chryostom on the Priesthood.

Mr. John Hughes, during the early part of the last century, was our principal lyric poet; and not only wrote for music, but was himself a performer in Britain, the small-coal man's concerts. He wrote the English opera of "Calypso and Telemachus," for Galliard to set, and "Apollo and Daphne," for Dr. Pepusch, with cantatas for both. His verses on Mrs. Barber's elopement, and on the rivalry of Margarita and Mrs. Tofts, shew that he interested himself in the transactions of the musical world, and was on the watch to ridicule the follies and display the talents of its professors.

HUGHESBURG, in *Geography*, a town of America, in Northumberland county, Pennsylvania, called also "Ca-

VOL. XVIII.

tawessy," situated at the mouth of Catawessy creek; 25 miles N.E. of Sunbury. It contains 1315 inhabitants. N. lat. 40° 54'.

HUGH-TOWN, a town of St. Mary's, one of the Scilly islands.

HUGO, CHARLES LOUIS, in *Biography*, a French writer, abbot of Ellival, and bishop of Ptolemais, died in 1735. His chief works are, "Annales Premonstratensium," which is a curious history of the monastic order. "Vie de St. Norbert, Fondateur des Premontres;" "Sacrae Antiquitates monumenta historica, dogmatica, diplomatica," 2 vols. fol. "Traité Historique et Critique de la Maison de Lorraine." This last, on account of the freedom with which crowned heads are treated in it, was published under the borrowed name of Baleicourt, and pretendedly printed at Berlin. Moreri.

HUGONIA, in *Botany*, so named by Linnæus in honour of Dr. Augustus John Hugo, physician to his British majesty at Hanover, the friend of Haller, and the companion of some of his botanical expeditions among the Alps. He graduated at Leyden in 1711, and published a thesis *de variis plantarum methodis*.—Linn. Gen. 349. Schreb. 457. Willd. Sp. Pl. v. 3. 694, Mart. Mill. Dict. v. 2. Juss. 275. Lamarck. Illustr. t. 572. Cavan. Diss. 177. Gærtn. t. 58.—Class and order, *Monadelphica Decandria*. Nat. Ord. *Malvacea*, Juss.

Gen. Ch. Cal. Perianth inferior, of five ovate, acute, concave, coriaceous, permanent leaves; the two outer ones largest. Cor. Petals five, roundish, large, spreading, emarginate, contracted at the base into a thin claw, attached to the cup formed by the stamens. Stam. Filaments ten, awl-shaped, equal, shorter than the corolla, united by their base into a little cup; anthers roundish, furrowed, incumbent. Pist. Germen superior, roundish; styles five, thread-shaped, longer than the stamens; stigmas capitate, orbicular, flat. Peric. Drupa globose, of one cell. Seed. Nut globose, deeply striated, of ten cells; kernels oblong, compressed, curved at the back.

Obs. "The two outer leaves of the calyx are entirely downy on their outside. The middle one is likewise downy, except a part of it covered by one of the former, where it is smooth and shining, like the two innermost, which are downy at their points only. Five of the filaments are a little shorter than the rest. Five of the kernels seem often to be abortive; hence perhaps it happened that Cavanilles took the nut to have but five cells. In that which I opened there were more than five kernels." Schreber.

Ess. Ch. Calyx simple, of five permanent leaves; two of them external. Petals five. Styles five. Drupa with a furrowed nut of about ten cells.

1. H. *Myrtax*. Linn. Sp. Pl. 944. Lamarck. Dict. v. 3. 149. Willd. n. 1. (Modera-canni; Rheede. Malab. v. 2. 29. t. 19).—Spines opposite, revolute. Leaves obovate, smooth, entire.—Native of the East Indies, in sandy ground. A slender shrub, about 12 feet high, with numerous, short, leafy, not quite opposite branches, each of which bears, about its middle, a pair of remarkable strong, revolute, finooth spines. The resemblance of these to a pair of mustaches, is said to be expressed in the Indian name *Modera*, as in the Latin one *Myrtax*. Leaves numerous, scattered, from one to two inches long, obovate, entire, rather pointed, finely veiny, smooth on both sides. Footstalks short, broad and downy. Stipules awl-shaped, downy. Flowers numerous, on axillary, simple, silky stalks, about the ends of the branches. Petals yellow, striated. Fruit shining, near half an inch in diameter.—The wood is said to be of a reddish brown, with a grateful aromatic odour. The root is esteemed

useful as a topical application to inflamed or swelled parts, and even in the bite of the hooded serpent, *Coluber Naja*. It is also given internally for febrile disorders in children, for the colic, worms, &c. The fruit has a red tasteless pulp.

2. *H. ferrata*. Lamarck. Dict. v. 3. 149. Willd. n. 2. (H. Mylax; Cavan. Diff. 177. t. 73. f. 1.)—Spines opposite, revolute. Leaves elliptic-lanceolate, ferrated, smooth, with glandular hairs at the origin of the veins.—Gathered by Commerçon in the island of Mauritius. Cavanilles mistook it for the former, from which it is very distinct. The leaves are larger, more acute, and strongly ferrated, furnished at the origin of their veins with tufts of hair as in the *Laurustinus*. The young leaves only are very silky. *Floer-stalks* somewhat corymbose. This is the species drawn in Lamarck's t. 572, after Cavanilles.

3. *H. tomentosa*. Cavan. Diff. 178. t. 73. f. 2. Willd. n. 3. Lamarck. Dict. v. 3. 150.—Leaves elliptic-oblong, ferrated, downy on both sides. Stipulas ovate.—Gathered by Commerçon in the isle of Mauritius, with the last, from which it seems sufficiently distinct in having broader, rather obovate, downy leaves.

HUGUENOTS, an appellation given by way of contempt to the reformed or protestant Calvinists of France.

The name had its first rise in 1560; but authors are not agreed as to the origin and occasion of it: but one of the two following seems to be the least forced derivation.

One of the gates of the city of Tours is called the gate Fourgon, by corruption from *feu Hugon*, i. e. the late Hugon. This Hugon was once count of Tours, according to Eginhardus, in his life of Charles the Great, and to some other historians. He was it seems a very wicked man, who by his fierce and cruel temper made himself dreadful; so that after his death he was supposed to walk about in the night time, beating all those he met with: this tradition the judicious Thuanus has not scrupled to mention in his history. Davila and other historians pretend that the nickname of Huguenots was first given to the French protestants, because they used to meet in the night time in subterraneous vaults near this gate of Hugon; and what seems to countenance this opinion is, that they were first called by the name of Huguenots at this city of Tours.

Others assign a more illustrious origin to that name; and say that the leaguers gave it to the reformed, because they were for keeping the crown upon the head of the royal line descended from Hugh Capet; whereas they were for giving it to the house of Guise, as descended from Charles the Great.

Others again derive it from a French and faulty pronunciation of the German word *eidgnossen*, signifying confederates, and originally applied to that valiant part of the city of Geneva, which entered into an alliance with the Swiss cantons, in order to maintain their liberties against the tyrannical attempts of Charles III. duke of Savoy.

These confederates were called *Eignots*, whence *Huguenots*.

The persecution which they underwent has scarce its parallel in the history of religion: though they obtained a peace from Henry III. in 1576, it was only of short continuance. This peace was the source of that civil war, in which the ambitious and powerful house of Guise, instigated by the sanguinary suggestions of the Roman pontiffs, aimed at nothing less than the extirpation of the royal family, and the utter ruin of the Protestant religion; while the Huguenots, on the other hand, headed by leaders of the most heroic valour and the most illustrious rank, combated for their religion and for their sovereigns with various success. These dreadful commotions, in which both the contending parties

committed such deeds as cannot be remembered without horror, were, at length, calmed by the fortitude and prudence of Henry IV. This monarch, indeed, sacrificed the dictates of conscience to the suggestions of policy; and imagining, that his government could have no stable or lasting foundation, as long as he persisted in disowning the authority and jurisdiction of Rome, he renounced the reformed religion, and made a solemn and public profession of popery. Perceiving, however, on the other hand, that it was not possible either to extirpate or suppress entirely the Protestant religion, he granted to its professors, by the famous edict of *Nantes*, (which see,) in the year 1598, the liberty of serving God according to their consciences, and a full security for the enjoyment of their civil rights and privileges, without persecution or molestation from any quarter whatever. The sufferings of the Huguenots were afterwards renewed, when every method which artifice or perfidy could invent had been practised in vain against the Protestants under the reign of Lewis XIV. The bishops and Jesuits, whose counsels influenced the cabinet of this prince, judged it necessary to extirpate, by fire and sword, this resolute people; and thus to ruin, as it were by one mortal blow, the cause of the reformation in France. Their insidious arguments and importunate sollicitations had such an effect upon the weak and credulous mind of Lewis, that, in the year 1685, trampling upon the most solemn obligations, and regardless of all laws, human and divine, he revoked the edict of Nantes, and thus deprived the Protestants of the liberty of serving God according to their consciences. This revocation was accompanied, indeed, with the applause of Rome; but it excited the indignation even of many Roman Catholics, whose bigotry had not effaced or suspended, on this occasion, their natural sentiments of generosity and justice. It was moreover followed by a measure still more tyrannical and shocking; even an express order, addressed to all the reformed churches, to embrace the Romish faith. The consequences of this cruel and unrighteous proceeding were highly detrimental to the true interests and the real prosperity of the French nation, by the prodigious emigrations it occasioned among the Protestants, who sought, in various parts of Europe, that religious liberty, and that humane treatment, which their mother country had so cruelly refused them. Those among them, whom the vigilance of their enemies guarded so closely as to prevent their flight, were exposed to the brutal rage of an unrelenting soldiery, and were assailed by every barbarous form of persecution that could be adopted to subdue their courage, exhaust their patience, and thus engage them to a feigned and external profession of popery, which in their consciences they beheld with the utmost aversion and disgust. In other countries, and particularly in our own, they found an asylum, and communicated in return for the protection they experienced the benefit of their skill and industry. Mosheim's Eccl. Hist. vol. v.

HUIDE, in *Geography*, a town of Norway, in the diocese of Christianland; 20 miles E. of Skeen.

HUIDINGS, a small island in the North sea, near the west coast of Norway. N. lat. 59° 3'. E. long. 5° 42'.

HVILGRUND, and **HVILGRUNDET**, two small islands on the west side of the gulf of Bothnia: the first in N. lat. 60° 47'. E. long. 17° 11'; the second in N. lat. 60° 36'. E. long. 17° 27'.

HUIS, L', a town of France, in the department of the Ain, and chief place of a canton, in the district of Belley; 6 miles W. of Belley. The place contains 1123, and the canton 6465 inhabitants, on a territory of 175 kilometres, in 13 communes.

HUISSEN, a walled town of Germany, in the duchy of Cleves; 10 miles N.N.W. of Cleves.

HUISSIER, a French name for an usher, serjeant, or beadle.

HUITAN, in *Geography*, a town of Sweden, in West Bothnia; 20 miles N. of Lulea.

HUITINGO POLLACHIUS, in *Ichthyology*. See GADUS *Pollachius*.

HVITTISBURG, in *Geography*, a town of Sweden, in the government of Abo; 12 miles N. of Biorneborg.

HUJUS, or HUSUCE DIEL, in *Mythology*, a surname given by the Romans to Fortune. She had a temple at Rome, erected by Q. Catullus.

HULDIBARRY, in *Geography*, a town of Bengal; 48 miles N.E. of Purneah.

HULDIPOOKRA, a town of Bengal; 46 miles S. of Jauldoe.

HULDOOA, a town of Hindoostan, in the circar of Doob; 50 miles N.W. of Pattiar.

HULDSCHIN, or HOLTSMIN, a town of Silesia, in the principality of Oppau; 11 miles E. of Troppau. N. lat. $49^{\circ} 48'$. E. long. $18^{\circ} 12'$.

HULET PANIAS, a lake of Palestine, anciently called lake "Merom," into which runs a river of the same name, anciently denominated the "Dan."

HULIN ROCKS, otherwise called *the Maids*, rocks in the North channel of the Irish sea, always above water, which lie about 6 miles N.E. from Lough Larne, on the coast of Antrim. N. lat. $54^{\circ} 57'$. W. long. $5^{\circ} 37'$.

HULKs are large vessels, having their gun-decks from a hundred and thirteen to a hundred and fifty feet long, and from thirty-one to forty feet broad, and fitted with an apparatus, in order to fix or take out the masts of his majesty's ships, as occasion requires. They will carry from four hundred to a thousand tons.

Anciently, the word *bulka* seems to have signified a small vessel.

HULK is also a name bestowed on any old vessel laid by, as unfit for farther service. It is probably derived from the *ολκας*; or vessels of burthen of the ancient Grecians.

HULL, or KINGSTON-UPON-HULL, in *Geography*, a borough, market-town, and sea-port in the East Riding of the county of York, England, is situated on the western side of the river Hull, and the northern bank of the river Humber, at the distance of about 25 miles from the mouth of the latter; nine miles S. of Beverley; 173 N. of London; and 38 S.E. of York. It extends nearly two miles in length, in a direct line, in which extent is included the adjoining parish of Sculcoates; and to rather more than half that distance in a parallel direction towards Beverley. The town originated in the year 1296, under the immediate patronage of king Edward I., who, on his triumphant return from Scotland, projected the foundation of a port, &c. at this place, then a small hamlet, called Wyke, and put his design immediately into execution. Peculiar privileges were granted to builders and residents, together with a royal charter, vesting the government in a warden and the body of freemen; and the new-formed town was distinguished by the appellation of Kingston, or Kingstown-upon-Hull. Edward founded a house of White friars, and caused a hall to be built for his own residence. This was probably given to the De la Poles, for soon afterwards a magnificent manor-house was erected by that wealthy family, which was frequently honoured with the royal presence, and falling to the crown by the attainder of Edmund de la Pole, earl of Suffolk,

in 1508, became for some time the residence of king Henry VIII.

So rapid was the progress of the place, that, in about sixty years from its foundation, it was called upon to furnish king Edward III. with 16 ships and 466 men. In Leland's time it was a fair and well built town; and, according to Camden, it possessed stately edifices, strong fortresses, ships well equipped, a number of merchants, and abundance of all kinds of wealth; having been favoured with not less than sixteen charters from various successive monarchs. It was first fortified under a charter from king Edward II., and the walls repaired and strengthened with towers of brick in the time of king Richard II. by sir Michael de la Pole, who appears to have revived in this place the art of brick-making, which had fallen into disuse since the time of the Romans. King Henry VIII. built two block-houses and a citadel on the east bank of the river Hull, at an expense of 23,000*l.*, although he drew great part of the materials from the dissolved houses of Black and White friars, and the church of St. Mary. King Charles II., in 1681, laid out a vast sum in improving the fortifications, which had suffered considerably from the severe siege of the town by the earl of Newcastle, and during the civil wars in the preceding reign. Within the last 35 years, the whole of these ancient works of defence, with the gates of the town, have been demolished, except two of the fortresses built by Henry, which, being guarded by several batteries and modern erections, are now converted into magazines, capable of containing more than 20,000 stand of arms, and ordnance stores for twelve or fifteen sail of the line, defended by a regular garrison.

Hull consists of three principal divisions, formed by the intervention of the docks, which, occupying the greater part of the space where the walls formerly stood, nearly insulate the old town. That on the north side of the old dock is in the parish of Sculcoates; all its buildings have been erected within the last thirty years, and form several spacious and handsome streets. A neat hall has been built for the administration of justice, &c. this part of the town being in the county of York, and not under the jurisdiction of the magistrates of Hull. The other division has arisen still more recently, and lies to the west of the Humber dock, occupying the situation of the ancient hamlets of Wyke and Myton; by which latter name it is now distinguished, and is included in the county of the town of Hull. A suburb also has lately sprung up, on the Holderness side of the river, in the parishes of Drypool and Sutton, encompassing the garrison, and connected with the town by a bridge of four stone arches, rebuilt in 1787, with a draw-bridge in the centre, which has this year (1811) been renewed on a very ingenious and novel construction, and is wide enough to admit the largest vessels that have occasion to pass through it. The whole town stands on a level tract of ground, within a short distance of the Yorkshire wolds; the principal streets are broad and well paved, and in lighting and watching it is not inferior to any place in the kingdom. A few years ago, it was computed that about 200 houses were built annually, but since the interruption to the Baltic trade, the principal source of revenue to this port, that number has been much diminished.

The edifices for religious worship belonging to the establishment are two parish churches, that of the Holy Trinity and St. Mary's; with a chapel of ease, and the chapels of the Trinity-house and Charter-house. The church of the Holy Trinity, a noble structure, was first erected in the reign of king Edward II.; the tower and west end were added about the time of king Henry VII., by whose successor, Hull

was made the see of a suffragan bishop, who possessed a stately palace in the High-street, long since destroyed. The church, however, remained under that of the neighbouring village of Hefle, until separated by an act of parliament in 1661. St. Mary's was formerly a much larger structure, and belonged to the priory of Ferriby. Great part of it, including the steeple, was pulled down by king Henry VIII. as obstructing the view from his palace. St. John's is a chapel of ease to the Holy Trinity, and was finished in 1792 at the sole expense of the Rev. Thomas Dikes, LL.B. the present incumbent. There are also various meeting-houses for the peculiar doctrines and worship of all the prevailing sects.

The charitable institutions in Hull are numerous. The most ancient and splendid is that of the Trinity-house, founded by subscription in 1369, and rebuilt in 1753: its funds have been progressively augmented by legacies and benefactions. It was incorporated by letters patent in the reign of Henry VI.; and its charters and grants have, at various subsequent periods, been renewed and extended. The fund is considerably increased by a monthly contribution of sixpence from every seaman sailing from this port; when superannuated, or disabled, they obtain relief, as do also their widows and children, from this charity. Several distinguished characters have been admitted to the freedom of this corporation, which is governed by wardens, brethren, and assistants. In a marine-school, connected with it, thirty-six boys are, for three years, clothed and educated for the sea service; the guild also provides North sea pilots for the royal navy, when required by government. The Charter-house hospital is worthy of particular notice; it was founded, together with an adjoining priory, by Michael de la Pole, for the support of a certain number of pensioners, denominated brothers and sisters; under the superintendance of a master, who enjoys a salary of 100*l.* per ann., with a house and garden. Several other smaller hospitals, for similar purposes, are distinguished by the names of the respective founders, *viz.* Lister's, Gregg's, Crowle's, Watson's, (bishop of St. David's,) Gee's, Harrison's, Ratchiff's, and Weaver hospitals. The workhouse is a large building, commonly known by the name of Charity hall. For the relief of the indigent sick and maimed, a general infirmary was erected, in 1782, by voluntary contributions, on a plan superior to most establishments of the kind, which has been the means of restoring to health near 9000 persons. Here are likewise a free grammar-school, founded by Alcock, bishop of Ely, in 1486, which enjoyed considerable reputation, especially under its late master the Rev. Jos. Milner, A.M.; the Vicar's-school, established by the Rev. W. Mason, father of the poet of that name; a school for girls, and a valuable institution for putting out poor boys apprentices, endowed by Ald. Coggan, and another for orphans, endowed by Ald. Ferris. Two handsome buildings have also been recently erected, capable of containing 500 boys, and 250 girls, who are instructed with great success, according to the improved system of education. The chief part of the expense, as also that of several Sunday-schools and other charities, is defrayed by voluntary subscriptions.

Besides the various buildings already noticed, there are the custom-house, intended originally as an exchange also, but having been long disused for that purpose, the present comfortable room, with a news-room over it, was designed and executed in 1794, by and at the expense of an individual, though with a view to his ultimate advantage; the assembly rooms, not now adequate to the wants and opulence of the town; the gaol; the Neptune hotel; the Rodney and

Minerva lodges of Free-masons, the former of which is a most elegant and handsome room; the subscription library, founded in 1775, and built in 1800, a great advantage to the inhabitants, and containing many thousand volumes; and the theatre royal, rebuilt in 1809, a spacious and convenient structure, the interior of which is fitted up in a superior style of comfort and elegance. The avenue from the market-place to the Humber was lately widened, by taking down the guild hall, a mean brick building, and on its site shambles were erected, which, for convenience, elegance, and ventilation, may challenge comparison with any in the kingdom. The old shambles being likewise removed, the beautiful east end of Trinity church is again thrown open to the market-place, in the centre of which stands an equestrian statue of king William III. erected in 1734. Until a new guild hall shall be provided, the corporation transact business in a large house fitted up for the purpose. Among the public accommodations enjoyed by the inhabitants, may be reckoned the Barton-boats, which cross the Humber every tide, to and from Barton, a distance of about seven miles.

The commerce of Hull will be best appreciated by a statement of the annual exports and imports for a few years. The tonnage of this port was, several years ago, inferior only to that of London, Liverpool, and Bristol; its customs only to those of the former two. It sends at present nearly thrice as many ships to the whale fisheries as London, and, exclusive of the latter port, more than all Great Britain besides. Its facilities of communication with the interior, by means of the Ouse and Trent, and the canals communicating with them are very great. The gross amount of the customs was

The dock was undertaken, according to act of parliament, in 1774, and completed within four years; the entrance is immediately from the river Hull; it extends in length about 600 yards; in width 85; and is 23 feet deep; is capable of containing 100 sail of square rigged vessels; and, with the wharfs and quay, occupies a space of more than thirteen acres; containing in the dock 48,188 square yards, in the quay 17,479; exceeding in capacity the largest in Liverpool, and now only surpassed by those of London: when made it was the largest in the kingdom. The subscribers to the dock are incorporated by the title of "The Dock Company at Kingston-upon-Hull." The original number of shares

was 120, but the trade of the port requiring further accommodation, two other acts of parliament were obtained in 1802 and 1805, by which the company was empowered to increase them to 180, the money arising from which, amounting to 82,390*l.*, was appropriated to the making of a new dock, which was completed under the title of the Humber dock, in 1809, at an expense of 220,000*l.* It opens into the Humber by a lock of excellent workmanship, large enough to admit a fifty-gun ship, crossed by an iron bridge in two parts, of very ingenious mechanism. The area of the dock and quays is ten acres, with a basin of four acres; its length 300 yards, width 114, and depth 29 feet; and it is intended to communicate with the old dock at some future time, which, when effected, will wholly insulate the old town. The company is entitled to certain duties on all ships entering the port; the profit divided on the shares was,

The manufactures of Hull are various and extensive; one of the principal branches is that of expressing and refining oil from linseed, and preparing the residue for feeding cattle: the process is chiefly effected by mills worked by the wind. The largest and finest mills in the kingdom of this kind, both for the above purpose and for grinding corn, are to be found in great numbers near this town; their machinery is excellent, and many of them are from 80 to upwards of 100 feet in height. An iron-foundry, two large sugar-houses, an extensive soap, and several white lead manufactories, Greenland yards, numerous dry-docks, shipbuilders' yards, and ropewalks, where a great number of hands are constantly employed; and several large breweries are amongst the most important, but do not comprize half the manufactories now existing in the town.

The entire civil authority over the town, and the several places within what is denominated the county of the town of Kingston-upon-Hull, a district of more than eighteen miles in circumference, west of it, is, by various royal charters, particularly those of king Henry VI. and king Charles II., vested in the corporation, which now consists of the mayor, the recorder, twelve aldermen, the sheriff, two chamberlains, a town clerk, a water-bailiff, and other officers, besides a high steward, who is generally some nobleman of rank. The mayor is admiral of the Humber, and possessed of the power of life and death over criminals within his jurisdiction. The judges of assize visited this town, but of late years this has been discontinued, and all trials are removed to York, though causing a great additional expense to those concerned.

Hull returns two representatives to parliament: the right of election of whom, as well as of the several principal members of the corporate body, except the recorder and high steward, is vested solely in the burgesses or freemen of the town, an important body, amounting to upwards of 2000. The population returns to parliament in 1801, specified, that the town and county contained 4767 houses, occupied by 29,516 persons, of whom 13,051 were males, and 16,465 females: this does not include the adjoining populous parish of Sculcoates, nor the suburb on the east of the river Hull. A fair is held annually in October, and the markets are abundantly supplied, especially when the tide suits for the Lincolnshire farmers to cross the Humber, on Tuesdays, Fridays, and Saturdays.

Hull has, at different times, given birth to men distinguished on various accounts. In the first rank must be placed her representative in parliament, that incorruptible patriot, Andrew Marvell, whose father was lecturer of Trinity church; and, in later times, a most worthy man and excellent poet, the Rev. W. Mason, A.M. son of the late vicar of the same. It likewise gave the titles of earl and duke, both now extinct, to the family of Pierrepont.

The village of Sculcoates, though not in the county, may justly be considered as forming a part of the town of Hull; a portion of the old dock is included within it. The church, situated towards the northern extremity of the parish, is a neat uniform structure, rebuilt in the year 1760, and contains some fragments brought from the neighbouring abbey of Meaux.

HULL River, in the East Riding of Yorkshire, is a small river, which falls into the Humber at the town of Kingston-upon-Hull, better known by the name of *Hull* only, and as being the fourth sea-port in point of importance in the British dominions. The Hull is made navigable from the Humber, about twelve miles, to Aike-beck mouth, the entrance of the Driffeld navigation. See CANAL.

HULL and Leven Canal, is an inland navigation in Yorkshire, East Riding, made in pursuance of acts of parliament obtained in 1801 and 1805; it extends about three miles from the Hull river up to the town of Leven. See CANAL.

HULL, the Indian *Nantasket*, a town of America, in Suffolk county, Massachusetts, containing about 21 houses, and 117 inhabitants. It is a peninsula 8 miles long, 9 miles E. of Bolton, on the S. side of the harbour.

HULL, Little, a small island in the East Indian sea, near the W. coast of the island of Poggy. S. lat. 2° 45'. E. long. 99° 32'.

HULL of a ship is her main body, without any masts, yards, sails, or rigging.

To HULL, or *lie a HULL*, is understood of a ship, when, either in a dead calm, or in a storm, she cannot carry all her sails, but they are taken in to preserve them; so that nothing but her masts, yards, and rigging are abroad, and her helm tied down to the lee side of the ship. In this state she will lie easily under the sea, if she be a good failer, and make her way one point before the beam.

To strike a HULL, is to lie closely or obscurely in the sea in a storm, or to tarry for some consort, bearing no sail, with the helm lashed a-lee.

To HULL a ship, is to fire cannon-balls into her hull, within the point-blank range.

HULL, in *Agriculture*, a term made use of to signify the chaff, or husk of grain.

HULLEAH, in *Geography*, a town of Hindoostan, in Benares; 20 miles S. of Merzapore.

HULLOCK of a Sail, at *Sea*, is when, in a great storm, some small part of a sail is cut and let loose. It is chiefly used in the mizen-sail, to keep the ship's head to the sea; then all the rest of the sail is made up, except a little at the mizen yard-arm. Also, when a ship will not *weather-coyle*, to lay her head the other way, they loose a hullock of her fore-sails, and then changing the helm to the weather-side, she is made to fall off, and to lay her head where her stern lay.

HULLUAH, in *Geography*, a town of Hindoostan, in Guzerat; 15 miles N. of Champaneer.

HULME, NATHANIEL, M.D. in *Biography*, was born at Halifax, in Yorkshire, in the year 1732, and was bred to the profession of a surgeon-apothecary. He afterwards served in the capacity of surgeon in the navy, and being stationed

nationed at Leith after the peace of 1763, he embraced the favourable opportunity of prosecuting his medical studies at Edinburgh, where he took his degree of doctor in the year 1765. His inaugural thesis was entitled "Dissertatio Medica Inauguralis de Scorbuto." Soon after his graduation, he settled in London as a physician, intending to devote his attention particularly to the practice of midwifery. This, however, he soon relinquished; and, on the establishment of the General Dispensary (the first institution of the kind in London), he was appointed its first physician. He was also some time physician to the city of London Lying-in-hospital. About the year 1775, he was, through the influence of lord Sandwich, then first lord of the admiralty, elected physician to the Charter-house. His other official situations he resigned many years before his death, and withdrew himself at the same time in a great measure from the active exercise of his profession; but the last he retained during the remainder of his life. In April, 1807, he was bruised by a fall, which he survived but a fortnight, being at the age of seventy-five.

Dr. Hulme was the author of several dissertations; viz. a republication of his thesis, with additions, 1768. "A Treatise on Puerperal Fever," 1772. An oration "De Re Medica cognoscenda et promovenda," delivered at the anniversary of the medical society in 1777, to which a small tract was annexed, entitled "Via tuta et jucunda Calculum solvendi in Vesica urinaria inhaerentem." An enlarged edition of this tract, in English, appeared in the following year, under the title of "A safe and easy Remedy for the Relief of the Stone and Gravel, the Scurvy, Gout, &c.; and for the Destruction of Worms in the Human Body; illustrated by Cafes: together with an extemporaneous Method of impregnating Water and other Liquids with fixed Air, by simple Mixture only, &c." 1778. In 1800, Dr. Hulme instituted a series of experiments "on the light spontaneously emitted from various bodies," an account of which was published in the Philosophical Transactions of that and the following year. Dr. Hulme was also one of the editors of the "London Practice of Physic." See *Transf. of the Med. Society of London*, vol. i. part 1, 1810.

HULPE, LE, in *Geography*, a town of France, in the department of the Dyle, and chief place of a canton, in the district of Brussels; 8 miles S.E. of Brussels. The place contains 897, and the canton 9244 inhabitants, on a territory of 115 kilometres, in 11 communes.

HULST, a town of France (formerly of Flanders), in the department of the Scheldt, and chief place of a canton, in the district of L'Escluse; 16 miles N.N.E. of Ghent. The place contains 1714, and the canton 11,581 inhabitants, on a territory of 205 kilometres, in 8 communes. It was formerly the capital of four offices, with twelve dependant villages; it is situated on a canal that communicates with the Scheldt, and is very strong, by its fortifications and position among the marshes. N. lat. 51° 14'. E. long. 3° 55'.

HULTSIO, a town of Sweden, in the province of Smaland; 26 miles N. of Wexio.

HULVER, in *Rural Economy*, a name by which the holly-tree is frequently known in some districts.

HULWAD, in *Geography*, a town of Hindoostan, in Guzerat; 55 miles N.E. of Wurwar.

HUMAGUACA, a town of South America, in the province of Tucuman; 65 miles N. of St. Salvador de Jugui.

HUMAN, a town of Persia, in the province of Segestan; 180 miles S.E. of Zareng—Also, a town of Russian Poland, in the palatinate of Braclau; 50 miles E.S.E. of Braclau. N. lat. 48° 42'. E. long. 30° 8'.

HUMAN, something that relates to man, or the nature of man. See NATURE.

Epicurus and his followers deny that the gods concern themselves with human affairs. See EPICUREANS.

Faith is distinguished into divine and human. See FAITH.

HUMAN Figure, *The*, in *Painting and Sculpture*. Amidst all the various beauties with which this earth abounds, and which attract the eyes and call forth the emulation of the artist, nothing is so astonishing and so engaging as the structure of the human form, and the elegance and variety of the actions of which it is capable. It has been the subject of panegyric in all ages. The naturalist, the moralist, the philosopher, and the divine, have dwelt, with holy reverence to its Maker, on its delicacy, its simplicity, yet variety of conformation, and on its intellectual and spiritual endowments; all of which are most justly combined in description, in the admired contemplative speech our own Shakspeare has put into the mouth of Hamlet. "What a piece of work is man! how noble in reason! how infinite in faculties! in form and moving how express and admirable! in action, how like an angel! in apprehension how like a god! the beauty of the world! the paragon of animals!"

To the painter and sculptor no object in nature is so interesting as the human figure; none requires more study and attention to enable them justly to display its various beauties of action and expression; and a long continued series of observation and practice will alone qualify them for the fulfilment of so arduous a task.

The sources of this difficulty are, the very great latitude of its motions, and the numerous combinations of them, added to the various possibilities of view, and of light and shade. Its beauty is indeed very great, independent of all these, but they serve to enhance its value and render delight to the artist, while they call for his utmost exertions in his endeavours to represent them. So much has already been said under the various articles BEAUTY, CONTOUR, COMPOSITION, DRAWING, EXPRESSION, FACE, &c. that it will only be necessary in this place to treat of the proportions of the human figure, the range of its powers of action, its varieties, and the most beautiful and just combinations of them.

It has long been acknowledged, among artists, that the sculptures of the Greeks, from the time of Pericles to that of Alexander the Great, afford the best examples of beautiful and characteristic proportion; and from them a scale has been drawn out, which, if it will not serve for every purpose, will always be of use, as well to depart from, as to follow. It is, in either case, a line to guide us, and should never be lost sight of. We shall transcribe the following one from the note given by sir Joshua Reynolds on ver. 144 of Mason's *Fresnoy*.

"Learn then from Greece, ye youths! proportion's law,
Informed by her, each just position draw."

"Du Piles has, in his note on this passage, given the measures of a human body, as taken by Fresnoy, from the statues of the ancients, which are here transcribed.

"The ancients have commonly allowed eight heads to their figures, though some of them have but seven; but we ordinarily divide the figure into ten faces (this depends on the age and quality of the persons: the Apollo and Venus de Medicis have more than ten faces); that is to say, from the crown of the head to the sole of the foot, in the following manner:

"From the crown of the head to the forehead is the third part of a face.

"The face begins at the root of the lowest hairs that grow on the forehead, and ends at the bottom of the chin.

"The

HUMAN FIGURE.

"The face is divided into three proportional parts; the first contains the forehead, the second the nose, and the third the mouth and chin; from the chin to the pit between the collar bones is two length of a nose.

"From the pit, between the collar bones to the bottom of the breast, one face.

"From the bottom of the breasts to the navel, one face. The Apollo has a nose more.

"From the navel to the genitories, one face. The Apollo has half a nose more, and the upper half of the Venus is to the lower part of the belly, and not to the privities.

"From the genitories to the upper part of the knee, two faces.

"The knee contains half a face.

"From the lower part of the knee to the ankle, two faces.

"From the ankle to the sole of the foot, half a face.

"A man, when his arms are stretched out, is, from the longest finger of his right hand to the longest of his left, as broad as he is long.

"From one side of the breasts to the other, two faces.

"The bone of the arm, called humerus, is the length of two faces, from the shoulder to the elbow.

"From the end of the elbow, to the root of the little finger, the bone called cubitus, with part of the hand, contains two faces.

"From the box of the shoulder-blade, to the pit betwixt the collar bones, one face.

"If you would be satisfied in the measures of breadth from the extremity of one finger to the other, so that this breadth should be equal to the length of the body, you must observe that the boxes of the elbows with the humerus, and of the humerus with the shoulder-blade, bear the proportions of a face when the arms are stretched out.

"The sole of the foot is in length the sixth part of the figure.

"The hand is the length of a face.

"The thumb contains a nose.

"The inside of the arm, from the place where the muscle disappears, which makes the breast, (called the pectoral muscle,) to the middle of the arm, four noses.

"From the middle of the arm at the top, to the beginning of the head, five noses.

"The longest toe is a nose long.

"The two outermost parts of the teats and the pit between the collar-bone of a woman, make an equilateral triangle.

"For the breadth of the limbs no precise measures can be given, because the measures themselves are changeable, according to the quality of the persons, and according to the movement of the muscles. Du Piles.

"The measures of the ancient statues by Audran appear to be the most useful, as they are accompanied with the outline of the figures which are most distinguished for correctness."

Audran, whose work Sir Joshua Reynolds thus recommends, takes a different plan from that of Fresnoy, and is more minutely accurate. He divides the figure into heads, each head into four parts, and each part into twelve minutes; which certainly has given with more accuracy the exact proportions of those figures he has measured; but Fresnoy's is fully equal to the general purposes of art; for where variety of character is requisite, it is evident that the same proportions would be an evil; therefore the more general scheme is quite adequate as a guide in drawing the figure.

The knowledge of these proportions, and of the forms and positions of the bones and muscles, which compose the human figure, may be regarded as the foundation on which to pro-

ceed to the more difficult task of becoming duly acquainted with its powers and varieties of actions. A perfect knowledge of the shapes of the bones is more particularly requisite in this matter; since by their projecting parts coming in contact with each other, a limit is put to the actions of the joints; and they are secured from dislocation by the natural extension of the muscles; and the muscles themselves directed and governed in their own actions.

Mr. A. Carline, professor of anatomy to the Royal Academy, in his able and useful lectures before that body, entered much at large upon this part of our subject, and in a very satisfactory manner demonstrated it on the skeleton and the living figure. To his kindness we are indebted for the following remarks, taken chiefly from angular measurements, and which will be found highly useful to all artists who apply their talents in the representation of the human figure.

"The motions of the head and trunk of the body are limited by the several joints of the spine.

"The motions of the whole body upon the lower limbs take place at the hip joints, at the knees, and at the ankles.

"The great limbs, technically called the upper and lower extremities, have rotatory motions at their junctions with the trunk, by means of ball and socket joints at the shoulders and the hips.

"The analogy of parts between the upper and the lower extremities is not carried throughout the structure of those limbs in the human body.

"The fulcrum of the upper limb is itself moveable upon the trunk, as appears by the extensive motions of the scapula, which so generally accompany the rotations of the shoulder, and which supply that limb with a greater range of movements than is possessed by the lower limb.

"The junction of the thigh, with the motionless mass of the pelvis, limits its rotation to its ball and socket-joint.

"The rotation of the head upon the neck takes place at the joint between the first and second vertebræ.

"When the nose is parallel with the sternum, the face may be turned towards each shoulder, through an angle of 60 degrees on each side, or the whole range of this turning will extend through 120 degrees.

"The lateral bending of the neck is divided equally between the junctions of the seven vertebræ; but the bowing of the head, and the act of throwing the head violently backward, are principally effected, at the joint of the skull and the first bone of the vertebral column, called the atlas.

"These last motions are consistent with an erect state of the neck, while the lateral motions demand a curvature of its whole mass.

"The movements of the trunk are limited to the rotatory and lateral motions, which are almost equally divided among the several joints of the vertebræ of the back and loins.

"The joints of the dorsal vertebræ are, however, more closely compacted than those of the loins, which allows of a wider range for turning and bending in the line of the loins, than in that of the back.

"The ribs and the sternum move upward, so as to expand the width of the chest at the lower margin of the ribs, and to draw the clavicles and shoulders upward: this takes place at each full inspiration of the breathing, and the contrary state follows in the act of expiration. Such apparent movements are characteristic of certain passions and actions, and are always observable in the naked figure.

"In stooping, to touch the ground, the thigh-bone forms

forms an angle of about 55 degrees with the average direction of the spine.

"The leg bends upon the thigh, at an angle of 75°, and the line of the tibia forms with the sole of the foot, when that is elevated, an angle of 65 degrees.

"The whole of this limb is capable of moving at the hip-joint forwards, to a right angle with its perpendicular position; and backwards, to an angle of about 20°. The leg will then continue to move by itself to its own angle of 75°, with the thigh. It has, besides this, a motion outwards to about 45°.

"When the shoulders are at rest, the two clavicles usually meet in an angle of 110 degrees at the sternum.

"The utmost elevation of the upper arm usually forms an angle of 155° with the spinal column, and about 125° with the line of its clavicle. The flexion of the fore arm upon the upper arm, is confined to an angle of nearly 40°.

"The whole arm is capable of moving forward or outward, through nearly half a circle, and backward to an angle of 80°, with its perpendicular situation.

"The actions of pronation and supination in the hand, range through 270°: but then 90° of the rotatory motion, in the act of pronation, are derived from the shoulder-joint.

"The palm of the hand admits of flexion and extension through 65 degrees in each direction; its lateral motions are 35° outward, and 30° inward.—The flexion of the fingers at each phalanx is 90°, or a right angle.

"These general rules govern the average and most natural actions of the living figure, but peculiar forms and acquired powers considerably change all such calculations; nevertheless it is expected in art that the knowledge of the true actions of the human figure should be derived from the general state of nature, and not from the distortions of the posture-master, or the acquired flexibility of the tumbler."

In drawing the joints of the limbs, considerable difference will be found in their length, according to the degree of action they are in; thus the elbow joint, when bent inwards, lengthens the arm nearly $\frac{1}{4}$ th. The same occurs, at the knees, and in the joints of the fingers; in the same manner as a hinge is extended when opened.

There is a very considerable difference noticeable between the joints of children before the age of 8 or 9, and those of grown persons. In the former they are small and surrounded by fat, which gives the appearance, when they are straight, of dimples in the surface; whereas, in men they are large, and always projecting; with nothing but strong tendons about them.

When the artist is fully acquainted with the proportions and capabilities of action in the human figure above-mentioned, and proceeds to represent it either in a tranquil position, or in motion, he will find it requisite to attend to the geometrical and mathematical principles on which it is constructed; and by which alone its acting powers, the muscles, are directed and governed. The due equipoise of its parts, either for its own support, or the compound admixture of the weight of other bodies, in lifting, pulling, pushing, &c. must be carefully regulated, or in vain will he attempt to effect his object. The following observations may be found useful on this subject.

When a man is entirely at rest, and standing equally on both feet, a line drawn perpendicularly from the pit between the clavicles will fall exactly in the midway between his feet.

If he moves, so as to stand upon one foot, it will fall upon the heel of that foot.

If he raises one arm, it will throw as much of his body on

the other side of the perpendicular, as is equal to the weight of, and is necessary to counterbalance, that arm.

If one of the legs is thrown back, the breast is brought forwards, so as equally to bring the centre of gravity of the whole frame always in the same relative situation to the parts, in every position in which the body can be thrown.

Thus the equipoise of the figure is of two sorts, simple and compound. Simple, when a man acts only by and upon himself; and compound, when any external weight be superadded; for that must be regarded in his actions, while suspending it, as a part of his own frame; and in order to lift or support it, he must throw as much of his own weight in a contrary direction on the central line, to that where the object is applied, as is equal to it; or it will overpower and draw him to the ground. Indeed it will be necessary, in lifting, to throw a larger proportion of weight or muscular force over, or it cannot be effected.

In action, the same principle governs the figure. Having, by the motion forwards of one part, in walking for instance, removed its centre of gravity, it endeavours, in the instant, to recover the balance lost, and brings up another to support itself; and these actions, going on progressively, carry it forwards. In running, a greater impetus is given; the breast is thrust farther forwards, and a quicker application of the support of the limbs is required; thus, the slower the motion, the nearer the support will be under the centre of gravity; and on the contrary, when the motion is quickened, the farther it will be removed from it.

When a man intends to strike a severe blow, he endeavours to add the weight of his body to the force of his arm, and to effect this he draws back himself over the perpendicular to a considerable distance, then, rushing forwards while he strikes, conveys his body as far on the contrary side.

Thus, the motions of the figure must be always regulated by its centre of gravity; the perpendicular of which is its centre of motion. The motion being created by the loss of equipoise, or inequality of weight, will, of course, be more or less violent, accordingly as a greater or less proportion of the body be removed from the perpendicular.

With regard to the muscular action of the figure, the plates of anatomy, and the descriptions given under that article, will sufficiently inform the reader. Each muscle has its individual or conjoint power and use. It is the artist's duty to select, in representation, those which more immediately are employed in, and characterize, an action; and not to make too great a display of anatomical knowledge, nor at all times, and in all the various actions of the human figure, represent the same muscles (when seen) with the same degrees of force, that is, equally tense; as if their power was requisite in every action; as is frequently the case among the imitators of M. Angelo. No matter how the man was employed, every muscle throughout the frame is rendered equally prominent; and the eye and the understanding bewildered, in endeavouring to comprehend which part was principally in motion. But more of this when we treat of *STYLE*, in *Design*; see that article.

HUMAN Fossil-remains, in *Natural History*. With early writers on natural history and geology, it was no uncommon thing to refer almost any large uncommon bones, which were met with in the earth, to giants of the human race. The pretended parts of a human skeleton by Scheuchzer, found in the slate-pit at Oningen, his anthropolith, protee, &c. are shewn in the *Annales du Museum*, vol. xiii. p. 411, to belong to a kind of salamander, and at page 198, the pretended human fossils of Cérigo are shewn to be devoid of that character. After all which has been said on the human bones
found

Found in the ossaceous rock of Gibraltar (Jones, *Phys. Diss.* p. 428.), and other places in the Mediterranean and coast of Dalmatia, the fact of their having any of them belonged to the human race may fairly be doubted. The arm and skeleton of a man, mentioned by Mr. Charlton, in his *History of Whitby*, p. 355, as found in the alum shale, were probably no such thing. The tooth which Mr. Jones mentions may, if really human, have been taken from some church-yard, or ancient burial-place, whose waters were of a petrifying quality, as well as the woman's hand which he mentions, p. 427. If such was not a mere deception, owing to the external form, like the pretended leg and foot of a child in black flint, which we have seen, that was taken out of a chalk-pit. The human tongue, or glossopetra of Pliny, and the human thigh of stone mentioned by Parkinson, (*Org. Rem.* p. 16 and 21.), and the two bones of a man's foot in iron-stone, which Dr. Grew mentions (*Rarities*, p. 332.), were probably all deceptions of a similar kind; and to one or other of these classes, *viz.* 1st, mistaken animal remains; or, 2d, deceptive forms of mineral nodules, may, perhaps, all the supposed human relics, found imbedded in the strata, be referred. A 3d class of human remains may be admitted with less hesitation, *viz.* bones found intermixed with works of art, and with circumstances attending modern alluvial deposits or soils, like the human ribs found along with a boat, under a stony or concreted gravelly stratum, near Peterburg (Kirwan's *Geo. Ess.* p. 442.); the skeletons found with beads, rings, armour, coins, &c. mentioned by Mr. Whitehurst (*Inquiry* 1st ed. p. 15.); and by many other writers, but which clearly did not belong to the stratified remains. A 4th class of human reliquia are found preserved in peat-bogs, some instances of which are said to occur in the peat-pits near Newbury (*Phil. Trans.* vol. i. p. 109.); a woman preserved in a moss, at Axholm, in Lincolnshire, and a man in a moss in Shetland (Jameson's *Shetland Isle*, p. 158.), and various similar instances, which are to be met with. Mr. William Martin, in combating the arguments formerly adduced to shew that the supposed human, animal, and vegetable remains of the strata were deposited at the Noachian deluge, or by parts of its waters left in inland lakes and seas, observes (*Outlines*, p. 30.), "According to sacred history, the full development of the animal kingdom, as well as the vegetable, had taken place, long before the period in which they were equally involved in one general inundation. And hence, in strata supposed to have been formed by depositions from water left by the deluge, not only might we reasonably expect to find vegetable and marine relics, but also the remains of *land animals*, of quadrupeds for instance, and even of *man* himself. For, however small a proportion the destroyed land animals bore among the general multitude of organic bodies overwhelmed by this catastrophe, as they *did* exist, and as the bones of quadrupeds are certainly as liable to subsidence in water as drifted timber or other vegetable matter, they no doubt would occasionally be met with in the strata in question, if such strata had really originated from the cause assigned in the hypothesis. But, on the contrary, it is an indubitable fact, that neither the remains of man nor of quadrupeds have ever been found in stones or earths constituting strata productive of genuine mineral coal, nor indeed as integrant parts of *any strata*, excepting those which are decidedly of much later formation, such as we are now treating of. To a far remoter period, therefore, than the flood, must we recur, in any endeavour to explain or illustrate the agency of nature, in collecting and depositing the minerals of regular disposed strata."

HUMANA DE TOMPIERES, in *Geography*, a town of New Mexico; 63 miles S.S.E. of Santa Fé.

HUMANITY, the nature of man, or that which denominates him human.

Nestorius would not allow the infirmities of humanity to be attributed to the Deity; nor the attributes of the Deity to humanity. See NESTORIANS.

HUMANITIES is used, plurally, for the *humaniores literæ*, *i. e.* the study of the Greek and Latin tongues, grammar, rhetoric, poetry, and the ancient poets, orators, and historians.

HUMAR, in *Geography*, a small island in the Red sea, near the coast of Arabia; three miles N.W. of Loheia.

HUMARES, a town of New Navarre; 120 miles S. of Cah Grande'.

HUMAS, an Indian village on the W. side of Mississippi river, in Louisiana, 60 miles above New Orleans. The Humas were formerly a considerable nation, but were reduced, about the year 1770, to about 25 warriors. The Alabamas, whose villages are near those of the Humas, had at the same period about 30 warriors. The Chetemachas have about 27 warriors.

HUMAXAR, a town of South America, in the government of Tucuman, on the river Dolce; 60 miles S. of St. Jago del Etero.

HUMATION, HUMATIO. The most ancient way of disposing of the dead was by humation, or interment. Pitiful. See BURIAL.

HUMBER, in *Geography*, a river of England, or rather a large estuary, formed by several considerable rivers, and especially by the Ouse and Trent, and flowing into the German ocean, N. lat. 58° 30'. E. long. 1° 15'. Besides the Trent, which enters the Humber after a direct course of about 100 miles, and which is navigable to Burton, in Staffordshire, and the Ouse, which runs by York, and is navigable to Rippon, the other principal rivers that issue into the Humber are the Dun, which runs by Doncaster; the Aire, navigable to Leeds; and the Calder, navigable to Halifax; the Warf, navigable to Tadcaster; the Derwent, navigable to New Malton; and the Hull. See CANAL.

HUMBER, a river of Upper Canada, in the E. riding of the county of York, which discharges itself into lake Ontario, eastward of the old fort Toronto.—Also, a river of Newfoundland island, which runs into the gulf of St. Lawrence, through the bay of Islands.

HUMBERSTONE, a township of Upper Canada, in the county of Lincoln, lying between Bertie and Wainfleet, and fronting lake Erie.

HUMBERT, in *Biography*, a cardinal in the 11th century, a native of Lorrain, embraced the monastic life in the diocese of Toul, in the year 1015. Here he acquired so high a reputation for talents and learning, that pope Leo IX. sent for him into Italy, where he promoted him to the bishopric of the White Forest. In 1049 he was raised to the purple by the same pope, who sent him his legate to Constantinople, to attempt to restore the ancient union between the eastern and western churches. In 1059, by the order of pope Nicholas II. he drew up the confession of faith for the famous Berenger to sign, in which he laid down the monstrous doctrine, that "the bread and wine, after consecration, were not only a sacrament, but the real body and blood of Jesus Christ; and that this body and blood were actually handled by the priests, and consumed by the faithful, in reality and truth as other sensible objects are." Cardinal Humbert died after the year 1069. His works are numerous and chiefly theological. Moreri.

HUMBLE-BEE, in the *History of Insects*. See **BOMBYLUS**.

HUMBLE-bee, Bastard. See **FAUX bourdon**.

HUMBLE-bee Flies, in *Natural History*, the name of a class of flies of different sizes, but all agreeing in the great resemblance they bear to the humble-bees, of the smaller or middle-sized species. These might, at first sight, very naturally pass for real humble-bees; but a closer examination will shew them not to be such, as they have not the trunk of the humble-bee, and have only two wings. The species of the humble-bee fly are many of them of absolutely different genera one from another, some of them having trunks, and others having a distinguishable mouth. See **CULEX**.

If the figure of these flies, in their winged state, attracts our curiosity and attention, their prior state, that of the fly-worm, of most of them ought surely much more to do so. The place nature has assigned the worms of these flies for their habitation is, indeed, a most strange one; there is no other place for them to live in under this form, to begin their destined growth, and be fitted for their transformations, but in the intestines of horses, or under the thick and firm skin of oxen. In the latter case, the worm hatched from the egg of its parent fly, deposited there, makes the tumour in the places which alone furnishes it with food and habitation, and in the middle of which it has a place to breathe. See **HIPPOBOSCA**.

It is not an invariable law of nature, however, that all the worms of the humble-bee flies are to feed on animal substances; for we find some delighted with vegetable food, and particularly one which loves none but the bulbous roots of flowers. Reaumur's Hist. Inf. vol. iv. p. 497, &c.

HUMBLE-Plant, in *Gardening*. See **MIMOSA**.

HUMBLED, in *Rural Economy*, a term that is frequently applied to neat cattle and sheep, in order to denote their being hornless.

HUMBOLDTIA, in *Botany*, so named by Vahl, who had first denominated it *Batfchia*, in honour of the celebrated traveller and botanist Von Humboldt. "Vahl. Symb. fasc. 3. 106." Willd. Sp. Pl. v. 1. 1147.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Ess. Ch. Calyx in four deep segments. Petals five. Legume oblong, compressed.

1. *H. laurifolia*. (*Batfchia laurifolia*; Vahl. Symb. fasc. 3. 39. t. 56.)—Native of Ceylon. A tree with jointed, zigzag, hollow branches. Leaves abruptly pinnate, of four or five pair of stalked, ovate-oblong, pointed, entire leaflets. *Stipulas* double; the outer ones horizontal, half arrow-shaped; the inner ovate, pointed, erect, much the largest. *Clusters* of many flowers, axillary, solitary, or in pairs. *Willdenow*.

HUME, DAVID, in *Biography*, an eminent historian, was born at Edinburgh in 1711. He was the youngest son of a man of good family, who died while David was in his infancy, so that his education was entrusted to his mother. He displayed, at a very early period, a great love for literature, which became his predominant passion. His patrimony was too slender to permit him to follow his inclinations without some view to profit, and he attempted to gain some commercial employment at Bristol. In a few months he found that kind of business totally unsuitable to his genius, and went to France with the intention of prosecuting his literary pursuits in a country retreat, resolving to supply by economy his pecuniary deficiencies. He resided first at Rheims, but chiefly in Anjou, and passed three years very agreeably in that kingdom. In 1737 he came to London, and in the end

of the following year published his "Treatise on Human Nature," which he had composed during his residence in France. Mr. Hume's ardent passion for literary fame received a severe mortification from the neglect attending his first publication, which "fell dead-born from the press, without reaching such distinction as even to excite a murmur among the zealots." He did not despair, but proceeded in his studies, and in 1742 printed his "Essays, Moral, Political, and Literary." These were so favourably received as to make the author amend for his former disappointment. In 1745 he received an invitation from the young marquis of Anandale to come and live with him in England. This connection lasted but a single year, when he stood forward as candidate for the professorship of moral philosophy in the university of Edinburgh, and was powerfully supported by persons of consideration and high rank. He was, however, unsuccessful. General St. Clair, in 1746, nominated him his secretary in an expedition designed for Canada, but which ended in an attack upon the French coast. In 1747 he attended the general, in the same station, upon a military embassy to the courts of Vienna and Turin. On his return, he re-published his piece on human nature, with alterations, under the title of "An Enquiry concerning the Human Understanding." It was scarcely more successful in this form than it had been before, but his other works were beginning to attract notice, and make their way rapidly. In 1752 he published his "Political Discourses," which were received with immediate approbation. In the same year his "Enquiry concerning the Principles of Morals" was published, which he considered as the best of all his writings, but which met with little notice. He obtained, in 1752, the appointment of librarian to the Faculty of Advocates in Edinburgh, which afforded him the command of a large and curious collection of books. It was this circumstance which seems to have inspired him with the idea of becoming an historical writer, as it was probably his local situation which suggested to him, as his first subject, the "History of England under the House of Stuart." The first volume, containing the reigns of James I. and Charles I. appeared in 1754, which was furiously assailed from all quarters, on account, as he thought, of what he had said in defence of the earl of Strafford; but it was probably owing to his undisguised contempt for all religions, of which he recognizes but two species, superstition and enthusiasm. This work was so completely neglected as well as derided, that, had not a war broken out between England and France, he would probably have retired to some provincial town of the latter kingdom, have changed his name, and for ever renounced his country. The second volume of his history, comprising the period from the death of Charles I. to the Revolution, appeared in 1756, and was received much better than the first had been. With this encouragement he published his history of the house of Tudor in the year 1759, which excited against him a renewed portion of rancour. His reputation as an historian continued to gain ground, so that he was induced to go back to the earlier periods, and write down to the point at which his last work had commenced. These two additional volumes appeared in 1761, and his history of England thenceforth became a standard book, read by all, at home and abroad, who wished to take a compendious and interesting view of the English affairs. The researches of Mr. Hume into the origin of the constitution are not remarkable for depth or accuracy; and he seems too ready to admit the idea that the liberties of the country are of modern date, and were so many forced concessions from the

sovereigns. In his history of the Tudors and Stuarts there seems a manifest design of exaggerating the despotism of the former, in order to lighten, by comparison, the usurpations and high pretensions of the latter. His style is clear, lively, sometimes eloquent, always agreeable, though not unfrequently careless and incorrect. The money which Mr. Hume obtained for the copy-right of his history, joined to a considerable pension granted him by the crown as a literary man, had now secured him an independence, with which he intended to retire to his native country, but in 1763 he received an invitation from the earl of Hertford to attend him on an embassy to Paris. This he accepted; and his character as a writer and philosopher being well known in that capital, procured him an excess of attention and civility, with which he was highly delighted. He remained at Paris as "Chargé d'affaires," after the departure of lord Hertford in 1765, and did not return to England till 1766, when he brought with him the celebrated Rousseau, who, having excited persecutions against himself in every country near him, was induced to seek for an asylum in the only true land of liberty. Mr. Hume's conduct towards his friend was extremely kind and generous; but so capricious was the temper of Rousseau, that he fancied all the world was leagued against him, and betrayed such groundless and unworthy suspicions as finally dissolved their friendship. In 1767 Mr. Hume accepted the office of under-secretary of state, which he held under general Conway till the resignation of that minister in 1769. He then retired to Edinburgh, expecting to enjoy a comfortable old age by means of the friends, the reputation, and opulence which he possessed. In that northern metropolis he drew around him a chosen circle of suitable associates, with whom he lived upon easy and very familiar terms. He died in 1776. The account which he has given of his last illness is as follows: "In spring, 1775, I was struck with a disorder in my bowels, which at first gave me no alarm, but has since, as I apprehend it, become mortal and incurable. I now reckon upon a speedy dissolution. I have suffered very little pain from my disorder; and what is more strange, have, notwithstanding the great decline of my person, never suffered a moment's abatement of my spirits, inasmuch that were I to name a period of my life which I should most chuse to pass over again, I might be tempted to point to this later period. I possess the same ardour as ever in study, and the same gaiety in company. I consider, besides, that a man of 65, by dying, cuts off only a few years of infirmities; and though I see many symptoms of my literary reputation's breaking out at last with additional lustre, I knew that I could have but few years to enjoy it. It is difficult to be more detached from life than I am at present." The account of his own life, of which the foregoing is an extract, was dated the 18th of April 1776, and he gradually grew worse till August the 25th, when he died, in the 65th year of his age. His character has been drawn by Dr. Adam Smith: "He was one," says he, "concerning whose philosophical opinions men will, no doubt, judge variously, every one approving or condemning them according as they happen to coincide or disagree with his own, but concerning whose character and conduct there can scarcely be a different opinion. His temper indeed seemed to be more happily balanced, if I may be allowed such an expression, than that perhaps of any other man I have ever known. Even in the lowest state of his fortune, his great and necessary frugality never hindered him from exercising, upon proper occasions, acts both of charity and generosity. It was a frugality, founded not upon avarice, but upon the love of independence. Upon the whole, I have always considered him, both in his life-time and

since his death, as approaching as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit." To this picture, drawn by the pen of friendship, we may add the observations of a very judicious biographer. "We may," says he, "reasonably demur to Dr. Smith's moral estimate, in attributing the perfection of virtue to a man whose leading principle was, by his own confession, selfish (the acquisition of literary fame), and who never seems to have made any of those sacrifices of interest and inclination to public good, in which virtuous action chiefly consists. Further, whatever degree of freedom of discussion may be justifiable, with the benefit of mankind in view, it may be doubted whether a mere fondness for speculation, or a love of philosophical applause, will morally excuse a writer for sporting with opinions which are commonly held of the highest importance to human welfare." Two of his posthumous works were published after the death of Mr. Hume, viz. "Dialogues concerning Natural Religion;" and "Essays on Suicide." The latter contain some of his most obnoxious principles, conveyed in the most offensive form. See Hume's account of his own life, and Dr. Smith's letter prefixed to the 8vo. edition of the History of England 1789. Gen. Biog.

HUMEA, in *Botany*, so named, by the writer of the present article, in just commemoration of the late right lady Amelia Hume, sister of the present earl of Bridgewater, and wife of sir Abraham Hume, bart. who first raised this plant in England, and communicated it to him. Her ladyship for many years cultivated successfully, and studied scientifically, a fine collection of plants, at her seat at Wormleybury, Herts, and was always distinguished by the liberality with which she imparted to others her acquisitions or discoveries. She departed this life, admired and beloved by all who knew her, in September, 1809, and is interred at Wormley.—Sm. Exot. Bot. v. 1. 1. (Calomeria; Venten. Jard. de la Malmaif. 73.)—Class and order, *Syngenesia Polygamia-equalis*. Nat. Ord. *Compositæ Discoidæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. Common Calyx of numerous, imbricated, obovate, obtuse, concave, coloured, pointless scales, the outer ones smallest and gradually more distant. Cor. compound, uniform, tubular, of very few florets, whose proper corolla has a cylindrical tube, and a bell-shaped limb, with five revolute segments. Stam. Filaments five, capillary; anthers united into a pentagon, with five sharp teeth. Pist. Germen oblong, glandular; style cloven; stigmas spreading, capitate. Peric. none, except the permanent scarious calyx. Seed oblong, without any crown or wing. Recept. very small, glandular.

Eff. Ch. Receptacle minute, glandular. Down none. Calyx loosely imbricated, membranous, pointless. Florets about three. Anthers awned.

1. *H. elegans*. Sm. Exot. Bot. t. 1. (Calomeria amarantoides; Venten. Jard. de la Malmaif. t. 73.)—Native of New South Wales, not far from Port Jackson, from whence we received specimens amongst the first plants sent from that country in 1791.

The root is biennial. Stem herbaceous, five or six feet high, erect, panicled, round, filled with spongy pith, and rough (like the leaves) with short rigid viscid pubescence. Leaves alternate, sessile, lanceolate, acute, from six to twelve inches long, slightly waved at their edges, and clasping the stem by their heart-shaped base, of a full green colour on both sides, and furnished with a midrib, with copious reticulated veins; the upper leaves gradually diminish into bractæas of a small lanceolate figure. Panicle drooping and widely spreading, of innumerable small pendulous flowers,

on capillary branched stalks. The florets are tipped with violet; the calyx is of a more or less deep rose-colour, crimson, or brownish red, sometimes white. The whole plant is fragrant, like red cedar wood, or the hautboy strawberry, but too strong to be agreeable if much handled. It is raised on a hotbed, and planted out for flowering.

The name *Calomeria* is a pun upon the word *Buonaparte*; from *καλος*, fair or good, and *μερη*, a part, and is, in every respect but its harmony, truly insufferable, especially as there is a plant already called, somewhere or other, *Buonaparte*; there is also a *Napoleona* and a *Josephinia* for those who desire them; the last being certainly well merited, and perhaps the least exceptionable of all.

HUMECTATION, formed of *humor*, moisture, moistening, in *Pharmacy*, the preparing of a medicine, by steeping it awhile in water, in order to soften and moisten it when too dry; or to cleanse it, or prevent its subtle parts from being dissipated in grinding, or the like.

HUMECTATION is also used for the application of moistening remedies.

HUMERALIS, in *Anatomy*, a name frequently given to the artery and vein of the arm.

HUMERUS, or **HUMERUS**, the bone of the upper arm. See **EXTREMITIES**.

HUMERUS, *Fracture of the*. See **FRACTURE**.

HUMERUS, *Luxation of the*. See **LUXATION**.

HUMERUS of Birds. See *Anatomy of BIRDS*.

HUMFRE, in *Geography*, a cape on the E. coast of the island of Guernsey.

HUMID, **HUMIDUM**, *moist*. The school philosophers make water the *primum humidum*, the first of humid bodies, and the cause or principle of humidity in others; which are more or less moist, as they partake more or less of this element.

HUMIDITY, **MOISTURE**; the quality or power of wetting or moistening other bodies.

Modern writers consider humidity as a particular species of fluidity; and define it a fluid, which, being applied on a solid body, adheres to, and communicates the quality to other bodies. Others, somewhat more accurately, call humidity the power whereby a body moistens another; but what that power is they do not shew.

But of this we are certain, humidity is only a sort of relative mode. So far as the component particles of a fluid, compared with respect to the pores and particles of other bodies, or the texture thereof, are apt and disposed to enter those pores, or stick to those particles, so far is that fluid humid: on the contrary, so far as there is a repugnance or incongruity between the particles, &c. in respect of such bodies, the fluid is not humid.

Thus quicksilver is not moist in respect to our hands or clothes, and other things, which it will not stick to; but it may be called humid, in reference to gold, tin, or lead, to whose surfaces it will presently adhere, and render them soft and moist. Even water itself, which wets almost every thing, and is the great standard of moisture and humidity, is not capable of wetting all things; for it stands or runs off in globular drops from the leaves of cabbages, and many other plants; and it will not wet the feathers of ducks, swans, and other water-fowl.

Add, that the texture alone may cause the fluid to be humid, as is plain, in that neither quicksilver, lead, nor bismuth alone will stick upon glass; yet being mixed together, they will form a mass that will do so; as appears from such a composition being frequently used in foliating looking-glasses. See **COHESION**, **FLUID**, and **HYGROMETER**.

HUMIDUM RADICALE, or *Radical Moisture*, in the pathology of the ancient philosophers, a supposed principle in the animal economy, which, together with the *radical heat*, was essential to life, or constituted the vital energy. The principle being altogether gratuitous, different notions were formed concerning it by different writers; and some confessed that they did not understand what was meant by these terms. See Sennert. lib. i. cap. 5. De Calido innato et Humido radicale. Fernel, lib. vi. cap. 4. entitled "Humidi primigenii, quod tum caloris tum spiritus subiecta est materia, demonstratio."

HUMILIATI, a congregation of religious in the church of Rome, established by some Milanese gentlemen on their release from prison, where they had been confined under the emperor Conrad, or, as others say, under Frederick I. in the year 1162. This order, which acquired great wealth, and had no less than ninety monasteries, was abolished by pope Pius V. in 1570, and their houses given to the Dominicans and Cordeliers, for their luxury and cruelty.

HUMILIATION, the act of humbling, *i. e.* of abating a person's pride, and bringing him lower in his opinion.

In this sense, humiliation stands distinguished from mortification: humiliation brings down the mind; mortification subdues the flesh.

HUMILIS MUSCULUS, in *Anatomy*, a name mentioned by Caserius, as given by some people of his time to one of the muscles of the eye, the *rectus inferior* of Fabricius, and depressors of Riolan: it is the depressor oculi of Albinus, being one of the quatuor recti musculi oculorum of that author. See **EYE**.

HUMILITY, in *Ethics*, is a virtue consisting in the moderate value which a person puts upon himself, and every thing relating to him. Or, more particularly, it consists in not attributing to ourselves any excellence or good which we have not; in not over-rating any thing which we have or do; in not taking an immoderate delight in one's self; in not assuming more of the praise of a quality or action than belongs to us, and in a lowly sense and acknowledgment of our imperfections, errors, and sins. This virtue expresses itself in the modesty of our appearance, of our pursuits, and of our behaviour towards other men. It is distinguished from affectation, bashfulness, and meanness.

HUMISUGA, the *Ground-sucker*, in *Natural History*, the name of a fly, so called, because it is supposed to live by sucking the juices of the earth, without taking in any solid food. It has a brownish or dun body; a white spot at the insertion of the wings, and another at the head; the legs are black; the back is grey, with four sullied white lines running longitudinally; the wings are silvery, and, if put into water, they shine with a bright light like that of the glow-worm. This creature is common with us about path-ways, on mole-hills, and in other places where the ground is newly turned up. We call it the *path-fly*.

HUMMEL'S TOWN, in *Geography*, a thriving town of America, in Dauphine county, Pennsylvania, containing a German Lutheran church, and about 90 houses, on the S. side of Swetara creek; 100 miles W.N.W. of Philadelphia.

HUMMET, **THE**, a small island in the English Channel, near the N.E. coast of the island of Guernsey.

HUMMING-BIRD, in *Ornithology*. See **TROCHILUS**.

HUMMOCK, in *Geography*, a small island in the East Indian sea; 15 miles S. of Mindanao. N. lat. 5 24'. E. long. 126 37'.

HUMMECK Point, a cape on the N. coast of the island of Celebes, so called by captain Carteret in 1767, who supposed

posed it to be the same with that which is also called "Stroomen Point." N. lat. $1^{\circ} 20'$. E. long. $121^{\circ} 39'$.

HUMMOCK, in *Geology*, is a term introduced by Dr. William Richardson (Phil. Transf. 1808.) to denote an important class of isolated *Hills* (see that article), and patches of strata, which are composed of piles of strata, known in the neighbourhood, but entirely detached from the continuous part of such strata, owing to the intervening strata having been carried away, or *abrupted*, as the doctor called it, a phenomenon which had been previously noticed and described by Mr. Farey, and called *Denudation*. (See that article in our work, and the Phil. Mag. vol. xxxiii. p. 258.) Dr. Richardson very aptly compares a hummock to one of those dead-men, buoys, &c. which labourers, employed to move ground by measure, leave in different parts of the space they have excavated, in order to mark the original height of the surface in that place. The following are the names of curious basaltic hummocks which Dr. Richardson has particularized in the north of Ireland; some of them being isolated, and higher knowls on the tops of hills and mountains, and others of them conical or grotesque knowls, in valleys or low tracts, which are equally the seats of hummocks in denudated districts; viz.

Altabrian, on the Derry mountains, hemispherical.

Clogher rock, near Bushmills, a small cone or knowl, stratified like the hummock of Dunmull.

Doland's hill hummocks, near Glennuller vale and Mayole vale.

Dunmull, 3 miles S.E. of Portrush, on a high ridge, cylindrical, like Fermayle and Clogher rock.

Fermayle, on the Derry mountains, cylindrical and flat at top, like Dunmull.

Knock Loughran, near Maghera.

Lisanoore, one mile E. of the town.

Magilligan, on the top of the mountain, irregular.

M'Art's Castle, on Cave-hill façade, irregular.

Sconce, on the Derry mountains, hemispherical.

Slemish, 23 miles S.E. of Portrush, on the ridge, very large, with a flat top.

Mr. Farey has given an ample list and account of the hummocks in and near Derbyshire, in the 1st vol. of his "Report to the Board of Agriculture," to which we must refer. The curious hummocks of sand-stone at Andernach, in Bohemia, and others near Tunis, resembling ruins, also at Namaquas, in Southern Africa, and on the banks of the Wolga, are noticed in our article FLETZ, where they are supposed, but not perhaps on sufficient ground, to be peculiar to a particular rock, or stratum, instead of occurrences peculiar to the strata of certain districts, however various, as in Derbyshire they appear to be.

The *partial tract* of William Martin, (Outlines, addenda, p. iii.) "under which the strata constituting the surrounding tract are observed to dip," includes our hummocks on the tops of hills, or isolated knowls in valleys or plains, whose nearly horizontal strata basset or shew their edges on all sides, and also the *Basin* or SWILLEYS (see that article) of coal and other strata, which are often met with, dipping towards a central point or line, and basset or rising to the surface round the circumference of such swilleys: of the latter character, some of the depressed hummocks of the Derbyshire Report partake, as Darley-flash, Goyte-mofs, and Shallerofs, of the second coal-shale; Combes-mofs of the first coal-shale; Wardlow-mines of the lime-stone shale; Peak Forest town of the third lime, &c. The accurate discrimination of tracts of strata, in conducting mineral surveys, seem of the utmost importance to the progress of geological science, as well as to the processes of the miner, collier, &c.

HUMMOCK, a term used by *Navigators* to express circular and elevated mounts, appearing at a distance.

HUMMUDNAGUR, a town of Hindoostan, in Bahar; 45 miles S.S.W. of Patna.

HUMOR, or HUMOUR. See HUMOUR.

HUMOR, in *Geology*, was introduced by M. de Luc, "Elementary Treatise on Geology," p. 55, and defined to mean water, not as a compound of hydrogen and oxygen, but as an elementary substance of the globe, distinct from the forms of water, ice, (or crystallized water,) or steam: supposing, says he, that "in its primitive state, when nothing of what we now observe upon the earth was produced, nor as yet disposed to be produced, this substance (humor) was neither water, nor ice, nor aqua: its elementary particles were intermixed with all those to which they are at present united by affinity, in the different bodies with which we are acquainted; and those particles, then acquiring liquidity by their union with fire, and thus immediately entering into all the associations, to which its numerous affinities gave birth among elementary substances, produced the *Primordial Liquids*; which see.

HUMORAL PATHOLOGY, that pathology, or doctrine of the nature of disease, which attributes all morbid phenomena to the disordered condition of the fluids, or *humours*, of the body, and attempts to explain the progress and changes of diseases by certain fermentative or digestive operations in the *humours*.

In many of our articles in *medicine* we have had occasion to allude to the *humoral pathology* as the foundation of many opinions and peculiar modes of practice, which a more-accurate pathology has confuted and exploded. It would be a fruitless labour to enter into a minute detail of all the absurd speculations respecting the morbid changes in the fluids of the body, which have been successively adopted, from the time of Galen downwards: for, not only the followers of Galen, but all those in modern times who have dissented from his opinions, and have transferred the doctrines of chemistry and of mechanics to the phenomena of the living body, have, nevertheless, admitted the changes of the fluids into their systems, as the principal causes of disease, and as the foundation for explaining the operation of medicines: nay, even after the peculiar property of living bodies, (the faculty of irritability, excitability, sensorial power, or nervous energy, as it has been variously denominated,) which is resident in the nervous system, came to be viewed as a principal agent in the production of disease, and in the restoration of health, according as it is influenced by morbid causes, or by salutary impressions; or when, as Hoffmann first maintained, (Medicin. Rational. System. tom. iii. § 1. chap. 4.) the affections of the living solids came to be admitted as the most probable grounds of disease, and as affording a more rational explanation of morbid phenomena, than the disordered conditions of the fluids; still a humoral pathology was received, and combined with these opinions, to a considerable extent. Dr. Cullen himself, who advanced far beyond Hoffmann in his appeal to the agency of the living solids, occasionally refers to certain supposed "acrimony of the fluids," as the essence of some diseases: and it was in the systems of Brown and Darwin that all consideration of the changes of the humours, as the origin of disease, was first rejected, and every morbid condition was referred to the agency of that power, the nervous energy, which distinguishes the living body from dead matter. (See EXCITABILITY and IRRITABILITY.) But the doctrines of the older physicians continue to be, in a great measure, the prevailing opinions of the vulgar, if not of the generality of unprofessional persons, and even of a great number of routinists in the profession.

We

HUMORAL PATHOLOGY.

We shall, therefore, briefly state the principles of those doctrines, and shew the futility of the arguments on which they rest.

The four elementary humours of Hippocrates and Galen, namely, *pituita*, or phlegm, blood, bile, and black bile (melancholia), were received as the principles of all the animal fluids and solids, constituting by their due proportion the health of the body, and by their *intemperies*, or undue proportion, the varieties of disease, until the time of Paracellus. This bold and conceited chemist, who set up for a reformer of all philosophy, renounced the system of Galen, denied the existence of the four humours, and contended that diseases were not produced by humours, but that humours originated from disease. At the same time he promulgated a system of his own, using a jargon which is not very intelligible, and to which it may be questioned whether either himself or his followers ever attached any clear ideas. He adopted the notion of three elementary substances, to which he applied the appellations of *salt*, *sulphur*, and *mercury*, with Basil, Valentine, and others; but these terms were employed in new acceptations, about which the chemists were not altogether agreed. They are to be considered, it would appear, as general expressions of some faculty or property, which they communicate. Thus mercury appears to represent the principle of fluidity, sulphur that of inflammability, and salt that of solidity. According to Severinus, one of the followers of Paracellus, "*salt* gives consistency, solidity, or coagulation to things; *sulphur* imparts a fat oleaginous quality, which tempers the consistency of the salt; and *mercury* gives fluidity to both, and facilitates their mixture." And Quercetanus, another writer of that school, says that things receive their various tastes from *salt*, their odours from *sulphur*, and their colours from both these, but most chiefly from *mercury*. (See Sennert. Tract de Consensu et Dissensu Galenicorum et Peripatet. cum Chymicis. cap. 11.) They speak also of animal sulphur, vegetable sulphur, and mineral sulphur; of animal salt, vegetable salt, &c.; so that it is obvious these were merely gratuitous and hypothetical expressions, which every one might use according to his own fancy, and which led to every species of absurdity. When they treat of the origin of diseases, this absurdity is manifest throughout. Paracellus lays down two genera of disease, one of which he calls, in barbarous language, *iliastrum*, the other *cagastrum*: the former including those disorders which grow "from seed, like apples and nuts," such as dropsy, jaundice, &c.; the other those which arise "from corruption, such as fevers, the plague, &c." (Paracel. Labyrinth. Medic. err. cap. 11.) We should consider our time, and that of our readers, as lost in examining the minutiae of this systematic jargon. If curiosity should impel any one to investigate the subject, he may peruse the various writings of Paracellus himself, or Scheuenemann's "*Hydromantia Paracelsica*," and "*Medicina reformata*;" as well as Quercetanus's "*Hermeticæ Medicinæ Defensio*," the works of Oswald Crollius, of Petrus Severinus, &c. Sennertus has attempted to refer the jargon of these chemists to the Galenic doctrines, from which, where it is intelligible, it seems to differ more in appearance than in essence: for it ultimately refers diseases to various conditions of the humours, which are estimated by the appearances and sensible qualities of the excretions and discharges, changing only the terms by which they are designated. (Loc. cit. cap. 16.) See *GALENICAL SYSTEM*.

As the study of chemistry advanced, and its various operations and products were investigated, pathologists began to modify the doctrines of Galen generally, and, laying aside the four humours of that writer, they designated the various humours, connected with different states of diseases, accord-

ing to analogous properties, fancied or real, in these morbid humours, and in the substances with which chemistry had made them acquainted. Thus we find the writers of the 17th century speaking of mucilaginous acid, vitriolic, tartarous, alkaline, corrosive, and acrid humours, of a saline, putrid, rancid acrimony, &c.; (see sir J. Floyer's "*Preternatural State of Animal Humours described by their sensible Qualities, &c.*") and likewise attributing much to the agency of the *spirits*, or animal spirits, which they seem to have considered as a secretion from the brain, communicated through the canals (as they were supposed to be) of the nerves, and constituting the most "exalted" portion of the animal humours. Our countryman, Willis, substituted this term for the *mercury* of Paracellus, and speaks of the *silt*, *sulphur*, and *spirits*, as the three principal elements of the humours, to which he likewise adds *earth* and *water*. (Willis, Diatriba de Fermentatione, cap. 2. et de Febribus, cap. 1.) The humours of Galen, he contends, are not parts of the blood, but its recements; the blood, properly so called, being the same in every part of the body, and the *pituita*, bile, and black bile, being the impurities thrown off by it, by means of a sort of effervescence or fermentation. In like manner, he observes, in the case of the fermentation of wine or porter, the lighter parts ascend to the top, forming the *foam* or yeast, and the thicker parts fall to the bottom, in the shape of dregs or tartar, leaving the liquor clear; yet no one, he says, could correctly affirm, that wine or porter is composed of yeast, tartar, and a vinous liquor.

But whatever notions pathologists have at different times adopted, in regard to the number and qualities of the elementary principles of the humours, they have all agreed in explaining the phenomena of diseases, by a certain intestine process, which has been variously compared to digestion, fermentation, effervescence, or ebullition, by which the humours were supposed to be purified, in consequence of the expulsion of the offending matter. The ancients considered this depuratory process as analogous to that of the digestion, or concoction (as they termed it) of the food in the stomach. For as the various substances, taken into the stomach for the purposes of nutrition, became gradually converted, by the process of concoction, which was carried on by the innate heat, into a bland homogeneous fluid, the chyle, which was absorbed by the mesenteric vessels for the nourishment of the body, while the dregs or fæces were carried off by the bowels, and discharged; in like manner they supposed that when the blood was in a state of *intemperies* or *dyserasis*, the constitution was excited to febrile action, during which a sort of concoction, or digestive process, was carried on, and the blood, being thus depurated, the morbid humours were discharged by some of the usual excrementitious passages, the bowels, the bladder, the vessels of the skin, &c. When this discharge, whether a diarrhoea, a sediment in the urine, a profuse perspiration, &c. took place, a *crisis* was said to occur; and the purpose of the febrile commotion having been effected, the constitution ceased from its inordinate action, and health was restored. (See *CONCOCTION AND CRISIS*.) These discharges, with which it was observed that fevers often terminated, were considered as the proofs of the existence of the morbid humours in the blood, and of the origin of the febrile commotion, which continued while they were retained in the body, and ceased when they were expelled.

After the revival of learning, when chemistry had made some advances, the process of *fermentation* was more commonly assumed, as explanatory of the nature of febrile diseases. The physicians of the 17th century, Willis, Floyer, and others, referred all the phenomena of acute diseases to this source; and Sydenham acknowledges a great analogy

HUMORAL PATHOLOGY.

In the two processes, yet remarks that the analogy is not perfect, and therefore prefers the term *commotion* to that of *fermentation* or *ebullition*, which other writers employ. (See his *Obs. Med.* § 1. cap. 4.) It is to be remarked, however, that the term "fermentation," in the acceptance adopted by Willis, signifies every species of chemical action, combination, or change, as well as the operations of animal and vegetable nutrition and growth, by which unorganized matter is assimilated with living bodies. See his *Diatriba de Fermentatione*.

During the 17th century, then, or rather from the latter part of the 16th century, nearly to the time of Dr. Cullen, the process of *fermentation* was considered as constituting the essence of all febrile diseases: and as fermentation, in regard to the production of vinous liquors, is excited commonly by some ferment introduced for that purpose, so a ferment was supposed to have found its way into the blood, when the animal system was excited into a febrile fermentation or commotion; and thus the blood was depurated, and the peccant matter expelled, or separated, like the dregs of wine. This ferment, or *cacoehymia*, was accounted for in various ways by different pathologists: but we may collect, on the whole, that they maintained the notion of two principal internal sources of *cacoehymia*, namely, improper food, and imperfect secretion from the different glandular organs. Fernelius remarks, "Omnis enim cacoehymia et humorum impuritas aut ex vitiosa viscerum affectione, aut ex improba vivendi ratione, non aliis ex causis, proficiscitur;" for, he adds, when the stomach, liver, spleen, and neighbouring organs, are diseased, either by *intemperies* or organic disorder, they produce humours, similarly diseased, even from pure and temperate aliment; and, when the food is immoderate, heavy, glutinous, or corrupted, it cannot be so wholly and perfectly changed by digestion, as not to carry some of its crude or unwholesome qualities with it to the blood and other humours. (See Fernel. *Febr. Curand. Methodus Generalis*, cap. 2.) In like manner, Willis observes, "Atque hujusmodi motus (nimirum sanguinis verè intestinum bellum) dependet tum à partium ipsius sanguinis heterogenitate, tum à variis fermentis, quæ à visceribus cruoris massæ inspirantur." (*Diatr. de Feb.* cap. 2.) It may be remarked, by the way, that in thus referring some of the morbid humours to the viscera, they seem to admit, though unintentionally, the primary action of the solids in the production of disease. In general, however, they looked to the concoction or fermentation of the aliment into chyle, as the source of the *cacoehymia*; and Sir John Floyer considers all the internal variations of the humours as originating from a *defective* or *excessive* degree of the fermentation by which nutrition is carried on. "If the chyle be rightly fermented, all the humours arising from it are rightly prepared; but if the fermentation of that is vitiated, all the other humours, produced from vitiated chyle, retain a tincture of its defect in their preparation. This fermentation, by which the chyle and blood are prepared, may be depraved both ways, for it may be depressed under its natural state, or exalted above that degree, which is suitable to the natural temper of any animal; of both of which errors, and the *cacoehymias* depending on them, I shall next discourse." (*Loc. cit.* p. 34.) He then informs us that if the animal humours are digested or fermented "to any degree *below* their natural state, some of the cold *cacoehymias* are produced." Among these he enumerates a mucilaginous or pituitous, a tartareous or acerb, a flatulent, and a ferous state of the humours. If the chyle be *ever-fermented*, or digested *too much*, "it becomes bitter, acrid, rancid, or putrid;" it also produces a viscid state of blood, which occasions pain and inflammations, and shews

itself in the *visciditas* of blood that is drawn in inflammatory diseases; as well as "a salt acrimony, which corrodes and eats the gums, infects the skin with spots, and is the hot scurvy." (*Ibid.*) These various species of *cacoehymia*, then, are deemed *ferments*, by which the blood is excited to violent fermentative commotions, or fevers. But there are other diseases, "which depend wholly on an outward ferment received into the flesh, as in hydrophobia," or arise from the poison of serpents, or from "the touch of a salt humour to which the morpheus, scab, pox, and scald-head are referable, and leprosy;" and "all malignant fevers, as the small-pox, measles, and plague, or pellential fevers, have their original from the malignity of the air, and the poisonous sulphurs of the earth." (Floyer on Preternat. State of Humours, p. 15.) In like manner, Sydenham ascribes all epidemic diseases to a ferment, poison, or peccant matter, introduced into the blood by respiration, the air inspired being impregnated with this poison, either from the bowels of the earth, or from some peculiar influence of the planets:—while he attributes sporadic febrile diseases to the particular ebullition or inflammation of the blood, occasioned by the peculiar *intemperies* of individuals, which he seems to impute chiefly to the influence of external temperature, and to errors in diet, and the other *non-naturals*. Sydenham, *De Morbis Epidem.* chap. 2. and *Traçtat. de Podagra*.

From whatever source these *cacoehymias*, or peccant humours originate, they are considered as inimical to the well-being of the body; in consequence of which enmity, nature, or the supposed presiding principle of the constitution (which has been variously personified by different writers, under the titles of *Archeus*, *Antocrateia*, *Anima medica*, &c.) begins a contest, in order to expel from the blood this intrusive peccant matter. "Reason informs us," says Sydenham, "If I have any judgment, that a disease is nothing else than a struggle of nature, labouring with all her might to expel the morbid matter for the health of the patient." And, he remarks, in another place, "the inordinate commotion of the blood, which is the cause or concomitant of continued fever, is excited by nature, either for the purpose of separating some heterogeneous matter, contained in and offensive to it, or in order that the blood may be somehow or other altered in its diathesis." (*Loc. cit.* cap. 4.) Willis, Floyer, and others, view the subject in the same light, except that they introduce the *spirits* as the agents employed by nature, for the purpose of exciting the commotion in the blood. "A fever," says Floyer, "is a preternatural fermentation or effervescence of the blood, occasioned by some ferment irritating the spirits of the blood and nerves, for the dissolving, or putrefying, and separating some part of the cacoehymical *succus nutritivus* from its mixture with the mass of humours. (P. 210.) According to the peculiar nature of the *cacoehymia*, or morbid humour, the nature of the fever was supposed to vary. "It is evident that every person has some antecedent *cacoehymia*," says the same writer, "by which the particular symptoms of the fever are produced, &c.—The several stages of the disease are very naturally described by the separation of the greater or less quantity of the *succus nutritivus* from the blood, in the increase of the fever, and the *crisis* is a full or perfect separation of all the depraved *succus nutritivus* from the mass of blood, when the fever is curable, and then the febrile effervescence ceases; but if the *succus nutritivus* be but in part separated, the mass of humours remains turbid and undepurated, and the fever becomes fatal." (Floyer, chap. 15. App. i. of Fevers.) When this morbid matter, instead of being thrown out by the excretions, as in the case of critical discharges by diarrhoea, turbid urine, or sweats, is

"evacuated

HUMORAL PATHOLOGY.

“evacuated upon particular parts, it produces the several inflammations; as quinies, apoplexies, lethargies, palsies, pleuritis, rheumatism, colics, which are the symptoms of the ordinary intermitting fever, and distinguish it into its several species.” Ibid.

But as *acute*, or febrile diseases, which terminate in a short time, (e. g. within the compass of fourteen or twenty-one days,) were considered as resulting from this active fermentation, and deuration of the humours; so, according to Sydenham, all *chronic* diseases, which run through a long and indefinite period, arise from an imperfect digestion or fermentation of the offending humours, and the consequent inability of nature to expel them. “For when any person has on the one hand, the principles of his nature debilitated or worn out, whether by old age, or by great and continual errors of the non-naturals, particularly in respect to food and drink; or, when, on the other hand, the organs of secretion have been so far weakened, as to be unable to deurate the blood, by carrying off its excrementitious and superfluous parts; in these cases, a greater quantity of humours is accumulated than the powers of the individual are capable of digesting or concocting, which humours, in consequence of their detention, undergo various degrees of fermentation and putrefaction, until at length they assume specific properties, and, according to the variety of deprivation, give rise to various forms of disease. They also fall upon particular parts, which are more disposed to receive them according to their peculiar qualities; and thus ultimately produce the long trains of symptoms, which are designated by the names of certain diseases, and which vary in relation to the nature of the morbid humour, and to the morbid condition of the part, respectively.” Sydenham, *Traçtat. de Podagra*.

It may be inferred, from the long and extensive prevalence of this humoral pathology, that it was not founded on mere fancy; but that something like sound observation and established facts could be adduced in support of it: and we have already hinted, that the common occurrence of certain profuse or altered excretions, towards the termination of febrile diseases, was deemed conclusive evidence of the truth of the hypothesis. But the doctrine was apparently strengthened still more, where there occurred not a mere increase of the ordinary excretions, but the discharge of a new and preternatural humour, altogether uncongenial with the healthy blood. Thus, when a tumour formed in any particular part, from the supposed settling of the peccant matter there, an inflammatory commotion or fermentation took place, in consequence of which, as the morbid matter became concocted, an abscess was formed, and the *pus* or *sanies*, which was at length discharged from it, was deemed a proof of the existence of the morbid ferment. In this way the buboes, which occur in the plague,—the abscesses in the different glandular, membranous, and muscular parts,—the eruptions in the skin in small-pox, measles, &c.—the formation of chalk-stones, after inflammatory gout,—and the expectoration of purulent and mucus sputa, in consequence of inflammation in the lungs and bronchial passages,—all these phenomena were believed to be conclusive proofs of the correctness of the humoral theory. And a still stronger proof appeared to exist in the well-known fact, that in small-pox, the plague, &c., the matter thus discharged was as completely a *ferment*, when received into the healthy humours of another person, as barm or yeast, introduced into a cask of infusion of malt or grape-juice. But this was not all: a sort of ocular demonstration of the existence of a morbid humour in the circulating fluids appeared to be deduced from the condition of the blood, which was drawn

from persons labouring under inflammatory diseases; and which, when it had cooled, exhibited a thick, tenacious *size* upon the surface of the coagulum, which has been called the *buff* or *buffy-coat* of the blood, and is not found on blood taken away, when no fever is present. Some collateral evidence was likewise deduced from other phenomena of diseases, and especially from the occasional occurrence of what is termed a *metastasis*, or the sudden translation, as it were, of a disease from one part of the body to another. As this was most commonly observed to take place between an external and internal part (as the gout, for instance, disappearing on the foot was transferred to the stomach;—or when an eruption faded on the skin, and vomiting or diarrhœa succeeded in the alimentary canal); so it was concluded, that the efforts of nature to expel the morbid matter had either been too feeble, or had been counteracted by improper treatment, and that the matter had fallen back upon the internal organs, where it excited the new struggle of nature to get rid of it by another channel.

This hypothesis, however, which is founded upon a coarse and vulgar analogy between a merely chemical process, and the operations of the living body, could only remain plausible, so long as the nature both of chemical combinations and of the properties of the animal economy had been the subject of very limited investigation: upon a more accurate inquiry, we find the points of analogy do not exist. The various changes, which take place in the fluids of the living body, do not occur from mere chemical action, as in the case of fermentation of the elementary parts upon each other; but arise from some peculiar action of the vessels, through which they circulate. Thus, the vessels of the liver alone elaborate the blood into bile; those of the kidneys form the urine; and those of the testes produce the seminal liquor. No admixture of the parts of the blood, in any other situation, is capable of generating these peculiar humours. In a similar manner, the morbid humours are the result of certain inordinate and irregular action of the vessels of particular parts. Thus, when any organ is in a state of inflammation, which, in fact, consists in an undue distention and activity of its vessels, the *pus*, or other matter, which is formed in consequence, is *generated in the inflamed part*, is the *effect* of the inflammatory action, and is not brought by the circulating blood, and deposited there, to be the *cause* of the inflammation. In small-pox, for example, or measles, the contagious matter is not found circulating with the mass of blood, but is *generated by the action of the vessels of the skin*, where alone it appears; if it contaminated the circulating mass, it would, doubtless, be deposited in the internal parts: but no pustules were ever found in these diseases, in any of the viscera or internal organs. No such change, as that occasioned by a ferment, therefore, takes place. This is farther proved by the fact, that by augmenting the action of the cutaneous vessels, on any particular part of the surface, (as by the application of heat, or any stimulating substance); on that particular portion, the quantity of pustules, in small-pox, will be augmented, and *vice versa*. In a word, it appears that, as neither bile, urine, nor saliva, is found circulating in the blood, so neither is the matter of contagious diseases existing there: just as in the diabetes *mellitus*, when the kidneys are constantly throwing out large quantities of saccharine matter, no traces whatever of sugar, or its elements, can be detected by the chemist in the circulating blood.

On the other hand, the inference drawn from the *size crust*, which is found upon the coagulum of blood, drawn under the circumstances of fever, is incorrect. For that *size* is simply the fibrin or coagulable lymph, which constitutes

HUMORAL PATHOLOGY.

tutes a part of the blood under all circumstances, and which shows itself apparently more or less according to the less or greater rapidity of coagulation; which again is influenced by the force or rapidity of the action of the vessel from which it flows, or by its manner of flowing; inasmuch that if the blood be received into different vessels, during the same bleeding, the buffy coat will appear on some, and not on the others. It may be likewise added, that many fevers terminate in health, where no *crisis* or sensible discharge has preceded recovery.

With regard to the argument deduced from the occurrence of *metastasis*, little can be inferred from it in support of any position: the fact is very difficult of explanation by any hypothesis. It is at least equally easy, and consistent with our knowledge of the animal economy, to refer the transition of morbid action to the communication of certain internal and external parts by nervous sympathy; as to conceive that a morbid matter is mechanically transferred, through the medium of the circulating mass of fluids, from one organ to another. The existence of a morbid matter is hypothetical; whereas the existence of a sympathetic connection, through the medium of nerves, is a matter of observation and experiment: of which the connection between the skin and the alimentary canal may be mentioned as an example. If we excite nausea or vomiting in the stomach, we induce a perspiration on the skin; and by moistening the surface, we speedily relieve the sensation of thirst, &c. Besides, there is no proof of the actual translocation of the morbid matter, or the same form of disease in cases of *metastasis*: for, to instance gout, we do not find the chalky matter of the hands or feet appearing in the stomach, when the disease is transferred to that organ, but what is inflammation on the surface, is commonly spasm in the stomach; and, on the principle of nervous sympathy, the identity of the diseases, thus excited in distant parts, is not a necessary supposition.

The arguments for the contrary doctrine, which refer the phenomena of life, whether in a state of health or disease, to the agency of the nervous energy or sensorial power, resident in the living solids, and to the various action of the moving fibres, have been deduced from a long series of observations and experiment. See LIFE, EXCITABILITY, &c.

The pernicious results of the practice, however, to which this humoral pathology led its advocates, afford an additional refutation of its principles. The doctrine, that nature instituted all morbid actions, for the purpose of expelling from the constitution certain offensive and dangerous matter, either conducted, on the one hand, to sanction a very feeble and inert practice, lest the salutary operations of nature should be impeded or deranged; or, on the other, to enforce an active practice, by which it was intended to aid and co-operate with nature in her supposed two-fold endeavours, first to concoct or duly ferment the morbid matter, which annoyed her, and secondly, to expel it by the proper emunctories. Of these two practical systems, the first, or *la médecine expectante*, the French have emphatically called it, is, doubtless, the least mischievous. It consisted in doing nothing, with the appearance of doing something; and, therefore, obtained the confidence of the patient, and tranquillized his mind, which constitutes one step towards a cure. The remedies consisted of what have been termed demulcents, diluents, humectants, &c. or aqueous liquors, with various vegetable mucilages, sugars, and starches, all abundantly harmless in their qualities, and certainly not interfering with any process of the constitution, whether salutary or deleterious. But if this be the highest reach of the medical art, (which, indeed, is rather the rejection of all art,) to what purpose have the

studies of scientific men been directed, the structure and functions of the human body been investigated, and a particular class of mankind devoted to the practice of medicine? *La médecine expectante* is surely the weakest of all empiricism.

It has always been a popular doctrine, and it is one that carries a great deal of plausibility in the face of it, that the main object, and the sum total of the powers of medicine, consist in aiding the natural efforts of the constitution for the removal of diseases. But this proposition requires considerable qualification. If it be merely meant, that medicine can only operate through the medium of the powers or energies of the living body, and that, independently of these vital energies, medicine has no operation, the position is a *truism* which cannot be questioned. But if it be meant, that the sole power and object of the medical art are limited to the furthering of all morbid excitement, and to the removal of obstacles to the completion of the purposes of that excitement; *i. e.* to assisting the efforts of nature or guarding them from interruptions, the assertion appears to be altogether gratuitous, and nothing less than an abuse of language. In the first place, it is founded on the assumption, that all diseased action is salutary; which the effects of numerous diseases directly contradict, and which has no better foundation than two other gratuitous assumptions, namely, the existence of a morbid ferment in the blood, and of an *archæus*, or rational soul, governing all the operations of the animal economy. But, secondly, admitting the salutary tendency of diseased actions, considered as the efforts of nature, by what signs are we to interpret her intentions, or to discover when she requires assistance, and when restraint? On this point the greatest practical errors are likely to be committed, and have, in fact, been constantly and extensively committed, by those humoral pathologists, who have presumed upon their knowledge of the intentions of nature. Had they been unbiassed observers of nature's indications, they would have attended, probably, to the suggestions of those sensations and instinctive feelings in the sick, which are generally deemed sufficient directions to the healthy, and which appear to be the universal guides to the physical conduct of the whole animal creation. They would have allowed the thirsty to drink, the hot to be cooled; and would have attempted to relieve the various painful sensations, according to the cravings which they suggested. But their practice was commonly the very reverse of this: for they deduced their inferences, not from these unequivocal guides, but from their *hypothetical* conceptions of the proceedings of nature. Their own proceedings, therefore, were directed to encourage the increase of the disease. Thus in all fevers, even in those where there was considerable inflammatory affection of the whole skin, (as in small-pox,) they accumulated the heat of the patient, already almost intolerable, with a view to perfect the fermentation or concoction, which they supposed nature was labouring to accomplish; and hence they rendered mild fevers severe, and severe ones certainly fatal. At the same time, they stimulated the action of the heart and arteries, by cordial, volatile, and aromatic medicines, and by heat conveyed internally in the drink, and thus still farther multiplied the evil. And it was particularly unfortunate for the patient, and for medicine, that this augmentation of the original disease, (as in the increase of the eruption in small-pox, scarlet fever, &c.) and even the actual excitement of new diseases, (as in the military eruption over the skin, which this heating practice frequently produced in all fevers,) were conceived by these pretended interpreters of nature, to be nothing less than new and ocular proofs of the truth of their doc-

trine, and of the efficacy of their practice! They had *brought out* the morbid matter! But the multitudes who perished notwithstanding this happy event, but too fully demonstrated that both nature and art were guilty of perpetual mistakes. The sagacious Sydenham, although under the influence of the humoral pathology, detected the fallacy of the heating and concocting practice, in respect to the cure of small-pox, while his contemporaries continued to be the slaves of hypothetical error. But it remained for the present age, not only to establish the practice, which he suggested, but to extend it to all febrile diseases, and to pursue it to a degree far beyond any conception which he had formed upon the subject.

It cannot be doubted, that one of the greatest improvements ever made in the medical art, is the discovery of the circumstances, under which a free application of *cold* may be made in febrile diseases, aided by the early use of purgatives, and the removal of every other species of irritation on the living solid, which constitute what has been called the antiphlogistic plan of treatment. For the establishment of this practice, in regard to the free use of cold, upon clear and philosophical grounds, we are principally indebted to the late Dr. Currie of Liverpool. So far from experiencing any injury or danger from not encouraging the supposed concoction, or from repelling the morbid matter, it is ascertained, by innumerable observations, that it is most salutary to reduce the temperature of the surface of the body, in the height of the eruptive fever of scarlatina, for instance, and that this otherwise formidable disease may be thus cut short in its duration, mitigated in its severity, and conducted mildly to a safe termination. (See *COLD, as a remedy*: also *HEAT, FEVER, and Scarlet Fever*.) In a word, it is now ascertained, that that practice, in febrile diseases, which is founded on the principle of removing or diminishing the excitement of the sensible and irritable solids, and thus of lessening the increased action of the vessels, generally and locally, without any reference to a peccant state of the humours, is attended with a degree of success, not to be compared with that of the humoral pathologists; and that man is more correctly treated as a being possessed of sensorial powers, than as a barrel of fermenting fluids.

It were unnecessary to enter into other practical absurdities of the humoralists; such as the frequent letting of blood, even in chronic diseases, upon the supposition that the morbid matter, which is believed to contaminate the whole circulating mass, should be all discharged with the small portion of this fluid, that escapes through the orifice made by the lancet, and leave the remaining mass thoroughly depurated;—the use of purgatives on the same principle:—the interdiction of purgatives in the early stage of febrile diseases, because the peccant matter is supposed to be yet in a crude or unconcocted state;—and lastly, the numberless farragos of useless and inert herbs, mixed together upon some fanciful notion of their properties for correcting various modifications of *cachexymia*, which they constantly prescribed in chronic maladies; the qualities both of the bane and antidote, the morbid humour and its corrector, being equally gratuitous and hypothetical.

We have said nothing on the subject of that humoral theory, which referred diseases to the two opposite conditions of the fluids, the *acid* and the *alkaline* cacochymia, upon which Boerhaave and some others reasoned with considerable ingenuity: for this doctrine was never generally received; and, except in so far as the contents of the stomach and first passages exhibited a tendency to one or other of these qualities, according to the modifications of indigestion, it is

obviously founded in misapprehension: (see Boerhaave, *Praxis Medica*, vol. i. p. 122. et seq.) and further, as Dr. Cullen remarks, it is not consistent with what Boerhaave himself has delivered elsewhere. (First Lines, pref. p. xxx.) The doctrine of a *spontaneous gluten* in the blood, inculcated by that celebrated author, (*loc. cit.* p. 145.) is also gratuitous. Some of the proofs adduced for its existence are manifestly founded on a mistake with respect to what has been called the buffy coat, or inflammatory crust; and the many examples given by Boerhaave of a *gluten* appearing in the human body, are all of them nothing more than instances of collections or concretions, found out of the course of the circulation.

To conclude with the words of Dr. Cullen, although the fluids of the human body may undergo various changes, we must “maintain that the nature of these changes is seldom understood, and more seldom still is it known when they have taken place; that the reasonings concerning them have been, for the most part, purely hypothetical; have therefore contributed nothing to improve, and have often misled, the practice of physic. In this, particularly, they have been hurtful, that they have withdrawn our attention from, and prevented our study of, the *moving powers* of the animal system, upon the state of which the phenomena of diseases do more certainly and generally depend.” First Lines, pref. p. xxxii.

HUMORISTS, *gli HUMORISTI*, the title of a celebrated academy of learned men at Rome. See *ACADEMY of Humorists*.

HUMOROSI, the name of an academy established at Cortona in Italy.

The Humorosi of Cortona must not be confounded with the Humoristi of Rome.

HUMOUR, or **HUMOR**, in its general sense, signifies the same as liquor, or liquid.

HUMOUR, in *Medicine*, is applied to any fluid part of the animal body, as to the blood, bile, mucus, serum, saliva, &c. as well as to the pus, sanies, &c. which result from disease. The ancient physicians, and after them the moderns down to a late period, considered health and disease as arising from a due proportion or disproportion of *four humours* in the body; namely, of blood, phlegm, yellow bile, and black bile. (See *GALEN*.) This doctrine, respecting the origin and nature of diseases, as dependent altogether on the state of the *humours* of the body, has been denominated the *HUMORAL Pathology*; which see.

HUMOURS of the Eye. Anatomists and opticians distinguish three particular humours of the eye (see *EYE*); which they call the aqueous, crystalline, and vitreous.

These three humours have each their share in the refraction of the rays of light necessary to vision.

Authors, both ancient and modern, speak of the regeneration of the humours of the eye; and give us instances of their reproduction, when, by any accident, they had been let out; but their instances, strictly considered, generally go no farther than to the aqueous and vitreous humours.

Borri only, in a letter to Bartholine, says as much of the crystalline. He affirms, that he has slit the pupil of the eye of divers animals, and squeezed out all the humours, even the crystalline, and has afterwards perfectly restored them again to sight; and that the eyes of the birds, whereon the operation had been performed, instead of being damaged thereby, were rendered more lively and vigorous than usual. He adds, that he had performed the same experiment on divers persons, with so much success, that there remained not the smallest appearance of a cicatrix in the eye. See *CATARACT*.

HUMOUR.

HUMOUR is also used, in *Dramatic Poetry*, for a subordinate species of what the critics call manners.

Humour is usually looked on as peculiar to the English drama, at least our comic poets have excelled therein, and carried it beyond those of any other nation; and our's is, perhaps, the only language that has a name for it. The nature of such a free government as our's; and that unrestrained liberty which our manners allow to every man, of living entirely after his own taste, afford full scope to the display of singularity of character, and to the indulgence of humour in all its forms. Hence comedy has a more ample field, and can flow with a much freer vein in Britain than in France, where a much greater uniformity has been spread, at least in former times, over the outward behaviour and characters of men, by the influence of a despotic court, subordination of ranks, and the rigid observance of the forms of politeness and decorum. As to our English dramatists, who does not acknowledge the transcendent excellence of Shakspeare in the province of humour? Of the later comic writers, Congreve has an exuberance of wit, but Farquhar has more humour. It has been observed, however, with too much truth, that, to the discredit of our stage, as well as of the national delicacy and discernment, obscenity has too often in English comedy been made to supply the place of wit, and ribaldry the place of humour. It should be acknowledged at the same time, that a considerable reformation has taken place in this respect.

Humour is usually considered by critics as a fainter or weaker habitual passion peculiar to comic characters, as being chiefly found in persons of a lower degree than those proper for tragedy.

Every passion may be said to have two different faces; one that is serious, great, formidable, and solemn, which is for tragedy, and another that is low, ridiculous, and fit for comedy; which last is what we call its humour.

Wit only becomes few characters; it is a breach of character to make one half the persons in a modern, or indeed in any comedy, talk wittily and finely; at least at all times, and on all occasions. To entertain the audience, therefore, and keep the dramatic persons from going into the common, beaten, familiar ways and forms of speaking and thinking, recourse is had to something to supply the place of wit, and divert the audience, without going out of character; and this end is attained by humour; which therefore is to be looked on as the true wit and humour.

A very good judge, the duke of Buckingham, makes humour, to be all in all; wit, according to him, should never be used, but to add an agreeableness to some proper and juil sentiment, which, without some such turn, might pass without its effect.

HUMOUR, or *continued wit*, in *Oratory*, is a certain sprightfulness and vivacity of thought, which runs through a discourse, and shews itself in agreeable images, beautiful turns, and a facetious manner of expression, suited to the subject, and affecting the hearers with pleasure and delight, though not to that degree as to excite laughter, or any great emotion of the passions.

The nature and efficacy of humour are unravelled by Dr. Campbell, in his "Philosophy of Rhetoric," in the following manner. A just exhibition of any ardent or durable passion, excited by some adequate cause, instantly attaches sympathy, the common tie of human souls, and thereby communicates the passion to the breast of the hearer. But when the emotion is either not violent or not durable, and the motive not any thing real, but imaginary, or at least quite disproportionate to the effect; or when the passion displays

itself preposterously, so as rather to obstruct than to promote its aim; in these cases a natural representation, instead of fellow-feeling, creates amusement, and universally awakens contempt. The portrait in the former case we call "pathetic," in the latter "humorous." The passion which humour addresses as its object is contempt; and the subject of humour is always character, but not every thing in character; its foibles, generally, such as caprices, little extravagancies, weak anxieties, jealousies, childish fondness, pertness, vanity, and self-conceit. In expressing passion as it appears in the more trivial occurrences of life, we commonly use this term, as when we talk of good humour, ill humour, peevish or pleasant humour; hence it is that a capricious temper we call humourfome, the person possessed of it a humorist, and such facts or events as afford subject for the humorous, we denominate comical. Accordingly, the term humour is used to express any lively strictures of such specialities in temper and conduct, as have neither moment enough to interest sympathy, nor incongruity enough to excite contempt. In this case humour, not being addressed to passion but to fancy, must be considered as a kind of moral painting, and differs from wit only in these two things; first, in that character alone is the subject of the former, whereas all things whatever fall within the province of the latter; secondly, humour paints more simply by direct imitation, wit more variously by illustration and imagery. Of this kind of humour, merely graphical, Addison hath given us numberless examples in many of the characters he hath so finely drawn, and little incidents he hath so pleasantly related in his *Tatlers* and *Spectators*. We might remark of the word *humour*, as well as of the term *wit*, that we scarcely find in other languages a word exactly corresponding. The Latin *facetia* seems to come the nearest. Thus Cicero, "Huic generi orationis aspergentur etiam sales, qui in dicendo mirum quantum valent; quorum duo genera sunt, unum facetiarum, alterum dicacitatis; uterque utroque, sed altero in narrando aliquid venustè, altero in jaciendo mitiendoque ridendo; cujus genera plura sunt." *Orator*. 48. Here one would think, that the philosopher must have had in view the different provinces of wit and humour, calling the former *dicacitas*, and the latter *facetia*: nevertheless these two words are often confounded both by him and other Latin authors.

Mr. Pope, in the second Canto of his "Rape of the Lock," has furnished us with an instance of wit and humour combined, where they reciprocally set off and enliven each other;

"Whether the nymph shall break Diana's law,
Or some frail China jar receive a flaw,
Or stain her honour, or her new brocade;
Forget her prayers, or miss a masquerade;
Or lose her heart, or necklace at a ball;
Or whether heaven has doom'd that Sheek must fall."

This is humorous, as it is a lively sketch of the female estimate of mischances, as our poet's commentator rightly terms it, marked out by a few striking lineaments. It is likewise witty, for not to mention the play on words like a trope familiar to this author, you have here a comparison of a woman's chastity to a piece of porcelain—her honour to a gaudy robe—her prayers to a fantastical disguise—her heart to a trinket;—and all these together to her *lip-dog*; and that founded on one lucky circumstance, (a malicious crime would perhaps discern or imagine more,) by which these things, how unlike soever in other respects, may be com-

pared, the impresson they make on the mind of a fine lady. Hudibras abounds in all the varieties of wit, nor is his poem destitute of humour, exhibited in the characters of the knight and his squire, and more especially in the consultation of the lawyer, part iii. canto 3. But there is perhaps no book in any language, in which the humorous is carried to a higher pitch of perfection, than in the adventures of the celebrated knight of La Mancha.

Humour, says Dr. Campbell, when we consider the contrariety of its effects, contempt and laughter, (which constitute what in one word is termed *derision*;) to that sympathy and love, often produced by the pathetic, may in respect of these be aptly compared to a concave mirror, when the object is placed beyond the focus: in which case it appears by reflection, both diminished and inverted, circumstances which happily adumbrate the contemptible and the ridiculous.

HUMOUR, *Crystalline, Diseas'd, and Opacity of*. See CATARACT.

HUMP, in *Geology*, is applied by Dr. Townson and others to express a sudden rising or bump in the terrestrial strata, in some instances, called ridges, horse-backs, &c. by practical miners. It seems probable, that many denuded patches of strata, like the limestone of *Crieh*, (see that article,) in Derbyshire, Breedon, and Cloud's-hill, in Leicestershire, Dudley Castle, Wren's-nest, and other adjacent hills in or near Staffordshire, &c. owe their origin to humps previously existing in the strata, thus locally exposed by the denudating or carrying off the thinner parts of the superincumbent strata, which covered these sudden limestone hills.

HUMP, *Naked, North-west, Scuth, and South-east*, in *Geography*, small islands in the Mergui Archipelago, in N. lat. 10° 23'—10° 19'—10° 9',—and 10° 12', respectively.

HUMPH, in *Mining*, signifies, in some parts of Scotland, a blind or foul sort of coal, of little value.

HUMPHREY, PELHAM, in *Biography*, was brought up with Blow and Mich. Wife, in the Chapel Royal, under Capt. Cook, who was appointed master of the children at the Restoration. When Humphrey lost his treble voice, he was admitted in 1666 a gentleman of his majesty's chapel, and on the death of Capt. Cook, 1672, was appointed master of the children. He did not, however, long fill this honourable station, as he died, very much regretted, at the early age of twenty-seven, in 1674.

His choral compositions are numerous for so short a life; as, besides his seven full and verse anthems, printed by Dr. Boyce, there are five preserved in score by Dr. Aldrich, in Christ-church, Oxford; and six in Dr. Tudway's collection, British Museum, that have never been printed.

As French music was much better known in England during the reign of king Charles II. than Italian, there are in the melody of this composer, and in that of Purcell, passages which frequently remind us of Lulli, whom king Charles pointed out to his musicians as a model. Indeed, it is said that Humphrey was sent to Paris by the king, in order to study under Lully; and that, besides his merit in composition, he was an excellent performer on the lute. Indeed, he seems to have been the first of our ecclesiastical composers who had the least idea of musical pathos in the expression of words, implying supplication or complaint.

His anthem for three voices, "Have Mercy upon me O God," has great merit on the side of expression, for the time in which it was composed, as well as harmony, in which there are several combinations that seem new

and boldly hazarded for the first time, at least in choral music.

In his verse anthems many new effects are produced by modulation and notes of taste and expression.

The favourite interval in the melody of this composer is the false 5th, and, if it be true, as related by Dr. Boyce, that Humphrey studied under Lulli at Paris, he probably acquired his partiality for this interval there, as it has long been in great favour in the serious French opera.

It is somewhat remarkable, that all the seven-verse anthems which Dr. Boyce has inserted in his collection, by this plaintive composer, should be in flat keys; most of them in C and F minor, which are much out of tune on the organ by the usual temperament of that instrument; however, if well sung, these crude chords may add to the melancholy cast of the compositions.

HUMPHREYS, LAURENCE, was born at Newport Pagnell, Bucks, about the year 1527. He was educated partly at Cambridge, and partly at Oxford. In 1549 he was admitted to the degree of B. A. and was elected fellow of Magdalen college, Oxford. In the year 1555 he obtained the permission of his college to travel for improvement for a year, on condition that he should avoid heretical company and places. This licence furnished him with means of withdrawing from the reach of queen Mary's persecution, and of pursuing his religious enquiries in company with men whose opinions were congenial with his own. He therefore wisely staid abroad till the death of the queen rendered his return safe. Upon his arrival in England, he was restored to his fellowship, which had been taken from him for his disobedience to the injunctions of the licence which had been granted him; in 1560 he was appointed the queen's professor of divinity at Oxford, and in the following year he was elected president of his college. He suffered a short imprisonment for refusing to take the sacrament in a kneeling posture, and though he was soon set at liberty, yet he got no preferment till he surmounted those scruples which amounted to non-conformity. After this he was created dean of Gloucester, and in 1580 he was removed to the deanery of Winchester, which was the highest preferment to which he ever attained. He died in 1590. His writings are very numerous, among which the following may be noticed: "Epistola de Græci literis et Homeri Læctione et Imitatione:" "De Religionis conservacione et reformatione deque primatu Regum:" "De ratione interpretandi Auctores:" "Optimates sive de nobilitate, ejusque antiqua Origine:" the Life of bishop Jewel, and sermons. Dr. Humphreys was a great and general scholar, an able linguist, and a deep divine.

HUMPHRIES, JOHN, a young English musician of promising abilities, and a good performer on the violin, published, before he was twenty years of age, six solos for that instrument, which manifested more genius than experience. However, they were well received by dilettanti performers, from being natural and easy. His success in that publication encouraged him to further attempts, and in the year 1728 he published, by subscription, twelve sonatas for two violins and a base, which had some originality and agreeable imitations of Corelli, that made them the delight of musical clubs and provincial concerts in our own memory.

Humphries died about the year 1730, and left in MS. twelve concertos on Corelli's model, which were printed after his decease, by Cooke, music-seller, in New-street, Covent Garden; but the more fanciful works of Vivaldi, Alberti, Taffarani, and Albinoni, being in circulation, and

the more solid productions of Handel and Geminiani having refined our taste, the posthumous work of poor Humphries followed him down the stream of Oblivion, unnoticed by the inhabitants of Earth.

HUMPOLETZ, in *Geography*, a town of Bohemia, in the circle of Crazlau; 8 miles S.W. of Teutsch-Brod.

HUMPPILA, a town of Sweden, in the province of Tavastland; 30 miles W. of Tavasthus.

HUMULUS, in *Botany*, the Hop. This name is derived by Linnæus from *humus*, moist earth, such as the plant in question prefers; but however ingenious this explanation may be, it appears that *Humulus* originated by corruption from *Humela*, a barbarous Latin word, of one common origin with *Urnula*, or *Huml*, under which appellations, or something like them, the hop is known amongst various nations of the north.—Linn. Gen. 522. Schreb. 689. Willd. Sp. Pl. v. 4 759. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1077. Juss. 404. Lamarck. Illustr. t. 815. (*Lupulus*; Gært. t. 75.)—Class and order, *Dioecia Pentandria*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juss.

Gen. Ch. Male, Cal. Perianth of five, oblong, concave, obtuse leaves. Cor. none. Stam. Filaments five, capillary, very short; anthers oblong, bursting by a pore on each side, at the summit.

Female, Cal. the scales of a catkin, ovate, large, tubular at the base, each containing two flowers, and at length scarious, permanent. Cor. of one petal, small, obtuse, lateral, enfolding the germen of each flower on one side. Pist. Germen small, roundish, compressed; styles two, very short; stigmas long, awl-shaped, downy. Peric. none, except the permanent scales and corolla. Seed one, roundish, with a spiral embryo.

Eff. Ch. Male, Calyx of five leaves. Corolla none. Anthers with two pores at the summit.

Female, Calyx the scales of a catkin, two-flowered. Corolla of one petal, lateral. Styles two. Seeds solitary, invested with the corolla.

1. *H. Lupulus*, the only species of this very natural and distinct genus. Linn. Sp. Pl. 1457. Engl. Bot. t. 427. Mill. Illustr. t. 88. Bulliard. t. 234.—Native of hedges and bushy places in a moist deep soil, in various parts of Europe, as well as in North America, blossoming in July. The roots are perennial, branching. Stems annual, twining, angular, rough, with deflexed prickles, leafy. Leaves opposite, stalked, heart-shaped, undivided or three-lobed, often five-lobed, serrated, veiny and harsh. Footstalks strong, angular, prickly. Stipules between the footstalks, reflexed, ovate, entire, smooth. Flowers green; the males paniced, numerous; females on a separate plant, in axillary, stalked, ovate, drooping catkins, of an aromatic scent, and bitter narcotic quality.

HUMULUS, in *Gardening*, comprizes a well-known plant of the more hardy, twining, perennial kind; of which the species is the cultivated hop (*H. lupulus*.)

There are plants of this kind which bear only male flowers, that grow in long clusters; and others which bear female flowers only, that are produced in roundish, scaly, and leafy clusters. The latter is the sort mostly grown; and which is distinguished into the early white, the long white, the oval, and the square garlic hop.

The hop-plant is principally grown in gardens, for the ornament and variety which it affords by twisting round different kinds of support to a very considerable height.

Method of Culture.—The hop is a plant which is usually increased by planting portions of the suckers taken from the

roots of the old stocks. They are commonly cut six or seven inches in length, each having three or four eyes or buds to throw out shoots from. And such as are of proper sorts should constantly be selected for this purpose, removing from each set every part of the old vine, as well as every portion that is hollowed or decayed in any way. The sets may be planted out in the autumn in any open place where the ground is well prepared and in a meilow condition.

The hop may also be raised by laying down the young shoots in the summer season, taking off their tops at the time the work is performed. These soon strike root, and form sets for use in the ensuing spring. See Hop.

Hop clumps have a good effect in many cases, in large gardens or pleasure grounds.

HUMUS, in *Natural History*, a term formerly used for the decayed vegetable and mineral mixtures, more commonly known by the name of virgin mould, and forming the superficial crust of the earth. Parkinson's Organic Remains, vol. i. p. 83.

HUN, in *Geography*, a town of Africa, in Fezzan; 20 miles N of Mourzouk.

HUNARY, two small islands near the W. coast of Hindoostan; 85 miles S. of Bombay. N. lat. 18' 47'. E. long. 72' 38'.

HUNAULD, FRANCIS JOSEPH, in *Biography*, an eminent anatomist and physician, was born at Chateau-Briant, in February 1701. His father was a physician, and practised at St. Malo. He studied first at Rennes, and afterwards at Angers and Paris, and received the degree of M. D. at Rheims in 1722. On his return to Paris he studied anatomy and surgery with great assiduity, under the celebrated teachers Winslow and Du Verney, and was admitted into the Academy of Sciences in 1724. Having been honoured with the appointment of physician to the duke of Richelieu, he accompanied that nobleman in his embassy to the court of the emperor Charles VI. at Vienna, and ever afterwards retained his entire confidence, and had apartments in his house. On the death of Du Verney, in 1730, Hunauld was appointed his successor, as professor of anatomy in the king's garden, where he soon acquired a reputation little short of that of his predecessor, and found the spacious theatre overflowing with pupils. Having been admitted a member of the faculty of medicine of Paris, he practised his profession with great success, and attracted the notice of the court. He took a journey into Holland, where he became acquainted with the celebrated Boerhaave, with whom he ever afterwards maintained a friendly correspondence; and, in 1735, he visited London, where he was elected a member of the Royal Society, at one of the meetings of which he read some "Reflections on the Operation for Fistula Lacrymalis," which were printed in the Transactions. He was cut off in the vigour of life by a putrid fever, in December 1742, being in his forty-second year. The greater part of his writings consist of papers, which were published in various volumes of the memoirs of the Academy of Sciences, between the years 1729 and 1742 inclusive. Osteology was a favourite subject of his enquiry, and some of the most curious of his observations relate to the formation and growth of the bones of the skull. He likewise traced with great accuracy the lymphatics of the lungs to the thoracic duct, and the progress of some of the nerves of the thoracic viscera. He published anonymously, in 1726, a critique, in the form of a letter, on his book of Petit, relative to the diseases of the bones, which occasioned some controversy, and received the formal disapproval of the academy. Hunauld had collected a considerable anatomical museum, which was especially rich in preparations illustrative of

of osteology and the diseases of the bones, and which came into the possession of the academy after his death. Eloy Dict. Hist. Gen. Biog.

HUNBERGS, in *Geography*, a town of Denmark, in North Jutland; 8 miles S.W. of Aalborg.

HUNDERBUHL, a town of Transylvania; 12 miles S. of Schesburg.

HUNDRED, *CENTUM*, *Cent.* the number of ten times ten or the square of ten.

The place of hundreds makes the third in order in the Arabic numeration.

We usually express the proportion of the profits made in the way of commerce, &c. by the hundred.

HUNDRED of Lins, a denomination of measure, in some places denoting 35, and in others 25 heaped bushels or bags of linc.

HUNDRED, in denomination of weights, of books is 104lb. avoirdupoise = .9285715 great cwts. (112) = .8684646 long cwts. (120.)

HUNDRED of Coals, at Asbourn, in Derbyshire, &c. = 128lb. = 8 stone of 16lb. = 1.142857 great cwts. = 1.0666 long cwts.

HUNDRED of Ling, Cod, &c. = 124lb. = 1.107143 great cwts. = 1.03333 long cwts.

HUNDRED, Great, or Standard, = 112lb. avoirdupoise = 112lb. = 4 quarters = 7 stone (of 16lb.) = 8 stone horseman's, (of 14lb.) = 14 stone, London (8lb) = 14 cloves (8b.) = 16 cloves (7lb.) = 1792 ounces avoirdupoise = 20,672 drams = .93333 long cwts. (120lb.) = 103lb. 2½oz. Dutch Scotch weight. This is the legal hundred-weight of the custom-house in London, and all the southern parts of England.

HUNDRED, Long, or Northern, = 12clb. = 8½ stones (14lb.) = 12 rations (10lb.) = 1.0714286 great cwts. (112lb.) This is the hundred-weight legalized on all or most of the canals and navigable rivers in the north of England, and of the midland counties; by their acts for collecting tolls, &c.

HUNDRED is also used as a measure to express a certain quantity or number of things. A hundred of salt at Amsterdam is fourteen tuns.

Deal boards are sold at six score to the hundred, called the *long* hundred. Pales and laths are counted at five score to the hundred, if five feet long; and six score if three feet long.

HUNDRED Weight, or the great hundred. See **QUINTAL**.

HUNDRED, Decimastie. See **CENTNER**.

HUNDRED, Hundredum, Centuria, is also a part or division of a shire or county. It was so called, according to some, because each hundred found a hundred shield-bearers, or sureties of the king's peace, or a hundred able men of war.

Others rather think it to have been so called, because originally composed of a hundred families. It is true, Brompton tells us, that a hundred contains *centum villas*; but then Giraldus Cambrensis writes, that the isle of Man hath three hundred and forty-three villas. In both these places the word *villa* must be taken for a country family; for it cannot mean a village, because there are not above forty villages in that island.

So, where Lambard tells us, that a hundred is so called, *a numero centum hominum*, it must be understood of a hundred men who are heads and chiefs of so many families. Hundreds were first ordained, or rather introduced, by king Alfred, the twenty-ninth king of the West Saxons: "Alfredus rex (says Lambard, verbo *centuria*) ubi cum Guth-

rano Dano fœdus inierat, prudentissimum olim a Jethrone Moisi datum fecutus concilium, Angliam primus in satrapias, centurias, et decurias partitus est. Satrapiam, shyre, a *Scyrian* (quod partiri significat) nominavit, centuriam *hundred*; et decuriam teaching five tiennantale; i. e. decemvirato collegium, appellavit; atque iisdem nominibus vel hodie vocantur, &c." See **COUNTY** and **TITHING**.

We have already said that the institution of hundreds was rather introduced than invented by Alfred. For they seem to have obtained in Denmark; and we find that in France a regulation of this sort was made above 200 years before; set on foot by Clotharius and Childbert, with a view of obliging each district to answer for the robberies committed in its own division. These divisions were, in that country, as well military as civil; and each contained 100 freemen, who were subject to an officer called the *centenarius*; a number of which *centenarii* were themselves subject to a superior officer called the *count* or *comes*. (Montesq. Sp. Laws. 30. 17.) And indeed something like this institution of hundreds may be traced back as far as the ancient Germans, from whom were derived the Franks, who became masters of Gaul, and the Saxons who settled in England; for both the thing and the name, as a territorial assemblage of persons, from which afterwards the territory itself might probably receive its denomination, were well known to that warlike people. "Centeni ex singulis pagis sunt, idque ipsum inter suos vocantur; et quod primo numerus fuit, jam nomen et honor est." Tacitus de Mor. Germ. 6.

Such is the original of hundreds, which still retain the name, though the jurisdiction be devolved to the county-court; some few excepted, which have been by privilege annexed to the crown, or granted to some great subject, and so remain still in the nature of a franchise.

This has been ever since the stat. 14 Edw. III. whereby these hundred courts, formerly farmed out by the sheriff to other men, were all, or most part, reduced to the county-court, and so remain at present; so that where we read now of hundred-courts, they are to be understood of several franchises, wherein the sheriff has nothing to do by his ordinary authority, except they of the hundred refuse to do their office. See **Hundred COURT**.

If any homicide be committed, or dangerous wound given in the day-time, and the offender escape, the town shall be amerced. And if out of a town the hundred shall be amerced. (2 Hawk. 74.) The hundred shall also make good the damage in case of robbery (see **HUE-AND-CRY**), cutting banks or hop-binds; burning houses, barns, out-houses, hovels, cocks, mows, or stacks of corn, straw, hay, or wood; mines or pits of coal; destroying granaries or corn intended for exportation; destroying turnpikes or works of navigable rivers, &c. 1 Geo. I. cap. 5. 9 Geo. I. cap. 22. 29 Geo. II. cap. 36. 8 Geo. II. cap. 22. 10 Geo. II. cap. 32. 11 Geo. II. cap. 22. 22 Geo. II. cap. 46.

HUNDRED, or *Hundredum*, is sometimes also used for an immunity or privilege, whereby a man is quit of the hundred-penny, or custom, due to the hundred.

HUNDRED-court. See **COURT**.

HUNDRED Lagb, signifies the hundred court, from which all the officers of the king's forest were freed by the charter of Canutus.

HUNDRED Suit, the payment of personal attendance, or rendering suit and service at the hundred court.

HUNDREDERS, or **HUNDREDORS**, *Hundredarii*, are men impanelled, or fit to be impanelled, of a jury, upon any controverted,

controversy, dwelling within the hundred where the land in question lies.

By the policy of the ancient law, the jury was to come *de vicineto*, from the neighbourhood of the vill or place where the cause of action was laid in the declaration; and therefore some of the jury were obliged to be returned from the hundred in which such vill lay; and if none were returned, the array might be challenged for defect of hundredors. This was supposed to qualify those who composed the jury for forming a proper judgment of the evidence adduced, as they were supposed to know before-hand the characters of the parties and witnesses. But this convenience was overbalanced by another very natural and almost unavoidable inconvenience; that juries coming out of the immediate neighbourhood, would be apt to intermix their prejudices and partialities in the trial of rights. This our law has been so sensible of, that for a long time it has been relinquishing this practice; the number of necessary hundredors in the whole panel, which in the reign of Edward III. were constantly *six*, being in the time of Fortescue reduced to *four*. Afterwards, indeed, the statute 35 Hen. VIII. c. 6. restored the ancient number of *six*, but that clause was soon virtually repealed by statute 27 Eliz. c. 6. which required only *two*. And sir Edward Coke also (1 Inst. 157.) gives us such a variety of circumstances, whereby the courts permitted this necessary number to be evaded, that it appears they were heartily tired of it. At length by statute 4 & 5 Ann. c. 16. it was entirely abolished upon all civil actions except upon penal statutes; and upon those also, by the 24 Geo. II. c. 18. the jury being now only to come *de corpore comitatus*, from the body of the county at large, and not *de vicineto*, or from the particular neighbourhood. See **ARRAY** and **CHALLENGE**.

HUNDREDER is also used for him who hath the jurisdiction of a hundred, and holds the hundred-court. See **HEAD-BOROUGH**.

Sometimes it is also used for the bailiff of a hundred. See **BAILIFF**.

HUNDREDS, in the construction of reeds for weavers, denote the number of divisions in any given length of the reed. A thorough knowledge of the adaptation of yarn of a proper degree of fineness to any given measure of reed constitutes one of the principal arts of the manufacturer of cloth, as upon this depends entirely the appearance, and in a great degree the durability of the cloth when finished. The art of performing this properly is known by the names of *examining*, *setting*, or *fleying*, which are used indiscriminately, and mean exactly the same thing. The reed consists of two parallel pieces of wood of any given length, as a yard, a yard and quarter, &c. The divisions of the yard being into halves, quarters, eighths and sixteenths, the breadth of a web is generally expressed by a vulgar fraction, as $\frac{3}{4}$, $\frac{1}{2}$, $\frac{2}{3}$, &c. and the subdivisions by the eighths or sixteenths or *nails*, as they are usually called, as $\frac{1}{8}$, $\frac{2}{8}$, $\frac{3}{8}$, &c. or $\frac{1}{16}$, $\frac{2}{16}$, $\frac{3}{16}$, &c. In Scotland the splits of cane which pass between the longitudinal pieces or ribs of the reed are expressed by hundred porters or splits. The porter is 20 splits, or $\frac{1}{5}$ th of an hundred. In Lancashire, Cheshire, and the other manufacturing counties of England, the divisions of the reed are different. A comparative table of the differences by which they are reduced, to the same standard as nearly as is possible, that is to say, within one split or division by which the Scotch or English manufacturer may at one glance ascertain the relation which the other modes of counting reeds bear to his own, is annexed to this article. In counting reeds by the number of hundreds in a determinate length, which is com-

mon to the manufacturers of the continent, as well as to those of Scotland, different lengths are used for the standard of fineness. In that part of France situated around Cambray, which is, or was, the principal seat of the cambric manufacture, the standard length of a reed, by which the fineness of the splits is ascertained, is 34 inches. In Holland, where the heavier fabrics of linen are chiefly produced, the standard of measure is 40 inches, and in Scotland the standard is 37 inches, or the Scottish ell. Now it is plain, that if 2000 or twenty hundred divisions or splits be contained in each of these respective measures, those which are contained in 34 inches must be finer and closer than those contained in 37, and still more so than those contained in 40. For the practical purposes of manufacture in this country it can be of little importance to ascertain with precision the relative proportions which these standards bear to each other, but to the wholesale purchaser it must be useful to have some correct idea of the mode by which both the value and quality of the commodity which he purchases may be ascertained with considerable precision merely by inspection.

In Lancashire and Cheshire a different mode is adopted both as to the measure and divisions of the reed. The Manchester and Bolton reeds are counted by the number of splits, or, as they are there called, dents contained in $24\frac{1}{2}$ inches of the reed. These dents, instead of being arranged in hundreds, porters, and splits, as in Scotland, are calculated by what is there termed *bars* or *wars*, each containing 20 dents, or the same number as the porter in the Scotch reeds. Formerly the number of dents in a *lare* was frequently 19, a number so ill calculated for any easy arithmetical calculation, that it is difficult to conjecture the causes which could have suggested its adoption, unless we suppose that the number 19, in place of 20, was adopted to leave room for the shrinking-in breadth when first immersed in any liquid, to which all newly woven cloth is liable. The Cheshire or Stockport reeds again receive their designation from the number of ends or threads contained in one inch, two ends being allowed for every *dent*, that being the almost universal number in every species and description of plain cloth, according to the modern practice of weaving, and also for a great proportion of the fanciful articles. The number of threads in the warp of a web is generally ascertained with considerable precision by means of a small magnifying glass fitted into a socket of brass, under which is drilled a small round hole in the bottom plate of the standard, the number of threads visible in this perforation ascertaining the number of threads in the standard measure of the reed. Those used in Scotland have sometimes four perforations over any one of which the glass may be shifted. The first perforation is $\frac{1}{4}$ of an inch in diameter, and is therefore well adapted to the Stockport mode of counting, that is to say, for ascertaining the number of ends or threads per inch. The second is adapted for the Holland reed, being $\frac{1}{5}$ th part of 40 inches. The third is $\frac{1}{5}$ th of 37 inches, and is adapted for the now almost universal construction of Scotch reeds, and the fourth, being $\frac{1}{5}$ th of 34 inches, is intended for the French cambrics. Every thread appearing in these respective measures, of course, represents 200 threads or 100 splits in the standard breadth, and thus the quality of the fabric may be ascertained with considerable precision, even after the cloth has undergone repeated wettings, either at the bleaching ground or dye work. By counting the other way, the proportion which the wool bears to the warp is also known, and this forms the chief use of the glass to the manufacturer and operative weaver, both of whom are previously acquainted with the exact measure of the reed.

Compara-

Comparative Table of 37-inch reeds, being the standard used throughout Europe, for linens, with the Lancashire and Cheshire reeds, and the foreign reeds used for Holland and Cambric.

Scotch.	Lancashire.	Cheshire.	Dutch Holland.	French Cambric.
600	20	34	550	653
700	24	38	650	761
800	25	44	740	870
900	30	50	832	979
1000	34	54	925	1089
1100	36	60	1014	1197
1200	40	64	1110	1300
1300	42	70	1202	1414
1400	46	76	1295	1464
1500	50	80	1387	1602
1600	52	86	1480	1752
1700	56	92	1571	1820
1800	58	96	1665	1958
1900	62	104	1757	2067
2000	66	110	1850	2176

In the above table the 37-inch reed is placed first. It is called Scotch, not because it either originated, or is exclusively used, in that country. It is the general linen reed of all Europe, but in Scotland it has also been adopted as the regulator of her cotton manufactures. In the table it is only compared with the nearest English reed actually in use, for in most cases there is some small difference, which, however, is not material for practical purposes. For the Holland and cambric reeds, the exact number of splits or dents is given merely for comparison, as these reeds are not at all used in Britain.

The art of proportioning the yarn to the reeds, for different fabrics, has been always regulated by the practical experience of the manufacturer, and the taste or fancy of his customers. Some attempts have been made to reduce it to a standard, and it is evidently a matter of no difficulty. Without analyzing particularly the plans which have been proposed, and the arguments for and against each of them, it seems that the following may, in general, be taken as a good approximation.

Every species of yarn used in the manufacture of cloth, may be assumed to be a cylindrical body of stuff of a certain diameter. Now as the area of every circle is as the square of its diameter, and as the cubical content of every cylinder is found by multiplying the area of its base by its height, we may reasonably infer, that if the diameter of a thread is squared, and that square multiplied by its length, it will give the solid content, and *vice versa*; that the square root of the number which ascertains the weight of yarn, is a symbol of its diameter. If this be granted, it follows, that when any particular denomination of yarn is found to produce a proper fabric of cloth when woven in a reed of any given dimension, the proper denomination for any other reed may be found. Or if the yarn is at hand, and the proper reed wanted, it may be found by exactly the converse of the former analogy. Upon this hypothesis the analogy will be

As the square root of the given yarn,
Is to the given dimensions of the reed;
So is the square root of another kind,
To the dimensions of the reed required.

But as few practical manufacturers or weavers are accustomed to the extraction of roots, the real description of the yarn may be taken, and the reed squared, or multiplied into itself, which will give exactly the same result. It may be necessary to observe, however, in this place, that as the fineness of cotton yarn is ascertained by progressive numbers; and that of most other kinds of yarn, by the weight of certain quantities, the proportion or analogy in the former case must be direct, and in the latter inverse, because a diminution of weight in a given quantity necessarily implies an increase of fineness. The two following examples will, it is hoped, render this sufficiently obvious.

If a manufacturer finds, by experience, that a fabric of goods, such as please his customers, is produced by weaving N 60 of cotton yarn in a reed of 1200 by the linen or Scotch reed, and wishes to ascertain what description of yarn he ought to employ for a web to be woven in a 1500 reed; the proportion will be

As 144, the square of the 1200 reed,
Is to 60, the number of the given yarn,
So is 225, the square of the 1500 reed,

To 94, the nearest integral number by calculation.

In the converse he would find the square of the reed, and would still find extraction of the root necessary.

But if a manufacturer of linen finds that a fabric of yarn, of any number of ounces to the spindle, is well adapted to a 1200 reed, and wishes to ascertain the weight or denomination of yarn fit for a 1500 reed as before, his proportion must be inverted.

The chief objection which practical men are apt to make to the above theory of adaptation, which is perhaps the best that has hitherto been found, is the following. That in finer fabrics of goods it is not found to produce the desired effect, and that experience proves, that were a practical manufacturer of cloth to adopt this rule implicitly, either his fine goods would be wanting in that show and elegance which is their chief recommendation, or that his coarse articles would be flimsy and deficient both in warmth and durability. Allowing to this objection, which is unquestionably well founded, in some respects, all the weight which it deserves, the answer to it is very easy. The chief recommendations of coarse goods are thickness and strength, those of fine goods lightness and elegance. These are not, nor can be regulated by any exact mathematical rule, as they are much dependant on fancy. No lady would expect, in a fine dress, the strength and durability of a sack, nor would any miller store his flour in a bag, possessing the principal requisites of a sieve. It is sufficient, if the manufacturer is enabled to obtain a fair proportion for the real fabric, and this he must afterwards vary, to suit his goods to the market for which they are intended.

HUNDSHUBEL, in *Geography*, a town of Saxony, in the territory of Erzgebirge; 23 miles S.S.W. of Chemnitz.

HUNDSMARCK, a town of the duchy of Stiria, on the Muehr; 14 miles W S.W. of Jadenburg.

HUNDSRUCK, a district of Germany, between the Rhine, the Moselle, and the Nahe; now a part of France.

HUNE, LA, a bay on the S. coast of Newfoundland; 90 miles E. of cape Ray.

HUNEFELD, a town of Germany, in the bishopric of Fulda; eight miles N.N.E. of Fulda.

HUNERWASSER, a town of Bohemia, in the circle of Boleslau; 10 miles N. of Jung-Buntzel.

HUNG-TEAP, a term applied in some districts to a small ram,

ram, in contradistinction to that of a *close-stap*, or one whose testicles are not come properly down into the cod. It is proper to attend well to these states of male sheep. See RAM.

HUNGARIAN MACHINE, in *Hydraulics*, is represented in *Plate XIII. Hydraulics, fig. 1.* In this figure, AA is the side of a hill close by the brink of the shaft or mine-pit BB, which is 104 feet deep below the surface of the ground C at the foot of the hill. In this hill is a large spring of water, 143 feet above the surface of the ground at C (taken in perpendicular measure) and the spring affords much more water than what the spring D, under ground, lets into the mine.

A pipe EFG lets the water down from the spring in the hill, into a close air-tight vessel H that stands at the foot of the hill, and contains 57½ cubic feet, or 430 gallons in wine measure. In this pipe is a cock *a*, which being opened or shut, lets the water of the spring run into H, or stops it, as occasion requires: and in H are two cocks *b* and *c*, the uppermost of which is for letting air into H, and the lowermost for letting the water out of it.

A small pipe I goes from the vessel H on the surface of the ground to a vessel K, in the bottom of the mine, and terminates in the top thereof. The vessel is air-tight, and contains 27½ cubic feet, or 205½ gallons in wine measure, which is forced up the ascending pipe LM, and runs off to waste, at N, above ground. The lower end of this pipe goes down so far into the vessel K, as almost to touch its bottom.

From this vessel, a pipe O goes to the spring D under ground, which lets water into the mine, and would overflow it if the water was not forced up or raised from the mine through the pipe LM. The pipe O lets this water into the vessel K when the cock *d* is turned open, and keeps back the water when the cock is shut,

The operation is as follows: the cock *b* being open, and the cocks *a* and *c* shut, and no water in the vessel K, open the cock *d* to let the vessel K fill with water from the spring in the mine. As this vessel fills, the water will drive the air out of it, up through the small pipe I into the vessel H, and all that air will go out of the vessel H by the open cock *b*, and then H will remain, as it was before, full of air in the same state of density as the common air is on the outside of H. When K is full of water, shut the cocks *b* and *d*, and open the cock *a*, to let water run down from the spring in the hill by the pipe EF, into the vessel H. As the water rises in that vessel, the air will thereby be driven out of it, down through the pipe I, into the vessel K: and as this air is compressed by the weight of the running water in the pipe EF, the compressed air will force all the water out of the vessel K, up through the pipe LM, from which it will run off at N on the surface of the ground; and then the compressed air will rush out, after the water.

When the vessel K in the mine is emptied of water, and the air is heard to begin to rush out, shut the cock *a* to stop the water from the spring, and open the cocks *b* and *c*: then the water that came from the spring will run out of the vessel H by the cock *c*, and air will go in by the cock *b*: at the same time, open the cock *d* in the mine to let the vessel K fill with water from D the spring in the mine; and as H empties above-ground, K will fill below it; and the air that remained in K will (by the rising of the water in it) be driven back into the vessel H through the pipe I.

When H is empty of water, and K full, shut the cocks *b*, *c*, and *d*, and open the cock *a*: then H will fill with water from the spring in the hill; and this water, as it rises in H,

will force the air out of H, down the pipe I, upon the water in K; and the force of the compressed air will drive all the water out of K, up the pipe LM, from which it will run off at N, as before.

And thus, wherever there is a spring in a hill, near a mine that affords more water than what flows into the mine from a spring under-ground; and the perpendicular height of the spring in the hill is greater than the depth of the mine, water may be thus raised from the mine, in a most simple and easy manner by an engine in which there are neither pumps, pistons, nor valves: and such an engine will not be liable to be out of order, nor need repairs in many years.

But as there are very few mines that have hills near them with high springs, water cannot then be raised from them in this manner; and therefore Mr. Blakey proposed another method, which was, to make H an air-vessel, with a pipe going from it to another vessel in which is water, kept boiling by a fire under it, and this vessel to have a cock to let out the steam occasionally that rises from the surface of the boiling water. When the cock is shut, the steam will go off from the boiler into the air-vessel H, and drive the air out of it, down through the pipe I into the vessel K in the mine: and the force of the air compressed by the elasticity of the steam, will raise the water from K, up through the pipe LM, till K be emptied of water. Then the cock in the boiler is to be turned open, to let out the steam, and the cock *d* to be opened to let the vessel K fill from the spring in the mine; and when it is full, both these cocks are to be shut, and the operation will go on as before.

That Blakey's scheme would do, the Hungarian machine puts beyond all doubt. In both of them the vessels must be made very strong, because every part of each vessel, equal in surface to the bore of the ascending pipe LM, will sustain an outward pressure equal to the whole weight of water in that pipe. It will not answer for such depths as the common fire-engine will, nor will it raise so much water; but it may be built for less than a third part of the expence, and would answer very well where the depth is not above a hundred feet.

HUNGARIAN MUSIC. There is no doubt (says Mr. Laborde) but that the Hungarians, in abandoning Asia, about the ninth century, in order to inhabit Europe, made use of Asiatic musical instruments during their first year's residence there.

These were almost all wind instruments; of which their names, that still retain their Hungarian appellations, and are of that kind, is a proof. As the trumpet, *buccina*, is called *kurt* in the Hungarian dialect, and the flute, *flp*, &c. Other instruments have names, derived from other languages, as *izimlalom* signifies cymbalum; *orgona organum*; *trombita tuba*. All these words are of Greek, Latin, or German extraction, whence we conclude that the Hungarians, in quitting Asia, had only wind-instruments. If they had had others, they would have had words to express them. We see likewise that the pike, the bow, arrow, and sabre, are the only arms of which the names are Hungarian, as these were the only arms which this people knew when they arrived in Europe: their other military weapons are expressed by foreign words.

Hungarian music remained in its pristine state of mediocrity till the reign of Corvinus, who was proclaimed king of Hungary at the age of 15, in 1458, and afterwards conquered the kingdom of Bohemia, and died at 47, in 1490.

This prince rendered Hungary equal to other countries in arts and sciences, by his patronage and by cultivating them himself. The pope's nuncio, who came to Buda in 1483,

to make peace between the emperor Frederic and Corvinus, in a letter to his holiness, says, "the fingers of this prince's chapel are the best of all those I have ever heard."

Music was cultivated with the same ease under king Ladislaus VI. and Lewis II., but not with the same pomp, the number of the musicians of the household was considerably diminished. It appears likewise by the state of music which is still preserved, that wind instruments have the precedence over all others.

The Hungarians, like all people not quite civilized, had tunes without time or key, to which they sung their coarse national ballads without harmony; however, though almost all uncultivated people love high tones and noisy music of a light and vulgar cast, the Hungarians preferred soft sounds and slow measures: which has rendered their music more of the feminine than the masculine gender. And we still see among the peasants who preserve their primitive manners longer than the higher orders of the people, that the girls assemble on great festivals, and sing in chorus odes and ancient poetry, which is never done by boys. Men, however, cultivated music: but it was only to celebrate the prowess of their ancestors in patriotic songs. It is related that in a repast given by Attila, the Euckelinus, or director of the music, had a seat on the right hand of the throne; and that after the service two men sung verses composed in honour of Attila's victories. Part of the audience wept, and, adds the historian, the rest grew furious and desired to be led to battle. Two stanzas of these songs have been preserved in their original language, and in Latin, to the following purport.

"Let us ever remember those ancient domains,
Which our ancestors left when they flew
To a climate more mild, from the Scythian plains,
Where dread mountains of snow are in view.

"To Hung'ry they hasten'd, with God for their guide,
And chose Transylvania for home;
Be their force and their courage for ever our pride,
But, like them, let us ne'er again roam."

The knowledge of music was introduced into Hungary by the Christian religion and belles lettres.

As to the time when music was first in use at court, there appears, in a diploma granted by king Bela III. in 1192, that a person was sent to Paris of the name of Elvin, to learn the French melody.

It likewise appears in the Journals of the kings of Hungary, that the Hungarians, who came from Asia into Europe, brought to their new habitations the Asiatic manners, airs, dances, and songs; but that in process of time they cultivated the music and dancing of the neighbouring nations of Europe, till at length these two arts, practised by the sovereigns themselves, were held in great favour throughout the kingdom of Hungary. *Essais sur la Musique.*

HUNGARICA BOLUS, in the *Materia Medica*, a medicinal earth, commonly known by the name bolus Toccavensis.

HUNGARICUS MORBUS, or *Febris Hungarica*, the Hungarian disease, an epidemic and fatal fever, which originated in the camp of the emperor Maximilian II. in Hungary, in the year 1566, and spread through the greater part of Europe, causing every where a terrible mortality, and almost depopulating Vienna, where the returning army halted in order to recruit. In some instances it seems to have put on the form of a remittent fever; but in general was a severe and malignant typhus, resembling the hospital or goal fever. (See FEVER and TYPHUS.) Consult Sennert. lib. iv. cap. 14. De Morbo Hungarico. Ruland. De Lue Hungarica:—

Jordan, De Pestis phœnom. cap. 19. Pringle on Dis. of the Army, part iii. chap. 4. § 4.

HUNGARY, in *History and Geography*, a country of Europe, formerly regarded as an independent kingdom, is bounded on the north by Poland, from which it is separated by the Carpathian mountains, on the east by Transylvania and Wallachia, on the south by Slavonia, and on the west by Moravia, Austria, and Stiria. Many authors comprehend under the general name of Hungary, Slavonia, Dalmatia, Bosnia, Servia, Transylvania, Moldavia, and Wallachia. The ancient inhabitants of the western parts of Hungary were Pannonians, those of the northern Jazygians. The Romans reduced Pannonia, and kept it almost 400 years, till they were driven out by the Vandals, who held it till the year 395, when the Goths took possession of their settlements, who, in their turn, yielded to the Huns. In the year 888, the Huns, under the name of Hungarians, made another irruption into Pannonia, against the Bulgarians and Slavonians, whom they reduced. They had seven commanders, and Germany and many parts of Italy felt the effects of their savage ferocity. By degrees they became more civilized, and in the 10th century their prince Geyza embraced the Christian religion. His son Stevin was the first king of Hungary, and he completed the establishment of the Christian religion about the year 1000. He erected bishoprics, abbeys, and churches; annexed Transylvania as a province to Hungary, and at his death he was canonized. After him followed a succession of kings, natives of the country, of whom may be mentioned Andrew II. who conferred great privileges on the nobility, and even empowered them to oppose the king if he should attempt any thing hostile to the laws of the country. In 1342 Louis I. furnished the Great, subdued a part of Dalmatia, and carried his arms into Italy. He was succeeded by his daughter Mary, who was styled King of Hungary. She died in 1392, and the succession, which was some time controverted, at length terminated in the election of Sigismund, marquis of Brandenburg, who, in 1411, was chosen emperor of Germany. Albert of Austria, having married Elizabeth the heiress of Sigismund, was, with her, crowned king and queen of Hungary in 1438, an event which is said to form the earliest basis of the Austrian claim to the Hungarian monarchy. Upon the death of Albert, Ladislaus, king of Poland, was chosen king of Hungary, but perished in the battle of Werna against the Turks. The celebrated John Hunniades was appointed regent of the kingdom. In 1458 Matthias Corvinus, son of Hunniades, was proclaimed king of Hungary by the states, and in 1485 he seized Vienna, and the other Austrian states, and retained them till his death in 1490. Matthias was the most renowned prince that ever sat on the Hungarian throne: he was the friend and patron of letters, and founded a magnificent library at Buda, and furnished it with the best Greek and Latin books, and many valuable manuscripts. After repeated contests, the house of Austria again filled the throne of Hungary, in the person of Ferdinand, 1527, but towards the end of his reign the Turks seized the greater part of this kingdom. On his being chosen emperor of Germany, Ferdinand retained the crown of Hungary till 1563, when he resigned it to Maximilian his son; and it has since continued a constant appanage of the house of Austria. The grand duchy of Transylvania was considered as a part of Hungary till the year 1540, when it began to be regarded as a distinct state. Stephen Batori was elected prince of Transylvania in 1571, and his family held the sovereignty till 1602, after which it continued subject to several elective princes, of whom the most distinguished was Bethlem Gabor, a noble Hungarian and Calvinist, who conquered great part

of Hungary in 1619, and died in 1629. The last prince of Transylvania was Michael Abaffi, who gave up the sovereignty to the emperor in 1694, since which period this country has formed a part of the Austrian dominions. In the year 1722, in the diet of Presburg, the hereditary succession of Hungary was secured to the house of Austria, and in case of failure of male heirs, it was enacted that females should be capable of holding the crown. Such are the historical epochs of this country. With respect to its surface, it is mountainous and barren towards the north: the air is cold but healthy. Towards the Danube the soil is level and sandy, and the climate very temperate. In the south the marshes are hot, moist, and unwholesome. Hot days, with cold nights, and habitual intemperance, occasion diseases, particularly what is called the Hungarian fever. The level country bears abundance of corn, excellent fruit, and almost all kinds of vegetables. The forests are beautiful, and the meadows feed numerous herds of cattle. The sides of the mountains are covered with vines, and in their bowels are found all kinds of metals and mineral substances. The chief mountains are the Carpathian or Crapack: the principal rivers are the Danube and Drave. The Hungarians and Slavonians are regarded as the only native inhabitants, though the Croats, Russians, Walachians, Vandals, Greeks, Jews, and Turks, likewise abound. Protestants are more numerous than Roman Catholics. Hungary is governed by the king and states: the latter are divided into four classes; to the first belong the prelates and other high orders of the church: to the second class belong the great barons, bans, or viceroys: to the third class belong the gentry, and to the fourth the royal free cities. Upon every view of the subject there appears to be between seven and eight millions of inhabitants, which are about one-third of the population of the Austrian dominions, and it yields about one-fifth of the whole revenue. The annual exports are equal in value to 1,600,000*l.* sterling, and its imports to little more than a million. The standing military force amounts to nearly ninety thousand men. Presburg is the capital. The Hungarians are tinged with the manners of the Germans, but they remain a spirited people, and affect to despise their masters. The nobility are numerous, well informed, and warlike. Their lands owe their sovereigns no service. The peasant possesses nothing, he can be nothing but a farmer, and the proprietor can dismiss him at his pleasure. Anciently the peasants might change their masters; they cannot do so now: they once had particular tribunals to which they might have recourse, but this privilege is no longer allowed. The Hungarian dress is well known to be peculiar, and is copied by our hussars. This dress, consisting of a tight vest, mantle, and furred cap, is graceful; and the whiskers add a military ferocity to the appearance. The languages spoken are numerous and discrepant: they belong chiefly to three grand divisions; the Gothic or German; the Slavonic; and lastly, the Hungarian proper, which has been considered as a branch of the Finnic.

HUNGARY-Town, a post-town of America, in Lunenburg country, Virginia; 215 miles from Virginia.

HUNGARY Water, Aqua Hungarica, a distilled water, so denominated from a queen of Hungary, for whose use it was first prepared, and who was cured by the continued use of it, of a paralytic disorder.

Hungary-water is one of the distilled waters of the shops; and is directed in the college dispensatory, to be made of rosemary flowers infused some days in rectified spirit of wine, and the spirit then distilled. The college of Edinburgh directs a gallon of rectified spirit to be drawn over in the heat of a water-bath from two pounds of the flowers as soon

as they are gathered; that of London takes the tops and a spirit not quite so strong; putting a gallon of proof spirit to a pound and a half of the fresh tops, and drawing off in the heat of a water-bath five pints.

It is an agreeable perfume, and its virtues are much the same as those of the simple it is drawn from. The Hungarian water brought from France is more fragrant than such as is generally prepared among us.

HUNGEN, in *Geography*, a town of Germany, in the circle of the Upper Rhine, and county of Solms-Braunfels; 14 miles S.E. of Wetzlar.

HUNGER, FAMES, a natural appetite or desire for food. For the symptoms, proximate cause, &c. of hunger, see *DIGESTION*. See also *ABSTINENCE, BULIMY, DIET, &c.*

HUNGER, in *Biography*, in 1772 organist of the Duomo, or Frauen-Kirche, at Dresden, of which church the organ was built by Silbermann, and is regarded as one of the largest and most complete in Germany. The longest pipe in the pedals is 32 feet, and there are 48 stops.

Though M. Hunger possessed neither great fancy nor finger, his performance was truly masterly, and manifested a perfect knowledge of his instrument.

HUNGER Creek, in *Geography*, a stream which supplies the water-machinery in the new and thriving manufacturing town of Hamilton, between Albany and Schenectady.

HUNGER Rot, the name of a morbid affection in sheep, which is commonly produced by poor stunted keep, especially in the winter season. It is known with facility by the peculiar appearance of the sheep, which becomes extremely thin, lean, ragged, and emaciated. The principal means of restoring such animals, are those of changing them to drier pastures, and the gradual introduction of them into those of richer and better kinds. See *ROT*.

It is sometimes termed the hunger, or hungry evil.

HUNGERFORD, in *Geography*, is a market-town and parish, situated principally in the hundred of Kintbury Eagle, in the county of Berks, England, though a considerable part of the parish is in the hundred of Kinwardstone, in the adjoining county of Wilts. The town stands on the banks of the river Kennet, near the road from London to Bath. Its ancient name, according to Camden, was Ingleford-Charnam-street; which Gough supposes to be a corruption from the ford of the Angles on Herman-street; a Roman road that crosses the town, the name of which appears to be yet preserved in one of its avenues, called Charman-street. The name of Hungerford, as now spelt, occurs in a record of the year 1204. At some distance west of the town is the church, an ancient structure, which appears to have been erected at different periods. It contains some old monumental memorials to the family of Hungerford, who derived their name and origin from this town. The civil government of Hungerford is vested in a constable, who is assisted in the execution of his office by twelve feoffees and burgesses, a bailiff, steward, town-clerk, &c. The market, which is on Wednesdays, has been held from time immemorial; it is mentioned as an established market in a record dated 1297. The market-house and shambles, which were erected in 1787, are roomy and commodious. Over the latter is a large room, used as a town-hall, for the dispatch of public business. In this room is deposited a curious relic of antiquity, denominated the Hungerford-horn, given, with an extensive right of fishery, by John of Gaunt to the inhabitants of the town. Here are three annual fairs. The town, by means of its canal navigation, has a considerable traffic; but no established manufactures. Hungerford is 64 miles from London: in the year 1801 it contained 454 houses, and 2292 inhabitants. At a short distance S.E. of the town is

Hungerford-park, the property of John Willes, esq. who purchased it of Mr. Dalbiac in the year 1796, since which time several improvements have been made to the house. Lysons's "Magna Britannia," vol. i. Beauties of England, vol. i.

HUNGERFORD, a township of Upper Canada, in the county of Hastings, lying in the rear and N. of the Mohawk tract. —Also, a township in Franklin county, Vermont, containing, in 1790, 40 inhabitants; 7 miles S. of the Canada line, and 14 E. of lake Champlain.

HUNGRY EVIL, a term used among the farriers for the fame distemper in horses, which in men we call a canine appetite. It manifests itself sufficiently in an inordinate desire to eat, and is sometimes the effect of long starving, sometimes of cold, or some other internal or external cause. In the latter case the horse not only eats a large quantity, but he devours it in a very remarkable manner, chopping it up, as if he would eat the very manger. The method of cure is to give him large toasts of bread, steeped in sack, or some other sweet wine; or give him a quantity of wheat flour in wine, or in milk, a quart or more at a time. These are very good remedies in case of extremity, but otherwise he may be cured by feeding him moderately with bean-bread several times a-day, allowing no other food.

HUNGRY Hill, in *Geography*, a high mountain in the county of Cork, Ireland, on the north side of Bantry bay, which is a remarkable landmark, and on which some alpine plants have been found, as *salix herbacea*, *empetrum nigrum*, &c. A fine cataract falls from it, especially after heavy rain.

HUNGRY Point, a cape on the E. coast of the island of St. Vincent. N. lat. 13° 28'. W. long. 61° 11'.

HUNGTONG, a town of Meekley; 35 miles S. E. of Munnypour.

HUNINGUE, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Altkirch, situated on the Rhine; 14 miles E. of Altkirch. The place contains 774, and the canton 13,089 inhabitants, on a territory of 140 kilometres, in 23 communes.

HUNNARYD, a town of Sweden, in the province of Smaland; 18 miles S. W. of Jonkioping.

HUNNEINE, a town of Algiers, near the coast; 10 miles N. N. W. of Tackumbrect.

HUNNERIC, in *Biography*, king of the Vandals, in Africa, succeeded his father Genferic in 477. He was a violent Arian, and though he at first gave his opponents toleration, he afterwards commenced a persecution against them, which, for savage barbarity, is said to have exceeded the persecutions under the heathen emperors. He died in 484.

HUNNIADES, JOHN CORVIN, one of the most considerable captains of his age, who contended with and defeated the Turks in 1442 before Belgrade and in Transylvania. When the peace which succeeded was violated by the Hungarians, Hunniades accompanied Uladisslaus to the battle of Varna in 1444, in which the Christian army was entirely defeated, with the death of the king. Hunniades drew off the remainder of the forces, and by his vigour put himself in a condition to act offensively with success against the Turks. He was declared governor of Hungary for the minor king Ladisslaus, then educating at the court of the emperor Frederic, who refused to give him up to the ambassadors of the nation. For a considerable time he was a terror of the Turks, but was at length defeated by them in 1448. In 1456 he compelled Mahomet II. to raise the siege of Belgrade. At this time Ladisslaus, who had been restored to his subjects, fled in alarm to Vienna, and the hostile torrent would have been irresistible, had not Hunniades, after de-

feating a Turkish fleet on the Danube, thrown himself into Belgrade. Capistran, a monk, by his success in preaching a crusade, was instrumental in bringing him large reinforcements; by the aid of which Mahomet was repulsed with great slaughter. Not long after this glorious success, Hunniades was seized with a fever, of which he died, at Zemlin, in September 1456, regarded as the hero of Christendom. Univ. Hist. Moreri.

HUNNIUS, GILES, a Lutheran divine, was born at Winende, in the duchy of Wirtemberg, in 1550. He was educated at Tubingen, and became professor of divinity at Marpurg, from whence he removed to Wirtemberg. In these situations his zeal for Lutheranism led him to act in a manner that reflects much infamy on his memory. He established a kind of inquisition which deprived many persons of their employments, and drove them from their country. If they refused to sign a formulary dictated by Hunnius and his colleagues, they were instantly regarded as Calvinists, and found no mercy. Hunnius, after a series of atrocious persecutions, died in 1603, in the 53d year of his age. He was a man of considerable learning and abilities, but bigotted and intolerant. He was author of many controverfial pieces: also of commentaries on the gospels; homilies, &c. His most celebrated work is entitled "Calvinus, Judaizans, &c." in which, says Bayle, Calvin was accused of so many heretical crimes that he might have been afraid of being treated like Servetus, had he lain at Hunnius's mercy. His works have been collected and published in five volumes, folio. Bayle.

HUNNOVER, in *Geography*, a town of Hindoostan, in Myfore; 13 miles E. N. E. of Cheneroypatam.

HUNS, in *Ancient Geography and History*, one of the northern nations, which, under the reign of Valens, threatened the empire of Rome, had been formidable, in a much earlier period, to the empire of China. Their ancient, perhaps their original seat, was an extensive, though dry and barren, tract of country, immediately on the north side of the great wall. These narrow limits, however, were extended by their valour; and their rustic chiefs, who assumed the appellation of "Tanjou," gradually became the conquerors and the sovereigns of a formidable empire. Towards the east, their victorious arms were stopped only by the ocean; and the tribes, which are thinly scattered between the Amoor and the extreme peninsula of Corea, adhered with reluctance to the standard of the Huns. On the west, near the head of the Irifish, and in the valleys of Imaus, they found a more ample space, and more numerous enemies. One of the lieutenants of the Tanjou subdued, in a single expedition, 26 nations; and the Igours, or Vigours, distinguished above the Tartar race by the use of letters, and consisting of three classes, of hunters, shepherds, and husbandmen, were in the number of his vassals. On the north, the ocean was the limit of the power of the Huns. The pride of the Tanjou might be flattered by the submission of so many distant nations; but the valour of the Huns fought the richer recompence of the wealth and luxury of the empire of the south. In the third century before the Christian era, a wall of 1500 miles in length was constructed in order to defend the frontiers of China against the inroads of the Huns; but this was an insufficient defence to an unwarlike people. The cavalry of the Tanjou frequently consisted of two or three hundred thousand men, formidable by the matchless dexterity with which they managed their bows and their horses; by their hardy patience in supporting the inclemency of the weather; and by the incredible speed of their march, seldom checked by torrents or precipices, by the deepest rivers, or by the most lofty mountains. They spread

spread themselves over the face of the country; and notwithstanding the elaborate tactics of the Chinese, directed in their operation by the emperor Kaoti, whose merit had raised him to the throne, were constrained to surrender to the victorious arms of the barbarians, B. C. 201. The successors of Kaoti, whose lives were dedicated to the arts of peace, or the luxury of the palace, submitted to a more permanent disgrace, and to purchase a temporary and precarious peace by the regular payment of a tribute of money and silk. Besides, a select band of the fairest maidens of China was annually devoted to the rude embraces of the Huns; and the alliance of the haughty Tanjous was secured by their marriage with the genuine or adopted daughters of the imperial family, which vainly attempted to escape the sacrilegious pollution. At length, however, the pride of the Huns was humbled, and their progress checked by the arms and policy of Vouti, the fifth emperor of the powerful dynasty of the Han. (B. C. 141—87.) Intimidated by the arms, or allured by the promises of Vouti and his successors, the most considerable tribes of the east and of the west disclaimed the authority of the Tanjou. (B. C. 70.) The Tanjou was compelled to renounce the dignity of an independent sovereign, and the freedom of a warlike and high-spirited nation. From this period the monarchy of the Huns gradually declined, till it was broken, by civil dissension, into two hostile and separate kingdoms. (A. D. 48.) One of the princes of the nation was urged, by fear and ambition, to retire towards the south with eight hords, which composed between forty and fifty thousand families. He obtained, with the title of Tanjou, a convenient territory on the verge of the Chinese provinces; and his constant attachment to the service of the empire was secured by weakness and the desire of revenge. From the time of this fatal schism, the Huns of the north continued to languish about 50 years, till they were oppressed on every side by their foreign and domestic enemies. The Sienpi, a tribe of oriental Tartars, retaliated the injuries which they had formerly sustained; and the power of the Tanjous, after a reign of 1300 years, was utterly destroyed before the end of the first century of the Christian era. (A. D. 93.) The era of the Huns is placed, by the Chinese, 1210 years before Christ, but the series of their kings does not commence till the year 230. About this period more than 100,000 persons of the poorest condition, and most pusillanimous temper were contented to remain in their native country, and to mingle with the victorious nation of the Sienpi. Fifty-eight hords, consisting of about 200,000 men, ambitious of a more honourable servitude, retired towards the south, and were permitted to inhabit and to guard the extreme frontiers of the province of Chanfi and the territory of Ortois. But the most warlike and powerful tribes of the Huns maintained, in their adverse fortune, the undaunted spirit of their ancestors; and resolved to explore the western world, and discover some remote country, inaccessible to the arms of the Sienpi, and to the laws of China. In the course of their emigration they soon passed the mountains of Imaus and the limits of the Chinese geography. Of these formidable exiles two divisions directed their march towards the Oxus, and towards the Volga. The first of these colonies established their dominion in the fruitful and extensive plains of Sogdiana, on the eastern side of the Caspian, where they preferred the name of Huns, with the epithet of Euthalites, or Nephthalites. Their manners were softened, and even their features were improved, by the mildness of the climate, and their long residence in a flourishing province, which might still retain a faint impression of the arts of Greece. These *white* Huns, a name which they derived from the change

of their complexion, soon abandoned the pastoral life of Scythia, and though their vicinity to the provinces of Persia involved them in frequent contests with the power of that monarchy, they respected, in peace, the faith of treaties; and, in war, the dictates of humanity. The *second* division of their countrymen, the Huns, who gradually advanced towards the north-west, were exercised by the hardships of a colder climate, and a more laborious march. Their independent spirits soon rejected the hereditary successions of the Tanjous; and while each hord was governed by its peculiar murfa, their tumultuary council directed the public measures of the whole nation. As late as the 13th century, their transient residence on the eastern banks of the Volga was attested by the name of Great Hungary. (See HUNGARY.) A chasm occurs in their history after these Huns of the Volga were lost in the eras of the Chinese, and before they appeared to those of the Romans, which is not easily filled up. There is reason, however, to apprehend, that the same force which had driven them from their native seats, still continued to impel their march towards the frontiers of Europe. The Huns, whose martial spirit had not been impaired by a long residence in China, with their flocks and herds, their wives and children, their dependents and allies, were transported to the coast of the Volga; and they boldly advanced to invade the country of the Alani, a pastoral people who occupied, or wasted, an extensive tract of the deserts of Scythia. (See ALANS.) The Huns united with the Alani in their invasion of the Gothic empire. (A. D. 375.) The numbers, the strength, the rapid motions, and the implacable cruelty of the Huns were felt, and dreaded, and magnified by the astonished Goths, who beheld their fields and villages consumed with flames, and deluged with indiscriminate slaughter. To these real terrors they added the surprize and abhorrence which were excited by the shrill voice, the uncouth gestures, and the strange deformity of the Huns. These savages of Scythia were compared (and the picture had some resemblance) to the animals who walk very awkwardly on two legs; and to the mis-shapen figures, the "Termini," which were often placed on the bridges of antiquity. They were distinguished from the rest of the human species by their broad shoulders, flat noses, and small black eyes deeply buried in the head; and as they were almost destitute of beards, they never enjoyed either the manly grace of youth, or the venerable aspect of age. A fabulous origin was assigned to them, worthy of their form and manners; that the witches of Scythia, who, for their foul and deadly practices, had been driven from society, had copulated in the desert with infernal spirits; and that the Huns were the offspring of this execrable conjunction. The Goths greedily embraced the tale, and were the more easily induced to exert themselves in repelling the invasion of such enemies. (See GOTHS.) Such is the character, with the addition of many other particulars, which Ammianus Marcellinus and Jornandes give of these Scythian and Sarmatian Huns, who anciently inhabited that part of Asiatic Sarmatia, which bordered on the Palus Mæotis and the Tanais, the ancient boundary between Europe and Asia. They are represented as the most savage and cruel of all the barbarous nations. Their cheeks were mangled and countenances distorted in their earliest infancy, with a view, in maturer age, of striking terror into their enemies. They lived in the open air, without house or even huts, and subsisted upon roots and raw meat; and inured themselves, in the woods and on the mountains which they inhabited, to every kind of privation and hardship. They were accustomed to eat and to sleep on horseback, scarcely ever dismounting; and they covered their nakedness with goat-skins, or the skins

of a fort of mice sewed together. They had no law, nor any kind of religion; nor did they observe any distinction between good and evil, or submit their inclinations and passions to any kind of restraint. In war, they began the battle with great fury and a hideous noise; but after the first onset, their fury abated and they fled, when resisted, in the greatest confusion. They were notoriously faithless, so that they disregarded the most solemn treaties. Sometimes they made incursions into the Roman empire in defiance of the most sacred oaths and engagements; and at other times they joined the Romans in fighting against the Goths, and other barbarous nations. They have fought against each other when they had prospect of gaining any advantage to themselves by such conduct. Of their disposition in this respect, Justinian was so fully apprised, that by promising a large sum to the Uturgurian Huns, who inhabited the south side of the Palus Mæotis, he prevailed upon them to fall upon the Cuturgurians, another tribe, which had occupied the territory north of the others, towards the Tanais. Their form of government was not strictly monarchical; but they were headed and conducted by some of their chiefs. It was about the year 376 that they entered the country of the Alans, and, obliging those who survived their cruelty to enlist under their standard, fell upon the Goths, called by Ammianus Greuthongi, and by Jornandes Ostrogoths, and drove them out of their country. The Visigoths were afterwards treated in the same manner. The Gothic nations, alarmed by the sudden and unexpected irruptions of the Huns, determined to abandon their territories, and to seek shelter within the Roman dominions, separated by the Danube from the countries which had been over-run by the Huns. Upon submissive application to Valens, the Goths were admitted into Thrace, and their number was so considerable, that Ammianus compares them to the sparks which at that very time issued out of Mount Ætna, and to the sands of the Libyan shore. Thus the Huns, in the year 376, not only settled in Europe, but made themselves masters of that immense country, which extends from the Tanais to the Danube, and which, before their arrival, was possessed by the Alans, the Goths, and several other barbarous nations, whom they either drove out, or forced to submit to their victorious arms. In the year 388 many of the Huns, who had settled in Europe, were induced by large sums to enlist under the Roman banner of Theodosius I., who was then emperor, and they were thus prevented from raising disturbances on the frontiers of the empire. In 391 they passed the Danube, and being joined by the Goths and other barbarians, committed dreadful havoc in Mœsia and Thrace; but their progress was restrained by the vigorous and successful attack of Stilicho. About four years after, *viz.* in 395, the Huns made an unexpected inroad into the eastern provinces, and penetrated as far as Antioch, destroying the country with fire and sword, and committing every where deplorable cruelties. Having over-run and plundered several provinces, they voluntarily returned home, loaded with spoils, and carrying with them an incredible number of captives. After this irruption they remained quiet for nine years, or till the year 404, when passing the Danube in great multitudes, they entered Thrace, and having traversed that province, penetrated into East Illyricum, committing wheresoever they went dreadful ravages. In the following year great numbers of them entered the Roman service, and joined Stilicho's army, in its march against Radagaisus, who had invaded Italy. They were led by Uldin, one of their chiefs, and contributed to the victory gained by Stilicho in Etruria; but in two years after the signal victory, obtained chiefly by his means over Radagaisus, Uldin became an irreconcilable enemy to the Romans; and passing the Danube,

entered Thrace at the head of a numerous army; but having offended some of his principal officers, who joined the Romans, he was forced to recross the Danube after having lost many of his men. From this period the Huns seem to have continued quiet till the year 423, when, upon the death of the emperor Honorius, John, his chief secretary, assumed the purple, and the celebrated Aetius (see his article) was prevailed upon to espouse the cause of the usurper. Aetius engaged 60,000 Huns to march to the assistance of the new emperor; but hearing of his death, the prudent leader submitted to Theodosius, and persuaded the Huns, not without distributing among them considerable sums, to return home. Soon after this event, which happened in 423, we find the Huns in possession of Pannonia. As they were much indebted to Aetius for the lands they held in this country, Roas, their chief or king, received this able commander with the greatest demonstrations of kindness and friendship, upon his being disgraced at the court of Placidia, mother of Valentinian III. and sent him back at the head of a powerful army of Huns, which so terrified Placidia, that she restored Aetius to all his employments, and raised him to the rank of patrician. In 435 a strong body of Huns marched through Germany and Gaul, and joined Aetius against the Burgundians, who, having been allowed to settle in that part which bordered on the Rhine, had revolted from the Romans, and ravaged Belgic Gaul. On this occasion 20,000 Burgundians, with their commander Gondiacius, were cut off. Soon after the Burgundians marched against the Huns, and surprising them when they were left destitute of a leader, by the sudden death of Uptar, their king, destroyed 10,000 of them, and obliged the survivors to save themselves by a precipitate flight. The Huns, notwithstanding this defeat, marched either in the same or the following year to the assistance of the Romans against the Goths, who had been allowed to settle in Aquitain, but who, not contented with the territory allotted them, had taken possession of several cities belonging to the Romans, and had laid siege to Narbonne. The Huns, having in the preceding year signalized themselves against the Goths in Armorica, marched against the Goths of Aquitain. In 425 Rouas, or Roas, king of the Huns, concluded a peace with Theodosius II., of which one of the conditions was, that the emperor should pay him a yearly pension of 350 pounds weight of gold. Soon after Rouas died, and was succeeded by his two nephews, Bleda and Attila. For the principal events that occurred under the reign of Attila, we refer to his biographical article. With the death of Attila the empire of the Huns is said to have terminated: for after this event they were so weakened by intestine wars and by the irruptions of the Gepidæ and Goths, that they continued quiet till the year 466, when passing the Danube on the ice, they made an incursion into Dacia, and committed dreadful ravages in that country. But their progress was interrupted by Anthemius the Roman commander, and in a pitched battle they were totally defeated. The Huns, dispirited by their losses and the death of their leader, were not in a condition to molest either the Romans or their neighbours for about 60 years. In 526 Boarex, queen of the Huns, took part with the Romans against the Persians, and led to the assistance of the emperor Justinian an army of 100,000 men, and obtained a victory, in the 13th year of Justinian's reign. The Huns, passing the Danube in great multitudes, laid waste Thrace, Greece, Illyricum, and all the provinces from the Ionian sea to the suburbs of Constantinople; and having crossed the Hellespont, extended their ravages to Asia, whence, after practising unheard-of cruelties, they returned home loaded with an immense booty. Justinian, in order to keep them quiet, allowed them some lands in Thrace, and

agreed to pay them an annual pension, upon their promising to serve when wanted in the Roman armies. These were the Cuturgurian Huns; the Uturgurians retired with their booty to their own country bordering on the Euxine sea, and enlarged their territory by encroaching on that of their neighbours, without giving any further molestation to the Romans. But the Cuturgurians, notwithstanding the pension annually paid them by the emperor, made several inroads into the neighbouring provinces. Whilst they were busily plundering the provinces lying on the Danube, the Uturgurians, at the instigation and bribe of the emperor, fell upon them unexpectedly, defeated them with great slaughter, obliged them to quit their booty, and drove them entirely out of the empire. In a few years after, *viz.* A. D. 558, the Cuturgurian Huns, availing themselves of the frost, passed the Danube, and laid waste a great part of Mysia and Thrace; but whilst they were pursuing their ravages, they were put to flight by the aged Belisarius, and by a youth of great promise, called Germanus. The next event in which the Huns were concerned was the war that took place between the two tribes of the Uturgurians and Cuturgurians, and which, after lasting many years, hastened their destruction. In the reign of Charles the Great the Huns were masters of Dacia, New Transylvania, and Walachia; of Upper Moesia, New Servia, and of the two Pomeranias, namely, the Upper containing the present provinces of Carniola, Carinthia, and the greater part of Austria: and the Lower, comprising Bosnia, Sclavonia, and that part of Hungary which lies beyond the Danube. In the year 776, two princes of the Huns sent ambassadors to Charles, while he was in Saxony, desiring his friendship and alliance. But as they proved unfaithful by entering into an alliance with Tassilo, duke of Bavaria, the enemy of Charles, he raised two armies, which, in 794, laid waste the territories of the Huns, burnt their villages, and took several of the strong holds to which they had fled for security. In the space of eight years, this warlike nation was entirely subdued, and almost wholly extirpated. The entire reductions of the Huns happened, according to the best chronologers, in the year 794. Some authors assert that by this long war the whole race of the ancient Huns was cut off; and that the country was afterwards peopled by the neighbouring nations, to whom the present Hungarians owe their origin. *Anc. Un. Hist.* vol. xvii. *Gibbon's Rom. Emp.* vol. iv. v. vi.

HUNT, JEREMIAH, in *Biography*, was born in London in 1678. He was educated under Mr. Thomas Rowe, and after he had finished his course with him, he went first to Edinburgh and then to Leyden; at the latter place he applied himself most diligently to the study of the Hebrew language and the Jewish antiquities. In Holland he preached to a small English congregation, and upon his return he officiated some time at Tunstead, in Norfolk, from whence he removed to London about 1710, and was appointed pastor of the congregation at Pinner's hall. In 1729 the university of Edinburgh conferred on him the degree of D.D. He died in the year 1744. He was author of several single sermons; and likewise of "An Essay towards explaining the History and Revelations of Scripture in their several Periods, to which is annexed a Dissertation on the Fall of Man." After his death four volumes of his "Sermons," with tracts, were published, to which was prefixed Dr. Lardner's Funeral Sermon for him: to this the reader is referred for farther particulars.

HUNT, MRS. ARABELLA, a lady much celebrated the latter end of the 17th century, for her beauty, fine voice, and musical talents. Congreve has left a rapturous and extatic ode on her performance, which, if not seraphically ex-

quisite, his verses must be the most *mendacious*, that is, the most *poetical*, that ever were written. It seems the most animated of all the author's fugitive pieces; and we should suppose that he felt strongly what he so warmly describes.

If matters of fact in our biographical articles were not more our business than amusement of our readers, we should insert this whole poem, as it surpasses in intelligible panegyric all that ancient poets have said of the miraculous powers of Orpheus, Amphion, or Linus. We cannot help giving the first strophe as a specimen of auricular rapture.

On Mrs. Arabella Hunt singing,

" Let all be hush'd, each softest motion cease,
Be every loud tumultuous thought at peace,
And every ruder gasp of *breath*
Be calm as in the *arms* of death.

" And thou most fickle, most uneasy part,
Thou restless wanderer, my heart,
Be still; gently, ah, gently leave,
Thou busy idle thing, to heaven.
Stir not a pulse, and let my *blood*,
That turbulent unruly flood,
Be safely staid.

" Let me be all, but my attention, dead.
Go, rest, unnecessary springs of life,
Leave your officious toil and strife,
For I would hear her voice, and try
If it be possible to die, &c."

Whether this fire was a professional singer, or a lady, does not appear; she was contemporary with Purcell, and gained her musical fame chiefly by her admirable performance of his compositions. She taught the princess Anne of Denmark to sing; and was in such favour with queen Mary, that she bestowed on her an employment in the household, for the sake of having her near her person, and was frequently entertained by her performance in private, even in singing to her majesty common popular songs and ballads.

Old Mr. Gostling of Canterbury, used to relate a story which he had from his father, (one of the priests of the chapel royal, subdean of St. Paul's in the time of Charles II. and in the reign of king William, a favourite singer at court,) that queen Mary having expressed herself warmly in favour of the old Scots tune of "Cold and raw the wind doth blow," Purcell made it a perpetual base to an air in the next birth-day ode, 1692; beginning "May her blest example chafe:" a piece of pleasantry occasioned by her majesty asking for this tune, after he, (Gostling,) and Mrs. Arabella Hunt, with Purcell to accompany them on the harpsichord, had exerted all their talents and abilities to amuse so great a personage with compositions which they mistakenly thought of a superior class.

Mrs. Hunt died in 1705, when Congreve, under her picture playing on the lute by sir Godfrey Kneller, furnished the following lines, which in his works are called an epigram.

" Were there on earth another voice like thine,
Another hand so blest with still divine;
The late afflicted world some hopes might have,
And harmony retrieve thee from the grave."

HUNTEBURG, in *Geography*, a town of Westphalia, in the bishopric of Osnabruck, situated on the river Hunte, which rises in the Dümmer see, and runs into the Weser, about 20 miles N.E. of Oldenburg; 18 miles N.E. of Vorden.

HUNTER, WILLIAM, M. D. in *Biography*, an eminent anatomical teacher and physician, was born on the 23d of May,

May, 1718, at Kilbride, in the county of Lanerk, in Scotland. His father, John Hunter, was descended from the family of Hunter of Hunterstown, and resided on a small estate, called Long Calderwood, in the parish of Kilbride. William, the seventh of ten children, was of a quiet and diligent disposition, and was sent to the university of Glasgow, at the age of fourteen, as a student of divinity. But after a sedulous study of theology, he conceived a repugnance to the subscribing to the articles of the Scotch church; and in this state of mind becoming acquainted with Mr Cullen (afterwards the celebrated professor at Edinburgh), who had just settled in practice at Hamilton, he was led to give a preference to the profession of physic, and in 1737 went to reside with this excellent friend and preceptor, with the consent of his father. The three years which he passed at Hamilton, he often declared were the happiest in his life. Mr. Cullen and he entered into partnership, with this liberal agreement, that each of them should alternately pursue further improvement in some medical school. Hunter, in consequence, went to Edinburgh in November 1740, where he attended the winter course of lectures, and among others those of the first Dr. Alexander Monro. In the summer of 1741, he arrived in London, with a recommendation to Dr. James Douglas, who was at that time engaged in a great anatomical work on the bones, which he did not live to complete. He was desirous of engaging a young man of abilities and industry to assist him in his dissections, and being favourably impressed with the conversation of Mr. Hunter, invited him to reside in his family for that purpose, and also to superintend the education of his son. Dr. Cullen readily gave his assent to a change of plan so favourable to his friend's advancement; and his venerable father, then near his end, reluctantly consented; he died in October of the same year. Mr. Hunter was immediately enabled, by Dr. Douglas's friendly assistance, to enter himself as a surgeon's pupil at St. George's hospital, and as a dissecting pupil of Dr. Frank Nichols, an anatomist of considerable reputation. He pursued his dissections with such assiduity and success, that Dr. Douglas was at the expence of having several of his preparations engraved. But he soon had the misfortune to lose this generous friend, who died in April 1742. He continued, however, to reside with the doctor's family, and to pursue his studies with the same diligence: for while he was convinced that he must now depend upon his own exertions for professional success, he also began to feel a consciousness of his own powers. In the following year, 1743, he communicated to the Royal Society a paper "On the Structure and Diseases of articulating Cartilages," which was printed in their Transactions, vol. 42, and was admired for the ingenuity of the observations on a subject not much investigated before. He now determined to become a teacher of anatomy; but difficulties at first presented themselves, and he was discouraged by Dr. Nichols, who about that time declined giving lectures in favour of Dr. Lawrence. A circumstance, however, soon occurred, which called forth his abilities in this way. A society of navy-surgeons had engaged Mr. Samuel Sharpe to deliver to them a course of lectures on the operations of surgery, at an apartment which they had in Covent-Garden. Mr. Sharpe at this time declined the task, and Mr. Hunter was solicited to continue it, which he did so much to their satisfaction, that they requested him to extend his plan to anatomy: and in the winter of 1746, he began his course of anatomical lectures in their room. At first he experienced considerable solicitude in speaking in public; but at length his diffidence was overcome, and he acquired that facility for which he was peculiarly distinguished, and which rendered the delivery of lec-

tures a source of real pleasure to him. We may here mention, that on returning home after his introductory lecture, accompanied by a young friend, Mr. Hunter, who had received about seventy guineas from his pupils, and had got the money in a bag under his cloak, observed, that it was a larger sum than he had ever been master of before: an anecdote which, as Dr. Simmons remarks, deserves to be recorded as an encouragement to young men, who with great merit possess but little advantages of fortune. Considerable as the emoluments of his two first courses were, by contributing to the wants of different friends, he found himself, at the return of the next season, obliged to defer his lectures for a fortnight, merely because he had not money enough to defray the necessary expence of advertisements. This produced a resolution to be in future as cautious in lending money, as he was averse to borrowing it. His own habits were strictly economical, and laid the foundation of that ample fortune, which he so freely expended upon subjects of public utility.

In the spring of 1748, he set out on a tour through Holland to Paris, with his pupil young Douglas. The only circumstance recorded of this journey, is his introduction to the celebrated Albinus at Leyden; whose admirable injections inspired him with a strong emulation to excel in that curious and important part of anatomy. Although admitted into the corporation of surgeons in the preceding year, he now relinquished that branch of practice, to which he had always a strong aversion, and directed his views to the practice of midwifery, in which his patron Dr. Douglas had acquired considerable reputation. His advancement in this department was accelerated by his being elected surgeon-acoucheur first to the Middlesex, and soon afterwards to the British Lying-in-hospital, as well as by the delicacy of his person and manners, which gave a great advantage over his countryman, Dr. Smellie. He was likewise recommended by several of the most eminent surgeons of that time, from a respect for his anatomical talents; and the death of sir Richard Manningham, and the retirement of Dr. Sandys, (who then had the most lucrative practice in that branch,) concurred to assist Mr. Hunter's progress. In 1750, he obtained the degree of M. D. from Glasgow; and as his reputation increased, he was much consulted as a physician, both in cases connected with his particular branch of practice, and in those which required peculiar anatomical skill in their investigation. About this time he quitted the family of Mrs. Douglas, and took a house in Jermyn-street.

In 1751, Dr. Hunter revisited his native country; but with the exception of this journey, to which he devoted only a few weeks, he was never absent from London but under professional engagements. In 1756 he was admitted a licentiate of the College of Physicians, and soon afterwards was elected a member of the Medical Society, recently instituted; the "Medical Observations and Inquiries" of which he enriched by many valuable communications, and of which he was deservedly chosen president on the death of Dr. Fothergill. It will be sufficient here to notice the most important of the contributions to medical science, of which Dr. Hunter was the author, in the excellent volumes published by this society. In his history of an aneurism of the aorta, contained in the first volume, 1757, he was the first to notice a peculiar form of this disease, occasioned by the wounding of an artery through a vein, with which vessel, after healing externally, the artery continues to maintain a communication. Of this disease he afterwards treated more at large (see Med. Obs. and Inquir. vol. ii. and iv.); and it has been since named an *aneurismal varix*, at the suggestion of Dr.

HUNTER.

Dr. Cleghorn. (Ibid. vol. iii.) In the second volume, among several other papers, is the description of a case of emphysema, followed by some judicious practical remarks on the cellular membrane and its diseases. He here maintained the opinion that the vesicles, in which the fat is deposited, are different from the cells that contain water in anasarca. In the fourth and fifth volumes he communicated his valuable observations relative to the retroversion of the uterus, which sometimes occurs in pregnancy, and is liable to produce a fatal event, if not remedied in time; a disease not understood till accurately described by Dr. Hunter. All his papers, published in the volumes alluded to, are worthy of attention.

In the year 1762 Dr. Hunter came forward as a controversialist, and with a degree of asperity, which has very commonly attended anatomical controversies, maintained his claims to different anatomical discoveries. In his "Medical Commentaries," to which a "Supplement" was afterwards added, he supported the priority of his discoveries over those of Dr. Monro, jun. professor of anatomy at Edinburgh, in respect to the ducts of the lachrymal glands, injections of the testicle, the origin and use of the lymphatic vessels, and absorption by veins. There is nothing more difficult to ascertain, as Dr. Aikin has justly observed (*Gen. Biog.*), than the exact share in the improvements of a professional science, due to the individuals who are simultaneously pursuing it, with equal ardour and advantages; nor is the determination of any consequence to the science itself. The great doctrine of the absorbent action of the lymphatic system, which is now fully received, at least by the anatomists of Great Britain, was taught and illustrated at the same time in the schools of London and of Edinburgh, and exercised the ingenuity of Hunter, Monro, Hewson, Cruickshank, and other anatomists. Dr. Simmons has shewn, however, that the principal points of this system had been stated, so long ago as the year 1726, by Mr. Noguez, in the second edition of a work entitled "L'Anatomie du Corps de l'Homme en abrégé," printed at Paris. Who may have first succeeded in a lucky injection seems a matter scarcely worthy of contest; but Dr. Hunter was extremely tenacious of any claims of this kind, and would not suffer the interference even of his own brother. Some papers, in which a claim of Mr. John Hunter, relative to the connection between the placenta and uterus, was disputed by the doctor in 1780, are preserved in the archives of the Royal Society. In the "Commentaries" there are also some observations on the inflexibility of the dura mater, periosteum, tendons, and ligaments, as taught with some slight difference by Haller; and likewise "Observations on the State of the Testis in the Fœtus, and on the Hernia Congenita, by Mr. John Hunter."

The professional reputation which Dr. Hunter had already attained was evinced by his being consulted in the pregnancy of the queen, in 1762. Two years afterwards he was appointed physician extraordinary to her majesty; a distinction for which he was indebted solely to his personal merit. In 1767 he was elected a fellow of the Royal Society; and in the following year he communicated to that body some observations on the bones found near the river Ohio, in America, which were commonly supposed to belong to the elephant. But he proved, chiefly from the structure of the teeth, that they belonged to some unknown quadruped, of a different species. (*Phil. Trans.* vol. 58.) In the 60th and 61st volumes of the same publication, were printed a memoir on some fossil bones, found in the rock of Gibraltar, and an account of the Nyl-ghau, a non-descript Indian animal. In 1768, Dr. Hunter was elected into the Society of Antiquaries, and was appointed by his majesty to the office of professor of anatomy to the Royal Academy of Arts, on its first institu-

VOL. XVIII.

tion. This appointment opened a new field for the application of his anatomical knowledge, in relation to external form, as the object of painting and sculpture. He engaged in it, as in every other pursuit of his life, with unremitting zeal, and the novelty and ingenuity of his observations displayed the extent and versatility of his talents. Finally, he received other literary honours from learned societies abroad; being chosen a foreign associate of the Royal Medical Society of Paris in 1780, and of the Royal Academy of Sciences, in the same city, in 1782.

So early as the year 1751, Dr. Hunter had commenced a work, upon which he continued to bestow incessant attention and great expence for several subsequent years; this was his splendid publication, "The Anatomy of the Gravid Uterus," which appeared in 1775, illustrated by 34 large engravings, executed from capital drawings of subjects and preparations, by the first masters. This great work, not less admirable for its accuracy than for its magnificence, exhibited all the principal changes that occur in the nine months of pregnancy, in a degree of perfection which had never before been approached. In this work he first delineated the retroverted uterus, and the membrana decidua reflexa, which he himself discovered. He drew up a detailed anatomical description of the figures, which he did not live to finish, but which was completed and published by his nephew, Dr. Baillie, in 1794, under the title of "Anatomical Description of the Gravid Uterus and its Contents." In 1778 he published his "Reflections on the Section of the Symphysis Pubis," an operation introduced by the French, but which the cooler judgment of English practitioners rejected upon the most solid grounds. Among Dr. Hunter's papers were found "Two Introductory Lectures" to his anatomical course, correctly written out, which were published in 4to. in 1785, and which complete the catalogue of his publications.

Having followed the course of Dr. Hunter's labours as a teacher and writer, we must go back a little in order to trace his progress in the foundation of a museum, which he destined for public use. His first desire, when he commenced the practice of midwifery, was to acquire a sufficient fortune to secure him ease and independence; and in a few years he found himself in possession of this competency. As his wealth continued to accumulate, he formed the laudable design of employing his superfluity in some scheme of public utility; and the foundation of an anatomical school in the metropolis naturally suggested itself. About the year 1765, therefore, he presented a memorial to the minister, Mr. Grenville, requesting a grant of ground in the King's Mews, on which he offered to build a proper edifice at the expence of seven thousand pounds, and to endow a professorship of anatomy in perpetuity. This offer was received coldly; and after some delay Dr. Hunter purchased a spot of ground in Great Windmill street, on which he built a house, together with an anatomical theatre, and a museum, and removed thither from Jermyn street in 1770. The first furniture of the museum consisted of an extensive collection of anatomical preparations, formed with great labour and expence; to which, however, he now added fossils, shells, and other objects of natural history; a great treasure of Greek and Latin books in the rarest editions; and, lastly, a cabinet of ancient coins and medals, which was collected progressively at the expence of upwards of 20,000*l.* A description of part of the coins, in this collection, struck by the free Greek cities, was published by his friend Mr. (now Dr.) Combe, under the title of "Nummorum Veterum Populorum et Urbium, qui in Museo Gulielmi Hunter asservantur, descriptio, figuris illustrata Opera et studio Caroli Combe, S. R. et S. A."

U u

Soc."

Soc." 4to. 1783. An easy access was always given to persons who wished to view and consult this museum, and its reputation among foreigners reflected honour upon the capital containing it.

Dr. Hunter continued to teach and to practise in his profession, with unabated assiduity, until March 1783, when an attack of a wandering gout, to which he was subject, obliged him to keep to the house for some days. A partial recovery induced him, contrary to the advice of his friends, to deliver a lecture; but the effort so much exhausted him that he fainted away, and a slight paralytic attack followed in the night. His intellects remained clear, however, until death, and he surveyed its approach with so much tranquillity, that in his last moments he said to Mr. Combe, "If I had strength enough to hold a pen, I would write how easy and pleasant a thing it is to die." He expired on the 30th of March 1783.

In person Dr. Hunter was slender, and rather below the middle stature. He was a man of mild and sedate character, easy in conversation, engaging in his address, steady in the pursuit of his objects, simple and regular in his mode of life. As a practitioner he was cautious, perhaps to the verge of timidity; but singularly qualified to inspire confidence in his patients. As a lecturer he peculiarly excelled in the clearness of his demonstrations. No man has so much contributed to the propagation of anatomical knowledge in this kingdom, and to the reputation of London as a school for that science. By his will he bequeathed to his nephew, Matthew Baillie, M. D. (his successor as a teacher of anatomy, and now the most eminent physician in the metropolis, 1810,) his museum, for a term of 30 years, with a sum for its augmentation, and annuities to three trustees for the care of it, while in London. At the end of that period it was to go to Glasgow; but Dr. Baillie has already had it removed to that university some years before the completion of that term. See an Account of the life, &c. of Wm. Hunter, M. D. by Dr. S. F. Simmons, 1783. Gen. Biog.

HUNTER, JOHN, a very eminent surgeon, brother of the preceding, and youngest of the family, was born in July 1728. Being his mother's favourite, and his father, through age and indolence, being unable to pay much attention to him, he was brought up in a course of indulgence, which proved injurious both to his temper and his progress in learning. It was late and with great difficulty that he was taught to read; and after his father's death, he was left, at the age of 10, an ill-governed boy, neglecting his education, and spending his time in idleness and country amusements. Yet he exhibited marks of an acute understanding and of a bold disposition. As he appeared to have a mechanical turn, and some manual dexterity, he was sent to Mr. Buchanan, a brother-in-law, lately settled in Glasgow, as a carpenter and cabinet-maker; but the want of success in this person's business left young Hunter again unemployed. Having heard of the reputation which his brother William was now acquiring in London, he wrote to request permission to visit him, and to try to make himself useful as an anatomical assistant, or, if that should be refused, to enter the army. The offer was readily embraced by William, and John arrived in London in September 1748, just before the commencement of the winter course of lectures. His first essays in dissection satisfied his brother of the certainty of his ultimate proficiency in anatomy, which he cultivated with such success, as to be capable of undertaking the demonstrations to the pupils in the dissecting room in the following winter. In the summer months he attended the practice of surgery at the Chelsea hospital, under Mr. Cheselden, and afterwards at St. Bartholomew's and St. George's hospitals, of which

last he was appointed house-surgeon in 1756. It does not appear with what intention he was entered as a gentleman-commoner at St. Mary's hall, Oxford, in 1753. Literary distinction seems never to have been his ambition, nor indeed within his reach. This probably he soon discovered; for we find no intermission of his professional pursuits in London. In the winter of 1755, Dr. Hunter admitted him to a partnership in his lectures. He applied himself to dissection, and to making anatomical preparations, with unexampled ardour and perseverance, in which he was highly useful to his brother's collection. Having thus laboured for ten years in the investigation of human anatomy, he turned his inquiries to the anatomy of other animals, with a view to elucidate the use of the different organs, by a comparative view of their structure, and thus to acquire a more certain knowledge of the general principles of the animal economy. He prosecuted these researches with the ardour of an enthusiast, and suffered no opportunity of examining animals of every description to escape him. His health was so much impaired, however, by this excessive application, that in the year 1760 he went abroad as surgeon on the staff, and served during the war in Belle-Isle and in Portugal, where he acquired his knowledge of gunshot wounds. On his return in 1763, he settled as a surgeon in London, and added to the scanty income derived from his practice, by teaching practical anatomy and operative surgery for several winters. His ardour for comparative anatomy continued unabated; and for the greater facility of carrying on his experiments, he purchased a piece of ground at Earl's Court, Brompton, where he built a house. Here he kept several foreign animals, of whose manners and habits he was a sedulous observer, and subsequently made his observations and experiments relative to the economy of the bee, the silkworm, and other insects; to the progress of incubation in the egg; to the growth of vegetables; to the transplanting of teeth into the combs of cocks, &c. &c. with the description of which he enriched the volumes of the Philosophical Transactions, and with his preparations formed that unrivalled museum, of which we shall presently speak. He was elected a member of the Royal Society in 1767; and, in order to promote scientific improvement more effectually than could be done by formal meetings, he was the means of associating some of the most active members in a conversation party at a coffee-house, after the public business of the society was ended. This at first consisted only of Dr. G. Fordyce, Mr. Cuming, and himself; but they were soon joined by sir Joseph Banks, Dr. Solander, Dr. Maskelyne, &c.

When Dr. Hunter removed to his new establishment in Windmill-street, he assigned the lease of his house in Jermyn-street to Mr. Hunter. About the same time Mr. Hunter became a member of the corporation of surgeons, and, through his brother's interest, was elected one of the surgeons to St. George's hospital. In 1771, finding his business increasing with his reputation, he married a lady to whom he had been long engaged, the eldest daughter of Mr. Home, a military surgeon, and sister to the present Mr. Everard Home. She was a person of elegant accomplishments, and has lately obliged the public with a volume of poems. His house was now frequented by medical students, who came to finish their education in London, and who were desirous of a residence in a situation so favourable to their improvement. Among others of his pupils, who have since attained to professional eminence, we may mention the name of Jenner, immortalized by the discovery of the preventive powers of the cow-pox. In 1771 he published his first work, "On the Natural History of the Teeth," in 4to. It displayed great accuracy of research, and was illustrated with excellent plates. In 1773 he commenced a course of lectures on the theory and

principles of surgery, in which he brought forward many peculiar opinions, expressed in a peculiar language, which he introduced into physiological and pathological science. Part of the peculiarity of his language, however, must be attributed to his want of a regular literary education, and arose from his misconception of its proper use; and to the same defect must be ascribed his failure to acquire that methodical arrangement of his ideas, and clearness and facility in expressing them, for which his brother was so much distinguished. However, he was a real improver of his profession, both in a theoretical and practical view. He suggested new methods of treatment in ruptures of the tendo Achillis, in the operation for hydrocele, and for fistula lachrymalis, &c.; but the most important of his surgical improvements was the method of operating for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh.

In the year 1776, Mr. Hunter was appointed surgeon-extraordinary to his majesty. In 1778 he published the second, or practical part, of his "Treatise on the Teeth," in which their diseases were considered. Soon afterwards, he was elected a member of the Royal Society of Gottenburgh, and of the Royal Medical Society, and Royal Academy of Surgery, at Paris. In the year 1783, the term of his lease in Jermyn-street expiring, and his collection being now too large to be contained in his dwelling-house, he purchased the lease of a large house on the east side of Leicestersquare, with premises extending to Castle-street, on which he erected a spacious building for his museum, at a cost much beyond the dictates of prudence. Had his age and state of health, indeed, justified the expectation of a long continuance of the emoluments which were beginning to flow in upon him, no expenditure connected with his fame could have been thought censurable. At this period his faculties of body and mind seem to have been exerted to the utmost, and every moment had its full employ. He was now engaged in a very extensive private practice; he was surgeon to St. George's hospital; he was giving a long course of lectures in the winter; he was carrying on his inquiries in comparative anatomy, and adding to his museum; he had a school of practical anatomy in his own house, and was constantly employed in some experiments respecting the animal economy. The post of deputy surgeon-general to the army was conferred upon him in 1786; and in the same year his great and long-expected work "On the Venereal Disease" made its appearance. Few medical performances have been more read; but it underwent some severe criticisms, both theoretical and practical: nevertheless it will ever remain a monument to his extraordinary sagacity and talent of observation. He also published in this year, "Observations on various Parts of the animal Economy," chiefly composed of papers already printed in the Philosophical Transactions. In the spring of this year Mr. Hunter was seized with a severe illness, from which he recovered slowly, and which left his constitution impaired; he became subject especially to an affection of the heart, which came on upon every violent agitation of the mind, or sudden exertion of the body. In 1790 he was appointed inspector-general of hospitals, and surgeon-general to the army, which gave him much additional occupation; and he then resigned his course of lectures to his brother-in-law, Mr. Home, still employing all his little leisure in scientific pursuits. From the autumn of this year, however, the series of spasmodic and other uneasy symptoms, connected with the affection of the heart, and constituting what is named angina pectoris, which had for some time harassed him, increased considerably in violence, and to himself and others portended a suddenly fatal termination.

During the years 1791 and 1792, he had many severe attacks, but of not more than a few hours duration. On the 16th of October 1793, when in his usual state of health, he went to St. George's hospital, where something occurred which irritated him, but of the circumstances of which he was not perfectly master. He therefore withheld his sentiments, and withdrew into the next room, where, in the act of turning round to one of the physicians, he gave a deep groan, and dropped down dead.

On dissection, the heart was found to be the principal seat of disease. That organ appeared as if shrunk in its size; the coronary arteries, which ramify in its substance, were completely ossified, or in the state of bony tubes; and the valves were in a state of incipient ossification.

Mr. Hunter was a man of a warm and impatient temper, but open and undisguised. He was naturally cheerful and social; and his countenance bore the stamp of frankness and animation, though in his latter years it was deeply impressed with thoughtfulness. The admirable print of him, from a portrait by sir Joshua Reynolds, strongly confirms the judgment made of it by Lavater: "This man thinks for himself." In originality of genius and powers of investigation, he appears to have surpassed his brother; industry and perseverance equally belonged to both.

In order to avoid interruption to the biographical narrative, we have omitted to notice the very numerous and important papers which Mr. Hunter presented to the Royal Society, in rapid succession, especially between the years 1773 and 1783, chiefly relating to comparative anatomy and physiology; nor have we room at present to enumerate their titles. His fame, however, will principally rest upon his various discoveries in this branch of science; and it would be injustice to his character not to describe, as amply as our limits will admit, the anatomical museum, the formation of which may be regarded as having been the main object of his life. In its plan it was absolutely unique, and the perfection to which he brought it rendered it the admiration of all who were capable of judging of its value. It embraced the grand design of exposing to view the gradations of nature, from the most simple state in which life is found to exist, to the most perfect and complete piece of animal mechanism, that of man. This collection of anatomical facts is arranged according to the functions they are intended to illustrate, the different parts of animal bodies intended for similar uses being brought together in series, so that the various links in the chain of perfection are readily followed, and clearly understood. This arrangement comprehends four great orders: the *first*, parts constructed for motion; *second*, parts essential to animals respecting their own internal economy and preservation; *third*, parts superadded for purposes connected with external objects; and, *fourth*, parts for the propagation of the species, and the maintenance of the young. The *first order* exhibits the fluids of living bodies in a series, from the simple colourless sap of some vegetables to the coloured and coagulating blood;—the muscles, from the straight simple muscle to the most complicated structure with elastic ligaments;—the growth of bone, horn, shell, &c.;—and the varieties of joints. The *second order* comprehends the organs of digestion, beginning with the hydatid, which is itself a simple pouch, and passing to the polypus, the leech, and more complicated animals, including a series of stomachs, of intestinal canals, and of the glands connected with them, as livers, spleens, &c. After the organs of digestion follows the system of absorbing vessels, from the roots of plants up to the lacteals and lymphatics of different animals. The next step is to the heart, which, in the caterpillar is a simple canal, and receives various additions as we

ascend in the scale, until we find it a double heart in man and quadrupeds: this leads to the structure of arteries and veins. Then the lungs are shewn in all their gradations, from the simple vascular lining of the egg-shell, which serves as lungs for the chicken, to those of the more perfect animals, including gills, &c. The windpipe and organs of voice are shewn under their different forms. And, lastly, the kidneys are exhibited, which separate the superfluous fluids from the circulation. The *third order* takes up the brain from its simplest state in the leech, to the snail, insects, fish, &c. upwards;—the varieties of all the organs of sense in the different tribes of living things; and, lastly, the external coverings of hair, feathers, scales, &c.; the weapons of offence and defence, as spurs, hoofs, horns, stings, and electric organs. As an appendix to this order, some peculiar structures are added, such as the air-bladder in fish, &c. The *fourth order* includes all the variety of parts connected with the process of generation in plants and animals, from the polypus and coral, to the perfect animals;—those of females in the maiden and impregnated state, including the products of seeds, spawn, eggs, &c.; the progress of incubation; the peculiarities of the fetus; and the various organs for the nourishment of the young. This sketch gives a very inadequate idea of the amazing number of objects, from every department of nature, which the collection comprised; but it contains, besides, a large series of whole animals, arranged according to their internal structure, many of them the rarest ever brought into this country; such as the camelopard, hippopotamus, &c. It comprehends, moreover, a series of skulls of different animals, and skeletons of almost every known genus;—an immense number of calculi, urinary, biliary, and intestinal;—a large collection of shells and insects;—and a most complete assortment of extraneous fossils. By his will, Mr. Hunter directed that this museum should be offered to the purchase of government; and, after some negotiation, it was bought for the public use for the sum of 15,000*l.* and given to the college of surgeons, on condition of exposing it to public view on certain days in the week, and giving a set of annual lectures explanatory of its contents. A large building for its reception has been completed in Portugal-street, connected with the college of surgeons, in Lincoln's-Inn-Fields; and in the spring of the present year (1810) the first course of lectures was delivered by Mr. Home and sir William Blizard.

At the time of his death, Mr. Hunter had made considerable progress in the printing of "A Treatise on the Blood, Inflammation, and Gun-shot Wounds," which was published in 1794, under the inspection of Mr. Home, who prefixed a biographical account of the author. See this Account; also Gen. Biog.

HUNTER, HENRY, a popular preacher and writer, was born at Culrofs, in Perthshire, in the year 1741. He had the best education that the circumstances of his parents would permit, and at the age of thirteen was sent to the university of Edinburgh, where, by his talents and proficiency, he attracted the notice of the professors, and at the age of seventeen he was appointed tutor to Mr. Boswell, afterwards one of the lords of session. When he left Edinburgh he accepted the office of tutor to lord Dundonald's sons at Culrofs abbey. In 1764 he was licensed to preach, having passed the several trials with great applause: and very quickly became much followed on account of his popular pulpit talents. He was ordained in 1766, and was appointed minister of South Leith. On a visit to London in 1769, he preached in most of the Scotch meeting-houses with great acceptance, and soon after his return he received an invitation to become pastor of the

Scotch church in Swallow-street, which he declined; but in 1771 he removed to London, and undertook the pastoral office in the Scotch church at London Wall. He appeared first as an author in 1783, by the commencement of his "Sacred Biography," which was at length extended to seven volumes octavo. While this work was in the course of publication, he engaged in the translation of Lavater's "Essays on Physiognomy," and in order to render his work as complete as possible, he took a journey into Switzerland, for the purpose of procuring information from Lavater himself. He attained, in some measure, his object, though the author did not receive him with the cordiality which he expected, suspecting that the English version must injure the sale of the French translation. The first number of this work was published in the year 1789, and it was finished in a style of respectability worthy the improved state of the arts. From this period Dr. Hunter spent much of his time in translating different works from the French language. In the year 1790 he was elected secretary to the corresponding board of the "Society for propagating Christian Knowledge in the Highlands and Islands of Scotland." He was likewise chaplain to the "Scotch Corporation," and both these institutions were much benefited by his zealous exertions in their behalf. In the year 1795, he published two volumes of sermons, and in 1798 he gave the world eight "Lectures on the Evidences of Christianity," being the completion of a plan begun by Mr. Fell. The whole contains a popular and useful elucidation of the proofs in favour of the Christian religion, arising from its internal evidence, its beneficial influence, and the superior value of the information which it conveys with respect to futurity. During the latter years of his life, Dr. Hunter's constitution suffered the severest shocks from the loss of three children, which, with other causes, contributed to render him unable to withstand the attacks of disease. He died at the Hot-Wells, Bristol, on the 27th of October 1802, in the 62d year of his age. Dr. Hunter was a man of learning: his writings are eloquent, and shew how well he had studied human nature. In the pulpit his manner was unaffected, solemn and impressive. He indulged his liberal and friendly heart in the exercise of hospitality, charity, and the pleasures of social intercourse, frequently beyond the limits which a regard to prudence and economy should have preferred. He was the translator of "Letters of Euler to a German Princess, on different Subjects in Physics and Philosophy;" "The Studies of Nature by St. Pierre;" "Saurin's Sermons;" "Sonnini's Travels." Miscellaneous pieces and sermons of his own have been published since his death, to which are prefixed Memoirs: from these the foregoing particulars have been taken. Dr. Hunter, about the year 1796 or 7, began "A History of London and its Environs," which came out in parts, and which has lately been finished by other editors. It makes two large quarto volumes.

HUNTER, a name given to a horse qualified to carry a person in the chaise. The shape of the horse designed for this service, should be strong and well knit together, as the jockies express it. Irregular or unequal shapes in these creatures are always a token of weakness. The inequalities in shape which shew a horse improper for the chaise, are the having a large head and a small neck, a large leg and a small foot, and the like. The head of the hunter should, indeed, always be large, but the neck should also be thick and strong to support it. The head should be lean, the nostrils wide, and the wind-pipe straight.

The whole shape of a horse intended for a hunter should be this: the ears should be small, open, and pricked; or though they be somewhat long, yet if they stand up erect,

HUNTER.

and bold, like those of a fox, it is a sign of toughness or hardiness. The forehead should be long and broad, not flat; or, as it is usually termed, mare-faced, but rising in the middle like that of a hare; the feather should be placed above the eye, the contrary being thought by some to threaten blindness. The eyes should be full, large and bright; the nostrils not only large, but looking red and fresh within; for an open and fresh nostril is always esteemed a sign of a good wind. The mouth should be large, deep in the wicks, and hairy. The wind-pipe should be large, and appear straight when he bridles his head; for if, on the contrary, it bends like a bow on his bridling, it is not formed for a free passage of the breath. This defect in a horse is expressed among the dealers by the phrase *cock-throated*. The head should be so set on to the neck, that a space may be felt between the neck and the chine; when there is no such space, the horse is said to be *bull-necked*, and this is not only a blemish in the beauty of the horse, but it also occasions his wind not to be so good. The crest should be strong, firm, and well risen; the neck should be straight and firm, not loose and pliant; the breast should be strong and broad; the ribs round like a barrel, the fillets large; the buttocks rather oval than broad; the legs clean, flat, and straight; and, finally, the mane and tail ought to be long and thin, not short and bushy, the last being counted a mark of dulness. When a hunter is thus chosen, and has been taught such obedience, that he will readily answer to the rider's signals, both of the bridle and hand, the voice, the calf of the leg, and the spurs; that he knows how to make his way forward, and has gained a true temper of mouth, and a right placing of his head, and has learned to stop and to turn readily, if his age be sufficiently advanced, he is ready for the field. It is a rule with all staunch sportsmen, that no horse should be used in hunting till he is full five years old; some will hunt them at four, but the horse at this time is not come up to his true strength and courage, and will not only fail at every tough trial, but will be subject to strains and accidents of that kind, much more than if he were to be kept another year first, when his strength would be more confirmed.

When the hunter is five years old, he may be put to graze from the middle of May till Bartholomew-tide; for the weather between these is so hot, that it will be very proper to spare him from work. At Bartholomew-tide the strength of the graze beginning to be nipped by frosts and cold dews, so that it is apt to engender crudities in the horse, he should be taken up while his coat is yet smooth and sleek, and put into the stable. When he is first brought home, he should be put in some secure and spacious place, where he may evacuate his body by degrees, and be brought, not all at once, to warm keeping; the next night he may be stabled up. It is a general rule with many not to clothe and stable up their horses till two or three days after they are taken from graze, and others who put them in the stable after the first night, yet will not dress and clothe them till three or four days afterward; but all this, except the keeping the horse one day in a large and cool place, is needless caution.

There is a general practice among the grooms, in many places, of giving their hunters wheat-straw as soon as they take them up from graze. They say they do this to take up their bellies; but there seems much reason to disapprove of this. The change is very violent, and the nature of the straw so heating and drying, that there seems great reason to fear that the astringent nature of it would be prejudicial, more than is at first perceived. It is always found that the dung is hard after this food, and is voided with pain and difficulty, which is in general very wrong for this sort of

horse. It is better, therefore, to avoid this straw-feeding, and to depend upon moderate airing, warm cloathing, and good old hay, and old corn, than to have recourse to any thing of this kind.

When the horse has evacuated all his graze, and has been properly shod, and the shoes have had time to settle to his feet, he may be ridden abroad, and treated in this manner: the groom ought to visit him early in the morning, at five o'clock in the long days, and at six in the short ones; he must then clean out the stable, and feel the horse's neck, flank, and belly, to find the state of his health, if the flank feels soft and flabby, there is a necessity of good diet to harden it, otherwise any great exercise will occasion swellings and goutiness in the heels. After this examination, a handful or two of good old oats, well sifted, should be given him: this will make him have more inclination to water, and will also make the water sit better on his stomach than if he drank fasting. After this he is to be tied up and dressed. If in the doing of this he opens his mouth, as if he would bite, or attempts to kick at the person, it is a proof that the teeth of the curry-comb are too sharp, and must be filed blunter. If after this he continues the same tricks, it is through wantonness, and he should be corrected for it with the whip. The intent of currying being only to raise the dust, this is to be brushed off afterwards with a horse-tail nailed to a handle, or any other light brush. Then he is to be rubbed down with the brush, and dusted a second time; he should then be rubbed over with a wet band, and all the loose hairs, and whatever foulness there is, should be picked off. When this is done, and he is wiped dry as at first, a large saddle-cloth is to be put on, reaching down to the spurring-place; then the saddle is to be put on, and a cloth thrown over it, that he may not take cold; then rub down his legs, and pick his feet with an iron picker, and let the mane and tail be combed with a wet mane-comb. Lastly, it is a custom to spurt some beer into his mouth just before the leading him out of the stable. He should then be mounted, and walked a mile at least to some running water, and there watered; but he must only be suffered to take about half his water at one drinking.

It is the custom of many to gallop the horse at a violent rate as soon as he comes out of the water, but this is extremely wrong for many reasons. It endangers the breaking a horse's wind more than any other practice, and often has been the occasion of hurrying very good horses. It uses them also to the disagreeable trick we find in many horses, of running away as soon as ever they come out of the water; and with some it makes them averse to drinking, so that they will rather endure thirst, and hurt themselves greatly by it, than bring on the violent exercise which they remember always follows it. The better way is to walk him a little after he is out of the water, then put him to a gentle gallop for a little while, and after this to bring him to the water again. This should be done three or four times, till he will not drink any more. If there is a hilly place near the watering-place, it is always well to ride up to it; if otherwise, any place is to be chosen where there is free air and sun. That the creature may enjoy the benefit of this, he is not to be galloped, but walked about in this place an hour, and then taken home to the stable. The pleasure the horse himself takes in these airings, when well managed, is very evident, for he will gape, yawn, and shrug up his body; and in these, whenever he would stand still to stale, dung, or listen to any noise, he is not to be hindered from it, but encouraged in every thing of this kind.

The advantages of these airings are very evident; they purify

purify the blood, teach the creature how to make his breathing agree with the rest of the motions of his body, and give him an appetite to his food, which hunters and racers, that are kept stalled up, are otherwise very apt to lose. On returning from airing, the litter of the stable should be fresh, and by stirring this, and whistling, he will be brought to stale. Then he is to be led to his stall, and tied up, and again carefully rubbed down; then he should be covered with a linen cloth next his body, and a canvas one over that, made to fit him, and reaching down to his legs. This, as the duke of Newcastle observes, is a custom which we learnt of the Turks, who are, of all people, the most nice and careful of their horses. Over this covering there should be put a body-cloth of six or eight straps; this keeps his belly in shape, and does not hurt him. This cloathing will be sufficient while the weather is not very sharp, but in severe seasons, when the hair begins to rise and start in the uncovered parts, a woollen cloth is to be added, and this will always prove fully sufficient.

Different horses and different seasons make a variety of the degree of cloathing necessary; but there always is an obvious rule to point out the necessary changes, the roughness of the coat being a mark of the want of cloathing, and the smoothness of it a proof that the cloathing is sufficient. Therefore, if at any time the hair is found to start, it is a notice that some farther cloathing is to be added.

If the horse sweat much in the night, it is a sign that he is over-fed, and wants exercise; this, therefore, is easily remedied. An hour or more after the horse is come in from his airing, the groom should give him a whisp of clean hay, making him eat it out of his hand: after this let the manger be well cleaned out, and a quartern of oats clean sifted be given him. If he eats up this with an appetite, he should have more given him; but if he is slow and indifferent about it, he must have no more. The business is to give him enough, but not to cloy him with food.

If the horse gets flesh too fast on this home feeding, he is not to be stinted to prevent it, but only his exercise increased; this will take down his flesh, and at the same time give him strength and wind. After the feeding in the morning is over, the stable is to be shut up, only leaving him a little hay on his litter. He need be no more looked at till one o'clock, and then only rubbed down, and left again till the time of his evening watering, which is four o'clock in the summer, and three in the winter. When he has been watered, he must be kept out an hour or two, or more, if necessary, and then taken home and rubbed as after the morning watering. Then he is to have a feed of corn at six o'clock, and another at nine at night; and being then cleaned, and his litter put in order, and hay enough left for the night, he is to be left till morning. This is the direction for one day, and in this manner he is to be treated every day for a fortnight, at the end of which time his flesh will be so hardened, his wind so improved, and his mouth so quickened, and his gallop brought to so good a stroke, that he will be fit to be put to moderate hunting. During the time that he is used to hunting, he must be ordered on his days of rest exactly as he is directed for the fortnight when he is in preparation; but as his exercise is now greatly increased, he must be allowed a more strengthening food, mixing some old split beans at every feeding with his oats.

And if this is not found to be sufficient, the following bread must be given: let two pecks of old beans, and one peck of wheat be ground together, and made into an indifferently fine meal; then knead it into dough, with some

warm water, and a good quantity of yeast: let it lie a time that it may rise and swell, which will make the bread the lighter; then make it into loaves of a peck each, and let it be baked in a slow oven, that it may be thoroughly done, without being burnt; when it is taken out of the oven, it must be set, bottom upwards, to cool; when it is one day old, the crust is to be chipped off, and the crumb given him for food. When this is ready, he should have some of it at least once in the day; but it is not to be made the only food, but some feeds are to be of oats alone; some of oats and this bread, and some of oats and beans mixed together. The making a variety in this manner, being the best of all methods of keeping up the appetite, which is often apt to fail.

The day before the horse is to hunt, he must have no beans, because they are hard of digestion, but only some oats with this bread; or if he will be brought to eat the bread alone, that will be best of all. His evening feed should, on this day, be somewhat earlier than usual; and after this, he is only to have a whisp of hay out of the groom's hand till he return from hunting.

The hunter, in order to his behaving well in the field, ought to have great care and indulgence in the stable: he ought to have as much rest and quiet as may be, to be kept well supplied with good meat, clean litter, and fresh water by him; he should be often dressed, and suffered to sleep as much as he pleases. He should be so fed that his dung may be rather soft than hard, and it must be of a bright and clean colour. All this may be easily managed by the continual observance and change of his food, as occasion requires. After his usual scourings he should have exercises and mashes of sweet malt, or bread and beans; or wheat and beans mixed together, are to be his best food, and beans and oats his worst.

Some very great sportsmen are for keeping their horses out at grafs all the buck-hunting season, never taking them up into the stable at all, but allowing them in the field as much oats with their grafs as they will eat. The horse may be thus rid three days in the week for the whole season, and never damaged by it, nor ever shewing any marks of harm afterwards.

HUNTER'S Bay, or *Rigg bay*, in *Geography*, a bay of Scotland, on the E. coast of the county of Wigton.

HUNTER'S Town, a town, or village, of Pennsylvania, situated in York county; 25 miles W. by S. of York town.

HUNTERDON, a county of New Jersey, in America, bounded N. by that of Morris, E. by Somerset, S.E. by Burlington, S.W. and W. by Delaware river, which separates it from the state of Pennsylvania, and N.W. by Suffex county; about 40 miles long and 32 broad, divided into 10 townships, containing 21,261 inhabitants, including 1220 slaves. On Muskonetcong mountain in this county, is a strong chalybeate spring, to which many persons resort; it issues from the side of an eminence into an artificial reservoir, for the accommodation of those who wish to bathe in, as well as to drink, the waters. The chief town of the county is Trenton.

HUNTING, the art, or act, of pursuing and chasing beasts of game. See *GAME*.

In its general sense, hunting includes the pursuit both of hairy and feathered game; but in its more proper and restrained signification, it is only applicable to beasts of venery and chase.

F. De Launay, formerly professor of the French laws, has an express treatise of hunting.

The antiquity of hunting may be traced back upwards of

HUNTING.

2600 years before the Christian era. The sacred history describes the first warriors under the name of hunters. Thus Nimrod is represented as "a mighty hunter before the Lord." (Gen. x. 9.) In the sequel, he made foldiers of his companions, who had assisted him in hunting and destroying the savage beasts that laid waste the country about Babylon, and employed them in extending and establishing his conquests.

" Bold Nimrod first the lion's trophies wore,
The panther bound, and lanc'd the bristling boar :
He taught to turn the hare, to bay the deer,
And wheel the courser in his mid career." Tickell.

We find, that among the more civilized nations, as the Persians, Greeks, and Romans, it always made one of their genteeler diversions; and as to the wilder and more barbarous, it served them with food and necessaries. The Roman jurisprudence, which was formed on the manners of the first ages, made a law of it, and established it as a maxim, that as the natural right of things which have no master belongs to the first possessor; wild beasts, birds, and fishes, are the property of him, whoever he be, that can first take them.

But the northern nations of barbarians, who over-ran the Roman empire, bringing with them a stronger taste for the diversion, and the people being now possessed of other, and more easy means of subsistence from the lands and possessions of those they had vanquished; their chiefs and leaders began to appropriate the right of hunting, and, instead of a natural right, to make it a royal one. Thus it continues to this day, the right of hunting, among us, belonging only to the king, and those who derive it from him.

And hence have arisen all our laws and charters of the forest, laws and regulations for preservation of the game, &c. See FOREST, GAME, and TRESPASS.

The hunting used by the ancients was much like that now practised for the rein deer; which is seldom hunted at force, or with hounds; but only drawn with a blood-hound, and forestalled with nets and engines. Thus did they with all beasts; whence a dog is never commended by them for opening, before he has discovered where the beast lies: hence they were not in any manner curious as to the music of their hounds, or the composition of their kennel or pack, either for deepness, loudness, or sweetness of cry, which is become a principal point in the hunting of our days.

Their huntsmen, indeed, were accustomed to shout and make a great noise, as Virgil observes in the third of his Georgics: "ingentem clamore preme ad retia cervum." But that clamour was only to bring the deer to the nets laid for him.

The Sicilian way of hunting had something in it very extraordinary. The nobles or gentry being informed which way a herd of deer passed, gave notice to one another, and appointed a meeting; every one bringing with him a cross-bow or long-bow, and a bundle of staves, shod with iron, the heads bored, with a cord passing through them all: thus provided they came to the herd, and casting themselves about in a large ring, surrounded the deer. Then, each taking his stand, unbound his faggot, set up his stake, and tied the end of his cord to that of his next neighbour, at the distance of ten feet from one another. Then taking feathers dyed in crimson, and fastened on a thread, they tied them to the cord; so that with the least breath of wind they would whirl round. Which done, the persons who kept the stands withdrew, and hid themselves in the next covert. Then the chief ranger entering within the line with hounds to draw after the herd, roused the game with their cry; which flying towards the line, were turned off, and

still gazing on the shaking and shining feathers, wandered about as if kept in with a real wall or pale. The ranger still pursued, and calling every person by name, as he passed by their stand, commanded him to shoot the first, third, or sixth, as he pleased; and if any of them missed, or singled out another than that assigned him, it was counted a grievous disgrace. By such means, as they passed by their several stations, the whole herd was killed by the several bands.

Hunting constituted a great part of the employment of the ancient Germans and also of the Britons, when the more furious occupations of war did not engage their attention. This was not merely an amusement to which, in many cases, the ferocity of their temper actually inclined them, but it was the principal means by which, in the uncultivated state of the countries which they inhabited, they procured their subsistence. Such was the case so late as the third century with those unconquered Britons who lived beyond Adrian's wall. With the Celtic nations hunting, to which they were inordinately attached, served as a preparatory discipline for war; and it has answered the same purpose in many other nations, which we have been accustomed to denominate barbarous. So general and so ardent was the attachment to hunting among the ancient Britons, that, whilst the chieftains practised it in order to prepossess their mistresses with a favourable opinion of their valour and agility, young ladies of distinguished rank and beauty devoted much of their time to the chase. On account of the general prevalence of this pastime, and its apprehended injury to the general interests of society, the liberty of the chase has been more or less restrained from early ages, and kings and princes have successively augmented their assumed rights in hunting; claiming to themselves the primitive and sole title to hunt, and controlling their nobles, and all persons of inferior rank, from enjoying this amusement, unless, as we have before observed, the privilege was granted by them, and liable to be revoked at their will. Hence arose the numerous and severe restraints and penalties of the game laws. See GAME.

Among the Mexicans hunting was a favourite exercise; and in pursuing it they used, with singular dexterity, bows and arrows, darts, nets, snares, and a kind of tubes, through which they shot out, by blowing, little balls at birds. Those instruments, of this kind, that were used by their kings and great men, were curiously carved and painted, and adorned with silver and gold. Besides their private hunting exercises, in which they engaged for amusement or subsistence, they had also hunting matches, either appointed by the king, or undertaken with a view of providing victims for their sacrifices. A wood, not far from the capital, was selected for this purpose; and it was enclosed by some thousands of hunters, who formed a circle of six, seven, or eight miles, according to the number of animals which they proposed to take. Fire was then set to the grass in a number of places, and a terrible noise was made with drums, horns, shouting and whistling. The hunters at the same time gradually contracted their circle, and thus enclosed the game in a very small space, and it was taken in the snares that had been previously set, or killed by the hunters. The number of animals, comprehending deer, wild goats, hares, rabbits, &c. collected and destroyed on these occasions, is almost incredible.

Hunting was also much practised by the savage and bloody conqueror Genghiz-Khan; and his method of employing his soldiers in a kind of warfare with the beasts, when they had no human enemies with whom to contend, was similar to that of the Mexicans. The chase is still an object to which the East Indian princes are much inclined,

Mr.

HUNTING.

Mr. Blanc, who attended the hunting excursions of Afoph ul Dowlah, visir of the Mogul empire, and nabob of Oude in 1785 and 1786, gives the following account of them.

The time chosen for the hunting party is about the beginning of December; and the diversion is continued till the heats, which commence about the beginning of March, oblige them to stop. During this time a circuit of between 400 and 600 miles is generally made; the hunters bending their course towards the skirts of the northern mountains, where the country is wild and uncultivated. The visir takes along with him not only his court and seraglio, but a great part of the inhabitants of his capital. His immediate attendants may amount to about 2000; but besides these he is also followed by 500 or 600 horse, and several battalions of regular sepoy with their field-pieces. Four or five hundred elephants are also taken along with him: of which some are used for riding, others for fighting, and some for clearing the jungles and forests of the game. About as many sumpter horses of the beautiful Persian and Arabian breeds also accompany him. A great many wheel carriages drawn by bullocks likewise attend, which are used chiefly for the convenience of the women; sometimes also he has an English chaise or two, and sometimes a chariot; but all these, as well as the horses, are merely for show, the visir himself never using any other conveyance than an elephant, or sometimes, when fatigued or indisposed, a palanquin. The animals used in the sport are principally greyhounds, of which there may be about 300; he has also about 200 hawks, and a few trained leopards for hunting deer. There are a great number of marksmen, whose profession it is to shoot deer; with many fowlers, who provide game: as none of the natives of India know how to shoot game with small shot, or to hunt with slow hounds. A vast number of matchlocks are carried along with the company with many English pieces of various kinds, 40 or 50 pairs of pistols, bows and arrows, besides swords, daggers, and sabres without number. There are also nets of various kinds, some for quail, and others very large, for fishing, which are carried along with him upon elephants, attended by fishermen, so as always to be ready for throwing into any river or lake that may be met with. Every article that can contribute to luxury or pleasure is likewise carried along with the army. A great many carts are loaded with the Ganges water, and even ice is transported for cooling the drink. The fruits of the season and fresh vegetables are daily sent to him from his gardens by bearers stationed at the distance of every ten miles; by which means each article is conveyed day or night at the rate of four miles an hour. Besides the animals already mentioned, there are also fighting antelopes, buffaloes; and rams in great numbers; also several hundred pigeons, some fighting cocks, with a vast variety of parrots, nightingales, &c.

To complete the magnificence or extravagance of this expedition, there is always a large bazar, or moving town, which attends the camp; consisting of shop-keepers and artificers of all kinds, money-changers, dancing-women; so that, on the most moderate calculation, the whole number of people in his camp cannot be computed at fewer than 20,000. The nabob himself, and all the gentlemen of his camp, are provided with double sets of tents and equipage, which are always sent on the day before to the place to which he intends to go; and this is generally eight or ten miles in whatever direction most game is expected; so that by the time he has finished his sport in the morning, he finds his whole camp ready pitched for his reception.

The nabob, with the attending gentlemen, proceed in a regular moving court or durbar, and thus they keep con-

versing together and looking out for game. A great many foxes, hares, jackals, and sometimes deer, are picked up by the dogs as they pass along: the hawks are carried immediately before the elephants, and let fly at whatever game is sprung for them, which is generally partridges, bustards, quails, and different kinds of herons; these last affording excellent sport with the falcons or sharp-winged hawks. Wild boars are sometimes started, and either shot or run down by the dogs and horsemen. Hunting the tyger, however, is looked upon as the principal diversion, and the discovery of one of these animals is accounted a matter of great joy. The cover in which the tyger is found is commonly long grass, or reeds of such an height as frequently to reach above the elephants; and it is difficult to find him in such a place, as he commonly endeavours either to steal off, or lies so close to the ground that he cannot be roused till the elephants are almost upon him. He then roars and skulks away, but is shot at as soon as he can be seen; it being generally contrived that the nabob shall have the compliment of firing first. If he be not disabled, the tyger continues to skulk along, followed by the line of elephants; the nabob and others shooting at him as often as he can be seen till he falls. The elephants themselves are very much afraid of this terrible animal, and discover their apprehensions by shrieking and roaring as soon as they begin to smell him or hear him growl; generally attempting to turn away from the place where he is. When the tyger can be traced to a particular spot, the elephants are disposed of in a circle round him; in which case he will at last make a desperate attack, springing upon the elephant that is nearest, and attempting to tear him with his teeth or claws. Some, but very few, of the elephants, can be brought to attack the tyger; and this they do by curling up their trunks under their mouths, and then attempting to toss, or otherwise destroy him with their tusks, or to crush him with their feet or knees. It is considered as good sport to kill one tyger in a day; though sometimes, when a female is met with her young ones, two or three will be killed.

The other objects of pursuit in these excursions are wild elephants, buffaloes, and rhinoceroses. Our author was present at the hunting of a wild elephant of vast size and strength. An attempt was first made to take him alive by surrounding him with tame elephants, while he was kept at bay by crackers and other fire-works; but he constantly eluded every effort of this kind. Sometimes the drivers of the tame elephants got so near him, that they threw strong ropes over his head, and endeavoured to detain him by fastening them around trees; but he constantly snapped the ropes like pack-threads, and pursued his way to the forest. Some of the strongest and most furious of the fighting elephants were then brought up to engage him; but he attacked them with such fury that they were all obliged to desist. In his struggle with one of them he broke one of his tusks, and the broken piece, which was upwards of two inches in diameter, of solid ivory, flew up into the air several yards above their heads. Orders were now given to kill him, as it appeared impossible to take him alive; but even this was not accomplished without the greatest difficulty. He twice turned and attacked the party who pursued him; and in one of these attacks struck the elephant obliquely on which the prince rode, threw him upon his side, but then passed on without offering farther injury. At last he fell dead, after having received, as was supposed, upwards of 1000 balls into his body. See ELEPHAS.

Hunting, considered as an exercise, is perhaps the best that can possibly be contrived for strengthening the general habit, and procuring health and vigour. The season of the year, the

HUNTING.

the time of the day defined for this amusement, and the motion necessary on this occasion, are all admirably adapted to the restoration and continuance of health. It is, besides, of no small importance to have the mind recreated at the time the body is exercised; for this admirably affils the due circulation of the fluids through the minute canals defined for their conveyance; and there are few people not utterly abandoned to idleness and debauchery of some kind or other, who do not perceive a spontaneous flow of spirits when they ride at or about the rise of the sun, when they respire the purest air, when variety of perpetually changing scenes present themselves, and when the mind is agreeably agitated concerning the event of the chase.

If we advert to the character of those nations in ancient times, which were most addicted to this exercise, we shall find that they delighted in war, and in oppressing and enslaving their own species. Nimrod, the mighty hunter, was a tyrant. The Lacedæmonians indulged themselves without controul in this exercise, whilst they cruelly oppressed those whom they had in their power. (See *HELOTS*.) The wise legislator Solon restrained the Athenians from gratifying themselves in this way, lest they should be led to neglect the mechanic arts. The Egyptians, Persians, and Scythians, &c. were fond of hunting and of war. As mankind became more civilized, hunting became less prevalent: such was in a degree the case with the Romans, although they continued to a late period to make death and slaughter familiar to the citizens, by the diversions of the amphitheatre and circus, which consisted of exhibitions of wild beasts, and of human gladiators, destroying one another. Those who think the exercise of hunting incompatible with the principles of humanity, allege that it is allowable only when an uncultivated country is over-run with noxious animals, or when it is necessary to kill wild animals for food. For a defence of this diversion, and an attempt to reconcile it with the sentiments and feelings of humanity, see *Manchester Transactions*, vol. i. p. 341, &c.

Hunting is practised in a different manner, and with a different apparatus, according to the nature, genius, and address, of the particular beast which is the object of it. These beasts are, the hart, hare, boar, wolf, buck, doe, fox, marten, and roe; the five first of which are denominated beasts of the forest, or venery, *sylvestres*; and the five latter, beasts of the field, or of chase, *campesfires*.

The gentlemen, and masters of the sport, have framed a new set of terms, which may be called the *hunting language*; a concise vocabulary of which we shall here give the reader.

The terms, then, used for beasts of venery and chase, as they are in company, are these: they say, a *herd* of harts, and all manner of deer; a *bevy* of roes; a *founder* of swine; a *rovt* of wolves; a *riebsfs* of martens; a *brace* or *leash* of bucks, foxes, or hares; a *couple* of rabbits or conies.

There are also terms for their lodging; a hart is said to *barbour*; a buck *lodges*; a roe *beds*; a hare *seats*, or *forms*; a coney *sits*; a fox *kenels*; a marten *trees*; an otter *avatches*; a badger *earths*; a boar *couches*.

Hence, to express their dislodging, they say, *unbarbour* the hart; *rouse* the buck; *start* the hare; *bolt* the coney; *unkennel* the fox; *untree* the marten; *vent* the otter; *dig* the badger; *rear* the boar.

The terms for their noise at rutting time are as follows: a hart *belleth*; a buck *growns* or *troats*; a roe *bellows*; a hare *beats* or *taps*; an otter *whines*; a boar *freams*; a fox *barks*; a badger *sbricks*; a wolf *howls*; a goat *rattles*.

Terms for their copulation: a hart or buck goes to *rut*; a roe goes to *tourn*; a bear goes to *brim*; a hare or coney

goes to *buck*; a fox goes to *clicketing*; a wolf goes to *match* or *make*; an otter *hunteth* for his kind.

Terms for the footing and treading: of a hart we say, the *stot*; of a buck, and all fallow deer, the *view*; of all deer, if on the grass, and scarce visible, the *foiling*; of a fox, the *print*; and of other the like vermin, the *footings*; of an otter, the *marks*; of a boar, the *track*; the hare, when in open fields, is said to *fore*; when she winds about to deceive the hounds, she *doubles*; when she beats on the hard highway, and her footing comes to be perceived, she *pricketh*; in snow, it is called the *trace* of the hare.

The tail of a hart, buck, or other deer, is called the *single*; that of a boar, the *wreath*; of a fox, the *brush* or *drag*; and the tip at the end, the *chape*; of a wolf, the *stern*; of a hare and coney, the *feut*.

The ordure or excrement of a hart, and all deer, is called *fecemets* or *seawisking*; of a hare, *crotils* or *crofing*; of a boar, *leffes*; of a fox, the *billeting*; and of other the like vermin, the *fuants*; of an otter the *spraints*. As to the heads of deer, something has already been spoken under the article *HEAD*.

For the attire or parts thereof, those of a stag, if perfect, are, the *bur*, the *pearls*, the little *knobs* on it, the *beam*, the *gutters*, the *antler*, the *sur-antler*, *royal*, *sur-royal*, and all at top, the *croches*; of the buck, the *bur*, *beam*, *brow-antler*, *back-antler*, *advancer*, *palm*, and *spellers*.

If the croches grow in the form of a man's hand, it is called a *palmed head*. Heads bearing not above three or four, and the croches placed aloft, all of one height, are called *crowned heads*. Heads having double croches, are called *forked heads*, because the croches are planted on the top of the like forks.

They say a *litter* of cubs; a *nest* of rabbits; a squirrel's *dray*.

The terms used in respect to the dogs, &c. are as follow: of grey-hounds, two make a *brace*; of hounds, a *couple*; of grey-hounds, three make a *leash*; of hounds, a *couple* and *half*:—they say, let *slip* a grey-hound; and *cast off* a hound: the string wherein a grey-hound is led is called a *leash*; and that of a hound a *lyome*: the grey-hound has his *collar*, and the hound his *couples*: we say a *kennel* of hounds, and a *pack* of beagles.

HUNTING, *styles* or *manners of*, are various, according to the country, the beast, and the means whereby he is to be caught.

Hunting, as practised among us, is chiefly performed with dogs; of which we have various kinds, accommodated to the various kinds of game: *hounds*, *grey-hounds*, *staunch-hounds*, *blood-hounds*, *terriers*, &c. See *DOG*, *HOUND*, &c.

In the kennels or packs, they generally rank them under the heads of *enterers*, *drivers*, *flyers*, *tyers*, &c.

On some occasions, nets, spears, and instruments for digging the ground are also required: nor is the hunting-horn to be omitted. See *HORN*.

The usual chases among us are, the *hart*, *buck*, *roe*, *hare*, *fox*, *badger*, and *otter*. We shall here give something of what relates to each of these.

With regard to the seasons of hunting: hart and buck hunting begins at the end of fence-month, which is a fortnight after Midsummer, and lasts till Holy-rod-day. The hind and doe come in course on Holy-rod-day, and last till Candlemas. Fox hunting comes in at Christmas and holds till Annunciation.

Roe hunting begins at Michaelmas and ends at Candlemas. Hare hunting commences at Michaelmas, and goes out at the end of February. Where the wolf and boar are hunted, the season for each begins at Christmas; the first

HUNTING.

ending at the Annunciation, the second at the Purification.

Here, too, is the place for some general terms and phrases, more immediately used in the progress of the sport itself; what belongs to the several sorts of game in particular, being reserved for the respective articles.

When the hounds, then, being cast off, and finding the scent of some game, begin to open and cry, they are said to *challenge*; when they are too busy before the scent be good, they are said to *babble*; when too busy where the scent is good, *lawl*; when they run it end-ways orderly, holding in together merrily, and making it good, they are said to be in *full cry*; when they run along without opening at all, it is called *running mute*.

When spaniels open in the string, or a grey-hound in the course, they are said to *lapse*.

When beagles bark and cry at their prey, they are said to *yearn*.

When the dogs hit the scent the contrary way, they are said to *draw amiss*.

When then they take fresh scent, and quit the former chafe for a new one, it is called *hunting change*.

When they hunt the game by the heel or track, they are said to *hunt counter*.

When the chafe goes off, and returns again, traversing the same ground, it is called *hunting the soil*.

When the dogs run at a whole herd of deer instead of a single one, it is called *running riot*.

Dogs set in readiness where the game is expected to come by and cast off after the other hounds are passed, are called a *relay*. If they be cast off before the other dogs be come up, it is called a *vaultlay*.

When, finding where the chafe has been, they make a proffer to enter, but return, it is called a *blemish*.

A lesson on the horn to encourage the hounds is named a *call* or *recheat*. That blown at the death of a deer is called the *mort*. The part belonging to the dogs of any chafe they have killed is the *reward*. They say, *take off* a deer's skin; *strip* or *case* a hare, fox, and all sorts of vermin; which is done by beginning at the snout, and turning the skin over the ears down to the tail.

HUNTING, *Laws relating to*. See GAME.

Notwithstanding all the game laws, and the various qualifications for hunting pointed out by statutes, which imply a power for persons so qualified to hunt, yet, according to judge Blackstone, no man but he who has a chafe, or free-warren, by grant of the crown or prescription, which supposes one, can justify hunting or sporting upon another man's soil; nor indeed, in thorough strictness of common law, either hunting or sporting at all. By stat. 1 Hen. VII. c. 7. unlawful hunting in any legal forest, park, or warren, not being the king's property, by *night*, or with *painted faces*, was declared to be single felony. But now by the statute 9 Geo. I. c. 22. to appear armed in any enclosed forest or place where deer are usually kept, or in any warren for hares or conies, or in any high road, open heath, common, or down, by day or night, with faces blacked or otherwise disguised, or (being so disguised) to hunt, wound, kill, or steal any deer, to rob a warren, or to steal fish, or to procure by gift or promise of reward any person to join them in such unlawful act, is felony without benefit of clergy. Persons so hunting are liable to actions of trespass by the possessors of the land. Comment. vol. ii. p. 418, and vol. iv. p. 174. See TRESPASS.

HUNTING, *Badger*. A badger is called by several names *viz.* a *grey*, *brock*, *boreson*, or *bauson*: the male is called a *badger*, or *boar-pig*, and the female a *sew*. See URSUS MILV.

This beast is very frequent in Italy, Sicily, the Alpine, and Helvetian coasts; and is not uncommon in France and England. It is found also as far north as Norway and Russia; in Siberia, about the rivers Tom and Lena; it inhabits China, and is exposed to sale for food in the markets of Pekin.

The badger is a very sleepy beast, especially in the day-time, seldom stirring abroad but in the night; whence the denomination *lucifuga*, q. d. *avoider of the light*. It burrows under ground like the fox, and forms several different apartments, though with only one entrance, carrying in its mouth grafs in order to form a bed for its young. It is so clearly an animal, that it never obeys the call of nature in its apartments, but goes out for that purpose. It breeds only once in a year, and brings four or five at a time.

The badger is a deep biting beast, having very sharp teeth; to guard against the effects of which, it is usual to put great broad collars about the dogs' necks. He fights on his back, and by this means is at liberty to use both his teeth and nails. He has a faculty of blowing up his skin after a strange manner, by which he defends himself against any blow or bite of the dogs; so that you may thresh on his back till you are weary to no purpose; but a small stroke on the nose dispatches him presently. The skin of the badger, when dressed with the hair, is used for pistol furniture. The Highlanders make their pendant pouches of it. The hair is often used for making brushes to soften the shades in painting, called sweetening tools. These animals are also hunted in the winter nights for the sake of their flesh, for the hind quarters may be made into hams, not inferior in goodness to the best bacon. The fat is much valued for ointments and salves.

The method of hunting the badger is thus: seek the earth and burrows where he lies, and in a clear moonshine night go and stop all the holes but one or two, and therein place sacks, fastened with drawing strings, which may shut him in as soon as he strains the bag. The bags thus set, cast off your hounds, and beat all the groves, hedges or tufts within a mile or two: the badgers that are abroad being alarmed by the dogs, will straight repair to their earths, and soon be taken. He that stays to watch the sacks must stand close, and upon a clear wind, or else the badger will find him, and fly some other way for safety. If the hounds either encounter him, or undertake the chafe before he can get into his earth, he will stand at bay like a boar, and make excellent sport.

If the badger be attacked in his earth, as soon as he perceives the terriers yearn him, he will stop the hole between the dogs and himself; and if the dogs continue baying, he removes his baggage with him, and goes into another apartment or chamber, of which he usually has half a dozen in the burrow; thus retreating from one to the other, till he can go no further, and barricading the way as he goes. In hunting the badger as well as the fox, a man cannot justify breaking the soil, and digging him out of his earth.

Another mode of catching badgers is by a "pit-fall" across their accustomed path. This should be five feet deep and four feet long, narrow at the top and bottom, and wide in the middle. This pit must be covered with small boughs or sticks, which retain their leaves (either withered or green, according to the season): they must be so laid, that the weight of the badger when he treads upon them will instantly make them give way. The digging of badgers is, without very good terriers, a work of time: for if terriers do not keep constantly at him, from his facility in penetrating and throwing back the earth (which he possesses beyond any other animal) he will, in loose sand, bury himself faster than the workmen

HUNTING.

workmen can sink pits, by which he may be got into an angle.

HUNTING, *Boar*. See *BOAR*.

HUNTING, *Buck*, or *hunting fallow deer*. See *BUCK*, and *CERVUS Dama*.

The female is called *doe*, or *doo*: the first year a *fawn*; second, a *togg*; the third, a *doe*. See *DEER*.

Less art and skill are required in lodging a buck, than in harbouring a hart or stag; nor does there need so much drawing after; it is sufficient that you judge by the view, and mark what grove or covert he enters; for he does not wander and rove so often as a hart, nor so frequently change his layer. When hard hunted he usually takes to some strong hold or covert, with which he is acquainted; not flying far before the hounds, nor crossing nor doubling, nor using any of the subtleties the hart is accustomed to.

The buck will beat a brook, but seldom a great river as the hart, nor can he stay so long at foil.

The greatest subtilty a huntsman need use in hunting the buck, is to beware of hunting counter or change, because of the plenty of fallow deer, which use to come more directly upon the hounds than the red deer do.

The buck herds more than the hart, and lieth in the driest places; but if he be at large, unconfined in a park, he herds but little from May to August, because the flies trouble him. He takes delight in hilly places, but chooses the dales to feed in.

HUNTING, *Fox*. See *FOX*. His nature, in many respects, is like that of a wolf; and both bring the same number of cubs at a litter: but the fox litters deep under ground, which the wolf does not.

The fox sleeps much and sound during the day, and, like the dog, lies in a round form, and may be approached without waking him; but he is in motion and seeking his prey the whole night. When only reposing himself he stretches out his hind legs, and lies on his belly: in this position he spies the birds, as they alight near him, and is ready to spring upon such as are within his reach. Crows, magpies, and other birds, which consider the fox as a common enemy, have such an antipathy to him, that they often give notice of his retreat, by the most clamorous notes. Jays and blackbirds, in particular, will incessantly repeat the watch cries; and when the hounds are in chase of him, crows and magpies will follow him with their screams from tree to tree to a considerable distance, and not unfrequently, when hounds are at a check, indicate which way the fox has shaped his course. The fox has proverbially a strong and offensive smell; he has also a yelping kind of bark, which consists of a quick succession of similar tones, at the end of which he generally raises his voice, like the cry of the peacock. In winter, and especially during frost and snow, and when going to clicket, he yelps much; but in summer he is almost entirely silent; and during this season he casts his hair.

A bitch fox is hard to take when breeding and with cub, in regard she lies near her burrow, into which she runs upon hearing the least noise: indeed it is no easy matter to take her at any time, as being a beast of exceeding subtilty. After littering, if she perceives her retreat is discovered, she carries off her cubs, one by one, to a more secure situation.

What makes fox-hunting the more entertaining, is the strong hot scent this creature affords, which keeps up an excellent cry; but as his scent is hotter at hand, so it dies sooner than that of a hare, &c. Add, that he never flies far before the hounds, as not trutting to his legs or the champaign ground, but has recourse to the strongest coverts. When he can no longer stand up before the hounds, he takes

earth, and must be dug out. When coursed by grey-hounds, on a plain, his last refuge is usually to piss on his tail, and flap it in their faces as they come near him; sometimes squirting all his thicker excrement upon them, to make them give over their course.

When a bitch fox goes a clicketing, and seeks the dog, she cries with a hollow voice, not unlike the howling of a mad dog; and the like noise she makes when she misses any of her cubs: but she never cries at all when she is about to be killed, but defends herself in silence to the last gasp.

The fox is taken with hounds, grey-hounds, terriers, nets, and gins. Of terriers there are two sorts: the one crook-legged, and commonly short-haired, which take earth well, and lie long at fox or badger; the other is shagged, and straight-legged, which will not only hunt above ground as others, but also enter the earth with great fury, though these cannot stay in so long on account of their vehemence.

The fox chuses to earth in ground hard to dig: as in clay or stony ground, or amongst the roots of trees; and his earth has commonly but one hole, which goes straight along in, before it comes at their couch: he sometimes by craft possesses himself of a badger's old burrow, which has variety of chambers, holes, and angles. Gesner relates, that he frequently cheats the badger of his habitation, by laying his excrement at the mouth of the other's burrow.

The modes of hunting the fox formerly, and that practised at present, are very different. In the earliest days, when this country was far more woody, and foxes so much abounded, as to be in a degree like wolves a general nuisance, what was then termed fox-hunting was effected by a great number of people, with dogs of all kinds, who assembled at the coverts where the foxes harboured. And whilst some beset the place, others went into the woods with some of the dogs and forced them out, to be either coursed by the rest of the dogs, which were held ready to be slipped at them, or they were taken in nets and hays set on the outides for that purpose.

As the covers were reduced in size and number, this system of self-defence against the fox's depredations, gave rise to the chase as an object of amusement; the season for hunting them began in November and ended in March, as in the cold weather the fox was supposed to leave a stronger scent; the earths were stopped in the course of the night before hunting, (which is perhaps the *only* point in which the fox-hunting of the former and present time concurs,) a huntsman was appointed, whose business was to take all his dogs in *couples* and *barrelled*, early the following morning to the wood designed to be tried, there to throw off his sure finders or *staunch hounds*, that would undertake no other scent, but that of the fox; if they struck upon a drag, he cast off more of his best hounds, and so continued to do until they ran the drag up to the fox's kennel, which was the most opportune moment to throw off the major part of the coupled hounds; the fox, finding himself thus hotly pursued, after trying to hunt the hounds, was compelled to forsake the cover and trust to his feet, fleeing from wood to wood, and sometimes extending his course for twenty miles; the huntsman on *foot* was to cross (with what hounds he had in reserve) the nearest cut from cover to cover, and to be as much as possible in the way to throw off those fresh hounds, either as an encouragement to the finders or staunch hounds that might begin to run lag, and which he was also to encourage by all possible means, or he was to keep back this *corps de reserve*, to have them, as occasion might offer, ready for a dead scent, or, as he judged prudent, for the latter end of the day. When the fox was killed the pack was to be all hallooed in to bay him, but they were not allowed to eat

HUNTING.

him, because his *flesh was hurtful* to them; his fat was however in high esteem for shrunk sinews.

If the fox ran to ground, the huntsman, who was to be provided with good trousers, was to lay him up in the earth, which, in the opinion of some, was sooner done by putting a collar of bells on the terrier's neck; when dug out, he was sometimes given to the hounds to be killed on the earth as an encouragement, and also to make them lie when they came to a strange wood and to an unknown earth, at other times he was reserved alive for a future day's sport; if the earth proved so deep that it was impossible to dig him out, steel-traps were set at the mouth of the hole, or hay nets pitched round it, to take him at his going off, and these implements were to be carefully watched.

The whole art of fox-hunting, says Daniel in his "Rural Sports," is to keep hounds (see HOUND) well in blood; and therefore every advantage is taken of the fox. Sport is a secondary consideration with a true fox-hunter: his first motive is the killing of the fox, by which he makes his hounds: present success is almost a sure fore-runner of future sport, and he is better pleased with an indifferent chase with death at the close of it, than with the best chase possible, if it terminates with the loss of the fox. Good chases are, generally speaking, long ones, and if unsuccessful, do more harm than good to hounds. It will be an advantage to hounds when out of blood to go out early. The morning is the part of the day which usually affords the best scent, and the animal itself, which you are at this time more than ever desirous of killing, is then least able to escape; the want of rest, added perhaps to a full belly, gives hounds a decided superiority over an early-found fox. Hounds should never be taken out in a very windy or bad day, because scent is at such times extremely precarious. (See SCENT.)

Two things, says Mr. Daniel (*ubi supra*), are ever to be remembered and accomplished in fox-hunting; the one is, to make hounds *steady*, the other to teach and compel them all to *draw*; never suffer any hounds out of cover, it is the effect of bad management if they attempt to be so; hounds once become steady will be more likely to draw well than if they were not, their eagerness is then to find their proper game, and they are indifferent to the scent or view of any other. Many huntsmen are fond of having hounds at their *horse's heels*, and it is a modern fashion for the huntsman and whippers-in to *ride into* the cover, and by their noise, in some measure, to *find* the fox for their hounds; but this proceeding invariably renders hounds *bad drawers*, independent of the great chance of stubbing the horses, which in an inclosed country too often occurs, without needlessly courting the danger; it is liable also, where there are but few finders, to have a fox found by them, which goes down the wind, and they are heard of no more that day; besides, hounds never get so well or so soon together as when they spread the cover.

There is infinite pleasure, says a sportsman, in hearing when a fox is well found, the chorus increasing from the first challenge, and the corresponding "Hark to Chirper" inspires a joy more easy to be felt than described; and one fox found with a good drag in this lively manner, surpasses the best hare chase that was ever ran.

Much so depends on the first finding a fox, who, if well found, may be said to be half killed. The huntsman should draw quietly, and *up the wind*; this is material; the fox, by drawing up the wind, does not hear the approach of the hounds, who by this means are also within hearing; besides, should the fox turn down the wind, as most probably he will, it lets the hounds all in. If covers are small, and

from which a fox cannot break unseen, *noise* can then do no hurt, but late in the season foxes are wild, particularly in covers that are often hunted, and should there be any noise, they will sink their kennels and get too much advantage; the whipper-in, where this is suspected to happen, should get the opposite side of the cover, *before* the hounds are thrown into it.

Judicious huntsmen will observe where foxes like best to lie; this must of course vary in different countries, and a knowledge of the country will best direct them in this respect. Where there are large tracts of cover, such observation will save time in finding; generally speaking, foxes prefer covers that lie high, are dry and thick at bottom, that are out of the wind, and are on the sunny side of hills. The cover where a fox is found, when it has remained still any time, will probably produce a second. In nutting time, *furze brakes* and two or three years coppices are then the only quiet places for a fox to kennel in; when pheasant shooting begins, older covers are more likely. The season when foxes are most wild and strong, is near Christmas; a huntsman must at that season lose no time in drawing, and be as silent as possible; three or four years coppices, with *beath or furze at bottom*, are then most likely. The *male* foxes, about Christmas, travel miles after the *females*, and when hunted, generally run directly for the country *from whence* they came; the huntsman has at that season, in the course of three weeks, killed two brace of dog foxes from one cover, where the least distance was twelve, and in one of the four chases was extended to double the number of miles, from the place of unkennelling, to the spot where the fox was killed.

When a string of small covers have plenty of foxes in them, some caution is necessary to prevent them being all disturbed in one day. Foxes are said to go *down wind to their kennel*, but however that may be, the huntsman should begin drawing at the farthest cover down the wind, and proceed from cover to cover *up the wind*, till he finds; these advantages will attend it, he will draw the covers more speedily, there will be less difficulty in getting hounds away, and as the fox most likely will run the covers already drawn, there is the less probability of *changing*, and the covers which are up the wind, *beyond* where the fox is found, remain perfectly undisturbed.

Never hunt the small, until the large covers have been well rattled; for it would be bad policy to drive from the former to the latter to increase the number. If foxes are meant to be thinned and dispersed, hounds must throw off at the same cover, so long as a fox can be found. Hounds that come away with the first fox that breaks, do not disturb the cover, and may expect to find there again the next day; but where foxes are scarce, the same cover should never be drawn *two days following*.

Furze covers cannot be drawn too close, and if a fox is there found, he should never be halloed until *quite clear* of them; from such places, hounds are sure to go off well with him, and it would be the height of cruelty to head him back into the hounds mouths.

Long drags in large covers give advantage to the fox, who frequently takes the hint and sets off; this may be prevented, by throwing hounds into that part of the cover where he is most likely to kennel, the huntsman should then be careful not to take the *heel* of the drag. When a fox gets so far the start of hounds, that they are obliged to hunt after him with a bad scent, if foxes are in plenty, they had better be stopped, and find another; yet if this was a constant practice, it might make the hounds indifferent when upon a *cold scent*, and hounds should be made to believe,

HUNTING.

they are to kill *that game* which they are *first* encouraged to pursue.

When hounds approach a cover intended to be drawn, and dash away towards it, whippers-in ride to stop them; they had better let them alone, it checks their drawing, and it will be soon enough to rate, when they have found and hunt improper game. Some hounds will in this dashing style break away from the huntsman, rush to the cover side, and then stop and not go into it; but hounds under such good command as not to break off from the huntsman until he encourages them, will be then so confident, that they will not return to him again, but proceed to find their game with an eager steadiness.

Whilst hounds are drawing, the company should place themselves so that a fox cannot go off unseen. Gentlemen should take this necessary part of fox-hunting to themselves; upon those occasions, when two gentlemen are seen *together*, it is a reasonable conclusion, that one of them at least knows nothing of the matter. The greater number of those who ride after hounds are no sportsmen; few gentlemen will take pains to stop a hound, although he should run riot close beside them, or will stand quiet a moment although it is to halloo a fox, and thereby to promote the amusement they are come in search of.

The first day a cover is hunted, where there is plenty of foxes, and blood is wanted, let them not be headed back into the cover, which is the usual practice, but allow some of them to get off, otherwise with continual *changing*, and sometimes running the *heel*, it is probable the hounds will not kill any. Another precaution may be also necessary, that is, to stop such earths *only as cannot* be digged; if some foxes go to ground, and blood be wanted at last, it will then be known where to get it.

Covers *near the kennel* should not be drawn while foxes can be found elsewhere, it will render them certain places when hounds go out late, or may otherwise be in want of foxes; they should not be much disturbed after Christmas, foxes will then resort to, and breed in them, and there they can be preserved with little trouble.

Before hounds are drafted, let the huntsman determine within himself the number it will be proper to take out, and also what young hounds he can venture in the country he is going into. Much accuracy is required in drafting hounds properly, nor can it be done with any expedition, without some method. Too many huntsmen deem it immaterial, which they take or which they leave, provided they have the number requisite. A perfect knowledge in feeding and drafting hounds, is the most essential part of fox-hunting; good hounds will need but small assistance afterwards. By *feeding*, is meant the bringing the hound into the field in his highest vigour, and this can be done but by a discernment of the different constitutions of so many animals, some of which must be fed sparingly, and yet frequently, to maintain the full force of their powers. By *drafting*, is particularly meant the taking out no unsteady hound, nor any that are not likely to be of service to the pack. To hunt two days following with a small pack, calls forth the greatest nicety to make the most of it; some consideration is also necessary to place hounds to the greatest advantage, where foxes are either plentiful or very scarce; a huntsman should be able to marshal every hound, giving to each his proper rank; without this knowledge, he cannot make a draft as he ought. There are in most packs some hounds that aid little in *killing* the fox; it is the *judicious drafting* of such hounds, that is a certain sign of an *intelligent* huntsman.

When foxes are numerous, there is no occasion for an

early hour, and when they are weak, by hunting late, they give better chases; when foxes are strong, hounds ought then to have the advantage which hunting early affords them. When hounds go out late, they should immediately proceed where it is likely to find, which, for the most part, is that cover where hounds have been least in; if a fox is not soon found, a long and tiresome day is generally the consequence; when the cover is thick, particularly if it be *furzy*, it should be drawn slowly, a fox at a late hour will keep his kennel, until hounds come close upon him.

A huntsman, although he ought to be as silent as possible when his hounds go into a cover, cannot be too noisy at their coming out of it again; and if at any time he should turn back suddenly, let him give as much notice of it as he can to his hounds, or many will be left behind, and should he turn *down* the wind he may see no more of them.

Gentlemen are generally in too great haste when a fox is first found, hounds are always mad enough when they find, and the enthusiasm attending this diversion, is at this crisis particularly to be restrained; it is quite time enough for it to appear when hounds are away, and well settled to the scent. The huntsman should set off with the foremost hounds, no hounds can then slip down the wind, and get out of his hearing; but in pressing hounds forward whilst the scent is good, care is to be taken that they are not hurried beyond it when it is bad; he should keep so close to them as to enable him to see how far they carry the scent, without this, he can never make a cast with any certainty. It is the huntsman's business to be ready at all times to lend that assistance, which when they are first at a fault is then most critical, a fox-hound at that moment will exert himself most, he afterwards becomes more indifferent about his game. Those huntsmen who do not get forward enough to take advantage of this eagerness, and direct it properly, are seldom sufficiently skilled in hunting to be of much use to hounds afterwards.

With a high scent, hounds cannot be pushed on too much; screams keep the fox forward, the hounds together, or let in the tail hounds, they enliven the sport, but in cover, should be given with the greatest caution; halloos are of service when hounds are running up the wind, for then none but the *tail hounds* can hear them; when running down the wind, there should be no more halloos than are necessary to bring the tail hounds forward, for hounds that know their business, when upon a scent, rarely want encouragement.

When hounds are at a check, every one should be silent and stand still; the huntsman had better let the hounds alone, or content himself with holding them forward, without taking them off their noses; should they continue at fault after having made their own cast, (in which not a word should be said to them, and which the huntsman should always first encourage them to do, as they will of themselves spread more, and try better for the scent than he can make them;) it is then his business to assist them, but except in some very particular instances, such as to get beyond the *taint of sheep*, or where a fox has been *coursed* by farmers' dogs; (in the former case, much time is saved in keeping hounds forward, and not suffering them to try through a flock of sheep; and in the latter it is the only chance of getting hounds to hit upon the scent, or its at all serving them to hunt up to their fox afterwards;) without these reasons, or others equally urgent, hounds should never be cast so long as they are inclined to hunt. It is the judiciously preventing hounds from losing time by hunting when they might run, and the encouraging them to hunt when they cannot run, that shows a good sportsman; for though too

much

HUNTING.

much help will make them slack, too little will make them tye on the scent and hunt back the heel. The huntsman should observe the tail hounds, they are least likely to overrun the scent, by them he may see how far they brought it; in moll packs there are some hounds that will shew the point of a fox, which, if attended to, may direct his cast; when such hounds follow slowly and unwillingly, he may be certain the rest are running without a scent; but a huntsman should by no means turn back on seeing hounds at head when first at a check, of which he has no opinion; they may be right, and he should by a short call forward be sure they are wrong, before his own suppositions of the fox being gone another way, are to be indulged.

When hounds are at fault, staring about and trausting to their eyes and ears, a forward cast is the least likely to regain the scent; the place where they left, is the most probable spot for them to hit the scent, and hounds knowing where they left the scent will there try to recover it, nor is a wide cast often to be made without good reason; the scent should be tried to be retrieved by *crossing the line* of it, and a huntsman, by attending to this, will not fail to make a good cast, if he observes the point of the fox. When hounds cannot hit off a fault by themselves, the first cast should be speedy, the scent is then good, and hounds not likely to go over it. Every huntsman should adopt these rules; with a good scent his cast should be *quick*, with a bad scent, *slow*, and when hounds are picking along a cold scent, *he is not to cast them at all*.

When a fox is killed, hounds should eat him ravenously: he should be flung across the branch of a tree, and the hounds suffered to bay him for some minutes before he is thrown amongst them, it will shew hounds the meaning of *tally ho*, and learn them to fly like lightning to it; it will also make the hounds more eager, will let them all in, they will recover their wind, and eat him more readily.

When a fox is suspected to be gone to ground, the huntsman should try all round, and be perfectly satisfied that the fox is not forward, *before* he tries the earth, as a fox will frequently run over an earth, and sometimes go into, and not stay in it. When a fox goes to ground, after a long chase, and hounds want blood, it is best to kill him *on the earth*, the holes should be all stopped whilst digging, lest he should bolt; when this happens, it causes no small confusion, the hounds are dispersed and asleep in different places, the horses often at a distance, and many a fox by taking this advantage of the moment has saved his life.

With respect to the digging of foxes which hounds run to ground, if the hole be straight and earth slight, follow it, and in following the hole, by keeping below its level, it cannot be lost; but in a strong earth, the best way is to let the terrier fix the fox in an angle of it, and a pit be then sunk as near to him as can be, a terrier should always be kept at the fox, who otherwise may move, and in loose ground dig himself further in; in digging keep plenty of room, and take care to throw the earth where it may not have to be moved again.

The time for leaving off hunting, as much depends upon the quantity of foxes as on the country hunted; no good country should be hunted after *February*, nor should there, where hounds regularly hunt in the season, be any hunting *at all after March*. Spring hunting is sad destruction to foxes, and ought not to be attempted but in countries never visited by hounds in the hunting season, or where the foxes are wished to be destroyed by wholesale; in one week, hounds by killing a brace or two of bitch foxes, either in cub, or that have just littered, murder as many as would shew diversion for a whole season.

Notwithstanding the *common* law allows of the hunting of foxes and badgers (being beasts of prey) in another mans' ground, because their destruction is a public benefit, and by the old law the parish officers are to give a certain sum by the head for both male and female, to promote it;) yet the digging and breaking the ground to unearth them, is held to be unlawful, and in the case of Gedge v. Minne, it was determined, that the defendant could not justify digging for a badger; the breaking ground to *stop* an earth is also illegal, and the owner of the ground may maintain an action of trespass; it was also decided in the aforementioned case, that if a person goes into the ground of another, to beat or draw for a fox or a badger in order to hunt it, this action for trespass lies. Daniel's Rural Sports, p. 84—133.

HUNTING, *Hare*. A hare the first year is called a *leveret*; the second year, a *hare*; the third, a *great hare*. See HARE.

Each part and member of the hare is formed for celerity. The head is round and short, of a convenient length; the ears long and lofty, to hear the enemy at a distance, and save itself in time; the lips continually move, sleeping and waking; and the eye is too big and round for the lid to cover it, even when asleep; so that the creature sleeps as it were on the watch. Straight forward there is a deficiency in the hare's sight, so that when closely pursued she will run against objects in her way. The breast is capacious, and fitted to take more breath than that of any other beast. They feed abroad, to conceal their forms; and never drink, but content themselves with the dew. The hare's ears lead the way in her chase; for with one of them (it has been said) she hearkeneth to the cry of the dogs, the other being stretched forth like a sail to promote her course.

Others, however, have asserted that this notion is ridiculous. Whenever the hare pricks her ears on end, or draws one apart from, or more forward than the other, it is to listen more distinctly on that side the forwardest ear inclines; had Nature designed any singular aid to her *feat* from stretching forth the ears, she would have supplied her with *two pair*, one to lie flat upon the shoulders for listening, whilst she sailed by the other, and never would she have had more occasion for *both*, than when severely coursed, at which time, the ears she has may be observed to lie close to the neck; and although she is compelled, when thus pressed, to try every shift to escape, this quality of *sailing* by the ears is never seen; both ears are very strictly applied to catch the smallest sound of the greyhound *behind*, by which she accordingly retards or increases her celerity.

The hares of the mountains often exercise themselves in vallies and plains, and through practice grow acquainted with the nearest way to their forms; those which frequent bushes and brakes are not able to endure labour; nor are very swift, being tender footed, and growing fat through discontinuance of exercise.

When the hare has left the dogs far behind, she goes to some hill or rising ground, where, rearing on her hinder legs, she observes at what distance her pursuers are.

The trail, *i. e.* the path which the hare takes in going to her seat is long, says Xenophon, in his Observations upon Hare-hunting, in proportion to the length of the night. In the winter, he says, there is no scent early in the morning, when either a hoar or a hard frost occurs. The trail is also spoiled by much dew, and by showers after a long drought.

The scent is naturally stronger in wood-hares than field-hares; but in all sorts it is strongest when they feed on green corn. The scent of young hares is said to be stronger than that of those full-grown, the weakness of their limbs suffering the whole body to touch the ground. In winter mornings,

the

HUNTING.

the scent does not lie till the frost be a little thawed ; and it may be added, that a hare always leaves more scent when she goes to relief, than when she goes to form.

Her footsteps are more seen in winter than summer ; because, as the nights are longer, they travel farther. Their prints are very uncertain at the full moon, at which time they leap and play together. The young, it is to be observed, tread heavier than the old, because their limbs are weaker. A buck, or male hare, is known by his beating the hard highways, feeding farther out in the plains, and making his doublings of a greater compass than the female, who keeps close by some covert side ; turning, winding, and crossing in the bushes, like a coney, and rarely running out an end ; whereas the buck, having once made a turn or two about his form, runs straight forward for four or five miles, or more, without once turning his head. Add, that the buck is known, at his rising out of form, by his hinder parts, which are more white, and his shoulder, which is redder than the doe's. His head is also shorter, and his ears more grey.

The hare regulates its conduct according to the weather. In a moist day she holds the highways more than at any other time, because the scent is then most apt to lie ; and if she come at the side of any young grove or spring, she forbears to enter, but squats down at the side, till the hounds have overhot her ; upon which she returns the same way she came, without turning into any covert, for fear of the wet and dew hanging on the boughs.

Regard is also to be had to the place where the hare sits, and upon what wind ; for if her form be either upon the north or south wind, she will not willingly run into the wind, but aside, or down the wind ; on the contrary, if she form on the side of the water, it is a sign she is foul and measles, and in the course will make all her doubling and crossing about brook-sides and near plasnes ; for her scent, under this condition, being very strong, she needs a place that will take but little. Sometimes, when hunted down, she will start a fresh hare, and squat in the same form ; at other times, she will creep under the door of a sheep-cote, and hide among the sheep, or run among a flock of sheep, and will not, without the utmost difficulty, be taken from among them. Add, that some will take the ground like a coney : this is called going to *wault*.

Some hares will go up one side of the hedge, and come down the other ; and it is said that a hare, being sorely hunted, has got upon a quickset hedge, and ran a good way on the top of it, and then leaped off upon the ground ; and that it is no unusual thing for them to take themselves to furze-bushes, and leap from one to another, whereby the hounds are frequently in default. These accounts, however, are disregarded by some as fabulous.

A hare, it is said, does not live above seven years at most, especially the buck ; and if he and the doe keep one quarter, they will not suffer any strange hare to sit by them : whence the proverb, " The more you hunt, the more hares you shall have ;" since, having killed one hare, another comes and possesses his form.

In entering a young kennel of hounds, regard must be had to the nature of the country and of the quarry ; for, according to the place wherein they are entered, and the game first given them, will they afterwards prove. Thus, if they be entered in a champaign country, they will ever after more delight to hunt there than on any other ground. The best time, it is said, for the entering of hounds is in the heat of the day, and about October or November, the weather being then temperate, and young hares that have not been hunted, are more easily taken

for their encouragement. Hounds, after the age of two years, should be hunted three times a week, if they feed well, and may be kept out the greatest part of the day, to try their strength. See ENTRANCE and HOUND.

Having found where a hare hath relieved in some pasture, or corn-field ; to find her form, the season of the year, and the state of the weather are to be considered. In the spring or summer, a hare will not sit in the bushes, because frequently offended with pismires, snakes, and adders ; but will sit in corn-fields, and open places. In winter they choose to sit near towns and villages, in tufts of thorns and brambles, especially when the wind is northerly or southerly. According to the season, and nature of the place where the hare is accustomed to sit, there beat with your hounds, and start her : which is better sport than trailing of her from her relief to her form. Having started her, step in, and halloo in the hounds till they have undertaken it : crying, *that, that*, or *there, there*, and go on with full cry ; then recheat them, and follow at a distance, taking care not to forward them too much at first, as being apt, if the first heat, to overshoot the game. Some of the early sportsmen never permitted the hare to be hallooted, or the bounds to be assisted when they were at fault, but suffered them to work it out by themselves, which, though tedious, was considered as a sure way to ascertain the goodness of the hounds. Above all things, mind the first doubling the hare makes, which is to be a key or direction for the whole day ; all the other doublings she afterwards makes being like the first. According to the policies you see her use, and the place where you hunt, make your compass, to help the defaults, great or little, long or short ; always seeking the moildest and most commodious place for the hounds to scent in.

A young huntsman, says an ingenious sportsman, should take care, when the scent lies well, always to keep himself far behind. At such a time, especially if it be against the wind, it is impossible for the hare to hold forward, nor has she any mode of escaping, but to stop short, and when all are past, to steal immediately back. This is often the occasion of an irrecoverable fault in the midst of the warmest sport, and is the best trick the hare has for her life in scenting weather. If the huntsman, therefore, is not too forward, he will have the advantage of seeing her manœuvre, and of assisting his hounds at this critical moment.

Upon sight of the hare, avoid, above all things, the vile practice of hallooting hounds off *a scent*, to lay them on after a *vieu*, it not only spoils the dogs, by accustoming them at every fault to listen for, and expect the halloo, but it is foul sporting ; equally unfair and to be condemned is, the suffering the pricks of the hare's footing to be smoothed when she runs the foil ; for although it is admitted that by such pricking and discovering her steps, no hare can escape, yet it is an unmanly mode of assisting hounds, which no huntsman, who is a *sportsman*, will ever be guilty of himself, or condescend to make use of when done by others.

The huntsman should never be noisy when a hare is first started ; let him not only check his own forwardness, but that likewise of the inexperienced sportsman. Hounds are apt enough in the first heat of their mettle to overshoot their game, and hours of sad sport have happened from driving them too fast. Too many people think a chief part of hunting consists in *hallooting loud* and *riding hard*, but they are mistaken, and must not be offended should the huntsman swear at their performances. No tongue can be allowed but his, nor, at this peculiar time, ought any one to be more forward.

The chief considerations for the huntsman, when the hounds

HUNTING.

hounds are at default, are, how long the hare has been on foot, and how far the hounds make it good; if she has *not* been long and hard pressed, he must expeditiously try a wide circle, and so persist in contracting his circles, until he returns to the place where the dogs threw up. Should the hare have been drove hard, or be nearly dead run, the huntsman need only try a small compass, and that slowly and cautiously, for she will only leap off a few rods and *quat*, until one or other of the dogs jumps upon her.

A huntsman should be careful of talking too loud to hounds, and in a *key* which instead of cheering confounds them. Give me, says this author, a fellow of everlasting patience and good temper, who does not consider hunting merely as his *business*, but who naturally loves it, one with a clear, moderate voice, that speaks to an old hound when at fault frequently and with quickness, and cherishes him in a tone that enforces courage, and induces him to stoop perpetually to recover the scent. It is by no means the huntsman's business to endeavour by pricking the hare to hit her off; in the first place it is unfair, and, secondly, whilst he is poring with his eyes upon the ground, not one in twenty of the hounds will have his nose to it. If there is a long default, the huntsman should attend to the tender-nosed dog, which perhaps he disregarded in the morning as a *babler*, and whom he pronounced worthy of a halter for opening at nothing; his superior excellence of scenting may now shew itself to have merited a different judgment, and may encourage some itauncher hound to stoop, which he would not otherwise do.

A huntsman is never to give up a default whilst day-light and weather permit; if the hare is not killed and taken up, there is no good reason why it is not to be recovered, and it should be a standing maxim, that it is always as easy to recover a *lost* hare as to start a *fresh* one.

In the opinion of Mr. Beckford, the number of hounds should not exceed twenty couple in the field, from the difficulty of getting a greater number to run well together, and a pack of harriers (as well as fox-hounds,) are incomplete if they do not. A hound that runs too fast for the rest ought not to be kept. Some huntsmen load them with heavy collars, or tie a long strap round their necks; a better way would be to part with them. Whether they go too *slow* or too *fast*, they ought equally to be drafted. The hounds most likely to show sport are between the large, slow hunting harrier, and the little fox beagle; the former are dull, heavy, and too slow; the latter are lively, light, and too fleet. The first sort have most excellent noses, and will kill their game at last, if the day be long enough. The other, on the contrary, dash and are all alive, but every cold blast affects them, and in a deep and wet country it is not impossible but that some of them may be drowned. His opinion respecting the huntsman is, that he should not be young, and for *patience* he should be a very *Grizzle*; the quieter he is the better, and he should have perseverance and never give up a hare when it is possible to hunt her, as she is sure to stop, and therefore may always be recovered; he jocularly remarks, that were it customary to attend to the breed of huntsmen as well as to that of hounds, the family of the *silent gentleman*, mentioned by the Spectator, would furnish an excellent cross, and that a female of his lineage, married to a knowing huntsman, would probably produce a perfect hare-hunter. The whipper-in to a pack of harriers should not be allowed to stop a hound or smack his whip, without the huntsman's order. Noise and rattle are directly adverse to the first principle of hare-hunting, which is to be quiet and leave the hounds to themselves. If a long fault makes the huntsman's

assistance necessary, and the hare should have headed back, he will observe whether she has turned of her own accord, or has met any thing in her course to turn her. When he casts his hounds, let him begin with a small circle, if that is unsuccessful, try a larger, and as a hare generally revisits her old haunts, and returns to the place where she was first found, if the scent be quite gone, and the hounds can no longer hunt, *that* is as likely a cast as any to recover her. Let him remember in all his casts, that the hounds are not to follow his horse's heels, nor are they to carry their noses in the air. At these times they must try for the scent, or they will never find it; and he is to make his cast either quick or slow, as he perceives his hounds try, and according to the goodness or badness of the scent.

When hounds are at a check, the huntsman should not move his horse one way or the other. Hounds lean naturally towards the scent, and if nothing be said, will soon recover it: if a hound is spoken to at such a time, calling him by his name, (which is too much practised,) he seldom fails, says Mr. Beckford, to look up, as much as to say, *What the deuce do you want?* Had he the faculty of speech, he would add, before he stooped to the scent again, *You fool, let me alone.* When hounds are at fault, not a word should be said; no other tongue should be heard but that of a hound; and so inflexible was a friend of Mr. Beckford who kept harriers, in this particular, that a gentleman accidentally coughing whilst his hounds were at fault, he rode up to him immediately, and said " *I wish, sir, with all my heart, that your cough was better.* "

When the hare is first started, says Mr. Beckford, sportsmen cannot be too quiet. Hounds through the whole chase should be left almost entirely to themselves, and never be much hallooed; when the hare doubles, they should hunt through these doubles; nor is a hare hunted *fairly* if hunted otherwise; they should follow every step she takes, as well over greasy fallows, as through flocks of sheep, nor should they be ever cast, if able to do any thing without it. On high roads and dry paths, the huntsman should always be doubtful of the scent, nor give them much encouragement; but when a hit is made on either side, it is then right to cheer them as much as you please. A hare generally describes a circle in her flight, larger or smaller, according to her strength and the openness of the country. In enclosures and where there is much cover, the circle is so small that it is a constant puzzle to the hounds. Besides running the foil, they frequently make doubles, which is going forward, to tread the same steps, back again, on purpose to confuse their pursuers; and the same manner in which the first double is made, they mostly continue, whether long or short. This information, says Mr. Beckford, if properly marked by the huntsman, may be useful in his calls. When hares make their doubles on a high-road, or dry path, and then leave it with a spring, it is often the occasion of a long fault: the *spring* which a hare takes on these occasions, is hardly to be credited, any more than her ingenuity in thus trying to escape. Often, after running a path a considerable distance, she will make a double, and stop until the hounds are past her, she will then steal away, and return the same way she came; this is the greatest of all trials for hounds. It is so hot a foil, that in the best packs there are not many hounds that can hunt it; those hounds must be followed that can, and the foil when she breaks it, (which in all probability she will soon do, as she now thinks herself secure,) be tried to be lit off. When the scent lies bad in cover, she will sometimes seem to hunt the hounds. Particular directions, says Mr. Beckford, should be given to the huntsman, to prevent the hounds all in

his

HUNTING.

his power, from *chopping* hares. In furze they lie very close, hedges are also dangerous: the best way is to have the hedge well beaten some distance before the hounds, for if the huntsman beats the hedge himself, as is the general practice, the hounds are always upon the watch, and a hare must have great luck to escape them all. Hares seldom run so gallantly as when they do not know where they are; in a fog they run well; if they set off down the wind, they rarely return, and hounds cannot then be pushed on too much; when the hare is sinking, the old hounds will get forward; they, *then*, will run at *head*.

Keep no *labblers* or hounds that run false; the loss of one hare is more than such dogs are worth.

HUNTING. Hart or Stag. (See *Cervus Elaphus*.) This animal the first year is called a *calf*, or *hind-calf*; the second year, a *knobber*; the third, a *brock*; the fourth a *flaggard*; the fifth a *stag*; the sixth a *hart*.

The female is called a *hind*. The first year she is a *calf*; the second a *bearse*, and sometimes a *brocket's sister*; the third a *hind*.

Terms occurring more especially in hunting the hart, and not yet explained, are as follow. The print or impression, where a deer has lain, is called a *layer*; if it be in covert, or a thicket, it is called his *harbour*; where a deer has passed into a thicket, leaving marks whereby his bulk may be guessed at, it is called an *entry*; when they cast their heads they are said to *mew*; when they rub their heads against trees, to bring off the peels of their horns, they are said to *fray*; when a deer, hard hunted, takes to swimming in the water, she is said to go to *soil*; when they turn head against the hounds, they are said to *bay*; when the hounds touch the scent, and draw on till they put up the hart, they are said to *draw on the slot*.

As to the nature and qualities of the hart, it is to be observed that he is an excellent swimmer; there being instances, when sore hunted, of his plunging in the sea, and being killed by fishermen twelve miles from land. When, in going to rut, they have occasion to cross a great river, or arm of the sea, it is said they assemble in great herds; the strongest goes in first, and the next of strength follows; and so one after the other, relieving themselves by staying their heads on the buttocks of each other.

The hind commonly carries her calf eight or nine months, which usually falls in May: some have two at once; and they always eat up the skin wherein the calf lay. As the young grow up, the old one teacheth it to run and leap, and how to defend itself from the hounds.

The hart is amazed at hearing any one call, or whistle, in his fist; if you cry *ware, ware, or take heed*, you will see him instantly turn back, and make some little stand. His sense of hearing is very perfect when his head and ears are erected; but very imperfect when he holds them down: hence when he pricks up his ears, he is known to be apprehensive of danger. When he is on foot, and not afraid, he wonders, and takes a pleasure to gaze at every thing he sees.

The hart is long lived, but less so than some persons have conceived. (See *Cervus Elaphus*.) The principal marks of his age are taken from his head, yet this is somewhat precarious; some having more croches thereon at the same age than others.

The capture of this beast requires great art and attention. When the hunter goes for sport, he is first to encompass the beast *en son giste*, in her own layer, and thus unharbour her in the view of the dogs, so that they may never lose her slot or footing. But note, a considerable degree of choice and discretion is here required; for he may not set off upon

every one, either of the herd, or those which wander solitary: the young, the small, &c. are to be passed over; and partly by sight, and partly by the footing, fewmets, the largeness of the layer, &c. he must make judgment of the game, singling out for that purpose the largest head in the whole herd.

There are divers means for knowing an old hart; *viz.* by the *slot*, the *entries*, the *abatures*, and *foils*, the *fewmets*, *gait*, and *walks*, *fraying-stocks*, and the *head* and *branches*. 1. As to the slot. The treadings of the hart's foot are to be carefully noted: if you find the treadings of two, the one long, and the other round, yet equally big, the longest slot declares the largest hart; add, that the old hart's hind foot never over-reaches the fore-foot, as that of the young one does. 2. The fewmishing is chiefly to be judged of in April or May: if it be large and thick, it signifies the hart to be old. 3. To know the height and thickness of the hart, observe his entries and galleries into the thickets, and what boughs he hath over-riden, and mark from thence the height of his belly from the ground; for a young deer usually creeps low, as he passes to his harbour, and goes through places which the old one, being stiff and stately, will not stoop to. 4. By his gait it may be known whether the hart be large, and whether he will stand long before the hounds: if he have a long step, he will stand long, being swift, light, and well breathed; if he have a great slot, which is the sign of an old deer, he will be a laister. As to his fraying-post, note, that the older the hart is, the sooner he goeth to fray, and the greater is the tree he chooses to fray upon; it being necessary it be such as may not bend. Now, to seek or find out a hart in his haunt, or feeding-place, it is to be observed, that he changes his manner of feeding every month. From the conclusion of the rutting time, which is in November, they feed in heaths and broomy places. In December they herd together, and withdraw into the strength of the forests, to shelter themselves from the severe weather, feeding on holm-trees, elder-trees, brambles, &c. The three following months they leave the herding, but keep four or five in a company, and in the corners of the forest will feed on the winter pasture, sometimes making their excursions into the neighbouring corn-fields, if they can perceive the blades of wheat, rye, &c. appear above ground. In April and May they rest in thickets and shady places, stirring very little till rutting time, unless disturbed. The three succeeding months they are in their pride of graze, and resort to springs, copes, and corn-fields. In September and October they leave the thickets, and go to rut; during which season, they have no certain place either for food or harbour.

Having found out the game, the hunters disengage and cast off the dogs; and some on horseback, others on foot, follow the cry with the utmost art, observation, and speed, remembering and preventing the subtle turning and heading of the hart; standing with dexterity and intrepidity to leap hedge, pales, ditch, &c.

The utmost address and circumspection are to be used to keep to the beast first attempted, and to prevent the dogs from pursuing any other: this, in effect, makes one of the principal difficulties and glories of the chase; the beast having a hundred devices to put off some other head for his own: sometimes he will send forth some other little deer in his stead into the dogs' way, laying close at this time himself; on which occasion the huntsman is to sound a retreat, and break off the dogs, and take them in leam, till the game be recovered.

Sometimes he will purposely seek out other deer at layer, and rouse them to make the hounds hunt change, himself lying

HUNTING.

down flat in some of their layers upon his belly, to make the hounds over-shoot him: add, that they may neither scent nor vent him, he will gather up his fore-feet under his belly, and blow or breath on some moist place of the ground, so that the hounds shall pass within a yard, without apprehending him. He will break into one thicket after another, to find deer, rousing, gathering them together, and herding with them, and even beating some of them into his treads, that he may the more easily escape. Finding himself spent, he will break herd, and fall to doubling and crossing in some hard beaten highway, always running against the wind, not only to cool himself, but the better to hear the voice of his pursuers.

The last refuge of a hart sorely hunted, is the foil; keeping the middle for fear, least by touching a bough, or the like, he may give scent to the hounds. He always swims against the stream; whence the old rule, "He that will his chafe find, let him try up the river, and down the wind." In taking foil, he will sometimes cover himself under water, so as to show nothing but his nose.

Where opportunity of water fails, he will fly into herds of cattle, as cows, sheep, &c. and will sometimes leap on an ox, cow, or the like, laying the fore part of his body thereon, that so touching the earth with his hinder feet, he may leave a foal or no scent behind. What is farther still, the chief huntsman of Lewis XII. relates, that a hart which they were in hard chase of, leaped into a great tall white thorn, which grew in a shadowy place, and there stood aloft till he was run through by a huntsman, rather than he would stir.

The hart being killed the huntsman with his horn windeth the fall of the beast; upon which every one approaches: the skilfullest opens the breast, rewarding the hounds with what properly belongs to them; and the huntsman, at the same time, dipping bread in the skin and blood of the beast to give the hounds their full satisfaction.

The hart is known to be spent by his running stiff, high, and lampering, by his mouth being black and dry, without foam on it, and his tongue hanging out; though he will sometimes close his mouth to deceive the spectators; and by his stot, for he will sometimes close his claws together, as if he went at leisure, and immediately again open them wide, making great glidings, and hitting his dewlaps upon the ground, &c. When quite spent, and close beset, or intercepted on all sides, the hart usually takes to bay, and makes force with his head against the first man or dog that closes in upon him, unless prevented with a spear, sword, or the like. Hence it is very dangerous going in to a hart at bay, either on land or in the water, especially at rutting time, for then they are more than ordinarily fierce.

The hart being killed, his death is solemnized with great ceremony. The first thing, when the huntsmen come in, is, to cry, *Ware haunch*, that the hounds may not break into the deer: having secured this, they cut his throat, and blood the younger hounds, to make them love deer; and learn to leap at his throat; then having blown the mort, and all the company being come in, the most distinguished person, who has not taken *sey* before, takes up the knife, and lays it across the belly of the deer, (some of the assistants holding by the fore-legs, and at the same the huntsman drawing down the pizzle,) and thus he draws the knife along the middle of the belly, beginning near the brisket, cutting deep enough to discover how fat he is. Then the most skilful person breaks up the deer, by first slitting the skin from the cutting of the throat downwards, making the arber, that the ordure may not break forth, and then paunching him, and rewarding the hounds with it.

Lastly, the person that took the *sey*, being presented with a drawn hanger, he is to cut off the head; which done, and the hounds rewarded with it, the concluding ceremony, if a buck, is a double; if a stag, a treble mort, blown by one, and a recheat in concert by all that have horns: the whole is then concluded with a general *whoop, whoop*.

HUNTING, *Otter*. See OTTER.

The otter is to be hunted by particular dogs, called *otter bounds*, and also with special instruments, called *otter spears*. To find him out, some are to go on one side of the river, and some on the other, beating all the way on the banks, with the dogs following. Thus it is soon found if there be an otter in that quarter; for the otter cannot endure long in the water, but must come forth to make his spraints, (excrements,) and in the night sometimes to feed on grass and other herbs. If the hounds find an otter, look in the soft and moist places, to learn by the prints which way he bent his head: if these make no discovery, it may be partly perceived by the spraints. This done, follow the hounds, and lodge him as a hart or deer.

The otter always endeavours to keep to the water, where he is master. In hunting him, therefore, you are to be ready with your spears, to watch its vents; for that is the chief advantage: if you perceive where he swims under water, strive to set a stand before him, where you expect he will vent, and there endeavour to strike him with the spear; if you miss, pursue him with the hounds; which, if they be good, and well entered, will come chaunting and trailing along the river-side and beat every tree, root, every osier-bed, and tuft of bulrushes; nay, sometimes they will take the water, and beat it like a spaniel; by which means the otter can hardly escape.

If the beast find himself wounded with a spear, he usually makes to land, where he will maintain a furious battle with the dogs.

HUNTING, *Roe-buck*. See ROE-BUCK, ROE DEER, and CERVUS *Capreolus*.

We have no roe-deer in England; but they abound in the Highlands of Scotland, Germany, Africa, &c. And it should seem that they have been more common among us, our huntsmen still retaining the proper terms for the chase.

They make good chase, stand long, and fly end-way. When a roe crosses and doubles, it is called *trapping*. Their swiftness appears not only on the earth, but in waters, through which they cut their way as with oars; whence they love lakes and streams, breaking the floods to come at fresh pasture, feeding on rushes, &c.

Horns grow only on the male; being set with six or seven branches not palmed, but branchy, yet shorter than fallow-deer. After rutting he casts his head.

They are said never to wink, not even when asleep; for which conceit their blood is by some fanciful people prescribed to persons dim-sighted or purblind. The tail of this beast is less and shorter than that of a fallow-deer, inasmuch that it is questioned whether it ought to have that denomination.

They keep mostly in mountains among the rocks: and when hunted; Martial tells us, will hang on them with their horns, to delude the dogs. They are often taken by counterfeiting their voice, which the huntsman does by the assistance of a leaf in his mouth.

When hunted, they turn much and often, and will come back on the dogs directly. When they can no longer endure, they also take foil, as the hart; and will sometimes hang by a bough in such a manner, as that nothing shall appear above the water but their snout.

HUNTING-match. The first thing that is to be considered by

By one who designs to match his horse for his own advantage, and his horse's credit, is not to flatter himself with the opinion of his horse, by fancying that he is a swift, when he is but a slow galloper; and that he is a whole running horse (that is, that he will run four miles without a fob at the height of his speed) when he is not able to run two or three. Very probably some gentlemen are led into this error, by their being mistaken in the speed of their hounds, who, for want of trying them against other dogs that have been really fleet, have supposed their own to be so, when, in reality, they are but of a middling speed; and because their horse, when trained, was able to follow them all day, and upon any hour, to command them upon deep as well as light earths, have therefore made a false conclusion, that their horse is as swift as the best; but upon trial against a horse that has been rightly trained after hounds that were truly fleet, have bought their experience perhaps full dear; therefore it is advisable for all lovers of hunting to procure two or three couple of tried hounds, and once or twice a week to follow after them a train-scent, and when he is able to top them on all sorts of earth, and to endure heats and colds stoutly, then he may better rely on his speed and toughness.

That horse which is able to perform a hare-chase of five or six miles briskly and courageously, till his body be as it were bathed in sweat: and then after the hare has been killed, in a nipping frothy morning, can endure to stand till the sweat be frozen on his back, so that he can bear being pierced with the cold as well as the heat, and then even in that extremity of cold to ride another chase as briskly and with as much courage as he did the former, that horse which can thus endure heats and colds is most valued by sportsmen. Therefore, in order to make a judgment of the goodness of a horse, observe him after the death of the first hare, if the chase has been in any degree brisk; if when he is cold he shrinks up his body, and draws his legs up together, it is an infallible sign of want of vigour and courage; the like may be done by the slackening of his girths after the first chase, and from the dulness of his teeth, and the dulness of his countenance, all which are true tokens of faintness, and being tired; and such a horse is not to be relied on, in case of a wager.

Here it will not be improper to take notice of the way of making matches in former times, and the modern way of deciding wagers. The old way of trial was, by running for many train-scents after hounds, as were agreed upon between the parties concerned, and a bell-course, this being found not so uncertain, but more durable than hare-hunting; and the advantage consisted in having the trains laid on earth most suitable to the qualifications of the horses. But now others choose to hunt the hare till such an hour, and then to run this *wild-geese* CHASE (which see), a method of racing that takes its name from the manner of the flight of wild-geese, which is generally one after another: so the two horses, after running of twelve score yards, had liberty, which horse soever could get the leading, to ride what ground he pleased, the hindmost horse being bound to follow him, within a certain distance agreed on by articles, or else to be whipped up by the triers or judges which rode by; and whichever horse could distance the other, won the match.

But this chase was found by experience so inhuman, and so destructive to good horses, especially when two good horses were matched; for neither being able to distance the other, till both were ready to sink under their riders through weakness, that oftentimes the match was fain to be drawn and left undecided, though both the horses were quite spoiled.

This brought up the custom of train-scents, which afterwards was changed to three heats, and a straight course; and

that the lovers of horses might be encouraged to keep good ones, plates have been erected in many places of England. The fewer of these before you come to the course, if your horse be fiery and mettled, the better, and the shorter the distance the better. Also, above all things, be sure to make your bargain to have the leading of the first train, and then make choice of such grounds where your horse may best show his speed, and the fleetest dogs you can procure: give your hounds as much law before you as your triers will allow, and then, making a loose, try to win the match with a wind; but if you fail in this attempt, then bear your horse, and save him for the course; but if your horse be slow, but well winded, and a true spurred nag, then the more train-scents you run before you come to the straight course, the better. But here you ought to observe to gain the leading of the first train; which in this case you must lead upon such deep earths, that it may not end near any light ground; for this is the rule received among horsemen, that the next train is to begin where the last ends, and the last train is to be ended at the starting place of the course; therefore remember to end your last on deep earths, as well as the first.

HUNTING Cap, in the language of the *Sportsman*, is a cap made of leather, and covered with black velvet, fitting close to the head behind, and having a semi-circular peak before, for the protection of the face in case of falls, as well as in passing through strong coverts during the chase. In the sporting world it is termed a "dasher."

HUNTING Whip, is of different lengths in the handle or stock, and has at one end a long thong and lash, to assist occasionally in managing the hounds, and at the other a hook, hammer, or claw, for the purpose of holding or opening gates.

HUNTING Saddle. See SADDLE.

HUNTING Creek, in *Geography*, a river of America, in Virginia, which runs E. into Potowmack river, at the S. corner of the territory of Columbia.

HUNTING Islands, a cluster of small islands in the Atlantic ocean, near Port Royal, in the state of South Carolina. N. lat. 32° 24'. W. long. 80° 35'.

HUNTING Sound, a narrow channel on the coast of North Carolina, between Core bank and the continent.

HUNTINGDON, the principal town in Huntingdonshire, England, is situated on the northern side of the river Ouse, and is nearly connected, by three bridges and a causeway, with the village of Godmanchester, whence, according to Camden, it sprung. This place is called Huntandene in the Saxon chronicle, and Huntantun in other ancient writings. Henry of Huntingdon, the archdeacon and historian, describes it as "surpassing all the neighbouring towns in pleasantness of situation, beauty of buildings, nearness to the fens, and plenty of game and fish." Most writers agree with Camden respecting the origin of this town; and like him, have placed the Deroliponte of Antoninus at Godmanchester; yet the nature of the ground affords almost decisive evidence that the Roman station could not have been at that village, but was rather at Huntingdon, where the entrenchments, yet remaining, shew the works to have been very strong and extensive; and even Camden's own testimony may be urged in support of the opinion, that these fortifications had a far more remote origin than is commonly assigned. "On the river near the bridge," he observes, "which is fair built of stone, are to be seen the mount and site of a castle, which, in the year 917, king Edward the Elder built anew; and David the Scot, (to whom, according to an ancient historian, king Stephen gave the borough of Huntingdon, for an augmentation of his estate.)

HUNTINGDON.

enlarged with many works." Now, the re-building of the castle by Edward evinces, in a great measure, its previous antiquity; and its site, as in Camden's time, still remains to prove, that no spot of ground in this neighbourhood could be better adapted for a station or fortress. On the south it is bounded by the river, from which it rises very abruptly to a considerable height; the outer ramparts inclose an area of several acres, of a square form, with the angles rounded off, and the whole was environed by a deep ditch; the banks on the south, and south east, are still very bold. Not any vestiges of buildings now remain, but the foundations may, in various places, be traced from the unevenness of the surface; the artificial mount, on which most probably stood the keep of the castle, was also surrounded by a ditch. Below the high ground, to the south-westward of the entrenchments, is an extensive and fertile meadow, called Portholm, which Camden describes as "the most fresh and beautiful that the sun ever shone upon." This meadow is partly surrounded by the Ouse river; and here the Huntingdon races are held; a small part of it, which belonged to the protector Cromwell, and is now the property of the earl of Sandwich, still bears the appellation of Cromwell's-Acres.

Huntingdon is a borough by prescription, and the only one in the whole county. In the time of Edward the Confessor, as appears from the Domesday book, there were in "this burgh, four ferlings, in two of which were 116 burgeses, paying custom and geld, and under them 100 bordarii, who help to pay the geld; in the other two ferlings were 140 burgeses, subject to all customs, and the king's geld."

Scarcely any historical events are recorded as happening in this town. During the civil war, in the time of Charles I., it was pillaged by the king's troops, who were commanded by the king in person.

The religious houses, of which there were formerly four of different descriptions, are almost as entirely obliterated as the buildings of the castle. The most ancient was a priory of Austin canons founded on the spot where St. Mary's church now stands, before the year 973, as appears from a charter of that date, granted by king Edgar to Thorney abbey. The buildings have long been demolished; but the lanes which separated the closes still retain their ancient appellation. The next foundation in order of time, was an hospital for a master and brethren, and several leprous and infirm people, to which Malcolm IV. king of Scotland, and earl of Huntingdon, was a great benefactor. Another hospital, for leprous and poor people, was founded by David, earl of Huntingdon, in the time of Henry II. A house of Augustine friars was also established at the north end of the town, previous to the nineteenth year of Edward I. Huntingdon is generally stated to have been once much larger than at present; and sir Robert Cotton, as quoted by Speed, ascribes its decay to some alterations made in the river by one Grey, a minion of the time, by which its navigation was impeded. Leland says, that some ages before it had fifteen churches, though, in his time, reduced to four; the rest fallen through time and neglect, but traces of their walls and yards remaining. There are now only two churches, those of St. Mary and All Saints; but the town still consists of four parishes; that of St. John being connected with All Saints, and that of St. Benet with St. Mary's. The church of St. Mary, which is the corporation church, was rebuilt in the reign of James I., between the years 1628 and 1629, as appears from those dates over the north door-way: on the tower is the date 1613. It consists of a nave, chancel, and aisle, with a handsome embat-

tled tower at the west end, having strong buttresses with ornamental niches at the angles. The chancel contains several monuments to the Sayer family, one of whom, George Sayer, gent. contributed largely towards the internal repairs of this edifice, and besides several other donations, gave 500*l.* to purchase lands, the rents to be appropriated to the ministers of the two churches. Nearly opposite to St. Mary's church is a respectable mansion, now the property and seat of sir John Arundel, bart. All Saints church, which stands on the north side of the market place, appears, from the character of its architecture and ornaments, to have been built in the time of Henry VII. It is an embattled edifice with a small tower at the north-west angle; below the battlements is a bold cornice, charged with a multiplicity of sculptures, representing human and animal heads, flowers, &c., and among them the Tudor rose and the portcullis.

The principal charitable establishments in this town are, a free grammar school, well endowed; and a green coat school, wherein twenty four boys are clothed and educated. This is called Walden's charity, from Lyonel Walden, esq. who, by will dated July 1719, left a sufficient endowment for the purpose of supporting it. Among various other donations for charitable uses in Huntingdon, was the sum of 200*l.* bequeathed by Richard Fishbourn, a citizen of London, who died in 1625; this money was to purchase lands, the rents of which were to be appropriated to the use of the poor: he made similar bequests to other places, the amount of the whole being 11,000*l.* The market place is a spacious area, on the south side of which stands the town-hall, a modern brick building, stuccoed, with a sort of piazza in front and at the sides for the market people; and behind it the butchers' shambles. The assizes for the town and county are held here twice a-year; the lower part of the building being divided for the purpose into two courts; one for criminal, and one for civil causes. Above is a spacious assembly room, ornamented with full length portraits of their majesties, George II. and III. with their respective queens; and also a well painted picture of John, earl of Sandwich, who died in 1792. The market, which is held on Saturdays, is well supplied with provisions in general; and great quantities of corn are sold. Huntingdon had its first charter about the year 1206; king John granted it a peculiar coroner, a recorder, town-clerk, and two bailiffs, with the receipt of tolls and customs. Charles II., by a new charter, vested the government in a mayor, twelve aldermen, and an indefinite number of burgeses or common council, chosen from the principal inhabitants. This borough sent members to parliament *ab origine*, from the twenty-third of Edward I.; the right of returning the two members is generally understood to be possessed by the freemen and inhabitant householders, paying scot and lot; the number of voters is about 200; both the representatives are however nominated by the earl of Sandwich. The town principally consists of one street, extending, in a north-westerly direction, from the banks of the Ouse, to nearly the distance of a mile, and having several lanes branching off at right angles. The streets are paved, and lighted in the winter by a small assessment levied on the householders. The ancient town appears to have spread further eastward; yet whatever might formerly have been the extent of Huntingdon, the population seems to be nearly the same as it was a century past; as bishop Gibson states the number of families it contained in 1717 to be 400, whilst the return made to parliament in 1801, records their amount to be 350, consisting of 2035 persons, inhabiting 356 houses.

Among

Among the more eminent natives of this town, was Henry, surnamed *de Huntingdon*, from the place of his birth, a distinguished ecclesiastic and historian; who lived in the reigns of Henry III. and Edward I.; and wrote a history of the Saxon heptarchy, with accounts of the succeeding kings to the reign of Stephen. Richard Fishbourn, gent. who has been already mentioned for his charities, was also a native. Huntingdon was likewise the birth-place of one of the most extraordinary characters that ever lived, the protector Oliver Cromwell, who, though prevented by considerations of policy from assuming the regal title, enjoyed all the essentials of sovereignty, and ruled this country with more than regal power. (See CROMWELL.) Beauties of England and Wales, vol. vii.

HUNTINGDON, an extensive and mountainous county in Pennsylvania, bounded N. and N.W. by Lycoming county, E. and N.E. by Mifflin, S.E. by Franklin, S. and S.W. by Bedford and Somerset, and W. by Westmoreland. It is about 75 miles long, and 39 broad; comprehending 1,432,960 acres of land, divided into 18 townships, containing 3068 inhabitants. In this county are found limestone, iron ore, and lead. Works have been established for the manufacture of iron and lead.

HUNTINGDON, the capital of the above county, which is a post-town, situated on the N.E. side of Juniatta river, and at the mouth of Standing-stone creek, 50 miles from the mouth of Juniatta, and containing about 90 houses, a court-house, gaol, and 1251 inhabitants; 184 miles W.N.W. of Philadelphia. About six miles N.N.E. of the town is a mineral spring, celebrated for relieving rheumatism, and curing cutaneous disorders. N. lat. 40° 26'. W. long. 78 2'.—Also, a post-town on the N. side of Long island, New York, at the head of a bay in Suffolk county, containing about 70 houses, a Presbyterian and an episcopal church; 38 miles E. by N. of New York city, containing 3892 inhabitants.—Also, a post-town in Fairfield county, Connecticut, containing 2792 inhabitants.

HUNTINGDON, *North and South*, two townships, in Westmoreland county, Pennsylvania, the former containing 1484, and the latter 2317 inhabitants.

HUNTINGDONSHIRE, one of the inland counties of England, is bounded on the south-east and north-east sides by Cambridgeshire, on the north and north-west by Northamptonshire, and on the south-west by Bedfordshire. Its limits are chiefly artificial: the river Nene, on the Northamptonshire border, with the King's Delf, the Old West Water, and the Ouse river, on the Cambridgeshire side, being the principal exceptions. The general form of this county is an irregular square: its extent, from north to south, is nearly thirty miles; its greatest breadth, from east to west, twenty-three; and its circumference about one hundred: its superficial contents have been estimated at from 220,000 to 240,000 acres. It contains four hundreds, six market towns, 107 parishes, 6976 houses, and 37,568 inhabitants, *viz.* 18,521 males, and 19,047 females, according to the late returns made under the population and poor acts. It sends four members to parliament; two for the shire, and two for the town of Huntingdon. The government of this county is very peculiar; Cambridgeshire being joined to it under one sheriff, who is chosen out of that county one year, out of the isle of Ely the second, and out of this county the third: and in the isle of Ely alternately out of the north and south parts. The whole of this county is in the diocese of Lincoln.

Ancient History.—Huntingdonshire, with the adjacent counties of Cambridge, Norfolk, and Suffolk, originally composed the territory of the Iceni; and in the Roman

division of the kingdom was included in the district named Flavia Cæsariensis. The principal Roman stations in Huntingdonshire, were Duroliponte at Huntingdon, and Durobrive, near Dornford Ferry, about midway between Cherterton in this county, and Caistor in Northamptonshire. The principal ancient roads, of which there appear to have been three, intersected each other near Huntingdon: one of them has been called the British Ermin. This seems to have entered the county from the vicinity of Cæsar's camp, or Salenæ, in Bedfordshire, and to have proceeded by Cranehill, in the track since known by the name of Hell-lane, whence passing through Tofeland, Godmanchester, and Huntingdon, it continued by Alconbury, Welton, and Upton; and entered Northamptonshire at Wandsford. The Roman Ermin-street came into this county from Cambridgeshire, near Papworth St. Agnes, and proceeded to Godmanchester; branching off to the eastward, it crossed Northamptonshire, and entered Rutlandshire, near Stamford. The *Via Devana*, the third and last of these roads, entered this county from Cambridgeshire in the neighbourhood of Fenny Stanton, and quitted it for Northamptonshire in the vicinity of Clapton. In the early Saxon times, this district formed a part of the kingdom of East Anglia, and was then called *Huntedunescyre*, and *Huntandunescyre*. It was afterwards subjugated by the Mercian sovereigns, and continued under their dominion till the union of the Saxon states into one monarchy, by Egbert. "In the decline of the Saxon government," Camden observes, "this county had an officary earl, Siward; for earldoms were not yet hereditary in England, but the governors of shires were, according to the custom of that period, called earls, with the additional title of the shires they presided over: as this Siward, while governor here, was called earl of Huntingdon, but afterwards having the government of Northumberland conferred upon him, he was called earl of Northumberland." The principal land owners in this county in the Norman times, as recorded in the Domesday book, were the king, the bishops of Lincoln and Constance; the abbots of Ely, Croyland, Ramfey, Thorney, and Peterborough; the countess Judith, sheriff Eustace, earl Eustace, earl of Ow, earl Hugh, Walter Giffard, William de Warren, Hugh de Bolebec, Endo Fitz-Hubert, Swain of Effex, Roger de Iveri, Arnulf de Hedding, Gilbert de Gaunt, Aubrey de Ver, Ralph Fitz-Osmund, and Rothais, wife of Richard Fitz-Gilbert.

Surface, Fens, Soil, &c.—Huntingdonshire, Leland says, "in old time, was much more woody than it is now, and the dere resorted to the fennes; it is full long fens it was deforested." Camden corroborates this, and states, "that the inhabitants say it was once covered with woods; and it appears to have been a forest, till Henry II., in the beginning of his reign, disforested the whole, as set forth by an old perambulation, except Waybridge, Sapple, and Herthei, which were the lord's woods and remain forest." Sir Robert Cotton says, "this country was not completely disforested till the time of Edward I., when that sovereign, in his twenty-ninth year, confirmed the great charter granted by Henry III., and left no more forest than his own demesne." This description of forest land cannot be supposed to apply to the fens, of which there are 44,000 acres in this county, exclusive of about 5000 acres of what are called skirty lands. These constitute nearly a seventh part of what is called the Great Bedford Level, but they belong to that division called the Middle Level, and are principally found on the north and north-eastern parts of the county. About 8000 or 10,000 acres of the fen-lands are productive, yet the expence of keeping them from inundation amounts to almost one-third of the rents, through the imperfect state of the drainage. "It may

may seem paradoxical," says Mr. Maxwell, "that the fens of Huntingdonshire, whose surface is comparatively high, should be worse drained than those that lie between them and the sea, the surface of which last is considerably lower; the natural supposition being, that water will inevitably fall from the higher to the lower level. But this is the case with all the fens that are upon the skirts of the high land, and proves only, that the general drainage was executed upon principles fundamentally wrong. The fact is, that there was not a proper outfall to the sea, at the time of the general undertaking to drain the fens, nearly a century and a half ago; and ingenious men employed themselves not in obtaining an outfall, as they ought to have done, but in constructing large drains, and high banks, within the boundaries of the fens, expecting the water would force its own passage, in spite of every impediment; though the distance between the fens and the sea was from ten to fifteen miles. This not proving to be the case, ingenuity was set to work, to invent engines for the purpose of throwing the water out of the lands into the internal rivers. Still it did not find its way to the sea, but overtopped the banks, or broke them down with the weight of its pressure; even to this moment, instead of resorting to the outfall, the engines have been increased in size, and the banks raised still higher, so that the water, which, if there had been an outfall, would have found its way to the sea, and left to itself, would have rested on the lowest of the land, has been forced in a retrograde motion, over the surface of the higher lands; and hence the deplorable state of the fens in Huntingdonshire." The skirted lands are those which border on the fens, and partake of the properties of moor, combined with whatever soil, whether clay, gravel, or loam, that may be prevalent in the adjacent uplands. These lands, in general, afford luxuriant grazing. The meadow lands, which are the next in order on the scale of elevation, consist of about twelve or fourteen hundred acres, bordering on the rivers Nene and Ouse, but chiefly on the latter. These are extremely productive, but the produce is frequently damaged by the floods, and the crops sometimes totally carried away; this chiefly happens along the banks of the Ouse from St. Neots to Erieth; and the numerous water-mills which are placed upon this stream increase the risk of damage. The soils in the upland parts of the county are various, but principally consist of a strong deep clay, more or less intermingled with loam, or of a deep gravelly soil, with loam. Of what are called the deep-stapled lands, great part is still in an open field state, where each particular occupier is necessarily obliged to pursue whatever course of tillage is practised by the parish at large. The woodlands are but of inconsiderable extent; and the country is thin of timber: this is attributed to the very great demand for it in the fens; and the underwood is sold at a higher price by the pole, than in most other countries. The high roads are in general pretty good; the cross roads are but indifferent; and in the winter season many of them become impassable. No manufactures of note are carried on in this county, nor hardly any thing that bears reference to them, except wool-stapling and spinning yarn: the latter is the chief business of the women and children in the winter season; in summer they seek a more profitable employ in the fields.

Rivers.—The principal rivers connected with Huntingdonshire, are the Ouse, and the Nene or Nen. The Ouse enters the county from Bedfordshire, and in its course towards Huntingdon is increased by a combination of small streams: having passed that town, it becomes the boundary between this county and Cambridgeshire, till it enters the Great Level of Fens near Erieth: this river is navigable along its whole line across the county. The Nene rises in North-

amptonshire, and flowing through a delightful vale, reaches Huntingdonshire near Elton, where it becomes the boundary between both counties: afterwards winding to the east, it pursues a devious course to Peterborough, below which it sinks into the Fens, and passes onward to the sea. Some smaller streams water the north-east side of this county, together with several large meres, or pools of water; namely, Whittlesea Mere, Ransey Mere, Ugg Mere, &c.: of these, Whittlesea Mere is by far the largest, and covers an area of several miles in extent: it affords excellent fishing and fowling, and is in the summer season much frequented by parties of pleasure. Most of the meres are visited by abundance of wild-fowl. Maxwell's General View of the Agriculture of Huntingdonshire. Beauties of England vol. vii.

HUNTINGTON, ROBERT, in *Biography*, an English divine, was born at Deerhurst, in Gloucestershire, in 1636, and educated at Bristol, from whence he was removed to Merton college, Oxford, of which he became fellow. In 1662-3, he was admitted to the degree of M. A.; after this he applied himself most diligently to the study of divinity and the Oriental languages. In 1670 he was appointed chaplain to the factory of Aleppo, where he improved himself in the Oriental languages, and collected many curious manuscripts. Having carefully visited almost the whole of Galilee and Samaria, and examined the opinions, customs, and religious books, he went to Jerusalem, from thence he embarked for Cyprus, for the purpose of examining the library of Hilarion Cigala, the primate of the island, but on his arrival at Cyprus he found the prelate had been obliged to seek his safety from the Turks in flight. In the following year he undertook the difficult journey of 150 miles to view the ruins of Palmyra, which he was prevented from examining, and was himself in considerable danger of his life from two Arab chiefs, who had taken possession of that district. He next went to Egypt, and continued during his whole residence in the East to improve himself, and benefit his country and the world, by rescuing from oblivion curious copies of the Gospels, and other books relating to polite literature. In the year 1682 he set out on his return home, and visited in his journey Rome, Naples, and other most considerable places in Italy. From Italy he went to Paris, thence he arrived safe in England, and was, almost immediately after his return, raised to the degree of D. D., and at the same time appointed master of Trinity college, Dublin. This promotion he very much disliked, regarding it as a kind of banishment: but he was persuaded by his friends to undertake the duties attaching to the office, which he performed very much to the benefit of the institution, and to the interests of literature in general. In 1691 he returned to England, resigned his mastership, and resolved never more to quit his country. He made a present to the Bodleian library of many valuable MSS., the curators of which purchased his others, to the number of about 600, for the sum of 700*l*. In the following year he was presented to the rectory of Great Hallingbury, in Essex. About the same time he was offered the bishopric of Kilmore and Ardagh, in Ireland, which he refused: but in 1701, notwithstanding his former determinations, he accepted the bishopric of Raphoe, in that kingdom. He survived his consecration but a few days, and died in the forty-sixth year of his age. Some of his observations are in Ray's Collection of Voyages and Travels; and in the Philosophical Transactions he gave an "Account of the Porphyry Pillars of Egypt." *Biog. Brit.*

HUNTINGTON, in *Geography*, a post-town in Chittenden county, Vermont, on the S. side of Onion river, 15 miles S. E. of Burlington, containing 405 inhabitants.

HUNTLY, is a considerable town and parish in Aberdeenshire, Scotland, situated on the point of land formed by the confluence of the rivers Bogie and Deveron. The former consists of two large streets, which cross each other at right angles, and form a spacious square, in which the markets are held. The town has greatly increased in population and active trade within the last sixty years: in the year 1792, there were fifty-two flax-dressers, whose manufactures, at an average, amounted to 16,224 $\frac{1}{2}$ annually, and 209 weavers, whose labours produced yearly 73,150 yards of cloth. The return to parliament, in 1801, stated the number of houses to be 498; of inhabitants 2863. Three fairs are held annually. Near the town, on the banks of the Deveron, is the elegant residence of the marquis of Huntly, eldest son of the duke of Gordon: and adjoining to Deveron bridge stand the ruins of Huntly castle, the magnificent mansion of that ancient family, built in 1602 by George, first marquis of Huntly. The parish of Huntly is about six miles in length and four in breadth; and was formed, in 1727, by uniting the two ancient parishes of Dumbenau and Kilmore. Sinclair's Statistical Account of Scotland, vol. xi.

HUNTORP, a town of Germany, in the county of Oldenburg; 9 miles N. E. of Oldenburg.

HUNT'S BAY, a bay on the S. coast of Jamaica. N. lat. 17° 52'. W. long. 79° 49'.

HUNT'S TOWN, the seat of justice in Jefferson county, Mississippi territory, situated on an elevated plain, near the middle fork of Cole's creek, about 25 miles N. from the town of Natchez, about 10 miles from the confluence of Cole's creek with the Mississippi river. This town is in the midst of a healthy and fertile country, settled by industrious and wealthy inhabitants. An elegant court-house, gaol, several store and dwelling houses have been built in this place.

HUNTSBURG, a post-town of America, in Franklin county, Vermont, situated on the Canada line, and containing 280 inhabitants.

HUNTSMAN, a person whose business it is to superintend every department of a hunting establishment, as well as to conduct a pack of hounds with skill and success in the field. According to the description given of such a person by Mr. Beckford, he should be strong, active, sensible, good-tempered, fond of the diversion of hunting, and indefatigable in the pursuit of it. He should also be sober, exact, civil, and cleanly; he should be a good groom, and an excellent horseman; his voice should be clear and strong; and he should have an eye so quick as to perceive which hound carries the scent, when all are running, and an ear so excellent, as always to distinguish the foremost hounds, when he does not see them; he should be patient, quiet, and without conceit. These excellencies, which constitute a good huntsman, he should not be too fond of displaying, until occasion calls them forth. Hounds should be let alone while they can hunt; and the huntsman should display his talents in assisting them, when they cannot. Subordinate to the huntsman is the "Whipper-in," who should possess nearly the same qualities with the huntsman, to whom he should be attentive and obedient. His station in the field is on the side of the cover opposite to the huntsman, whose halloo he should be near enough to hear, and ready to obey. More foxes, it is said, will be killed with an excellent whipper-in and a moderate huntsman, than with the best of huntsmen without such an assistant, because hounds oftener need the one than the other.

HUNTSVILLE, in *Geography*, a post-town of America, in North Carolina; 16 miles from Rockford.

HUNYAD, a town of Transylvania, on a small river, which runs into the Maros; 54 miles E. N. E. of Temesvar. N. lat. 45° 51'. E. long. 22° 44'.

HUPPOOAH, a town of Bengal; 47 miles N. W. of Ramgur.

HURA, in *Botany*, a name of barbarous origin, but, contrary to his usual practice, adopted by Linnaeus. It appears to be the name of the tree in question among the inhabitants of Guiana, not, as professor Martyn reports, of Mexico, where it is said, in Hernandez, to be distinguished by the sesquipedalian appellation of *Quantilatlatzin*, which, it seems, means a *cracking tree*. Linn. Gen. 504. Schreb. 660. Willd. Sp. Pl. v. 4. 592. Mart. Mill. Dict. v. 2. Juss. 391. Lamarek. Illustr. t. 793. Class and order, *Monocia Monadelphica*. Nat. Ord. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Catkin oblong, drooping, obtuse, covered with sessile florets; scales oblong, with a pair of very short internal abrupt ones besides. *Cor.* none. *Stam.* Filament cylindrical, rather longer than the scales, rigid, peltate, with two or three whorls of tubercles near the top; anthers two sunk in each tubercle, oval, cloven.

Female, *Cal.* Perianth of one leaf, inferior, cylindrical, furrowed, abrupt, entire, closely enclosing the germen. *Cor.* none. *Pist.* Germen roundish, within the calyx; style long, cylindrical; stigma large, peltate, convex, coloured, in twelve equal reflexed lobes. *Peric.* Capsule woody, orbicular, depressed with twelve furrows and twelve cells, each with two elastic, semi-lunar, pointed valves. *Seeds* solitary, orbicular, compressed, large.

Ess. Ch. Male, Catkin imbricated, with three scales to each floret. Corolla none. Stamen peltate at the top.

Female, Calyx cylindrical, entire. Corolla none. Stigma peltate, in twelve segments. Capsule of twelve cells, with two elastic valves to each. Seeds solitary.

1. *H. crepitans*. Sand-box tree. Linn. Sp. Pl. 1431. Hort. Cliff. 486. t. 34. Trew. Ehret t. 34, 35. f. 1.—Native of South America.—A tree of considerable height. The leaves are large, alternate, stalked, heart-shaped, serrated, rugged, rough. Flowers small and inconspicuous, except for their purple stigma, from the forks of the branches. Fruit large, often brought to Europe, and used as a sand-box, but if suffered to hang too long before gathering, it will, in a dry warm room, explode with great violence and noise, like the sound of a pistol. The seeds are emetic and purgative.

HURCHUNCHUCK, in *Geography*, a town of Bengal; 25 miles E. S. E. of Boglipour.

HURCHUNDY, a town of Bengal; 10 miles S. of Chimary.

HURCHURNPOUR, a town of Bengal; 17 miles N. of Rajemal.

HURCOS, or **URCOS**, a town of Peru, in the diocese of Cusco; 21 miles S. of Cusco.

HURDAH, a town of Hindoostan, in the Candehish country, on the S. of the Nerbuddah river; 22 miles S. S. E. of Hindia. N. lat. 22° 23'. E. long. 77° 19' 45'.

HURDES, or **HARDS**, of *flax* or *bemp*, the coarser parts, separated in the dressings from the tear or fine stuff. See **HEMP** and **FLAX**.

HURDLE is the name of the sledge used to draw traitors to the place of execution.

HURDLE, in *Agriculture*, the name of a light wooden frame, formed of small bars, or otherwise, somewhat in appearance similar to the low common field gate. It is principally employed for the purpose of constituting a sort of moveable fence for inclosing and confining sheep, and other kinds of live stock, during the time they are consuming some
fort

fort of rich green, or other luxuriant food. The usual materials for the forming of hurdles are those of some sort of light split wood, or hazel rods of rather young growth. In the former case they are commonly put together by means of framing or nailing, and in the latter by wattling the rods in between a fort of small flakes. Hence they are often denominated *framed* or *wattled* hurdles by way of distinction.

Besides the above uses, hurdles are necessary in folding sheep on arable lands, and also in feeding off turnips, either by them or neat cattle, on the land, in order to keep them upon a certain space of ground, and thus afford them a limited portion of food at a time, by which a considerable saving is effected in its being eaten up more cleanly and with less waste, than would be the case if they ranged over the whole. And on the tillage lands the sheep, by being so closely confined, contribute in a very high degree to its fertility and improvement.

It has been lately observed, that "in the grazing of a large field, for instance, when the sheep or cattle are turned upon it early in the spring, they tread down and destroy a great deal of the grass; and by dropping their dung and urine upon the remainder, injure it so much as to render it unpalatable to the stock. In this way a great proportion of the grass is lost in every field of considerable extent: whereas when the stock is first put upon the field, if hurdles or flakes were run across a small part of it, as is the case with turnips, and the grazing stock kept there till they had eaten the herbage clean up, they would then, from necessity, eat a great deal that is entirely lost, when they are permitted to range over the whole field. In this way considerably more stock might be fed upon a given space, than is done at present. It is to be observed, however, that the first space divided off by the flakes should be next the water, especially if the field is grazed by black cattle or horses, and that progressively, as the stock is removed from the watering place, a lane should be left, by which the cattle may travel to the pond. It is also to be noticed, that after the first space allowed to the grazing stock is eaten clean up, and as soon as they are shifted to a new place, a course of flakes should be placed behind them, to prevent them from going backward upon the pasture that has been already eaten bare. By this management the whole of the herbage, upon every space allotted to the stock, will not only be completely eaten up, but, by dividing or fencing off that part which has been eaten, the plants are allowed to recover; and, long before the whole field is gone over, the space first eaten will be in a situation to receive the stock a second time. By this method the dung and urine of the stock, instead of rendering the herbage nauseous and unpalatable, and thereby preventing them from eating it, will, by its fertilising powers, assist its growth, and render it sooner fit for being eaten a second time, and by that means afford three or four crops in the space of a year instead of one. Experience has sufficiently evinced the great profit and advantage that attend the practice of tending cattle or horses upon good pasture, or of feeding them in the house with cut grass. The benefit in both these cases arises from the whole of the herbage being completely eaten up, without any part of it being lost. The same benefit, but with infinitely less trouble, may be reaped from *hurdling* or *flaking* grass fields: every possible advantage will be made of them in this way; and in very many instances it will happen, that before a half or two-thirds of the field are gone over by flaking, the part first eaten will be in a situation again to receive the stock. By that means a part of the field may be saved for hay; or, if the views of the occupier be of another kind, the num-

ber of the grazing stock may be increased in a proper degree."

The writer is "aware, however, that it may, and no doubt will be argued by many, that this management will be attended with much trouble and expence; and after all, that the profit resulting therefrom will be but small, and scarcely prove equivalent to the trouble and extra expence. From the acknowledged value of hurdling, however, in the consumption of turnips, cabbages, &c., and the great profit which arises from giving the stock only a certain quantity of food at once, and withholding any more from them till that is eaten up, some idea may be formed of the vast advantage that would attend the flaking of a grass-plot in different cases. He by no means, however, wishes these observations to be understood as applying to grass pastures of every description; quite the contrary, as there are many situations where the expence and trouble of flaking would prove more than an equivalent for any advantage that could be reaped from the practice. But upon all rich pastures, the benefit arising from the practice of flaking will be found very considerable, and a single experiment will be sufficient to convince the most incredulous."

It is obvious that in parks, pleasure-grounds, and other ornamented places, the eating of the grass may be the most conveniently and economically accomplished by means of hurdles, as, in this way, the danger of injuring the trees and shrubs is most effectually prevented; and from the hurdles being capable of a ready removal, any portion can at pleasure be eaten down in the most desirable manner.

In regard to the expence of hurdles, those of the framed kind are usually from about 12s. to 18s. or 20s. the dozen, according to the manner of making them, and the nature of the wood employed. The wattled sort are commonly much cheaper, being seldom higher than from 10s. to 12s. the dozen. A representation of a framed hurdle is given in the plates on fences. See FENCE.

It is found from actual trials, that a dozen and a half are sufficient for folding thirty sheep; and that about twelve dozen will answer the purpose for one thousand in most cases.

HURDLE, *lamb*, the title of another sort of hurdle, constructed for the purpose of protecting and preserving lambs soon after they have been dropped, and while they continue in a weakly state. It is suggested in the survey of Lincolnshire, that "vigilance in the lambing season prevents much of the danger in bad weather, but that in addition," a provision against the loss of lambs in the ditches of the breeding pastures, has there been made at a small expence, by means of lamb-hurdles.

These are constructed of two thin rails, with heads at the ends and proper braces; the space between the rails being closed in by having tarpauling nailed securely to each of the rails, &c. But it is hinted, that "as the tarpauling would require many nails, and as canvas is a dear article," the space may perhaps "be better filled, by a slit deal held in its place by having braces on both sides, one of which might be moveable, and fix with nuts on the rivets, by which means the board might be put in only occasionally when wanted." This description of hurdle is represented in the plates on fences. See FENCE.

It is further noticed, that this hurdle, "when the lower rail touches the ground, is a perfect defence against the wind, and of a sufficient height to prevent the lambs driving before a storm into the ditches; so that it answers two good purposes." And that, "at other seasons also, these hurdles may come into use for guarding the brows of banks against sheep.

HURDLES, in *Fortification*, twigs of willows or osiers, interwoven close together, in the form of a long square, five or six feet long, and three or three and a half broad, sustained by strong stakes, and usually laden with earth. Hurdles, called also *clayes*, serve to render batteries firm, to consolidate the passage over muddy ditches, and cover traverses and lodgments, for the defence of the workmen against the artificial fires or stones that may be cast upon them.

HURDLING, a term signifying the art or practice of dividing land by the use of hurdles, in the view of improving the grounds or consuming the food with greater economy and advantage, by the confining of different sorts of live stock, within certain limits. It is a highly beneficial method of management in a great number of instances. See *FOLDING of Sheep*, and **HURDLE**.

HURDS, in *Rural Economy*, a name given to the coarser parts of flax and hemp, which in the dressing of them are separated from those of the fine stuff of either of such matters.

HURDWAR, in *Geography*, a town of Hindoostan, in the northern part of the country of Delhi, on the Himalah, near the W. coast of the Ganges, where it enters the plains of Hindoostan, on the borders of Thibet; 86 miles N. of Delhi. N. lat. $29^{\circ} 55'$. E. long. $78^{\circ} 23'$. See **GANGES**.

HURDY-GURDY. See **MONOCHORD**.

HURE, CHARLES, in *Biography*, an eminent French divine, was son of a labourer at Champigny-sur-Yonne, where he was born in the year 1639. As he shewed a strong inclination for learning, his father caused him to have a good education, and obtained for him assistance from the archbishop of Sens, who gave him an exhibition in the college des Grassins at Paris, where he distinguished himself greatly among his contemporaries. Having completed his academical studies he was admitted into holy orders, and appointed one of the preachers of his college. He was afterwards made professor of the belles lettres; and at length became principal of the college of Boncourt, where he died in 1717, in the seventy-eighth year of his age. His principal works are, "A Dictionary of the Bible," in two volumes folio. "A Translation of the New Testament into the French Language with Notes," and "A Sacred Grammar," intended to illustrate the New Testament. He was a man of great simplicity of manners, who united to much candour, ardent piety and a solid judgment. Moreri.

HUREEPOUR, in *Geography*, a town of Hindoostan, in Lahore; 95 miles E.N.E. of Lahore. N. lat. $32^{\circ} 5'$. E. long. $75^{\circ} 42'$.

HURENHUTTERS, in *Ecclesiastical History*. See **HERRNHUTERS**.

HURFWA, in *Geography*, a town of Sweden, in the province of Skone; 10 miles N.E. of Lund.

HURIEL, a town of France, in the department of the Allier, and chief place of a canton, in the district of Montluçon; six miles N.W. of it. The place contains 1628, and the canton 10,178 inhabitants, on a territory of 400 kilometres, in 16 communes.

HURKUTTA, a town of Bengal; 40 miles S.S.E. of Curruckdeah.

HURLE BONE, in a horse, is a bone near the middle of the buttock; very apt to go out of its sockets with a slip or strain.

HURLERS, a number of large stones, set in a kind of square figure near St. Clare, in Cornwall, so called from an odd opinion held by the common people, that they are fo

many men petrified, or changed into stones, for profaning the sabbath-day by hurling the ball, an exercise for which the people of that county have been always famous.

The hurlers are oblong, rude, and unhewed. Many authors suppose them to have been trophies erected in memory of some battle; others take them for boundaries to distinguish lands. Lastly, others, with more probability, hold them to have been sepulchral monuments.

HURLEY, in *Geography*, a township of America; in Ulster county, New York; containing 1159 inhabitants.

HURLOCK, in *Mining*, signifies the harder beds of chalk in the lower parts of the series N. of Dunstable, which is principally used for burning lime, for mortar-making in that district, for the use of lime in agriculture is there almost unknown. The hurlock is without layers of flints, and contains very minute grains of silex distributed through its mass; some large cornu ammonias and others of an oval figure, according to Mr. Parkinson, and other shells are found in it; the lower beds are mostly siliceous, and they terminate below in the Totternhoe freestone, of which Woburn abbey, the Swan Inn at Bedford, and many other good houses are built; this, at the foot of the North Downs, near Ryegate, Godstone, &c. is a fire-stone; at the foot of the South Downs in a similar situation it has not been discovered, because not sought after, we believe.

HURLY-BURLY, in *Vulgar Language*, denotes confusion, or tumult, and is said to owe its origin to two neighbouring families, Hurleigh and Burleigh, which filled their part of the kingdom with contest and violence. Johnson.

HURON, in *Geography*, one of the five principal lakes of North America; lying between $43^{\circ} 30'$, and $47^{\circ} 30'$ N. lat. and between $80^{\circ} 45'$, and $84^{\circ} 45'$ W. long., and reckoned upwards of 1000 miles in circumference. The fish of this lake are similar to those of lake Superior, with which it communicates by the straits of St. Mary, about 40 miles in length, and in some places only one or two miles in breadth, with a rapid towards the N.E. extremity, which may however be descended by canoes, and the prospects are here delightful. Another short strait leads into the lake called Michigan, and it communicates with lake Erie on the S. It is of a triangular shape; and on the S.W. part is Saguinum or Sagana bay, 80 miles long and about 18 or 20 broad. The other most remarkable bay is Thunder bay. On the banks of the lake are found great quantities of sand cherries. The land on the western shore is much inferior in quality to that on lake Erie. It is mixed with sand and small stones, and is covered chiefly with pines, birch, and some oaks; but at a little distance from the lake the soil is very luxuriant. Some few years ago, a part of the Indian nations, called Chepaways and Ottaways, who inhabited round Sanguinum bay, and on the banks of the lake, could furnish 200 warriors; and those of the latter nation, who lived on the E. side of lake Michigan, 21 miles from Michilimackinack, could furnish 200 warriors. Those who lived on the E. side were called Hurons.—Also, a small river of the north-west territory, which, after a course of 38 miles, falls into lake St. Clair from the N.W.—Also, another small river in the same territory, which runs north-eastward into lake Erie; 40 miles westward of Cayahoga, and 15 S.E. of the mouth of Sandusky lake.

HUROUNG, a town of Bengal; 35 miles S.S.E. of Islamabad.

HURPEYA, a town of Hindoostan, in Moultan; six miles N.W. of Shawanaz.

HURPLE, in *Rural Economy*, a term applied in many places to cattle, when they set up their backs in the cold severe winter season.

HURPOIS, in *Geography*, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 18'. E. long. 21° 34'.

HURRAI, a town of Hindoostan, in Oude, on the left bank of the Ganges; 12 miles S. of Corah.

HURRERS, in our *Old Writers*. The cappers and hat-makers of London, formerly one company of the haberdashers, were called by this name.

HURRIAPOUR, in *Geography*, a town of Hindoostan, in Bahar; 13 miles N. of Durbungah.

HURRICANE, a very violent wind, such as to blow down trees, unroof houses, and produce other destructive effects. Though hurricanes are observed occasionally in most parts of the earth, it is in the torrid zone, and particularly in the West Indies, where their devastations are more peculiarly observed. In Long's history of Jamaica, we find a chronological table of the most remarkable hurricanes which took place in the West Indian islands for more than a century. The times and places are as follow :

Hurricanes.	
1670	at Barbadoes,
1674	Do.
1675	Do.
1691	Antigna,
1700	Barbadoes,
1702	Do.
1707	Caribbee islands in general,
1712	Jamaica,
1720	at Barbadoes,
1722	Jamaica,
1733	Caribbees in general,
1744	Jamaica,
1764	Martinico, Carthagena, and particularly at some of the Caribbee islands,
1772	Most of the Caribbee islands,
To which may be added	1780 October 3d, Jamaica.

The one that happened Aug. 31, 1722, was very terrible and destructive, it extended 700 leagues or upwards.

Few people of scientific observation have had opportunities of marking the phenomena which attend these West Indian hurricanes. A writer, giving an *Account of the European Settlements in America*, observes, "It is in the rainy season, principally in the month of August, more rarely in July and September, that they are assailed by hurricanes, the most terrible calamity to which they are subject from the climate. This destroys at one stroke the labour of many years, and frustrates the most exalted hopes of the planter, and often just at the moment when he thinks himself out of the reach of fortune. It is a sudden and violent storm of wind, rain, thunder, and lightning, attended with a furious swelling of the sea, and sometimes with an earthquake; in short, with every circumstance which the elements can assemble that is terrible and destructive. First they see as a prelude to the ensuing havoc, whole fields of sugar-canes whirled into the air, and scattered over the face of the country. The strongest trees of the forest are torn up by the roots and driven about like stubble. Their wind-mills are swept away in a moment. Their works, their fixtures, the ponderous copper-boilers and stills of several hundred weight, are wrenched from the ground and battered to pieces. Their houses are no protection, the roofs are torn off at one blast, and the rain, which in an hour rises five feet, rushes in upon them with an irresistible violence. There are signs which the Indians of these islands taught our planters, by which they can prognosticate the approach of a hurricane. It

comes on either in the quarters or at the full or change of the moon. If it will come on at the full moon, you being at the change, observe these signs. That day you will see the sky very turbulent. You will observe the sun more red than at other times. You will perceive a dead calm, and the hills clear of all those clouds and mists which usually hover about them. In the clefts of the earth, and in the wells, you will hear a hollow rumbling found like the rushing of a great wind. At night the stars seem much larger than usual, and surrounded with a sort of burs. The north-west sky has a black and menacing look, and the sea emits a strong smell and rises into vast waves, often without any wind. The wind itself now forsakes its usual steady easterly stream, and shifts about to the west, from whence it sometimes blows with intermissions violently and irregularly for about two hours at a time. You have the same signs at the full of the moon. The moon itself is surrounded with a great bur, and sometimes the sun has the same appearance." Another author, Captain Langford, (see *Philos. Trans.* abridged, vol. ii. p. 105.) makes the following observations amongst others: "It is to be observed, that all hurricanes begin from the N. to the westward, and on those points that the easterly wind doth most violently blow, doth the hurricane blow most fiercely against it; for from the N.N.E. to the E.S.E. the easterly wind bloweth freshest, so doth the W.N.W. to the S.S.W. in the hurricane blow most violent, and when it comes back to the S.E. which is the common course of the trade-wind, then it ceaseth of its violence and so breaks up.

Though hurricanes may be deemed extraordinary events, and therefore may be ascribed to the operations of extraordinary causes, it is more probable that they arise principally from the ordinary causes of wind, which are the unequal temperature of the earth's surface in the different parallels of latitude, or rather of the incumbent atmosphere, and the diurnal rotation of the earth; to which may be occasionally added the precipitation of uncommon quantities of rain, accompanied with thunder and lightning. See WIND.

It has been the custom of late times to assign electricity as the cause of every inexplicable phenomenon in meteorology. Not only hurricanes but winds in general have been referred to electricity as their cause; but it will be time enough to introduce this cause when the common principles of the mechanical philosophy have been fairly applied and found inadequate to the explication.

Switzerland is subject to very violent hurricanes, which do great mischief, and that in a very singular manner. Thunder and lightning are frequent with them in winter as well as in summer; and the more violent storms of these are sometimes attended with whirlwinds and hurricanes, which will raise the waters of some lakes in form of a thick pillar up to the clouds, and carrying on before the wind this vast body of water, will sometimes fall on other places on dry land, and drown the houses and gardens where it chanceth to fall.

HURRIERS, in *Mining*, are those persons employed in a coal-pit, who hurry or drag the corves of coals from the banks where they are dug to the bottom of the winding shaft to be drawn up.

HURRIES, in *Engineering*, is sometimes applied, at Newcastle and other places, to the strong stages of wood erected by the sides of the navigable rivers and harbours, on to which the rail-ways are conducted from the coal-pits; by which means the load is at once emptied, by help of a spout, from the rail-way waggons into the holds of the ships. See STAIR.

HURRY, in *Agriculture*, a term often applied in the south-western and other districts of the kingdom, to a small load of corn or hay.

HURRYAL, in *Geography*, a town of Bengal; 20 miles S.E. of Nattore. N. lat. 24° 18'. E. long. 89° 28'.

HURRYPOUR, a town of Hindoostan, in Sanore; 17 miles S. of Ranny Bednore.

HURSALOO, a town of Hindoostan, in the circle of Nagore; 12 miles W. of Catchwana.

HURST, or **HYRST**, in our *Old Writers*, denotes a wood or grove of trees. Hence such places as have this word for part of their names, have been situated near a wood. In Kent, Suffex, and Hampshire, there are many such, because formerly the great wood called Anderwald extended itself through these counties.

HURTER, in *Artillery*, a flatted iron fixed against the body of an axle-tree, with straps to take off the friction of the naves of wheels against the body.

HURTERS, in *Fortification*, denote pieces of timber about six inches square, placed at the lower end of the plat-form, next to the parapet, to prevent the wheels of the gun-carriages from damaging the parapet.

HURTS, in *Heraldry*, by some wrote *Heurts*, and by others *Huerts*, are azure or blue rundles.

The English heralds distinguish between the colours of rundles, and give them different names agreeable thereto: those of other nations content themselves to call those *tor-teaux d'azure*; and in other cases only add the respective colour to the term *tor-teaux*.

But these being blue, some will have them to signify bruises or contusions in the flesh, which often turn to that colour: others suppose them whortle berries.

HUS, or **HUSSU**, in *Geography*, a town of European Turkey, in the province of Moldavia, the see of a Greek bishop, situated on the Pruth; 70 miles S.W. of Bender. N. lat. 46° 35'. E. long. 28° 34'.

HUSACKER, one of the small Shetland islands between Mainland and Yell. N. lat. 60° 48'. W. long. 1° 35'.

HUSBAND, **MARITUS**, a man joined or contracted with a woman in marriage. See **COVERTURE** and **MARRIAGE**. See also **DIVORCE**, **DOWER**, **FEME-COVERT**, &c.

HUSBAND Land, a term used in Scotland for a portion of land containing six acres (= 7.624464 English statute acres) of fock and scythe land; that is, of land that may be tilled with a plough, and mown with a scythe.

HUSBANDMAN, in *Agriculture*, the common name of the labourer or person who is engaged in the tillage and cultivation of the soil. It has been, in general, too much the practice to despise and depress the habits and talents of this most valuable class of society; as by such means the necessary ardour and spirit of exertion are much abated, and the improvement of husbandry greatly retarded.

The ingenious author of the "Wealth of Nations" has drawn the following curious and interesting comparison between this sort of labourer, and the artizan or mechanic. He says, that "not only the art of the farmer, the general direction of the operations of husbandry, but many inferior branches of labour require much more skill and experience than the greater part of mechanic trades. The man who works upon brass and iron works with instruments, and upon materials of which the temper is always the same, or very nearly the same: but the man who ploughs the ground with a team of horses or oxen, works with instruments of which the health, strength, and temper are very different upon different occasions. The conditions of the materials which he works upon, too, are as variable as that of the instruments he works with, and both require to be managed

with great judgment and discretion. The common ploughman, though generally regarded as the pattern of stupidity and ignorance, is seldom defective in his judgment and discretion: he is less accustomed, indeed, to social intercourse than the mechanic who lives in town. His voice and language are more uncouth and more difficult to be understood by those who are not used to them. His understanding, however, being accustomed to consider a greater variety of objects, is generally much superior to that of the other, whose whole attention, from morning to night, is commonly occupied in performing one or two simple operations. How much the lower ranks of people in the country are really superior to those of the town is well known by every man, whom either business or curiosity have led to converse much with both. In China and Hindoostan, accordingly, both the rank and the wages of country labourers are said to be superior to those of the greater part of artificers and manufacturers. They would probably be so every where, if corporation laws and the corporation spirit did not prevent it."

There can be no doubt of the vast utility and national advantage of promoting the spirit, and encouraging the exertions of the labourers in agriculture; as, however high the benefits of commerce may be estimated, it is only the raising of the necessary food for the support of the population of a nation within itself, that can render it truly great, happy, and independent.

HUSBANDRY, a general name applied to the art, business, or employment of the farmer, or of those engaged in the tillage and cultivation of the soil. There are various descriptions of husbandry depending on the particular views of the cultivator, and the methods of management which are adopted.

Hence, in regard to tillage or arable lands, these are the *broad-cast* and *drill-husbandry*, and it is often further divided by the way of distinction into what are termed the *old* and *new* husbandry; the former of which is supposed to be that which has been had recourse to from the most early periods; and the latter that which has been said to have been introduced and inculcated by the intelligent Mr. Tull and his followers. This last is likewise occasionally distinguished by the title of the *horse-boeing* husbandry. But though this husbandry be generally denominated *new* in this country, there is reason to believe that it is not so modern as has been commonly supposed, as it has been ascertained that in many of the eastern nations, where very few, if any, changes in their agricultural practices have occurred for many ages, it is for most sorts of crops the most usual mode. See **HUSBANDRY**, *Drill*.

It may be further noticed here, that the broad-cast husbandry is that kind of arable management in which the seed is thrown and dispersed over the ground by a sort of cast of the hand, without much regard being paid to the regularity of the crop, or the means of its after-culture. Besides, it was supposed by some farmers, that in this mode much less preparation of the land was necessary, but the contrary has been fully proved by later and more extensive experience.

And the drill-husbandry is that in which the grain or other kinds of crops are sown, set, or put into the soil, in rows, drills, or trenches, at different distances, by tools and machines contrived for the purpose, in order to be cultivated afterwards with implements particularly suited to them. In this way the seed is put into the soil with much more regularity and exactness, both in respect to evenness and depth, as well as the after-culture performed with much greater correctness and attention by the use of proper hoes and horse labour.

HUSBANDRY.

In cases where neither of these modes is exactly followed, but there is a kind of mixture of them both; or where two sorts of crops of different descriptions are cultivated together, in alternate rows, there is what has been frequently denominated *half-husbandry*: and where the ground is cultivated alternately in tillage and grass, there is that sort which is usually called *convertible husbandry* by modern farmers.

There are also particular methods of cultivation adopted on extensive tracts of ground in the state of commonage, which afford what is frequently denominated *common-field husbandry*.

With respect to lands in the state of grass, there are likewise *dairy*, *grazing*, and *grass* husbandry, according as the grounds are appropriated to the keeping of cows for milk, butter, or cheese, the feeding or fattening of different sorts of live-stock, and the making of grass into hay to be used as fodder.

The culture of particular sorts of crops also gives rise to different terms of this nature; hence there is *turnip*, *cabbage*, *carrot*, and *potatoe* husbandry, &c.

In these different points of view, husbandry, of course, comprises the whole of the numerous operations, processes, and modes of management which are necessary in the extensive business of cultivation, either in regard to tillage or grass, or the breeding, rearing, and keeping all sorts of live stock of the domestic kinds.

It is sufficiently evident, that very great improvements have been accomplished in the various branches of husbandry within these few late years by the introduction of more correct and better modes of cropping and managing lands, as well as by the gradual influence and adoption of better and more suitable tools and machines for executing the business of the farmer.

A late writer has laid down the following comparative estimates of the difference in the advantage between an acre of land cultivated under the old plan of fallowing once in every three years, or two crops and a fallow, which is supposed not to run out or exhaust the ground; and that of the more modern system of alternating green, or smothering crops, with those of the grain kind.

Balance in favour of the new system 7 17 6

8 5 6

Hence it would appear that the expences of the new method of husbandry are not only less by eight shillings the acre than those of the old the first six years, but will somewhat decrease in the next six, except in manure, which will be more, as in the new mode the reservoir and five crops of straw will, it is supposed, produce nearly double the quantity. Besides, in the first way, the manure is all raised from the produce of the land it is laid on: but to make the twelve loads, the old farmer robs the meadow, or any piece of fresh land he is permitted to plough up. This is supposed the principal cause why so many tenants are restricted from ploughing old fwards, as they do not return the manure to its proper situation, or lay it on in such a manner as is proper.

HUSBANDRY.

In all these estimates it is supposed that every acre of straw, where the crop is a good one, is capable of affording two loads of manure; consequently, by the old plan, even admitting the crop to be good, which is often not the case, there would be only eight loads of manure raised in six years; but, by the new, 10 loads, even without the assistance of the reservoir; and in the following six years, where the new system is pursued, 14 loads may be expected. In these statements the manure is charged as an expence, which is not right, where it is not purchased but raised on the ground.

If these calculations can be depended upon, there can be no doubt of the great superiority of the green-crop practice over that of the fallow method.

Other statements, by the same writer, on the differences of these different systems of management, on farms of different kinds, render the matter still more obvious.

Profit brought from account of 10 acres managed according to the new system, as seen below	80	0	0
	932	0	0
Profit	452	10	0

It is imagined that the whole of the houses, barns, buildings, and fences of the farm may occupy nine acres, which will leave 10 acres for the keep of the cows, horses, &c. To answer which purpose they are advised to be cropped in this way: three acres and a half with winter tares; two and a half with summer cabbages, and potatoes under them; and the four that remain with spring tares, or a part of them with buck-wheat. These 10 acres are to supply the place of the 59½ allowed for the same use under the old plan, constantly supposing the farm buildings to occupy the quantity above stated. These 10 acres must necessarily cost something in cultivating; but when well managed, they will, it is supposed, keep 40 head of neat cattle and horses in summer with cut straw; and the farmer will thereby have 120 a res of straw, clover, &c. where he had, under the old mode, only 59½; besides, the crops will be much more

bulky, and the quantity of manure constantly increase by the keeping so many cattle, horses and pigs, in the yards, summer and winter; and as the food that is advised is too rich for breeding flock where six cows are kept, as already noticed, 26 feeding beasts will be also wanted, which may afford an average profit of five guineas each, though more may be produced; as two returns may be made. But as these profits may be doubted by some, they are explained more fully by a debtor and creditor account; and the 10 are supposed to be set with potatoes at first, to clean and prepare the land for the tares, &c. carrying the profit on them to the general account, as being part of the crop of the first year of the improved husbandry.

Under Potatoes 10 Acres.

New System of Husbandry.

Dr. to Expences.

	£.	s.	d.
Ploughing 10 acres, at 7s. per acre	7	0	0
One hundred and twenty sacks of potatoes for seed, at 3s. per sack	18	0	0
Harrowing at different times, at 2s. per acre	1	0	0
Ploughing up at 5s. per acre	2	10	0
	25	0	0

Cr. by Produce.

	£.	s.	d.
By 10 acres, sold at 10l. 10s. per acre	105	0	0
Profit carried to the general account of one years profit	80	0	0
	185	0	0

It is supposed that in this case the potatoe crop is sold upon the land, as it is not easy to estimate the expences when the potatoes are disposed of at the market, or double the sum stated would be made of them; as 100 sacks, at 3s. each, would afford 15l. the acre, or 150l. in the whole; but if they were properly cultivated there would be 150 sacks to the acre.

Land under the New System of Husbandry.—10 Acres.

Dr. to Expences.

	£.	s.	d.
Three and a half acres ploughing, harrowing, and sowing, at 7s. per acre	1	4	6

	27	18	6

Cr.

HUSBANDRY.

Cr. by Produce.

	£	s.	d.
By the profit of 32 beasts, at an average of 5 <i>l.</i> 5 <i>s.</i> per beast	168	0	0
Profit by this mode	140	1	6

It is noticed that this return of profit seems great, but arises from the vast supply of food that is afforded by the 10 acres of land under tares and rye, when combined with cut straw in the keeping of live stock. As 10 horses have been found capable of being kept thirteen months on six acres of wheat-scourge, and the same extent of oats, it may be readily conceived that 10 acres of green fodder, in connection with the same number in wheat for straw, will keep 40 head of neat cattle and horses for the summer; consequently, 40 acres of wheat straw, 20 acres of clover twice mown, 20 acres of barley-straw, and 20 acres of pea-straw, in combination with 20 acres of turnips, will keep with facility 32 head of beasts, and eight horses, through the winter season. It is evident, therefore, that the produce of the ten acres in green food, in connection with the straw and clover of the other portions, will, under proper management, accomplish what has been stated.

It may be added, that cabbages of the early kind will be ready to cut early in June, and may be kept in use all the summer, as, before one portion is cut over, the sprouts of another will be in a state to cut again. These cabbages should be given to such beasts as are the nearest ready for the market. As soon as the winter tares and rye have been consumed, Savoy cabbages should be put in the land. The tares will be mown in summer, and the cabbages will serve the cattle in winter, and be soon enough off the ground to sow it with tares in the spring. The land where the spring-cabbages have grown should be sown with winter-tares, in the drill method, in the autumn, using from four to six loads of dung to the acre for each crop. In the manner of the garden, therefore, these 10 acres are to be constantly covered with crops, for the use of neat cattle and other sorts of live stock.

Though 20 acres have been put down for turnips, to be employed in feeding neat cattle in the yard, the whole will not by any means be wanted, so that one-half, or perhaps more, may often be converted to the use of the sheep, and in that way a profit be afforded, which has not been taken into the account. Besides, the quantity of manure stated under the improved husbandry is supposed much less than will be produced.

But allowing, under the improved practice, an additional man and boy to look after the live stock, the former, at the expence of 12*s.* a-week, and the latter at 6*s.* per week; rejecting the fractional parts, and taking 52 weeks for the year, there will be 46*l.* 16*s.* to deduct, which will leave the balance of 405*l.* 14*s.* Thus the profit by the old method being 130*l.* 8*s.* 6*d.* which, taken from the 405*l.* 14*s.* leaves the net balance of profit in favour of the improved husbandry to be 275*l.* 5*s.* 6*d.*

On the old plan, the profit of a horse in two years was estimated at 16*l.* which, taken for one year only, or one half, is 8*l.* and for pigs 5*l.* as already stated, which sums, added to 275*l.* 5*s.* 6*d.* make, in the whole, 288*l.* 5*s.* 6*d.*; and the 80*l.* for the potatoes being only brought to the account, though the net profit from the 10 acres, in green crops, is 140*l.* 1*s.* 6*d.* the aggregate sum will be 348*l.* 7*s.* which seems a large amount.

But, in this improved management in tillage and live stock, manure is raised of so much better quality, in such

plenty, and at so much cheaper a rate, than by purchasing it, as is the general custom of the vicinity of the farm, that it is hardly worth fetching from the large towns; and as it is the very soul of husbandry, every crop will be raised in far greater abundance.

It is however remarked, in conclusion, that there are different advantages, in regard to situation, that attend this farm, which, from their local nature, will not apply to those afterwards noticed. It may be supposed that the profit on the beasts is laid too high; for though, when cattle are fed on grass, the season may possibly vary so much that double the quantity of stock may be carried at one time to what the same land is capable of at another; of course, as it is common to put on the same number of cattle every year, it may, in some dry periods, be much overloaded with stock, while in others, which are more moist, there may be a deficiency, under either of which circumstances there must be loss sustained; but where food is provided in the way just stated, the green-crops mostly become so forward before the dry weather occurs, that they are not injured by it, and the stock, where properly chosen, by the use of the fold or stall-feeding, with certainty becomes quickly fat. Every thing is in this mode daily regular, and the animals daily increase to the profit of their owners. Advantages are also afforded, in different ways, by the contiguity of markets, as in the sale of, and jobbing in neat cattle, horses, &c. and likewise in the strength of the teams that may be necessary.

It may be noticed, that, in these estimates, it is supposed that all the ploughing, sowing, and leading should be had and paid for. As the accounts are drawn out, they of course incline much in favour of the old plan of husbandry, as the expences are less in number than will be actually incurred in that way, being made for the purpose of exhibiting at one view the vast disparity which is really found to exist in the practice of the two different modes on farms of a similar description. That the profits can be ascertained with exactness is probably impossible, in consequence of the great fluctuation of markets, by which no person can be exact in the estimates of the value of corn or cattle for the space of six months together. The expences have, however, been constantly estimated at a higher rate than it is known they can be done for, that the old method of husbandry might not be supposed to be unfairly dealt with.

These estimates of profits, whether they rest upon the basis of experience or not, sufficiently point out, that vast benefits may be drawn from the culture of green and other cattle crops, and the conversion of them to the feeding and fattening of various kinds of domestic animals.

II. *A Mixed or Grazing, Breeding, and Tillage-Farm.*

Extent 314 Acres.—It is situated in the county of Lincoln.

The estimates here display the benefits of different modes of management, where several kinds of husbandry are carried on in combination.

At present part of the farm is divided into four divisions for the plough, each division consisting of twenty-four acres. And there is an additional division of the same land, comprising sixteen acres, and about fourteen acres of clay land, which is also under the plough. The four large divisions, and that of sixteen acres, are on a lime-stone soil, but the remainder on clay, and liable to rot sheep. These together make 126 acres, all under the plough on the old plan. There is of course remaining 188 acres, which are wholly in grass, and converted to the purpose of raising 140 lambs, or tuppings 140 ewes, the hog sheep being fold off in the spring, and the drapewees at Michaelmas, and the support-

HUSBANDRY.

ing of twelve horses and thirty head of beafts. The manner of cropping is that of the old method, of turnips, barley, clover, and wheat, which perhaps is as good as any, the farm being converted to the breeding of sheep, which is highly lucrative.

The expences and produce are thus stated.

Annual Mode of Husbandry, under the old System.

Profit	596	8	4	

This management is explained in this way.

100 Acres of grafs, three sheep to every two acres	150	sheep
10 Ditto, for feeding bealts, and a few tups	4	tups
72 ditto, for ploughing (in three plats) as before described: with		
24 Ditto, sown with graffes to keep sheep upon, five to an acre	120	sheep
	274	
84 Ditto clay soil, under rotation of crops		
16 Ditto of faintfoin for hay		
8 Ditto of meadow to cut green, for the purpose of foiling horses in the fold or stable:		
314 Acres.		

which is conceived the most beneficial mode of keeping them, and beyond comparison preferable to letting them run over the grafs, if it were only for the advantage of the manure, which is extremely valuable to the land.

It is hinted, that on such a farm, at least forty head of neat

HUSBANDRY.

neat cattle and horses should be kept, winter and summer, in the yards and stable, but twice that number might be had; which, by the use of the green food, would furnish a vast supply of good manure, far better than such as is raised in the usual way during the winter season. And by blending the straw with the green fodder, it may be eaten up with much more profit than in the usual way; while the stock are kept in far better condition.

It is believed that the evil of the land rotting sheep stock is remedied by the conversion of the eighty-four acres of clay land into tillage, and the custom of eating off the seeds, faintfoin, edish, &c. The horses may be foiled in the stalls and yards, to avoid the injury of poaching, and thereby most of them be kept up.

And as the stock of sheep is increased by seventy, provided the statement be accurate, in the place of felling the hog-sheep, they may be kept for wedders. However, if danger from rot be apprehended, the cattle stock may be augmented, and be probably as profitable; the old number of sheep (200) being only retained to clip; the seeds on the twenty-four acres, part of the ninety-six estimated to keep five sheep per acre, by being sown with grafs seeds, in the spring, being eaten by the proportion of four sheep to the acre: but suppose the number to be a hundred, as fifty of the last sheeder hogs, and the same quantity of shearing ewes, there only remain then a hundred sheep for one hundred acres of grafs-land, and of course there must be the means of keeping a number of beasts in addition, or of having some portion of the land under meadow.

And in the common custom of felling off the drupe-ewes by removing the lambs from them early in June, or the succeeding month, it is supposed the ewes may have sufficient time to become fat before the setting in of the winter, and be fold; and the sixteen acres of faintfoin-edish being supposed to insure a profit on the sheep greater than that usually obtained. Farther, that the lambs, by being put to the faintfoin, would be preserved sound, while the ewes were in a fattening state.

Farm consisting of Open Tillage-land.

Extent several Hundred Acres.—It is situated in the north-riding of Yorkshire, and managed on the old plan adopted in many parts of that district as the most beneficial.

The course of husbandry pursued is one fallow and two crops, in this way.

- 1st year, fallow, manured,
- 2d year, barley,
- 3d year, beans,
- 4th year, fallow,
- 5th year, wheat,
- 6th year, oats.

Profit of one acre of land for six years -	17	6	9

On these data it is concluded that under the old plan of management, the farmer obtains only 1l. 9s. 3d. profit per

acre from his land in six years, or 4s. 10½d. per acre per annum. And the expence of labour is said to be stated higher than it really is, or he could not support his family and pay his rent: while under the improved husbandry, in the same length of time, the profit is 17l. 6s. 9d. which is 2l. 17s. 9½d. per acre per annum, or more than 100 per cent. in its favour.

It is stated, that in this farm there is an open pasture, that is let at 2s. 6d. the acre, and the tenants consider it of no use to them: but under proper management, it is supposed, that 5l. per acre of profit might be annually derived from it. Of course, the tenant may well be surprised at being charged a new rent of 1l. 8s. the acre, though he now pays only 15s. and is supposed highly rented according to his plan of management.

It is estimated, that the loss sustained at this rate on two thousand acres, is 29,625l. in six years. If that number of acres were let at 1l. 8s. the acre yearly, there would be an advance of 13s. the acre, which would raise the sum of 7000l. more for the tenants to pay in six years. And that sum taken from 29,625l. would still leave them a profit of 21,825l.

Though these estimates may appear extraordinary to those not conversant with the business, they are founded in truth; and by pursuing proper courses, such profits as have been stated may be afforded to the landlord, as well as the tenant, independent of the benefit of green food during the summer. By a superiority of management in this way, the farmers in East Lothian are enabled to pay three or four pounds the acre. And if a person who lives by garden culture were to dig his ground one year in three, and that year raise no crop, he would be supposed a madman. Yet the two crops and a fallow are worse, as the land in this way is robbed of one-third of its manure. This may, indeed, be supposed to open the eyes of the landlord, but it is also much to the benefit of the tenant.

These facts and statements fully display the vast benefits and improvements that are capable of being derived from the adoption of improved modes of husbandry in all cases where they can be admitted; though such detailed statements must necessarily have regard, in some degree, to the peculiar situations and other circumstances of the farms and lands.

A Farm conducted under different Modes of Husbandry.

In the view of displaying more fully the benefits of different modes of managing land, comparative statements of the profits resulting from a farm of four hundred acres employed under different modes of husbandry, in different circumstances, are given:

- 1st. *In the grazing system.*
- 2d. *— the dairy practice.*
- 3d. *— the hay-felling custom.*
- 4th. *— the tillage plan, near a large town.*
- 5th. *— the tillage plan more distant'y situated.*
- 6th. *— the tillage plan with improved course of crops.*

Having noticed, that it is not rent that causes the poverty or riches of the farmer, but the difference in his mode of managing it, or the method of husbandry pursued, as a good plan of management improves land, especially under tillage in the most expeditious way of any; some estimates are given which clearly point out the great superiority of the tillage plan over any other that is had recourse to on the same ground in the way of a farm. In this case the rent is 50s. the acre, and the land sufficiently rich for affording profitable crops under judicious management.

HUSBANDRY.

I. Under the grazing System of Husbandry.

The extent of grazing land in this case is stated to be 300 acres, seventy in meadow, and thirty in tillage. The live stock on 200 acres, 150 oxen, bought in at 25*l.* per head, and fold off at 30*l.* each; and on the remaining 100 acres, 75 cows at 17*l.* each, 4 milch cows; 300 ewes bought in at 45*s.* each, and fold off at 70*s.* to breed lambs for market; and 3 tups, at 5*l.* each. The lambs produced 400. fold at 35*s.* each; the wool of the ewes 5*lb.* each fleece, and fold at 40*s.* the tod. Eight horses and six pigs.

These are thus stated:

Expences of stock, &c. (Account 1.)

	£.	s.	d.
Purchase of 150 oxen, at 25 <i>l.</i> each	3750	0	0

II. Under the Dairy Practice.

In this case the farm is supposed to be principally in the state of grass, and employed in dairying; in which there are 220 acres in pasture, 150 in meadow, and 30 in tillage. The cow stock allowing $1\frac{1}{2}$ acre to each, will be 140; with a bull or two, and six horses. The profit on cows, in calves, butter, and milk for the use of the hogs, 15l. each. The sheep flock, one ewe to the acre, on the pasture land, is 200 ewes bought in to breed lambs; the ewes and lambs to be made fat, and sold off, fresh stock being purchased annually; the produce in lambs will be 250, selling at 35s. each; and the ewes will cost 45s. each, which, when fat, will sell for 70s. each; their wool, at 5lb. each fleece, will make 35 tods of 20lb., selling at 40s. the tod. The cows, if bought in at three years old, will cost 17l. each, and after having three calves, sell for 20l. each: consequently in this way, there will be about thirty-five cows to be changed annually. One horse will also be to be sold yearly, and one bought in. The tillage part, the same as in the grazing farm; 10 acres of wheat, 10 acres of beans, and 10 acres in summer fallow. The whole of the statement is thus made out.

IV. Under Tillage near a large Town.

The farm in this instance consists of 264 acres of land in tillage, thirty-six in meadow, and the remainder in grazing ground. The stock is supposed to be 12 horses for market work, and six for the purposes of tillage. The 100 acres of

grazing land being stocked with oxen, at the rate of three to four acres; also six milch cows; and 100 ewes, one to the acre, to produce lambs; the produce about 125 lambs; consequently fresh stock will be yearly wanted. The oxen should be bought in, in the spring season at about 25*l.* a piece, being fold off at about 30*l.* The lambs, when fattened, will fetch about 35*s.* each. The ewes are purchased in at about 45*s.* each; and disposed of at about 75*s.* each, being fattened on rape or turnips, sown on the land from which the garden peas had been taken. And the hay from the thirty-six acres of meadow land can, it is supposed, from the situation of the farm, be sent to market with more profit than by consuming it; there being two loads to the acre; the eddish being eaten off by oxen and sheep stock.

Expences of Stock, &c. (Account 1.)

	£.	s.	d.

						37	8
Profit	341	5	0				

The expences of making the hay are noticed to be estimated at 10s. the acre only, as the quantity being only 36 acres, it may be done wholly by the farmer's family; but where the business is hired, 20s. are as little as can be charged.

That part of the farm which is under tillage may be managed in such a mode of cropping, as to produce 14 crops in the course of 11 years, somewhat in this way:—

Courses of Crops.

- 1st. Year, Potatoes manured for with 12 loads of dung per acre.
- 2d. — Wheat, limed with 30 bushels, mixed with earth, per acre.
- 3d. — Flax; rape being sown after it is off, for seed.
- 4th. — Rape for a crop, straw burnt after it is taken off, for wheat.
- 5th. — Wheat.
- 6th. — Garden peas drilled, and manured with four loads of dung per acre, and turnips afterwards; eight loads of dung per acre broad-cast, and drilled.
- 7th. — Barley sown with clover.
- 8th. — Clover, manured with six loads of compost per acre.
- 9th. — Wheat; limed with 30 bushels, mixed with earth, per acre.
- 10th. — Beans, manured with 12 loads of dung per acre, and hoed.
- 11th. — Oats.

V. Under the Tillage more distantly situated.

This is similar in all respects to the above, except in situation, which renders it necessary to confume the hay and straw upon the farm; consequently the statements demonstrate the variations in value of different situations. It is supposed, as above, that 264 acres of the land are in tillage; 36 in meadow, and the remaining 100 in pasture. The last portion, stocked as before with 70 oxen; ewes, one to the acre, 100; these are supposed to afford 125 lambs, which are to be sent to the market, and the ewes fattened on the rape after the peas. The profit on these articles is explained in

HUSBANDRY.

in account N^o 2; the oxen 5*l.* each profit; the lambs 35*s.* each; the ewes bought in at 45*s.* and sold off at 75*s.* being brought to the market in winter, when mutton is dear. Ten horses only, as fewer will answer, there being only the corn to take to market; but more oxen should be kept. Such as are bought in, in the summer, should be fed on straw in the winter; four or six being employed in carting dung, harvest-work, &c. More pig-stock may likewise be kept; fifty being put in the yards. And as the clover hay is here to be eaten, the oxen should have some in the spring in the yard, to forward them for fattening off in the pastures. Consequently there is no profit in the hay, only from the oxen. Six of the horses to be annually fold, and others bought in. The oxen should be bought in, as there may be room in the summer; 88 being provided annually, and fattened, so as to have fresh stock every season: 18 being fed out in winter, and 70 in the summer season.

Expences of Stock, &c. (Account 1.)

	£.	s.	d.
Purchase of 70 oxen, at 20 <i>l.</i> each, being bought in the summer, and wintered at straw	1400	0	0

Total	3469	9	3
Expence	2524	10	0
	945	19	3
Profit	945	19	3

By a trifling mistake in most of the above statements, the house-keeping and expences have been put into one of the separate accounts, instead of the general account, at the end of each farm; and in the same manner, the rent charged in account four, should have been brought into account 5; but these are of little consequence, as the sums of *total profit* must have been the same.

The tillage-land in this case is under the same courses as in the preceding farm.

(Account 3.)

Total profit	2737	15	4

It is shewn by these estimates, that the annual profit on one acre of land, under each of these different methods of husbandry, is in the following ratio :

	£.	s.	d.
On grazing farm - - - - -	0	6	6
— dairy-farm - - - - -	0	14	6
— hay-farm - - - - -	1	9	9
— tillage-farm, 1st situation - - - - -	8	17	10
— tillage-farm, 2d situation - - - - -	6	17	0

It is supposed, that in both the systems of management on the tillage-farm there are twelve horses employed for the purpose of market-work, and bringing in return such things as may be wanted ; and six of a lighter kind for the plough-teams, to be provided at less expence, and do more work in an equal portion of time.

And it is suggested, that by the improved manner of cropping employed there will never be more than twenty-four acres to manure at any one time, except at the wheat sowing season, and then even the quantity may be divided by that part of the land which has grown the potatoes being sown first, at the time they are taken up. By pulling up all the tops, and depositing them in the farm yards as litter, they, as well as the earth that is carried with them, will be restored to the land. The small potatoes should be used for the pigs. And by sowing the wheat immediately on the land cleared from the stems of the potatoes previous to their being ploughed up, an advantage is said to be derived. But from the danger of frost, no more of the tops should be removed at a time than can be ploughed up during the day.

In following this method, the next sowing of wheat will, it is supposed, be on the land that has grown rape for seed. It may likewise be sown first, where the potatoes are not ready to be taken up. And the third time of sowing wheat will be on the clover lay ; in which case there is plenty of time, as it may be done in winter, with nearly equal success, as from September to January. This, however, is not the case with spring crops, as all those of the grain kind should be got in as speedily as possible. But bean and pea crops may always be put in the soil a fortnight or three weeks previously to those of the corn kind ; and it is noticed, that where the land is all prepared, and the teams taken off for the purpose, there will be nine pair of horses, which will be capable of harrowing in the whole of these crops in three days. And the twenty-four acres of barley, and the twenty-four acres of wheat may be harrowed in the same space of time. This is considered as one of the great benefits of large teams, as such a great number being employed in carrying the produce, they are capable of being made use of for about twenty days in seed-time and harvest, and, of course, to earn nearly what they cost in keep in the whole of the year.

Other benefits are supposed to result from this scheme of cropping ; the harvest labour is more divided ; the flax and pea crops are ready in July, afterwards the oats, then the wheat, and lastly the beans. This, while it increases convenience, lessens expence. The rape may be threshed in the field, and sold early in August, furnishing money for the expences of the remaining harvest. Besides, there is hardly a month of the year, in which considerable returns of money are not coming in from one or other of the different operations. The flax may be sold on the ground to pull in July by the purchaser, which usually affords from seven to nine guineas the acre, which, though apparently a small sum in comparison with some other sorts of crops, is stated as paying well for the time it occupies the ground ; which is only about three months, being sown in April and pulled in July. By all these means the expences are diminished, and of course larger profits afforded. In short, these detailed accounts furnish the cultivator with the means of judging of the most advantageous modes of employing his land in the view of profit. They seem to prove three of the methods of farming to be very indifferent concerns, tillage husbandry having vastly the advantage over them ; and it is supposed that many further improvements are still to be made in it ; for which various hints are thrown out, and different calculations introduced.

It must constantly be kept in mind that, in all the different schemes of husbandry, the profits and benefits are to proceed, not only from the superiority of the management that may be employed, but the nature of the situation in regard to the facility and cheapness of stocking the land, and the ease of cultivating it ; as in some places the expences

HUSBANDRY.

of the former will not be more than from five to seven or eight pounds the acre; while, in others, it may be from ten to twelve or thirteen pounds the acre, as is the case in several parts of Essex; and consequently the expences in the same proportions, though the variations in the markets for the disposal of the produce may be but trifling.

It would be easy to introduce other calculations on arable, and farms of other kinds, where great improvements are to be effected by claying, chalking, marling, liming, &c.; but as they must invariably be regulated by the local nature of the different situations, they could be of but little utility in guiding the practice of the farmer.

It does not admit of a doubt, that husbandry has been greatly improved in most of its different branches within these few late years in this country. Far better modes of cropping land, and of combining the feeding of cattle stock with arable management, have been introduced and adopted. More appropriate, cheap, and convenient tools for various purposes of tillage and other practices of farming have been invented; and most of the processes and operations of the art rendered more simple and easily performed. Yet still, if those laws and regulations which repress the efforts of the cultivator were modified or removed; leases more generally and liberally granted, for moderate periods of time; and the dissemination of useful information on rural business carefully attended to, the state of cultivation would soon be advanced to a much higher degree of perfection than it has yet attained.

HUSBANDRY, *Broad-cast*. See BROAD-CAST.

HUSBANDRY, *Drill*, that sort in which the seed is deposited in small furrows, drills, or openings, in rows, at different distances, according to the nature and circumstances of the soils and the crops by suitable machinery, and in which the after-culture is performed by the use of the horse-hoe, or other tools of a similar kind. See *How*, *HOING*, and *MACHINE Drill*.

For the introduction and extension of this method of husbandry in this country, we are principally indebted to Mr. Tull and his followers, who, in promoting it, seem to have considered it as altogether *new*; but this would appear from the account which has lately been published in the first volume of Communications to the Board of Agriculture, by Mr. Halcott, not to be the case, as it has been found to be the general practice in the Innacondah district in the East Indies, in the cultivation of all sorts of grain, except those of the horse kind, as well as in the growth of hemp, tobacco, cotton, and even the castor oil plant. And it is asserted on good authority, that, in Arabia, China, and Japan, where the modes of husbandry have not undergone any material change for thousands of years, they not only drill, but dibble corn of every description. It is of course probable, that the drill method of husbandry is of considerable antiquity, and that it was brought to Europe from some of the eastern nations.

But though this method of husbandry obviously possesses many advantages over that which is generally employed by farmers, it is far from being in general use in this kingdom; the reason of which is supposed to proceed from the difficulty of making common labourers acquainted with the nature of the practice; the incorrectness of the machinery that is made use of in delivering the seed, and the expence which is necessary for the first undertaking of the business. Other causes have likewise a tendency to impede its advancement, such as the introduction of it on land that is not in a proper state of preparation for its reception, either in regard to quality or the nature of the tillage, and the

neglecting in some measure the after-culture of the crops, upon which so much of its success depends. The attempting too great savings in the quantity of seed employed, by sowing too thinly in the drills, as well as at too great distances between the rows, has also in many instances operated much against it.

The soils that are most proper for this sort of husbandry, are all those of the more light and friable kinds, which are not so strong, heavy, or wet, as to prevent the working of the machinery which is necessary in executing the business. It can scarcely ever be had recourse to with much advantage; except for particular sorts of crops, on the stiff, heavy, wet, clayey soils, as the work must constantly be liable to be performed in an incomplete manner; nor even in such as are of a very stony quality, as those obstructions will constantly be apt to derange the operations of the machines, and thereby render the sowing irregular and improper.

But whatever the nature or quality of the soil may be on which this sort of husbandry is attempted, it should constantly be brought into a fine state of tilth by repeated ploughing, and other modes of pulverization, before the crops are put into the ground.

In doing which it will also be necessary to suit them, and the proportion of seed to the nature and quality of the land, and the distance of the rows to their growths; as well as to preserve a continued attention to their after-culture while on the ground.

In the practice of this mode of culture different distances in the rows and intervals have been advised, as disadvantages must obviously proceed from their being either too narrow or too large; in the former little benefit being capable of being derived in the cultivation of the crops after they have been deposited in the soil; while in the latter there will be great loss sustained in the over quantity of land that is taken up. It is probable, that in regard to distances, as well as the modes of drilling, much must constantly depend on the state and quality of the land.

Upon dry light soils, whether of the loamy, gravelly, or chalky kinds, which can be constantly ploughed and preserved on the flat, as is the case in East Kent, narrow distances are supposed the most proper. But where ridging up is required, they should be somewhat wider. It was found by actual trials that drilling three rows eleven or twelve inches asunder, on three bout ridges, generally succeeded in a perfect manner. In this way, the three bouts constitute a ridge about four and a half feet in breadth; the three rows as just mentioned occupying two feet, and the horse-hoe going on the side of each outside row, at the distance of three inches, leaves the ridge two and a half feet broad, and the intervals between them nearly two feet. But it has been suggested, that, in these cases, as the outside rows constantly afford the strongest and most healthy plants, two rows only, on two-bout ridges, would be equally productive, and leave the ground in a better state of tilth. However this may be, the very wide intervals of the more early drill practice are to be discarded as highly improper in all crops of the grain kind, not only in consequence of the great loss of ground that must necessarily be sustained by such wide intervals; but because the spaces between the rows, when much narrower, can, in the improved mode of horse-hoeing, be stirred with equal correctness and facility.

In practicing this system of husbandry, it has been hinted by an experienced cultivator, that, with regard to wheat and barley, the distance of the rows should greatly depend on the quality of the soil. In cases where it is poor, the spaces between the rows should not be more than about

eight inches; where of a medium quality about nine inches, and where rich, not more than ten inches. The quantity of seed being made to vary in the same way, from about nine pecks to eight and seven. And the depth of depositing it from two inches and a half to two inches.

In the extensive experience of the late Mr. Close, nine inches was the distance that answered best for white corn crops. See SEMINATION, and SOWING of Grain.

But for various sorts of green crops, such as those of the potatoe, cabbage, rape, turnip, carrot, parsnip, bean, pea, tare, and other similar kinds, much wider distances are required, as is sufficiently shewn under the culture of these different descriptions of crops.

The great advantages of this method of husbandry, are those of its affording the means of distributing the seed with much greater correctness in regard to depth, as well as regularity in the rows, by which the growth of the crops is not only more uniform, but their after-culture capable of being more effectually executed, and at the same time some saving in seed effected. And as the seed grain in this way is neither too closely crowded together, nor too thinly scattered in the drills, there is less danger of injury in the weakness of the produce from the former cause, or of loss from the too scanty number of stems in the latter, which is almost constantly the case in the common mode of management. Besides, by the equality of the depth to which the seed is deposited in this way, the crops become ripe in a more equal and uniform manner. Further benefits are likewise derived in different ways, by the frequent stirring and breaking down of the mould about the roots and stems of the plants, while the crops are upon the ground. By such frequent turnings the soil becomes newly and fully aerated, in consequence of which different nutritious matters are more abundantly formed and provided for the support of the crops; and the earth at the same time rendered more easily penetrable by the superficial roots of the grain, and its power of tillering increased by the mould being laid up to the joints of the stems, just above the surface of the land. There are also other ways in which benefit is derived in this mode of cultivation; as by the more effectual eradication of weeds that constantly takes place, the harvesting of the crops is more readily and certainly accomplished, and at less trouble and expence; while the land is left in a more mellow and fine state for the production of future crops, as well as for the immediate putting in of succeeding ones. See HOEING.

HUSBANDRY, *Implements of*, the various sorts of tools that become necessary in the cultivation and management of land, as those of the tillage, dairy, and other kinds. See IMPLEMENTS of Husbandry.

HUSBANDRY, *Virgilian*, a term used by authors to express that sort of husbandry, the precepts of which are so beautifully delivered in Virgil's Georgics. The husbandry in England is Virgilian in general, as is seen by the method of paring and burning the surface, of raftering or cross-ploughing, and of the care in destroying weeds upon the same principle, and by much the same means. In those parts of England along the southern coast, where the Romans principally inhabited, not only the practice, but the expressions are in many respects the same with those of the ancient Romans, many of the terms used by the ploughmen being of Latin origin, and the same with those used by those people on the like occasions. And on a strict observation, more of Virgil's husbandry is at this time practised in England than in Italy itself. This change in the Italian husbandry is, however, much more to the credit of that people than the retaining the Virgilian scheme is to our's.

Tull, who has established a new method of husbandry, observes that it is upon the whole so contradictory to this old plan, that it may be called the anti-Virgilian husbandry; and adds, that no practice can be worse than the Virgilian.

HUSBRECE, in our *Old Writers*, an offence now called burglary.

The word is Saxon, from *hus*, a house, and *brice*, a breaking. Blount, in voc.

HUSBY, in *Geography*, a town of Sweden, in Dalecarlia; nine miles N. of Hedemora.

HUSCANS, in our *Old Writers*, a sort of boot or buskin made of coarse cloth, and worn over the stockings. We find them mentioned in the stat. 4 Edw. IV. cap. 7.

HUSET, in *Geography*, a town of Hungary; 24 miles E. of Munkacz.

HUSGABLE, HUSGABLUM, in our *Old Writers*, denotes house-rents, or some tax or tribute laid upon houses.

HUSHING, in *Mining*, is applied, in Cornwall, to a mode of discovering float and shoad tin, or alluvial collections of tin ore, by turning a strong stream of water successively over different parts of the surface, to wash away all the vegetable soil and loose earth. (William's Mineral Kingdom, vol. i. p. 313, 2d edit.) Around Merthyr Tydvil, and other places in South Wales, much of the iron ores are obtained by this destructive process, equally depriving the sides of hills of their soil, and covering valuable meadows with this earth and stones: many hundred acres of valuable meadows below Merthyr town have, within a few years past, been covered several feet deep with earth and stones, over which every flood of the river spreads and moves and disturbs it, so that the whole width of the valley is without vegetation, and presents a scene of devastation, nowhere else to be witnessed, but on the sand and beach of the flat shores of the ocean: already a strong wall has been found necessary to confine the stream and this torrent of earth from overwhelming the lower part of the town, which is increasingly in danger of the fate of Ostia on the Tiber, if this destructive mode of disposing of the rubbish from the iron-stone mines is suffered much longer to exist.

HUSK, among *Botanists*, the part which a flower grows out of. See GLUMA.

The husks or cups of the flowers of plants are not so much regarded with a view to their medicinal virtues as they deserve. Petiver, in the Philosophical Transactions, speaking of the virtues of the verticillate class of plants, among which are included the sage, rosemary, and the like, observes that it is an erroneous, though general opinion, that the flowers of these plants contain their principal virtues, for that the husks are the part in which it is lodged. For instance, in the rosemary, the fine scent of the Hungary-water is not in the flowers, but husks; and the flowers alone, when clean picked from them, yield very little odour. The cup, in this and other plants of the same class, is the only part in which their viscous and sulphureous qualities are lodged, and that something of this kind is deposited particularly there, may be perceived by the touch and smell; for they appear moist, and feel clammy; and this clammy matter, when received upon the fingers, is of a very strong and agreeable smell, much more so than the rest of the plant.

HUSK denotes a disease of young bullocks. See COUGH.

HUSKS, *Fossil*, in *Natural History*. The husks, shivers, juli or catkins, and other light parts of hazel, alder, willow, &c. are found in great quantities deep in the alluvial earth, and peat, of wide and flat valleys. Parkinson's Org. Rem. vol. i. p. 94.

HUSO GERMANORUM, in *Ichthyology*, the name of a large fish of the sturgeon or acipenser kind, without tubercles, caught in the Danube, Boristhenes, and other large rivers, and passing at times into the sea. It has a very long snout, and under it either four or eight beards; it has one back-fin, which is placed near the tail, and two pair under the belly; its general shape somewhat resembles that of the pike, and its back is black and its belly yellow; it has thirteen dorsal and forty-three caudal scales, and has cartilages instead of bones. It is caught in October and November, and in some places till January; and great numbers of them are usually brought to market together in those months in the countries where they are caught. They always swim in shoals. It grows to twenty-four feet long, and weighs one, two, three, or even four hundred pounds. The drug called isinglass, and the food called caviar, are prepared from this fish.

HUSS, JOHN, in *Biography*. See **HUSSITES**.

HUSSARS, HUSSARDS, or *Huffarts*, an order or species of soldiery in Poland and Hungary, commonly opposed to the Ottoman cavalry.

The hussars are horsemen, whose uniform is a large furred cap, adorned with a cock's feather; those of the officers with an eagle's or heron's; a very short waistcoat with breeches and stockings in one piece; short light boots; and a doublet, having five rows of buttons, which hangs loosely on the left shoulder. Their arms are, a long crooked sabre, light carbines, and pistols. Before they begin an attack, they lay themselves flat on the necks of their horses; but being come within pistol shot of the enemy, they raise themselves with such quickness, and fall on with such alertness, that it is very difficult for the troops they oppose to preserve their order. In a retreat no other cavalry can pretend to follow them; as they leap over ditches, and swim through rivers with a surprising facility. Most of the princes on the continent have troops under this name.

HUSSEIANABAD, in *Geography*, a town of Asiatic Turkey, in the government of Sivas; 42 miles S. W. of Amasieh.

HUSSEINGUNGE, a town of Hindoostan, in Rohilcund, on the Ganges; 26 miles W. S. W. of Budayoon.

HUSSES, a town of Arabia, in Yemen; seven miles E. of Sana.

HUSSEY, GILES, in *Biography*, a painter, born of a good family, in Dorsetshire. He was the pupil of Richardson in England, and afterwards of Damini and Ercole Lelli, in Italy, where, during a stay of some years at Rome and Bologna, he raised expectations which were grievously disappointed on his return. Disdaining portraiture, discountenanced in history, Hussey was reduced to the solitary patronage of the then duke of Northumberland, who offered to receive him into his family, and give him a handsome pension, with the attendance of a servant, upon the condition that he should employ his talents chiefly, though not exclusively, for the duke. This offer he rejected, because the duke did not comply with his request of keeping a priest in the house for him. Hussey, a bigot in religion, was attached to the creed of Rome; but had he not been so, commissions and patronage, almost confined to drawing copies, even from the antique, was certainly sufficiently provoking for a man of an original turn of mind to be rejected. He afterwards became exceedingly distressed for the means of living; but upon making his wants known to his brother, who had succeeded to the family estate, he was treated in the most kind manner; and, after his generous brother's decease, enjoyed himself the estate for some years, after which he disposed of it, and retired to Bealton, in Devonshire, where he died, in 1788, at the age of 71. He was a complete instance of the danger

of philosophizing too much upon art, which requires more practice and good sense than over-refined syllems of thinking. He spent the best part of his life in reducing, uselessly, the proportions of the human form, in all its various actions, to the musical scale of concords, and produced fanciful analogies which no painter, whose mind is capable of grasping the true beauties of art, will stay, or ought to stay, to consider. Thus he lost the time which should have been devoted to the practice of art, and when the hand and the imagination were required, both were found deficient. But he was an ingenious and highly respectable character.

HUSSINGABAD, in *Geography*, a town of Hindoostan, in the circar of Hindia, on the S. bank of the Nerbuddah river; 120 miles N. E. of Barhanpour. N. lat. 22° 42' 30". E. long. 77° 54'.

HUSSITES, in *Ecclesiastical History*, a party of reformers, the followers of John Hufs.

John Hufs, from whom the Hussites take their name, was born in a little village, called "Huffinez," in Bohemia, about the year 1376, and lived at Prague, in the university of which he was educated, in the highest reputation, both on account of the sanctity of his manners, and the purity of his doctrine. In the year 1396 he took the degree of M. A., and soon after that of B. D. In 1400 his abilities and piety had so far recommended him, that he was chosen confessor to the queen, and eight years after he was elected rector of the university. He was distinguished by his uncommon erudition and eloquence, and performed at the same time the functions of professor of divinity in the university, and of ordinary pastor in the church of that city. During the course of these honours he obtained a benefice amply endowed by John Mulheim, a person of large fortune at Prague. By the marriage of Ann, sister of the king of Bohemia, with Richard II. of England, in 1381, a communication and intercourse were opened between England and Bohemia; and a young Bohemian nobleman, who had finished his studies in the university of Prague, spent some time at Oxford; and on his return put into the hands of Hufs the writings of Wickliff. He adopted the sentiments of Wickliff, and the Waldenses; and in the year 1407 began openly to oppose and preach against divers errors in doctrine, as well as corruptions in point of discipline, then reigning in the church. Hufs likewise endeavoured to the utmost of his power to withdraw the university of Prague from the jurisdiction of Gregory XII., whom the kingdom of Bohemia had hitherto acknowledged as the true and lawful head of the church. This occasioned a violent quarrel between the incensed archbishop of Prague, who was an illiterate man, to such a degree that he was called "Alphabetarius," or the A B C doctor, and who, without sufficient authority from the pope, had committed the works of Wickliff to the flames; and the zealous reformer, which the latter inflamed and augmented, from day to day, by his pathetic exclamations against the court of Rome, and the corruptions that prevailed among the sacerdotal order. The archbishop, by his own authority, prohibited Hufs from preaching in his chapel of Bethlem, to which he had been appointed by Mulheim; upon which Hufs, as a member of the university, which held immediately of the Roman see, appealed to the pope.

There were other circumstances that contributed to inflame the resentment of the clergy against him. He adopted the philosophical opinions of the Realists, and vehemently opposed and even persecuted the Nominalists, whose number and influence were considerable in the university of Prague. He also multiplied the number of his enemies in the year 1408, by procuring, through his great credit, a sentence in favour of the Bohemians, who disputed with the Germans concerning the

HUSSITES.

number of suffrages which their respective nations were entitled to in all matters that were carried by election in this university. In consequence of a decree, obtained in favour of the former, which restored them to their constitutional right of three suffrages, usurped by the latter, the Germans withdrew from Prague, and in the year 1409, founded a new academy at Leipsick. This event no sooner happened than Hufs began to inveigh with greater freedom than he had before done against the vices and corruptions of the clergy, and to recommend, in a public manner, the writings and opinions of Wickliff, as far as they related to the papal hierarchy, the despotism of the court of Rome, and the corruption of the clergy. Hence an accusation was brought against him, in the year 1410, before the tribunal of John XXIII. by whom he was solemnly expelled from the communion of the church. Notwithstanding this sentence of excommunication, he proceeded to expose the Romish church with a fortitude and zeal that were almost universally applauded.

Some tumults having taken place among the followers of Hufs, in which he had no concern, and which, indeed, he lamented, and endeavoured to suppress, Winceflaus, king of Bohemia, banished him from Prague, upon which he retired to his native place, and lived there unmolested. During his retreat at Hussinez he composed his celebrated treatise "Upon the Church;" and here he also dated a paper entitled "The Six Errors;" which he fixed on the gates of the chapel at Bethelam. It was levelled against indulgences, the abuse of excommunication, believing in the pope, the unlimited obedience required by the see of Rome, simony, and making the body of Christ in the mass.

This eminent man, whose piety was equally sincere and fervent, though his zeal was perhaps too violent, and his prudence not always circumspect, was summoned to appear before the general council of Constance, convened in the year 1414; whither princes and prelates, clergy and laity, regulars and seculars, flocked together from all parts of Europe. Secured, as he apprehended, from the rage of his enemies by the safe conduct granted him by the emperor Sigismund, for his journey to Constance, his residence in that place, and his return to his own country; John Hufs obeyed the order of the council, and appeared before it, to demonstrate his innocence, and to prove that the charge of his having deserted the church of Rome was entirely groundless. However, his enemies so far prevailed, that, by the most scandalous breach of public faith, he was cast into prison, declared a heretic because he refused to plead guilty against the dictates of his conscience, in obedience to the council, and burnt alive July 6th, 1415; a punishment which he endured with unparalleled magnanimity and resignation.

We shall here subjoin some farther interesting particulars relating to the close of this eminent reformer's life. Whilst his fate was in suspense, his friends in Bohemia were sufficiently active; and at length a petition was sent through the kingdom, and subscribed by almost the whole body of the Bohemian nobility and gentry. It was dated in May, 1415, and was addressed to the council of Constance. The first petition, complaining of the treatment which he had received, soliciting that a speedy end might be put to his sufferings by allowing him an audience, having been disregarded, a second and a third were presented, urging his release, and offering any security for his appearance. The last petition to the council was accompanied by another to the emperor, pressing upon him a regard to his honour solemnly engaged for the security of Hufs, and imploring his protection and interest with the council. The emperor in this case was undoubtedly chargeable with a most notorious breach of faith;

though the blame is generally laid, and with some reasons, upon the council, who directed his conscience. Hufs was at length, after repeated delays, summoned to appear before the council; but as soon as he began to reply to the first charge, a most indecent and tumultuous clamour began; and the disorder and noise were so great that he could not proceed. "In this place," said Hufs, who was the most dispassionate of men, looking round him, "I hoped to have found a different treatment." His rebuke increased the clamour; and without attempting any further defence he held his peace. "He was now confounded," exclaimed the tumultuous assembly with seeming triumph, "silenced, by confession guilty." On the next day the council resumed its meeting, and the emperor Sigismund, disgusted and offended at its preceding conduct, determined to maintain a more decent behaviour. The first charge exhibited against Hufs was his denying the real presence. To which he had only to answer, that he had always held the true Catholic doctrine, which was a known fact among his friends, for he had ever believed transubstantiation. He was next charged in general with maintaining the pernicious errors of Wickliff. To which he answered, that he had never held any error which he knew to be such; and that he desired nothing more than to be convinced of any errors into which he might have inadvertently fallen. Wickliff's doctrine of tythes was objected to him, which he owned he knew not how to refute. He had also expressed himself against burning the books of Wickliff, and he acknowledged that he had spoken against burning them in the manner practised by the archbishop of Prague, who condemned them to the flames without examining them. He was further charged with saying, that he wished his soul in the same place where Wickliff's was. He owned having used this expression, which afforded matter of great mirth to his hearers. He was afterwards charged with sedition, in exciting the people to take arms against their sovereign, from which charge he entirely exculpated himself. After the discussion of some other trifling particulars the council rose, and Hufs was carried back to prison. In his way thither the emperor turned to him and told him, that he had given him his safe conduct, which he found was more than was well in his power, that he might have an opportunity to vindicate his character. "But, depend upon it," said he, "if you continue obstinate, I will make a fire with my own hands to burn you rather than you shall escape." To which address Hufs replied, that he could not charge himself with holding any opinions obstinately, that he came thither with joy rather than with reluctance; that if any doctrine better than his own could be laid before him in that learned assembly, he might see his error and embrace the truth. Upon again appearing before the council, not fewer than 40 articles were brought against him. Of these the chief were extracted from his books, and some of them by very unfair deduction.

The following opinions, among many others, which gave offence, were esteemed most criminal: "That there was no absolute necessity for a visible head of the church; that the church was better governed in apostolic times without one; that the title of holiness was improperly given to man; that a wicked pope could not possibly be the vicar of Christ, that he denied the very authority on which he pretended to act; that liberty of conscience was every one's natural right; that ecclesiastical censures, especially such as touched the life of man, had no foundation in scripture; that ecclesiastical obedience should have its limits; that no excommunication should deter the priest from his duty; that preaching was as much required from the minister of religion, as alms-giving from the man of ability; and that neither of them

HUSSITES.

them could hide his talent in the earth without incurring the divine displeasure." Paletz and the cardinal of Cambray were the chief managers of this examination.

Besides these opinions, most of which were proved and acknowledged, he threw out many things in the course of his examination which were eagerly laid hold on; particularly against the scandalous lives of the clergy of every denomination; the open simony practised among them, their luxury, lewdness, and ignorance.

Hufs having now been examined on all those articles, which the nicest scrutiny into his books, and the most exact remembrance of his words could furnish, the cardinal of Cambray thus accosted him: "Your guilt hath now been laid before this august assembly with its full force of evidence: I am obliged, therefore, to take upon me the disagreeable task of informing you, that only this alternative is offered to you: either to abjure these damnable errors, and submit yourself to the council; in which case these reverend fathers will deal as gently with you as possible, or to abide the severe consequence of an obstinate adherence to them." To this Hufs answered, "that he had nothing to say, but what he had often said before; that he came there not to defend any opinion obstinately; but with an earnest desire to see his errors and to amend them; that many opinions had been laid to his charge, some of which he had never maintained, and others, which he had maintained, were not yet confuted; that as in the first case, he thought it absurd to abjure opinions which were never his; so in the second, he was determined to subscribe nothing against his conscience."

The emperor told him, he saw no difficulty in his renouncing errors which he had never held. "For myself," said he, "I am, at this moment, ready to renounce every heresy that hath ever existed in the Christian church; does it therefore follow that I have been an heretic?"

Hufs respectfully made a distinction between abjuring errors in general, and abjuring errors which had been falsely imputed; and prayed the council to hear him upon those points which to them appeared erroneous; were it only to convince them that he had something to say for the opinions he maintained. To this request, however, the council paid no attention.

Here Paletz and De Cassis took an opportunity to exculpate themselves of any appearance of malice in this disagreeable prosecution. They both entered upon the task with great unwillingness, and had done nothing but what their duty required. To this the cardinal of Cambray added, that he could sufficiently exculpate them on that head. They had behaved, he said, with great humanity; and to his knowledge might have acted a much severer part.

The emperor observing, that every thing, which the cause would bear, had now been offered, arose from his seat, and thus addressed himself to the council:

"You have now heard, reverend fathers, an ample detail of heresies, not only proved, but confessed; each of which unquestionably, in my judgment, deserveth death. If, therefore, the heretic continueth obstinate in the maintenance of his opinions, he must certainly die. And if he should even abjure them, I should by no means think it proper to send him again into Bohemia; where new opportunities would give him new spirits, and raise a second commotion worse than the first. As to the fate, however, of this unhappy man, be that as it may hereafter be determined; at present, let me only add, that an authentic copy of the condemned articles should be sent into Bohemia, as a ground-work for

the clergy there to proceed on; that heresy may at length be rooted up, and peace restored to that distracted country."

The emperor having finished his speech, it was agreed in the council to allow Hufs a month longer to give in his final answer. With the utmost difficulty he had supported himself through this severe trial. Besides the malice of his enemies, he had upon him the paroxysm of a very violent disorder. On this last day he was scarcely able to walk, when he was led from the council. His consolation in these circumstances was a cold and hungry dungeon, into which he was inhumanly thrust.

His friend, the baron, attended him even hither, and with every instance of endearing tenderness, endeavoured to support him. The suffering martyr wrung his hand; and looking round the horrid scene, earnestly cried out, "Good God! this is friendship indeed!" His keepers soon after put him in irons; and none but such as were licensed by the council were allowed to see him.

The generous nature of Sigismund, though he was not unversed in the artifices of the cabinet, abhorred a practised fraud. The affair of Hufs, amidst all the casuistry of the council, gave him keen distress; and he wished for nothing more ardently than to rid his hands of it with honour. On the other side, his vanity and his interest engaged him to appear the defender of the Catholic cause in Germany. If he suffered Hufs to be put to death one part of the world would question his honour; if he interfered with a high hand in preserving him, the other part would question his religion. The perplexity was great; from which he thought nothing could relieve him but the recantation of Hufs.

To obtain this he tried every means in his power. He had already endeavoured to intimidate him with high language which he had used, both in the council and in other places. But this was ineffectual. He had now recourse to soothing arts. The form of a recantation was offered; in which Hufs was required only to renounce those heresies which had been fairly proved. But he continued still inflexible. Several deputations were afterwards sent to him in prison; and bishops, cardinals, and princes in vain tried their eloquence to persuade him.

Sigismund, seeing the conclusion to which this fatal affair was approaching, might probably have interested himself thus far, as thinking he had been too condescending to the council. The flame also, which he saw kindling in Bohemia, where he had high expectations, and was willing to preserve an interest, might alarm him greatly. He had gone too far, however, to recede, and knew not how to take Hufs out of the hands of the council, into which he had given him with so much zeal and devotion.

In the mean time Hufs remained master of his fate, and shewed a constancy which scarce any age hath excelled. He amused himself, while it was permitted, with writing letters to his friends, which were privately conveyed by the Bohemian lords who visited him in prison. Many of these letters are still extant. The following, which is the substance of one, of them, may be a test of that composed piety and rational frame of mind which supported him in all his sufferings.

"My dear friends, let me take this last opportunity of exhorting you to trust in nothing here, but to give yourselves up entirely to the service of God. Well am I authorized to warn you not to trust in princes, nor in any child of man, for there is no help in them. God only remaineth stedfast. What he promiseth, he will undoubtedly perform. For myself, on his gracious promise I rest. Having endeavoured to be his faithful servant, I fear not being deserted by him. Where I am, says the gracious Promiser, there shall my servant be. May the God of heaven preserve you!—This is

probably the last letter I shall be enabled to write. I have reason to believe I shall be called upon to-morrow to answer with my life. Sigismund hath in all things acted deceitfully. I pray God forgive him! You have heard in what severe language he hath spoken of me."

The month, which had been allowed by the council, being now expired, a deputation of four bishops came to receive his last answer, which was given in the same language as before.

The sixth of July was appointed for his condemnation, the scene of which was opened with extraordinary pomp. In the morning of that day, the bishops and temporal lords of the council, each in his robes, assembled in the great church at Constance. The emperor presided in a chair of state. When all were seated, Hufs was brought in by a guard. In the middle of the church a scaffold had been erected; near which a table was placed, covered with the vestments of a Romish priest.

After a sermon, in which the preacher earnestly exhorted his hearers to *cut off the man of sin*, the proceedings began. The articles alleged against him were read aloud; as well those, which he had, as those which he had not allowed. This treatment Hufs opposed greatly; and would gladly, for his character's sake, have made a distinction; but finding all endeavours of this kind ineffectual, and being indeed plainly told by the cardinal of Cambrai, that no farther opportunity of answering for himself should be allowed, he desisted; and falling on his knees, in a pathetic ejaculation, commended his cause to Christ.

The articles against him, as form required, having been recited, the sentence of his condemnation was read. The instrument is tedious: in substance it runs, "That John Hufs, being a disciple of Wickliff, of damnable memory, whose life he had defended, and whose doctrines he had maintained, is adjudged by the council of Constance (his tenets having been first condemned) to be an obstinate heretic; and as such, to be degraded from the office of a priest; and cut off from the holy church."

His sentence having being thus pronounced, he was ordered to put on the priest's vestments, and ascend the scaffold, according to form, where he might speak to the people; and, it was hoped, might still have the grace to retract his errors. But Hufs contented himself with saying once more, that he knew of no errors which he had to retract; that none had been proved upon him; and that he would not injure the doctrine he had taught, nor the consciences of those who had heard him, by ascribing to himself errors, of which he had never been convinced.

When he came down from the scaffold, he was received by seven bishops, who were commissioned to degrade him. The ceremonies of this business exhibited a very unchristian scene. The bishops, forming a circle round him, each adding a curse took off a part of his attire. When they had thus stripped him of his sacerdotal vestments, they proceeded to erase his tonsure, which they did by clipping it into the form of a cross. Some writers say, that in doing this, they even tore and mangled his head; but such stories are unquestionably the exaggeration of Protestant zeal. Their last act was to adorn him with a large paper cap; on which various and horrid forms of devils were painted. This cap one of the bishops put upon his head, with this unchristian speech, "Hereby we commit thy soul to the devil." Hufs smiling, observed, "It was less painful than a crown of thorns."

The ceremony of his degradation being thus over, the bishops presented him to the emperor. They had now done, they told him, all the church allowed. What remained was of civil authority. Sigismund ordered the duke of Bavaria to receive him, who immediately gave him into the

hands of an officer. This person had orders to see him burned, with every thing he had about him.

At the gate of the church a guard of 800 men waited to conduct him to the place of execution. He was carried first to the gate of the episcopal palace, where a pile of wood being kindled, his books were burned before his face. Hufs smiled at the indignity.

When he came to the stake, he was allowed some time for devotion; which he performed in so animated a manner, that many of the spectators, who came there sufficiently prejudiced against him, cried out, "What this man hath said within doors we know not, but surely he prayeth like a Christian."

As he was preparing for the stake, he was asked whether he chose a confessor? He answered in the affirmative; and a priest was called. The design was to draw from him a retraction, without which, the priest said, he durst not confess him. "If that be your resolution, said Hufs, I must die without confession: I trust in God, I have no mortal sin to answer for."

He was then tied to the stake with wet cords, and fastened by a chain round his body. As the executioners were beginning to pile the faggots around him, a voice from the croud was heard, "Turn him from the east; turn him from the east." It seemed like a voice from heaven. They who conducted the execution, struck at once with the impropriety, or rather profaneness of what they had done, gave immediate orders to have him turned due west.

Before fire was brought, the duke of Bavaria rode up, and exhorted him once more to retract his errors. But he still continued firm. "I have no errors," said he, "to retract; I endeavoured to preach Christ with apostolic plainness; and I am now prepared to seal my doctrine with my blood."

The faggots being lighted, he recommended himself into the hands of God, and began a hymn, which he continued singing, till the wind drove the flame and smoke into his face. For some time he was invisible. When the rage of the fire abated, his body, half consumed, appeared hanging over the chain; which, together with the post, were thrown down, and a new pile heaped over them. The malice of his enemies pursued his very remains. His ashes were gathered up and scattered in the Rhine, that the very earth might not feel the load of such enormous guilt.

From this view of the life and sufferings of Hufs, it is hard to say what were the real grounds of the animosity he had raised. His creed unquestionably was far from being exactly orthodox; yet it is plain how very ill able his adversaries were to gather from it offensive matter enough for an accusation. He believed transubstantiation; he allowed the adoration of saints; he practised confession; he spoke cautiously of tradition, and reverently of the seven sacraments; and whatever latitude he might give himself on any of these articles, it was not more than had been often taken, inoffensively taken, by Gerson, Zabarelle, and other spirited divines of the Romish church.

Besides, the great pains the council took to avoid a public question, and the great confidence with which Hufs desired one, are presumptions very strong in his favour.

It is the opinion of Lenfant, that the great cause of his condemnation was his introducing Wickliff's doctrine into Bohemia; and chiefly perhaps that offensive part of it which struck at the temporalities of the clergy. And, indeed, this is extremely probable from the whole conduct of the council; for though it is apparent, that he never adopted the entire system of that reformer; yet his principles, it is certain, would have led him much farther than they had hitherto

done; and the fathers of the council being aware of this, seem to have determined, though at the expence of justice, to crush an evil in its origin, which appeared teeming with so much mischief.

Besides this, there seems to have been another cause for that unabated prejudice which ran so high against him. The warmth with which he treated the corruptions of the clergy, and the usurpations of the church of Rome, was a crime never to be forgiven by the ecclesiastics of these times; and added the keenest edge to their resentment. But as this was an unpopular cause to appear in, it is plain they wanted to have it believed their resentment arose upon another account. This seems to have been the foundation of a speech, attributed by Varillas to cardinal Perron; "My learned friends," (he would say) "you cannot employ your time worse than in giving the world any account of the affairs of Hufs."

His life, however, was the severest satire upon the clergy. It was a mirror which reflected their distorted features. In him they saw the true ecclesiastic and the real Christian, characters so different from their own. Gentle and condescending to the opinions of others, this amiable pattern of virtue was strict only in his own principles. The opinions indeed of men were less his concern than their practice. His great contest was with vice; and he treated the ministers of religion with freedom, only as he thought their example encouraged, rather than checked, that licence which prevailed. The great lines in his character were piety and fortitude. His piety was calm, rational, and manly; his fortitude nothing human could daunt. The former was free from enthusiasm; the latter from weakness. He was in every respect an apostolical man. "From his infancy," (says the university of Prague in a voluntary testimonial,) he was of such excellent morals, that during his stay here, we may venture to challenge any one to produce a single fault against him.

As to his parts and acquirements, he seems to have been above mediocrity; and yet not in the highest form in respect of either. A vein of good sense runs through all his writings, but their distinguishing characteristics are simplicity and piety.

To preserve the memory of this excellent man, the sixth of July was, for many years, held sacred among the Bohemians. A service, adapted to the day, was appointed to be read in all churches; and instead of a sermon, an oration was spoken in commendation of their martyr, in which the noble stand he made against ecclesiastical tyranny was commemorated, and his example proposed as a pattern to all Christians.

In some places large fires were lighted in the evening upon the mountains, to preserve the memory of his sufferings; round which the country-people would assemble, and sing hymns in his praise.

A very remarkable medal was struck in honour of him, on which was represented his effigies, with this inscription, CENTUM REVOLUTIS ANNIS DEO RESPONDEBITIS ET MIHI. These words are said to have been spoken by him to his adversaries a little before his execution; and were afterwards applied by the zealots of his sect as prophetic of Luther, who lived about an hundred years after him. The story carries with it an air of irrational zeal, and seems calculated only for the credulous.

The same unhappy fate was borne by Jerome of Prague, his intimate companion, who attended the council, in order to support his persecuted friend. Jerome, indeed, was terrified into temporary submission; but he afterwards resumed his fortitude, and maintained the opinions, which he had for

a while deserted through fear, in the flames, in which he expired the 30th of May, 1416. See JEROME.

The disciples of Hufs adhered to their master's doctrine after his death with a zeal which broke out into an open war, that was carried on with the most savage and unparalleled barbarity. John Ziska, a Bohemian knight, in 1420, put himself at the head of the Hussites, who were now become a very considerable party, and threw off the despotic yoke of Sigismund, who had treated their brethren in the most barbarous manner. Ziska was succeeded by Procopius, in the year 1424. The acts of barbarity that were committed on both sides were shocking and horrible, beyond expression; for notwithstanding the irreconcilable opposition between the religious sentiments of the contending parties, they both agreed in this one horrible principle, that it was innocent and lawful to persecute and extirpate with fire and sword the enemies of the true religion; and such they reciprocally appeared to each other. These commotions in a great measure subsided by the interference of the council of Basil, in the year 1433.

The Hussites, who were divided into two parties, viz. the Calixtines and Taborites, spread over all Bohemia and Hungary, and even Silesia and Poland; and there are some remains of them still subsisting in all those parts. Mosheim's Eccl. Hist. vol. iii. p. 406—412, 446—448, &c. Eng. ed. 8vo. 1790. Gilpin's Lives.—Life of John Hufs.

HUSSUNABAD, in *Geography*, a town of Bengal; 15 miles W. of Dacca.

HUSSUN-ABDAL, a town of Hindoostan, in Lahore, 130 miles N. W. of Lahore. N. lat. 33°. E. long. 71° 45'.

HUSTINGS. See *COURT of Hustings*.

HUSUM, in *Geography*, a sea-port town of Denmark, on the W. coast of the duchy of Sleswick, constituted a city in the year 1608, formerly famous for exporting great quantities of malt. It was also famous for the oyster trade. The chief commerce at present consists in beer, cattle, and horses; 18 miles W. of Sleswick. N. lat. 54° 32'. E. long. 9° 6'.

HUSWA, a town of Hindoostan; 20 miles N.W. of Allhabad.

HUT, or HUTT, from the Saxon *hutte*, a small cottage or hovel.

The word is also used for the soldiers' lodges in the field; otherwise called barracks or caserns.

HUT, in *Rural Economy*, the common name of a low sort of building of the cottage kind generally constructed of an earthy sort of material, such as strong loamy clay, &c. A number of huts of this description have within these few years been built on the borders of the South Esk river in Scotland, which have a very neat and rural appearance, affording the idea, at a distance, of their being formed of a kind of brown brick-work.

In this case the composition of the materials which are employed is a sort of muddy clay blended with the roots of plants of the aquatic kind, which are dug from out of the flood mark of the river, in such sizes and shapes as may be suitable for the purpose that is intended. The pieces or peats, as they are there called, are generally cut out in the form of bricks, but somewhat larger, being prepared in every respect in the manner of peat-fuel. It is usual, in some cases, to build these huts with lime-mortar, but more commonly with clay only.

These huts are usually preferred by the cottagers to those which are built of stone, being warmer, and not much less durable.

It seems not improbable but that a similar sort of material for building this sort of cottages may be met with in many situations

situations where it has not yet been discovered, and be made use of in this way as well as for fences of the wall kind. See COTTAGE.

HUTA, a town of Lithuania, in the palatinate of Novogrodek; 40 miles E.N.E. of Novogrodek.

HUTCH, among *Farmers*, denotes a vessel or particular place in which to lay corn; also, a kind of hollow trap for the taking of weasels or other vermin alive; and it also signifies a sort of case, formed of boards and slips of wood, opening in front, and divided within for keeping and breeding rabbits.

HUTCHESON, FRANCIS, in *Biography*, an elegant writer and ingenious philosopher, son of a dissenting minister in the north of Ireland, was born on the eighth of August, 1694. After receiving a proper education at a grammar school, he was sent to an academy to begin his philosophical course. In 1710 he was entered a student at the university of Glasgow, in Scotland, where he renewed his application to the study of the languages, but chiefly devoted himself to the divinity course. After spending six years in the university of Glasgow, he returned to his native country, and undertook the care of an academy at Dublin. Scarcely had he fixed himself in that city, when his accomplishments and talents attracted the general notice of persons of all ranks who had any taste for literature. Lord viscount Moleworth took much delight in his conversation, and is said to have assisted him with his criticisms and observations upon his "Enquiry into the Ideas of Beauty and Virtue," before it was committed to the press. He received a similar favour from Dr. Syngé, lord bishop of Elphin, with whom he lived in habits of great friendship. The first edition of this work made its appearance anonymously, but its great merit did not suffer the author to remain long concealed. Lord Granville, the lord lieutenant, sent his secretary to enquire at the booksellers for the author, and when he could not learn his name, he left a letter to be conveyed to him, in consequence of which he soon became acquainted with his excellency, and was ever after treated by him with distinguished marks of familiarity and esteem. From this time his acquaintance began to be still more courted by men of distinction, either for station or literature; among these was the celebrated archbishop King, who screened him from two attempts made to prosecute him, for venturing to take upon himself the education of youth without having first subscribed the ecclesiastical canons. In the year 1728, Mr. Hutcheson published "A Treatise on the Passions." Having conducted his private academy in Dublin for several years with reputation and success, he was invited into Scotland in 1729, to fill the chair of professor of philosophy in the university of Glasgow. Here he spent the remainder of his life, in a manner highly honourable to himself and useful to the university of which he was a member. About this time the degree of doctor of laws was conferred upon him. At Glasgow his time was divided between his studies and the duties of his office. He was in every respect a valuable member of the university, his abilities qualifying him, and his zeal prompting him, on all occasions, to promote its civil and literary interests. His constitution seemed to promise his friends a long enjoyment of his valuable life, but a sudden attack terminated it in 1747, in the 53d year of his age. His posthumous work, published from the original MS. of his father, a "System of Moral Philosophy," in 2 vols. 4to. In this work the author endeavours to unfold the principles of the human mind, as united in a moral constitution, and from thence to point out the origin of our ideas of moral good and evil, and of our sense of duty, or moral obligation; he next enquires what must be the supreme happiness of a spe-

cies constituted as mankind are, after which he deduces the particular laws of nature, or rules necessary to be observed for promoting the general good in our common intercourse with one another as members of society. Dr. Hutcheson was of that class of philosophers, who deduce all moral ideas from what they call a moral sense, implanted in our natures, or an instinct like that of self preservation, which, independently of any arguments taken from the reasonableness and advantages of any action, leads us to perform it ourselves, or to approve it when performed by others. This moral sense they maintain to be the very foundation of virtue. Dr. Hutcheson was a man of considerable and various learning. He was not only acquainted with those subjects most intimately acquainted with his profession, but was a good mathematician and natural philosopher; and was desirous of applying all his knowledge to the grand purpose of establishing the truths of the existence, the perfections and government of God.

HUTCHINS, JOHN, was born in 1698, at Bradford-Peverell, in Dorsetshire, and educated at Baliol-college, Oxford, for the church. He took orders, and was presented successively to different livings, the last of which was the rectory of the church of the Holy Trinity, at Wareham. He died in June 1773. He was author of the History and Antiquities of the County of Dorset, which he was nearly forty years in compiling, and which, though he lived to see it put to press, was not published till 1774, when it was given to the world for the benefit of his widow and children. It was comprized in two volumes folio, and is adorned with many plates contributed by the patrons of the work.

HUTCHINSONIANS in *Ecclesiastical History*, a kind of cabalistic sect, that sprung up in this country towards the beginning of the last century, and that derived its name from John Hutchinson, who was born in Yorkshire, A. D. 1674. Having been educated in his father's house, with a view to the office of steward to some gentleman or nobleman, he was advanced at an early period of life to this station in the service of the duke of Somerset; and his business calling him to London about the year 1700, he became acquainted with Dr. Woodward, who employed him in making that large and noble collection of fossils, &c. which the doctor bequeathed to the university of Cambridge. Mr. Hutchinson, being desirous of prosecuting his literary studies, begged leave to quit the service of the duke, who appointed him his riding-purveyor, with a fixed salary of 200*l.* per annum; and this place he enjoyed till his death in 1737. In 1724 he published the first part of his *Moses's Principia*, in which he ridiculed Dr. Woodward's Natural History of the Earth, and his account of the settlement of the several strata, shells, and nodules, by the law of gravity; attempting also, with no small degree of presumption, to refute and explode Newton's theory of gravitation; and from this time to his death he continued publishing a volume every year, or every other year; which, with the manuscripts left behind, were published in 1748, in twelve volumes octavo, by the Rev. Julius Bate, a strenuous advocate for his doctrine: an abstract of his works was also published in 1752. In 1712, Mr. Hutchinson completed a machine of the watch kind for the discovery of the longitude at sea, which is said to have been so contrived, that the spring, wheels, and pivots, &c. were not in any considerable degree influenced by heat, cold, moisture, and drought, and to be capable of that degree of exactness which is requisite for the purpose. Having obtained the testimonials of Newton, and some others to whom it was referred for examination, expressing their opinion of its excellence and utility, application was made for a parliamentary reward, but the author, exasperated at his disappointment,

relinquished his pursuits of this kind, and destroyed at his papers. In 1727 he published the second part of Moses's Principia, containing the principles, as he apprehends, of the scripture philosophy; which are, a plenum, and the air. The air he supposes to exist in three conditions, *viz.* fire, light and spirit; the two latter are the finer and grosser parts of the air in motion; from the earth to the sun, the air is finer and finer, till it becomes pure light near the confines of the sun, and fire in the orb of the sun, or solar focus. From the earth, towards the circumference of this system, in which he includes the fixed stars, the air becomes grosser and grosser, till it becomes torpid and stagnant, in which condition it is at the utmost verge of this system; from whence, he says, the expression of "outer darkness, and blackness of darkness," used in the New Testament, seems to be taken. The sun, which he places in the centre, is the active vivifying agent, which, by melting the spirit or grosser parts of the air into atoms or finer parts, or æther, sets the machine forward and keeps it a-going; for the light is pressed out by the influx of spirit, and the spirit is pressed in by the efflux of light; and thus the whole matter of the heavens or air is perpetually changing conditions and circulating. In the introduction to this work, Mr. Hutchinson suggested, that the idea of the Trinity was to be taken from the three grand agents in the system of nature, fire, light, and spirit; which are three conditions of one and the same substance, and wonderfully answer in a typical or symbolical manner to the three persons of one and the same, essence. He also discovers the doctrine in the term *cherubim*, which is derived from *כרוב*, *sicut*, denoting *similitude* or *resemblance*, and *רביים*, plural of *רבי*, a *great* or *mighty one*; and so the cherubim, *i. e.* the similitude of the great ones, were represented by a bull the chief of the tame animals, the lion the chief of the wild, and the eagle of the winged; and these were again figures of the celestial cherubim, or fire, light, and spirit. The bodies of these three animals were all joined in one, in order to signify the unity of the essence, and the distinction of the persons, and man taken into the essence by his personal union with the second person, whose constant emblem was the lion; and Mr. Hutchinson contends, that the very name of the figure was an hieroglyphical representation of the Trinity. The same doctrine is also taught by the word *שמיים*, translated *heavens*; but which the Hutchinsonians suppose to signify *names*, being, as they say, the plural of *שם*, a *name*; and the heavens, according to them, are called names; because the material heaven, having in its one substance three conditions of fire, light, and spirit, is the proper name or representation of the Deity in its unity of essence, and trinity of persons; or of the *אלהים*, *Elohim*, or *Alim*, which they derive from *אל*, *alah*, an *oath*, or *conditional imprecation*, and therefore, must signify persons that have bound themselves by an indispensable obligation; hereby intimating that the three persons of the Godhead have absolutely covenanted together to redeem man. On this account the singular Jehovah, *g. d.* the essence-existing, is so commonly found in conjunction with the plural *Alim*, *i. e.* the *confederates* or *adjurators*. They derive *אלהים*, *Eleah*, also from the same root, and translate it the *accursed one*, referring to Christ, who was really made a curse for us. The word *ברית*, which we translate *covenant*, they derive from *ברר*, *to purify*, and render *purifier*; and thus *ברית*, which is commonly rendered to *make a covenant*, they translate *to cut off the purifier*. In this way Mr. Hutchinson and his followers have founded their whole system of theology and philosophy on a forced and fanciful etymology of Hebrew words; indulging their minds in all the wildness of imagination and unbounded whim, making

words signify what they please, turning the plainest history into sublime prophecy; and constraining sentences to be circular in various ways, and meanings which they were never designed to bear, and which they are incapable of bearing. The scriptures, according to this author, written in Hebrew without points, which is the language framed in Paradise, and each root of which represents some obvious idea of action or condition, raised by the sensible object which it expresses, and farther designed to signify spiritual or mental things; the Hebrew scriptures, he says, rightly translated and understood, comprise a perfect system of natural philosophy, theology, and religion. Mr. Hutchinson expressly says, that as God was primarily represented by the heavens, so emblems or draughts of these, or descriptions in Hebrew words, were no more than copies of the archetype; and thus the knowledge of the *Alim* is derived from the light of nature, not as that phrase is vulgarly understood, by any innate or inbred power in man, but by the immediate instruction of the Most High, the alone Interpreter as well the Lord of nature. The Greek, he says, that language of erring heathens, became of necessary use to the apostles, to spread the history of facts, which it behoved all men to be apprized of; but Christ and his disciples knew too well its imperfection and unfitness to give just ideas of the divine economy to make use of it for that purpose. The original scriptures in Hebrew were distinct permanent evidence; to these references are always made, and there complete satisfaction is to be found. He also observes, that as the material machine is primarily suited to the service of the body, so its secondary, but most important use, is to treasure up ideas for the immortal soul, by affording types and evidences of the otherwise unutterable attributes of the Deity. Hence it must follow, that the language of scripture, which is admirably adapted to convey true and literal descriptions, will also in many places require an emblematical or spiritual interpretation, corresponding to the circumstances of that creature who has a *soul* of *lives* to provide for. The Hutchinsonians not only erect their fanciful system of theological and philosophical opinions on the construction of roots and symbols, to the ruin of natural religion and morality, but they loudly declaim against human learning and reason; and they expressly call abstract reasoning the very province of the devil.

The reader may find a distinct and comprehensive account of the Hutchinsonian system in a book, entitled "Thoughts concerning Religion, &c." printed at Edinburgh, 1743; and in a Letter to a Bishop, annexed to it, first printed in 1732.

It is not improbable that Mr. Hutchinson's death was hastened by too intense an application to his studies; for neglecting his usual summer excursion in 1737, in order to complete a work which he was preparing for the press, he became unable to resist the attack of a bilious fever, to which he fell a sacrifice. notwithstanding the advice of sir Edward Wilmot and Dr. Mead, in the 63d year of his age. His judgment seems to have been much inferior to his learning, and his temper appears from the tenor of some of his publications to have been irritable and dogmatical.

HUTKA, in *Geography*, a town of Hungary; 12 miles S. S. E. of Caschau.

HUTOW, a town of Lithuania, in the palatinate of Brzesc; 28 miles W. S. W. of Pinsk.

HUTTANY, a town of Hindoostan, in the country of Viliapour; 30 miles S. S. W. of Viliapour. N. lat. 17° 5'. E. long. 75° 6'.

HUTTEN, ULRIC DE, in *Biography*, one of the early reformers, was the son of a Franconian gentleman, and was born.

born in 1488. He studied at the university of Frankfort on the Oder, where he took the degree of M. A. Being destitute of patrimony, he entered into the army of the emperor in Italy, and was at the siege of Parma. He afterwards maintained himself by teaching at Roitock, and made himself known by some publications. At the command of his father he attempted to study the law, but finding the profession ill accord with his temper, he enlisted in the army again and served in Italy. He was a man of great courage, and in 1515, learning that his cousin John Hutten, marshal to the court of the duke of Wirtemberg, had been killed by that prince, he drew his pen in his kinsman's cause, and published some very severe harangues against the duke, which have been compared for eloquence and bitterness to Cicero's Catilinarian orations. After attacking the duke with his pen, he employed his arms against him in a war which drove him from his dominions. Having become a proselyte to the opinions of Luther, he published the bull of pope Leo X. against that reformer, with marginal remarks, in which he treated the holy pontiff with so little respect, that orders were transmitted from Rome to the elector of Mentz to send Hutten thither in fetters. He was on this occasion obliged to quit Mentz, but such was the vigour of his spirit, that he wrote a letter to the elector in which was the following passage: "If you burn my books, I will burn your towns." He afterwards wandered from place to place, and was at Basil in 1523, where the senate made him a considerable present. He received, however, the mortification of having his visit refused by Erasmus, then residing in that city. Hutten was indignant at this treatment, and wrote a book against Erasmus, which that learned man answered. Some farther quarrels drove him from Basil, and he took refuge in the isle of Uffnau, in the lake of Zurich, where he died in 1523, in the 36th year of his age. He was considered as a man of learning, and published various Latin works in prose and verse. He edited two new books of Livy, and discovered some MSS. of Pliny, Quintilian, and Marcellinus. Moreri.

HUTTER, ELIAS, was born at Ulric in 1553, and died at Nuremberg about the year 1603. He published an edition of the Hebrew Bible, entitled "Via Sancta, five Biblia sacra Hebræa Veteris Testamenti." At the end is given the 119th Psalm in thirty different languages. He also published two polyglots of the Bible; one at Hamburg in 1596, in Hebrew, Greek, Latin, and German; and the other at Nuremberg in 1599; and in the following year he published a polyglot of the New Testament in twelve languages. Bayle.

HUTTING of GRAIN, the name of a practice employed in some places in the northern part of the kingdom, for preserving the corn in wet bad harvest-seasons. See HARVESTING.

HUTTWEIL, in *Geography*, a town of Switzerland, in the canton of Berne, on the frontiers of Lucerne; 22 miles N.W. of Lucerne.

HUTTYBARRY, a town of Bengal; 45 miles S. E. of Nattore.

HUXHAM, JOHN, in *Biography*, a physician of considerable reputation, who practised his profession at Plymouth, where he died in the year 1768. It is remarkable, that no biographical memoirs of this able and learned practitioner are extant. His writings display a most intimate acquaintance with the writings of the ancients, and a great veneration for those of Hippocrates in particular; and he quotes the ancient languages, and writes the Latin with great fluency and familiarity. He appears to have spent his life at Plymouth in the active exercise of his profession; for he kept

a register of the state of health and reigning diseases at that place, together with an account of the variety of the seasons, for nearly 30 years (namely, from the year 1724 to 1752 inclusive); which were published in Latin, under the title of "Observationes de Aëre et Morbis Epidemicis, &c." in 3 vols. 8vo. The first of these volumes commences with an account of the year 1728; but in the dedication to sir Hans Sloane, he refers to an account of the constitution and diseases of the seasons, from 1724 to 1727 already published. The third volume was edited in 1770, after the death of the author, by his son, J. Cor. Huxham, A.M. F.R.S.; who, it is to be regretted, did not insert any memoirs of his father's life.

Dr. Huxham was, at an early period, elected a member of the Royal Society, and communicated several papers on the subjects of pathology and morbid anatomy, which were published in the Philosophical Transactions. But the work upon which his reputation principally rests, is his "Essay on Fevers," published about the year 1739, of which a fifth edition appeared the year before his death, containing also "A Dissertation on the Malignant, Ulcerous Sore Throat." His accuracy and acuteness, as an observer of the phenomena of disease, were particularly exemplified in his discriminative history of the "Slow Nervous Fever;" to which his name is often annexed, when this fever is mentioned by succeeding authors. His theory was the ancient humoral pathology, which much influenced his practice; but that was the general fault of the age. He was the author of some "Observations on Antimony," 4to. 1756; and was elected a fellow of the Royal College of Physicians at Edinburgh. He has given few prescriptions in his works; for he observes, with Hippocrates, that the physician, who knows a disease, cannot be at a loss in respect to the form of his remedy; but, having mentioned a favourite formula for the preparation of a tincture of the Peruvian bark, in his Essay on Fevers, in which the bitter is corrected by aromatics, his name has become attached to the tincture of bark, which is commonly prepared in the shops according to his prescription, which is also adopted in the Pharmacopœia of the College of Physicians. See the works of Huxham.

HUXING of PINK, among *Fishermen*, a particular method of catching that fish.

For this purpose, they take thirty or forty as large bladders as can be got; blow them up, and tie them close and strong; and at the mouth of each tie a line, longer or shorter, according to the depth of the water. At the end of the line is fastened an armed hook, artfully baited; and thus they are put into water with the advantage of the wind, that they may gently move up and down the pond. When a master pike has struck himself, it affords great entertainment to see him bounce about in the water with a bladder fastened to him; at last, when they perceive him almost spent, they take him up.

HUY, in *Geography*, a town of France, and principal place of a district in the department of the Ourte, situated on the Meuse, which divides it into two parts; 12 miles S.S.W. of Liege. N. lat. 50 31'. E. long. 5 15'. The place contains 4871, and the canton 10,674 inhabitants, on a territory of 110 kilometres, in 12 communes.

HUYGENS, CHRISTIAN, in *Biography*, was born at the Hague in the year 1629. He was educated chiefly under his father, and exhibited very rare talents at an early age. At thirteen years of age he was a good mathematician, and began to study mechanics, having discovered a marked genius for this branch of science by his great curiosity in examining different kinds of machines and pieces of mechanism. In the year 1645 he was sent to the university of Leyden to study

fluffy law; but this pursuit did not prevent him from going on with his mathematical pursuits. At the end of one year he removed from Leyden to Breda, where an university had been recently founded, the direction of which was given to his father. In 1651 he published the first fruits of his studies, in a treatise entitled "Theoremata de Quadratura Hyperbolæ, Ellipsis, et Circuli, ex dato Portionum Gravitatis Centro, &c." and in 1654 he gave the world another work, "De circuli magnitudine inventa: accedunt Problematum quorundam illustrissimæ Constructiones." In the following year he was admitted to the degree of doctor of laws at Angers. In 1657, Dr. Huygens published a short piece, entitled "De Ratiociniis in Ludo Alæ," annexed to a mathematical work of professor Schooten's, in order to shew the usefulness of algebra. In the same year he printed his "Brevis Institutio de Ufu Horologiorum ad inveniendas Longitudines." An attempt was made to deprive him of the honour of the discovery, which obliged him to publish another piece to shew that his pendulum was very different from that invented by Galileo. This philosopher, in the course of his observations on the planet Saturn, had discovered what he imagined to be two satellites, almost in contact with his body, which some time after disappeared. Huygens, being desirous to account for these appearances and changes, applied himself to the improvement of the telescope, and he constructed one possessing a higher power than any which had been before invented. With this he discovered the ring, and he ascertained that the appearances which Galileo had taken for satellites were only Anse, or the extreme parts of the ring. He also discovered a satellite belonging to that planet which had never been before. These discoveries he communicated to the world in a work entitled "Systema Saturninum sive de Causis mirandorum Saturni Phenomenon, et Comite ejus Planetâ novo." In the year 1660 he came to England, where he communicated his art of polishing glasses for telescopes, and was admitted a member of the Royal Society. Here he made considerable improvements in the air-pump, and discovered the laws of the collision of elastic bodies. In 1663 he was invited by the minister Colbert to settle at Paris; the offer of a handsome pension in the king's name induced him to accede to the minister's proposal, and he resided at Paris from 1666 to 1681, where he was admitted a member of the Academy of Sciences. In 1673 he published "Horologium Oscillatorium; sive de motu Pendulorum ad horologia aptato, Demonstrationes Geometricæ;" discovering a method of rendering clocks exact, by applying the pendulum, and of rendering all its vibrations equal by the cycloid. In consequence of the revocation of the edict of Nantes he determined to leave France, though every effort was made to prevail upon him to remain there. Nothing he said should induce him to live in a country where his religion was proscribed, and its professors harassed by the most cruel persecutions. He accordingly quitted Paris, and returned to Holland, where he spent the remainder of his life in scientific pursuits and employments. His last work, and which he did not live to see through the press, was a tract on the plurality of worlds, and the probability that the planets are inhabited. Huygens died in 1695, when he was in the 67th year of his age. He was, unquestionably, one of the ablest mathematicians of the age. His temper was cheerful, his manners amiable, and he was in all respects a good man. Many of his works were published after his death. Moreri.

This great mathematician seems to have been as well acquainted with practical music, as the philosophy of sound. Dr. Smith, in his Harmonics, quotes his authority for an

observation which could only be made by a very nice and practised ear.

M. Huygens observed long ago, "that no single voice, or perfect instrument, can always proceed by perfect intervals, without erring from the pitch at first assumed; as in singing the sounds in the base C, F, D, G, C, the voice would sink insensibly so much, that the last C would be considerably lower than the first."

Because of those perfect intervals, which are as 4 to 3, 5 to 6, 4 to 3, 2 to 3, an account is made in such a proportion, as 160 to 162, that is, as 80 to 81, which is what calculators call a comma. Cornthecoros, lib. i. p. 77.

This, says Dr. Smith, is also confirmed by what we are told of a monk, who found by subtracting all the ascents of the voice in a certain chant from all its descents, that the latter exceeded the former by two commas; so that if the ascents and descents were constantly made by perfect intervals, and the chant were repeated but four or five times, the final sound, which in that chant should be the same as the initial, would fall about a whole tone below it.

We have always found ourselves, that voices, singing without an organ or instrumental accompaniment, gradually sink to a lower pitch than that in which they began. And in singing a ballad with many different stanzas to the same air, the depression is proportionably considerable. But Huygens has assigned a scientific reason for the descent. Dr. Smith frequently refers in his Harmonics to the *Cycelus harmonicus* of Huygens at the end of his works, or in *PHistoire des Ouvrages des Scavans*, October, 1691.

HUYGENS, GOMARUS, was born at Liere, in the territory of Antwerp, in the year 1631. He was educated at the university of Louvain, where he was so much distinguished among his contemporaries, that he was appointed professor of philosophy when he was only twenty-one years of age. In 1668 he began to confine his studies solely to divinity, and in the same year was admitted doctor, and deputed to proceed to Rome, to defend the privileges of the university of Louvain before pope Clement X. Having succeeded in his object he returned to Louvain, where he was incessantly employed in his studies till the year 1677, when he was appointed president of the college by pope Adrian VI. In the year 1682, his Catholic majesty, without solicitation, bestowed on him a canonry of St. Peter, at Louvain. Soon after this he was involved in disputes with the Jesuits, and his enemies procured an interdict against him, by which he was prohibited the exercise of his functions as president, preacher, and confessor. Both parties appealed to the pope, who decided in favour of Huygens. A temporary peace was produced among the several combatants, during which Mr. H. died in 1702, at the age of 71. He was author of many theological works, among which are his "Breves Observaciones," which, notwithstanding the title, are extended to fifteen volumes, 12mo. Moreri.

HUYGENS'S *Temperament of the Musical Scale*. In his *Cycelus Harmonicus*, at the end of his works, and in *Hist. des Ouvrages des Scavans*, 1691, p. 78, M. Huygen's adopts a system of temperament of the musical scale, in which the octave is divided into 31 equal parts, whereof the mean tone is 5, and the major limma 3. Dr. Robert Smith, in his *Harmonics*, 2d edit. p. 158, calculates the temperaments of the Vth, IIIrd, and VIth in this system, and Mr. Farey has done the same in schelium 12 to his *Theorems*, *Phil. Mag.* vol. xxxvi. p. 52. where it appears, that the fifths in this system are each flattened 2.6518 Σ , each major third is sharpened .4006 Σ , and each major sixth is also sharpened 3.0524 Σ . At page 224, Dr. Smith gives the lengths of a monochord string for each of the 21 notes of this scale, for instruments with

with notes sufficient, and which will equally serve for tuning the common douzeave instruments, by taking the seven natural notes C, D, E, &c. and C ♯, E ♭, F ♯, G ♯ and B ♭ for the short keys of the instrument. And at page 207 he shews, that by help of the first table of beats in plate 20, answering to the pitch 262, (that being nearly $\frac{1}{4}$ th of a mean tone, or 24.71654 lower than our present CONCERT pitch, see that article); this system may be tuned, on common, or on more perfect instruments. In 1725 Ambrose Warren published a thin quarto, under the title of the "Tonometer," wherein he pretends to the discovery of this system of 31 intervals in the octave, but which he more probably took from our author, as Mr. Farey has remarked in the page of the Phil. Mag. above referred to.

HUYSMAN, or HOUSEMAN, CORNELIUS, in *Biography*, a painter, born at Antwerp in 1648. He studied the art under Gaspar de Wit, but seeing some of the works of Artois, he was so struck with them that he went to Brussels to place himself under him.

In some time he copied his manner, but afterwards adopted one of his own, yet retained somewhat of Artois, with a mixture of the taste of the Italian schools, and he is considered as one of the best landscape painters of the Flemish school. He died in 1727, aged 79.

HUYSUM, JOHN VAN. This illustrious painter hath surpassed all who have ever painted in that style; and his works excite as much surprise by their finishing, as they excite admiration by their truth.

He was born at Amsterdam in 1682, and was a disciple of Justus Van Huysum, his father. He set out in his profession with a most commendable principle, not so much to paint for the acquisition of money, as of fame; and therefore he did not aim at expedition, but at delicacy, and if possible, to arrive at perfection in his art. Having attentively studied the pictures of Mignon, and all other artists of distinction who had painted in his own style, he tried which manner would soonest lead him to imitate the lightness and singular beauties of each flower, fruit, or plant; and then fixed on a manner peculiar to himself, which seems almost inimitable. He soon received the most deserved applause from the ablest judges of painting; even those who furnished him with the loveliest flowers, confessing that there was somewhat in his colouring and pencilling that rendered every object more beautiful, if possible, than even nature itself. His pictures are finished with inconceivable truth; for he painted every thing after nature, and was so singularly exact, as to watch even the hour of the day in which his model appeared in its greatest perfection.

By the judicious he was accounted to paint with greater freedom than Mignon or Brueghel; with more tenderness and nature, than Mario da Fiori, Michael Angelo di Campidoglio, or Segers; with more mellowness than De Heem, and greater force of colouring than Baptist. His reputation rose to such a height at last, that he fixed immoderate prices on his works; so that none but princes, or those of princely fortunes, could pretend to become purchasers. Six of his paintings were sold, at a public sale in Holland, for prices that were almost incredible. One of them, a flower-piece, for fourteen hundred and fifty guilders; a fruit-piece, for a thousand and five guilders; and the smaller pictures for nine hundred.

The vast sums which Van Huysum received for his works, caused him to redouble his endeavours to excel; no person was admitted into his room while he was painting, not even his brothers; and his method of mixing the tints, and preserving the lustre of his colours, was an impenetrable secret which he never would disclose. Yet his conduct is certainly not to his honour; but rather an argument of a low mind,

fearful of being equalled or surpassed. From the same principle he would never take any disciples, except one lady, named Haverman, and he grew envious and jealous even of her merit.

By several domestic disquiets his temper became changed; he grew morose, fretful, and apt to withdraw himself from society. He had many enviers of his fame, which has ever been the severe lot of the most deserving in all professions; but he continued to work, and his reputation never diminished. It is universally agreed, that he has excelled all who have painted fruit and flowers before him, by the confessed superiority of his touch, by the delicacy of his pencil, and by an amazing manner of finishing; nor does it appear probable that any future artist will ever become his competitor. The care which he took to purify his oils, and prepare his colours, and the various experiments he made to discover the most lustrous and durable, is another instance of his extraordinary care and capacity.

From having observed some of his works that were perfectly finished, some only half finished, and others only begun, the principles by which he conducted himself may perhaps be discoverable. His cloths were prepared with the greatest care, and primed with white, with a less possible purity, to prevent his colours from being obscured, as he laid them on very lightly. He glazed all other colours, except the clear and transparent, not omitting even the white ones, till he found the exact tone of the colour; and over that he finished the forms, the lights, the shadows, and the reflections; which are all executed with precision and warmth, without dryness or negligence. The greatest truth, united with the greatest brilliancy, and a velvet softness on the surface of his objects, are visible in every part of his compositions; and as to his touch, it looks like the pencil of nature.

Whenever he represented flowers placed in vases, he always painted those vases after some elegant model, and the bas-relief is as exquisitely finished as any of the other parts. Through the whole he shews a delicate composition, a fine harmony, and a most happy effect of light and shadow. Those pictures which he painted on a clear ground, are preferred to others of his hand, as having greater lustre; and as they demanded more care and exactness in the finishing; yet there are some on a darkish ground, in which appears rather more force and harmony.

It is observed of him, that in the grouping of his flowers, he generally designed those which were brightest in the centre, and gradually decreased the force of his colour from the centre to the extremities. The birds' nests and their eggs, the feathers, insects, and drops of dew, are expressed with the utmost truth, so as even to deceive the spectator. And yet, after all this merited and just praise, it cannot but be confessed, that sometimes his fruits appear like wax or ivory, without that peculiar softness and warmth which is constantly observable in nature.

Beside his merit as a flower-painter, he also painted landscapes with great applause. They are well composed; and although he had never seen Rome, he adorned his scenes with the noble remains of ancient magnificence which are in that city. His pictures in that style are well coloured, and every tree is distinguished by a touch that is proper for the leafing. The grounds are well broken, and disposed with taste and judgment; the figures are designed in the manner of Laireffe, highly finished, and touched with a great deal of spirit; and through the whole composition, the scene represents Italy, in the trees, the clouds, and the skies. He died in 1749, aged 67. Pilkington's Dict.

HUZANKA,

HUZANKA, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 36 miles S.E. of Novogrodek.

HUZZARD, in *Mining*, signifies ochry, foul, or bad; as huzzarded limestone in Derbyshire, is the ochry and cherty mixtures of stone found in the rocks where they skirt the veins, and in the stony lenticular masses, found in the veins called *Riders*, which see. Sometimes this kind of stone, unfit for lime-burning, is called bastard-limestone.

HWARE, in *Geography*, a town of Sweden, in West Gothland; 63 miles E. of Uddevalla.

HWEN, **HVEN**, or *Ween*, a fertile island of Sweden, to which country it was granted by the treaty of Roschild, in 1658, situated in the Sound, about 8160 paces in circuit, and having at a distance the appearance of a high mountain. This island was granted by Frederick II. king of Denmark, to Tycho Brahe (see **BRAHE**). The whole island contains but one parish, or village, with about 50 houses; 15 miles N. of Copenhagen. N. lat. 55° 54'. E. long. 12° 42'.

HWITTIS, a town of Sweden, in the government of Abo; 15 miles N. of Biorneborg.

HYACINTH, in *Botany*. See **HYACINTHUS**.

HYACINTH, *African blue unbellated*. See **CRINUM**.

HYACINTH, *Grape*. See **HYACINTHUS**.

HYACINTH, *Lily and Starry*. See **SCILLA**.

HYACINTH, *Tuberosa*. See **POLYANTHUS**.

HYACINTH, in *Natural History*. See **GEMS** and **ZIRCON**.

HYACINTHIA, in *Antiquity*, feasts held at Sparta in honour of Apollo, and in commemoration of his favourite Hyacinth.

This Hyacinth was the son of Amyclas, king of Sparta, and was beloved both by Apollo and Zephyrus. The youth shewing most inclination to the former, his rival grew jealous; and to be revenged, one day, as Apollo was playing at the discus, *i. e.* quoits, with Hyacinth, Zephyrus turned the direction of a quoit which Apollo had pitched, full upon the head of the unhappy Hyacinth, who fell down dead. Apollo then transformed him into a flower of the same name; and, as a farther token of respect, they say, commanded this feast. The Hyacinthia lasted three days; the first and third whereof were employed in bewailing the death of Hyacinth, and the second in feasting and rejoicing.

The persons who assisted at the ceremony were crowned with ivy: because, says Vossius, *De Idolol. lib. ii. cap. 14.* Bacchus and Apollo were the same person.

HYACINTHUS, in *Botany*, *ἵακινθος*, a name adopted from the ancient Greeks, who applied it to the flower supposed to have sprung from the blood of Hyacinthus, the favourite of Apollo, when accidentally slain. Great differences have arisen amongst commentators concerning the plant of the ancients, which we cannot presume to settle, but there seems no paramount authority for the present application of the name in question.—Linn. *Gen.* 170. Schreb. 225. Willd. *Sp. Pl.* v. 2. 166. Mart. *Mill. Dict.* v. 2. Ait. *Hort. Kew.* ed. 2. v. 2. 282. Juss. 52. Lamarck. *Illustr.* t. 238. Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronariz*, Linn. *Aphod. li.* Juss.

Gen. Ch. *Cal.* none. *Cor.* of one petal, bell-shaped; its limb in six reflexed segments. Nectary three pores near the summit of the germen. *Stam.* Filaments six, awl-shaped, uniform, shorter than the corolla, inserted into the tube; anthers approaching each other. *Pist.* Germen superior, roundish, with three angles and three furrows; style simple, shorter than the corolla; stigma obtuse. *Peric.* Capsule roundish with three angles, of three cells and three valves. *Seeds* mostly two in each cell, roundish.

Ess. Ch. Corolla inferior, of one petal; tube swelling;

limb regular, in six segments. Germen with three honey-bearing pores.

Obs. The tube of the corolla, and even its limb, varies so much in shape, that Tournefort, and recently Mr. Ker, in Curtis's Botanical Magazine, have divided this genus; their *Muscari*, separated from it, having a globular tube. In some species, as *H. romanus*, the limb is more deeply divided; but in *H. non scriptus* of Linnæus the corolla is actually of six petals, and we therefore presume this species is properly removed, in the *Fl. Brit.* and English Botany, t. 377, to *Scilla*. Considerable doubts have, moreover, arisen respecting the melliferous pores described by Linnæus upon the germen, which are certainly not discernible in every one of the species, but indeed they are to be seen at a particular period only in any.

Willdenow has thirteen species, of which *H. non scriptus* is a *Scilla*, as we have said, and *cernuus* also; but the loss of these may be supplied by two of the *Muscari* tribe from Desfontaines, *maritimus* and *parviflorus*.

Fair examples of the genus are the common garden Hyacinth, *H. orientalis*, whose numerous and gorgeous varieties are the delight of florists; see *Curt. Mag.* t. 937; and *H. amethystinus*, prettily figured in Redouté's *Liliacées*. t. 14.

H. Muscari, figured in *Curt. Mag.* t. 734, and Redouté *Lil.* t. 132, a native of the Levant, is hardy in our gardens, and valuable for its delicious musky scent, though not conspicuous for beauty, its flowers being of a dusky green.

H. racemosus, *Curt. Mag.* t. 122. *Engl. Bot.* t. 1931, the Starch Hyacinth, so called from the peculiar smell of its dark blue flowers, is wild or naturalized on walls or in sandy fields in England, flowering in May.

H. corymbosus, Linn. *Mant.* 223, is made a *Maffonia* by Mr. Ker, in *Curt. Mag.* t. 991, but we are at a loss to understand the reason of this measure, against which the habit strongly revolts.

HYACINTHUS, in *Gardening*, comprehends plants of the bulbous-rooted, flowering, perennial kind; of which the species principally cultivated are the eastern, or garden-hyacinth (*H. orientalis*); the common hyacinth or hare-bells (*H. non-scriptus*); the bending hyacinth (*H. cernuus*); the late-flowering hyacinth (*H. serotinus*); amethyst-coloured hyacinth (*H. amethystinus*); the musk hyacinth (*H. muscari*); the feathered hyacinth (*H. monstrosus*); the purple grape hyacinth (*H. comosus*); the blue grape hyacinth (*H. botryoides*); and the clustered grape hyacinth (*H. racemosus*).

The first species and varieties are the sorts that are the most usually raised, and esteemed by those engaged in the culture of flowers.

The varieties of this species are numerous; as those with single white flowers; with double white flowers; with red single and double flowers; with flesh-coloured single and double flowers; with blue single and double flowers; with purple blue-coloured single and double flowers; with yellow flowers; with double white flowers with red eyes or middles; with double white with purple eyes; with double white with flesh-coloured eyes; with double white with yellow eyes; with double agate blue; with double and single porcelain-blue; and with double and single violet-coloured flowers.

And besides, there are also a number of intermediate varieties which have been obtained from seed, and by which many new ones of the chief sorts just noticed are yearly produced; each being distinguished either by the name of the place where it was first raised, the person who raised it,

HYACINTHUS.

or that of illustrious personages, such as great kings, generals, poets and historians, as well as gods and goddesses, &c.

The principal circumstances by which the properties of a good double hyacinth are known, are that the stem or stalk be tall, strong, and upright; the flowers or bells sufficiently numerous, each being suspended by a short strong peduncle, having a horizontal position; the whole presenting a compact pyramidal form, with the crown or uppermost flower perfectly erect: the flowers should be large and well filled with broad bold petals, appearing to the eye rather convex than flat or hollow; they should extend to about the middle of the scape or stalk. The plain colours should be clear and bright, strong ones being generally preferred to such as are pale, and those which are mixed should blend together in an elegant manner.

In the fifth sort most of the flowers have white stripes and edges; occasionally varying to pure white, and a fine pale red colour, with deeper coloured veins running along the three outer segments. It was formerly known to gardeners under the title of Coventry blue hyacinth.

The sixth species also affords varieties that have ash-coloured purple flowers on the lower part of the spike, but which are larger and have more of the purple cast than in that sort; and those on the upper yellow with a very grateful odour, and with very large yellow flowers.

The eighth sort, which is termed the two-coloured or tassel hyacinth by Mr. Curtis, has varieties with white and with blue flowers.

This is esteemed more for its singularity than any beauty it displays.

The ninth species has likewise varieties with blue, with white, and with ash-coloured flowers.

Method of Culture.—The first of these sorts and varieties, are all increased by planting the off-sets from the roots, in the manner of other bulbous-rooted perennial plants; and by sowing the seed to produce new varieties of the flowers.

And they succeed best in a light soil, but will prosper in any common earth, particularly in moderate sandy ground, in a dry, open, sunny situation. These bulbs, if planted in strong or very moist land, are apt to rot in winter, or become diseased. Where, therefore, the soil of the flower-borders or beds is of a strong heavy quality, the part designed for hyacinths should have light materials incorporated with it, such as any light sandy earth, from the surface of some common or other place; drift sea-sand, or any upper sandy soil, or light earthy compost; and where the soil of the borders, &c. is of a very light, sharp, sandy nature, a portion of light, mellow, loamy earth and neat's dung, or well rotted dung of old hot-beds, should be mixed with it, which make a fine compost surface mould for the hyacinth, when blended and laid on long enough before for the dung to be converted into mouldy earth.

The ground should be well wrought over as a preparation for the plants, one spade deep at least, raising the bed or border a little above the general level to avoid moisture; and raking the surface as smooth and even as possible.

The florists mostly prepare a compost for their rare kinds of hyacinths, with light sandy loam, or any sandy earth from a pasture field, taking only the top spit, ten or twelve inches deep, adding about one-third, from the surface, to one of drift or sea-sand, and the same quantity of rotten neat's dung; mixing the whole in a heap ridge-ways, in some dry sunny exposure, to lie several months, or if a year or more the better it will be.

To the above materials some also add a quantity of rotten leaves of trees, thoroughly decayed tanner's bark, or any

perfectly rotten earthy wood, or rotten saw-dust; all of which together greatly improve the composition; but as these are not always readily obtained, the other compost is frequently used with success. With these composts a bed is prepared in the beginning of autumn, four feet wide and two deep, a cavity being dug out that width and depth, and filled up entirely with the composition, six inches above the common level, to allow for settling, leaving it a fortnight or a month to settle; when it is ready for the reception of the bulbs of the plants.

The custom with the curious in these plants, is never to plant the fine sorts two years together in the same bed or earth, without some previous renewal, as by planting them every year in a fresh bed, or fresh prepared compost, it greatly improves the size and beauty of the flowers.

The most proper season for planting them is either in October or the beginning of November; as those then planted shoot early in spring, and flower strong at their usual season; but those planted later in autumn, or continued out of the ground till January and February, for a late bloom, flower weaker and with inferior beauty; the principal part should always be planted in the autumnal season.

Where any of the common kinds are intended to be planted to adorn the open borders contiguous to the principal walks, or lawns near the habitation, to increase the variety in assemblage with other bulbous-rooted spring flowers, as early tulips, narcissuses, or anemones, ranunculuses, &c., they should be disposed towards the front, more or less in a varied order, in patches of three roots in each, three or four inches deep; and the patches may be from about one yard to three or four distance, letting them stand to take their chance, without any further care in their culture.

And in planting the fine double sorts, four or five rows may be planted on each bed lengthways, about nine inches distant in each row, and about four inches deep, either in drills the above depth, by dibble, or by bedding them in; and as soon as they are planted in either method, the surface of the bed should be raked smooth and even on the upper side.

The bulbs being thus planted, the choicest sorts should be protected in the beds occasionally, during winter, from severe frost. They may be readily protected by a covering of straw, or any kind of dry, strawy litter, three or four inches thick; or by arching the beds with hoops or rods, or with moveable arched frames of open-work, covered with mats, the coverings being immediately removed when not wanted. The same caution should be continued in the spring.

When the flower stems are advanced nearly to their full height, it is proper to support them, by placing a small stick, fifteen or eighteen inches long, close to each plant, being careful not to thrust it into the bulb, and to tie the stems neatly to each stick, by which the spikes of flowers will be preserved in an upright position.

When in bloom, the curious sorts may be preserved much longer in beauty, by being screened occasionally from the sun and rain, by an awning or umbrella of mats or canvas: they should, however, be shaded only from the mid-day sun, from about ten to three or four o'clock, and only from excessive rains and boisterous winds.

But when the flowers begin to fade, all coverings should be entirely removed, that the bulbs and increasing off-sets may derive all possible benefit from the free air, dews, &c. When the season for flowering is over, the bulbs should be taken up, which, in the florist's language, is called lifting the roots. The fine sorts should be taken up at this period to separate the off-sets for increase, as well as to benefit

HYACINTHUS.

benefit the main bulbs, which will always flower stronger than such as are suffered to remain two or more years unremoved.

The proper time for this work is in summer, soon after they have done flowering, when their leaves begin to turn yellow, as then the bulbs have had their full growth for that season, and should by no means remain longer in the ground, as they will rot.

Dry weather should be chosen, and a trowel or small spade is proper for lifting them, taking them up one by one, and breaking off the stem within an inch or two of its origin; then laying them in an airy room, out of the mid-day sun, to dry off the grass moisture very gradually, and to ripen the bulbs to a due hardness, when they appear of a purplish tinge, otherwise they are apt to rot and be destroyed.

When the bulbs are properly hardened and ripened, they should be taken up and separated from any off-sets, well cleared from earth, loose skins, and fibres at bottom; then, after exposing them a few hours to the sun, put up in boxes singly or upon dry shelves out of the sun, to remain till the season for planting them again arrives.

All the off-sets appearing about the main bulbs at the lifting season, are to be carefully separated from them, either as soon as they are taken up, or after the bulbs have lain to ripen, being kept separate, and planted in the early autumn, in beds by themselves, in rows six inches asunder, and two or three deep, where they should remain a year or two; then be taken up at the proper lifting season in summer, and managed as the large blowing roots.

In raising these bulbs from seed, which is practised by the curious, to obtain new varieties, to increase their stock; from the time of sowing, it will be four or five years before the bulbs produce flowers: the seed ripens in the summer, which may easily be saved, by suffering some of the finest singles and half doubles to stand to ripen it in perfection. The proper season of sowing it is about the beginning of autumn, in which case the plants will appear in the following spring. It grows perfectly well in a bed or border of light earth in the open ground; but where only a small quantity is to be sown, it may be done in pots or boxes, and be thereby much more convenient to remove into different situations at different seasons, as there may be occasion. Whichever mode is adopted, light rich mould should constantly be chosen for the purpose, the surface being rendered perfectly even and smooth, and the seeds sown with regularity over it, and covered in to the depth of from an inch to an inch and a half. Where sown in pots or boxes, they should be plunged up to their brims in the mould, in some dry situation, and as the winter begins to set in, be removed either under the occasional protection of a hot-bed frame, or be covered with some light dry litter in frosty weather, but letting them be fully exposed whenever it is mild.

As soon as they first appear in the spring, with very small leaves, they should be kept perfectly free from weeds, and have a little fine mould lifted over them in the autumn in the beds, being protected in the winter season as before directed. When their leaves begin to decay in the second summer, the young bulbs should be taken up, and replanted in nursery beds, about the end of August or beginning of the following month, in small drills, two inches in depth, letting them be three or four inches apart. They may remain in this situation two years, only lifting over the surfaces of the beds about half an inch thickness of fine mould in the autumn, and giving them occasional protection by coverings or other means, during the winters. After this they are to be managed in the usual manner, being taken up at the gene-

ral lifting season, and planted out where they are to flower in the autumnal months.

All the other species are capable of being readily increased by planting out the off-sets in the method that has been already directed, as they each of them afford them in great plenty. They may be taken up every second or third year, at the time the leaves decay, and the off-sets be separated and managed in the same mode as has been directed for those of the first species.

Method of blowing the Bulbs in Water-Glasses, &c.—Bulbs of this sort may be brought to flower in the winter and early spring, by having them put in root-glasses filled with water, or in pots, or small light boxes filled with sand, or light dry sandy mould, in the beginning of the autumn, and depositing them in a warm room, green or hot-house. In all these situations they blow in a highly agreeable manner, and earlier or later in these different seasons, according to the periods at which the bulbs have been introduced and planted.

The sorts of bulbs commonly employed for glasses and pots, &c. are principally the varieties of the oriental kind, especially where they are to be blown in water. In providing these, care should be taken to select such bulbs as are perfectly found and firm, having the root part at the bottom full, plump, and solid.

The glasses for this purpose are of the bottle kind, having straight upright bodies gradually narrowing towards the tops, where they terminate in wide concave mouths, capable of containing one root or bulb in each. They are usually sold at the glass-shops, seed-shops, and nurseries, at from about five to nine shillings the dozen. In using them they should be filled with soft clear water up to the necks, and a little way into the cavity of the mouths, one bulb being then placed in each glass, with the bottom or root part a little in the water, and the top upright, setting them in the window of a room which faces the sun, or upon a chimney-piece, or the shelves of a light room where there is a fire, as the growth of the bulbs is thus greatly promoted. And they soon put forth strong root-fibres into the water, and at the same time push out leaves and flower-buds at the tops, which advance in a regular manner to flowering, in their peculiar habits. It is necessary to renew the water occasionally, as it becomes foul, or affords a foetid smell, by discharging the old, and immediately filling up the glasses with such as is fresh, which is the whole of the trouble that is requisite in their management. As soon as the stalks and flower-spikes are advanced to a tolerable height, a neat small stick should be placed to each as a support to keep it in an upright direction.

But in order to have the bulbs in blow at the most early season, the glasses that contain them should be placed in a hot-house, or other forcing-house.

And by planting some bulbs in pots or neat boxes of light sandy earth, or pure sand, in the autumn, and putting them in a warm sitting room, green-house, &c. they will flower at an early period.

The bulbs in the glasses usually flower in about six, eight, or ten weeks, according to the warmth of the situation in which they are placed. And they generally continue in blow for three or four weeks.

Where bulbs of this sort are to be forced by fire or bark-heat, some middling small pots should be provided, or small, neat, oblong boxes, six inches in depth, filling them half way, or a little more, with light dry earth, or that of a sandy nature, or with sand, planting one, two, three, or more bulbs in each pot or box, according to the size of them, pressing the bottoms gently into the earth, and filling up with more earth or sand over the crown of the bulbs. After they have been thus planted, the pots or boxes should

should be placed in the houses, &c. watering the bulbs moderately with soft water, when the earth appears dry. They soon come into blow in this way, and, when the flowering is over, and the stems and leaves are decayed, the old bulbs should be taken up, cleaned and dried; being afterwards planted out in the open ground to recover strength, and produce good effects in the future year.

These are all highly beautiful plants, that afford much ornament and variety in gardens and pleasure-grounds. The more hardy common sorts are proper in the borders, clumps, and other parts towards the fronts; and those of the double finer kinds, in beds, pots, glasses and boxes, to be set out for variety.

HYADES, Ἥαδες, from ἕω, to rain, in *Astronomy*, are seven stars on the bull's head, famous among the poets for the bringing of rain.

The principal of them is in the bull's left eye, by the Arabs called Aldebaran. See TAURUS.

The poets feign them to have been the daughters of Atlas and Pleione; and we have the names of six of them, viz. Eudora, Ambrosia, Prodice, Coronis, Philito, and Poliso, others add a seventh, viz. Thione. Their brother Hyas being torn in pieces by a lioness, they wept his death with such vehemence, that the gods, in compassion to them, translated them into heaven, and placed them in the Bull's forehead; where, as they say, they continue to weep: this constellation being supposed to preface rain.

Others represent the Hyades as Bacchus's nurses, and the same with the Dodonides, who fearing the resentment of Juno, and flying from the cruelty of king Lycurgus, were translated by Jupiter into heaven.

It is probable that these pretended Hyades, a Greek term signifying rainy, were merely poetical personages, whose names were given to certain stars discovered by Atlas.

HYÆNÆ, or ΗΙÆΝΑ, in *Natural History*, a species of the canis, with a straight annulated tail, and the hairs of the neck long and erect; naked ears, and four toes on each foot. It has six cutting teeth, and two canine in each jaw; and between the tail, which is short, and the anus, a transverse orifice. The animal which is known to us by this name is a quadruped almost as large as a wolf, excepting that its legs are not so long; the hair of it is rough, and its skin spotted with divers colours. Hyænas were formerly produced at Rome in the public games, and they have been represented on some medals on account of their rarity. Spanheim, who had copies of it engraved from medals, describes it with the head of a mastiff, with short triangular ears, a lion's tail and feet, and hair spotted all over like a tyger's. It inhabits Asiatic Turkey, Syria, Persia, and Barbary.

Pliny's account of this animal is very fabulous. He says, that it changes its sex every year; and that from its eyes are taken precious stones, called *hyænia*. Aristotle and Ælian say, that it makes dogs dumb with its shadow; and that it imitates the speech of mankind in order to deceive them, and thus draw them out of their houses and devour them. The superstitious Arabs carefully bury the head when they kill a hyæna, lest it should be applied to magical purposes, as the neck was of old, by the Thessalian forcerers. Lucan. lib. vi. 672.

Busbequius, in his travels to Amasia, relates several particulars of this animal. He says, it is almost of the shape of a wolf, but not so tall; that its hair is like that of a wolf, except its being more bristly, and marked at certain distances with great black spots; it has no neck, but its head is fastened to the vertebræ of the back, so that it is forced to turn itself quite round, whenever it would look behind. It is very cruel and voracious; it drags dead

bodies out of graves, and carries them to its den. It also preys on the herds and flocks. It is said to imitate the voice of a man, and that by this means it often deceives travellers. It is a solitary unfociable animal, and inhabits the chafms of rocks. These animals have a most malevolent aspect; and they are in their nature cruel, fierce, and untameable.

HYÆNÆ, *fossil remains of*. M. Cuvier, in his Report to the National Institute of France, of the Transactions of the Physical and Mathematical Class in 1806, mentions, that the bones of hyænas have been found in a great number of caverns in the mountains of Hungary and Germany, in company with the skeletons of tigers, bears, and other animals of unknown species: they are also found in loose recent alluvial soils, in some vallies, he says, in the Report for 1809. Phil. Mag. vol. 35. p. 388.

HYÆNIUS LAPIS, the name of a stone said to be found in the eyes of the hyæna. Pliny tells us, that these creatures were anciently hunted and destroyed for the sake of these stones, and that it was supposed they communicated the gift of prophecy, on being put under the tongue.

HYAGNIS, in *Greek Mythology*, the Oxford marbles tell us, was of Celene, and according to Alexander, cited by Plutarch in his Dialogues, he was the most ancient performer on the flute in Greece.

He was contemporary with Erichon, 1506 years B. C., who instituted the Panathenæan games at Athens. He was said to be the author of the nomes consecrated to Cybele, to Bacchus, to Pan, and to many other divinities.

He added a sixth string to the lyre of Mercury. Some make him the inventor of the Phrygian mode, and double flute. He was the father of Marfyas, according to Plutarch and Nonnus. Apuleius says, that he brought the flute to its highest perfection.

HYALE, in *Mythology*, one of the nymphs of Diana.

HYALINÆ, in *Natural History*, derived from ἕαλον, glass, the name of a genus of fossils, of the class of the tales, the characters of which are, that they are composed of separate plates, of considerable thickness, and those not fissile into any thinner.

There is but one species known of this genus, which is found lodged in the clay, in the steep banks of the river Aube in Champagne, near the town of Bar, and in some other places along that river; but so far as is yet known, in no other part of the world.

HYALINGE, in *Geography*, a town of Sweden, in the province of Bleckingen; 20 miles S. S. E. of Konfsbeck.

HYALITE, in *Mineralogy*, occurs in wacke, in reniform masses, and is chiefly found at Frankfort on the Mayne. It has a considerable resemblance to gum, and is nearly allied to opal. The masses are usually much cracked. Its colour is yellowish and greyish-white, and it occurs in thin crusts on other minerals. Externally and internally it is shining, and its lustre is vitreous. The fracture is small and flat conchoidal. The fragments are indeterminately angular, and sharp edged. It is translucent, passing to semi-transparent. It is intermediate between the hard and semi-hard: is brittle and frangible. The specific gravity is 2.11. It is infusible at 150° of Wedgwood, but yields to soda. Jameson's Min. Thomson's Chemistry.

HYALOIDES, in the *Natural History of the Ancients*, the name of a transparent stone fit to engrave seals on, which was the great use they made of the gems, and very bright and readily reflecting the images of things. We have this stone to this day in many parts of America, particularly about the river of the Amazons, from whence many fair stones of it have at times been brought, and have been by some

some mistaken for diamonds; they are a sort of pebble crystal, approaching to what the jewellers call the white sapphire. Hill's Theophrast. p. 80.

HYALOIDES, from ὑάλος, *glass*, in *Anatomy*, is sometimes applied to the vitreous humour of the eye, contained betwixt the tunica retina, and the uvea.

HYANCHE, a word used by the old medicinal writers to signify a quinsy, attended with a swelling on each side of the throat.

HYARON, in *Geography*, a small island in the Grecian Archipelago, near the coast of the Morea, between the gulf of Napoli and the gulf of Engia.

HYAT, a town of Hindoostan, in the circar of Solla-pour; 12 miles E. N. E. of Solla-pour.

HYATNAGUR, a town of Hindoostan, in Bengal; 18 miles N.W. of Mauldah.

HYBERNICUS LAPIS. See *Iris* SLATE.

HYBLA, in *Ancient Geography*, a town of Sicily; of which Stephanus gives an account, distinguishing three places of this name under the appellations of *major*, *minor*, and *parva*. The first, or *Hybla major*, was situated near and south of mount Ætna. Pausanias, in his "Eliac," l. i. c. 25, says, that it was situated in the territory of Catania, and entirely depopulated. Avola, 16 miles from Syracuse, which formerly stood on a hill, boasts of having been the *Hybla major*, so celebrated for its honey: but to this title so many places lay claim, that it is not easy to decide on the subject. See **AVOLA**, **MELILLI**, and **PATERNO**. *Hybla minor*, or *minima*, called also *Heræa*, was situated in the southern part of Sicily; and is placed in the Itinerary of Antonine on the route from Agrigentum to Syracuse. This is now "Calata-Girone." *Hybla parva* was a maritime town of Sicily, on the eastern coast. It was also denominated *Galaotis*, and more frequently *Megara*, from which the gulf, to the south of which it was situated, was called "Megarensis sinus."

HYBLA, *Mount*. See **MELILLI**.

HYBLÆANUM BITUMEN. See **BITUMEN**.

HYBOMA, a word used by the old surgical writers for a gibbosity of the spine.

HYBRISTICA, of ὑβρις, *injury*, in *Antiquity*, a solemn feast held among the Greeks, with sacrifices, and other ceremonies; at which the men attended in the apparel of women, and the women in that of men, to do honour to Venus in quality either of a god, or a goddess, or both. Or, according to the account given by others, the *hybristica* was a feast celebrated at Argos, wherein the women, being dressed like men, insulted their husbands, and treated them with all marks of superiority, in memory of the Argian dames having anciently defended their country with singular courage against Cleomenes and Demaratus.

Plutarch speaks of this feast in his treatise of the great actions of women. The name, he observes, signifies *infamy*; which is well accommodated to the occasion, wherein the women strutted about in men's clothes, while the men were obliged to dangle in petticoats.

HYDAGE. See **HIDAGE**.

HYDARTHURUS, in *Surgery*, signifies the disease of the joints, better known by the name of white-swelling. The term is derived from ὑδωρ, *water*, and ἄρθρον, *a joint*.

HYDASPES. See **BEHUT**.

HYDATID, ὑδατις, in *Medicine*, from ὑδωρ, *water*, in the genitive case, ὑδατος, literally a *vesicle* containing a watery or transparent fluid, denotes certain spherical bodies, which are found occasionally in man, as well as in other animals, lodged in, or adhering to, the different viscera.

The term *hydatid* has been applied to *two species* of vesic-

cular bodies, which appear to differ very materially in their nature: one of these, which, in the human subject, is commonly found adhering to the liver, spleen, or mesentery, and appears to have no farther connection with the body, than as it furnishes a nidus, is commonly supposed to be of an animal nature, and to possess an independent vitality: the other species, which is found attached to the kidneys, uterus, ovaries, or placenta, is considered as dependent on a mere morbid alteration of the structure of these parts. The first of these may be called the *true*, the second the *spurious* hydatid, for the sake of distinction; although at present we cannot consider the nature of either variety as satisfactorily ascertained, or the appellations as strictly correct.

1. *Of the true Hydatid*. The first authors, who described the hydatids accurately, and observed that they possessed the power of motion, were Phil. Jac. Hartmannus, who published his discovery in the year 1685 (see *Miscell. Natur. Curios.* Dec. 2, Ann. 4.); and Dr. Tyson, whose account was printed in the Philosophical Transactions for the year 1692, and who appears to have been unacquainted with Hartmann's observations. Tyson, who described and figured the hydatid, as found in sheep, observed the neck and mouth of the animal, and saw them in motion; Hartmann farther saw the whole body in motion, by putting them into warm water. Professor Pallas afterwards examined them very minutely, and finding their heads of the same structure as that of the *tænia*, or tape-worm, he gave them the name of *tænia hydatigena*. (See his *Miscellanea Zoologica*.) The abbé Fontana also observed them in sheep, saw the young ones adhering to the sides of the parent bag, and also with a microscope examined the heads of them, and found them resembling those of *tæniæ*. (*Opuscoli Scelti*, tom. 6.) Dr. Baillie says, "there is no doubt at all, that the hydatids in the livers of sheep are animalcules: they have been seen to move when taken out of the liver, and put into warm water; and they retain this power of motion for a good many hours after a sheep has been killed." (*Morbid Anatomy*, p. 224. ed. 2d.) The late Dr. John Hunter gave the following account of some hydatids, that were found in the abdomen of a sheep, adhering to the fat about the kidneys, and to the liver, in considerable number.

"The hydatids in the sheep were exactly the same with those described by Tyson. They consist of a mouth, neck, and oblong spherical body. The mouth had nothing of the cruciform appearance, if I may be allowed the expression, that late writers have made the characteristic mark of *tænia*, and which they say is to be found in all hydatids. The mouth, examined with some care with the microscope, appeared to be a simple longitudinal aperture. The neck was composed of rings, and there appeared very fine circles surrounding the body. They varied in size, from that of a chestnut to the dimensions of a turkey's egg. When put in warm water, though it must have been twelve or fourteen hours after the sheep had been killed, they moved briskly, with a kind of peristaltic motion all over the body. Each hydatid was lodged in a separate sac, which was little more than sufficient to hold it, for the neck was reflected upon the body. The sides of the sac were lubricated with a mucous fluid." See *Transactions of a Society for the Improvement of Med. and Chirurg. Knowledge*, vol. i. p. 50.

Hydatids are also found in the *brain* of sheep, in which case they produce the disease, called, in some parts of the country "the staggers." The hydatid is lodged in the substance of the brain; in one sheep there were two hydatids, one in each hemisphere of the brain; they were of an irregular oval shape, they had no mouth; their coats had the same appearance as in the hydatids found in the abdomen; and,

and, when put in warm water, they had a strong peristaltic motion. In some there were clusters of young ones adhering to their inner coats. These were somewhat oval in their shape, and adhered by one end; but on detaching them carefully, and examining them with good magnifiers, I could never find the cruciform mouth described by some writers." Dr. Hunter, loc. cit.

The hydatids, found in, or attached to, the liver, in the human subject, bear a strong analogy to those of sheep above described; whence it is concluded, that they are most probably also animalcules. They have never been seen to move, indeed, when taken out of the body, and put into warm water; a circumstance which may be explained by the length of time which elapses after death, before the human body is examined; during which the hydatids must have lost their living principle. There is undoubtedly some difference between the hydatids in the liver of sheep, and in that of the human subject, in simplicity of organization, the hydatid in the human liver being a simple uniform bag, and the hydatid in that of the sheep having a neck and mouth appended to the bag. But "this difference," Dr. Baillie remarks, "need be no considerable objection to the opinion above stated: life may be conceived to be attached to the most simple form of organization. In proof of this, hydatids have been found in the brains of sheep, resembling almost exactly those in the human liver, and which have been seen to move, and therefore are certainly known to be animalcules." (Morbid Anat. p. 225.) In other respects, too, they bear a considerable analogy to each other.

The hydatids of the liver in man are commonly found inclosed in a cyst, which is frequently of considerable size, and is formed of very firm materials, so as to give to the touch almost the feeling of cartilage: it is endowed with a strong contractile power, so as forcibly to protrude its contents, through any opening made into it. It consists of two coats, the outer one of which is thick and laminated, the inner a soft and pulpy lining, like coagulable lymph. A cyst may contain one hydatid, or a greater number of them: they lie loose in the cavity, swimming in a fluid; or some of them are attached to the side of the cyst.

As to the structure of the hydatids themselves, they consist of a transparent, or semi-transparent bag, uniformly round and smooth, and contain a clear fluid capable of coagulation. The common colour of them is white, but they are occasionally seen of a light amber colour. The bag of the hydatid consists of two laminae, and possesses a good deal of contractile power. They are commonly unconnected with each other, or with the cyst which contains them; but sometimes they have been said to inclose each other in a series, like pill-boxes. On the inside of an hydatid smaller ones are sometimes found, which are commonly not larger than the heads of pins, but sometimes they are even larger in their size than a gooseberry. These are attached to the larger hydatid, either at scattered irregular distances, or so as to form small clusters; and they are also found floating loose in the liquor of the larger hydatids. Dr. Hunter observes, that when the young ones, growing in the coats of the larger ones, were examined with the microscope, they were found not to be set in the coats like pearls, but to be covered by a thin transparent membrane, so as to lie between two layers. The most common situation of hydatids of the liver is in its substance, and inclosed in a cyst; but they are occasionally attached to the outer surface of the liver, hanging from it, and occupying more or less of the general cavity of the abdomen.

There are many instances of hydatids, occurring in the

situation last mentioned, and terminating life, in consequence of the derangement produced by the prodigious pressure on the viscera, which they occasioned. In these cases, a large swelling of the abdomen takes place, yielding a distinct sensation of fluctuation, as in ascites, or abdominal dropsy, attended with emaciation of the limbs, difficulty of breathing, œdema of the legs, and other symptoms of impeded functions. In one case, related by Dr. Simmons, a cyst was found after death, of immense size, filled with hydatids of various sizes, and attached to the liver, omentum, mesentery, and peritoneum. It also penetrated the diaphragm, and then, expanding again, filled almost the whole of the left cavity of the thorax, adhering to the pleura and mediastinum. The upper part of this sac communicated in several places with the lungs, which were ulcerated; so that if the patient had lived long enough, she would probably have coughed up hydatids, as one of the openings from the cyst into the lungs was large enough to admit a goose-quill. In the substance of the liver, which weighed sixteen pounds and a half, another large cyst was found. This contained ten pints of hydatids, and sixteen pints had been taken out of the abdominal cyst before the part in the thorax was examined. (See Medical Communications, vol. 1. art. 5.) A similar case is related in the Edinburgh Medical and Surgical Journal, vol. 2. p. 170. in which "an immense cyst, occupying the whole cavity of the abdomen," was found after death, connected to the mesentery. It was distended to the utmost, and contained thirty-five pints of hydatids, many of them exceeding the largest oranges in size. In both these cases, the disease was supposed to be common ascites during life; and in both a fruitless attempt was made to draw off the fluid by tapping.

In the first of these histories, we have seen that a small communication actually existed between the sac of hydatids, and the cells of the lungs, although none of the hydatids had passed that way. But there are instances on record, in which the true hydatids were coughed up from the lungs. A lady of Lancaster, during an illness which continued more or less for three years, "coughed up several hundreds of hydatids, most of which were burst, and of these many must have been as large as a pullet's egg: those which were not burst, were only about the size of a nutmeg." (London Med. Journal, vol. 6. p. 293, for the year 1785.) This lady recovered her health; she had been considered as dropical, and having disease in the liver. Another lady, who had a tumour in the right hypochondrium, in which fluctuation was distinctly perceived, expectorated 135 hydatids in the course of four months, after which she began to amend. Med. Transactions of the Coll. of Physicians, vol. 2. art. 22.

In some cases these abdominal cysts form adhesions to, and communications with, the alimentary canal, through which the hydatids are discharged. A lady at Windsor was treated with mercurials, under the supposition that hepatitis, and consequent suppuration in the liver, had taken place. "In about ten days the mercury began to affect her mouth, and at the same time she voided an incredible quantity of the *tonia hydatigena*, or hydatides, by stool and by vomiting. Her attendants reckoned she passed to the number of a thousand; there being as many as filled two large chamber-pots. They were from the size of a small pea, to an inch and a half in diameter, &c." An hepatic abscess afterwards opened externally, a gall-stone was discharged from it, and she ultimately recovered. (Lond. Med. Journal, vol. 10. for 1789, p. 76.) An example of fatality occasioned by a sac of hydatids, situated in the *porta* of the liver, which, by its pressure on the vessels, produced complete obstruction and jaundice,

jaundice, is related by Dr. Duncan, sen. in the Ed. Med. and Surg. Journal, vol. 4. p. 187.

In a few instances, small hydatids, formed in the kidneys, have been discharged by urine; as in a case related by Dr. Baillie, who observes, that "sometimes the true hydatid is formed in the kidneys, having exactly the same nature with that which grows in the liver." (Morbid Anat. p. 279.) The hydatids, in this instance, differed much in size, from that of a small orange, to that of a pin's head: the smaller ones only were of course passed with the urine; but in consequence of the increased exertion, necessary to drive these through the urethra, the bladder had acquired a considerable thickness in its muscular coat, as in other cases of obstruction to the free passage of the urine. In a case related by Dr. John Hunter, death was occasioned by a collection of these hydatids, lodged between the bladder and *rectum*, filling the pelvis, and producing a fatal suppression of urine. Dr. Hunter puts the following query respecting the manner in which the hydatids came to be lodged in that situation. "It has been observed," he says, "that they are most commonly found in the liver and spleen, and in the present case their original seat would appear to have been in the last of these viscera: may not, however, one of the sacs or bags in the spleen have burst, by which the contents would be spread all over the abdomen, and from their own gravity would naturally fall into the pelvis; and may they not have adhered to the neighbouring parts, and so multiplied there?" See Trans. of a Society, &c. before quoted, vol. 1. p. 48.

Lastly, these hydatids are said to have been discharged from tumours in different parts of the body. See Philof. Trans. vol. 25.

Such are the situations in which the true hydatids have been observed to occur, and the modes in which they have eventually been discharged or have destroyed the patient. Dr. Hunter remarks, that of the various cases related by writers scarcely any proved fatal, when the hydatids found an outlet. But, however desirable it might, therefore, be to procure such an outlet, where the presence of hydatids is suspected, it is obvious that, as they are generally seated in the abdomen, art can seldom if ever interfere, and the business must be left entirely to nature.

2. The *spurious hydatids*, if that term be allowable, which are found connected with the kidneys, the placenta, the ovaries, and uterus, appear to differ greatly in their nature from the hydatids above described. They are not inclosed in firm cysts, nor exist without any attachment to each other, or the surrounding parts, nor do the larger ones contain others attached to their internal coats, or swimming in the fluid, as in the true hydatids. "Their coats are also thinner, and less pulpy, and not uncommonly they are almost as thin as any membrane of the body." It is, therefore, probable that they depend on a diseased alteration of the parts in which they are seated, and are not distinct organized simple animals. (Baillie Morb. Anat. p. 278.) The hydatid structure of the placenta is a disease not very uncommon, and usually occasions miscarriage; for when it takes place, Mr. Home has remarked, "the natural healthy actions for the support of the fœtus are so much impeded, that its growth is arrested. This evidently happened in a case published, with an engraving of the placenta and fœtus, by Dr. Denman: and when the patient does not early miscarry, the fœtus disappears; and in all the instances where miscarriage has taken place in a more advanced stage of the disease, I believe no fœtus has been found." (Mr. Home, in Trans. of a Soc. for the Improvement of Med. and Chir. Knowledge, vol. 2. p. 300.) The hydatids, in these cases, are commonly small, from the size of a pin's head, to that of a

large pea or common grape, are clustered together, and individually connected with the placenta, or with each other, by a narrow stalk or pedicle. Lieutaud has mentioned the circumstance of large masses of hydatids being found in the uterus. (Hist. Anat. Med. tom. 1. p. 335.) But it is probable, as Dr. Baillie suggests, that these were only hydatids of the placenta which had been retained there. Loc. cit. p. 379.

Hydatids are, perhaps, sometimes found connected with the ovaria: but it is not improbable, as the same author remarks, that the cysts, in ovarial dropsy, have been occasionally confounded with the true hydatids, to which they bear some resemblance. They are, however, really very different. They have much firmer and less pulpy coats than hydatids; they contain a different kind of fluid; and they are differently connected among themselves: for they adhere to each other laterally by pretty broad surfaces; do not inclose each other; and appear to have no power analogous to generation, like hydatids, by which smaller cysts are formed, that are attached to others of a larger size. It appears not improbable, that these ovarial cysts are formed by a gradual enlargement of the small vesicles, which make a part of the natural structure of the ovaria. (Baillie, p. 392.) See *Encysted Dropsy*.

HYDATIDES, ὑδατιδες, of ἕδα, for ὑδαρ, *water*, in *Natural History*, a name given by some writers to a species of astroites, the lineations of which resemble waves. It is by others used as a name of the anhydros.

HYDATIS, in *Medicine*. See HYDATID.

HYDATIS, in *Zoology*. See TÆNIA.

HYDATISM, in *Surgery*, a word used by some writers to express the noise or found made by the fluctuating humours contained in abscesses.

HYDATOCHOLOS, of ἕδα, *water*, and χολη, *bile*, an epithet used by the old writers on medicine for stools more than ordinarily liquid or bilious.

HYDATOIDES, ὑδατοειδης, formed of ἕδα, ἕδατος, *water*, and εἶδος, *form, resemblance*, a name some authors give to the aqueous humour of the eye, inclosed between the cornea and uvea.

HYDATOSCOPIA, compounded of ἕδατος, the genitive of ὑδαρ, *water*, and σκοπεω, *I view, I consider*, called also *hydromancy*, a kind of divination, or method of foretelling future events, by means of water.

There is a natural or allowable kind of hydatoscopia: it consists in foretelling storms, tempests, hurricanes, &c. from natural signs or indications in the sea, air, clouds, &c.

HYDE, EDWARD, earl of Clarendon, in *Biography*, was born at Dinton, in Wiltshire, in February 1608. He was educated in the elements of learning, under his father's roof, by the vicar of the parish, and his progress was so great that he was deemed fit for the university at the age of thirteen. He was intended for the profession of the law, and was entered very early of the Middle Temple. Here he was under the protection of his uncle Nicholas Hyde, afterwards chief justice of the King's-bench. He had the happiness of being introduced early to a very respectable set of acquaintance, among whom were persons of the first rank for talents and learning in the kingdom, such as lord Falkland, Selden, Kenelm Digby, Carew, Waller, Sheldon, Hales of Eton, Chillingworth, &c. of whom he has, in his memoirs, given very characteristic and entertaining sketches. To their conversation and example he has ascribed much of his own greatness, and he has strongly expressed his sense of the benefit of such society, by saying that "he never was so proud, or thought himself so good a man, as when he was the worst man in company." He engaged in a cause on the

the

the part of the merchants of London, which was the means of introducing him to the notice of archbishop Laud, then a commissioner of the treasury, who became very serviceable to him in his future professional advancement. His connections were the means of throwing a deal of business into his hands as a barrister, but he did not so immerse himself in legal pursuits as wholly to neglect polite literature, and by his manner of living, and the company which he kept, he seemed to affect the gentleman rather than the man of business. In the year 1640, on occasion of the Scotch rebellion, he was chosen burgher, and sat in parliament for Wootton-Basset. Almost as soon as he had taken his place in the house of commons, he brought forward a complaint of the illegal practices and oppressions of the earl marshal's court, but the speedy dissolution of the parliament prevented any proceedings upon it at that time. In the new house he sat for the borough of Saltash, and renewed, with so much effect, his attack upon the marshal's court, that he procured its suppression. He now laid aside his business at bar, and gave himself up entirely to the public concerns of the country, and being an independent gentleman, enlisted under the banners of no party, he was frequently appointed chairman of committees in matters of great importance. One of these, was that which drew up the charges against the judges for their decision in the case of ship-money. In this case he opposed the court, but at the same time shewed such an attachment to regal government, and to the established church, that he was regarded with suspicion by the heads of that party. The king was sensible of the obligations he was under to him, and took an opportunity of expressing his sense of gratitude for the services towards himself, and his regard for the national religion. Flattered, perhaps, by his sovereign's condescension, he was from this time looked upon as one of the royal party: he avows that "he had a very particular passion and devotion for the person of the king; and a most zealous esteem and reverence for the constitution of government, which he believed to equally poised, that if the least branch of the prerogative were torn off, the subject suffered by it, and he was as much troubled when the crown exceeded its just limits." When the commons' remonstrance on the state of the nation came out, Mr. Hyde, as he says, only to give vent to his own indignation, and without the least purpose of communicating it, drew up a reply, which, however, he shewed to lord Digby, and at length suffered it to appear as the king's answer with the advice of his council. Soon after this he was offered the place of solicitor-general, which he declined, but agreed to be one of a private consultation on the king's affairs and their management in parliament, with lord Falkland, and sir John Colepepper. In this office he stood apart from the others, by opposing the king's assent to the bill for depriving the bishops of their seat in the house of lords, which, however, his majesty was prevailed on to give. In April 1642, Mr. Hyde was sent for by the king to York; and repairing thither he assisted in drawing up many papers in the royal cause, and in private consultations. The parliament recalled him, but refusing to comply with their order he was exempted from pardon by a special vote. After the commencement of the civil war; Hyde was nominated to the chancellorship of the exchequer, sworn of the privy-council, and knighted. He remained with his majesty till March 1644, when he accompanied prince Charles into the West, and afterwards attended him to the island of Jersey. After the prince left the kingdom, sir Edward Hyde remained in the island two years longer, pursuing his studies in great tranquillity, and attending to the composition of a history of the transactions in which he had borne a conspicuous

part. In 1648 he was ordered to attend the prince at Paris. Upon his arrival he found great differences prevailing between the queen-mother, and the duke of York. The king's court at the Hague was not in a better state of union, and he found so little good to be done by a personal attendance, that he obtained leave to retire to Antwerp, where his wife and children were, with whom he lived in a studious and domestic retreat, and in a style suited to his reduced circumstances. After this he removed to Breda, at the desire of the prince of Orange, the late king's eldest daughter, who proposed to take his daughter as one of her maids of honour, to which, with much hesitation, he agreed. In 1657 he was appointed to the post of lord chancellor of England, which he very unwillingly accepted, properly judging that it was ridiculous, as the office proceeded from a king without a kingdom, but it appeared that Charles, not able of himself to reject the importunities of those who were continually applying to him for contingents, grants, and reversions, wished to throw the burden upon one who had firmness enough to refuse improper requests. At the Restoration, the chancellor might be considered as the king's first and most confidential minister; and it is agreed, that he displayed great wisdom and integrity in settling the many difficult affairs which this event brought for decision. He is particularly praised for rejecting the proposal of raising a great standing revenue, which would have made the king independent of future parliaments; and for the earnestness with which he proceeded to disband the army. He also moderated the forward zeal of the royalists, and checked their appetite for revenge. His honours naturally rose with his power, and in 1660 he was created a peer, and elected chancellor of the university of Oxford, and in the following year he was advanced to the titles of viscount Cornbury and earl of Clarendon. He also received various grants from the crown, which rendered his estate adequate to his dignity. A short time after the king's return, it was discovered that his daughter, at the prince of Orange's court, had attracted the notice of the duke of York, who, failing of success in an attempt to obtain her favours upon easy terms, had entered into a private contract of marriage with her. Lord Clarendon was excessively indignant at this transaction, and advised the king to send his daughter to the Tower, and bring her to condign punishment. The king, however, felt less keenly on the subject, and behaved with great justice and propriety in the business, though the duke basely denied his marriage, and even encouraged scandalous reports against his wife. The queen-mother also expressed the utmost rage at the connection, but she was nevertheless at length acknowledged as duchess of York, and eventually gave two queens to England. This marriage was made a step for alienating the king from his chancellor, and in 1663 the earl of Bristol exhibited various charges against him in the house of lords, which he was unable to substantiate, and which terminated greatly to the honour of the chancellor. Many other charges were brought against him; his opposition to a bill for liberty of conscience, and many of his public measures rendered him very unpopular: his admonitions of a corrupt prince alienated from him his sovereign's affection, so that, notwithstanding all his faithful services to the crown, he was, without reluctance, given up as a sacrifice to the national odium. In August 1667, he was required to resign the great seal, and was at the same time removed from all offices of public trust. He was afterwards impeached of high treason by the house of commons, but the lords refused to commit him upon their charge, and during the debates upon this head he received the king's commands to withdraw from the kingdom. Before his departure he sent an apology to the

house of peers, which was voted to be a libel, and burnt by the hands of the common hangman. A bill was now passed against him as a fugitive from justice. He landed at Calais, but received an order from the court of France to quit their territory instantly. A fit of illness rendered this impossible, and he finally obtained permission to reside in that country. He had nearly lost his life by an attack of some English seamen, with whom he was very unpopular; after this he proceeded to Montpellier, where he employed himself in writing a vindication of his conduct. He died at Rouen, in the month of December 1674. His body was brought to England and interred in Westminster-abbey. He left several children, of whom his eldest son succeeded him. Lord Clarendon was author of "Contemplations and Reflections on the Book of Psalms:" "A brief View of the Errors in Hobbes' Leviathan:" "The History of the grand Rebellion," in three volumes folio, to which was added his life, and a continuation of his history published in 1759, by the university of Oxford. This, his great work, is regarded as a valuable source of information on the events of that unhappy period. According to Mr. Hume, it is, excepting Whitelock's memorials, the most candid account of those times composed by any contemporary author. Clarendon, says the same historian, was always a friend to the liberty and constitution of his country. It is said that when he first engaged in the study of the law, his father exhorted him with great earnestness to shun the practice, too common in that profession, of straining every point in favour of prerogative, and perverting so useful a science to the oppression of liberty, and in the midst of these rational and virtuous counsels, which he reiterated, he was suddenly seized with an apoplexy, and expired in a few hours in his son's presence. As an historian, Clarendon will ever be esteemed as an entertaining writer, even independently of our curiosity to know the facts which he relates. He is more partial in appearance than in reality. He is less partial in his relation of facts than in his account of characters: he was too honest a man to falsify the former; his affections were easily capable, unknown to himself, of disguising the latter. "An air of probity and goodness," says Hume, "runs through the whole work, as these qualities did in reality embellish the whole life of the author." See Hume's Hist. vol. vii. octavo. Biog. Brit.

HYDE, THOMAS, a most profound Oriental scholar, who flourished in the seventeenth century, was born at Billingsley, near Bridgenorth, in Shropshire, in the year 1636. He received the elements of a learned education under his father's instructions, and at the age of sixteen he was entered of King's college, Cambridge. In the course of two years he was sent to London to the learned Walton, afterwards bishop of Chester, as a person very capable of assisting him in preparing for publication the grand polyglot bible, on which he was then engaged. Mr. Hyde rendered this undertaking the most essential services: he transcribed the Persian Pentateuch out of the Hebrew characters, in which it was first printed, at Constantinople, into the proper Persian characters. Of this Pentateuch, Mr. Hyde added a Latin translation; and he further assisted in correcting different parts of Walton's work, in the Arabic, Syriac, and Samaritan languages. In 1658 Mr. Hyde went to Oxford, and was admitted of the Queen's college, and soon afterwards appointed Hebrew reader in that society. Soon after the restoration of king Charles II. Mr. Hyde was made under-keeper of the Bodleian library, which furnished him with ample opportunities of prosecuting his favourite studies with singular advantage, and in 1665 he was elected to the office of head-keeper. In the same year he published "Versæ Latinae

Lingua Persica, et Commentarii in Observationes Ulug-Beigi, de Tabulis Longitudinis, et Latitudinis Stellarum fixarum." About the time when this version was published, Mr. Hyde became acquainted with the great Mr. Boyle, to whom he communicated several remarkable passages relating to chemistry, physics, and natural history, which he had collected from Oriental writers. In 1666 he was promoted to a prebend in the cathedral church of Salisbury, and in the following year he published "Quatuor Evangelia, et Acta Apostolorum, Lingua Malaicâ, Characteribus Europæis," printed at the expence of Mr. Boyle. In 1674 he gave the world "Catalogus impressorum Librorum Bibliothecæ Bodleianæ in Academia Oxon:" and in 1678 he was made archdeacon of Gloucester. Two years after this he was admitted to the degree of doctor of divinity, and from this period he was frequently giving additional proofs of his unremitting study, and singular skill in all kinds of Oriental learning. An account of his several learned works will be found in the Biographia Britannica, and also in a more abbreviated form in the General Biography. In 1697, Dr. Hyde was appointed regius professor of Hebrew, and canon of Christ-church. Shortly after this he published "the Religion of the ancient Persians." Dr. Hyde's profound skill in Oriental literature, and desire to promote it, would have led him to publish many more learned works than he did, could he have obtained encouragement from the public. The want of this obliged him to decline running the risk of printing any thing more, and on a similar account the writings which he left behind him were suffered to lie neglected, till it was too late to recover them, though the loss has ever since been regretted by the learned, and those who knew how to estimate their value. In 1701 Dr. Hyde resigned the office of head-keeper of the Bodleian library, on account of his great age and infirmities. During the reigns of Charles II., James II., and William III. he had occupied the post of interpreter and secretary in the Oriental languages; and in the course of his employment, had made himself most intimately acquainted with the policy, ceremonies, and customs of the Oriental nations. Dr. Hyde died in the year 1702, at his apartments in Christ-church, in the sixty-seventh year of his age. We shall transcribe the character of this great man as given by Granger: "Dr. Thomas Hyde," says he, "is a great character, but is much less known than he deserves to be, because the studies in which he was occupied are but little cultivated. Those that are acquainted with the Oriental languages, are astonished at the progress which was made in them by one man, though aided by the power of genius, supported and strengthened by incessant industry. There never was an Englishman, in his situation of life, who made so great a progress in the Chinese. Bochart, Pococke, and Hyde, are allowed to be the greatest Orientalists that any age or nation have produced. I am informed that Dr. Hyde's mind had been so much engrossed by his beloved studies, that he was but ill qualified to appear to any advantage in common conversation." Dr. Gregory Sharpe, master of the Temple, collected and republished some of his pieces which were formerly printed. These made their appearance in two volumes quarto, under the title of "Syntagma Dissertationum et Opuscula." Anthony Wood has preserved a catalogue of MSS. which Dr. Hyde had either completed, or in part prepared for the press. Biog. Brit.

HYDE, in *Geography*, a maritime county of America, in Newbern district, North Carolina, bounded E. by the ocean, W. by Beaufort county, N. by Tyrrel, and S. by Carteret, it contains 4783 inhabitants, of whom 1386 are slaves.

HYDE of Land. See HIDE.

HYDE-gild. See HIDE-gild.

HYDEPARK, in *Geography*, a township of America, in Orleans county, in Vermont; containing 110 inhabitants.

HYDER ALLY, in *Biography*, was a soldier of fortune in the East, and the son of a person who served in quality of a "killatar," or governor of a small fortress, to one of the kings of Myfore. He is said to have acquired the rudiments of war in the French camps; and in the year 1753, distinguished himself as their auxiliary, in the plains of Trichinopoly. About 10 years afterwards, being then at the head of the Myfore army, he dethroned his sovereign, and governed under the title of regent. Soon after, he extended his dominions on every side, the Carnatic excepted: the fine province of Bednore (or Biddanore) and the Patan nabobships of Cuddapah, Canoul, &c. besides some Mahratta provinces towards the river Kistnah, and the country of the Nairs, and other small states on the Malabar coast, were added to his original possessions; until at last he was at the head of a state, in extent equal to Great Britain, and producing a gross revenue of four millions sterling. The civil broils and revolutions in the western Mahratta state, particularly in latter times, allowed Hyder to aggrandize himself at its expence, but not without receiving some severe checks from that quarter. Before he had arrived at the height of his power, the war between him and the English broke out in 1767; nevertheless his power alarmed his neighbours, and a resolution was formed for attacking him. The Mahrattas under Maderow entered Hyder's country on the side towards Vissapour; and the Nizam, joined by a detachment of British troops, moved from Hydrabad towards the frontier of Myfore, soon after. Hyder first contrived to buy off the Mahrattas with a large sum of money, and the restitution of some of the places which he had taken from them. He next negotiated with the Nizam, and succeeded not only in detaching him from the English, but in drawing him over to his party: so that the English detachment was compelled by necessity to retire to the Carnatic; on the frontiers of which their great army was now assembling. The superiority of the Nizam in the Carnatic had been always nominal; however, Hyder who now meditated the conquest of it, was glad to obtain from the Nizam a grant, or "fannud," for the nabobship of it; and from this time, at least, he considered Mahomed Ally as his rival. In the days of this last mentioned prince's distress, when he possessed only a small part of the Carnatic, he had engaged to cede the fortresses of Trichinopoly, a most important post in the southern division of it, to the king of Myfore, for the assistance then afforded him; but this engagement never being performed, Hyder adopted the claims and resentments of the prince, of whose throne he had taken possession; and never lost sight of his title to Trichinopoly. In the war that immediately ensued, a strong detachment of the British army seized on Hyder's province of Coimbatore, a fertile district on the south of Myfore, and commanding a ready pass to Hyder's capital, Seringapatam. During the years 1767, 1768, and part of 1769, the war was continued with various success. (See HINDOOSTAN.) In 1771 Hyder suffered a total defeat from the Mahratta army within a few miles of his capital, into which he escaped with great difficulty, and after having sustained a great loss. Here, as his enemies had neither skill nor the ordinary requisites for a siege, he remained unmolested, and patiently waiting the retreat of his enemies after they had desolated the country. Some subsequent years of peace very much improved both his army and revenues; and the distractions that subsisted among the Mahrattas afforded him an opportunity of extending his territories at their expence. Hyder's projects of ambition were counteracted by two unsuccessful campaigns, in which he combated with the British troops under sir Eyre Coote; so that

in October 1782, he was reduced to the necessity of earnestly wishing for peace. Soon after Hyder died, and was succeeded by his son Tippoo. (See HINDOOSTAN.) Major Rennell, at the close of the short abstract which he has given in the introduction to his "Memoir" of the history of Hyder, subjoins the following outline of his character, which, as he conceives, has been little understood. "His military success, founded on the improvement of discipline; attention to merit of every kind; conciliation of the different tribes that served under his banners; contempt of state and ceremony, except what naturally arose from the dignity of his character, and his consequent economy in personal expences (the different habits of which form the chief distinction of what is called character among ordinary princes) together with his minute attention to matters of finance, and the regular payment of his army:—all these together raised Hyder as far above the princes of Hindoostan, as the great qualities of the late Prussian monarch raised him above the generality of European princes; and hence I have ever considered Hyder as the FREDERIC of the East. Cruelty was the vice of Hyder; but we are to consider that Hyder's ideas of mercy were regulated by an Asiatic standard; and it is not improbable that he might rate his own character for moderation and clemency, as far above those of Tamerlane, Nadir Shah, and Abdallah, as he rated his discipline above theirs."

HYDERGUNGE, in *Geography*, a town of Hindoostan, in Oude; 21 miles W.N.W. of Fyzabad.

HYDERGUR, a town of Hindoostan, in Bednore; nine miles S.W. of Bednore.

HYDNOPHYLLUM, or **HYDNOPHYLLON**, in *Botany*, a name given by the ancient Greeks to a plant which they tell us grew on those places where the tubera or truffles lay underneath.

HYDNORA. See **APIRYTEIA**.

HYDNUM, an ancient name adopted by Linnæus, but misapplied, as the *ἵδιον* of Dioscorides, *ἵδιον* of Theophrastus, so called from *ἵδεναι*, to swell, is the Truffle or *Tuber*.—Perfoon Syn. Fung. 554. Linn. Gen. 568. Syst. Veg. ed. 14 978. Schreb. 769. Mart. Mill. Dict. v. 2. (Erinaceus; Dill. Giff. 188. Mich. t. 72.) Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Ess. Ch. Cap turbinate; smooth above; echinated beneath with awl-shaped fibres.

Obs. These awl-shaped bodies which Linnæus compares to the prickles of a hedge-hog, are soft, solid, conical, or cylindrical substances, emitting seeds from every part of their surface. *Bulliard*.

This is a very extensive genus of *Fungi*, Perfoon in his Synopsis having described 26 species, most of which have been figured either by Sowerby, Bulliard, Jacquin, or Schrader.—Linnæus was acquainted with only six species of *Hydnum*. These plants are chiefly found in moist situations upon the decayed trunks of trees. It will be sufficient to enumerate a few of the most striking species.—*H. imbricatum*, Sowerb. Fung. t. 73, was communicated from lord Ongley's plantations in Bedfordshire. Its colour is a dusky yellow, having a reddish brown border.—*H. repandum*, t. 176, is found plentifully in Peckham and Hornsey woods, during autumn. This is of a fine reddish buff colour, and very brittle in substance.—*H. Davisii*, t. 15, is a small yellow or brown fungus; when fresh of a pure white, more rare than beautiful, very similar in texture to *Boletus versicolor*, and was first discovered in Angelsea by the Rev. H. Davies.—*H. sublamelliforme*, t. 112, of a delicate white colour, was sent from Bedfordshire by the Rev. Dr. Abbot.—*H. auriscalpium*, *Barba Jovis*, *coralloides*, *membranaceum*, and *ramosum*, less conspicuous species are also figured by the same author. *H. auriscalpium*, beautifully displayed

in Curt. Lond. fasc. 3. t. 68, is of a brownish colour and grows upon the cones of fir-trees. Curtis mentions it as an excellent example of this genus for the instruction of a young botanist.

Most *Hydra* are furnished with stems, but not all. *H. parasiticum* is the only Linnæan species that is stemless.

HYDRA, in *Astronomy*, a southern constellation, consisting of a number of stars, imagined to represent a water serpent. The stars in Hydra, in Ptolemy's Catalogue, are twenty-seven; in Tycho's, nineteen; in Hevelius's, thirty-one; and in the Britannic Catalogue, sixty. See **CONSTELLATION**.

HYDRA, in *Geography*, a small island in the Grecian Archipelago, about 10 miles long, and two broad. N. lat. 37° 20'. E. long. 23° 30'.—Also, a town of Africa, in the kingdom of Tunis, on the frontiers of Algiers, situated in a narrow valley, near a running stream and the site of extensive ruins; 90 miles E.S.E. of Constantina.

HYDRA of Lerna, in *Mythology*, a terrible monster, born of Typhon and Echidne, according to Hesiod; which was destroyed by Hercules. The poets represent it sometimes as a serpent, branched out into several other serpents, and sometimes with a human head, bearing serpents instead of hair; and they add, that when one of the serpents heads were cut off, a double head sprouted in its place.

This hydra with many heads is said to have been only a multitude of serpents, which infested the marshes of Lerna, near Mycenæ, and which seemed to multiply as they were destroyed. Hercules, with the assistance of his companions, cleared the country of them, by burning the reeds in which they lodged. See **HERCULES**.

HYDRA, in *Zoology*, a generic name of the polypes. See **POLYPE**.

HYDRA is also a synonymous name given by different authors to various animals, as, for instance, by Linnæus to *Tænia globosa*, by Bohadsch to *Holothuria tubulosa*, and again by Linnæus with the specific term of *glomerata* to *Corallina pencillus*.

HYDRABAD, or **BAGNAGAR**, in *Geography*, a city of Hindoostan, and capital of a province, to which it gives name, now called *Golkonda*, (which see,) is the present capital of the Nizams of the Deccan; who, since the dismemberment of their empire, have left Aurungabad, the ancient capital; which is not only in a corner of their dominions, but in that corner which lies near their hereditary enemy, the Poonah Mahrattas, and which is also the least defensible. Hydrabad was formerly only a palace of pleasure, and celebrated for the beauty of its gardens and delightfulness of its situation; but in the 16th century, the king of that period was induced, by the persuasion of one of his wives, to build a city, after whom he called it Bagnagar, or the gardens of Nagar. It is of large extent, surrounded with walls, and defended with towers; and is supposed to contain upwards of 100,000 inhabitants. The suburbs are extensive, and inhabited by merchants and tradesmen; 352 miles N.N.W. of Madras. N. lat. 17° 12'. E. long. 78° 51'.

Hydrabad is also the name of a fortress of Hindoostan, situated on the Indus, not far above the head of the Delta, and in the vicinity of Nasserpouree; the usual place of residence of the prince of Sindy.

HYDRACHNA, in *Entomology*, a genus of the apterous order, established by Müller, the character of which, as reduced by Gmelin to the arrangement of the "*Systema Naturæ*," consists in the head, thorax, and abdomen being united; the feelers jointed and two in number; the eyes either two, four, or six, and the legs eight.

Till within the space of the last few years, almost every

author, not excepting Linnæus and Geoffroy, have confounded the hydrachna with the acarus tribe; while, from their similarity of aspect, the globular form of the body, and the length of their feet, these insects were considered by general observers as no other than a race of spiders, to which the significant appellation of aquatic was most commonly annexed, because they inhabit watery places, and thus appear from their habits, though not in form, to constitute a distinct family from the true or terrestrial spiders. Both Roefel and Degeer have entered with a peculiar share of minuteness into the history of these animals; and it is more than probable the observations of these naturalists might furnish many very useful suggestions to the ingenious Müller, whose monograph on this curious race appeared in 1781. This conjecture is doubtless correct, but nevertheless the tract, or rather history, published under the title last mentioned, contains a fund of new and valuable information; it elucidates in a very comprehensive manner their internal as well as external conformation, and besides, condenses into one point of view a series of no less than fifty distinct species, the far greater part of which was totally unknown to any of his predecessors. These species are divided into three families, according to the number of eyes in each, which are either two, four, or six; those of the first division have the body of the male terminated in a kind of tail or elongated process.

After the publication of this useful work the genus hydrachna, as proposed by that author with some slight amendments or deviations, was embraced by the generality of naturalists, and still continues to be approved by the best authorities. Fabricius is indeed an exception; that excellent entomologist perhaps, without mature consideration, and certainly without affording us any reasonable grounds for believing he was so well acquainted with this tribe of creatures as Müller, rejects the genus altogether, and refers the few species he describes, which really belong to that tribe, to his genus *Trombidium*. Gmelin, on the contrary, differs from Fabricius in this respect, and adopts the genus together with its numerous species as described by Müller. The most material, and in our opinion the most able deviation from Müller, hitherto proposed, is that submitted by Latreille; this very assiduous and intelligent naturalist agrees with Müller in considering the hydrachna as a distinct natural family, but instead of allowing them to remain with the insect tribe in conformity with preceding writers, he referred them in the first instance to the crustacea, and since that time to the Arachnides, in which latter they constitute his family *Hydrachnelles*. The *Hydrachnellæ* of this writer are divided into three different genera, *eylais*, *hydrachna*, and *limnochare*; the first of which is furnished with mandibles, as we find exemplified in the Fabrician *Trombidium extendens*. That to which the name of hydrachna is retained has no mandibles, and is furnished with a projecting siphon in the form of a beak, the feelers are advanced, and have a moveable appendice, and the body is of a globular figure: *Trombidium geographicum* of Fabricius is an illustrative example of this genus. The *limnochare* genus has no mandible; a siphon not at all, or very little projecting; feelers curved, without appendices, and the body depressed; the Linnæan *Acarus aquaticus* is of this genus.

The hydrachnæ, as we have before said, are vulgarly called water spiders; they are all of the aquatic kind, residing among plants that grow in the water, or in the banks of ditches, and other situations contiguous to their favourite element. When in the water they swim with great facility by means of their feet, which in most species, when attentively examined, appear ciliated, and admirably adapted for that purpose;

their skin is thick, and their body covered more or less with down, hair, or spines. The females are larger than the males, and often different in colour. In general their colours are remarkably bright, and possess a peculiar degree of brilliancy when seen in the water; the prevailing hues red or green, and silvery. They are excessively abundant in spring, and some of the species are almost constantly seen at that season of the year, on the surface of stagnant pools of water: they couple in the midst of summer, and deposit their eggs in clusters, chiefly among the weeds; these eggs are of a red colour, and at first spherical, but afterwards change to a femilunar form; the larvæ are furnished with six feet, and have a proboscis of very singular structure. The hydrachnæ prey upon the larvæ of the tipulæ and monoculi, and the juices of decayed vegetables, and are themselves the food of fishes, of many insects that reside in the water while in the state of larva, of polypes, and many of the larger kinds of aquatic worms.

Species.

* *Section. Eyes two; Body tailed.*

GLOBATOR. Globular; eyes red. Müll.

Abundant in ditches, and other stagnant waters; the male greenish spotted; female blueish, without spots, and twice the size of the male.

TABULATOR. Globular, yellowish, with spotted disk; tail cylindrical and equal. Müll.

Inhabits stagnant waters, and in some respects resembles the former.

BUCCINATOR. Obovate, red, behind black; tail cylindrical, yellow and narrow at the base. Müll. *Trombidium caudatum*, Fabr. *Acarus caudatus*, Degeer.

Lives in banks, the body beneath black; eyes reddish; legs black.

CUSPIDATOR. Brown, truncated before, and mucronated behind; tail depressed and bidentated. Müll.

Body depressed, and broader on the anterior part; behind narrow, and armed with an erect triangular spine; eyes black; legs pale. Lives in fish-ponds.

PUSTULATOR. Gibbous, red; tail depressed, with obtuse angles. Müll.

Body smooth, and generally covered with animalcules of the vorticella tribe. In grassy streams.

ALBATOR. Rounded, grey, with a white disk; tail depressed, and armed with three teeth. Müll. *Acarus globosus*, &c. Schranck. *Acarus fluvialilis*, Ströem.

Found in fish-ponds.

MACULATOR. Rounded, cinereous, spotted, and mucronate behind; tail depressed, and armed with three teeth. Müll.

In ditches; breast whitish; legs green.

TRICUSPIDATOR. Red, with a triple gibbosity on the back; tail depressed, and three-toothed. Müll.

The body is somewhat reticulated; breast blackish; feelers and legs whitish. Found in pools.

EMARGINATOR. Red, with the back gibbous; tail depressed and emarginate. Müll.

Feelers and legs greenish. Occurs in boggy situations.

SINUATOR. Grey; the back yellowish on the fore part, and tripunctated behind; tail depressed and sinuated. Müll. Body reticulated; feelers and legs white. Found in stagnant waters.

INTEGRATOR. Green and without spots; tail depressed and entire. Müll.

Found in ditches; the body roundish oval, depressed, and contracted behind; breast yellowish; legs hyaline.

PAPILLATOR. Rounded, purple with an excrescence each side the tail; legs black.

Inhabits wet meadows.

** *Section. Eyes two, Body marked with a Fork.*

GROSSIPES. Nearly square, white, with three spots and a rufous fork; anterior legs thick.

Body pellucid and glabrous; legs twice as long as the body. Inhabits ditches.

CRASSIPES. Obovate; black, the disk black with a reddish fork; tail papillous; anterior legs thick. Müll.

Found in fish ponds and dykes; legs three or four times the length of the body; pellucid; breast whitish; eyes black.

GROSSIPES. Nearly square, white, with three spots and a rufous fork; anterior legs thick. Müll. Geoffr.

Inhabits fish-ponds; body glabrous; legs twice the length of the body.

CLAVICORNIS. Obovate, rufous with a yellow fork; feelers clavated; legs pale. Müll.

Found in ponds; the eyes black; legs and feelers white.

SPINIPES. Oval, greenish yellow, with eight dots and a rufous fork; legs spinous. Müll.

Inhabits pools. The body polished, with the eyes, breast, legs, and dots on the back black.

LONGICORNIS. Nearly square, white with five brown spots and a rufous fork; feelers long. Müll.

Frequents rivulets; pellucid; eyes black; breast pale yellow.

VERNALIS. Oval, greenish with a deeper disk, and rufous fork. Müll.

Inhabits overflown meadows; and has the appearance of a grey dot; the legs white.

LUNIPES. Oval, white, spotted, with a clear white fork; fourth joint of the posterior legs lunated. Müll.

Found in ditches, the body pellucid, with large eyes, and the legs and feelers pale.

TRIFURCALIS. Oval, whitish, with a brown back and triple silvery fork. Müll.

Frequents wet meadows; the feelers ending in a claw, and with the legs pale greenish white; eyes black; abdomen beneath, sometimes brown with a white line.

ORBICULARIS. Depressed, orbicular, pale yellow with black spots on the disk and a rufous fork. Müll.

Eyes black; legs white. This species occurs in rivers.

STELLARIS. Globular, blue, with a cinereous back and stellated fork. Müll. Subzer, &c.

In the banks of rivulets; the body of this kind is reticulated; and the legs somewhat longer than the body.

OVALIS. Ovate, compressed, greenish and flattish above, carinated and yellow brown beneath; feelers placed beneath. Müll.

Found in overflown meadows. Eyes and legs black.

ELLIPTICA. Rounded, blue with fulvous spots and dots. Müll. *Acarus maculatus aquaticus*, Degeer.

A scarce species found in rivers; eyes black; legs white, breast, tail, and posterior margin yellowish.

ORBICULATA. Depressed, orbicular, violet, with a white spot and circle. Müll.

Breast fulvous with the tip green; feelers and thighs whitish; eyes black. Inhabits muddy ditches.

LUGUBRIS. Globular, brownish, with black streaks; legs green. Müll.

In boggy places; eyes black; feelers green.

TRUNCATELLA. Grey, oblong, truncated behind, with dusky dots and lines. Müll.

Inhabits marshes; eyes black, feelers white.

*** Section. Eyes two; Body glabrous.

DESPICIENS. Rounded, red, with numerous spots; eyes placed beneath. Müll. *Aranca aquatica*, Frisch.

Found in ditches; body slightly depressed, thick and wrinkled; eyes blackish; legs pale yellow.

GEOGRAPHICA. Spherical, black with four scarlet spots and dots. Müll. Roef, &c.

The largest and most beautiful of its genus; eyes, feelers, and last joint of its legs red. Inhabits ditches.

ABSTERGENS. Globular, red without spots; legs black. Müll. Roef., &c.

Inhabits stagnant waters; lines on the body beneath, with the eyes and legs black.

EXTENDENS. Rounded, red; hind legs contracted. Müll.

In ditches; body convex, and shining.

CRUENTA. Distended, red; legs equal. Müll. *Trombidium globosum*, Fabr. *Acarus aquaticus globosus*, Degeer.

Found in overflown meadows; eyes red; feelers downy.

IMPRESSA. Distended, red, with impressed dots; feelers short. Müll. *Acarus aquaticus ruber*, Degeer. *Acarus holosericeus subglobosus aquaticus*, Schranck.

Found in marshes; a supposed variety has the feelers longer.

OVATA. Obovate, grey-brown, with a triangular fulvous spot; legs pale black. Müll.

Another analogous kind, an apparent variety of ovata, has the body marked with a fulvous cross, and the legs with the eyes and feelers black. Both are found in ditches.

LUNARIS. Oval, rufous, with a black lunate spot on the back. Müll.

Inhabits fish-ponds; the eyes are black, and the legs grey.

LILIACEA. Obovate and whitish, the disk lily-white, with a black spot each side. Müll.

The feelers, legs, and breast are pale, the latter spotted with black. This kind inhabits fens.

TORRIS. Oval, yellowish, with lateral black spots, and red in the middle; hind shanks lamellated. Müll.

Found in ditches, the eyes black, and legs white.

STRIGATA. Oblong, yellowish-green, the fore part depressed, with two blackish streaks united behind. Müll.

Near the banks of rivers; the eyes are black; feelers and legs white.

OBSOLETA. Rounded, reddish-brown, with a double obsolete streak behind the eyes. Müll.

Frequents the waters of woody situation; the eyes are black; feelers pellucid; and the legs pale-brownish.

NODATA. Red, truncated before, and spotted each side; posterior legs knotty. Müll.

Occurs in ditches; the eyes are black; feelers annulated; legs yellowish and longer than the body.

COMPLANATA. Green, depressed, and emarginate before, with a white band in the middle. Müll.

The body elliptic; eyes black; legs and feelers pellucid.

MUSCULUS. Green, oval, compressed, grooved above, beneath carinated. Müll.

Varies in colour; the eyes are black, feelers white, and pellucid. Found in marshes.

LATIPES. Oval, yellowish, and spotted each side; fourth joint of the posterior legs dilated. Müll.

In marshes; the legs pale-blueish, with the tip brown.

VERSICOLOR. Nearly square, with whitish, blue, and brown spots. Müll.

Found in wet meadows; the body white, beneath brown, with a yellow margin; feelers and legs pellucid, white.

**** Section. Eyes four.

CALCAREA. Rounded, brown, with a clear white disk. Inhabits marshy woods; the eyes are black; feelers pointed, and the legs pale and pellucid.

FUSCATA. Ovate, reddish-brown, with a darker disk, and pale rufous fork. Müll.

The body is convex, and spotted on the back; eyes black; legs and feelers white and pellucid. Found in muddy ditches.

UNDULATA. Oval, pale-yellow, with flexuous black streaks. Müll.

In marshes. The body sub-globular, pellucid, with black eyes.

MACULATA. Oval, red, with black spots on the back. Müll.

Eyes black; legs and feelers pale-yellow, and pellucid.

***** Section. Eyes six.

UMBRATA. Rounded, red, with numerous darker spots Müll.

Inhabits marshy woods; the body glabrous, sub-depressed with ten darker spots above, beneath blackish; eyes black; feelers yellowish at the tip; legs yellow.

HYDRAGOGUES, **HYDRAGOGA,** ἡδραγωγός, from ἡδρα, water, and ἄγω, to draw, in Medicine, an application given to those purgatives which produce copious watery stools.

The most acrid and drastic purgative drugs are those to which the epithet of *hydragogue* is particularly applicable; not as the ancients conceived, because they have a particular attraction for the watery part of the circulating fluids; but because, by their powerfully stimulant operation on the mouths of the exhalent arteries, which open every where along the inner surface of the intestinal canal, they occasion those vessels to pour out their fluids in great abundance, and thus render the stools thin and watery. Of the more active hydragogues in modern use are the elaterium, scammony, camboge, &c.: jalap, calomel, colocynth, and some other substances of a less acrid quality, when administered in large doses, likewise excite a copious excretion of watery fluids from the intestines. Some caution is requisite in the administration of these active cathartics, especially in habits originally delicate or weakened by disease, or in those whose bowels are peculiarly irritable. Fainting, convulsions, and even death have been the consequence of excessive purging: these results appear to have been not very rare among the ancients, who were obliged to have recourse to such medicines as white hellebore, when a considerable catharsis was necessary. "Convulsio post helleborum lethale," is an aphorism more than once expressed by Hippocrates. A *hypercatharsis*, with bloody stools, is a more common consequence of hydragogue purging in modern times. See **HYPERCATHARSIS**.

Drastic hydragogues are seldom indicated, except in dropsy especially of the belly, in which a copious watery discharge from the intestines occasionally effects a cure of the disease;—or in cases of paralytic torpor extending to the bowels, in hemiplegia;—or in the painter's cholera, after the spasm has been relaxed by opiates. In enteritis, or inflammation of the bowels, hydragogues should be cautiously shunned, notwithstanding the constipated state of the canal; for since the constipation arises from the inflammatory condition of the intestines, every acrid stimulant applied to them must inevitably augment, rather than alleviate the disease. See **CATHARTIC**.

HYDRANGEA, in Botany, from ἡδρα, water, and ἄγω, a vessel, so named by Gronovius, in allusion to the pitcher-like shape of the seed-vessel. Linn. Gen. 222. Schreb.

299. Willd. Sp. Pl. v. 2. 633. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 76. Juss. 310. Lamarck. Dict. v. 3. 150. Illustr. t. 370. Gært. t. 30. (Hortensia; Juss. 214. Primula; Loureir. Cochinch. v. 1. 104.) Class and order, *Decandria Digynia*. Nat. Ord. *Succulentæ*, Linn. *Caprifolia*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, superior, five-toothed, permanent, small. *Cor.* Petals five, equal, roundish, larger than the calyx. *Stam.* Filaments 10, longer than the corolla, but sometimes alternately longer and shorter themselves; anthers roundish, twin. *Pist.* Germen roundish, inferior; styles two, short, distant; stigmas obtuse, permanent. *Peric.* Capsule roundish, twin, the double style forming two beaks to it, angulated with many nerves, crowned by the calyx, two-celled by a transverse partition, opening by a hole between the horns. *Seeds* numerous, angulated, pointed, very small.

Ess. Ch. Calyx superior, five-toothed. Corolla of five petals. Capsule of two cells and two beaks, containing many seeds.

1. *H. hortensis*. Chinese Guelder-rose. Willd. Sp. Pl. No. 2. Sm. Ic. Pic. t. 12.—“Leaves elliptical, serrated, very smooth. Stamens all of an equal length.”—This shrub is a native of the East, and is usually cultivated in the gardens of China and Japan, from whence it was introduced into Kew gardens by Sir Joseph Banks in 1790.—*Root* fibrous, much branched, whitish. *Stems* erect, shrubby, having a smooth brown bark. *Branches* opposite, leafy, green, speckled with dark purple spots, flowering at the top. *Leaves* opposite, spreading and curved backwards, bright green, veiny. *Clusters* of flowers terminal, of a beautiful rose-colour, inodorous, green when young as well as in decay. *Calyx* only seen by us in a luxuriant state of deformity, very large, composed of four (rarely three or five) spreading unequal, obovate leaves, which are entire, smooth, rose-coloured, slightly ribbed and permanent. *Petals* generally four, nearly equal, small, obovate, concave, of the colour of the calyx, fading. *Filaments* awl-shaped, red; anthers greyish, with yellow pollen. *Styles* purple.

This plant, which is nearly allied to *Viburnum* and *Sambucus*, is much esteemed for its very elegant flowers and easy culture. We have selected *H. hortensis* for a specimen of the genus, as it is the most beautiful species, out of the four described by Willdenow. The others, *H. arborescens*, *radiata*, and *quercifolia*, are of American origin, tolerably hardy in the gardens of Europe.

HYDRANGEA, in *Gardening*, comprehends plants of the shrubby and flowering perennial kinds; of which the species cultivated here are; the shrubby hydrangea (*H. arborescens*); and the garden hydrangea, or Chinese guelder rose (*H. hortensis*.)

The latter of these sorts is held in high estimation on account of the number of elegant flowers which it displays.

Method of Culture.—The first of these plants is increased by slipping off or parting the roots in the early autumn, and planting them out where the plants are to grow. It succeeds best on a moist soil, and requires no trouble but being kept free from weeds, by digging the ground about it in the winter. When the stems are destroyed in severe frosts, new ones are put forth in the ensuing spring season.

And the second sort is easily increased by planting cuttings of the young shoots, in pots of rich loamy earth in the spring, plunging them in a moderate hot-bed. When they have stricken good root, they should be removed, with balls of earth about their roots, into separate pots, and be placed in the green-house or under other similar protection.

But though this plant is capable of standing the open air

in mild winters, in warm dry situations, it does not flower so well as in the green-house. Superfluous plants should therefore only be employed in this way as they may frequently be destroyed.

These are ornamental plants; the former in fronts of clumps and borders, and the latter among green-house collections and other potted plants, where it produces a fine appearance during the flowering season.

HYDRAOTES, in *Ancient Geography*. See RAUVEE.

HYDRARGYROSIS, a term used by the chirurgical writers to express the anointing of the body with a mercurial unctio, in order to the raising a salivation.

HYDRARGYRUM, Ἵδραργυρον, a name given to mercury, or quicksilver.

The word is formed of ἵδρα, *agua*, *water*, and ἀργυρος, *argentum*, *silver*; *q. d.* *water of silver*, on account of its resembling liquid or melted silver. For an account of mercury and its different preparations, see MERCURY.

HYDRASPIS, *water shield*, or *water buckler*, a machine of wood, invented by John Christopher Wagenfeil, a German, by the help of which a person may walk on the water, without fear of sinking. It encompasses the breast, serving the office of the chest in water-fowl, and is furnished with apertures for receiving a quantity of food, or for preserving money, writings, or other valuable things, in case of an inundation. The person who uses it is provided with paddles for the feet, consisting of moveable flaps of very thick leather, which open and shut, and are fastened to a wooden sole, on which the foot rests, by an iron pin passing through their hinges. They are fastened to the feet by straps or thongs. The inventor of this machine made trial of it in a whirlpool of the Danube, where he moved about in the current without danger. He proposes, that this machine should be used in a shipwreck, in escaping the danger of sudden inundation in passing a river, for the service of war, and hunting and taking water-fowl, &c. Aët. Erud. ann. 1691, p. 40.

HYDRASTIS, in *Botany*, so named by Mr. John Ellis, who probably, as professor Martyn conjectures, received it from Miss Colden, daughter of governor Colden. From some confusion, perhaps, in the history of the discovery, or of the communication, Linnæus was led to understand the appellation given by his friend as intended to commemorate “a young lady of noble birth;” whereas it appears rather to have a reference to the native situation of the plant, from ἵδρα, *water*, or ἵδρασις, *an imbibing of water*.—Linn. Gen. 283. Schreb. 379. Willd. Sp. Pl. v. 2. 1339. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 273. Juss. 232. Lamarck Dict. v. 3. 151. Illustr. t. 500.—Class and order, *Polyandria Polygynia*. Nat. Ord. *Multiflora*? Linn. *Ranunculaceæ*, Juss.

Gen. Ch. *Cal.* Perianth none. *Cor.* Petals three, ovate, regular. *Stam.* Filaments numerous, linear, compressed, a little shorter than the corolla; anthers compressed, obtuse. *Pist.* Germens numerous, ovate, forming themselves into an ovate head; styles very short; stigmas broadish, compressed. *Peric.* Berry composed of oblong grains. *Seeds* solitary, oblong.

Ess. Ch. Calyx none. Petals three. Nectary none. Berry composed of single-seeded grains.

1. *H. canadensis*. Canadian Yellow-root. Linn. Sp. Pl. 784. (*Warneria canadensis*; Mill. Dict. 190. t. 285. *Hydrophyllum verum canadensium*; Linn. Sp. Pl. ed. 1. 146.)—This bog plant is a native of Canada, and flowers in May or June. It was first cultivated by Mr. P. Miller in 1759.—*Root* of a deep yellow colour within, whence its English name, throwing out fibres in the spring. *Stems* about nine inches high, at first light green, but afterwards tinged with

with purple, hairy towards the top. *Leaves* two on each stem, petioled, emarginate at the base, palmate, ferrate, three, four, or five-lobed, the lobes having a smaller lobe on each side, changing from light to dark green, or a purplish colour. *Flower* solitary, white, of short duration. *Fruit* red, and succulent. *Berry* resembling the raspberry or mulberry more than the strawberry.—Jussieu says it has the fruit and habit of a *Rubus*, and is allied to *Podophyllum*.—It is remarked by Linnæus, in his herbarium, that the flowers of this plant were unknown to his pupil Kalm. We are not aware that it has been figured by any author except Miller, as quoted above.

HYDRATE, in *Chemistry*, a term that has been applied by some modern chemists to express the chemical union of water with any substance, and more particularly with certain metallic oxyds; thus from the salts of copper precipitates are thrown down by the alkalies, and some of the earths, which are either of a green or blue colour, and which were formerly regarded as mere oxyds. According to Proust, the green is a sub-salt, or an oxyd with a small portion of acid, and a quantity of water; the blue a compound of black oxyd with water alone, in the proportion of 24 parts of water to 76 of oxyd, and is denominated a *hydrate* of copper. The water is thought to be in a state of chemical combination, and to be the cause of the blue colour. This hydrate, by the same chemist, is supposed to be the base of a number of salts. The water may be expelled with a low red heat.

HYDRAULICON, in the *Ancient Music*, an organ blown by the fall of water. From the description of this instrument by Vitruvius, cap. xiii. it seems as if the water which forced the air into the pipes was pumped by men. Indeed, it has been much disputed whether it was played with *fingers*, by means of levers or *keys*; and yet the description of it by Claudian seems such a one as would suit a modern organ, only blown by water instead of bellows.

“Vel qui magna levi detrudens murmura tactu
Innumeras voces fegetis moderator ænæ
Intonet erranti digito, penitusque trabali
Vestæ laborantes in carmina concitet undas.”

In Athenæus, lib. iv. p. 174. there is a history and description of this instrument. He tells us that it was invented in the time of the second Ptolemy Euergetes, by Ctesibius, a native of Alexandria, and by profession a barber; or rather, that it was improved by him, for Plato furnished the first idea of the hydraulic organ, by inventing a night-clock, which was a *clepsydra*, or water-clock, that played upon flutes the hours of the night at a time when they could not be seen on the index.

The anecdote in Athenæus concerning the mechanical amusements of the great ideal philosopher, is curious. What a condescension in the *divine* Plato to stoop to the invention of any thing useful! This musical clock must have been wholly played by mechanism. But neither the description of the hydraulic organ in Vitruvius, nor the conjectures of his innumerable commentators, have put it in the power of the moderns either to imitate, or perfectly to conceive the manner of its construction; and it still remains a doubt whether it was ever worthy of the praises which poets have bestowed upon it, or superior to the wretched remains of the invention still to be seen in the grottos of the vineyards, near the city of Rome.

The pneumatic organ, or instrument blown by bellows, and furnished with keys, such as are in present use, though perhaps a descendant from the hydraulicon, will have a distinct article, where its invention will be discussed, and its improvements traced, among those of modern instruments.

HYDRAULICS, that part of statics which considers the motion of fluids, and particularly water; with the application of it in artificial water-works. Hydraulics, as distinguished from hydrodynamics, is that science which treats of certain machines or engines, in which fluids are principally concerned.

The word is derived from the Greek, ὑδραυλιος, *soundings water*, formed of ὑδρα, *aqua, water*; and αυλιος, *tibia, pipe*, or *flute*: the reason of which is this, that at the time of the first invention of organs, being unacquainted with the method of applying bellows to blow them, they made use of a cataract or fall of water to make a wind, and found them.

To hydraulics belong not only the conducting and raising of water, with the construction of engines for those purposes, but also the laws of the motion of fluid bodies, the nature of springs, the course of rivers, the agitation of waves, the theory of the tides, &c.

Hydrostatics explain the equilibrium of fluids, or the gravitation of fluids at rest: upon removing that equilibrium, motion ensues; and here hydraulics commence.

Hydraulics, therefore, suppose hydrostatics; and the generality of writers, from the immediate relation between the two, join them together, and call them both either hydraulics or hydrostatics.

The laws of hydraulics the reader will find under **FLUID**. The art of raising waters; with the several machines employed for that purpose, as siphons, pumps, syringes, fountains, jets d'eau, fire engines, &c. are described under these, and other articles of a similar kind, respectively.

The science of hydraulics must be allowed to be of as great importance to civil life, and especially to a maritime nation, as any department of practical mechanics. Let us only reflect for a moment to what state the metropolis of England would be reduced, if deprived of pipes for the conveyance of water, of pumps, and fire engines; and how much the commerce of the whole kingdom has been facilitated and increased by the formation of navigable canals, and we shall be convinced of the importance and utility of the art of modifying the motion of water, and of the principles of hydraulics, on which that art depends.

The principal writers who have cultivated and improved hydraulics, are Archimedes in his *Liber de Siphonibus Humido*; Hero in his *Liber Spirituum*, who is the first who has written on hydraulic machines; Marinus Ghetaldus in his *Archimedes promotus*; Jo. Ceza, in his *Geometria Motus*; Jo. Bap. Balianus, *De Motu Naturali Graviorum, Solidorum et Liquidorum*; Mariotte, in his *Mouvement des Eaux et autres Fluides*; Boyle, in his *Hydrostatical Paradoxes*; Fr. Tertius de Lanis, in his *Magisterium Naturæ et Artis*; Lamy in his *Traité de l'Equilibre des Liqueurs*; Rohault; Dr. Wallis in his *Mechanics*; D. Guglielmini, in his *Mensura Aquarum Fluentium*, where the higher laws of hydraulics are reduced to practice; sir Isaac Newton, in his *Phil. Nat. Prin. Mathematic.*; Varignon, in the *Memoirs of the Royal Academy of Sciences*; Jurin, Belidor, Bernouilli, Solomon de Caux, in a French treatise of *Machines*, and chiefly hydraulic ones; Casp. Scottus in his *Mechanica Hydraulico-pneumatica*; De Chales, in his *Mundus Mathematicus*; Boecler, in his *Architectura Curiosa*; Luc. Antonius Portius; Herman; Wolfius; S'Graveande; Muschenbroeck; Leopold; Sturmius, in his *Treatise on the Construction of Mills*; Switzer's *Hydrostatics*; Euler; Emerson; Defaguliers; Clare; Ferguson; Berda; D'Alembert; Lagrange; Boffut; Buat; Ximenes; Lametherie; M. Young; Berohard; Prony; Lorgna; Vince; Venturi; &c. &c. &c.

HYDRAULO-PNEUMATICAL, a compound term, applied by some authors to such engines as raise water by means of the spring of the air. See **AIR**, **WATER**, and **ENGINE**.

Mr. Boyle mentions a very pretty fountain, which he calls hydraulo-pneumatical; made by the spring of the air pressing up water in a pipe upon the air's being exhausted out of a receiver, and thus the weight of the atmosphere taken off. See **FOUNTAIN**.

HYDREA, in *Ancient Geography*, an island of the Hermonitic gulf, situated S.E. of the Argolide peninsula. See **HERMIONE**.

HYDRELÆON, ἡδρελαίων, compounded of ἕδρα, *water*; and ἔλαιον, *oil*, in *Pharmacy*, a mixture of common oil and water.

The hydrelæon was taken internally to excite vomiting; externally it is anodyne, and promotes suppuration.

HYDRENTEROCELE, a term in *Surgery*, denoting a hydrocele complicated with an intestinal hernia. Hydrenterocele is compounded of three Greek words, *viz.* ἕδρα, *water*, ἕντερον, *an intestine*, and κελύκη, *a tumour*. See **HYDROCELE**.

HYDRIA, in *Ancient Geography*, an island of the Adriatic sea, placed by P. Mela before the Electrides.

HYDRIA, or *Idria*, in *Geography*, a town of Germany, in the duchy of Carniola. N. lat. 46° 14'. E. long. 14°.

HYDRIA, in *Mythology*, the name given by the Egyptians to the god of the water, which they represented by a vase, perforated on all sides. According to Vitruvius (lib. viii.) the priests upon certain days filled this vase with water, adorned it with great magnificence, and then placed it upon a kind of public theatre, where all prostrated themselves before the vase, with hands lifted up to heaven, and gave thanks to the gods for the benefits they received from this element. The intention of this ceremony was to teach the Egyptians that water was the principle of all things, and had communicated life and motion to every thing that breathes.

HYDRIAPHORÆ, compounded of ἕδρα, *water*, and φέρω, *I carry*, among the *Athenians*, a designation given to wives of strangers residing at Athens.

They were thus called, as being obliged during the procession of the festival Panathenæa, to carry vessels of water. Potter, tom. i. p. 56 and 401.

HYDRIAS, in *Ancient Geography*, a country of Asia Minor, in the vicinity of the river Marlyas. Herodotus.

HYDRINUS, a name given by some authors to the *ophites*, or serpent-stone.

HYDROCANISTERIUM, a fire engine; or a machine which spouts water plentifully, and with force; used to be applied to the extinguishing of fires, and conflagrations of houses, &c. We have various contrivances to this effect: the first, and which is, as it were, the basis of all the rest, is a pump inclosed in a cistula, or wooden vehicle filled with water, and mounted on wheels; the pump being wrought with long levers which come out of the cistula: and the water it raises directed to the place by means of a jointed tube.

The Dutch and others use a long flexible tube of leather, fail-cloth, or the like, which they carry or conduct in the hand from one room to another as occasion requires; so that the engine may be applied where the fire is only within-sight, and does not burst out to expose it to its external action. To improve on this original fire-engine, they have since contrived to make it yield a continued stream; by substituting a forcing or pressing pump in lieu of the sucking pump. See **FIRE-ENGINE**, and **FORCING PUMP**.

HYDROCANTHARUS, in *Entomology*. See **DYTISCUS Marginalis**.

HYDROCARBONATE GAS, in *Agriculture*, an ærial fluid formed during the decomposition of water, which is said to be useful in promoting the process of vegetation. It is supposed by the author of the work entitled "Phytologia," that during the process of putrefaction "carbon is not only converted into carbonate acid, but there appears to be a decomposition of water, as is known by the smell of hydrogen; and it is probable that this inflammable body may unite with carbon, as in hydrocarbonate gas, and thus render them both soluble in water, and absorbable by the vessels of vegetable roots, without their passing into an acid or gaseous form, and may contribute much to the nutriment of vegetables." This hint requires the further attention of the philosophical agriculturist.

HYDROCARDIA, a term invented by Hildanus to express a serous, sanious, or purulent tumour of the pericardium.

HYDROCELE signifies, in *Surgery*, any preternatural collection of water in the scrotum. The term is derived from ἕδρα, *water*, and κελύκη, *a tumour*. In this disease the fluid may occupy various parts of the scrotum. In some cases it is situated in the cellular membrane, which affection receives the appellation of *hydrops seroti*. In most instances it is contained in the tunica vaginalis testis. In some examples it is lodged within the sheath of the spermatic cord; in others it is included in a preternatural cyst; occasionally the water is contained in a true hernial sac; therefore we have five different kinds of hydrocele distinguished by the particular situation of the fluid.

Hydrops Seroti.—The first species, namely, the *hydrops seroti*, is nothing more than an œdematous swelling of the scrotum. The water is diffused throughout all the cellular membrane of this part of the body, causing every where an equal distension, so that the raphe is not pushed out of the central situation which it naturally holds. The swelling has all the character of œdema; the pressure of the end of the finger makes an impression upon it; the surface of the scrotum is smooth and shining, without any vestige of the corrugations; the part retains its natural colour, is generally very soft, and has a cold feel. In most cases the prepuce is also affected with a similar sort of swelling, so that the patient is actually troubled with a phymosis. In certain instances vesicles make their appearance on the integuments of the penis. We may add, that the tumour is quite free from pain. In some cases one side of the scrotum is more distended than the other, and, consequently, the raphe is not situated in the middle. It is deserving of notice, that women are sometimes affected with a similar swelling of the labia.

The *hydrops seroti* is generally a symptom of another constitutional disease, especially of ascites and anasarca, in which event it is commonly attended with an œdematous swelling of the feet. However, it is occasionally quite a local disease; and in this case it is usually a consequence of pressure upon the returning vessels, produced by a dislocated thigh-bone, a badly made truss, an indurated omental hernia, &c. Sometimes the disease is noticed in new-born children, and it has been observed to follow contusions of the scrotum, and exposure either of this part, or of the whole body, to certain degrees of cold.

An analogous disease may proceed from an extravasation of urine in the cellular membrane of the scrotum. This particular case is sometimes the consequence of a retention of urine. When the last affliction has attained a high degree, gangrenous specks are apt to be formed on the posterior

HYDROCELE.

rior and inferior parts of the bladder, so as to let the urine escape into the cellular substance of the perineum and scrotum. In this instance the swelling of the latter part originates suddenly; and in proportion as it increases, all the symptoms of a preternatural distention of the bladder undergo a diminution. The urine sometimes passes through an ulcerated aperture in the urethra into the cellular membrane of the scrotum. Hence fistulæ in perineo may be attended with this sort of extravasation. When, also, by external violence the tunica vaginalis has been burst, while distended with water, the fluid has been known to escape from the cavity of that membrane into the cellular substance of the scrotum, the case changing at once from a common hydrocele into an hydrops scroti. Lastly, we have to remark, that a similar extravasation of fluid sometimes happens in the palliative operation for the ordinary hydrocele, when the puncture is executed with a lancet, and the opening in the skin happens to slip away from that in the tunica vaginalis, while the water is flowing out.

In the treatment of the hydrops scroti, it is always an indication to remove the causes of the disease, whether they are of a local or general nature. When a dropsy of the abdomen is fortunately cured by medical means, the hydrops scroti spontaneously disappears. The swelling of the scrotum, likewise, proceeding from the pressure of an ill made truss, a dislocated thigh-bone, &c. will subside as soon as such pressure is removed. But surgical writers appear to coincide in opinion, that cases may present themselves in practice where local treatment is indispensably proper. An instance of this kind may be where the general or local cause does not admit of a removal in a complete or sufficiently speedy manner, and where the tumour of the scrotum is attended with serious inconvenience, or any degree of danger. Thus, when urine is effused into the scrotum an immediate operation is proper, in order to avert inflammation, suppuration, sloughing, and fistulæ, effects which would otherwise quickly follow. In cases of the common hydrocele of the tunica vaginalis, erysipelatous inflammation, ulcerations, and gangrenous complaints may occur when the swelling is exceedingly large. The prepuce is sometimes so swollen that the urine cannot escape from the orifice of the urethra. Yielding as the integuments of the scrotum are, they may yet be burst by being excessively distended with fluid, as the observations of Mr. Warner confirm. Local means are also obviously requisite whenever the hydrops scroti arises from a local cause.

The most common and effectual means of relieving the hydrops scroti is letting the fluid out of the cellular membrane by suitable punctures. In a few instances, indeed, a milder plan will answer the purpose. The complaint in new-born infants may usually be cured by bathing the scrotum with warm wine. The hydrops scroti, consequent to a bruise, or exposure to cold, may in general be very soon dispersed by the use of a suspensory bandage, and repeatedly washing the tumour with brandy, lime-water, wine, vinegar, or any decoction of astringent and aromatic herbs. The same remedies will also be found to avail when the swelling remains after its cause has been removed. When the tumour is exceedingly large, and the symptoms pressing, the surgeon is not to consume time in the trial of these applications, but immediately make the necessary punctures. If urine should happen to be the fluid in the cellular membrane of the part, proper incisions should be directly made for its escape, lest inflammation, abscesses, and gangrenous mischief ensue.

The fluid of hydrops scroti may be discharged either by an incision or a puncture. Five or six superficial scarifications

with a lancet will in general be found to answer the purpose. If such openings should be closed the day after making them, before all the fluid has been discharged, the practitioner is called upon to use the lancet in the same manner again. When incisions are preferred, it is customary to make one about an inch long on each side of the raphe, and deep enough to extend through the skin into the cellular membrane. Scarifications are commonly deemed the most advisable. It is true that they do not let out the fluid so quickly as incisions, but they are safer, as every material wound in dropsical parts is very apt to fall into a gangrenous state. It is remarked, that frequently the incision soon begins to be painful, its edges to be affected with hardness and inflammation, while an erysipelas seizes the whole circumference of the wound, and rapidly induces gangrenous disorder.

Such evils are most liable to occur when the operation has been performed at a period when the scrotum is excessively distended, and already somewhat affected with an erysipelatous redness, and when care has not been taken to keep the parts quite dry, during the issue of the fluid. Hence it is an important rule to keep the scrotum from being wet, by laying over and under it dry compresses. When pain and inflammation follow the operation, the most eligible applications are the saturnine lotion, lime-water, the decoction of bark, a solution of alum, &c. Should mortification actually take place, the patient is always in considerable danger, and the event is too frequently fatal. Sometimes the whole scrotum sloughs and is cast off, both the testes being left entirely denuded. Notwithstanding all this mischief, the testes usually become furnished with a new sort of covering.

We know of only one example in which incisions are decidedly better than scarifications, and this is where urine is lodged in the cellular membrane of the scrotum, and where a speedy discharge of this irritating fluid is urgently required.

Of the Hydrocele of the Tunica Vaginalis Testis—This is the chief and most interesting form of the disease. It is situated in the cavity of the tunica vaginalis testis. It makes its first appearance as an oval swelling at the lower end of the spermatic cord, seeming, indeed, to arise from the testis itself. In proportion as it increases in size it approaches more and more towards the abdominal ring; but between this opening and the upper part of the tumour, the spermatic cord may always be felt quite free. The swelling continuing to grow larger, it arrives at length as high as the ring, so that the spermatic cord cannot be at all distinguished; yet it is worthy of notice that the upper roundish end of the tumour may still be plainly felt, particularly on laying the hand under the scrotum, and pressing the swelling upwards; for when this is done the upper margin of the tumour projects so much forwards that it may always be distinctly perceived. The finger can even be put between the upper part of the swelling and the abdominal ring, by which means the surgeon can constantly ascertain that the tumour does not come out of the latter aperture. Besides, the disease cannot be easily mistaken for a hernia, especially as the swelling is subject to no variation of size, whether the patient is in an erect or recumbent posture, whether he coughs, holds his breath, or the tumour itself is compressed. We may also observe that all the other general symptoms of a hernia are absent.

The swelling is commonly of an oval shape, the greatest diameter extending downwards. Sometimes the position of the tumour is oblique, or even completely transverse. In this last circumstance it may be necessary to make the puncture

HYDROCELE.

ture on the right side of the scrotum in performing the palliative operation, notwithstanding the collection of fluid may be situated in the cavity of the left tunica vaginalis, and *vice versa*. Probably this unusual shape of a hydrocele may be caused by tight breeches or the pressure of the suspensory bandage. The larger the tumour is the rounder does its figure become; but in some cases the shape is very different from what it is in others. Hydroceles have been observed to have occasionally quite a cylindrical appearance. The tumour is occasionally divided by a sort of contraction. When a hydrocele is the consequence of inflammation, the tunica vaginalis is sometimes adherent in different places to the tunica albuginea, and of course the swelling has an irregular knobby shape.

The tumour feels like a bladder distended with water. In its commencement it is soft and yielding; but the tension and hardness increase in proportion to the quantity of fluid, and the quickness with which it has accumulated. It deserves attention, however, that there are some hydroceles of considerable magnitude, which are so remarkably soft that they may be made quite flat by pressure, and allow the testes to be plainly felt. The freer the swelling is from tension the more evident is the fluctuation; but even in cases which are exceedingly tense a certain degree of fluctuation can be distinguished on applying the palms of the hands on opposite sides of the tumour. Schmucker has seen hydroceles which felt as hard as a sarcocele, and Saviard mentions their being occasionally attended with the hardness of horn. In such instances the tunica vaginalis is in general thickened and indurated in an extraordinary degree, and, in certain cases, that membrane, instead of containing merely an aqueous secretion, has been found to include cysts or vesicles filled with a yellow fluid.

When either the patient himself or the surgeon handles the tumour, the same kind of sensation is communicated to the fingers, whatever part of the swelling is touched. The surgeon perceives every where the same kind of feel as he would be sensible of in handling an elastic distended bladder, and the patient suffers no pain from any manual examination of the disease. The whole circumference of the swelling is smooth and even, except just at one place, which is where the testis is situated, and is usually at the hinder and middle part, though not unfrequently at the upper portion of the tumour. In such situation the surgeon may feel an inequality and an inelastic hardness, and when the part is compressed the patient is afflicted with the peculiar pain which is always produced by squeezing the testis. This gland may almost always be felt at the back part of the swelling, at various heights, according as the tunica vaginalis happens to have been dilated upwards or downwards by the increasing quantity of the fluid. B. Bell twice saw the testis in front of the tumour. The same gland, though at the back part of the swelling, has been found adhering to the fore part of the tunica vaginalis, in consequence of inflammation, which was prior to the hydrocele. Mr. Else had an opportunity of seeing a case, where the oval swelling of a hydrocele was in an horizontal position from before backwards, while the testis could be plainly felt at the bottom of the scrotum.

When the end of the finger is pressed upon the hydrocele of the tunica vaginalis, it does not leave after it any impression or dent. How large soever the swelling may be, the skin of the scrotum always retains some vestiges of the corrugations, or, at least, is never so smooth and shining as it is in the case of hydrops scroti. Frequently, when the tumour has acquired a considerable size, the penis becomes retracted in such a manner, that the prepuce has somewhat the appear-

ance of a navel at the upper and forepart of the scrotum. The disease is entirely free from pain, except when it increases very quickly, in which circumstance a degree of uneasiness is experienced in the swelling, at the same time that painful sensations are felt in the loins, probably excited by the weight of the tumour, when the patient has been a long while in a standing posture. We find, therefore, that such pain may be relieved by the patient's lying down. As this species of hydrocele commonly affects only one side, or since, when in a few instances, it happens at the same time on both sides of the scrotum, it is not equally large on each side, the raphe is never seen exactly in the middle. The integuments of the scrotum have their natural colour. Most hydroceles of the tunica vaginalis are attended with a certain degree of transparency, and the knowledge of this circumstance is of infinite importance to the practitioner, since it will often enable him to form an accurate judgment respecting ambiguous cases. In order to learn whether the swelling is transparent, the chamber should be darkened, while a lighted taper is held just on one side of the scrotum, while the surgeon looks at the other, which ought to be in the shade. It is necessary, however, for every surgeon to be aware that transparency is by no means a constant symptom of a hydrocele, and is never present, either when the tunica vaginalis is preternaturally thick and indurated, or when it is filled with a dark turbid fluid, or cysts resembling hydatids.

By paying attention to the foregoing symptoms, the surgeon will be able, in all ordinary cases, to discriminate the hydrocele of the tunica vaginalis from every other kind of tumour to which the scrotum is liable. But yet it must be allowed that there are cases where the diagnosis is attended with considerable difficulty, certain diseases having so much similitude to the hydrocele of the tunica vaginalis, that they may deceive the most attentive and experienced surgeon. One of such cases is the sarcocele, which has the same shape as the hydrocele, and, like it, is situated at the lower end of the spermatic cord. The chief difference, therefore, between the two diseases, seems to be, that the sarcocele is hard, while the hydrocele has a soft, yielding, elastic feel, accompanied with a fluctuation. The sarcocele itself, however, is not always remarkably hard, and the hydrocele is now and then very indurated. The sarcocele, indeed, is not transparent; neither is the hydrocele in certain instances; and these are cases where a mistake may easily be made. Still, with due attention, both diseases may be discriminated with tolerable precision. The sarcocele, when held in the surgeon's hand, seems heavier than the hydrocele. The testis is seldom equally indurated every where, and the sarcocele is usually much softer in some places than others. The hydrocele presents the same kind of feel at every point, except behind, where the testis is felt. When, in the case of hydrocele, pressure is made in this latter situation, the patient experiences a much more acute sensation than when the pressure is made upon any other part of the tumour; but in the example of sarcocele, the patient commonly has the same kind of feel, let the pressure be applied to any part of the swelling whatsoever. The hydrocele may be compared with a bladder full of water, the surface of the tumour being every where smooth and even, except in the situation of the testis. This gland itself, when hardened, seldom undergoes a regular, uniform enlargement; but generally has a surface more or less uneven. When the upper portion of the spermatic cord can be felt, and it seems quite hard and thickened, the surgeon has reason to suspect that the case is a sarcocele. Lastly, though a hydrocele, when gently handled, may seem to be considerably hard; yet, on being more strongly compressed, it will generally betray a soft elastic

HYDROCELE.

elastic feel, which is never the case with an indurated sarcocele.

A hydrocele is sometimes conjoined with a fleshy enlargement of the testis, which case is well known among surgeons under the appellation of *hydro sarcocele*. As the diseased testis is here surrounded with water, it cannot be felt nor examined by the fingers. However, when an unusual degree of hardness is perceptible at the back part of the tumour, where the testis is situated, or when the upper portion of the spermatic cord is found to be quite indurated, the surgeon has reason to suppose that the testis is affected with sarcocele. The latter is commonly the original and principal disease, the hydrocele first coming on subsequently to the enlargement of the testis. To the experienced practitioner this circumstance often affords useful light. We learn from the observations of that very excellent surgeon, Mr. Warner, that omental hernia in young children are sometimes so transparent, that they may be mistaken for hydroceles. But all the other ordinary characters of these fluid swellings are absent. A cystocele, or hernia of the urinary bladder, has some resemblance to a hydrocele, though the two affections may easily be distinguished from one another by paying attention to the particular symptoms of each, as described in a foregoing part of this work, (see *HERNIA*.) and in the present article.

The diagnosis is always apt to be attended with a degree of obscurity, when the hydrocele is complicated with other diseases of the scrotum. Sometimes it is conjoined with a hernia. On other occasions, the hydrocele of the tunica vaginalis exists in conjunction with one of the spermatic cord. The surgeon can only acquire a perfect knowledge of such cases by paying close attention to the peculiar symptoms of each of the diseases. When the requisite information cannot be thus obtained, it may often be procured by adverting to circumstances which presented themselves in an early stage of the case; for frequently the hydrocele is at first simple, and does not become complicated till an advanced period. The nature of the case is often elucidated on the palliative operation for the hydrocele being performed, as the other disease of the scrotum becomes quite obvious immediately the fluid is discharged from the tunica vaginalis.

The species of hydrocele, now engaging our attention, continues for a long while unattended with any serious inconvenience, or pressing symptoms: it only annoys the patient by its size and weight. When it is exceedingly large, the penis is drawn completely back, so that the urine dribbles over the forepart of the scrotum, and, unless particular care be taken to maintain cleanliness, is liable to excite inflammation and painful excoriations. When a hydrocele is the consequence of an inflammation of the testis, the fluid generally accumulates with great quickness. But the progress of the disease is occasionally so slow, that the palliative operation has not been required till twenty years after the commencement of the disorder. In general, the water only collects in one tunica vaginalis; sometimes in both. In the latter kind of case, a preternatural communication has been noticed between the opposite sides of the scrotum, though we believe such a circumstance is very uncommon. See Richter's *Anfangsgrunde der Wundarzneykunst*, Band 6. Kapitel 5.

The hydrocele appears to be one of those diseases, the causes of which are far from being well understood. In a natural, healthy state, the cavity of the tunica vaginalis always contains a small quantity of a fine fluid, exhaled from capillary arteries, and constantly absorbed by vessels for that purpose. This fluid, in the natural small quantity, serves to keep the tunica albuginea moist, and to prevent a cohesion between it and the vaginalis; a consequence which almost

necessarily follows any such diseased state of these parts as prevents the due secretion of it. On the contrary, if the quantity deposited be too large, or if the regular absorption of it be by any means prevented, it will be gradually accumulated, and, by distending the containing bag, will form the disease in question.

It is a disease from which no time of life is exempt; not only adults are subject to it, but young children are frequently afflicted with it, and infants sometimes born with it. The great Mr. Pott professed himself incapable of determining the immediately producing cause. Ruysch thought that the complaint might proceed from a varicose state of the spermatic vessels. What real foundation there may be for such conjecture, Pott could not say, and, at the same time that he acknowledges the frequently varicose affection of the spermatic vessels in cases of hydrocele, he seems to consider it as unproved whether such state be a cause or an effect of the disease. It is also remarked by Mr. Ramsden, that though we often find the hydrocele present with the varicocele, we much more frequently meet with this last disease, even in its most advanced states, unaccompanied by any accumulation of fluid within the sacculus. (*Practical Observations on the Sclerocele*, &c. p. 196.) The hydrocele of the tunica vaginalis may frequently, perhaps commonly, be regarded as a disease altogether local, and dependent upon local causes. According to surgical writers, contusions of the scrotum often give rise to the complaint, and hence it is said to occur with particular frequency in persons who are in the habit of riding a great deal on horseback. In such cases the tumour is sometimes formed with surprising quickness. Pressure made upon the upper part of the spermatic cord by an ill constructed truss, or by an indurated omental hernia, may also be a cause of an hydrocele. Sometimes the latter malady is joined with a sarcocele, when it may be considered only as an effect of the disease of the testis. A hydrocele may likewise originate from an inflammation of this last gland. In some instances the disease appears to depend upon general and less manifest causes. We are informed of its having arisen in the space of four days, after exposure to cold. (See Richter's *Anfangsgrunde*, &c. Band 6. p. 67.) Warner and other authors have taken particular notice how prevalent the disease is in warm climates, and they make mention of patients who got well on removing from a hot into a cold country, but suffered relapses on their return into a warm part of the world. We deem the opinion, that hydroceles are ever connected with a venereal cause, entirely destitute of foundation.

Mr. Ramsden has recently advanced a new doctrine respecting the cause of hydroceles. This experienced surgeon has established three forms of the disease, as occurring within the tunica vaginalis; namely, the acute, the spurious, (*hydro-sarcocele*), and the true, or chronic hydrocele. He endeavours to prove that all these cases may be dependent upon excitement within the urethra. He remarks, "that the testicle will become hardened and enlarged, and that the sacculus of the tunica vaginalis will be distended with watery fluid, in consequence of various degrees of excitement within the urethra, from the irritable and acutely painful stricture, down to that concealed, subtle, and local derangement of the membrane, which is totally free from pain, until it is pressed upon by the bougie, and which may exist for years without the patient being conscious of its presence.

"It cannot therefore be unreasonable to suppose that an habitual susceptibility of the whole membrane of the urethra may, in some instances, be induced by general or local causes, and although it create no conscious sensation to the patient, may have the power of gently provoking the excre-

HYDROCELE.

tory vessels of the testicle somewhat beyond their natural action, and thus, by destroying the balance of fluid, in course of time establish that undue accumulation which characterizes the chronic, or true hydrocele.

"I am induced," says Mr. Ramsden, "to offer this opinion from a variety of facts which have presented themselves to my observation, and which lead me to suspect, that in almost every case of true hydrocele the urethra will be found either to have been exposed at some previous time to excitement or inflammation, or to be in a present state of increased tension, from constitutional irritability, from the membranous fence, or from some other of the several general or local causes, to which I have in the preceding pages referred the derangement of this membrane.

"The prevalence of hydrocele in the East and West Indies, instead of being attributable to the relaxation of the climate, may more reasonably be referred to the constant excitement to which the urethra is exposed from the habits of the table; since it is well known that, in those hot countries, every individual indulges in high-seasoned dishes, and in the most stimulating description of diet.

"The frequency of the hydrocele being present with the varicocele may also be satisfactorily explained, by referring to that state of continual excitement, which is kept up by the distention and weight of the loaded vessels. In the more advanced states of varicocele, nothing is more common than an habitual gleet or weeping from the urethra, which is occasioned by the dragging of the varicose vessels; and it certainly appears not difficult to suppose, that such excitement in the urethra, when once established, may in its turn re-act upon the testicle, and produce a case of hydro-varicocele." P. 193—201.

For the cure of the hydrocele of the tunica vaginalis, a surgical operation is generally necessary, as it is only in a few instances that the complaint yields to internal or external remedies. The observations of writers prove, however, that in young children the disease may sometimes be dispersed by emetics. A boy, twelve years old, was cured of a hydrocele by means of the steam of vinegar, the saturnine lotion, and repeated purgative doses. (See Richter's Chir. Bibliothek, 5. b. p. 120, 9. b. p. 593.) Morand succeeded in curing several hydroceles by making an issue on the scrotum; and Douglas found similar success from placing an issue near the groin. Schmucker dispersed a hydrocele by fumigating the scrotum with vinegar every morning and evening, and in the intervening time compresses wet with the same fluid. In the course of a few days the tumour subsided, the scrotum emitting a large quantity of perspiration. Warner frequently cured hydroceles in young subjects by means of purgatives, and stimulating astringent applications. Mohnheim succeeded in dispersing a hydrocele, which arose from exposure to cold. (Richter's Anfangsgr. &c. Band 6. p. 68.) Mr. Keate has recommended the following lotion, as an efficacious remedy: ℞ Sul. Ammon. Pulver. ʒj Acet. Spir. Vin. R. ʒiſ. āā ʒiv Misce. Compresses, wet with this mixture, are to be laid upon the scrotum, and kept there with a bag-truss. They should be dipped in the liquid three times a day. Mr. Keate assures us, that when this plan is properly followed up, the water of the hydrocele not only gradually disappears, but that it does not accumulate again, and the cure is radical and permanent, if the application be continued about a month. This method may be tried, either while the tumour is filled with water, or after the fluid has been let out. In the first instance it excites the absorption of the water; in the second it prevents a new collection. When the application happens to make the integuments red or painful, it must be left off a few days. The observations of

Mr. James Earle, however, tend to evince, that the preceding practice does not always answer, and is not to be depended upon. From the account which Mr. Ramsden has lately published, of the hydrocele being connected with a morbid state of the urethra, one might suppose that the disease would yield to the proper treatment of this last canal. This gentleman remarks, however, that in cases of chronic hydrocele, the use of the bougie is not attended with the same degree of success as in the examples of the acute and spurious forms of the complaint. We may again state, that by a spurious hydrocele is meant a collection of fluid in the tunica vaginalis, accompanied by an enlargement of the testicle. The simple indurated enlargement of this gland, unattended with any subversion of its organization, we conceive to be the case, which Mr. Ramsden has lately signified by the appellation of sclerocele, and which, being sometimes joined with an accumulation of fluid in the tunica vaginalis, constitutes an instance of spurious hydrocele, or what this eminent surgeon has named hydro-sclerocele, in order to distinguish the disease from the hydro-varicocele where the organization of the testicle is actually more or less subverted. Now Mr. Ramsden has endeavoured to prove, that the acute hydrocele, as well as the hydro-sclerocele, may be cured by treating the urethra with bougies, so as to destroy the morbid irritation in that canal. "The sclerocele of the testicle, whether with or without fluid in its sacculus, yields most readily to the use of the bougie, when the progress of induration in the gland has been most rapid, and the point of irritation within the urethra, on which it depends, is most susceptible; but the chronic hydrocele being slow in its progress, and dependant on a much more modified state of derangement in the urethra, is, on such account, very little under the influence of the treatment of that membrane, and must be referred to some other operation for its permanent cure." (P. 202—203.) From a note, it appears to be Mr. Ramsden's opinion, that when a tumour of the scrotum presents itself under the external appearances of true chronic hydrocele, and is co-existent with an acutely deranged urethra, and especially if the patient has any dislike to the hydrocele being tapped, the treatment of the urethra by the bougie will always be a fair experiment previous to the letting out of the water. Mr. Ramsden can assert, from his own experience, that it will, in some few instances, prove successful in curing the hydrocele. He thinks it probable, that in the cases in which this treatment succeeded, there might be concealed sclerocele; but he considers that such a fact would not lessen the propriety of the experiment. When the true hydrocele is not attended with an urethra so obviously deranged, Mr. Ramsden believes, that an attempt to cure the complaint by the use of the bougie will only be waste of time. See Practical Observations on the Sclerocele, &c. by T. Ramsden, surgeon to Christ's Hospital, &c. &c.

For relieving the present disease, two operations are practiced; one called palliative, the other radical. In the first, the design of the surgeon is merely to discharge the water, which usually accumulates again, and the malady returns. By the second he permanently frees the patient from the complaint, and hinders any relapse, this object being accomplished by exciting an inflammation of the whole surface of the tunica vaginalis, and a consequent universal adhesion of this membrane to the testis. In short, the cavity of the tunica vaginalis, which is the seat of the disease, is thus obliterated. This is the commonly received opinion; but at the same time we are not unaware of a different sentiment upon this same point having been lately advanced by Mr. Ramsden, who has adduced cases in which, from the transparency manifested in the scrotum, a considerable time after the radical operation

HYDROCELE.

had been performed, the doctrine of the disease being always cured, by the obliteration of the cavity of the tunica vaginalis, is called in question. The surgeon cannot invariably and indiscriminately undertake either of the preceding operations, at his own pleasure, with equal prudence and propriety. The palliative operation is entirely exempt from danger, and when a sufficient quantity of fluid is collected in the tunica vaginalis may be safely undertaken, even though the testis may not be altogether undiseased, nor the patient in good health. On the other hand, the radical operation, executed in any way whatsoever, demands more caution, and if done in improper cases, may be followed by dangerous and unpleasant consequences. In determining which method is to be adopted, the surgeon should attend to the following directions.

When the hydrocele is exceedingly large, it is not advisable to perform the radical operation, the great distention which the parts have just suffered placing them in not the most advantageous state for bearing inflammation. It is much better, in a case of this sort, to be at first content with merely letting out the water, and to undertake the radical operation afterwards, when a moderate quantity of fluid has accumulated.

When any suspicions are entertained of the testicle being diseased, the surgeon must restrict himself to discharging the water, a plan which can always be securely undertaken, though the testicle may not be found, and has the advantage of enabling the practitioner to feel and examine distinctly this latter part.

Should any radical operation be done, unpreceded by tapping the tumour, and the testicle prove to be affected with sarcocele, castration ought to be immediately performed, since the irritation excited would, in all probability, bring on a malignant change in the disease of the testicle. If an attempt at the radical cure should have been made, and the testicle be found thus diseased, yet, without the case admitting of the performance of castration, the patient is put into a very unpleasant and precarious condition.

When the patient's health is very bad, the radical operation ought not to be undertaken, for fear of inducing alarming symptoms. This observation, however, must not be extended to a class of subjects, who, though not in health, are neither affected with extreme weakness, nor any pressing indisposition. The palliative cure, being free from danger, may be undertaken in almost any states and circumstances.

When the hydrocele is complicated with other diseases of the scrotum, it is a wise maxim to rest satisfied in the first instance with simply discharging the fluid. The surgeon can then examine more accurately the nature of the other disorder, and, at a future period, attempt the radical cure of the hydrocele, if judged prudent, with greater safety.

Of the Palliative Operation.—The intention of this proceeding is to relieve the disease for the present, by discharging the accumulated fluid. The operation by which the water is let out is a very simple one. The only circumstances requiring our attention in it, are the instrument wherewith we would perform it, and the place or part of the tumour into which such instrument should be passed.

The two instruments in use are the common bleeding lancet, and the trocar.

“The former having the finer point (says Mr. Pott), may possibly pass in rather the easier, though the difference is hardly perceptible, but is liable to inconveniences, to which the latter is not. The trocar, by means of its cannula, secures the exit of the whole fluid, without a possibility of prevention, the lancet cannot. And, therefore, it frequently happens, when this instrument is used, either that some of

the water is left behind; or that some degree of handling and squeezing is required for its expulsion; or that the introduction of a probe, or a director, or some such instrument, becomes necessary for the same purpose. The former of these may in some habits be productive of inflammation: the latter prolongs what would otherwise be a short operation, and multiplies the necessary instruments; which, in every operation in surgery, is wrong. To which it may be added, that if any of the fluid be left in the vaginal coat, or insinuates itself into the cells of the scrotum, the patient will have reason to think the operation imperfect, and to fear that he shall not reap even the temporary advantage which he expected. The place where this puncture ought to be made is a circumstance of much more real consequence; the success of the attempt, the ease, and even sometimes the safety of the patient, depending upon it.

“All the anterior and lateral parts of the vaginal coat are loose and detached from the albuginea; in its posterior and superior parts, these two tunics make one; consequently the testicle is, as it were, affixed to the posterior and superior part of the cavity of the sac of an hydrocele, and consequently, the water or fluid can never get quite round it. This being the state of the case, the operation ought always to be performed on that part of the tumour where the two coats are at the greatest distance from one another, and therefore, where the fluid must be accumulated in the largest quantity, and never on that part of it where the fluid cannot possibly be. The consequence of acting otherwise, must not only produce a disappointment, by not reaching the said fluid; but may prove, and has proved highly, and even fatally mischievous to the patient.” (Pott on the Hydrocele.) In short, it must be plain to every person, who has any knowledge of the present disease, that in all common cases, the proper place for making the puncture is at the lower and fore-part of the scrotum. It ought, however, to be understood, that surgical writers make mention of examples, in which the hydrocele has an unusual shape, in consequence of the pressure of a bag-truss, &c. Instances have been observed, in which the hydrocele was of an horizontal oval form, with the testicle plainly perceptible underneath at the bottom of the scrotum. In all such cases, the surgeon should first examine the situation of the testicle, and choose a place for making the puncture, where there will be no risk of injuring the latter part. The oval sac of an hydrocele of the left tunica vaginalis, has been known to have so oblique a position, that its bottom could be felt on the right side of the raphe at the inferior part of the scrotum, while its upper end lay on the left side of the scrotum, near the abdominal ring. This hydrocele of the left tunica vaginalis was tapped on the right side of the raphe at the bottom of the scrotum, and as soon as half the fluid had been discharged, the sac became situated quite on the left side of the raphe, the exit of the water ceased, and the cannula fell out. Even in cases where the swelling has had the ordinary shape, the testicle has occasionally been seen at the fore-part of the tumour. Hence practitioners should remember, that making the puncture at the lower and anterior part of the hydrocele is not a matter of course; and that it is their duty, in every instance, to endeavour to ascertain the precise situation of the testicle, in order that it may be more certainly avoided. Richter's *Anfangsgrunde*, &c. Band. 6, p. 73.

After letting out the water of an hydrocele by the palliative operation, it is prudent to cover the puncture with a bit of lint and a plaster, to keep up the scrotum with a bag-truss, and direct the patient to keep himself quite still for the first twenty-four hours afterwards. The bag-truss gently

HYDROCELE.

gently supports the suddenly relaxed parts, and thus tends to prevent any painful swelling of the testicle, as well as hemorrhage in the tunica vaginalis, and too rapid an accumulation of the water again. Although no painful and inflammatory symptoms usually follow the operation, and the orifice heals in a few hours, like that made in blood-letting, and this notwithstanding the patient neither pays attention to regimen, nor abstains from his ordinary pursuits; yet the contrary sometimes happens. We learn, on the authority of Mr. Pott, that in some habits and circumstances, the puncture inflames and festers. Such festering is generally superficial only, and is soon quieted by any simple dressing; but it is sometimes so considerable, and extends so deeply as to affect the vaginal coat, and by accident produce a radical cure. Mr. Pott has likewise seen it prove more troublesome, and even fatal, when the circumstances of the patient, and the case have been particular. The accounts delivered to us by surgical authors confirm, that in persons of bad constitutions, pain, inflammation, and fever are apt to succeed, if the scrotum be too much rubbed or agitated. A patient, immediately after the operation, went several miles, and brought on by this means so high a degree of inflammation, swelling, and fever, that the consequence was a radical cure of the hydrocele. (Default, *Journal de Chirurgie*, tom. i.) Theden has recorded a case where similar symptoms were produced, only in a more severe form. Upon the whole, however, the palliative operation is not very liable to any disagreeable consequences. If pain, inflammation, and fever occasionally arise, it almost always will be found, that the patient has been guilty of imprudent exertion, or that the habit is exceedingly bad. In some instances, these symptoms are to be ascribed to the circumstance of the end of the cannula having been rubbed against the testicle during the escape of the fluid. An hæmatocele, which is occasionally produced after the operation, proceeds either from the great determination of blood to the relaxed parts, or from an actual injury of one of the blood-vessels of the tunica vaginalis with the lancet or trocar. When, from the colour of the water, there is reason to apprehend that a vessel has been wounded, the surgeon may often succeed in preventing any serious collection of blood, by taking care to cover the scrotum with cold applications, and support it well with a bag-truss. Should he however be unable to hinder such collection from taking place, both the hæmatocele and hydrocele may be radically cured by laying open the cavity of the tunica vaginalis. See HÆMATOCELE.

It is said, that when the tunica albuginea is unfortunately wounded with the point of the trocar, the substance of the testis is protruded through the puncture of that membrane, and forms a swelling which may create a necessity for castration. When the trocar happens to injure any varicose blood-vessels of the integuments of the scrotum, an extravasation of blood in the cellular substance may ensue, and end in ulceration, unless speedily dispersed. But while we are noticing these occasional evils, let us not forget to state, that the palliative operation sometimes proves beneficial beyond expectation, no water collecting again, and the patient remaining for ever afterwards free from the disease.

Wiseman and others have advised deferring the puncture till a pint of fluid has collected. On the contrary, Mr. Pott expresses his decided opinion, that when the water is in sufficient quantity to keep the testicle from the instrument, there can be no reason for deferring the discharge; and he contends, that the single point on which this argument ought to rest is this: whether the absorbent vessels, by which the extravasation should be prevented, are more likely

to re-assume their office, while the vaginal coat is thin, and has suffered but little violence from distention; or after it has been stretched and distended to ten, or perhaps twenty times its natural capacity; and by such distention is, like all other membranes, become thick, hard, and tough? Mr. Pott believes the probability so much more on the side of the former, that he should never hesitate a moment about letting out the water, as soon as he found that the puncture could be made securely. And, from what has happened within the small circle of his own experience, he is inclined to think, that if it was performed more early than it generally is, it might sometimes prevent the return of the disease.

Although we have given a general preference to the trocar, as the best instrument for tapping hydroceles; we can conceive a few instances in which the employment of a lancet for the purpose might be attended with advantages. Supposing the surgeon has to operate upon a very small hydrocele, which contains only a little quantity of fluid, it is better to use the lancet. The trocar must always be introduced more deeply than the latter instrument, and is therefore more apt to injure the testicle. In such a case, also, there is no danger of the lancet occasioning an hæmatocele, since the vessels of the tunica vaginalis have suffered no dilatation. On the same principle, the lancet ought to be preferred in all cases where the hydrocele is complicated with either a hernia, or an exceedingly large sarcocele, and it is impossible to ascertain the exact position, size, and quantity of parts in the scrotum.

Sir James Earle thinks, that the palliative operation ought to be performed at least once on those who determine to submit to the radical method of cure, as it enables the surgeon to examine the state of the testicle, and affords an opportunity of operating in the other way afterwards, when the tunica vaginalis is not more distended than is proper. On the Hydrocele, p. 13, edit. 2.

We shall conclude the observations which we have to offer on the palliative operation, with noticing the circumstance of the fluid sometimes not flowing through the cannula of the trocar, or of escaping only just at first, and then stopping, notwithstanding the introduction of a probe. This occurrence may depend on various causes. The fluid in the tunica vaginalis is occasionally as thick and viscid as white-of-egg. (Warner.) Sometimes the cavity of the tunica vaginalis is divided by several partitions formed of a loose sort of cellular substance. In certain instances, the cavity has appeared to be filled with hydatids, or transparent cysts. Should the patient be in a fit state for the radical operation, it would undoubtedly be right, in a case of the foregoing description, to perform it at once. The plan by injection being here quite inapplicable, the surgeon should introduce a director through the cannula of the trocar, withdraw the tube, and, with the aid of the director and a curved bistoury, lay open the cavity of the tunica vaginalis.

Of the Radical Method of Treatment.—The great object in the radical operation is to produce an entire obliteration of the cavity of the tunica vaginalis, which is the seat of the disease, and thus render a recurrence of the complaint impossible. This purpose has been fulfilled in two manners, viz. by cutting the whole of the tunica vaginalis away, or by exciting such an inflammation of this membrane as makes it universally adherent to the testicle. In the latter method, it is a principal indication to have an effectual, yet not too violent a degree of inflammation. When it is too slight, or does not extend to the whole of the membrane, it is ineffectual. In the first of these circumstances no cohesion follows, and the operation completely fails; in the second, the

tunica

HYDROCELE.

tunica vaginalis only becomes adherent to the testicle at those places where the inflammation exists, while elsewhere a cavity remains, in which the fluid re-accumulates. When there are several such parts, to which the inflammation does not extend, the hydrocele recurs in the form of several distinct swellings, and the water is contained in separate cysts. On the other hand, the inflammation is too violent, when it is such as brings on severe febrile symptoms, and affects the testicle even more than the vaginal coat. The means employed to raise the necessary inflammation ought always to be calculated to affect the latter membrane chiefly, and the testicle as little as possible; a considerable inflammation of this gland not being essential to the radical cure of a hydrocele, and being invariably attended with more severe symptoms, than those which result from an inflammation of the vaginal coat. With the preceding intentions, various methods of operating have been practised, the chief of which we shall now proceed to describe.

Incision.—In this plan, an incision of some length is made through the integuments of the scrotum and the tunica vaginalis, by which means, not only the fluid is discharged, but such inflammation excited as ends in a cohesion of the whole of the vaginal coat with the testicle, and, of course, the recurrence of the hydrocele is effectually prevented. This mode of effecting the radical cure of the hydrocele is the most ancient of all, having been described by Celsus. The operation is performed as follows: the point of a straight bistoury is to be placed on the fore-part of the swelling, while the back of the instrument is to rest against the index-finger of the surgeon's left hand. The knife is to be pushed into the tumour, and an opening of such size immediately made as will let the operator introduce completely into the tunica vaginalis his finger, on which the further course of the bistoury is to be directed. Directly the first puncture is made, the fluid is apt to gush out all on a sudden, leaving the tumour collapsed, and the operator incapable of easily introducing the instrument, with which he purposes to enlarge the first wound. In order to prevent any inconvenience of this kind, surgical authors direct us to place the end of the left index finger close behind the point of the knife, and to take care to make it pass into the wound immediately behind the latter instrument. This being done, the surgeon, with the aid of his left thumb, can take hold of the involvements of the hydrocele, and hinder a closure of the opening just made. A blunt-pointed crooked bistoury is then to be introduced, and, guided by the fore finger, will serve for enlarging the incision downwards and outwards, in such manner, that the wound may extend down the middle of the front of the tumour to its lower part. When the hydrocele is small, or complicated with a sarcocele, or hernia, or when any doubts exist concerning the real nature of the case, writers advise us to let the first incision only divide the integuments of the scrotum, and then to open the tunica vaginalis separately.

Should any modern practitioner choose to perform this operation, he would find it very advantageous to make the first opening into the hydrocele at the upper part of the swelling, as all the fluid would then not make a sudden escape, so as to occasion a collapse of the tumour, and difficulty in effecting the necessary dilatation of the wound.

The incision must be carried to the bottom of the tunica vaginalis, or else blood and matter will be very likely to lodge there, and create trouble.

The cavity of the hydrocele having been thus laid open, is to be dressed with soft pieces of lint; these are to be covered with a pledget; and a suspensory, or T bandage.

The dressings are to be changed at proper intervals, until the part is completely healed.

Much more might be said concerning this method of effecting the radical cure of the hydrocele; but we suppress many particulars, conceiving them to be superfluous in the present almost exploded state of the operation. Whoever will take the trouble to read the accounts of this plan, as delivered to us by surgical writers, will find that, according to Monro and Acrell, its consequences are sometimes dangerous, and even fatal, while, in other instances, the inflammation of the testicle has been so violent, as to end in suppuration. (See Richter's *Anfangsgr.* &c. Band 6. p. 92.) Hence it has been commonly found proper to employ a strict antiphlogistic treatment, which is acknowledged to have occasionally defeated the very object of the operation, by preventing the kind of inflammation necessary for the completion of the radical cure. Thus, severe as the method is, it is uncertain, and its failures are confirmed by the testimony of Bertrandi, Sabatier, and sir James Earle. We will not dwell upon the objections which might be urged against the practice, from the disagreeable and dangerous bleedings which sometimes follow the operation, or the painful excoriations which frequently arise. The method has no advantage over a milder operation, which we have to recommend, and it is altogether severe, as well in its performance as in its consequences. We should, however, have deemed it our duty to enter into a more particular detail of the reasons against the plan, had not the disrepute into which it has now sunk rendered this task unnecessary.

Extirpation.—It sometimes happens, after performing the foregoing operation, that the tunica vaginalis is found in a thickened and indurated state. Certain writers and practitioners have fancied, that when this is the case, such an inflammation as is essential to the radical cure will not take place. Under this impression, they recommend scarifying the inner surface of the tunica vaginalis, or even cutting this membrane entirely away. Many eminent surgeons of past times have adopted the latter proceeding with success, as for instance, Douglas, Saviard, White, Gooch, and Louis. Indeed, it was remarked by Bertrandi, that the symptoms are generally milder after the excision of the tunica vaginalis, than after a mere division of it. The method consists in dissecting away portions of the membrane, after laying open its cavity, care being taken not to cut too closely to the testicle, for fear of exciting a violent degree of hernia humoralis.

Certainly we can conceive a case in which the tunica vaginalis may be so diseased, as to justify the tedious and painful plan of removing a part of it by dissection. But an instance of this kind must be very uncommon; and the observations of sir James Earle confirm, that the radical cure, by means of an injection, can be accomplished without any excision, notwithstanding the tunica vaginalis is thickened. The method of extirpation, however, is not only objectionable, as being productive of avoidable pain; it is liable to bring on troublesome hemorrhages both during and after the operation, and to be followed by fistulae and fistulous abscesses, which are a very long time in healing.

Tent.—Experience having shewn that, in many instances, moderately stimulating the tunica vaginalis will bring on a sufficient inflammation of this membrane to effect a radical cure; and likewise, that the common palliative operation, done with a trocar, is sometimes followed by the same beneficial consequence; attempts have been made to free the patient permanently from the disease by milder methods than those which we have just now been describing. After the palliative operation with a trocar, Monro suggested leaving

the

HYDROCELE.

the cannula in the wound until the necessary inflammation had been excited, and he assures us, that in this manner he often accomplished a radical cure with the utmost success.

Warner used to puncture the swelling with a lancet, and, after letting out the fluid, introduce into the opening a tent, which was left there until an adequate degree of inflammation had come on.

The last mode of operating has been the most extensively adopted. It is executed as follows: a puncture is made with an abscess-lancet in the anterior and inferior part of the tumour, and the fluid discharged. A tent is then introduced into the aperture, so as to lie betwixt the tunica vaginalis and the testicle. The opening is next covered with a pledget. The wound in the integuments and vaginal coat ought to be about an inch and a half in length. We are also advised by some authors to introduce the tent while the water is making its escape; as, in consequence of the way in which the sac occasionally collapses, the operator may afterwards have trouble in getting the tent into the tunica vaginalis, and, perhaps, force it into the cellular substance of the scrotum, instead of the proper situation, in which circumstance the attempt at a radical cure would fail. The tent ought to be at least an inch long, have a ligature attached to it, and be made either of sponge, or a soft dosil of lint. The latter can be best introduced by means of a probe. A fresh tent should be put in every day, and the length and thickness of it may be gradually diminished. This mode is to be followed up, until an effectual inflammation is excited, which commonly happens on the second or third day, though sometimes later. The tent is afterwards to be discontinued, and an emollient poultice applied. In general, suppuration very soon commences. Occasionally abscesses form, and require to be opened. Frequently the symptoms are so mild that the patient scarcely finds it necessary to keep his bed; but sometimes they are so severe, that a rigorous employment of antiphlogistic treatment is indispensable.

Franco is said to have made the first mention of the cure by the tent. The method has been practised by a long list of eminent surgeons of later date; but it has now been abandoned by all practitioners in this country. Mr. Pott objected to the cannula, that it was very inconvenient, as, by reason of its inflexibility, it hurt the testicle whenever the patient moved; consequently he preferred a tent or bougie; but, according to his account, the method is attended with a considerable degree of uncertainty.

Cautic.—The ancients employed caustic for the purpose of forming in the tunica vaginalis such an opening as would extend the whole length of this membrane. The common consequence of the method was a train of severe and violent symptoms, and, on this account, the practice was for a long while entirely given up. It was afterwards revived, by reason of the favourable reports made of it by Else, Acrell, &c.; but these later surgeons did not use the caustic exactly in the same way as the old surgeons, as their object was not to make an opening through the vaginal coat with it, but only to irritate the membrane, and make it inflame. Caustic has this effect, when employed according to the following directions.

The caustic must be applied to the inferior and anterior part of the scrotum, and, in order that it may not act too extensively, the part should be covered with a piece of plaster, in which a hole has been cut. When the hole is about as large as a half guinea, the eschar produced by the caustic will generally equal a guinea in size, which, according to Mr. Else, in all common instances, will be quite large enough. Other writers have advised making a more exten-

sive slough, and to proportion its size, in some measure, to that of the swelling, and to the degree of hardness and thickness with which there may be reason to suppose the tunica vaginalis affected. The caustic which has been mostly used is the kali purum blended with quicklime, and made into a paste. Acrell made the suggestion of mixing opium with the caustic, with a view of lessening the pain of the application.

In attempting the radical cure of the hydrocele by this method, it was the design of the surgeon to make the action of the caustic extend through the integuments and cellular substance, and affect the surface of the tunica vaginalis sufficiently to make this membrane inflame. The caustic-paste was generally left on about six or seven hours, and after its removal a pledget was applied, the patient enjoined to keep quiet in bed, and an antiphlogistic regimen directed. The denuded tunica vaginalis did not often burst of itself, or at least not till a considerable time after the detachment of the slough, so that it was generally necessary to make a puncture with a lancet. It was accounted a matter of much importance that the fluid should not be discharged too soon after the application of the caustic, lest the very purpose of the operation should be defeated. About the eighth or tenth day was usually reckoned the best time for making the opening; but the criterion of the proper period was when the patient began to experience a sense of heaviness and heat about the scrotum, and the swelling was every where painful and inflamed.

When the inflammatory symptoms prevailed, it was customary to apply emollient poultices. These complaints were often exceedingly severe, and attended with pain in the back and abdomen. Bleeding was sometimes required for their alleviation. Surgeons, indeed, found it prudent to prepare their patients for this mode of treatment by diet and medicines, and, after the caustic had been applied, a strict observance of an antiphlogistic plan was deemed generally advisable.

The method, however, was apt to fail when the caustic did not act deeply enough, and the requisite inflammation could not then be excited, without repeating the painful application again.

The treatment of the hydrocele with caustic has now quite fallen into disuse, as being attended with an avoidable destruction of parts, a degree of efficacy not equal to that of an injection, and often creating a painful and ill conditioned sore, besides being subject to other inconveniences obvious in the foregoing account.

The desire of Mr. Else to regulate the caustic with such precision as just to burn down to the tunica vaginalis, or just through it, could not, in general, be realized; and the opening could only be completed by employing a lancet, or using the caustic again.

Seton.—The seton was preferred by the celebrated Mr. Pott, as the means of effecting the radical cure of the hydrocele; and, next to the injection, this, perhaps, is to be considered as the most eligible method. The swelling is to be first punctured with a trocar in the ordinary place; an eye probe is next to be introduced through the cannula into the cavity of the hydrocele, and its end pushed to the upper and anterior part of the tunica vaginalis. Just where this extremity of the probe is felt, the surgeon is to make an incision for the passage of the instrument, which will convey with it the seton through the cavity of the tunica vaginalis. But, as the probe is apt to slip away at the moment of cutting upon it, and the skein of silk is liable to rub against the testicle, when drawn through the cavity of the disease, the method

method

HYDROCELE.

method adopted by Pott is undoubtedly that which deserves imitation. The instruments used by this consummate practitioner, consisted of a trocar, the cannula of which was about a quarter of an inch wide; a seton cannula, which was made of silver, was about five inches long, and was just small enough to pass with ease through the cannula of the trocar; and, lastly, a probe six inches and a half in length, furnished at one end with a fine steel trocar-point, and, at the other, with an eye which served to carry the seton. The seton was composed of as much white sewing thread as would fill the cannula, and yet pass through it with facility. The operation was performed in the following way. The tumour was punctured in the common manner with a trocar, and the fluid discharged. The end of the seton cannula was then introduced, through the cannula of the trocar, to the upper and fore-part of the cavity of the tunica vaginalis, and there pressed against the integuments, so as to be externally perceptible. The needle, provided with the seton, was next conveyed through the seton cannula, and pushed from within outwards through that part of the scrotum, with which the end of the tube was in contact. The skein of thread was thus drawn through the cavity of the hydrocele, and both the cannula, having fulfilled their office, were taken away.

The operation occupied but a short time, and was productive of no severe pain. The patient was generally put to bed immediately afterwards, and took about twenty, or five and twenty drops of the tinctura thebaica. On the third day the scrotum was usually affected with swelling and inflammation, symptoms which were soon appeased by means of a bag-truss, emollient poultices, clysters, and a low regimen. The inflammation commonly subsided about the tenth day. From this time, the seton was lessened every day by withdrawing some of the threads, and the discharge of matter from the openings was generally inconsiderable. Pott believed, that, in this method, the tunica vaginalis did not suppurate, but was only made to inflame and become adherent to the testicle. Other surgeons, however, have sometimes found the plan tedious, the seton not becoming loose for more than a fortnight, and large abscesses being occasionally produced, which stood in need of being opened. Upon the whole, however, the seton may be considered as one of the mildest and surest modes of cure, and, perhaps, ought to be preferred to all the other plans, excepting one, of which we shall now speak.

Injection.—The method of injecting into the cavity of the tunica vaginalis a stimulating fluid, for the purpose of bringing on an inflammation of this membrane, and thereby a radical cure of the hydrocele, is by no means one of modern invention. Of late years, however, it has been more particularly practised, and the manner in which it has been recommended, and perfected by sir James Earle, together with its confirmed mildness and success, has almost entirely set aside all the other modes of cure. According to the statement of the preceding author, even the celebrated Mr. Pott lived to express his approbation of the method, notwithstanding the great partiality which he has evinced in his writings to the seton.

Many different kinds of injection have been employed for the radical cure of the hydrocele. The principal are wine mixed with water; a solution either of two grains of kali purum, or of two grains of cuprum vitriolatum, in an ounce of water; lime-water, either alone, or containing hydrargyrus muriatus; a strong solution of alum, or acetite of lead; brandy diluted with water; an infusion of red roses, or of oak-bark, &c. However, at present, the injection universally employed in this country is composed of port wine

and water, in the proportion of two parts of the former to one of the latter ingredient. On the continent, it is not uncommon to use five parts of claret, or Burgundy wine, to one of water.

We learn from sir James Earle's treatise, that he commonly uses about two-thirds of port wine to one of water. When the parts appear insensible, and no pain at all is produced on introducing the first quantity of the injection, he withdraws the syringe, and increases the proportion of wine. On the other hand, when the complaint is recent, and the parts irritable, he increases the proportion of water, the strength of the injection, in fact, being principally regulated by the degree of pain experienced by the patient. The syringe preferred for this operation is made of elastic gum. The pipe formerly employed by sir James Earle was furnished with a stop-cock, in order to hinder the injection from making its escape, whenever it was necessary to remove the syringe. Of late years he has used a pipe, one end of which fits the cannula of the trocar, while the other is adapted to receive the neck of the elastic bottle; and instead of a stop-cock, which required a hand to turn it, and was therefore found inconvenient, the pipe is furnished with a valve, which allows the injection to pass into the tunica vaginalis, but not back again. The operation is generally performed as follows: the hydrocele is first tapped with a trocar at its anterior and inferior part, and after all the fluid has been discharged, the cavity of the tunica vaginalis is to be distended to its former dimensions with the vinous injection, which, upon an average, is to be kept in the part about five minutes, after which it may be let out through the cannula. The patient commonly feels pain in the groin, and about the kidneys, on the injection being introduced; a circumstance which is rather desirable, as it shews that the stimulus of the fluid is likely to have the wished-for effect of exciting the necessary degree of inflammation.

When the hydrocele is exceedingly large, sir James Earle recommends practitioners to be at first content with merely discharging the fluid, and to take a future opportunity, when the tumour is smaller, for putting into practice the attempt at a radical cure.

The experience of the same gentleman has proved, that the injection is adequate to the accomplishment of a permanent cure, even though the tunica vaginalis may be indurated and thickened.

The treatment of hydroceles with the vinous injection is now generally acknowledged to be the mildest and most certain method, and hence it is universally practised by all the most eminent surgeons of this country, in preference to the other plans. One great advantage attending it must be immediately obvious,—it does not commonly occasion any suppuration or sore; and it is so efficacious, that many very experienced surgeons have never known an instance of its failing.

It remains for us to give one caution; let every operator be sure that the end of the cannula is in the tunica vaginalis before he ventures to introduce the injection. It has sometimes happened that the cannula has slipped out of the puncture in that membrane, just after the fluid has been discharged, so that its extremity became situated in the cellular substance of the scrotum. Now when the surgeon injected the wine and water, this liquid, instead of passing into the cavity of the hydrocele, was forced into the cellular membrane. Mistakes of this kind have brought on violent attacks of inflammation, abscesses, and sloughing, without there being any chance of a radical cure of the hydrocele. Whenever such an accident happens, it is considered best

HYDROCELE.

to defer the operation till the fluid of the hydrocele is accumulated again in sufficient quantity.

No objection can be reasonably urged against the method, on account of the preceding accident, which is easily avoidable, and is always imputable either to awkwardness or negligence.

After the operation, the puncture is to be covered with a piece of lint and soap-plaster, and the scrotum is to be supported in a bag-truss. As soon as the parts begin to inflame and become tense and painful, then an emollient poultice is to be applied to them, care being taken to employ the sufficiency, keep the patient on an antiphlogistic regimen, and quiet in bed. If the inflammation should appear to exceed the requisite degree, leeches may be put on the scrotum, the patient gently purged, and even bled in the arm.

Congenital Hydrocele of the Tunica Vaginalis.—The disease is so named when the tunica vaginalis, besides containing a preternatural quantity of fluid, is unclosed above, so as to have an open communication with the cavity of the abdomen. In most cases the fluid, in all probability, is secreted by the peritoneum, and then descends by its weight into the scrotum. This form of the hydrocele has escaped the notice of the generality of surgical writers. The French surgeon, Desault, however, has given a description of it, and we find that he was in the habit of effecting a radical cure by means of a vinous injection. The nature of the disease cannot be difficult of discrimination, when the surgeon adverts to the transparency and fluctuation of the tumour, the absence of pain, and the disappearance of the swelling in the recumbent posture, or on pressure being made.

Desault used to cure the complaint in the following manner. After letting out the fluid with a trocar, he took care to reduce any viscera which happened to be protruded, and directed a confidential assistant to close the communication between the abdomen and tunica vaginalis by pressure. The injection was then introduced through the cannula into the cavity of the hydrocele. In this way, Desault not only cured a boy of a hydrocele, but also of a hernia, with which he was afflicted. *Cœuvres Chirurgicales de Desault, par Bichat, tom. ii.*

Hydrocele of the Spermatic Cord.—In this case the fluid is contained in the cellular substance which surrounds the spermatic vessels, and forms what is sometimes named the common sheath of the cord. The water is not diffused in all the cellular membrane of the scrotum. Some writers think that the complaint might, with greater propriety, be called an œdema of the spermatic cord. However this may be, it is certain that this species of hydrocele is the least frequent. In external appearance it is subject to considerable variety, according to the stage in which the disease presents itself. In the early state, the swelling merely surrounds the lower part of the spermatic cord, and has no connection with the abdominal ring, the upper portion of the cord remaining quite free. The shape of the tumour is generally pyramidal, having a kind of apex above, and a broad base below. The testicle can be quite plainly felt just below the swelling. The tumour is unattended with pain, has a doughy feel, and allows its shape to be altered by pressure. The scrotum retains its natural corrugated appearance, being only somewhat more full and distended on the affected side than the other. In a more advanced state, the swelling undergoes two alterations; it ascends up to the abdominal ring, so that the upper portion of the cord can no longer be felt; and it descends so far down by the side of the testicle, that this gland is likewise completely concealed. In the extreme stage of the disease, not only the cellular substance which surrounds the spermatic cord in the scrotum is distended with water; but

even that which forms the investment of the spermatic vessels in their course from the inner to the outer opening of the abdominal ring.

The first stage of the hydrocele of the spermatic cord may easily be distinguished from all other tumours of the scrotum, for there are none which bear so much resemblance to it as to be readily mistaken. But in the very advanced period of the disease, the swelling has much of the appearance of an omental hernia. It has the same soft flabby feel; it passes up into the abdominal ring; and the latter opening is wide and dilated. When the patient has been long in a standing posture, the water descends from the cellular substance which surrounds the spermatic vessels within the ring, and passes into the cellular membrane, with which they are invested below this aperture; consequently, the external swelling undergoes an increase of size. On the other hand, when the patient lies down for a time, the tumour diminishes. It may also be lessened by external pressure, and even nearly pushed within the ring. Likewise, when the patient coughs, or holds his breath, the tumour swells and becomes larger. Such symptoms correspond with those of an omental hernia. The two diseases, however, may, with a little attention, be easily discriminated from one another. By adverting to the early stage of the disease, and recollecting that the swelling first made its appearance at the lower part of the spermatic cord, had then no connection with the ring, and afterwards gradually ascended into this opening, the surgeon may know with certainty that the case cannot possibly be an omental rupture. A careful examination of the swelling will also discover the difference. An epiplocele communicates the feel of several lumps or masses, and is softer in some places than others. On the contrary, the hydrocele of the spermatic cord has every where a smooth uniform feel. Its shape also undergoes alterations according to posture. When the patient observes an horizontal position, and the scrotum does not hang down, the hydrocele becomes oblong, equally thick, and cylindrical. But when the patient continues in a standing posture, and the scrotum is unsupported, the swelling becomes pyramidal, that is to say, broad below and thin above. Its shape may be altered by making pressure on it for a little while. When the lower part is thus pressed it becomes thin, while the upper portion increases in thickness; and *vice versa*. Although an omental hernia alters in size, it undergoes no change of shape, at least none that is so plain and durable. When the horizontal posture or external pressure is long continued, the hydrocele of the spermatic cord, like the epiplocele, becomes smaller, or even appears to pass entirely within the abdominal ring. Like this hernia, also, it seems to descend again, when the patient continues erect, or the pressure is removed; but still a difference is observable in the modes in which the two diseases return. For on applying two fingers to the abdominal ring, at the period when the hydrocele is ascending or descending, nothing can be felt to pass up or down; but if the case be an epiplocele, the viscera can be distinctly felt to pass into, or out of, the abdominal ring. The descent and reduction of an omental rupture are moreover observed to happen more quickly than the ascent and falling down of the fluid of the hydrocele. When the latter tumour is large, the patient suffers shooting pains in the loins, at the period of urging the fluid upwards by pressure.

If the disease has made considerable progress, a fluctuation may be distinguished in the swelling, upon laying one hand upon its upper part and the other below, and making pressure with the first downwards, and with the second upwards, in an alternate manner. The abdomen, in the vicinity

HYDROCELE.

nity of the ring, is alleged to appear sometimes preternaturally prominent, on pressing the fluid upwards.

Lastly, it deserves attention, that, in the hydrocele of the cord, no complaints of the stomach and bowels prevail, as they usually do in cases of epiplocele.

The hydrocele of the spermatic cord is generally a local disease, which proceeds from causes altogether local. Sometimes it arises from wearing an ill made truss. Children are occasionally born with it. (Delattre *Journal de Médecine*, t. 32.) In certain instances it appears to originate from contusions. Frequently it is the consequence of a general dropsical affection of the system.

Should the disease depend upon internal causes, it is the business of the surgeon to endeavour to remove them. When it arises from local causes, a surgical operation is commonly necessary for its cure, discontents very seldom being found effectual. It is to be observed, however, that when this kind of hydrocele is small, it is hardly an object of surgery; the pain or inconvenience which it produces being so little, that few people would choose to submit to an operation to get rid of it; and (as Pott says) it is very seldom radically curable without one. But when the hydrocele is large, or affects the membrane within the abdominal ring as well as without, it becomes an apparent deformity, is very inconvenient both from size and weight, and the only method of cure which it admits is far from being void of hazard.

Authors describe two operations for the relief of this disease, one is called palliative, and consists in making a few punctures with a lancet in the tumour; the other is named radical, and is executed by making an extensive incision into the swelling.

The generality of patients are content with the relief derived from the employment of a suspensory; and, except in bad cases, an operation seems scarcely advisable.

Encysted Hydrocele of the Spermatic Cord.—The fluid is sometimes observed to be contained in a preternatural cyst formed in the cellular membrane, and resembling such as commonly compose the investment of encysted tumours. This species of hydrocele is mostly met with in children and young subjects; and not often in adults and old persons. The swelling is most frequently situated about the middle of the spermatic cord, and is more or less of an oval shape. In some cases it lies close to the cord; in others it is so distant from this part, that the finger may be put between them. Below the tumour is the inferior portion of the spermatic cord, together with the testicle; while above, the upper part of the cord can be plainly felt to be quite free, so that the swelling manifestly has no connection with the abdominal ring. But there are examples in which the disease acquires such magnitude, that it mounts upwards as far as the ring, and descends down to the bottom of the scrotum. In this circumstance the case may somewhat resemble the hydrocele of the tunica vaginalis. The testicle, however, can always be distinctly felt on the outside of the swelling, a fact which immediately makes an experienced surgeon acquainted with the nature of the disease. A mistake would be attended, indeed, with no serious ill consequences, the treatment of both tumours being similar. It may be remarked, likewise, that the swelling is completely circumscribed, has a very even surface, and is entirely free from pain. A distinct fluctuation cannot often be felt.

In young subjects, the tumour may frequently be dispersed by external means; but in ordinary cases a surgical operation is indispensable for the cure of the disease, and is of two kinds; one palliative, the other radical. The first consists in merely discharging the fluid with a lancet or trocar. Care must be taken to avoid injuring the spermatic

cord. Here a lancet is mostly preferred to a trocar. In children, tapping the tumour is often productive of a radical cure. The cyst is frequently found filled with a fluid of so viscid a quality, that it will not pass through the cannula of a trocar.

The radical operation, formerly practised, was to lay open the swelling its whole length, and cut away as much of the cyst as could be accomplished, without risk of wounding the spermatic vessels. The wound was afterwards dressed with digestive applications. Modern experience proves, however, that this case can be radically cured with the port wine injection, just like the hydrocele of the tunica vaginalis, and as the method is free from all severity and danger, it certainly deserves to be recommended. Sir James Earle assures us, that he has successfully treated the disease in this way.

In certain examples, two or three separate cysts, filled with fluid, are met with in the cellular membrane of the spermatic cord or serotum. While small, they can easily be distinguished from each other; but when they have acquired a considerable size they lie so close together, that they seem like one single uniform swelling. Furrows, however, may frequently be felt between them, and some information may be obtained from a recollection of the early stage of the disease. But in operating, the nature of the case cannot fail to shew itself, it being impossible to discharge all the fluid, unless an opening be made into each of the cysts. Every operator should use the utmost care not to injure the testicle and spermatic cord, as these parts have no fixed situation with respect to the tumours. The place of the testicle may, indeed, be often ascertained beforehand, by the peculiar pain which is occasioned by pressing it.

Encysted hydroceles have occasionally been remarked in women. They are mostly situated in the vicinity of the groin (*Journal de Médecine*, t. 82.) or else in one of the labia. Authors advise us to treat them just like other encysted hydroceles. We see no reason why they should not be extirpated in the manner of common encysted tumours.

Hydrocele of Hernial Sacs.—Hernial sacs occasionally contain, besides the protruded viscera, a quantity of fluid, which is frequently so copious, that the bowels cannot be felt, the water alone being perceptible, and the case apt to be mistaken for a common hydrocele of the tunica vaginalis. But the diagnosis can be attended with no difficulty, when the viscera admit of being reduced. However, in some cases, the protruded parts are adherent to the neck of the sac in such a way, that, besides being incapable of reduction, they prevent the fluid from passing up into the cavity of the abdomen. In this circumstance, the surgeon may fall into error, though a correct judgment can always be formed by paying a little attention. In the early state the disease has commonly been nothing more than an ordinary intestinal or omental hernia. The recollection of this fact throws much light on the nature of the case. The swelling at its commencement is always connected with the abdominal ring. The testicle can be plainly felt at the under and lower part of the tumour. The patient is likewise afflicted with the usual symptoms of an enterocele or epiplocele. Were any of the operations, employed for the cure of common hydroceles, erroneously practised in the preceding case, excepting that of merely letting out the fluid, the consequences would be highly perilous, and, in all probability, fatal.

When a hernia has been reduced, and the descent of the bowels again effectually hindered by the gradual closure of the neck of the sac, a collection of fluid sometimes takes place in the cavity of the latter part. We have already described

scribed the congenital hydrocele, where water collects in the tunica vaginalis, and the sac has an open communication with the abdomen. We have further recorded the success with which Default freed a lad not only of such a hydrocele, but also of a hernia, by the employment of an injection. Certainly, the hydrocele of a hernial sac, when the neck of the latter part is closed, may be safely treated just like an ordinary hydrocele. But should the sac communicate with the abdomen, or contain any protruded parts, such treatment would be rash and almost certainly fatal.

HYDROCELODES ISCHURIA, in *Surgery*, a retention of urine, produced by a rupture of the urethra. The term is derived from ἵδωρ, *water*, and κτλωδεις, attended with swelling.

HYDROCEPHALUS, in *Medicine*, from ἵδωρ, *water*, and κεφαλον, *cephalon*, the *head*, signifies strictly *dropsy*, or *water*, in the *head*.

For the knowledge that we possess, relative to the nature and characteristic symptoms of effusion of water within the cranium, we are indebted almost entirely to modern observation. Hippocrates, Aëtius, Celsus, and some other ancient physicians, speak of the presence of water between the cranium and the surface of the brain, and of an external hydrocephalus, or dropsy of the teguments of the head; but the writers of the 16th century first mention the occurrence of water in the ventricles of the brain itself. (See *Mercurialis*, *Opuscula Aurea*, lib. de Morb. puerorum.) After this occurrence had been observed by a number of writers, and had even been mentioned by the celebrated Boerhaave, the symptoms, by which it might be distinguished from other diseases of the brain, remained still unknown. The disorder was briefly and inaccurately described in the *Memoirs of the Academy of Sciences at Paris*, for the year 1718, by M. Petit; but it was not until the publication of a posthumous essay of Dr. Whytt, professor of medicine at Edinburgh, in 1768, that a well-connected history of the symptoms accompanying the effusion of water into the ventricles of the brain was clearly made out, or that hydrocephalus was known as a distinct disease. Immediately after this publication, Dr. Fothergill, whose sagacity had already detected most of the peculiarities belonging to the disease, read a paper on the subject to a medical society in London, which was published in 1772 (see *Med. Observ. and Inquiries*, vol. iv. art. 3.), since which period the disease has been well known to medical practitioners.

Before the appearance of Dr. Whytt's Essay, the term *hydrocephalus* had been almost entirely confined to a chronic affection, analogous in its causes and progress to other forms of dropsy in the human body. This disorder, commencing soon after birth, before the sutures of the skull are united, proceeds very slowly, continuing even for years, until the head becomes enormously large, without producing any very extraordinary symptoms. After death, which is usually preceded by convulsions, the brain is found so exceedingly distended by water within the ventricles, as to be rendered extremely thin; or, on the other hand, so much oppressed by the water, collected between it and the skull, as to assume rather the appearance of a small gland than that of a brain. This form of the disease, or the *chronic hydrocephalus*, we have described under the article, *Dropsy in the head*. The variety of the disease, to which our attention is at present directed, differs altogether from the one just mentioned; and, being accompanied by febrile symptoms, and generally of short duration, has been distinguished by the appellation of *acute hydrocephalus*, or

HYDROCEPHALUS ACUTUS. This name was first appropriated to the disease in question by Dr. Charles William Quin, of

Dublin, in his inaugural dissertation, published at Edinburgh in the year 1779. He pointed out the febrile, or rather inflammatory nature of the affection of the brain, in the commencement of the complaint, of which the effusion of water appeared to be a consequence, and by which the disease was distinguished from the ordinary dropical effusions. Dr. Cullen, being convinced of the accuracy of this statement when he republished his "*Nosologia Methodica*," in 1780, removed the *acute hydrocephalus*, from the dropsies to the apoplexies, with the new appellation of *apoplexia hydrocephalica*, and retained only the *chronic* form as one of the genera of dropsies, with the old name of hydrocephalus. Dr. Rush, of Philadelphia, having taken the same view of the disease with Dr. Quin, and deeming it inflammatory in the commencement, called it *phrenicula*, from its being a diminutive species or state of *phrenitis*, or inflammation of the brain. See his *Med. Inquiries and Observations*, vol. ii. p. 215. Philad. 1793.

Physicians have acknowledged the extreme difficulty of detailing a distinct history of the symptoms of hydrocephalus, which shall be exemplified in every case; and they have, especially, differed in describing the appearance which the disease assumes in its commencement, and the length of time which it usually occupies in its progress. The truth is, we believe, that each writer has seen what he has described; for that the malady actually puts on a considerable variety of character, both in respect to its phenomena and duration. The latest writer on the subject, Dr. Cheyne, now of Dublin, has described three different modes in which it has made its attack in different instances which have fallen under his observation (see his *Essays on the Diseases of Children*, Essay III. Edinburgh, 1808.); and a similar division of the varieties of the disease has also been made by professor Kuhn of Leipsic. (See *Edinburgh Med. and Surg. Journal*, vol. iii. p. 13.) These are, 1st, when the symptoms come on slowly and gradually; 2d, when the attack is sudden and the progress more rapid; and 3d, when the disease ensues upon some previous indisposition. The first of these Dr. Kuhn terms the *nervous*, and the second, *inflammatory hydrocephalus*; the third he mentions only as a sequela of scarlet fever. These varieties of the symptoms, however, only mark the attack of the disease; for in the latter stages there is little diversity in the appearances.

In the first, or gradual mode of attack, before any characteristic signs of the disease appear, the child for some days, or even weeks, has complained of pains in his head or belly, while at the same time he has been slightly feverish, dull, ill-complexioned, without appetite, or perhaps with an increased appetite, and with some disorder in the functions of the abdominal viscera. These complaints rise gradually; but are seldom alarming; and the child's friends are not awakened to a sense of his danger, until, advancing a step farther, the disorder begins to shew itself more distinctly. The dulness is accompanied with pains in the head, which is also connected, upon getting up in the morning perhaps, or after he has begun to stir about, with vomiting. Yet even this symptom is often disregarded, until the second or third day of its recurrence, and the disease has made considerable progress, before the illness of the patient is suspected to arise from a disordered condition of the brain. When the attention is more particularly excited by these symptoms, the head-ache, which is chiefly in the forehead, or sometimes in the crown, will be found to return at shorter intervals. The child often affectingly complains of his head. He sighs frequently, is dull, his head requires to be supported; he complains of weariness in his eyes; the pupils are sometimes unusually contracted, and he has an aversion

HYDROCEPHALUS.

to light; his tongue is white, and his belly generally costive: the stools are first clayey; as the disease advances they become of a gelatinous consistence, of a dark green colour, sometimes as dark as tar, and of a sickly smell. The pulse becomes quick; and at particular times of the day these symptoms are attended with febrile heat and irritability, and the child complains not only of head-ache, but of pains in different parts of the body, sometimes extremely acute. At one time he complains of pains in his limbs, at another of pains in his breast, or in the nape of the neck, very often in his bowels; and before the anxiety of his friends can make any preparations to relieve him, the pain is gone, or fled to some other part; at another time he lies on his mother's knee, restless and whining, as from dull rheumatic pain. These disorders necessarily impair the child's strength, and in the course of ten days or a fortnight his appearance is considerably altered; he is peevish and feeble.

In the second form of the attack, Dr. Cheyne observes, the disease runs a more rapid course. After the child has been drooping for a short time, which, although it sometimes escapes observation, is generally recollected, there is a sudden change to a fever, attended even from the first with a great degree of heat and irritation, with frequent but short and irregular remissions, flushing, severe head-ache, tenderness all over the abdomen, and increased sensibility, with sometimes brilliancy of the eyes. It is said to be often difficult immediately to distinguish hydrocephalus from fever, and this is the form of the complaint in which there is the greatest resemblance between the two diseases; but we are led to suspect some deeply seated evil, from the frantic screams, and complaints of the head and belly, alternating with stupor, or rather lowness; and we are struck with the irritability of the stomach, in a degree beyond what we find in fevers of this country, retching and vomiting being often brought on by a change of posture, certainly by every attempt to sit up in bed, and with the disordered state of the bowels which attends this irritability of the stomach; and when at any time the child has a little respite from the violence of these symptoms, we find our suspicions confirmed by his look; for, in this disease, when the features do not express pain or terror, there is not unfrequently an expression, which it has in common with some other diseases of the brain, of dejection, bordering upon insensibility, which is quite insupportable to those who are interested in the patient's recovery.

In the third mode of attack, when hydrocephalus arises after an imperfect state of health, as where there had been a serofulous action which has abated, or where the child has had some epidemic disease formerly (perhaps many months before), from which he has not perfectly recovered, or regained sound health, the attack is sometimes made with all the violence distinguishing the second form just described. When again the attack comes on as the sequel of an acute disease, as fever, hooping-cough, perhaps dentition, or during some actually existing serofulous disease, the child almost imperceptibly slips into hydrocephalus; there are scarcely any of the acute symptoms; and the palsies or convulsions are the first indications of the new disorder.

In whatever mode the disorder commences, it is marked in what has been called, by Dr. Whytt, the *first stage* by a febrile condition, varying much in degree and regularity; the sleep becomes imperfect and apparently uneasy, the little patient often grinding his teeth, picking his nose, and starting with a scream, as if he were terrified. There is great fluctuation in the feverishness: at one time the pulse is quick and throbbing; the heat of the body is increased; the skin parched; there is a deep blush on the face, more especially

on one cheek; and the breathing is sighing, laborious, and quick; at another time the blood circulates more equally; the skin is of a natural warmth, or moist with temporary perspiration; the countenance is pale; and the breathing so soft that it cannot be heard. There is also great fluctuation in the state of the other functions. Sometimes the state of the stomach appears to be nearly natural; at other times the heavy smelling breath, that has been supposed by Dr. Whytt to be peculiar to this disease, the total absence of appetite, and constant vomiting, even for days, shew the stomach to be in the greatest disorder. The bowels are never regular; they are generally slow, requiring cathartic medicines, and now and then a constant and severe bilious purging attends the vomiting. The urine is sometimes withheld for 24 or 36 hours; occasionally a frequent desire to pass it has been observed. And not only are the vital and natural functions irregular; we find the same extremes in the animal functions; to this, indeed, the diseases of the brain owe much of their interesting character. The senses and judgment are often perfect and entire, sometimes morbidly acute; in general the retina is painfully sensible to light, and the child is sometimes unpleasantly affected by slight sounds: on the contrary, sometimes, even in the early days of the disease, the mind is subdued, and there is the greatest dulness of apprehension.

It generally happens, but by no means with the certainty which the description of Dr. Whytt would lead the student to expect, that after the first or febrile symptoms have continued an indefinite time, from a few days to a fortnight or more, a remarkable change takes place in the disease, especially in the condition of the pulse, by which the commencement of the *second stage*, according to Dr. Whytt and others, is marked. The pulsations become slow, even slower than in health, and at the same time unequal and irregular, both as to strength and the intervals between the strokes; but, as Dr. Cheyne remarks, they are easily doubled by the least exertion. With the slowness of the pulse, a greater degree of dulness and torpor comes on; the pain of the head seems to abate, or at least the patient becomes apparently less sensible of it; and as this stage advances, he grows drowsy and lethargic, yet moans heavily, without being able to tell what distresses him; and often starts and cries in a wild manner, as if from momentary attacks of acute pain. The pupils are observed to be dilated, and a want of consent between the two eyes, attended with imperfect, and not unfrequently double vision, takes place. As the disease proceeds, the fainting and dilatation of the pupil increase; the patient lies with one or both eyes half closed, which, when minutely examined, are often found to be completely insensible to light; and they now lose their vivacity in consequence of a filmy covering of the cornea. The sickness ceases, and whatever food or medicine is offered, is usually swallowed with apparent voracity; the bowels generally remaining obstinately costive.

These symptoms are soon succeeded by others, which mark the *third stage*, and announce the approach of death within five or six days, or sometimes within a much shorter period. The pulse now becomes equal and regular, and rises to a rapidity greater than ever; which continues to increase while life remains. There is no disease, we believe, in which the pulsations become so frequent, and yet continue distinctly numerable, as in the closing scene of hydrocephalus. Dr. Whytt says, that no patient dies of this disease, while his pulse remains under 130 beats in the minute; in one case he counted it 210 in the minute on the day of death. We have distinctly enumerated 190 beats under the same circumstances.

A comatose.

HYDROCEPHALUS.

A comatose state now comes on. The patient lies with a frequent hectic flush on his cheek, alternating with a deadly paleness; drawing a long sigh at intervals; often grinding his teeth; incoherent, or in a state of complete insensibility; perhaps picking about or fawing the air with one hand, while the opposite side is palsied; with a burning fever on his skin, or sweat forced from every pore; and all these symptoms alternating with, and at last finished by, apoplectic breathing, and convulsions.

The whole concurrence of the symptoms, as well as the changes in the state of the pulse, which occur in each of the three stages, constitutes a very remarkable peculiarity in this disease, and gives a character to each stage. The *first* has been called the stage of increased sensibility, or inflammatory irritation: the *second*, that of decreased sensibility, or torpor; and the *third*, the paralytic or convulsed stage. In the *first*, every stimulus produces an inordinate effect: there is great aversion to light and to sounds; watching, sickness, pain, and quickened pulse. In the *second* stage, the child is not easily roused, his pupil is dilated, and does not contract on the approach of light, his pulse is slow, he is lethargic, with often an obstinately costive belly. In the *third* stage, which may, perhaps, be considered as a continuation of the second, there is squinting, rolling of the head, delirium, stupor, convulsions, with a rapid thready pulse.

Physicians have represented the duration of the disease differently: Dr. Whytt supposed it to extend to four, five, or six weeks, from the date of the first symptom; while Dr. Fothergill commonly found it to terminate in three weeks. On the whole, experience seems to have corroborated the observation of Dr. Fothergill. But, like every other disease, of the brain, hydrocephalus is uncertain in its duration, especially when the pulse has become slow, or the stage of torpor has arrived. Sometimes, in the course of two or three days from this change, the child shall be carried off; while, in other cases, even the last stage continues day after day, for upwards of a week, when, at every visit, the observer would conceive that the patient had only a few hours to live. In cases of the second, or acute mode of attack, and also in the third, the whole disease sometimes runs its course in a few days; while, in the first mode, from the great length of the first stage, it has been observed to last many weeks. Dr. Quin states, apparently on conjecture, that the disease may be expected to be more rapid in its course, in adult persons, than in young children. But our observation accords with that of Dr. Cheyne and others, in stating the contrary. In a boy of twelve years old, we once saw the disease run on, in a very gradual course, to the length of eight weeks, and then terminate fatally.

Nor is there less variety in the symptoms and progress of the disease, than in its duration; inasmuch that Dr. Quin has called it a "truly Proteiform distemper;" and Dr. Rush accords in the justness of the appellation. Cases have terminated fatally, in which some one or more of the characteristic symptoms have not appeared, and sometimes when "no one symptom afforded any suspicion of the real cause of death," which was ascertained by dissection. (See Dr. Quin's Essay, p. 43.) The same author mentions another case, which terminated fatally in seven days, and dissection determined the nature of it; "yet the usual variations of the pulse in the several stages did not take place; the pupils were not dilated until the last day of the child's life; he never once vomited, never expressed a dislike to light, and the head-ache, though constant, was not violent." Dr. Rush observes, "I have not found the dilated and insensible pupil, the puking, the delirium, or the strabismus, to attend

universally in this disease. I saw one case in which the appetite was unimpaired from the first to the last stage of the disorder." (Med. Inq. and Obs. vol. ii. p. 209.) On the contrary, we lately saw a case, in which the chief symptom of indisposition, for the first four or five days, was a constant sickness in the stomach, which rejected almost every thing as soon as swallowed while the head remained apparently free from uneasiness. Other cases are mentioned by Dr. Rush, in which no head-ache occurred during the course of the disorder; in which no preternatural slowness or intermission was ever perceived in the pulse; and in which no dilatation of the pupil, squinting, sickness, or loss of appetite had attended: and others, in which an uncommon acuteness of hearing, palsy of one side, and the symptom of hydrophobia, had respectively occurred. Dr. Whytt also mentions an irregularity in the state of the pupil. "Three or four days before the death of a boy of five years old," he says, "I was surprised to find the pupils, which had been much dilated before, no larger than natural. At first I flattered myself that the disease had taken some favourable turn; but was soon undeceived: for, upon giving the child a spoonful of weak cinnamon water, with some drops of *Spiritus volatilis oleosus*, the pupils became as wide as they had been the day before. In less than half an hour after they contracted again; but immediately dilated upon holding some spirit of *sul ammoniacus* to his nose. I have since observed the same interchanges in the pupils of a boy of four years old, on the third day before he died. In this case the pupils not only were enlarged, by giving him a spoonful of wine, or holding volatile spirits to his nose, but also by so small a stimulus as my lifting up his eyelids, which had lost all their motion, and had fallen so far down as to cover near the half of the eye." Observations on Dropsy in the Brain, Whytt's Works, p. 733.

Dissection.—The circumstance which was first noticed, on examining the head by dissection, in patients who had died of this disease, was the constant occurrence of a limpid watery fluid, distending the ventricles of the brain, and amounting in different instances to the quantity of from two to six ounces. In some cases, only one of the lateral ventricles has been found thus distended. A small quantity of fluid is also commonly found between the membranes surrounding the brain, especially under the *tunica arachnoidea*, both above and at the base of the brain. The water, collected from the ventricles in hydrocephalus, does not coagulate by heat; in which respect it differs from the serum of the blood, from the water that is found in the *pericardium*, and from that which is taken from the abdomen, by tapping, in dropsy.

But in addition to this effusion of water, later authors have observed, in many instances, the marks of congestion in the blood-vessels of the brain, and of different degrees of inflammatory action. Dr. Cheyne remarks, "upon dissection, we generally find within the cranium, the veins, particularly those of the membranes on the surface of the brain, and lining of the ventricles, gorged with blood; sometimes considerable adhesion between and thickening of the membranes, and minute and florid vessels upon the *pia mater*." (Loc. cit. p. 31.) And Dr. Quin has related several cases, "wherein the quantity of fluid found in the ventricles was very considerable; but at the same time, there were signs so visible of an increased flow of blood to the brain, that in all of them the vessels were remarkably turgid; in most of them a degree of inflammation had taken place, as appeared at the time of dissection, either by preternatural adhesions of the membranes, or by a partial opacity and increased thickness of them, together with patches of inflammatory crust, very similar to those which are found on the abdominal

HYDROCEPHALUS.

minal viscera of persons whose death has been the consequence of *enteritis*; or on the lungs and *pleura* of those who have sunk under pulmonic inflammation." P. 51.

In investigating the seats of diseases by dissection, physicians are too apt to confine their examinations to that part of the body, in which the most prominent symptoms of derangement had occurred during life; by which practice a very imperfect knowledge of the morbid changes is often acquired. This error is too frequently committed in respect to hydrocephalus, when the contents of the *cranium* alone are examined; for it appears that the viscera of the abdomen often suffer in this disease. "In the abdomen," says Dr. Cheyne, "I have found the intestines inflamed, and constricted from spasm, and the surface of the liver of a bright red colour, abounding in minute vessels; and sometimes extensively adhering to the peritonæum. In several dissections, I have found the surface of the liver studded with small white tubercles, not larger than a grain of mustard. The glands of the mesentery are often diseased, &c." (P. 31.) And, in another place, the same writer remarks, "upon dissection of hydrocephalic children, I have found in the liver the remains of great inflammatory action, and also proofs that undue irritation had existed in the alimentary canal." P. 46.

Causes of Hydrocephalus.—This subject remains in some degree of obscurity, more especially in what regards the exciting causes. A *predisposition* to the disease is pretty obviously found in that peculiarity of constitution which is allied to scrofula, and which is characterized by a frame of body that is rather delicate and irritable, and often beautiful—and by acuteness of intellect and liveliness of disposition—the skin being fair and well coloured, the eyes blue, and the hair light. This predisposition is often *hereditary*, and attached to particular families. Dr. Cheyne attended two families, in one of which four children, in the other three, died of this disease; and he had "heard of an unfortunate family who lost seven children of hydrocephalus." We are acquainted with one, in which seven children perished from this malady, when they arrived at a certain age, apparently of sturmountous constitutions. Sauvages has a similar observation. "*Novi familiam,*" he says "cujus infantes circa sextum ætatis annum omnes periere ex hoc morbo, scrofula huic effusioni ansam præbente." (See his Nosol. Method. class. iv. gen. xii. 5. Convulsi ab Hydrocephalo:—also, gen. xviii. 14. Ecclampsia ab Hydrocephalo.) Dr. Percival states, that of twenty-two cases of which he kept notes, eleven were certainly sturmountous children, and four were probably so. (Med. Facts and Obs. vol. i. p. 129.) Hydrocephalus is more particularly a disease of *childhood*, occurring most frequently in the middle years, between weaning and puberty. Occasionally, however, it is seen at every period of life, with the exception, perhaps, of old age. A state of *imperfect convalescence* from scarlet fever, measles, small-pox, whooping cough, and other acute diseases, appears to generate a predisposition to hydrocephalus. Many cases of hydrocephalus occur, of which no *exciting cause* can be traced, sometimes, indeed, little accidents, as falls and blows, are collected, when the disease has made its appearance, which had occurred several weeks or months before, and had excited little attention at the time. Whether these accidents were actually the causes of the disease, which thus ensued, after a long interval of health, is certainly a matter of doubt. Dr. Cheyne observes, that, in upwards of a hundred cases which he had attended, he had only met with one, in which external violence could be considered as the origin of the disease, and that in an indirect manner. This child had, at the same time, a severe and obstinate catarrh; which he deemed more likely to impair the general

health, and thus to predispose to hydrocephalus. He adds, that he has repeatedly seen symptoms of scrofula following a severe accident, which may thus intermediately induce hydrocephalus, by deranging the general health, and calling into action what, from a good and fortunate management, had hitherto been latent.

It would seem, however, that any circumstance which can produce a state of general debility, but especially any cause exciting an active feverish state, of the inflammatory kind, in children predisposed to the disease, will call it into action. Hence the irritation of teething, and of worms in the alimentary canal, especially if attended with convulsions; sudden exposure to cold; fevers; rheumatism; pulmonary consumption; colic, and other diseases, have been mentioned among the causes of hydrocephalus. (See Rush, Med. Inquiries, vol. ii. p. 211, et seq. and the references there given.) Some other causes have been alleged; such as a suppression, or spontaneous metallaxis, of eruptions, especially of the scald head; the healing of old ulcers; the cessation of customary discharges; a serous colluvies of the blood; ruptured lymphatics, &c.; but these are apparently hypothetical suppositions, and their operation is not very obvious.

The *proximate cause*, as in many other diseases, has been the subject of considerable difference of opinion. Dr. Whytt, Dr. Fothergill, and other authors, viewed the malady in the light of a mere dropical effusion into the cavities of the brain, partaking of the nature of ordinary dropsy in other parts of the body, and originating from the same causes. Dr. Quin, however, pointed out the error of this opinion, and the proper distinction between the chronic and the acute hydrocephalus, of which we now treat. There are many reasons for adopting the opinion of Dr. Quin, and attributing the peculiar symptoms of the disease, not so much to an effusion of water in the ventricles, as to a morbid circulation or accumulation of blood in the vessels of the brain, which sometimes proceeds to a degree of inflammation, which is generally followed by such an effusion. Dr. Cheyne adopts a notion very similar to this. "I would venture to submit the following," he says, "as a more consistent view of the pathology of hydrocephalus. That in this disease there is produced a venous congestion, in addition to, and probably arising from, the increased arterial action: that the effusion of serous fluid arises from this venous congestion: that this effusion has a tendency to counteract the baleful effects of the increased action, and to retard the fatal termination of the disease: of course, that the effusion into the ventricles is not the cause of the violent symptoms; and that the increased arterial action, though perhaps varied, does not cease when the congestion and effusion have taken place." P. 59.

There are many facts and observations which tend to corroborate this opinion. Dr. Quin mentions two cases, in which the symptoms preceding death were, to all appearance, so unequivocal, that the physicians not only pronounced the disease to be water in the head, but likewise foretold the symptoms that were to be expected a few days before dissolution: the looked for changes did accordingly take place, and the patients died. "In both cases, to the astonishment of those who were present, and prepared to find on dissection a great redundancy of water within the cranium, *none could be discovered* in any part of the brain; but the *blood-vessels were so unusually distended*, that the whole of the cerebrum and cerebellum resembled an anatomical preparation, in which the utmost force of injection had been employed." (P. 50.) Dr. Cheyne mentions two cases of a similar nature; in one of which the progress of the disease, although rapid, was regular, the three stages of Dr. Whytt being well marked. Scarcely a spoonful of water was found in the

HYDROCEPHALUS.

the ventricles; "but the brain was so turgid, that when the bones were sawed fairly round, the section was thrust up half an inch by the sudden and forcible protrusion of the cerebrum: not only the veins of the pia mater were loaded with blood in a very remarkable degree; the medullary substance of the brain was finely dotted with numerous red points, and the cortical substance streaked with pencils of red parallel lines." In the other instance, "no effusion was discovered in the ventricles" after death. It was an extreme case of the acute hydrocephalus, where the excitability was suddenly exhausted by the violence of the attack. "When, as in this case, Dr. Cheyne adds, "the child dies early in the disease, with every symptom of accelerated arterial action, but before the subsequent congestion has existed for any length of time, the dissection will never afford much effusion. When, on the contrary, the patient long survives the slow pulse; and when, from the continuance of the disease, we have reason to think that the congestion has existed for a considerable time; then we find a large effusion. In such cases I have discovered, within the head, little appearance of arterial action, as marked by the tissue of minute and florid vessels: this stage of the disease was over; yet the effects of inflammation abundantly appeared in the thickened and greater adhesion of the membranes; in the great congestion; and indeed, from the pain, suffusion of the eye, &c. we cannot doubt that it exists to the last." (Cheyne, p. 63.) Dr. Quin details several cases, in which, together with considerable effusion of water, the vessels were found extremely turgid, and the previous existence of a degree of inflammation was demonstrated "by preternatural adhesions of the meninges, or by a partial opacity and increased thickness of them, with patches of inflammatory crust," &c.

On the other hand, numerous cases are on record, in which quantities of effused fluid have been found, on dissection, in the ventricles, when no complaint of pain in the head, or symptom denoting an oppressed brain, had existed before death. Maniacal patients, in whose ventricles many ounces of fluid have been found, have died without evincing any hydrocephalic symptoms. And, in fact, there is scarcely any organic disease of the brain which is not accompanied by effusion.

These facts being admitted, we think it were unnecessary to argue the point taken up by Dr. Cheyne, against Dr. Quin and Dr. Rush, *viz.* whether "the morbid arterial action" in the brain amounts to such a degree of inflammation as entitles it to be compared with *phrenitis*, or to be called *phrenicula*; or whether we must be content to say, with Dr. Cheyne, that it appears "to consist of a diseased action of a peculiar kind." P. 82.

This view of the disease, however, although doubtless correct as far as it goes, does not embrace the whole phenomena. It has often been observed that a train of symptoms, similar to those of hydrocephalus, has arisen from the sympathy which subsists between the brain and other organs, especially the alimentary canal, the liver, and the urinary organs. (For instances of sympathy with the last mentioned organs, see Sauvages, class vi. gen. xxix. 4. *Carus ischurius*, and the references there given: also Med. Facts and Obs. vol. i. art. 1.) It is chiefly, however, as Dr. Cheyne observes, from a morbid state of the liver and alimentary canal, that we find the hydrocephalic symptoms by association to arise. Every practitioner of observation has probably been occasionally surprised by the recovery of children under many of the symptoms of hydrocephalus, while purgative medicines, especially of the mercurial class, were administered. Dr. Willan states, that the hydrocephalus of Dr. Quin, marked by the presence of inflammatory irritation in the head, as

above described, "should be distinguished from the symptomatic hydrocephalus, which often takes place, with very similar symptoms, after the crisis of malignant fevers; during the *bedica infantilis*; and in some other acute diseases of children, particularly the febrile state produced by dentition, worms, and disorders of the bowels and mesentery. Cases of this kind are usually removed, within a week or two, by the use of calomel or other active purgatives, and blisters." Reports on the Diseases in London, p. 270.

Now we think this statement much too general. It is certain that these irritations and morbid conditions of the bowels are common concomitants of the ordinary and fatal form of hydrocephalus. In his description of the second stage of the disease, Dr. Whytt mentions the discharge of worms, or of some substance like worms in a dissolved state, as a "frequent" occurrence (Works, p. 732.); and we have more than once seen a *lumbricus* voided under the same circumstances. The condition of the stools, when hydrocephalus is established, is so peculiarly morbid, that several practitioners speak of "hydrocephalic stools," as sufficiently intelligible to those who have made any observation on the subject. The evacuations appear to consist solely of a dark glazy bile, mixed with the mucus of the intestines. There are many other considerations, too, which tend to prove the connection of the proper hydrocephalus with this morbid condition of the abdominal viscera, and to support the opinion of Dr. Cheyne, Dr. James Curry, and others, that this disease "is often fairly and incurably established by the sympathy which the brain has with these organs." Cheyne, loc. cit. p. 38.

In the first place it would appear that hydrocephalic symptoms, arising from sympathy with disordered digestive organs, have sometimes proved fatal, without producing any obvious change of structure in the brain. Mr. Abernethy examined the body of a child, who had unequivocal symptoms of hydrocephalus, in which the brain was found perfectly healthy, the only diseased appearance being in the bowels. (See his Surgical Observations, part ii. p. 193.) Again, Dr. Hamilton has observed, that "hydrocephalus often steals slowly on the devoted victim, with symptoms resembling those of marasmus;" whence he thinks it not unreasonable to suppose that the marasmus, which is clearly the result of a morbid state of the liver and bowels, may occasionally give rise to hydrocephalus. (See his Observations on Purgative Medicines.) Dr. Cheyne advances similar observations. "In many cases," he says, "previously to the hydrocephalic symptoms, the chylopoetic viscera have been disordered for many weeks. The appetite has been bad; the bowels costive, the stools betraying disorder in the hepatic system; there has been all that want of alacrity, both of body and mind, so invariably the consequence of the derangement of the biliary secretion; and in several children, previous to the existence of any morbid sensation, the first symptom of ill health was the loss of the healthy colour of the skin. In children predisposed to the disease, I have, while removing, by a course of purgative medicines, a vitiated biliary secretion and disordered state of the bowels, removed also the very symptoms which had presented themselves in other children of the same family, when the attacks of a hydrocephalus, which actually proved fatal, were supposed to have been established. In children, where I did not know of any family predisposition, I have, by the same means, in many instances, removed the symptoms which are always found in the beginning of hydrocephalus." — "The increased arterial action on the surface of the liver, the remains of which I have observed in my dissections, to every appearance had been of some standing, and in two or three instances,

from

HYDROCEPHALUS.

from the extent of the adhesions, it evidently had been of great intensity. While the disease is forming, there is generally a defect in the function of the liver: it seems to admit of only a scanty and imperfect formation of the bile, insufficient to stimulate the intestinal canal, which becomes torpid, and is sometimes loaded with fœtid clay-coloured excrement." Pp. 45.—47.

We omit many other circumstances, occurring in other diseases, which might illustrate the influence of a morbid condition of the chylopoetic viscera in producing coma, lethargy, apoplectic symptoms, affections of vision, &c., as well as several striking cases mentioned by Dr. Cheyne. It appears, from what has been stated, in the highest degree probable, that hydrocephalus, when it makes its attack especially in the first mode above related, frequently originates from the sympathy of the brain with such a morbid condition in the viscera of the abdomen; and that the instances which Dr. Willan would separate, as distinct from the most acute form, differ principally in the degree of mildness, or in being treated properly before the disease was too firmly established. It may not be easy, indeed, to frame rules, to use the words of Dr. Cheyne, "by which we may decide, when the symptoms arise from the morbid sympathy between the brain and a deranged state of the liver or the intestines, or when they originate from the disordered state of the brain, unconnected with any distant organ. This investigation is important, but not easily prosecuted: perhaps future observation may prove that we shall not be wrong to trace the disease to the organ which first has its functions sensibly impaired; in a great many cases it has appeared to me that a series of diseased actions has commenced with the disordered state of the abdominal viscera." Loc. cit. p. 50.

An explanation of the symptoms, then, may be thus given. The first stage of the disease is principally referable to increased arterial action in the brain, not yet, however, so great as to have produced any material change in its condition, which could be detected by dissection, until near the approach of the second stage. The patient is then feverish, averse to light, sick, disturbed in his sleep, fretful, and complaining of head-ache. When the pulse is becoming irregularly slow, the inflammatory congestion is considerably increased, and the effusion of water into the ventricles is probably beginning: and as the pressure augments, the effects of it upon the root of the optic nerves, (or the *thalami nervorum opticorum*.) become obvious in the squinting and dilatation of the pupil, which last arises from the beginning insensibility of the retina, and the squint from the irregular influence of the nerves connected with the muscles of the eye-balls. At the same time the lethargic disposition, the cruel pains darting through the head, exciting screams and starting from sleep, the slowness and irregularity of the pulsations of the heart and arteries, all denote the impeded functions of the brain from the increasing congestion and pressure within it. Then succeed complete blindness, often accompanied by convulsions or paralytic symptoms, as the disease approaches to its termination; after which we discover all the remains of great arterial action, adhesions of the membranes, great congestion, effusion, and even obvious change of structure; more particularly when the last-mentioned symptoms have been severe and of some duration. It is not very easy, as Dr. Whytt admits, to explain the origin of the extraordinary rapidity of pulse which ensues towards the close of the disease, since the third stage appears to be but a continuation and increase of the second. Whether the sickness, in the beginning, arises from the sympathy of the stomach with the disordered state of the brain, or from the state of the bilious secretion and of the bowels, is not clear, and probably it originates from one

or the other in different circumstances; but the vomiting in the more advanced stages of the disorder is more naturally explained (according to Dr. Whytt) by the sympathy of the stomach with the oppressed brain. The great torpor of the bowels, which arises in the first instance, probably from the scanty and imperfect formation of the bile, may be afterwards augmented by the disordered condition of the brain and nerves.

The Diagnosis.—Having stated the phenomena of hydrocephalus at considerable length, it will be unnecessary to dwell minutely upon the peculiar diagnostic symptoms. It is of the utmost importance, however, that the nature of the disease should be detected as early as possible; and it is not too much to say, with Dr. Cheyne, that the physician should be ever on the watch for it, in attending to the disorders of children, and should never hear a little patient complain of head-ache, without investigating the history of his health preceding this complaint, and comparing it with every ambiguous symptom. Loc. cit. p. 89. See also Dr. Quin's Treatise, p. 44.

The principal difficulty is to distinguish incipient hydrocephalus from the fevers, occasioned by the irritation of dentition, or of worms in the intestines; or "the infantile remittent fever" of Dr. Butler. These fevers have several symptoms in common with hydrocephalus: but the commencement of hydrocephalus is generally more gradual; the disorder of the stomach is more constant, especially the frequent recurrence of vomiting; there is an aversion to light; the stools are dark, of a dirty green colour, and glairy; the pain of the head, when fixed, is oftener dull than acute, but so overpowering that it does not admit of the head being raised from the pillow; sometimes it is a very acute pain; at intervals, and these sometimes regular, it darts through the centre of the brain, and the child is roused with an expression of helpless anguish from the dozing which precedes this acute pain, and into which he instantly relapses when it is gone: the intermissions of the disease are very irregular. In children of some growth, a peculiar expression occurs in hydrocephalus; the countenance has a sort of stare of vacancy, with much appearance of anxiety, and great caution evinced in moving the head. In the remittent fever the affection of the head is commonly much less obvious; the remissions are generally regular and complete, there being one in the morning or early in the forenoon, followed by an exacerbation in the afternoon, which continues through the night; the stools are usually dark-brown, or mud-like; a glairy dark-green discharge, however, has been sometimes observed in this fever. All organic diseases of the brain have a general resemblance to hydrocephalus, and to each other, such as scrofulous tumours, abscesses, caries of the bones, &c.; but the disorder, in these cases, is much more tedious than hydrocephalus. Cheyne.

The Prognosis in hydrocephalus is always doubtful, and, on the whole, unfavourable, even in the first stage of the disease; in the second stage it is extremely unfavourable; and in the third it is almost uniformly hopeless. Dr. Whytt considered it, indeed, as hopeless under all circumstances, and acknowledged that he never saw a patient recover. But subsequent experience has taught us, that it ought not to be held an incurable disease: several instances of recovery are on record. Dr. Percival of Manchester, and Dr. Dobson of Bath, both effected a cure in their own family, by timely attention to the disease; several examples are related in the periodical publications, (Lond. Med. Journ. vol. iv. p. 82. vi. 113. i. 424.—See also Med. Obs. and Inq. vol. iv. and vi. Edin. Med. Com. vol. vi. p. 220 and 224. viii. 325 and 332. ix. p. 240. x. 299, &c. and other journals,) and in the ap-

HYDROCEPHALUS.

pendix to Dr. Cheyne's treatise. Dr. Willan mentions three cases out of eight which terminated favourably, "two recovered about the eighteenth day of the disorder, the third, an infant, at the end of the fifth week, after having been long abandoned to its fate." (Reports on the Dis. in London, p. 269.) The chance of cure in general, however, is nearly in the inverse proportion to the duration of the symptoms.

It has been observed by Dr. Cheyne, that a great increase of urine has often occurred when the disease has terminated in recovery; and that when the urine flows freely after giving mercury, it may be deemed a favourable prognostic. Occasionally a copious diaphoresis, especially from the head, has also preceded recovery. In one case, after a child had been condemned as in a hopeless state, and the physicians had discontinued their visits, "a profuse sweat broke out on the head and neck, and flowed so copiously that the pillows had to be shifted one after another. From that moment the child is said sensibly to have recovered, and yet lives. Seven years have elapsed since his recovery." P. 87, note. See also a case in the Edin. Med. Comment. vol. x. p. 299, and Dr. Quin's Treatise, p. 73.

Of the Cure.—In a disease which, from its very commencement, is of a most dangerous tendency, and when completely established is commonly fatal, it is obvious that, in order to have any tolerable chance of success, the treatment should be entered upon early, in a decisive manner, and pursued with steadiness and vigour. The principal indications of cure appear to be, 1st, to diminish the inflammatory activity of the circulation in the brain; and, 2dly, to remove all irritations, especially in the alimentary canal, and to correct the hepatic secretion or congestion, which, by morbid sympathy, may have given rise to, or may have assisted in prolonging the diseased action in the brain.

In the very early periods of the disease, indeed, our first attention should be directed to the state of the alimentary canal, and an active cathartic should be given, and repeated according to circumstances. Should we ascertain that the canal is torpid, and imperfectly performing its functions, admitting an accumulation of feculent matter; or that the secretions flowing into it are vitiated or diminished in quantity, (which we discover by the peculiarity in the appearance, or the pungent fætor of the stools,) we must endeavour, by steadily pursuing the purgative plan, to effect a change: for while this is produced in the appearance of the stools, by the stimulating quality of the medicines, a most important change is effected in the hepatic system, intestinal canal, and all the parts including every organ essential to life, which is by sympathy connected with them. The purgative plan may be pursued without inducing debility; on the contrary, with evident accession of strength, so long as there is foulness of the bowels, either while the stools are fætid and clay-coloured, or while they are dark and slimy. In the advanced stages, however, when the oily-looking, or glazed dark-green stools, almost peculiar to this disease, are evacuated, we cannot hope to effect a cure by purgatives. But in the earlier periods, should little disorder in the alimentary canal and biliary secretion be observed, if the strength of the patient be unimpaired, and his constitution originally sound, the exhibition of purgative medicines, perhaps every second or third day, may be advantageous.

For these purposes preparations of mercury, and especially calomel, appear to be the most suitable, as the first doses of them seldom fail to stimulate the bowels. When this does not happen, and the purgative effect is not produced, some other medicine, as jalap, aloes, scammony, must be given in addition. Dr. Cheyne says, "purgatives have generally been given in this disease; but, when called early, what

I recommend is, the exhibition of the largest dose, which can with safety be prescribed, of some powerfully cathartic medicine, two, three, or four times a day, and this continued for several days, or until natural stools are procured. The advantage of keeping the intestinal canal under the continued influence of a stimulus, I have, in various instances, found to be so great, that I am induced to repeat the declaration of my belief, that the happiest result may be expected from this measure." P. 95.

It may be added, that should the symptoms indicative of commencing hydrocephalus, prove to be in fact the symptoms of remitting fever, or to arise from worms in the intestines, this practice fortunately proves the most efficacious means of removing these diseases. On the whole, therefore, the free administration of cathartics may be recommended, under all circumstances, in the commencement of the disease.

In regard to the means of fulfilling the indication of reducing inflammatory action within the head, especially by blood-letting, there has been some difference of opinion. Dr. Rush recommends general bleeding indiscriminately, in the first stage of the phrenicula (as he denominates the disease), even to an extent greater than is requisite in the more acute phrenitis, except in very young children. It has not appeared, however, that this practice is entitled to more credit, even in his hands, than other modes of treatment. Where the constitution is robust, and the attack is of the most acute form, general blood-letting may, doubtless, be resorted to with great benefit, and is especially serviceable, as Dr. Rush intimates, in preparing the way for the operation of mercury. In less active forms of the disease, however, and in delicate habits, and more particularly when it arises after the constitution has been exhausted by preceding disorders, local evacuations of blood by means of leeches, or cupping, should be preferred; and the operation may be repeated, according to the urgency of the symptoms, the state of the pulse, and the general strength of the patient. We agree with Dr. Cheyne in looking upon the inflammatory action in the brain as going on during the whole progress of the disease, and not ceasing with the first stage of increased sensibility, or before the stage of torpor has begun; and, therefore, in considering local bleeding, as a proper expedient, when otherwise indicated, even to a late period of the disease. At the same time, the prospect of deriving benefit from the practice is trifling, when much organic change has already occurred. Dr. Whytt mentions, as the only benefit he had ever observed from medicine, a temporary relief, in the second stage of the disease, from the use of local evacuations; and probably almost every practitioner has witnessed the same effect of them, even in this stage.

Blisters applied over the whole scalp, or to the forehead, occiput, and sides of the head, in succession, may be considered as important *juvantia* in relieving the internal inflammatory action of the brain; especially some evacuation of blood has been procured. They often afford obvious relief to the pain, and therefore should not be omitted at any stage of the disorder. Several instances of recovery from hydrocephalus are on record, in which the agency of blisters appears to have constituted a very important part in the cure. (See Dr. Quin, loc. cit.) This intelligent physician generally applied a large blister over the whole head, and dressed it with an ointment of cantharides: Dr. Cheyne uses the strong mercurial ointment for that purpose.

With a view to lessen the activity of the circulation, the use of *digitalis* has likewise been resorted to, as well as for the purpose of increasing the urinary discharge, and exciting absorption of the effused fluids. Its qualities of diminishing the irritability, retarding the pulse, and quickening the action of

the absorbents, seem to render it a medicine of great promise in fulfilling the indication now under consideration, without endangering the constitution of a delicate child, in the same degree as blood-letting. In a few cases it has been employed with apparent advantage. It is a medicine, however, of extreme uncertainty in its operation, and has not answered the expectations at first entertained of it in the cure of some other diseases; it can only be used, with any probability of success, when administered with activity, and it can only be given with safety in adequate doses, when its operation is cautiously and unremittingly watched. Dr. Cheyne, who has well described the peculiarities of its operation, adds, "The method which I have for some time followed in using digitalis is the most obvious: it accords with the view which I have given of its powers, and does not appear ill adapted to the attainment of a safe and quick effect. I begin with a moderate dose, eight or ten drops of the saturated tincture; and to every succeeding dose, which is generally given at an interval of six hours, I add two or three drops; so that, in a day or two, generally some part of the system is affected. I proceed with great caution, ascertaining, while augmenting it, the effect of the medicine after each increased dose." P. 103.

In aid of the means of diminishing inflammatory action in the brain, already mentioned, the *application of cold*, or, more correctly speaking, the abstraction of heat from the head, particularly in the more acute forms of hydrocephalus, may be resorted to with advantage. Frequent washing of the face and neck with cold water, the application of linen cloths to the forehead wetted with cold vinegar or water, or with æther (which produces cold by its rapid evaporation), contribute much to relieve the pain in the head. In a case mentioned by Dr. Rush, a solution of ice in vinegar appeared to afford the most obvious relief of this distressing symptom. Med. Inq. vol. ii. p. 227.

Of those individuals who have been known to recover from hydrocephalus, the greater number have taken mercury in one form or other; several of them to a very great extent, sometimes with the effect of inducing salivation, often without that result. Drs. Dobson and Percival first recommended and successfully employed that practice, (see Edinburgh Med. Comment. vol. vi. pp. 220 and 224.) and it has been since employed by other practitioners, with a happy effect, in a number of instances. (See many of the references to cures above given.) It has, indeed, frequently disappointed the hopes of the practitioner, even after salivation was induced; although, from the general difficulty of producing this discharge in patients labouring under hydrocephalus, it was at one time thought that the failure of mercury to accomplish a cure, arose from its failure to excite salivation. The superior success of the practice has been such, however, on the whole, that it will be admitted, with Dr. Cheyne, that "when the existence of the disease becomes probable, there ought to be no other delay than that occasioned by our endeavours to subdue the disorder in the bowels, in commencing a *mercurial course*, which, it must be allowed, has cured hydrocephalus, even when far advanced." That intelligent physician adds, that "it should give us more confidence in this remedy, that I have several times observed, when the mercurial stimulus was fully established, that the symptoms were interrupted, and the termination of the disease, although fatal, unlike what we find in cases where mercury has not been used. The convulsions were suspended; the senses, both external and internal, restored; the disease appeared to be checked; but the debility was such, that the vital functions languished; and the constitution had sustained so great a shock, that every effort

to invigorate them was unavailing." Cheyne, loc. cit. p. 99.

The plan pursued by Dr. Percival, and subsequently followed by others, consisted in giving repeated doses of calomel internally, (such as the quantity of two grains at intervals of a few hours,) and at the same time using the strong mercurial ointment by friction upon the skin. It was suggested, that the salutary influence of the mercury was chiefly the operation of the calomel upon the alimentary canal and hepatic system; but Dr. Percival and other practitioners conceived that the effects of the remedy were decidedly more obvious and salutary, when it was thus administered in a two-fold manner. We have been occasionally surprized, indeed, by the prodigious quantity of calomel which has been taken by children, in this disease, within a short space of time, without producing any obvious effect whatever, either on the bowels, the salivary glands, or the system at large. It is not easy to induce salivation in children under ordinary circumstances; but in this disease there is a peculiar degree of torpor in the advanced stages, which renders the constitution much less susceptible of the influence of medicine in the common doses.

Much has been written respecting the best method of restoring the strength of the patient after the decline of the disease. But in this, as in other instances of acute disease, when the great cause of irritation is removed, if there be any strength left, the system never fails to act with vigour, and requires little assistance from art. With the exception of a moderately nourishing diet, scarcely any thing is required to further the progress of convalescence.

In regard to the *prevention* of hydrocephalus, perhaps the most important precept relates to a constant attention to the state of the bowels. "The mother must be taught," to adopt again the words of Dr. Cheyne, "to attend to and to understand every irregularity in the state of her child's bowels. It is not merely costiveness which is to indicate the propriety of a purgative course: costiveness is not to be neglected; but constitutional costiveness may perhaps exist without danger. Attention must be paid to every deviation (not absolutely temporary) from a natural appearance of the intestinal evacuation;" p. 108. (See DEJECTION.) The propriety of instituting a drain, by means of an issue or seton, in the neck, in the surviving children of families where the disease has already occurred, and in whom the marks of predisposition are visible, has been suggested and carried into execution, in some cases, with apparent success. In the family to which we formerly alluded, the last surviving child was supposed to be preserved from the disease by the use of a seton in the neck: it may be remarked, however, that he has now, after attaining the adult age, become the subject of insanity.

All the general means of supporting the general health in children predisposed by constitution to hydrocephalus, such as regular moderate exercise, the occasional use of the cold bath, regularity in diet, &c. must be combined with the attention to the state of the intestinal canal.

HYDROCERATOPHYLLON, in *Botany*. See CERATOPHYLLUM.

HYDROCHARIDES, a natural order of plants named from HYDROCHARIS, which is one of the genera; see the next article. This order is the 22d in Jussieu's system, or the 4th of his 4th class, *monocotyledones, Stamimbus epigynis*. The character he gives is,

"Calyx of one leaf, superior, undivided, or divided, the segments disposed either in a simple or double row, the inner ones often petal-like. Stamens either definite or indefinite, situated upon the pistil. Germen simple, inferior;

style either simple, or definitely manifold, or none; stigma simple or divided. Fruit inferior, of one or many cells. The plants are herbaceous aquatics."

As Jussieu included the *Cyamus*, or *Nelumbo*, in this order, he was obliged to make an exception, on account of its superior germen, but there having been scarcely any other reason for such an arrangement than its being a water plant, the cotyledons being two, and the other characters as different from the *Hydrocharides* as can well be, this difficulty is removed, and *Cyamus* goes to the *Papaveraceæ*, with *Nymphaea*, and *Nuphar* of Smith in Prodr. Fl. Græc. Sibth. —The other genera in Jussieu are *Valisneria*, *Stratiotes*, *Hydrocharis*, *Trapa*, *Proserpinaca*, and *Pistia*, the three last very dubious at best as to their claim to a place here.

Mr. R. Brown, in his Prodr. Nov. Holl. v. 1. 345, reckons *Najas*, *Lemna*, and *Chara*, as akin to the natural order in question.

HYDROCHÆRIS, in the Linnæan system of Zoology, a species of hog found at Surinam. See *CAVIA Capybara*.

HYDROCHARIS, in Botany, from ὕδωρ, water, and χαίρειν, to rejoice, because this genus, from its beauty, may be considered as the glory or pride of the water.—Linn. Gen. 527. Schreb. 695. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. v. 3. 1084. Ait. Hort. Kew. v. 3. 409. Juss. 67. Lamarck Illustr. t. 820. (*Stratiotes*; Dill. Gen. 9.)—Class and order, *Diccia Enneandria*. Nat. Ord. *Palmeæ*, Linn. *Hydrocharidites*, Juss.

Gen. Ch. Male, *Cal.* Spathe three-flowered, of two leaves, oblong; perianth of three ovate-oblong, concave leaves, membranaceous at the margin. *Cor.* Petals three, roundish, flat, large. *Stam.* Filaments nine, awl-shaped, erect, arranged in three rows, of which the middle row puts forth an awl-shaped stem, from its inner base, like a style, which is placed in the centre; the two other rows are so connected at the base, that each inner filament coheres with the outer; anthers simple. *Pist.* none, except the above rudiment of a germen. Female, *Cal.* Spathe none; flowers solitary; perianth as in the male, superior. *Cor.* as in the male flowers. *Pist.* Germen roundish, inferior; styles six, as long as the calyx, compressed, bifid, channelled; stigmas bifid, pointed. *Peric.* Capsule leathery, roundish, six-celled. *Seeds* numerous, very small, roundish.

Eff. Ch. Male, Calyx three-cleft. Petals three. The three interior filaments beaked. Female, Calyx three-cleft. Petals three. Styles six. Capsule inferior, with six cells, and many seeds.

Obs. This genus is very nearly allied to *Stratiotes*.

1. *H. Morfus Ranæ*. Common Frog-bit.—Linn. Sp. Pl. 1466. Engl. Bot. t. 808. Curt. Lond. fasc. 3. t. 64. (*Morfus Ranæ*; Ger. Em. 818.)—Found on the surface of ditches and slow streams, plentifully in the neighbourhood of London, flowering in July and August. This perennial aquatic, every part of which is smooth, floats on the surface, throwing out from its joints clusters of leaves and flowers. *Roots* straight and simple, descending into the mud. *Leaves* on footstalks, kidney-shaped, entire, generally purple beneath. The female stalks are quite simple, single-flowered, having a spathe at the base; males umbellated, three or four-flowered, with a pair of bractæas at the base of the partial flower-stalks. *Flowers* white, elegant, and showy, with large, roundish, corrugate petals, yellow at the base.—Ray mentions a variety with fragrant double flowers, which Mr. Relham informs us is not now to be found in the place he indicates. Flowers with six petals now and then occur. Engl. Bot.

HYDROCHOOS, in *Astronomy*, derived from ὕδωρ, water, and χῶρ, I pour. See *AQUARIUS*.

HYDROCORAX, in *Ornithology*. See *HORN-bill*.

HYDROCOTYLE, in Botany, from ὕδωρ, water, and κοτύλη, a cavity which forms a sort of cup, because the leaves of the original species are round and concave, and it grows in watery places. This name was bestowed by Tournefort. Its English appellation is Pennywort, or White-Rot.—Linn. Gen. 127. Schreb. 178. Willd. Sp. Pl. 1360. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. v. 1. 290. Ait. Hort. v. 1. 327. Juss. 226. Tournef. t. 173. Lamarck Dict. v. 3. 151. Illustr. t. 188. Gært. t. 22.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbelliferæ*, Juss.

Gen. Ch. *Cal.* Umbel generally simple; involucre most commonly of four leaves, small; perianth scarcely any. *Cor.* Universal, uniform in figure, not in situation; all the flowers fertile; partial, of five ovate, acute, spreading, entire petals. *Stam.* Filaments five, awl-shaped, shorter than the corolla; anthers very minute. *Pist.* Germen erect, compressed, circular, inferior, peltate; styles two, awl-shaped, very short; stigmas simple. *Peric.* none; fruit orbiculate, compressed, transversely divisible into two parts. *Seeds* two, semi-circular, compressed.

Eff. Ch. Umbel simple. Involucre of about four leaves. Petals undivided. Fruit orbiculate, compressed.

Linnæus originally reckoned only five species of *Hydrocotyle*; professor Martyn enumerates fifteen, and Willdenow eighteen, from the Supplementum and other books. The author of English Botany observes that "the name of White-rot was given to *H. vulgaris*, from a supposition that this plant caused the disease in sheep called the rot; but it is doubtful if they will ever taste it, and most people now attribute that disease to the animals inhabiting wet pastures, where indeed the *Hydrocotyle* grows, but which are in some other way noxious to their constitution."

1. *H. vulgaris*. Marsh Pennywort. White-rot. Linn. Sp. Pl. 338. Engl. Bot. t. 751. Curt. Lond. fasc. 6. t. 19.—"Leaves peltate. Umbels of five flowers."—Found on marshes, and in moist places that are subject to be inundated, flowering throughout the months of May and June.—*Root* perennial. *Stems* creeping, thread-shaped. *Leaves* opposite, on foot-stalks, peltate, horizontal, roundish, crenate, pale green, smooth, clear. *Flower-stalks* axillary, solitary, or twin, having a pair of bractæas at their base. *Umbel* small, dense, generally five-flowered, often producing another umbel from its centre. *Flowers* white or bluish-coloured, with acute petals.

The leaf of this plant is usually referred to as a perfect specimen of what Linnæus intended for a peltate leaf. The common Nasturtium of our gardens, *Tropæolum majus*, is however a more familiar and an equally correct instance.

2. *H. inundatum*. Floating White-rot. Sm. Fl. Brit. v. 1. 290. (*Sifon inundatum*; Linn. Sp. Pl. 363. Engl. Bot. t. 227.)—"Leaves pinnate, jagged; those which are immersed, in capillary segments. Umbels in pairs, each consisting of five flowers."—Not very unfrequent in ditches and pools among other aquatics, flowering in May.—*Root* most probably biennial. *Stems* creeping, floating, round. *Leaves* alternate, on dilated stalks which embrace the stem, unequally pinnate; leaflets oblong, trifid, often pinnatifid. *Flower-stalks* opposite to the leaves, bifid, divaricated. *Umbels* solitary, five-flowered. *Flowers* white, having acute, equal petals. *Fruit* elliptical, striated.

This species of *Hydrocotyle* is referred hither from *Sifon* solely on the authority of the *Flora Britannica*. This and the preceding are the only species indigenous to Great Britain.

3. *H. umbellata*. Linn. Sp. Pl. 338. Swartz Obs. 111. —Leaves

—Leaves peltate, umbels many-flowered.—Native of damp places in America, and particularly in Jamaica.—This species is very nearly allied to *H. vulgaris*, but differs in having the flower-stalk twice as long as the leaves, and instead of five flowers, more than twenty crowded together so as to form a simple umbel.

4. *H. bonariensis*. Willd. n. 3. Lamarck Dict. v. 3. 153.—“Leaves somewhat peltate, kidney-shaped or roundish, crenate. Umbel compound; rays branched, flowering at the top and sides.”—Found by Commerçon on the sea-shore of Buenos Ayres near Monte Video.—The whole plant is smooth. Branches trailing on the ground, a foot or more in length. Leaves on foot-stalks, crenulated, or obscurely lobed, having a sort of arch-work from the base to the centre. Foot-stalk inserted close to the summit of this arch, so as to make the leaves umbilical or imperfectly peltate. Flowers yellowish.

5. *H. americana*. Linn. Sp. Pl. 338. Lœfl. it. 281.—“Leaves kidney-shaped, somewhat lobed, crenate.”—A native both of North and South America.—Similar in appearance and magnitude to *H. vulgaris*, but it differs in having its leaves separated half way down by a narrow sinus, their margin divided into nine obsolete lobes, each of which is marked by three smaller crenulations. Umbel five-flowered.—A variety of this, much smaller in all its parts, appears in the Linnaean herbarium communicated by M. Cuffon.

6. *H. hirsuta*. Willd. n. 5. Swartz. Ind. Occ. n. 1. 560. Hairy.—Leaves kidney-shaped, lobed, crenate. Whorls four-flowered.—Native of St. Domingo, flowering in June and July.—Stem herbaceous, creeping. Leaves on foot-stalks, obtusely five or seven-lobed, nervose, veined. Stipulas small, at the base of the footstalks. Flowers whorled, greenish, each one furnished with a linear, obtuse, hairy leaflet not longer than the germen. The whole plant is thickly covered with whitish hairs.

7. *H. mesobata*. Willd. n. 6. Forst. Prod. n. 135.—Leaves kidney-shaped, seven-lobed, ferrated, villose. Umbels many-flowered.—This is a native of New Zealand. We know nothing of it but from the authorities above quoted.

8. *H. asiatica*. Linn. Sp. Pl. 338. (Ranunculo affinis; Pluk. Alm. 314. t. 106. f. 5.)—“Leaves kidney-shaped, equally toothed or crenate.”—Native of the East Indies and Cape of Good Hope, flowering in July. It was introduced into this country by Mr. F. Masson in 1774.—This species is nearly allied to *H. americana*, but differs in having the denticulations of its leaves equal or regular; the leaves are twice as thick, and almost hoary, with many footstalks from the joints of the stem, whilst in *H. americana* the leaves are solitary.

9. *H. chinensis*. Linn. Sp. Pl. 339.—“Leaves linear, umbels many-flowered.”—Native of North America, not of China.—Stem creeping. Leaves linear, smooth, obtuse, flat, often in pairs at the joints of the stem. Scapus the length of the leaf. Umbel many-flowered.—We are not acquainted with any figure of this species.

10. *H. erecta*. Willd. n. 8. Linn. Suppl. 177.—“Leaves heart-shaped, crenate. Stalk with few flowers, the length of the leaf-stalks.—Native of Jamaica.—Leaves obtuse, acutely dentated, an inch long; footstalks radical, a span long, hairy at the top. Scapi radical, with a few flowers at their summit, erect, as is the whole plant, not creeping.

11. *H. villosa*. Willd. Sp. Pl. n. 9. Linn. Suppl. 175.—“Leaves heart-shaped, entire, downy or villose.”—A native of the Cape of Good Hope.—Root fibrous. Stems prostrate, bearing leaves and flowers at their summits.

Leaves on foot-stalks, undivided, resembling *Viola obovata*. Flower-stalks many, from the top of the stems, filiform, shorter than the leaves, single-flowered. Flowers small.

12. *H. glabrata*. Willd. Sp. Pl. n. 10. Linn. Suppl. 176.—Leaves obovate or lanceolate, acute, three-nerved, very smooth.—Found at the Cape of Good Hope.—Whole plant extremely smooth. Stem angulated, rigid, geniculated; leaves growing at the joints, and both leaves and flowers towards the summit of the stem.

13. *H. Spananthe*. Willd. Sp. Pl. n. 11. (Spananthe paniculata; Jacq. Ic. Rar. v. 2. t. 350.)—Stem erect. Leaves triangular, pointed, ferrated, bearded at their base.—Native of South America.—Referred to this genus by Willdenow, of which we doubt the propriety. It has a tall branching stem, and prolificus umbels.

14. *H. ranunculoides*. Willd. n. 12. Linn. Suppl. 177. Leaves cut into five deep segments. Umbels simple.—Sent by Mutis from Mexico.—Stem creeping, jointed, fibrous. Leaves solitary, or in pairs, very similar to those of a *ranunculus*; the segments three-lobed, obtuse; foot-stalks about three inches long. Flower-stalk an inch in length. Umbel simple. Petals white.

15. *H. funiculifolia*. Willd. n. 13. Lamarck Dict. v. 3. 154. Illustr. t. 188. f. 1.—Leaves three or five-lobed, toothed. Umbel compound.—Gathered by Commerçon at Buenos Ayres, and on his authority referred by Willdenow to this genus.

16. *H. folandra*. Willd. n. 14. Linn. Suppl. 176. Lamarck Illustr. t. 188. f. 5. (Solandra capensis; exclusis synonymis; Linn. Sp. Pl. 1407.)—Leaves wedge-shaped, ovate, retuse.—Sent from the Cape of Good Hope.—Root branching on the surface of the ground. Whole plant covered with whitish downyness. Leaves alternate, wedge-shaped or obovate, seven-toothed. Flower-stalks amongst the lower leaves, lateral. Receptacle of the flowers dark purple. Petals white.

17. *H. tridentata*. Willd. n. 15. Linn. Suppl. 176.—Leaves linear-wedge-shaped, three-toothed at the top.—Found by Sparrmann at the Cape of Good Hope.—Very similar in habit to the preceding species, but differs in having the stems shorter, woolly, and not prostrate. Leaves with three equal teeth at their top. Flower-stalks much shorter than the leaf.

18. *H. linifolia*. Willd. n. 17. Linn. Suppl. 176.—Leaves linear-lanceolate, hirsute, entire.—A native also of the Cape of Good Hope, and very nearly akin to the following species.

19. *H. virgata*. Willd. n. 18. Linn. Suppl. 176. Thunb. Prod. 49. Lamarck Illustr. t. 188. f. 3.—Leaves linear, smooth.—Communicated to Linnæus by Thunberg, from the Cape of Good Hope.—Stem upright, jointed, nearly smooth. Leaves channelled withinside, dilated at their base. Umbels lateral, simple.

HYDRODES FEBRIS, in *Medicine*, a fever in which the patient is, from the beginning, afflicted with very copious and weakening sweats, and great weakness.

HYDRODYNAMICS, of ὑδρῶς, *water*, and δυναμις, *force*, is used for the science of the laws of the motion of fluids, and denotes much the same with hydraulics. See FLUID and HYDRAULICS.

HYDROENTEROCE'LE See HYDRÉENTEROCÉLE.

HYDROGEN, HYDROGENOUS GAS, or *Inflammable Air*, is an elastic fluid of extreme subtilty and levity. It is ascertained to be nearly $\frac{1}{12}$ th of the weight of an equal bulk of common air, or only $\frac{1}{137500}$ th of the weight of an equal bulk of water, being by much the lightest ponderable substance with which we are acquainted. It is, on this account,

HYDROGEN.

that balloons are filled with it. The weight of a cubic foot of hydrogen gas, at the common temperature and pressure, is not more than $2\frac{1}{2}$ grains; whereas the same volume of common air weighs 31 grains. It is not only in the elastic state that hydrogenous gas exhibits extreme levity, but also the ultimate particle of it, according to the investigations of Mr. Dalton, is lighter than that of any other body, on which account he makes it the unit or standard of comparison in weight. See GAS.

Hydrogenous gas may be procured by various processes; the most simple and easy one is to take some turnings or filings of zinc or iron, and put them into a gas bottle, to which add their weight of water, and about $\frac{1}{3}$ th of its volume of concentrated sulphuric acid. A violent effervescence ensues, and the gas is generated in great abundance, and may be received over water in the usual way. The rationale of the process seems this; the metals have a strong affinity for oxygen, but not equally so for hydrogen; they are not of themselves sufficiently powerful to effect an union with the oxygen and a detachment of the hydrogen, but by the aid of the acid they can accomplish it, and the acid afterwards unites with the new compound or oxyd, forming a salt, called a *sulphate*. Hence the hydrogen is derived from the water. Another method of obtaining hydrogen is to send steam over red-hot iron shavings in a gun-barrel; in this case, the iron unites with the oxygen, and the hydrogen is liberated in the gaseous form.

The properties of hydrogen gas are, 1st. *It is the lightest of all gases*, as has been observed, and may be proved, by actually weighing it in an air-bottle fitted up for such purposes, which has previously been exhausted and weighed. But there are several simple experiments by which it may be shewn to be much lighter than common air; namely, if a jar be filled with hydrogen, and then uncovered for a moment, the hydrogen will escape, but not if the jar be placed with its mouth downwards, as will be proved by putting a lighted taper into the jar, which will not be affected in the former case, but extinguished with a slight explosion in the latter. 2d. Instead of a jar, a tube of 12 inches long and $\frac{1}{4}$ inch diameter be filled with hydrogen, it will be five minutes in losing one-half of its gas, and that the same whether held up or down. (See Nicholson's Journal, vol. viii. p. 148.) This serves to shew that the effect of a difference in specific gravity is not perceived unless a sufficiently large volume or body of air can move together. If bubbles of soap and water be raised with hydrogen they ascend in the air like balloons. If a volume of hydrogen be gently placed over a volume of common air, they do not mix immediately, but in due time they are found mixed completely, whatever caution may be used to prevent agitation, and they remain mixed ever afterwards. (See Manchester Mem. vol. i. second Series, p. 262, and Memoires d'Arcueil, tom. ii. p. 466. This curious fact, which is of a general nature, and by no means peculiar to hydrogen and common air, was first observed by Priestley, and is ascribed by Dalton to the mechanism of elastic fluids; but most others have thought it an effect of chemical affinity.) 3d. *Hydrogen gas is fatal to animals*, as is proved by confining a mouse or other small animal in it for a few moments. 4d. *It is inflammable*. This quality is shewn by applying a taper to a phial of the gas with its mouth downwards; a slight explosion will be observed succeeded by a lambent flame. If a bladder be filled with the gas, and then the gas be gently driven out through a small tube, such as a tobacco-pipe, it will take fire with a candle and burn with a reddish flame. A mixture of one part hydrogen and two common air, or two hydrogen and one oxygen, in a small phial, ex-

plodes violently by being presented to a flame. The same effect may be produced by an electric spark in a glass vessel, called an inflammable air-pistol; or a strong brass tube, called Volta's eudiometer, may be partly filled with a mixture of hydrogen and oxygen, and the mixture exploded over water or mercury by electricity. In this way the quantity of hydrogen or oxygen in mixtures of gases may be ascertained. (See EUDIOMETRY.) If a bladder, filled with hydrogen and common air, or oxygen, in the proportions above-mentioned, have its contents infused into bubbles of soap and water, they will explode with a loud report by a taper, and the bladder itself will burst with a tremendous report if the flame be applied to it or to the bubbles before they quit the pipe of the bladder. 4th. *Hydrogen gas, though inflammable itself, yet extinguishes flame*. If a jar of hydrogen be put over the flame of a candle, so as to surround it, the flame is instantly extinguished. 5th. A mixture of oxygen and hydrogen has been made to explode by mechanical condensation, by M. Biot. 6th. In the slow combustion of hydrogen, when the flame is confined in a long tube, under certain circumstances, a musical sound is produced. 7th. Hydrogen, when united to oxygen, produces water; when it is united to azote the product is ammonia; when united to carbon it forms olefiant gas, carburetted hydrogen, oil, &c. 8th. It contains half as many atoms in the same volume as oxygen gas.

HYDROGEN, *Sulphuretted*, in *Chemistry*, a compound of sulphur and hydrogen, which usually owes its origin to the decomposition of water in the processes by which it is formed, and is generated in various processes, in which its elements are presented to each other in a nascent or condensed state. It was first procured from solutions in water of the compounds of sulphur with the fixed alkalies. When sulphur is combined with potash, soda, or lime, on dissolving the compound in water, a partial decomposition takes place; one part of the sulphur combines with part of the oxygen of the water, forming sulphuric acid, which unites with the potash; another part of the sulphur unites with the hydrogen of the water, forming sulphuretted hydrogen. This gas is produced likewise by exposing to a strong heat mixtures of sulphur with vegetable matter, as sugar, oil, or powdered charcoal; the hydrogen existing in vegetable substances combining with the sulphur; in these processes the gas is, very rarely, quite pure, or of an uniform composition. The specific gravity of sulphuretted hydrogen is to that of atmospheric air, as about 1.14 to 1.00, a hundred cubical inches weighing 33 grains. Its smell is extremely fetid; the effluvia disengaged in putrefaction consist chiefly of this gas. Its properties are, that it extinguishes combustion, and is wholly incapable of supporting animal life. It is absorbed by water, the water taking up more than its volume, or 100 cubical inches of water will absorb 108 inches of this gas. It has a peculiar action on the metals, and tarnishes them very quickly, communicating shades of yellow, brown, or purple, with a diminution of metallic lustre. This curious gas is possessed of the properties of an acid, enters into combination with the alkalies, and forms compounds, some of which are crystallizable. It is capable of changing vegetable colours to a red. It decomposes soap, combines with the metallic oxyds, and precipitates sulphur from its combinations. The compounds of sulphuretted hydrogen with the fixed alkalies, are readily formed by passing a current of it in its elastic state through the alkaline solution. These compounds are called HYDRO-SULPHURETS, which see. Sulphuretted hydrogen is capable of combining with an additional proportion of sulphur, and in this state the compound is denominated super-sulphuretted

retted hydrogen. "The knowledge," says Mr. Murray, "which we have acquired of sulphuretted hydrogen, and of its combinations, has thrown light on the composition of mineral sulphureous waters, and of the changes which they suffer. As sulphur is itself insoluble in water, and as frequently no traces of an alkali, by which it might be rendered soluble, could be discovered in these waters, chemists found it difficult to conjecture by what means its solution was effected. The discovery of sulphuretted hydrogen, and of its solubility in water, solved this difficulty, and the mutual action exerted between it and oxygen, elucidates the changes these waters suffer from exposure to the air." Murray's Chemistry, vol. 2. See MINERAL WATERS.

HYDROGEN, *Super-sulphuretted*. See HYDRO-SULPHURETS.

HYDROGEN Gas, in Agriculture, the modern name of an elastic fluid, formerly denominated inflammable air. Its effects on vegetation have not yet been ascertained.

HYDROGETON, in Botany, from ἵδωρ, water, and γειτῶν, a neighbour, from the circumstance of its being an aquatic plant. Such is the name given by Loureiro, which is of a rather extensive application, but justifiable by the analogy of *Potamogeton*, which it evidently imitates.—Loureir. Cochinch. v. 1. 244.—Class and order, *Octandria Tetragynia*. Nat. Ord. *Inundata*, Linn. *Naiades*, Juss.

Gen. Ch. Cal. Perianth none. Cor. inferior, petals four, roundish, inflexed, furnished with a slender, short, incurved claw. Stam. Filaments none; anthers eight, ovate, affixed to the receptacle. Pist. Germens four, ovate, style none; stigmas four, oblong, erect. Peric. Capsules four, ovate, single-seeded. Seeds of a similar shape.

Eff. Ch. Calyx none. Corolla of four roundish petals, each furnished with a claw. Capsules four. Seeds solitary.

1. *H. heterophyllum*. Loureir. Cochinch.—"Lower leaves awl-shaped, or linear, upper ones ovate, pointed."—Native of rivers and marshes in Cochinchina. Stem pro-cumbent, long, branching, immersed in the water. Leaves entire, smooth. Flowers green, small, in oblong, arched, terminal, naked spikes.

Loureiro observes that he separated the present genus from *Potamogeton* chiefly on account of the number of its stamens. Whether this distinction be sufficient to establish his genus, we greatly doubt, or rather, we think it quite inadequate. The Cochinchinese name of the plant is *Raong bai thá lá*.

HYDROGRAPHICAL MAPS, more usually called *sea charts*, are projections of some part of the sea, in plano, for the use of navigation.

In these are laid down all the rhumbs, or points, of the compass, the meridians, parallels, &c. with the coasts, capes, islands, rocks, shoals, shallows, &c. in their proper places, proportions, &c.

Christopher Columbus, the first great discoverer of America, was a man that earned his living by making and selling hydrographical maps. He happened to be heir to the memoirs or journals of a noted pilot, one Alonzo Sanchez de Huelvá, captain of a ship, who, by chance, had been driven by a storm to the island of St. Domingo, and died at Columbus's house soon after his return. This gave Columbus the first hint to attempt a discovery of the West Indies, in which he succeeded.

For the construction of the several kinds of hydrographical maps, see CHART.

For their uses, see SAILING.

HYDROGRAPHY, compounded of ἵδωρ, aqua, water, and γράφω, I describe, that part of geography which considers the sea; principally, as it is navigable.

Hydrography teaches how to describe and measure the sea; it gives an account of its tides, counter tides, currents, soundings, bays, gulfs, &c. as also of its rocks, shelves, sands, shallows, promontories, harbours, distances, &c. from port to port; with all that is remarkable, either out at sea, or on the coast.

Some of the best authors use the term in a more extensive sense; so as to denote the same with *navigation*.

In this sense hydrography includes the doctrine of sailing; the art of making sea charts, with the uses thereof; and every thing necessary to be known, in order to the safest and most expeditious performance of a voyage. See SAILING.

Hydrography is the most perfect of all the mathematical sciences; there being scarcely any thing wanting to its perfection, but the accurate discovery of the longitude.

The Jesuits Ricciolus, Fournier, and De Chales, have written on the subject of hydrography.

In France they have professors of hydrography established in all their sea-ports, who are to instruct the youth intended for the sea in all the parts of navigation, sailing, steering, &c. with the several branches of mathematics necessary thereto; as arithmetic, and the doctrine of the sphere, and trigonometry.

They are royal professors, and teach gratis; having salaries allowed them. They are also charged with the examination of pilots, &c.

HYDROLEA, in Botany, was so named by Læssing, though we are unable to trace its derivation.—Læss. It. 310. Linn. Gen. 124. Schreb. 173. Willd. Sp. Pl. v. 1. 1327. Mart. Mill. Dict. v. 2. Juss. 134. Lamarek. Illustr. t. 184. Gært. t. 55.—(Coutarde; Lamarek. Dict. v. 2. 161.)—Class and order, *Pentandria Digynia*. Nat. Ord. *Convolvuli*, Juss.

Gen. Ch. Cal. Perianth of five, awl-shaped, erect, unequal, permanent leaves. Cor. of one petal, wheel-shaped or campanulate; tube shorter than the calyx; limb spreading, divided into five, ovate, incumbent, obtuse segments. Stam. Filaments five, awl-shaped, incurved, heart-shaped at the base; anthers oblong, curved, incumbent. Pist. Germen superior, ovate: styles two or three, thread-shaped, spreading; stigmas truncated. Peric. Capsule ovate, two-valved, two-celled, with a parallel partition. Seeds numerous, very small, imbricated; receptacle ovate, large.

Eff. Ch. Calyx of five leaves. Corolla wheel-shaped. Filaments heart-shaped at the base. Capsule of two cells and two valves.

Obf. Aublet has remarked that in some flowers the calyx and corolla are six-cleft, with six stamens.

1. *H. spinosa*. Linn. Sp. Pl. 328. Aubl. Guian. 281. t. 110.—Leaves lanceolate, hairy. Flowers clustered, terminal.—Native of South America, particularly in moist situations at Guiana and Cayenne, flowering at various times of the year.—The whole *strub* is extremely bitter, having a fibrous root, from which arise one or more stems about three feet high, straight, branched, woody, overspread with a viscous downyness. Leaves alternate, nearly sessile, lanceolate, entire, downy, clammy. Spines axillary, awl-shaped, straight, spreading. Flowers corymbose, of a blue colour, each one furnished with a sort of leafy scale at the base.

2. *H. inermis*. Loureir. Cochinch. 172. Mart. Mill. Dict. v. 2.—Stem spineless. Flowers solitary, lateral.—Found in moist places about Canton. Stem herbaceous, annual. Leaves lanceolate-linear, smooth, sessile, scattered. Flowers blue. Loureiro observes that he could not distinguish whether or not the filaments were cordate at their base.

3. *H. trigyna*. Willd. n. 2. Swartz. Ind. Occ. v. 1. 558.—Leaves

Leaves oblong, hairy. Flowers with three styles, axillary. Found by Dr. Houtton near Vera Cruz. *Shrub* armed with spines, hairy. *Leaves* alternate, sometimes approaching to nearly opposite, oblong, rather acute, entire. *Spines* foliary, half an inch long, spreading. *Flowers* blue, axillary, generally solitary, on stalks.

4. *H. zeylanica*. Willd. n. 3. Vahl. Symb. p. 2. 46. (Nama; Linn. Fl. Zeylan. 117. t. 2. N. zeylanica; Sp. Pl. 327. Steris javana; Mant. 54.)—*Leaves* lanceolate, smooth. *Flowers* with two styles, somewhat clustered.—Native of the East Indies.—*Stem* herbaceous, about six inches high, erect, branched. *Leaves* alternate, on footstalks, smooth, entire, spreading. *Clusters* simple, erect, the length of the leaves. *Flowers* alternate, as long as the partial stalks.

HYDROLOGY, compounded of ὕδωρ, *water*, and λογος, *science*, denotes that part of natural history which examines and explains the nature and properties of water in general. See **WATER**.

HYDROMANCY, ὑδρομαντεια, compounded of ὕδωρ, *water*, and μαντεια, *divination*, the act, or art, of divining, or foretelling future events, by means of water.

Hydromancy is one of the four general kinds of divination (see **DIVINATION**); the other three respecting the other elements, viz. fire, air, and earth, are denominated pyromancy, aeromancy, and geomancy.

Varro mentions the Persians as the first inventors of hydromancy, adding, that Numa Pompilius, and Pythagoras, made use of it.

This species of divination was performed in various ways: sometimes they used invocations and magic ceremonies, in consequence of which they discovered the names of certain persons, or events, which they wished to know upon the water: sometimes they suspended a ring by a thread over a vessel full of water, and struck the sides of the vessel with it a certain number of times; they also formed presages by casting small stones into still water, and observing the circles hereby formed on the surface of the water; by examining the various agitations of the waves of the sea; by observing the colour of the water, and the figures represented in it, &c. &c. See an account in Delrio Disquis. Magic. lib. iv. quest. 6. sect. 3.

The writers in optics furnish us with divers hydromantic machines, vessels, &c.

To construct an hydromantic machine, by means whereof an image, or object, shall be removed out of the sight of the spectator, and restored again, at pleasure, without altering the position, either of the one or the other. Provide two vessels, A B F, C G L K (*Plate VIII. Hydraulics, fig. 4.*); the uppermost filled with water, and sustained by three little pillars, one whereof, B C, is hollow, and furnished with a cock B. Let the lower vessel C L be divided by a partition H I into two parts; the lower of which may be opened, or closed, by means of a cock at P.

Upon the partition place an image, which the spectator in O cannot see, by a direct ray G L.

If now the cock B be opened, the water descending into the cavity C I, the ray G L will be refracted from the perpendicular G R to O; so that the spectator will now see the object by the refracted ray O G. And again shutting the cock B, and opening the other P, the water will descend into the lower cavity H L; whence the refraction ceasing, no rays will now come from the object to the eye: but shutting the cock P again, and opening the other B, the water will fill the cavity again, and bring the object in sight of O afresh.

To make an hydromantic vessel, which shall exhibit the images of external objects, as if swimming in water. Pro-

vide a cylindrical vessel A B C D (*Plate VIII. Hydraulics, fig. 5.*) divided into two cavities by a glass E F, not perfectly polished: in G apply a lens convex on both sides; and in H incline a plain mirror, of an elliptic figure, under an angle of 45°; and let I H and H G be something less than the distance of the focus of the lens G: so that the place of the images of an object radiating through the same may fall within the cavity of the upper vessel: let the inner cavity be blackened, and the upper filled with clear water.

If, now, the vessel be disposed in a dark place, so that the lens be turned towards an object illuminated by the sun, its image will be seen as swimming in the water.

HYDROMEL, ὑδρομελι, compounded of ὕδωρ, *water*, and μελι, *honey*, a drink made of water and honey, nearly in equal quantities; called also by the Greeks, μελιπικρον.

When this liquor has not fermented, it is called *simple hydromel*; and *compound* when other ingredients are added to the water and honey, in order to improve and exalt the flavour and virtues.

When it has undergone the spirituous fermentation, it is called the *vinous hydromel*, or mead and metheglin. To induce this fermentation, nothing is necessary but to dilute the honey sufficiently in water, and to expose the liquor to a convenient degree of heat.

Hydromel is the common drink of the Poles and Russians. Diodorus Siculus, lib. v. and Aristotle, relate, that the Celtiberi, and Taulantii, ancient people of Illyria, drank hydromel instead of wine.

HYDROMELON, a name given by the ancients to a liquor prepared with one part of honey, impregnated with the juice of quinces, and two parts of boiled water, set in the sun during the dog-days.

HYDROMETER, compounded of ὕδωρ, *water*, and μετρον, *measure*, an instrument wherewith to measure the gravity, density, velocity, force, or other properties of water.

The extensive use of the knowledge of the specific gravities of bodies has produced a variety of contrivances, under the name of *Essay Instrument*, *Hydrometer*, *Areometer*, *Gravimeter*, *Pesc-liqueur* or *Water-weigher*, for the purpose of ascertaining the specific gravities of different bodies, both solid and fluid, in an expeditious manner.

From Lowthorp's abridgment of the Philosophical Transactions, vol. i. p. 516, &c. or Boyle's Works, 4to. London ed. 1772. vol. iv. p. 204, &c., it appears, that the hydrometer was first invented by Boyle, and described under the name of a New Essay Instrument. It consisted of a ball, somewhat less than an hen's egg, with a graduated stem, four or five inches in length, soldered to the upper part, and by means of a stirrup or slit piece of brass underneath, it was applied, as perfectly as a graduated instrument could be, to ascertain the specific gravities of solids as well as fluids. To extend the use of the instrument, Boyle proposes that the ball should be made large, and provided with an appendage for occasionally changing the quantity of ballast applied beneath the ball. (See **AREOMETER**) Boyle's instrument was intended to be used in water, and, consequently, the graduations of its stem denoted certain invariable weights. But when the hydrometer is to be used in various fluids, it diminishes the accuracy of the results, if those spaces be taken for absolute weights; or, at all events, it brings forward a rather intricate consideration of the relation which the bulks of the spaces, or parts of the stem, have to the whole immersed part. Hence Fahrenheit first applied a dish, or scale, for weights at the top, in order to ascertain the specific gravities of fluids truly, and his instrument had only a single mark, that, in all cases, was to be brought to the surface of the fluid, by means of weights added in the above-mentioned scale;

HYDROMETER.

scale; as may be seen in Reid and Grey's abridgment of the Phil. Transf. vol. vi. pt. 1. p. 294.

The general principle on which the construction and use of the hydrometer depends, has been illustrated under the article *SPECIFIC GRAVITY*: for it has there been shewn, that a body specifically lighter than several fluids will serve to find out their specific gravities; because it will sink deepest in the fluid whose specific gravity is the least, or, that a greater addition of weight is required to keep the same part of the floating body below the surface of a heavier than of a lighter fluid.

Thus, let A B, (*Plate IX. Hydraulics, fig. 1.*) be a small even glass tube, hermetically sealed, having a scale of equal divisions marked upon it, with a hollow ball of about an inch in diameter at bottom, and a smaller ball C under it, communicating with the first. Into the little ball put mercury or small shot, before the tube be sealed, so that it may sink in water below the ball, and stand upright, the divisions on the stem shewing how far it sinks. If this instrument be dipped in common water and sink to D, it will sink only to E in salt water; but in port wine it will sink to F, and in brandy under proof, it will perhaps sink to B. It is evident that an hydrometer of this kind will only shew that one liquid is specifically heavier than another; but the true specific weight of any liquid cannot be determined without a calculation for this particular instrument, the tube of which should be truly cylindric, and not tapering as they commonly are. Besides, these instruments will not serve for fluids, whose densities are considerably different. With a view of remedying these and some other inconveniences, Mr. Clark, in the year 1730, seemingly unapprized of what had been done before by Boyle and Fahrenheit, constructed a new hydrometer, for the use of dealers in brandy and spirits, that they might be able to determine, by inspection, whether any spirituous liquor be proof, above proof, or under proof, and exactly in what degrees. This instrument is made of copper, because ivory imbibes spirituous liquors, and glass is apt to break. It consists of a brass wire about one-fourth of an inch thick, passing through and foldered into the copper ball B b, (*see fig. 2.*) The upper part of the wire is filed flat on one side of the stem of the hydrometer, and marked at m, to which division it exactly sinks in proof-spirits. There are two other marks A and B; the one shewing that the liquor is one-tenth above proof, when this instrument sinks to A, and the other indicating one-tenth under proof when it emerges to B; a brass weight, as C, having been previously screwed on to the bottom at c. There is a great variety of weights of different sizes, as K, &c. adapted to liquors that differ more than one-tenth from proof, and for determining the specific gravities of all such liquors as occur in trade, as well as for shewing the specific gravities of all fluids quite to common water. The round part of the wire above the ball may be marked across, as in *fig. 3*, so that with the weight as C, which fits the instrument for the trial of river water, in which it sinks to R W, it may serve for wines or other waters: thus in spring water it will sink to S P; in mineral water to M I; in sea-water to S E; and in the water of salt springs to S A: and the marks *br, ra, po, mc*, denote the divisions to which the instrument descends in Bristol water, rain water, Port wine, and Mountain wine, respectively. Phil. Transf. abr. vol. vi. p. 326, &c.

This hydrometer, says Mr. W. Nicholson, (*ubi infra*), is inferior to Fahrenheit's in two respects. In the first place, either a bubble of air, or a portion of the fluid, will be hid in that part of the cavity of the ballast weight, which is not filled by the screw; and it is of very different

consequence, which of the two is there. And secondly, the weights acting on the instrument, by their residual gravity, will not be constant; or, in other words, an additional weight will be accompanied by an addition to the bulk of the immersed part of the instrument; and in the case where the specific gravity of the liquid is not given, but required, it will not be easy to determine how much the operation of the one is counteracted by that of the other. However, though this last consideration evinces that the instrument is not fit for general use, yet it is accurate for the trial of ardent spirit, or any other particular liquid, when the weights are adjusted by experiment to the intended use.

Dr. Defaguliers contrived an hydrometer, for determining the specific gravities of different waters to such a degree of nicety, that it would shew when one kind of water was but one forty thousandth part heavier than another. This instrument (*see fig. 4.*) consists of C B b, a hollow glass ball of about three inches in diameter, and a small ball under it of about an inch in diameter. To a short neck at C there is fixed a brass head, with a fine screw, into which the piece C c is to be screwed; and this piece is joined to a wire C A, about one-fortieth part of an inch in diameter, and ten inches long, which is divided into inches, and tenths of inches. Having put a certain quantity of small shot into the ball b, so that when the head C c with its wire C A is screwed on, it shall sink as far as D, *e. g.* five inches, in river or soft spring water, we may know by observing how far this hydrometer sinks lower in one kind of water than another, their different specific gravity to a forty thousandth part, which corresponds with one-tenth of an inch marked on the stem A C. For let the hydrometer float in water in the jar I K L M, and the surface of the water cut the stem at D, a grain weight laid on the stem at A will cause the instrument to sink, till the mark D of the stem settles one inch under the surface; and, therefore, a grain depresses it an inch. The hydrometer weighs four thousand grains, and every inch of the graduated wire weighs ten grains; and, therefore, the part of it D C B b c D must weigh three thousand nine hundred and fifty grains. But it is known, from the principles of specific gravity, that a bulk of water equal to D C B b c D the immersed part, weighs just as much as the whole hydrometer, or four thousand grains: and, therefore, this instrument serves to compare together the different bulks of four thousand grains of water, according to their different specific gravities: and since the whole instrument is sunk an inch by the weight of one grain, and the instrument will stand at one-tenth of an inch, the difference indicated by it in waters in which it floats, it is evident that it will distinguish the tenth of a grain in four thousand, or the forty thousandth part of the whole bulk of water. By altering the quantity of shot in the ball b, the instrument may be prepared for the comparison of any other two liquors that are nearly of the same specific gravity. Defaguliers, &c. vol. ii. p. 234.

This instrument is capable of still greater exactness, by making the stem of a flat thin slip of brass or of steel, by which means we increase the surface without diminishing the solidity: on one side of this stem may be several marks denoting the depths to which the instrument would sink in various sorts of water, as rain water, river water, &c. and on the other side may be the divisions to which it would sink in lighter fluids, as hot Bath water, Bristol water, Port wine, &c. but in determining the strength of spirituous liquors, a cylindric stem is best.

Dr. G. Fordyce constructed an instrument, which is the most perfect we possess, its weights being adjusted to the different

HYDROMETER.

different specific gravities of spirits by experiments made at numerous varieties of strength and temperature.

Mr. Quin's hydrometer has been recommended by many distillers, &c. on account of its accuracy, which requires only eighteen weights used on the top of the instrument, to shew all the under and over proofs to the certainty of one pint in a hundred gallons, from proof to seventy gallons to one hundred over proof, and to fifty gallons in a hundred under proof, which would require nine hundred and sixty-eight weights, besides forty-five air weights, according to the old construction of Clark's hydrometers. The weights are numbered 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 30, 40, 50, 100, 200, 300, 600, grains. He has also formed a table shewing the degrees of the thermometer, and the number of grains corresponding with each degree; the number of grains required for each strength; the over proofs, or the quantity of water necessary to reduce one hundred gallons of proof, with the former manner of expressing the several preparations, as one to two, one to three, &c. and likewise the under proofs.

There is one circumstance, which deserves particular attention in the construction and graduation of hydrometers for determining the precise strength of different brandies, and other spirituous liquors. M. Reaumur, in making his spirit thermometers, discovered, that when rectified spirit and water, or phlegm, the other constituent part of brandy, are mixed together, there appears to be a mutual penetration of the two liquors, and not merely juxtaposition of parts; so that a part of the one fluid seems to be received into the pores of the other; thus, *e. g.* if a pint of rectified spirit be added to a pint of water, the mixture will be sensibly less than a quart. The variations hereby produced in the bulk of the mixed fluid render the hydrometer, when graduated in the usual way, by equal divisions, an erroneous measure of its strength; because the specific gravity of the compound is found not to correspond to the mean gravity of the two ingredients. M. Montigny constructed a scale for this instrument in the manner before suggested by Dr. Lewis, on an actual observation of the sinking or rising of the hydrometer in various mixtures of alcohol and water, made in certain known proportions. *Hist. de l'Acad. Roy. Sciences, &c. Paris, for 1768. Memoire iv. Neumann's Chem. by Lewis, p. 450, note r. See Specific Gravity.*

M. De Luc has published a scheme of the construction of a comparable hydrometer, so that a workman, after having constructed one after his principles, may make all others similar to each other, and capable of indicating the same degree on the scale, when immersed in the same liquor of the same temperature.

For this purpose he proposes to use an hydrometer of the common construction, such as is represented in *fig. 5.* made of flint glass; because glass is a substance which undergoes the least change of bulk by heat, and its changes are the most regular. The ball *a* should be one and a half inch in diameter, with which should communicate a small hollow cylinder *b*, containing such a quantity of quicksilver for a ballast, that the instrument may sink nearly to the top in the most spirituous liquor, made as hot as possible. To the ball *a* is cemented a thin brass tube silvered over, or a silver tube *c c*, made perfectly cylindrical, by drawing it through a hole. This tube, or *branch*, as he calls it, should be long enough to admit the immersion of a small part of it in the less spirituous liquors, *e. g.* wine reduced to congelation. In order to determine a standard for the construction of the scale of this instrument, he forms a weak spirit of wine, by mixing one part of water with six parts of such spirits of wine as fire gun-powder, or lichen steeped in them. He also finds the

specific gravity of the mixture, at the temperature of fifty-four and a half of Fahrenheit's thermometer, by a nice hydrostatical balance. Having dipped the hydrometer into this spirit of wine, at the fixed temperature, he marks upon its branch or stem with a thread, the point to which it sinks; then preparing a sort of brandy stronger than the common; by mixing three parts of water with seven parts of this same spirit of wine, he determines the point on the stem to which the instrument would sink in it at the same temperature, and marks it with a thread. These points, *viz.* 45 and 15 in the figure, are the fixed points of the hydrometer. The interval between them may be divided into thirty equal parts, each of which will represent one-thirtieth part of the total effect of the superadded water, on the specific gravity of the liquor. This fundamental interval in instruments for common use may be divided into fifteen parts, which will then be double degrees. In order to find a convenient place for the 0 of this scale, M. De Luc proposes to reduce one of the wines of which brandy is commonly made, to the temperature of water in ice, and dipping the hydrometer in it, to observe how much higher it will stand than the inferior fixed point. This excess of emersion, compared with the fundamental scale, and reduced to the nearest number of degrees, which will be an aliquot part of it, will be a proportional quantity invariably fixed, to be added to the scale below the inferior fixed point, for determining the place of 0; *e. g.* let this excess of emersion be about 15, or half the fundamental scale; then one should constantly add half the fundamental distance below the inferior fixed point, and thence begin to count the degrees: so that 0 would be at the bottom of the whole scale, the inferior fixed point would be at 15, the superior at 45, and the scale could be prolonged at the top as much as may be necessary for the essays of the most spirituous liquors. Another scale may be applied on the opposite side of the stem, for trying merely the specific gravity of the liquids in which the hydrometer may be dipped. The particular fixed points of this scale, *e. g. d, d*, may be taken in any two liquids, whose specific gravities, tried by the hydrostatic balance, shall have a convenient relation, and the space between those two points will be divided into a convenient number of equal parts. For the correction on account of the differences of heat, M. De Luc would take a liquor of mean spirituousity; *e. g.* a mixture of one part of water, and seven parts of the spirits of wine determined by the hydrostatic balance; reduce this liquor to the temperature of 45 of Fahrenheit; plunge into it the hydrometer already graduated, and observe the point to which it sinks; he proposes afterwards to heat the liquor to 65, and then to observe the sinking of the instrument. From this observation a table might easily be formed, in which we might express in degrees of the hydrometer, the effects of the differences of heat corresponding to each degree of the thermometer, beginning from a fixed point: or, a particular scale might be prepared for experiments of this nature, by changing the number of degrees contained between the fixed points, in order to establish an easy proportion between them and the degrees of the aerometer; and thus the correction might be made without tables. If an hydrometer of this kind were brought into general use, the police of the places in which the trade of spirituous liquors is carried on might take cognizance of it; and keep the public standard of the hydrometer or aerometer, as they keep the standard of weights and measures. *Phil. Transf. vol. lxxviii. part 1. art. 20. p. 500, &c. M. Le Roi has also published a proposal for constructing comparable hydrometers. Hist. de l'Acad. des Scien. Paris, for 1770. Mem. 7.*

Mr. William Nicholson some years ago made an attempt

HYDROMETER.

to combine Boyle's and Fahrenheit's instruments, and thus to adapt the hydrometer to the general purpose of finding the specific gravity, both of solids and fluids. A (*fig. 6.*) is a hollow ball of copper; B is a dish affixed to the ball by a short slender stem D; C is another dish affixed to the opposite side of the ball by a kind of stirrup. In the instrument actually made by the inventor, the stem D is of hardened steel, $\frac{1}{8}$ th of an inch in diameter, and the dish C is so heavy as in all cases to keep the stem vertical, when the instrument is made to float in any liquid. The parts are so adjusted, that the addition of 1000 grains in the upper dish B, will just sink it in distilled water, at the temperature of 65° of Fahrenheit's thermometer, so that the surface shall intersect the middle of the stem D. Let it be required to find the specific gravity of any fluid. Immerse the instrument in it, and by placing weights in the dish B cause it to float, so that the middle of its stem D shall be cut by the surface of the fluid. Then, as the known weight of the instrument, added to 1000 grains, is to the same known weight added to the weights used in producing the last equilibrium, so is the weight of a quantity of distilled water displaced by the floating instrument to the weight of an equal bulk of the fluid under consideration. And these weights give the ratio of the specific gravities. (See *Specific Gravity.*) Again, let it be required to find the specific gravity of a solid body less than 1000 grains. Place the instrument in distilled water, and put the body in the dish B. Make the adjustment of sinking the instrument to the middle of the stem, by adding weights in the same dish. Take those weights from 1000 grains, and the remainder will be the weight of the body. Place now the body in the lower dish C, and add more weight in the upper dish B, till the adjustment is again obtained. The weight last added will be the loss the solid sustains by immersion, and is the weight of an equal bulk of water. Consequently the specific gravity of the solid compared with water is as its weight to the loss it sustains by immersion. (See *Specific Gravity.*) When the instrument has been once adjusted in distilled water, common water may be afterwards used. Now the ratio of the specific gravity of the water made use of to that of distilled water being known ($= \frac{b}{a}$), and the ratio of the specific gravity of the solid to the water made use of being also known, ($= \frac{c}{b}$), the ratio of the specific gravity of the solid to that of distilled water will be compounded of both, (that is, $\frac{cb}{ab}$.) This instrument has been found to be sufficiently accurate to give weights true to less than one-twentieth of a grain. Manchester Memoirs, vol. ii. p. 386, &c. Nicholson's Introd. to Nat. Phil. vol. ii.

The hydrometer of Mr. Nicholson is highly commended by citizen Guyton in the description which he has given of a gravimeter, or instrument for measuring the specific gravity of solids and fluids, read to the National Institute at Paris, and inserted in the 21st volume of the *Annales de Chemie.* At present, he says, it is very much used; and gives, with considerable accuracy, the ratio of the specific gravity to the fifth decimal, water being taken as unity. It is susceptible of correction for the variations of temperature, and the impurity of the water which it is sometimes more convenient to use. It does not appear that any better instrument need be wished for in this respect. But this instrument, having hitherto been constructed in metal only, could not be applied either to salts or acids. M. Guyton, in order to remedy this and some other inconveniences to

which hydrometers are subject, has proposed, by following the principles of Fahrenheit, and executing the instrument of Nicholson in glass, with a slight addition, to render it more generally useful and commodious, without diminishing its accuracy in any respect. To his instrument he has applied the name of gravimeter. It is made of glass, of a cylindrical form, as being that which requires the smallest quantity of the fluid. Like the instrument of Nicholson it carries two basons; the one superior, at the extremity of a thin stem, towards the middle of which the fixed point of immersion is marked. The other lower bason terminates in a point; it contains the ballast, and is attached to the cylinder by two branches. The moveable suspension, by means of a hook, has the inconvenience of shortening the lever which is to secure the vertical position. The cylinder is 22 millimeters (0.71 inches) in diameter, and 21 centimeters (6.85 inches) in length. It carries in the upper bason an additional constant weight of five grammes. Guyton has added a piece which he calls the diver (*plongeur*), because it is in fact placed in the lower bason when used, and consequently is entirely immersed in the fluid. This is a bulb of glass, loaded with a sufficient quantity of mercury, in order that its total weight may be equal to the constant additional weight, added to the weight of the volume of water displaced by this piece. The weight, being determined at the same temperature at which the instrument was originally adjusted, will sink to the same mark on the stem, whether it be loaded with a constant additional weight in the upper bason, or whether the effect of this weight be produced by the additional piece (*plongeur*) in the lower dish. In using this instrument for solids, it differs in no respect from the hydrometer of Nicholson. The only condition being, like that in his, that the absolute weight of the body to be examined should be rather less than the constant additional weight, which in this instrument is five grammes (115 grains.) For liquids of less specific gravity than water, the instrument, without the above additional weight, weighs about two decigrammes (459 grains) in the dimensions before laid down. We have therefore the range of one-fifth of buoyancy, and consequently the means of ascertaining all the intermediate densities from water to the most highly rectified spirit of wine, which is known to bear in this respect the ratio of eight to ten with regard to water. When liquids of greater specific gravity than water are to be tried, the constant weight being applied below, by means of the additional piece (*plongeur*), which weighs about six grammes (138 grains), the instrument can receive in the upper bason more than four times the usual additional weight, without losing the equilibrium of its vertical position. In this state it is capable of shewing the specific gravity of the most concentrated acids. It possesses another property in common with the instrument of Nicholson, *viz.* that it may be used as a balance to determine the absolute weight of such bodies as do not exceed its additional load. And, lastly, the purity of the water being known, it will indicate the degrees of rarefaction and condensation in proportion to its own bulk. This instrument is rendered portable by means of a case, in which all the delicate parts are secured from pressure, and the heavier parts so supported as to resist the excess of motion which they are capable of acquiring in consequence of their mass. For a further account of this instrument, illustrated by figures, the manner of using it, and its application to the results of tables of specific gravity, we refer to Nicholson's Journal, vol. i.

HYDROMETRA, in *Medicine*, from ὑδρ, *water*, and μέτρα, *metra*, the *womb*, signifies a dropsy of the womb.

If such a disease as dropsy of the womb, or a collection

of water in its cavity, independent of pregnancy, ever occurs, it is at least a very rare disease, and its symptoms are not easily detected. Dr. Cullen, however, has given such a disease a place in his system of nosology, although he has made no mention of it in his First Lines. (Nosol. Method. Gen. lxxx.) Boerhaave mentions it in his 122th aphorism; but the commentary of Van Swieten seems to relate principally to larger collections than usual of the fluids in the gravid uterus. Sauvages speaks of a simple dropsy of the cavity of the uterus on the authority of Astruc (Hydrometra ascitica, sp. 1.), and includes the ovarial dropsy under the same genus, as well as the formation of hydatids in the uterus (H. hydatica), which, however, is altogether distinct from the true dropsy. (Nosol. Method. Cl. x. Gen. 13.) See DROPSY and HYDATID.

HYDROMETRIA, HYDROMETRY, the mensuration of water, and other fluid bodies, their gravity, force, velocity, quantity, &c.

Hydrometria includes both hydrostatics and hydraulics.

The term is modern, but very little in use. The first instance where we meet with it, is in the year 1694, when a new chair, or professorship of hydrometry was founded in the university of Bologna, in favour of S. Guglielmini, who had carried the doctrine of running waters, with respect to rivers, canals, dykes, bridges, &c. to an unusual length.

HYDROMPHALON, in Surgery, a dropical swelling of the navel. The word is compounded of ὑδρῶς, water, and φάλαξ, the navel. See DROPSY.

HYDROMYSTES, or HYDROMISTA, compounded of ὑδρῶς, water, and μυστήρ, a person set apart for the offices of religion, a name anciently given to certain officers in the Greek church, whose business was to make the holy water, and sprinkle it on the people.

HYDROPARASTATÆ, or HYDROPARASTÆ, formed of ὑδρῶς, water, and παρῆστημι, I present, in Ecclesiastical History, a sect of heretics, the followers of Tatian; called also Encratitæ, Apotactitæ, Saccophori, Severiani, and Aquarians.

The hydroparastatæ were a branch of Manichees, whose distinguishing tenet was, that water should be used in the eucharist instead of wine.

HYDROPELTIS, in Botany, from ὑδρῶς, water, and πέλτα, a shield, as being an aquatic plant with peltate leaves. Michaux. Boreal.-Amer. v. 1. 323. Sims in Curt. Mag. 1147.—Class and order, Polyandria Polygynia. Nat. Ord. Multiflora, Linn. Ranunculaceæ, Juss.

Gen. Ch. Cal. none. Cor. Petals six, oblong, permanent, somewhat spreading; the three outermost shortest, and externally resembling a calyx. Stam. Filaments numerous, about 36, inserted into the receptacle, thread-shaped, much shorter than the corolla; anthers vertical, erect, oblong, obtuse. Pist. Germens several, about 12 or 16, superior, erect, oblong, acute, each sessile on a mammillary point of the receptacle; styles short, thread-shaped, incurved; stigmas obtuse. Peric. Capsules several, inclosed in the permanent corolla which exceeds them in length, erect, oblong-ovate, pointed, somewhat fleshy, of one cell, not bursting. Seeds one or two, somewhat globose, inserted at the future on the inner edge of the capsule.

Ess. Ch. Calyx none. Petals six, permanent; three of them external and shortest. Nectaries none. Capsules several, superior, with one cell and two seeds.

Obs. The seed is described by Mr. König as monocotyledonous, if so it cannot belong to the Ranunculaceæ. Aquatic plants in general require reconsideration in this respect, some of them, as we have observed, having been judged monocotyledonous by analogy only, and few properly investigated. The late Dr. Solander had made a

genus of this plant which he referred to the Linnæan natural order of Multiflora, and called *Ixodia*, from ἰξωδία, viscid, very aptly alluding to the extremely viscid coating of the young shoots and buds, which is insoluble in water; but the name given by Michaux being printed, and liable to no exception, is properly retained by Dr. Sims.

The only known species is

1. *H. purpurea*. Michaux. Boreal.-Amer. v. 1. 324. t. 29. Curt. Mag. t. 1147.—Native of lakes and still pools in North America, from Upper Canada to South Carolina. It was communicated to Dr. Sims from the late collection of E. J. Woodford, esq. at Springwell, Herts. The stems are long, floating, round, and leafy. Leaves alternate, stalked, floating, orbicular, entire, peltate, with many veins radiating from their centre, and branched towards the margin. Flower-stalks from the side of the leaf-stalks, simple, single-flowered. Flowers dull purple, closing and lying down on the surface of the water at night, and expanding again in the morning, like those of *Nymphaea alba*, as observed by Mr. S. Edwards while making his drawing for the Botanical Magazine.

HYDROPHACE. See LEMNA.

HYDROPHANES, in Mineralogy, some varieties of opal which appear to have lost the water which they naturally contain, from exposure to the air, and in consequence of this have become opaque, recover their transparency when immersed in water; these have been named hydrophanes. See OPAL.

HYDROPHILUS, in Entomology, a genus of the aquatic kind of coleoptera, nearly allied in appearance and manners of life to the dytisci; its generic distinction consists in having the antennæ clavated, and the club perfoliated; the feelers four and filiform; and the posterior legs formed for swimming, with the inner edge in general ciliated and armed with small claws.

Linnæus has not very accurately discriminated the difference between the dytisci and the hydrophili, both which he confounds under the comprehensive term dytiscus, excepting only that he divides this genus into two sections, one having clavated and perfoliated antennæ (as in hydrophilus) and the other antennæ of a setaceous structure. His generic character is consequently adapted to include both those sections, and is for this reason rather curiously, and somewhat too loosely defined; the antennæ of the dytiscus, says Linnæus, are either setaceous, or increase in size towards the end, and have a perfoliated capitulum or head; the hind feet hairy, formed for swimming, and armed with small claws. (Ord. et Gen.) And again in Syst. Nat. "Antennæ setaceæ aut clavato-perfoliatæ; pedes postici villosi, natatorii submutici." In the tenth edition of Syst. Nat. Linnæus however divides the dytisci into three sections instead of two, as **Antennis perfoliatis*, ***Antennis setaceis*, and ****Antennis clavatis*. Ray had long before his time called this tribe of water beetles by the significant term of hydrocantharus.

The dytiscus genus, as established by Linnæus, is separated by Geoffroy into two genera, dytiscus and hydrophilus, the latter of which, according to this author, contains those with perfoliated antennæ (which he observes are shorter than the feelers); the rest, having the antennæ filiform, (and longer than the head,) he retains under the name assigned to them by Linnæus. Schæffer admits the two last-mentioned genera with some amendment; the tarsi of the dytiscus, he remarks, have five joints, the body oblong, and the head obtuse. The mouth of the hydrophilus, according to this author, is armed with jaws, and has four palpi or feelers, two of which are longer and two shorter than the antennæ.

HYDROPHILUS.

In the Gmelinian edition of "Systema Naturæ," the two genera hydrophilus and dytiscus are adopted nearly in the manner of the writers last-mentioned, except that, according to Fabricius, he adds that the hydrophili have only four feelers, the dytisci six. Lamarck again observes of the "hydrophile" (hydrophilus), that the antennæ are short, with a perfoliated club; feelers four and unequal, the anterior ones longer than the antennæ. The "dytique," (dytiscus,) he adds, has filiform-fetaceous antennæ of the same length as the corselet (thorax); six unequal feelers; and simple jaws ciliated within. The body in both, he says, is elliptic; in hydrophilus the sternum is spinous; and the four posterior legs formed for swimming, in dytiscus only the two behind. Mr. Marsham notices the trifid structure of the antennæ in the hydrophili, the inferted position of the head, the oval convex form of the body, and the ciliations observable on the posterior legs in most species, "Antennæ clava perfoliata, trifida, palpis breviores; caput infertum; thorax transversus; corpus ovale, convexum; pedes postici in plerisque ciliati." Ent. Brit. And these he divides into two families, the one having the thorax smooth, the other longitudinally rugose.

The hydrophili either as a genus (hydrophile), or a family (hydrophiliens), containing several distinct genera, appear to have been long since admitted among the French writers. Walcknær, in his "Faune Parisienne," has the genera spercheus (from Fabricius) and also hydrachna, in addition to hydrophilus and dytiscus, all which belong, according to most other writers, to one of the two genera last-mentioned. In describing the hydrophilus, he notices the cleft on the jaw, and the texture as well as form of the lip, in addition to the characters assigned to it by others. "Palpes, quatre alongés filiformes. Machiøre bifide. Lèvre cornée, légèrement échançée. Languette légèrement échançée. Antenne en massue perfoliée." The family hydrophiliens, as a sub-division of the "Sphéridiotes," is described at some length by Olivier; from which they have been lastly removed by Latreille, and now constitute the fourteenth family of the "Pentameres."

Latreille divides the hydrophiliens into two sections, one of which has the jaws entire at their extremity, the maxillary feelers rather shorter than the antennæ, the body oblong and nearly plain above, and the breadth of the thorax never much exceeding its length. This section contains the two genera elophorus and hydræna (the hydræna of Illiger.) The insects of the second section are known by having the jaws bidentated at their extremity; the maxillary feelers also as long, or longer than the antennæ; the body hemispherical, or ovoid and convex; and the thorax transverse. This last contains likewise two genera, as spercheus and hydrophilus. The genus elophorus is distinguished by clavated antennæ, the club of which commences at the sixth joint; and the feelers terminate in a large oval joint. The club of the antennæ in hydræna begins at the third articulation; and the feelers end in a joint much smaller or thinner than that of the preceding. In spercheus the antennæ consist of six joints, and the limbs are destitute of conspicuous spines, or spurs. And lastly, that genus, to which the name of hydrophilus is retained, includes those only which have nine joints in the antennæ, and the limbs terminated in a kind of spurs or spines. The greater number, if not the whole, of those, appear to be hydrophili of continental writers in other parts of Europe.

Like the dytisci the hydrophili inhabit ponds of stagnant waters, residing in the aquatic element during the day-time, and venturing abroad on the wing in the night season, at

which period they become the prey of the owl, the goat-sucker, and other nocturnal birds. The males are distinguished from the females by having a horny flap or shield of a concave form on the anterior legs. The posterior legs are adapted in an admirable and peculiar manner to its mode of life, being long, curved, and flattish, and furnished on the inner side with a series of close-set filaments, resembling a fin, by means of which it is enabled to swim, and perform its various evolutions in the water with the utmost ease and velocity. The larvæ, as in the dytisci, are hexapodal creatures which live in the waters and prey upon insects, the fry of fishes, and other inhabitants of its aquatic regions. It is supposed to live between two and three years in the state of larva before it assumes the pupa form, previous to which latter change it buries itself in some bank of earth or sand contiguous to the boundaries of its usual haunts, and remains, while in the state of pupa, inclosed within a covering of its own formation, the shape of which is usually oval or spherical. The opinion of Degeer that the hydrophili, in the last or winged state, are carnivorous, seems to be in some degree refuted by the more recent observations of naturalists, the result of which appears to be that they subsist chiefly, if not entirely, on vegetable food; and we may further add that their internal conformation pretty clearly proves the truth of this interesting discovery.

Species.

PICEUS. Black and smooth; sternum furrowed, with a long spine pointing backwards. Fabr. Donov. Brit. Inf. &c. *Hydrophilus ruficornis*, Degeer. *Le grand hydrophile*, Geoff. *Dytiscus piceus*, Linn.

Native of Europe.

OLIVACEUS. Olive, sternum grooved with a long curved spine; wing-cases emarginate. Fabr.

Inhabits Coromandel, and less than the former.

CARABOIDES. Black and polished, the wing-cases somewhat striated. Fabr. Donov. Brit. Inf. *Hydrophilus nigricornis*, Degeer. *Hydrocantharus niger subrotundus*, Ray.

An European species.

LATERALIS. Black and glossy; margin of the thorax and wing-cases yellow. Fabr.

Half the size of the former, the sternum projecting backwards into a sharp point, with a yellow dot in the middle, and the legs ferruginous. Inhabits South America.

RUFIPES. Shining black; legs rufous; sternum with a recurved spine. Fabr.

Size of the last, and inhabits China. The antennæ are ferruginous, with the club brown; the body glabrous, and without spots.

EMARGINATUS. Dusky-brown; shield emarginate. Fabr. &c.

Found on aquatic plants in Europe. Body gibbous and opaque.

FUSCIPES. Black; wing-cases striated with dots; margin livid; legs fuscous. Marsh. Ent. Brit. *Dytiscus fuscipes*, Linn. Fn. Succ. *Dytiscus gyrioides*, Schrank. *L'Hydrophile noir strié*, Geoff.

An European species.

SCARABÆOIDES. Oval, convex, black, and very smooth; wing-cases striated; legs pitchy. *Dytiscus scarabæoides*, Linn. Syst. Nat. X. Roefel. &c.

Native of waters in Europe.

PICIPES. Black; legs pitchy; wing-cases smooth. Fabr.

Inhabits Germany.

ORBICULARIS. Subrotund; body glabrous and black; Fabr. *L'Hydrophile lisse à points*, Geoff.

HYDROPHILUS.

Same country as the preceding; and is likewise found in France and other parts of Europe.

SUBROTUNDUS. Roundish, glabrous and black; wing-cafes striated. Fabr.

Smaller than the last, and inhabits America.

BICOLOR. Ovate; above yellowish, beneath black. Fabr. &c.

Native of Denmark.

COLLARIS. Black; mouth, thorax at the sides, and a few abbreviated lines on the wing-cafes ferruginous. Fabr.

Inhabits South America.

UNDATUS. Ovate, black; thorax pale; wing-cafes striated grey. Fabr.

The head of this species is glossy black; antennæ and feelers yellow; thorax with a double black dorsal line; wing-cafes obscurely undulated with black; body black, and legs yellow. This insect inhabits South America.

OBSCURUS. Glossy black; wing-cafes striated and ferruginous at the base and tip. Fabr.

Native of Germany; the head and thorax smooth and without spots; legs somewhat ferruginous. Obs. This must not be confounded with *Hydrophilus obscurus* of Müller (Zool. Dan.), which is described of a livid colour, with the abdomen black, and the wing-cafes glossy with crowded spots. This last mentioned insect is perhaps a variety of the following species.

LURIDUS. Thorax and striated wing-cafes brown-cinereous; body black. Gmel. Degeer, &c.

Inhabits Europe.

ERYTHROCEPHALA. Ovate, black; head, thorax, and border of the wing-cafes rufous. Fabr.

Country unknown. The legs rufous, thighs black.

HEMORRHOIDALIS. Black; wing-cafes striated, the tip with the shanks ferruginous. Fabr. &c.

Inhabits Germany.

MARGINELLUS. Glossy black; thorax and wing-cafes edged with rufous. Fabr.

Size of the last, and inhabits the same country; the wing-cafes smooth; legs black; tarsi ferruginous.

SORDIDUS. Black, and somewhat glossy; margin of the thorax livid; wing-cafes livid, with black spots. Marsh.

Inhabits Britain in stagnant waters.

VERRUCOSUS. Dull black, ferruginous; abdomen beneath verrucose. Marsh.

Legs and abdomen black; tubercles beneath resembling those on some species of the Lichen genus. Native of Britain.

LIVIDUS. Ovate, livid, and very smooth. Oliv. *Dytiscus lividus*, Forster. *Hydrophilus lividus*, Marsh.

Antennæ testaceous at the base; legs black, the shanks and tarsi testaceous ferruginous. Found in maritime marshes in Europe.

DERMESTOIDES. Hemispherical-ovate, and lurid; head black; thorax at the sides dull ferruginous. Marsh. *Dytiscus dermestoides*, Forster.

Inhabits stagnant waters; the head black and glossy; thorax black except the margins; legs ferruginous.

TORQUATUS. Ovate testaceous; head behind black. Marsh.

The head is yellow; abdomen black; legs pitchy black. A British species.

MINUTUS. Ovate and black; wing-cafes and legs grey. Fabr. &c.

Head pitchy, black and glossy; thorax at the sides pale; abdomen beneath pitchy black. Native of Europe.

GRISEUS. Above cinereous, beneath fuscous. Fabr.

Size of the last, and inhabits Europe.

BIPUNCTATUS. Thorax black, edged with grey; wing-cafes brown with a whitish margin and dot behind. Fabr. *Hydrophilus coccinelloides*, Hellw. *Dytiscus coccinelloides*, Schrank.

A small species found in Europe.

LUTOSUS. Fuscous; wing-cafes striated with impressed dots. Marsh.

A small species; the thorax is rugose, with transverse flexuous raised lines. Native of Britain.

NITIDUS. Black and polished; margin of the thorax with the legs rufous. Marsh.

Inhabits Britain.

MOLLIS. Black and glossy; thorax and wing-cafes brown, testaceous. Marsh.

Head and abdomen black. A small species found in Britain.

PICINUS. Ovate, pitchy, and glossy; legs rufous. Marsh. Size of the last, and inhabits Britain.

LONGIPALPIS. Black; feelers antenniform; antennæ and feet red. Marsh.

Length rather more than one line; the feelers advanced and three-jointed, the first articulation long as in the antennæ of some curculionides; head black; thorax black and attenuated behind, line in front transverse and impressed; wing-cafes black and striated with dots. A British species.

IMPRESSUS. Black; thorax with a large impressed dot on each side; legs testaceous. Marsh.

Body entirely black; wing-cafes striated. Inhabits Britain.

FULVUS. Fulvous; wing-cafes lineated with dull black; abdomen black. Marsh. *L'Hydrophile fawæ*, Geoff.

Antennæ fuscous; feelers testaceous, with the tip black; head fulvous and dotted; eyes black; thorax fulvous and dotted, the front black; wing-cafes fulvous with longitudinal obsolete lines of black; abdomen beneath black, covered with fine hairs; legs testaceous and downy. Native of Europe.

MARGIPALLENS. Pitchy and entirely glossy; margin of the thorax pale. Marsh.

A British species.

OCHROPTERUS. Black; sides of the thorax and wing-cafes, with a spot before each eye, lurid. Marsh.

Length two lines; the head black, except the two lurid spots before the eyes; thorax and wing-cafes very finely dotted; tarsi ferruginous. Native of Britain.

AFFINIS. Cinereous; wing-cafes each with two black dots, and striated with punctures; thorax emarginate, brassy-green. Marsh. *Hydrophilus griseus?* Herbst.

Inhabits stagnant waters in Europe.

DORSALIS. Fuscous; thorax green; wing-cafes striated, testaceous with a common black spot, inclosing two testaceous ones. Marsh.

Native of Britain.

CINCINDELOIDES. Black brassy; eyes prominent; wing-cafes with ridged striæ. Marsh.

Body entirely black and brassy; head advanced; thorax with three hollows; wing-cafes with two lines of impressed dots between the ridges.

A British species.

PYGMÆUS. Grey; head black behind; thorax yellowish. Fabr.

A minute kind found in South America; the wing-cafes without spots.

TRICOLOR. Black; wing-cafes pitchy edged with black, and ochraceous at the tip; legs tawny. Herbst.

Inhabits Prussia.

CORDIGER. Black; wing-cafes and margin of the thorax ferruginous,

ferruginous, the first with a common heart-shaped spot. Herbil.

Inhabits same country as the former.

PUSILLUS. Black; wing-veins very smooth; antennæ and tarsi brown. Müll.

Native of Denmark.

PILULA. Black; above polished with crowded dots. Müll. *Hydrophilus punctatus*, Geoffr.

An European species; as are also the two following.

NIGER. Glossy black; wing-veins finely striated with distant dots; antennæ and tips of the legs ferruginous. Linn.

ATER. Black and glabrous; antennæ and flanks reddish. Linn.

HYDROPHOBIA, in *Medicine*, from ὕδωρ, *water*, and φόβος, *I fear*, signifying, literally, a *dread of water*, is the term employed by medical writers to denote the disease occasioned by the bite of a rabid animal; an aversion to liquids being one of the characteristic symptoms of that disease. Some have used the more general term *hydrophobia*, from ὕδωρ, *liquid*.

Of the impropriety of these appellations, deduced from one symptom only, and that neither exclusively belonging to the disease, nor invariably present in it, we shall have occasion to speak presently. In the mean time, we may observe, that the older writers, as we are informed by Cælius Aurelianus (*Acutor. Morb. lib. iii. cap. 9. and 12*) used the terms *ærotophobia*, or a *dread of air*, and *pantophobia*, or a fear of *all things*, as appropriate names for the disease, since the impression of cold air sometimes excited terror, and the disorder is marked by a singular degree of general timidity and distrust. Others called it *phobodipsion* (φόβος, signifying *thirst*), because the patient is *thirsty*, yet *fears* to drink. Several modern authors, however, objecting to an appellation expressive only of one symptom, have more correctly denominated the disease *rabies*, and *rabies canina*, or canine madness. The French call it *la rage*.

It is uncertain at what period this disease became known. Its symptoms are never mentioned by Hippocrates, which affords a strong presumption that it did not exist in his time; for it is a disease so singular and striking in its appearances, that it could never be seen by any one without leaving the deepest impression upon the mind. Aristotle is the first writer who expressly mentions it. He says that all animals, except man, are infected by the bite of a mad dog, and destroyed by it. This imperfect state of his knowledge respecting the malady, is a proof that it was a matter of recent observation; for although several persons might be bitten without suffering the disease, and, from the length of time which commonly elapses between the infliction of the bite and the appearance of the symptoms, several cases might occur before it was referred to its true source; yet no very long time would be requisite to clear up these doubtful points. Accordingly, we find subsequent writers treating of the disease in a familiar manner. Plutarch affirms that the hydrophobia was first seen at Rome in the days of Asclepiades. See Aristot. *Hist. Anim. lib. viii. cap. 22*. Plutarch, *Sympoſiacion, lib. viii. probl. 9*. Le Clerc. *Hist. de la Médecine, p. ii*.

The origin of the poison, by which hydrophobia is generally communicated, is likewise a subject of much uncertainty. It is known that animals of the dog-kind, including the wolf and the fox, are most frequently the subjects of *rabies*; and some writers have maintained that, although it may be received and propagated by other animals, yet it always originates with some of the canine race. (See Hillary on *Dis. of Barbadoes, p. 246*.) But it is still a matter of

doubt, whether it occasionally arises spontaneously in these animals; or whether, like the small-pox in the human species, it is propagated only by contagion. There are some facts, which, though they do not prove the negative, in respect to the spontaneous origin, yet afford sufficient evidence that the disorder, even among dogs, is most commonly the result of infection. Great heat has been said to excite *rabies* in the dog-tribe. But if that were the case, it ought to be, as it were, endemic in tropical countries. Dogs are more numerous, Dr. J. Hunter has affirmed, in the island of Jamaica than perhaps in any other part of the world. It is the ambition of every negro to be master of a dog; "yet notwithstanding their great numbers, particularly in the towns, forty years have elapsed without a dog being known to go mad. The insular situation of the country secures to it in some degree the advantages of a quarantine; and the rare occurrence of the disease proves that it seldom, if at any time, originates of itself. (See *Trans. of a Society for the Improvement of Med. and Chirurg. Knowledge, v. i. art. 17*.) It is also stated, that the most eminent sportsman in this country, Mr. Meynell, to whom the preservation of his kennel from madness was an object of great importance, preserved his dogs from the disease, during a long series of years, by making every new hound perform a quarantine before he was allowed to join the pack. *Ibid*.

There is reason to believe, however, that the *rabies*, in the animal race, occurs at times spontaneously; but whether from the causes which have been stated by authors it were not easy to decide. Among these causes, Boerhaave enumerated "a very hot climate, or one exposed to the extremes of heat and cold; a very hot and dry season; feeding upon putrid, stinking, and maggoty flesh; want of water; worms bred in the kidneys, intestines, brain, or cavities of the nose (*Aphorism 1134*); but the influence of these circumstances in producing the disease is not established by a sufficient number of observations.

All domestic animals, birds as well as beasts, are susceptible of the poison of the rabid dog. Indeed our experience has not yet taught us that there is any race of animals exempted from its effects. But whether every animal labouring under the disease is capable of infecting others, or whether this power is confined to a few only, we are yet to learn. Boerhaave affirms that the disease has been communicated by infection to others by dogs, cats, wolves, foxes, horses, asses, mules, swine, apes, cocks of the poultry breed, and men, when affected with *rabies* (*Aph. 1132*); and the cow has also been said to propagate it. Van Swieten has stated some instances, from old authors, of hydrophobia occasioned by the beak of an enraged cock wounding the hand and arm. But there is little doubt that, in such cases, the spasmodic and fatal disease, which ensued, was *tetanus*, and not hydrophobia. (See *TETANUS*.) This notion is confirmed by the early occurrence of the symptoms after the bite, namely, within the first or second day, which is not unusual in *tetanic* affections, but never perhaps occurs in hydrophobia. (See Van Swieten's *Comment. on Aph. 1132*. Also, Hamilton on *Hydrophobia, vol. i. p. 107, 2d edit.*) It is certain, however, that not only animals of the canine species, but cats, have produced hydrophobia in the human species by their bite. Were we to judge from analogy, from seeing two animals, so different from each other as the dog and the cat, capable of infecting others, we might be led to infer, that every animal susceptible of the disease had the power of communicating it, provided their natural habits led them to bite and tear with their teeth such animals as came in their way, while in an enraged state. With respect to men, under the influence of hydrophobia, although

HYDROPHOBIA.

though the popular notion of their general disposition to bite those around them is erroneous, yet there are instances on record in which hydrophobic patients did bite some of their attendants, but no ill consequences have been known to follow. From this, however, as Dr. John Hunter justly remarks, we can draw no positive inference; for it is but a small proportion of such persons as are bit by dogs undoubtedly mad, who are infected with the poison. *Transf. of a Society, &c.* p. 300.

With regard to the activity of the poison of the rabid dog, the facts which have been collected have been as vaguely stated, and the inferences, therefore, are as inconclusive as those relative to the topics just mentioned. Among the older writers, indeed, there was much credulity, and they have transmitted to us many fabulous histories in regard to the operation of the rabid virus. "Scarce any poison known," says Hillary, (relying upon the truth of those tales,) "is so infectious, or so easily and readily communicated by so many and various ways as this of a mad dog is; for the slightest bite, only tearing the skin, without drawing blood; or the smallest quantity of the flaver of the mad animal, either fresh or dried for some time, taken upon the tongue or lips; or rending a person's clothes and leaving the flaver on them to dry, has produced this disease; as a woman had her coat torn by a mad dog, which she a considerable time after sewed up, and bit off the thread with her teeth, and some time after died rabid from biting off that thread. (*Hildanus Obs. Chir.*) Also a man only kissing his children to take his leave of them when he had the rabies upon him, they all soon after died rabid. (*Palmarius de Morb. Contag.*) Kissing a favourite dog that was mad had the same effect, &c. has produced this most fatal disease." (*On Diseases of Barbadoes*, p. 249. See several similar cases quoted by Dr. Hamilton, vol. i. p. 98—104.) Hillary admits, however, that the poison does not appear to infect a person through the unbroken skin: and there is certainly a defect of accurate detail, in the cases quoted by Dr. Hamilton, where the infection was said to have been communicated when no bite was inflicted. Some excoriation or rupture of the cuticle may have existed, although unnoticed, in the hands of those who examined the mouths of dogs in this malady. (See Hamilton, case iii. p. 100, case ix. p. 103.) Where the disease was produced by a rabid dog, licking a fore until it bled, we understand how the infection would be occasioned by absorption. See Dr. Hunter, in *Transf.* before quoted, p. 301.

As the bite only serves the purpose of *inoculation*, the danger arising from it will be various, as it happens to be inflicted in a part more or less vascular; or as the teeth are more or less loaded with the poison. There is the greatest danger from bites in the face, and the symptoms come on soonest; bites in the hands also, which are generally bare, are full of danger. In other parts of the body, the clothing, by wiping the teeth of the animal, greatly lessens the danger of infection. It is fortunate that the human species is much less susceptible of the infection than the dog. Four men and twelve dogs were bit by the same rabid dog, and every one of the dogs died rabid, while all the four men escaped, though they used no other means of prevention but such as we see every day to fail. There is also an instance of twenty persons being bit by the same mad dog, of whom only one had the disease. (See Dr. Hunter's paper, p. 302.) Some writers have calculated, indeed, that, on an average, only *one* person in *twenty-five*, who are bitten by rabid dogs, suffer hydrophobia. Dr. Hamilton, however, on collating a great number of instances of bites received, found that the average did not amount so high; he

thinks that not more than *one* in *sixteen* of the human species, who are bitten, take the disease. *Loc. cit.* vol. i. p. 31.

Some experiments, made by Mr. Cline, respecting the communication of rabies by inoculation with the saliva of a hydrophobic man, in the last stage of the disease, would throw great doubt on the infectious qualities of that secretion in the human subject. He took particular pains in inserting the saliva, while perfectly fresh, into a dog, three rabbits, and several fowls: "but in none of these instances was there the least appearance of the disorder at the expiration of three months."—Mr. Astley Cooper, on the other hand, inoculated a dog, a pig, a fowl, and a rabbit, with the saliva of a dog, which had recently died of rabies, by inserting, from the point of a lancet, between two and three drops under the skin of the inner part of the thigh of each." The dog and fowl were kept confined for nine weeks, and the pig seven, but without any appearances of hydrophobia. The dog afterwards became the property of a gentleman, who kept him nearly twelve months, and he had never any marks of the disease. The rabbit was accidentally killed on the fourth day from the experiment." See two cases of Rabies Canina, by Dr. Babington, &c. in the *Medical Records and Researches*, Lond. 1798, p. 136—8.

On the whole, therefore, the evidence is of an unsatisfactory and even contradictory nature, in respect to the qualities and operation of the *virus* of rabies; and much remains to be ascertained by future experiment and investigation. We know, however, too well, that the fatal consequences of the poison have appeared, in some instances, in which every practice had been adopted, after the infliction of the bite, to remove the bitten part, as well as every portion of the poison that could be supposed to lodge in the wound.

We should now have proceeded to describe the symptoms of the disease, as it affects the dog, in order that it might be speedily recognised, and distinguished from other diseases, to which that animal is subject: but this has been already so fully and distinctly done, by a writer possessed of an extraordinary degree of experience upon the subject, that we must refer our readers to his description (see the article Dog); and proceed to give an account of the symptoms of the disease, as it occurs in the human subject. We may just remark, by the way, that the influence of *names*, in respect also to the disease in the dog, has led to some dangerous popular mistakes, which are pointed out in the article just referred to. The term *hydrophobia*, being erroneously applied to the rabies of the dog, has induced a supposition that no dog is rabid, while he continues to drink; whereas he is constantly endeavouring to quench his thirst in that disease. And again, the appellation of *madness* has led to a belief that violence and fury are characteristic of rabies in the dog; but, though he is irritable and peevish, there is nothing of wildness in his disposition. In consequence of this mistake, dogs have been allowed to go about, fondled, and even slept with (see *Mem. of Swedish Acad.* 1777) in a rabid state.

History of Symptoms.—The wound inflicted by the bite of a rabid animal has nothing peculiar in its appearance, and heals as readily as the bite of an animal that is not rabid. From the time of the bite until the period when the symptoms appear, there is no derangement of health, nor any perceptible change in the constitution, provided the person bitten be not under the influence of fear. The interval between the infection and the commencement of the disease varies considerably in different instances: the most common period, as it was long ago stated by Cælius Aurelianus, appears to be about forty days or six weeks. Dr. Mead states
the

HYDROPHOBIA.

the ordinary interval at between thirty and forty days: (Mead on Poisons, p. 130.) and Dr. Babington from three to five weeks; some instances occurring much earlier, and others not for many months, so that he considers the average from four to twelve weeks. (Med. Records and Researches, before quoted.) In the cases laid before the Society for the Improvement of Medical and Chirurgical Knowledge, the interval varied from thirty-one days to seventeen months. Dr. Hamilton draws the following conclusions, as to the interval between the bite and the occurrence of the disease, from a table of 131 cases. Only three took the disease before the 18th day, none before the 11th—from the 18th to the 30th, *seventeen* were seized:—*sixty-three* began to be ill from 30 to 59 days after the bite;—*twenty-three* were attacked from two to three months inclusive;—*nine* from three to four months;—*two* at five months;—*one* at five months and eleven days;—*one* at six months;—*one* at seven months;—*two* at eight months;—*one* between eight and nine months;—*two* at nine months;—*one* at eleven months;—*one* at fourteen months;—*two* at eighteen months;—and *one* at nineteen months. (Vol. i. p. 113.) The last-mentioned interval is, he thinks, the longest to which any credit can be given. On the other hand, a case is related by Dr. Bardley of Manchester, which proved fatal, as is usual; and every inquiry respecting which corroborated the patient's repeated assertion, "that he had never suffered the least injury from any animal, except the bite, inflicted *twelve years since*, by an apparent mad dog." (See Memoirs of the Liter. and Philos. Society of Manchester, vol. iv. part ii. p. 431.) In this instance, the nature of the disease was perfectly clear, and the evidence as to the bite not less satisfactory: so that we must either admit the latent state of the poison for this long interval, or the *spontaneous* origin of hydrophobia in man. Dr. Bardley's paper, which contains a reference to numerous cases, in which the latent period of the poison was long, is worthy of perusal. But to proceed.

At an uncertain time after the infliction of the bite, the patient feels some degree of pain or uneasy sensation in the bitten part, which is sometimes compared to a scorching by heat, is sometimes attended with itching, and sometimes supposed to be rheumatic. This pain, when the bite, as is most frequent, is in the hand, spreads up the outside of the arm to the shoulder, (not affecting the axilla,) and the neck. In some cases the cicatrix left by the bite is said to become inflamed, and even to discharge. These pains are soon succeeded by a general depression of spirits, and especially a sense of undefinable listlessness and anxiety. Sometimes a general rigor or chill occurs, as in the commencement of a fever. The night is passed in the same restless state, without sleep. The appetite begins to fail, and some thirst is present. And now the peculiar symptom which gives the disease its name, the *dread of liquids*, is discovered, often accidentally, on attempting to take drink; as the liquid approaches the lips, a sudden convulsive sob, or catch in the breath, with a momentary sensation of choking, takes place, which is renewed at every attempt. As the disease advances, this attempt is not thought of without horror, and the very idea excites these spasmodic fits of choking in the throat, and catching of the breath. This may be best illustrated by examples. "On our proposing to him to drink," says Dr. Marcet, speaking of a hydrophobic patient, "he started up, and recovered his breath by a deep convulsive inspiration; yet he expressed much regret that he could not drink, as he conceived it would give him great relief, his mouth being extremely parched and clammy. On being urged to try, however, he took up a cup of water

in one hand and a tea-spoon in the other. The thought of drinking out of the cup appeared to him intolerable; but he seemed determined to drink with the spoon. With an expression of terror, yet with great resolution, he filled the spoon, and proceeded to carry it to his lips: but before it reached his mouth, his courage forsook him, and he was forced to desist. He repeatedly renewed the attempt, but with no more success. His arm became rigid and immovable, whenever he tried to raise it towards his mouth, and he struggled in vain against this spasmodic resistance. At last shutting his eyes, and with a kind of convulsive effort, he suddenly threw into his mouth a few drops of the fluid, which he actually swallowed. But at the same instant he jumped up from his chair, and flew to the end of the room, panting for breath, and in a state of indescribable terror." (See Medico-chirurgical Transactions, vol. i. p. 138. Lond. 1809.) A patient of Dr. Bardley's, having eaten some bread and butter, with great difficulty, was requested to wash down this solid food with some liquid; and he expressed a readiness to make the trial. "On receiving a basin of butter-milk, he hastily applied it, with a determined countenance, to his lips;—when he was instantly seized with to severe a spasm and rigidity of the muscles of the neck, that he was compelled, in an agony, to desist from drinking. Shortly after, he raised himself upon his knees in bed, took the bowl again into his hands, and by forcibly stretching his neck forward, at the moment he received the liquid into his mouth, and then violently throwing his head backwards, he succeeded in swallowing a small portion. He appeared highly gratified by the success of this effort, and the fortitude he had exhibited; and exultingly demanded another draught of the butter-milk, as he now thought he could conquer the difficulty he had hitherto experienced. But a violent return of the spasms in the throat and neck checked this attempt. These convulsions were terminated by the stomach discharging the liquid previously swallowed, highly tinged with bile." (Memoirs of Manchester Society, vol. iv. p. 439.) In a word, it is obvious to the bystander, that every attempt to pass liquid over the root of the tongue excites convulsions in the larynx and pharynx, and even in the muscles of the chest and abdomen; and therefore this symptom, the *hydrophobia*, as Dr. Mead and others have remarked, is not a delirious dread, or hallucination of the mind, but a matter of experience, which at first excites the surprise of the patient. Mead affirms that it should have been called, not *hydrophobia*, but *δυσκαταποσις*, *dyscataposis*, or difficulty in swallowing. (See his Mechanical Account of Poisons, p. 146, 3d edit.)

But the dread of swallowing liquids, although the most singular symptom of the disease, and the origin of its name, constitutes but a small part of this distressing malady. It is only one among many other effects of the poison upon the nervous system at large. The state of disease into which the nervous system is thrown, is evinced by the extreme irritability of the whole frame, mind and body, and the excessive susceptibility to all impressions; hence the constant watching and inquietude; and the sudden fits of anger and impatience, arising from the most trifling causes, as the patient himself readily allows, and even wonders at, and apologizes for, in the succeeding moments of composure. Hence also the distress, and even the recurrence of his spasms, occasioned often by the slightest motion of the air, as from opening the door, from the approach of any person, or even of a person's hand, in front of him; from hearing water poured from one vessel to another; or even by the buzzing of a fly. This morbid excitability of the nervous system, is farther manifested in the extreme timidity and suspicion of

HYDROPHOBIA.

the patient, in the imaginary objects of terror and uneasiness which the senses frequently represent to him, and in the occasional delirium and incoherence of ideas, from which, however, he easily collects himself. The circumstances may be illustrated by referring to almost every case on record. Dr. Bardsley, speaking of the patient before mentioned, says, "He was now alarmed to a degree of distraction at being left alone; he examined every object with a timid and suspicious eye; and, upon the least noise of a footstep in the gallery, he begged, in the most piteous accents, to be protected from harm."—"I observed he frequently fixed his eyes, with horror and affright, on some ideal object; and then, with a sudden and violent motion, buried his head underneath the bed-clothes. The last time I saw him repeat this action, I was induced to inquire into the cause of his terror. He eagerly asked if I had not heard howlings and scratchings? On being answered in the negative, he suddenly threw himself upon his knees, extending his arms in a defensive posture, and forcibly throwing back his body and head. The muscles of the face were agitated by various spasmodic contortions;—his eye-balls glared, and seemed ready to start from their sockets; and at that moment, when crying out in an agonizing tone—"Do you not see that black dog?"—his countenance and attitude exhibited the most dreadful picture of complicated horror, distress, and rage, that words can describe, or imagination paint."—"His mental faculties at this period (a short time before death) suffered very little derangement; for although, when not attending to external objects, he would utter some incoherent sentences; yet, the moment he was spoken to, he was perfectly collected, and returned rational answers." (Bardsley, loc. cit.) Dr. Marcet observes, in regard to his patient, on the fifth day of the disease—"He appeared still coherent and distinct in his ideas; but some of his conceptions were considerably disturbed. His sight was not materially impaired, for he could tell what hour it was by looking at the clock: but he often fancied he beheld objects which were not before him. He thought, for instance, that he saw various insects and reptiles crawl about him. 'My sight is queer,' said he, 'I think I see strange animals,' &c. Once or twice he exclaimed with an accent of terror, 'Who is pouring cold water down my head?'—yet no one was near him. He was conscious of his extreme irritability, and often prayed to be kept tranquil. This unfortunate man, in the height of his distress, still apologized for his acts of violence, and declared that he could not conceive what occasioned this extraordinary agitation." *Medico-chirurgical Transac.* vol. i. p. 147.

These statements may convey to the reader some notion of the miserable condition of the sufferer, afflicted by this malady, and of its peculiar and characteristic symptoms; the impression of which cannot be easily effaced from the recollection of those who have witnessed them. There are some other circumstances belonging to the disease, of less note, which remain to be mentioned. One of these is a constant collection of a thick, ropy, and tenacious saliva in the fauces, which is often productive of extreme distress; for as the miserable sufferer is unable to make the smallest attempt to swallow it, without exciting the convulsive choking, he spits it out incessantly, and with great vehemence and difficulty, often cautioning the bystanders to keep out of the way. "Oh! do something for me;" exclaimed Dr. Marcet's patient, "I would suffer myself to be cut to pieces! I cannot raise the phlegm; it sticks to me like bird-lime." Dr. Wavell's patient, at times, drew the viscid phlegm from his mouth with his fingers, and with inconceivable rapidity and eagerness, threw it against the wall. The

pulse in the beginning is not quick, nor is the skin hot; and there is none of the muscular debility so remarkable in fever: but as the disease proceeds, there is some feverish heat, and the pulse becomes quick, varying, however, exceedingly as slight causes of irritation influence the patient: as death approaches, it usually becomes very quick and tremulous. Sickness and vomiting often occur, when a little phlegm, tinged with brown or yellow bile, is brought up. There is often a sense of great oppression and stricture about the breast, or what has been called anxiety about the præcordia, and which is probably an affection of the heart; for it is accompanied with sighing and deep irregular inspirations, and the patients find some relief from motion, as running and walking, which shew the lungs not to be the seat of the oppression. The countenance is generally forrowful, and often expressive of a great degree of horror and distress.

There is a considerable variety in the symptoms in different constitutions: even the hydrophobia, or dread of swallowing liquids, occurs in very different degrees. But there is no part of the disease that admits of greater variation than the degree of mental derangement, which in some does not amount to more than extreme irritability and impatience; in others to muttering and incoherent talking, yet giving rational answers when questions are asked; and in a few it rises into short fits of the most violent rage and fury, in which the patients bite and tear themselves and every thing near them. In general they manifest no disposition to mischief; yet popular prejudice is still on the watch for the "barking and biting like a dog," as the disease advances. In the case related by Dr. Marcet, the bystanders confidently expected the symptom of *barking*, which they "thought at last to have clearly discovered in the peculiar noise which he made in breathing." Dr. Wavell, speaking of this sort of respiration, says, "the noise he made in drawing air into his lungs was undoubtedly peculiar; but neither in my opinion, nor in that of any other medical gentlemen who attended him, did it bear the least resemblance to the barking of a dog." (*Med. Records and Researches*, p. 151.) Were this notion of the canine metamorphosis, which the disease has been supposed to effect in man, merely speculative, it would be less important to confute it; but it is to be lamented, that the practical result of it, in the cruel and murderous plan of suffocating the patient, has been followed, both in France and in this country, within the last twenty years of the eighteenth century. See Hamilton on Hydrophobia, vol. ii. p. 140, and App. p. xxviii.

The duration of life, after the commencement of the symptoms of hydrophobia, has been on an average about *four days*; it varies from thirty-six hours to five, or even, though rarely, six days. The termination of life is likewise various in different instances: death is often very sudden, being produced by one of the convulsive attacks, such as occur on the attempts to drink; at other times, more general convulsions carry off the patient; while in other instances, again, the strength sinks suddenly, the patient becomes quiet and calm, and dies with a placid countenance, and without a struggle.

Dissections.—With the hope of acquiring some knowledge of the nature of this disease, and of the organs in which it is principally seated, physicians have ardently pursued the investigation of the changes of structure connected with it, by careful and almost innumerable dissections of those who have died of it. But it is to be lamented that no light whatever has been thrown upon the subject by these ample examinations. For, although in general some morbid changes in the structure of different parts has been discovered, yet these have been found in various organs, in different cases; those

HYDROPHOBIA.

organs, which appeared to be the principal seat of disease in one instance, being found altogether found in another, and *vice versa*; and the morbid changes observed in general, are by no means adequate to account for the phenomena of the disease.

The most frequent appearances which have presented themselves on dissection, have been marks of slight inflammation in the inner coat of the stomach, near the *cardia* or upper orifice, consisting of red spots or blotches, or merely of an increased number of red vessels, with small streaks of red blood; in many cases a similar inflammatory appearance has been found in the *pharynx*, or upper part of the gullet, sometimes extending along the whole of that passage to the stomach. This state of the throat, *oesophagus*, and stomach, seems to afford an explanation, in some measure, of the pain and difficulty of deglutition, especially of liquids, which require a more active contraction of the passage: but the excessive dread at the attempt, and the convulsions excited by it, can only be ascribed to that peculiar state of irritability of the nervous system, which characterizes the disease. On the other hand, however, cases of hydrophobia have occurred, in which no inflammation in those parts have been found. (See Dr. Babington's in Med. Records, &c. p. 124.) In some cases, a glairy fluid has been found in the stomach in considerable quantities; in others a dark bilious matter has been said to line its cavity. Hamilton, vol. i. p. 232.

Many dissections of persons who had died in a state of rabies are recorded, in which appearances of inflammation and great congestion of the blood-vessels were discovered in other viscera, especially in the brain and its surrounding membranes, and in the lungs. Sometimes not only an increased vascularity of the *pia mater*, the choroid *plexus*, and the brain itself has been found, but also slight watery effusions on the surface of the brain. A state of congestion in the lungs, resembling that which is discovered after a fatal peripneumony, has occurred in many instances to a considerable extent; and the vessels of the diaphragm have also been observed to be unusually turgid. (See Dr. Babington's cases in Med. Communic. and Med. Records, &c.—Mead on Poisons.—Ferriar's Med. Hist. and Reflections, vol. iii.) Dr. Ferriar, indeed, is disposed to attribute much of the disease to this pulmonary derangement. "If future dissections should prove," he says, "that congestion in the lungs generally appears in those who die of rabies, I confess that I should be disposed to consider this disease as dependent on the obstruction of the circulation in that important organ. Accumulation of blood in the head, and compression of the brain, must be the consequence of such an obstruction, rapidly formed. The quick panting respiration, anxiety, and sudden debility, may be referred to the same cause. In fact, we find a similar degree of tremor attendant on the croup, which consists in inflammation of the trachea, and destroys by suffocation. That degree of inflammation in the stomach and *oesophagus*, which produces the difficulty of swallowing liquids, may not only arise from sympathy, but the symptom itself may occur in consequence of the state of the lungs alone." (Loc. cit. p. 34.) But in forming these conjectures, this intelligent physician has overlooked the circumstance, that, however rapidly such congestion may take place, in common peripneumony, no approximation of any of the symptoms to those of hydrophobia is ever seen to occur; and the peculiar affection of the nervous system is surely inexplicable upon any such mechanical grounds.

Some writers have described various derangements of the liver and other abdominal viscera, which dissection has discovered, especially appearances of congestion or slight inflammation: Mead, Hillary, and others, have mentioned a

peculiar dryness of the pericardium, &c. But these changes appear to be accidental, and are more frequently not to be found. So that, on the whole, it would appear, that the nature of the malady is not manifested by any peculiar disorder of structure in any organ of the body, and therefore is beyond the reach of anatomical investigation.

Diagnosis.—From the peculiar nature of the symptoms above detailed, it might be conceived that no difficulty could occur, in distinguishing *rabies canina* from every other disease to which the human body is liable. But this is very far from being the case, as the records of medicine evince. For many histories are related, in which, although the disease was the consequence of a bite, it partook more of the nature of some other malady; and others are detailed, in which no bite had preceded the disease, or had occurred at so distant a period as to render its influence in exciting the disease extremely questionable: not to mention the number of mistakes which have been committed, in consequence of the symptom (*hydrophobia*, or *dread of water*,) being supposed to be the essence, or pathognomonic symptom of the disease.

In many circumstances the *tetanus* bears a considerable resemblance to *rabies*, and has, doubtless, been mistaken for it. (See TETANUS.) This most violent and fatal disease is most frequently occasioned by slight wounds, especially about the hands or other tendinous parts; it seldom appears till after some little time has elapsed, and the wound has healed; it is marked by paroxysms of violent general spasms, beginning in the neck and throat, and accompanied by difficulty of swallowing, or total loss of that power; these spasms are excited by the slightest causes, "for almost every attempt at motion, as attempting a change of posture, *endeavouring to swallow*, and even to speak, sometimes gives occasion to a renewal of the spasms over the whole body." (See Cullen, First Lines, vol. iii. chap. on *Tetanus*); and the disease generally proves fatal by one of these convulsions about the fourth day. In all these circumstances there is much similarity with those of rabies, inasmuch that some practitioners have denied the existence of rabies, as the result of the poison of a rabid animal; and contended that the disease is, in all cases, a tetanus, excited only by the wound which the teeth inflict. Instances certainly occur, in which, from a view of the symptoms, it might be difficult to decide, whether the disease were tetanus or hydrophobia. Dr. Bardley describes the case of a young gentleman, who, after having had his finger slightly wounded by a splinter of wood, was affected in about a week with spasms about the lips, locked jaw, and paroxysms of general spasm. On the third day after the attack he could not swallow any watery fluids. "Whenever they approached his mouth, the convulsive spasms of the face returned, and his head was forcibly drawn backwards." (Mem. of the Manchester Soc. vol. iv. p. 477.) The person who communicated this case, had formerly seen the same symptoms produced by the bite of a horse. Both these patients recovered. Similar examples of the occurrence of hydrophobic symptoms, arising in cases of local injury, are mentioned by Hildanus, Cælius Aurelianus, and others.

It must be observed, however, that the *tetanic* spasms generally commence within a few days after the injury, or in a much shorter period than those of rabies; that the jaw is commonly rigidly locked in tetanus, and the muscles of the neck and back most particularly affected; that the spasms are of a more fixed or "*tonic*" species, (in the language of Cullen) consisting of rigid and long-continued contraction, rather than of short convulsive action, and are relieved rather by remission of their violence, than by a com-

HYDROPHOBIA.

plete solution of the spasm; that there is less feverishness, quickness of pulse, and thirst in tetanus; and above all, that there is little of that extreme mobility of feeling, and anxious, impatient, and apprehensive state of mind, which marks the hydrophobic condition.

There is another disease, *hysteria*, which, in some of the many forms which it assumes, occasionally puts on a hydrophobic appearance. The leading symptoms of this disease are often of a violently spasmodic nature; and one of them, which has been considered as pathognomonic, the *globus hystericus*, consists in a spasmodic affection of the gullet, and is often connected with difficulty of swallowing. But the concurrence of symptoms in hysteria, generally differs altogether from those of rabies, and could lead to no mistake, had not the error of regarding the *dread of water* as the essence of that disease been adopted. In consequence of this error, and the improper application of the term *hydrophobia*, as the name of the disease, extreme confusion has occurred in the history of canine madness.

Thus while some physicians, misled by this name, have described cases of *spontaneous hydrophobia*, *i. e.* hydrophobia arising without any obvious exciting cause; others have referred the origin of the disease to various causes, altogether different from each other. Dr. Rush, for instance, enumerates *twelve* causes of hydrophobia, besides the bite of a rabid animal; among these are cold night air, worms, eating beech nuts, great thirst, fear, hydrocephalus, and typhus fever. (See *Med. Inq. and Obs.* vol. v. p. 213.) The truth is, that the symptom *hydrophobia* is so far from being peculiar to canine madness, that it occurs in a number of other diseases; and, on the other hand, it is in some cases said to be actually *absent* from the true rabies. A fatal case of canine madness is related by Hildanus, (p. 365. observ. 88.), in which there was no hydrophobia. And three cases of the same nature are mentioned by Dr. Mead. (On Poisons, p. 147.) But the number of disorders in which a difficulty of swallowing, and a concomitant hydrophobia occurred, is very great. Mead, Morgagni, Plater, and others notice it as accompanying hysteria. "I have known it," says the first named physician, "in the height of a violent hysterical disorder, to have continued for many hours, till the convulsive motions in the throat were quieted by proper medicines; and I remember a case, in which fits of a palpitation of the heart were attended with so great a degree of it, that it seemed not to differ from the true hydrophobia." (Loc. cit.) Boerhaave used to mention an instance of it accompanying a fever occasioned by heat and fatigue, joined to the abuse of spirituous liquors. It has been observed connected with various inflammatory and spasmodic affections of the throat, gullet, and stomach. Thus Sauvages quotes one case, where it supervened to typhus; and another, where it accompanied the variolous sore throat. (See *Nosol. Method.*) But the most remarkable cases of this nature are to be found in the *Edin. Medical Essays*, (vol. i. p. 222 and 227,) in which hydrophobia was produced by unusual irritation in the stomach, without the most distant suspicion of rabid poison. In one of these cases there was violent inflammation of the stomach, the patient frequently spouted saliva from his mouth, and had all the horror at the sight of water, which occurs in cases of true rabies, where the difficulty of drinking has been experienced. Both these persons recovered (See *GASTRITIS*.) The symptom hydrophobia, or *dread of water*, has also accompanied pleurisy and peripneumony (see Ferriar's *Med. Hist. and Res.* vol. iii. p. 24—26.); and the writer of this article once saw it connected with St. Vitus's Dance.

But farther, this symptom, the dread of liquids, un-

connected with rabies, does not always arise from local irritation; it has been brought on by violent affections of the mind, in irritable and delicate habits, and terminated fatally. (See two cases from Plater and Sauvages, quoted by Dr. Bardley, in *Manchester Transf.* vol. iv. p. 470.) Dr. Percival has remarked, that it has sometimes been brought on by the imagination alone; and Dr. Ferriar, in illustration of this remark, says, "I met with an instance of this kind lately, in which it was very difficult to prevent a person from rendering himself completely hydrophobic. Himself and his wife had been bitten by a dog which they supposed to be mad. The woman thought herself well, but the man, a meagre hypochondriacal subject, fancied that he had uneasiness in his throat, and that he could hardly swallow any thing. When he first applied to me, a medical friend who was present, asked him whether he had any sensation of heat at the pit of the stomach. He answered in the negative, doubtfully; but, next day I found him in bed, complaining of *heat in the pit of the stomach*, difficulty of swallowing, tremors, and confusion in the head. He continued to persuade himself he was ill of rabies, and confined himself to bed, expecting death for near a fortnight. At last I remarked to him, that persons who were attacked by rabies never survived more than six days; this drew him out of bed, and he began to walk about. By a little indulgence of his fears, this might have been converted into a very clear case of *spontaneous hydrophobia*, and the patient would probably have died."

The use of the appellation hydrophobia, then, deduced from a single symptom, which belongs to a variety of diseases, evidently tends only to mislead, as the respectable physician just quoted remarks, by diverting the attention of practitioners to supposed analogies, which have no other foundation than the abuse of a word. To be correct, *we must preserve the distinction* between rabies, and diseases which are essentially different from it in their usual appearance, and which only acquire an adventitious resemblance to it under uncommon circumstances. We may, therefore, reasonably question the existence of such a disease as *spontaneous hydrophobia*. "If those cases be analyzed," Dr. Ferriar remarks, "they will be found to belong to the class of hysterical, febrile, mental, or spasmodic disorders, and by ranking them under their proper titles, we shall at once clear this subject from a great and accumulating mass of error. By considering the matter in this point of view, we are also enabled to explain the contradictory reports hitherto so perplexing, on the effects of remedies in rabies. It is easy to perceive, that evacuant and antispasmodic remedies would remove a difficulty in swallowing, occasioned by inflammation or spasm in the stomach or œsophagus; that bark and wine would cure it in cases of typhus and low mania; and that opium and the cold bath would be successful, when it is accompanied by tetanus." Vol. iii. p. 30. See also Hunter, in *Transf. of a Society*, &c. p. 203. Mease on Hydrophobia, p. 6—11.

Prevention and Cure.—As no remedy has been discovered which has any effect in the removal of this extraordinary disease, when its symptoms have commenced, the means of prevention have ever been deemed objects of the first importance. For this purpose numerous prophylactics have been proposed from early times, and many are in general use, which are supposed to counteract or expel the poison, by their effects upon the constitution. Notwithstanding, however, the testimony of discerning physicians, expressed in terms of the greatest confidence, in favour of particular preventive medicines; upon fairly weighing the proofs of their efficacy, not one appears entitled to the smallest credit.

HYDROPHOBIA.

It will be almost sufficient to enumerate the remedies which have been suggested for this purpose, without any comment. The absurd jumbles of *theriaca*, whether old or new, Mead admits to be unworthy of notice; and from this censure we cannot except the ashes of river craw-fish, burnt alive upon copper, which Galen and Dioscorides aver to be invariably successful;—the roasted liver of the mad dog;—the sponge or excrescence of the dog-rose;—the famous aromatic opiate of Scribonius Largus;—the powder of tin with mithridate, so extolled by Mayerne, Grew, &c.;—nor even the *lichen cinereus*, (ash-coloured liver-wort,) or the *pulvis antilyssus* (composed of this lichen and pepper), which Mead himself introduced into the pharmacopœia of the London college, and which he affirms he had never known to fail of success, though he had used it a thousand times. (See Mead on Poisons, p. 158. et seq.—Boerhaave, Aphorism 11.7, with Van Swieten's commentary.) So confident, indeed, was that learned physician in the powers of this drug, that he affirms, "I have often wished, that I knew so certain a remedy in any other disease!" Another preventive, which was introduced from China by sir George Cobb, and has been called the *Tonquin* medicine, has been equally extolled as an infallible prophylactic: this consists of large doses of *musk* and native *cinnabar*. The Chinese give it in the dose of sixteen grains of musk, conjoined with a scruple of native, and the same quantity of facitious cinnabar, which, if it fail to procure sleep and sweating, is repeated in three hours. (See Hillary on the Dis. of Barbadoes, p. 266.) But this medicine, like the preceding, has been found to fail altogether. There is another pretended specific, which claims our attention chiefly because it stood high in reputation for many years, and is even now scarcely laid aside: this is the famous *Ormskirk* medicine, prepared by Mr Hill of that town. It has been too clearly proved, however, that this medicine is incapable of preventing the accession of rabies in persons bitten by rabid dogs. Dr. Fothergill was among the first to represent, from a very clear case, (that of Mr. Bellamy, Med. Obs. and Inquiries, vol. v. art. 19.) that its virtues were not equal to its reputation: and other cases have subsequently occurred, in which the disease ensued and terminated fatally, notwithstanding the fullest use of the medicine. (See Dr. Babington's case in the Med. Records and Researches, Hamilton, vol. i. p. 165, &c.) Indeed, if the analysis of Dr. Heysham, which was repeated by Dr. Black, be correct, it would seem pretty evident *à priori*, that this celebrated Ormskirk nostrum could not possess any active properties; its principal ingredient being *chalk*! From the analysis of this eminent professor and his pupil, the whole composition is as follows; namely, half an ounce of powdered chalk, ten grains of alum, three drams of Armenian bole, one dram of the powder of elecampane root, and six drops of the oil of anise. (See Heysham. Diss. Inaug. De Rabie Caninâ, Edin. 1777.) After the failure of so many medicines, which have been reputed infallible, and after such men as Dr. Mead could be deceived into the belief of such infallibility, the writer of the article Dog, in this work, must expect that another "specific" will be received by most readers with a great degree of scepticism, notwithstanding the number of experiments which he alleges in its support. This remedy consists of a decoction of the fresh leaves of rue and of the tree-box, of each two ounces, and of sage half an ounce. He avers that this medicine was given to ninety animals, of which only one went mad; and that about forty human persons have taken it, of whom none suffered the disease. But we are disposed to fear that this will be found liable to the same censure which is applicable to all the rest.—"No one of them," to borrow the words of Dr. Rush,

"has, I believe, done any more good, than the boasted specifics which have been used to eradicate the gout or to cure old age."

But how, it will be asked, have these medicines obtained the credit which they have for a long time possessed? Probably, from some of the following circumstances attending the bite. 1. The animal may have been enraged, but not diseased. 2. He may have been diseased, but not rabid. There is no doubt that *the distemper*, and other febrile disorders of dogs, have been mistaken for rabies. (See a paper of Dr. Jenner's on this subject, Medico-Chirurg. Transf. vol. i. p. 236.) 3. The saliva, when infectious, may have been so wiped off the teeth in passing through the clothes of the person bitten, as not to have entered the wound. This is rendered extremely probable by the circumstance that bites in the face have been most frequently followed by hydrophobia. But 4th, and above all, it is now a well ascertained fact, that of those who have been bitten by dogs, actually rabid, a very small number have been afterwards seized with hydrophobia, whatever treatment was adopted, or even when nothing whatever was done with a preventive view. It may be added, however, that, as mental impressions occasionally both excite and cure hydrophobic symptoms, and especially the supposed incipient symptoms, so any of these nostrums, in which the patient placed confidence, would remove these imaginary threatenings of the disease. See Dr. Percival's Letter to Dr. Haygarth, in the London Med. Journal for 1789, vol. x. p. 300.

We are induced to notice another prophylactic, chiefly from the antiquity of its origin, and the general credit which it obtained even to recent times: this is the employment of cold-bathing. Celsus first mentions this remedy, but recommends it principally as a cure; and apparently upon theoretical principles, though he calls it *unicum remedium*. (De Med. lib. v. cap. 27.) For, as the patient both desires liquids and fears to drink, he advises that he be thrown unawares into a fish-pond; and, if he cannot swim, that he be ducked several times and taken up again, and, if he can swim, that he be forcibly immersed, and compelled to swallow water, "so that his thirst and dread of water may be cured together." From this absurd notion, apparently, the practice of half-drowning persons bitten by rabid animals, in modern times, has arisen: but ample experience has demonstrated that the practice is not less frivolous than the theory upon which it was built; and among those who have undergone the operation of immersion, whether by mere dipping, or to the extent of "drowning and recovering by turns," as Mead calls the ancient practice, an equal proportion have been subsequently attacked with rabies, as among those who have not been submitted to this mode of treatment.

Notwithstanding the inefficacy of all the alleged antidotes to the poison of a rabid animal, there still remains a method by which it is probable that the occurrence of hydrophobia may be effectually prevented: this consists in the local treatment of the wound occasioned by the bite. As the subsequent malady originates from the operation of the poison, introduced with the saliva of the rabid animal, any expedient by which the poison could be destroyed or removed, previous to its operation on the constitution, would of course secure the individual from its effects. Upon this principle, the ancients recommended the enlargement of the wound by incision, the application of a cupping-glass, and of the actual cautery, and the maintenance of a discharge for many days, (see Celsus, lib. v. cap. 27. Galen. de Ther. lib. i. cap. 16.) a practice which has been followed by more modern practitioners. Hildanus Obs. Cent. i. Obs. 87. Mead, loc. cit. p. 156.

HYDROPHOBIA.

In order to fulfil this indication by the local treatment of the wound, the following points appear to deserve attention ; 1st. The removal of the poison by washing the parts simply ; 2dly. The destruction of the part by *caustic* ; and, 3dly. The excision of it by the knife. The first measure, or ablation of the wound, has been strongly recommended by Drs. Haygarth and Percival, to be commenced immediately after it may have been inflicted. The practice is safe, and may possibly be beneficial, when thus early resorted to ; it may also be advisable, where the wound has been inflicted in the face, near the eye, or near some large blood-vessel ; or where the patient resists all sollicitation to submit to the knife ; or where there may be so little probability of the madness of the dog, as to render it unjustifiable to subject the patient to present pain, and future deformity. (Percival, in Lond. Med. Journal, vol. x. p. 308.) This washing, however, must be conducted with the most persevering attention, in bad cases, for several hours, first by an abundant effusion of cold water, and afterwards of warm water ; “ a continued stream of it, poured from the spout of a tea-kettle, held up at a considerable distance, is peculiarly well adapted to this purpose. If the canine poison infused into a wound were of a peculiar colour, as black like ink, we should all be aware that plenty of water and patient diligence would effectually wash out the dark dye ; but this could not be expected by a slight and superficial ablation.” (Haygarth, *ibid.* p. 297.) Whence Dr. Haygarth advises the plan of colouring the wound with saliva tinged with ink, after it has been carefully washed ; and, after a few hours, to wash out the stain ; by which we obtain a sort of ocular proof of the complete ablation. Dr. J. Hunter remarks, that as there may be cases in which insurmountable objections to more effectual steps may render this method worthy of trial, it would probably be more successful, if, after washing copiously with cold water, the caustic alkali was to be added to the water, in such proportion as the part could easily bear, and the washing to be continued with this for some time. *Transf. of a Society, &c.* before quoted.

The same author observes, that *caustics* may be admissible in some cases, when the knife cannot be used ; and though they have failed in certain instances, yet that was probably owing to their not having been applied to all the infected surfaces : and he suggests the propriety of employing for this purpose the caustic vegetable alkali in a solid form, because it acts more speedily, and also more completely destroys and dissolves all animal substances. It appears that this caustic substance has actually been employed for many years by Mr. Simmons, and the other surgeons at the Manchester infirmary, with uniform success ; in upwards of forty cases, in which Mr. Simmons applied the *kali purum*, or caustic potash, to the bitten parts, no hydrophobia ensued. *Ferriar's Med. Hist. &c.* vol. iii. *append.* p. 221.

The only certain means, however, hitherto employed as a preventive of the disease in question, are to be found in the excision of the parts wounded ; and, therefore, whenever the parts can be cut out, it ought always to be done. This operation must be performed with a bold hand, and the utmost care must be used to effect the removal of every part with which the dogs teeth may have come in contact ; for the smallest portion left might produce the disease. It becomes, therefore, necessary for the operator to examine accurately every portion of the wound, and to ascertain to what depth, and in what direction, the teeth may have penetrated, keeping in his mind the situation of the parts in the act of biting, in which the skin and flesh are pinched up, and therefore put out of their natural position, before the teeth penetrate them. He should again cautiously examine the wound, after the

excision has been made, in order to ascertain that every part lacerated by the teeth has been removed,

An important question here arises, in regard to the period after the bite, at which the operation of excision may be performed with security to the patient. This can only be solved after a long and cautious experience, which, on this subject is rendered uncertain and difficult to be obtained, by the numerous failures of the poison to excite the disease, independently of any preventive measures. And, in a theoretical point of view, it may seem to involve another question, which has been much discussed ; namely, whether the poison produces its deleterious effects on the constitution, in consequence of being taken up by the absorbents, and carried into the circulation ; or whether it acts merely upon the extremity of the nerves of the part, and through the medium of them influences the rest of the nervous system. Such a question, however, is perhaps beyond our decision, and is not necessarily connected with the practical one previously stated. We may just mention, that, in the case related by Dr. Marcet (*Medico-Chirurg. Transf.*), in one of those described by Dr. Babington, and in another, detailed in the *Medical Communications*, vol. ii. the pain, originating in the bitten part, at the commencement of the hydrophobia, seemed to follow the course of the nerves, rather than that of the absorbents, and was not connected with any affection of the axillary glands, in the two former cases, in which the bite was in the hand, nor of the inguinal glands in the latter, where the bite was in the leg. Mead imagined that, as the poison “ immediately affects the nervous liquor, the mischief must have taken place before any applications of this kind can be made.” But while, on the one hand, we have instances on record, in which the excision was performed with success many hours, and even four or five days, after the bite ; so we observe, on the other, that the poison appears to lie long dormant in the part, and only to affect the system, after the new inflammation or pain occurs, which gradually extends to the centre. Whence the most rational conclusion appears to be that, which Drs. Cullen, Babington, John Hunter, Marcet, and others have adopted, that the poisoned part might be removed not only many days, but many weeks after the bite, or, in short, *at any time antecedent to the appearance of the symptoms* just mentioned, which indicate the passage of the poison into the system and the consequent impending rabies. Analogy, Dr. Babington remarks, as well as observation, seems to lead to this inference. “ For it is universally understood, that, in other diseases communicable by inoculation, that is to say, by the local application of the infection or poison producing them, there is a specific period, prior to which the disorder may be at any time prevented, by the removal of that part where the matter was at first introduced.” (*Med. Records and Researches*, p. 127.) See also *Mémoires de la Soc. Roy. de Médecine de Paris*, where there are many instances of local treatment being effectual in preventing the disorder in question, at the expiration of many days.

An account of the *treatment of hydrophobia*, when the disease has already appeared, will not occupy much of our attention ; as it must be a mere enumeration of fruitless expedients, and of medicines altogether destitute even of palliative influence. Nevertheless, it is well that we should be acquainted with the unsuccessful indications, which different practitioners have heretofore pursued, and with the active agents, which they have diligently, but in vain, employed ; in order that we may not be occupied in useless repetitions in future. The want of preconceived method, indeed, in investigating the cure of this disease, is very apparent in most of the writers on the subject, and is probably one of the principal

principal causes of the little progress that has been made in that important inquiry.

Among the various articles of the *Materia Medica*, that have been administered to persons affected with hydrophobia, *opium* would seem, from analogy, to be peculiarly adapted to relieve the symptoms; especially the extreme irritability of mind and body, the complete loss of sleep, and the convulsions. Accordingly it has been administered in various forms, in some cases, to an extent that is scarcely conceivable *à priori*, and yet without having been found to do any evident good. In a case related by Dr. Vaughan, fifty-seven grains of solid opium were taken in the course of fourteen hours, in addition to half an ounce of liquid laudanum, which was injected in an enema: in another instance, attended by Dr. Wavell, four grains of opium were swallowed every hour, until fifty-four grains had been taken, besides ten grains in an enema: and in a third, under the direction of Dr. Babington, the enormous doses of twenty-five grains, and *half a drachm of solid opium*, were repeated at short periods, so that in *eleven hours* no less than *a hundred and eighty grains of opium were taken without any benefit, and even without producing any sleep.* (See *Med. Records and Researches*.—Vaughan on Hydrophobia, Mead on the same, &c.) After such evidence of its inefficacy, we may almost affirm, with Dr. J. Hunter, “that it can be only imputed to the want of method and order above-mentioned, that this medicine still continues to be given in almost every case of this disease.”

Blood-letting has been a favourite expedient from the earliest records of the malady, and has been frequently employed to a very great degree. Boerhaave considered the disease as highly inflammatory, and Mead suggested the use of early and copious bleeding, till fainting was produced; Fothergill, and others of a later time, employed it freely; and Dr. Ferriar, deeming an inflammatory congestion in the lungs an essential part of the disease, as well as a similar condition in the contents of the cranium, says that “blood should be drawn from the jugular veins, and perhaps the head and lungs would be best relieved by the repetition of bleedings.” Dr. Nugent’s case is quoted as an example of the efficacy of blood-letting in the disease; but that case is a questionable example of rabies; and both from the series of preceding symptoms of declining health and spirits, and from the course of the disorder itself, appears to be rather referable to hysteria than to rabies. In one of the cases, described by Dr. Babington, blood-letting was practised without the smallest benefit; and in the other it appeared to do harm.

Cold bathing, or the *affusion of cold water* over the body of the patient, has been frequently employed as a curative, as well as a preventive measure. Celsus recommended it only when the hydrophobia had appeared; and Van Helmont affirms, that he cured an old man by submersion in salt water, (*Ortus Medicinæ*.) But in the hands of Boerhaave, Mead, Vaughan, and many others, this expedient has been as inert as any of the preceding. (See Mead, *loc. cit.* p. 173. 182. Hamilton, vol. ii. p. 14.) In tetanus the cold affusion has of late been found beneficial; and it is probable that the spasmodic affections, cured in this manner, were of a tetanic nature, and not rabies.

The *warm bath* has proved equally inert; and the free administration of *mercury*, both internally and by friction, has evinced no greater powers. The use of *oil*, which was recommended by Celsus and Cælius Aurelianus, and suggested more strongly from its beneficial effects in cases of poisonous bites inflicted by insects and reptiles, was revived a few years ago by Dr. Shadwell, of Brentwood (see *Memoirs of the Med. Soc. of London*, vol. ii.); and it has been employed in the way of a bath, by friction, and also

taken internally; but it has proved altogether inert, and some patients, immersed in an oil bath, have appeared to have their sufferings increased. (See Hamilton, vol. ii. p. 54. 56.) In one case, indeed, the patient is said to have recovered: but the course of the symptoms, and the duration of the disease, did not strictly accord with the ordinary appearance and brevity of hydrophobia. The employment of various antispasmodics, as *camphor*, *assafatida*, *castor*, &c.; of the metallic tonics, as the oxyd or flowers of *zinc*, the *cuprum ammoniatum*, &c. (largely administered in Dr. Vaughan’s cases); and of *sudorifics* and *diuretics*, (see Mead,) of *vinegar*, of *cantharides*, of *blisters*, and *rufefacients*, has been attended with the same failure as that of the medicines already detailed.

Such being the inadequacy, then, of all the expedients hitherto adopted for the cure of rabies, and such the difficulty of acquiring any accurate notion of the nature and seat of the disease, even by the most accurate anatomical investigation, we acknowledge ourselves altogether unable to suggest any system of treatment, which might be particularly worthy of trial, in future cases of the disease. Dr. John Hunter proposes a trial of *arsenic*, which is the principal ingredient in a pill, used in the East Indies, and said to be a specific against the poison of serpents, and also against the bite of a mad dog. He also suggests the probability of diminishing the effects of the poison, (which is apparently confined to the part bitten, until the symptoms actually begin,) by making numerous and deep scarifications where the wound was, and applying cupping glasses repeatedly; by using ligatures; or by applying ice or a freezing mixture to the part, so as to benumb it, and to arrest for a time all motion, and of course that of the absorbent vessels. Dr. Rush believes, that “the disease produced in the human species by the bite of a rabid animal is a *malignant fever*;” and that the great debility, which ensues in its course, is the result of inflammatory action, and to be removed only by early and copious blood-letting, according to circumstances of the case, the strength and age of the patient, the state of the pulse, &c.; and Dr. Ferriar has, like Dr. Rush, experienced a similar change in his opinions, both having originally considered the debility as primary, and not as the result of increased excitement; and both have decided to treat future cases of the disease upon that principle, by depletion, and evacuations.

HYDROPHORIA, formed of *ὕδωρ*, *water*, and *φορῶν*, *I bear*, in *Antiquity*, a feast, or funeral ceremony, held among the Athenians, and people of Ægina, in memory of those who perished in the deluge of Deucalion and Ogyges.

HYDROPTHALMIA, from *ὕδωρ*, *water*, and *ὀφθαλμῶν*, *the eye*, signifies in *Surgery*, a morbid enlargement of the eye, arising from a preternatural increase in the quantity of the aqueous and vitreous humours.

In certain cases, it is the aqueous humour which collects in this manner, and then the disease is principally situated in the anterior and posterior chambers of the eye. In other instances, the vitreous humour is chiefly concerned, not merely accumulating in a preternatural degree, but also in general losing its wonted consistence, and becoming thinner and more watery. In the commencement of the disorder, the patient experiences no complaints, excepting a sense of tension about the eyeball, a kind of stiffness when the organ is moved, and a diminution in the acuteness of vision. The globe of the eye by degrees acquires a state, in which its enlargement is quite manifest, its feel harder than natural, the pupil dilated, the motion of the iris feeble, the impairment of sight much more serious, and the painful sensation of tightness about the affected organ a great deal more distressing. At length, the eyeball attains such magnitude, that it projects out of the orbit, and the patient is afflicted with complete blindness.

HYDROPTHALMIA.

The pain now becomes excessively severe, extending all over one side of the head, and frequently affecting the teeth, so as to disturb the patient's rest day and night. As the eyelids can no longer be closed, the tears fall over the cheek, and the friction of the eyelashes against the eye make this latter part inflame and ulcerate. The case, when it has made such progress, often receives the name of buphthalmos, the eyeball being, indeed, in many instances, as large as a hen's egg.

When the disease is principally situated in the anterior and posterior chambers, the cornea, not only becomes distended forwards away from the iris, but undergoes a considerable enlargement in diameter, so that the anterior chamber is frequently of extraordinary size. When the vitreous humour has the chief share in the disorder, no increase in the dimensions of the cornea is observable, and the iris, instead of being at a greater distance than usual from this membrane, is often approximated to it.

We are then to understand by the term hydrophthalmia, a dropical enlargement of the eye, and not a swelling, or protrusion, of this organ from other causes, a case to which surgical writers assign the name of exophthalmia. See EXOPHTHALMIA.

No doubt, the causes of the dropfy of the eye are as numerous as those which give rise to the same disease in other parts of the body. But, even the most credulous writers are willing to own the difficulty of ascertaining such causes in a clear and satisfactory manner. If we can trust the assertions of Richter, all the known causes of hydrophthalmia have the immediate effect of interrupting the due absorption of the humours of the eye, and act in this manner, either by producing obstruction, weakness, or irritation. The celebrated oculist, Janin, fancied, that in the healthy state there was a continual excretion of the aqueous humour through the pores of the cornea, and that the dropfy of the eye was principally owing to a closure of these pores, and a consequent stoppage to the exudation of the above mentioned fluid. Scarpa, in criticising this opinion, maintains, with much reason, that its adherents evince their imperfect acquaintance with the activity of the absorbent system in the animal economy. Besides, as Richter has well observed, the cornea, in most cases of hydrophthalmia, retains its transparency, and is to all appearances free from disease; while, in the leucoma, where it is completely opaque, indurated, and thickened, and where, in all probability, its pores are entirely impervious, we find not the least tendency to hydrophthalmia.

The dropfy of the eye is very difficult of cure, and, indeed, frequently incurable. When the disorder has once made such progress, as to have entirely deprived the patient of sight, the case no longer admits of a complete recovery. Nothing can be more obvious, than the impossibility of rectifying the injury, which the interior parts of the eye must suffer from much distention; and hence, if a perfect cure can ever be effected, it is only when the surgeon has it in his power to hinder the excessive enlargement of the eyeball. The disease may even increase in such a degree as to prove fatal. (Louis, Mem. de l'Acad. de Chir. tom. 5. Terras, Journ. de Médecine, tom. 45.) In cases of this aggravated description, the bones of the orbit are in general carious. A radical cure of hydrophthalmia is reckoned a very difficult thing to accomplish, for, when the complaint has been removed it generally returns, and the relapses are not easily prevented. The cure is equally difficult, whether the disease be chiefly occasioned by the aqueous, or the vitreous humour.

In the treatment, it is an indication of the highest importance to trace, and remove the causes of the disease. This is the only way to effect a radical and lasting cure. In

proportion as the cause is removed, the preternatural accumulation of fluid in the eye spontaneously diminishes, and does not take place again. Authors inform us, that the same causes, which produce dropfy in other parts, may also produce it in the eye. However this may be, certain it is, that practitioners are seldom enabled to ascertain the cause of the complaint with precision, and they are, therefore, compelled to treat the case on empirical principles. We learn from Scarpa, that hydrophthalmia is sometimes preceded by blows on the eye, or adjoining temple; sometimes, by an obstinate internal ophthalmia; that, in certain instances, it is preceded by no inconvenience, except an uneasy sensation of tumefaction and distention in the orbit, a difficulty of moving the eye-ball, and an impairment of sight; and, lastly, that it is occasionally preceded by none of these causes, and no other manifest one whatsoever, especially when the complaint occurs in young children, from whom no information can be obtained.

The surgeon, who acts empirically, merely endeavours to procure a dispersion, or removal, of the preternatural accumulation of fluid, and though he afterwards generally employs tonics to obviate the weakness, which he supposes to have been produced in the eye by distention, and to be likely to bring on a return of the disease, yet, as he does nothing towards the removal of the original cause, he seldom succeeds in preventing a relapse.

The internal remedies, which have been administered with a view of dispersing the redundancy of fluid in the eye, consist of emetics, purgatives, diaphoretics, and diuretics, and the selection is regulated by the particular constitution of the patient. Sometimes one class of medicines have powerful effects, while the operation of another is quite inefficacious; and a short trial of the various kinds will soon inform the skilful surgeon which ought to be preferred. Nitre and squills, juniper berries in powder, or decoction, &c. are mentioned by authors as proper diuretics. The digitalis purpurea is alleged to have proved beneficial. With regard to purgatives, the kali tartarizatum is said to be the best in the generality of instances. In obstinate cases, emetics are frequently of considerable service, and, even when unaided by other means, often disperse the fluid collected in dropical diseases. They also not unfrequently promote the efficacy of diuretics and purgatives, and the latter remedies, after appearing to be ineffectual, are often rendered productive of the desired effect, by being preceded by emetics.

When none of the foregoing medicines answer the purpose, resolvents may occasionally be prescribed with advantage. Mercurial and antimonial preparations are particularly recommended. The proper plan is to give them alternately with doses of purgative and diuretic medicines. The patient may take a grain of calomel, ten grains of cicuta in powder, and a grain of sulphur auratum antimonii. When there is any reason for suspecting that the dropfy of the eye is owing to an irritation, acting on that organ, opium, castor, and saffron are recommended, in conjunction with evacuants. When debility is thought to have a share in bringing on the disease, bark, steel, and aromatic bitters, may be ordered together with diuretics.

Besides these internal remedies, several topical means have been tried, for the purpose of promoting the absorption, or dispersion of the redundant fluid in the eye. 1. Blisters applied either behind the ears, or over the eyebrows, and kept open a considerable time. 2. Issues and fetons in the arms, or nape of the neck. 3. Sternutatories. Richter mentions an instance of inveterate hydrophthalmia being cured in a few days, by the patient introducing every now and then into his nostrils a kind of snuff thus composed:

HYDROPTHALMIA.

hellebori albi gr. x. herb. majoran. ꝑiv. misce. 4. Electricity sometimes appears to have done good. 5. Bathing the eye with emollient collyria was recommended by Janin, under the idea, that this method would tend to open the pores of the cornea, so as to let the aqueous humour exude. 6. Spirituous and ammoniacal vapours to excite the action of the absorbents of the eye. 7. Applications, containing borax, muriate of ammonia, &c.

It is not to be dissembled, that, in the treatment of the present disease, all internal and external remedies are, for the most part, quite unavailing. Scarpa acknowledges, that he has never yet met with a single well-detailed history of a dropsy of the eye being cured by such internal medicines as are most recommended by the best surgical authors. With regard to externals, he has learnt from his own experience, that when the disorder is manifest, astrigent and corroborant collyria, as well as compression of the protuberant eye, are highly prejudicial. In this circumstance, a seton in the nape of the neck, bathing the eye in a lotion of mallows, and applying a plaster composed of this plant, have enabled him to calm, for a time, the tense and painful sensation generally experienced in the orbit, and about the temple and forehead. But Scarpa assures us, that as soon as the eyeball begins to project from the orbit, beyond the eyelids, there is no means of opposing the grievous dangers, likely to be induced by the disease, except an operation, which consists in letting out the superabundant humours of the eye by an incision, and afterwards causing the interior of the organ to inflame and suppurate, so that the eye may gradually shrink within the orbit, and heal. Were the operation deferred, the patient would be left to suffer frequent attacks of ophthalmia, and to run the risk of ulceration taking place in the eyeball and subjacent cheek: nay, what is worse, the disease is liable to degenerate into carcinoma.

The operation, which, until lately, has been generally advised for the relief of hydrophthalmia, is, what has been named, *paracentesis oculi*. When the aqueous humour is supposed to be too abundant, certain authors direct us to puncture the cornea, at a little distance from its edge with a lancet, or cataract-knife. When the vitreous humour is principally concerned in the disease, they tell us to proceed as in the extraction of the cataract, divide one-half of the cornea, open the crystalline capsule, and press out, together with the lens, a sufficient quantity of the vitreous humour to reduce the eyeball to its natural size. In doing this, considerable caution is necessary; for, too much of the vitreous humour is apt to be lost, especially when it is preternaturally liquid, and a permanent and irremediable collapse of the eye may even happen.

The apprehension of such an event introduced the plan of puncturing the eyeball with a very small trocar, at the distance of about two or three lines from the margin of the cornea, and thus discharge as much of the humours as necessary.

The redundant contents of the eye may, indeed, be evacuated by an operation; but there is greater difficulty in preventing a fresh accumulation of fluid, and the disease generally returns. The operation, when done only once, promises some chance of durable benefit, if the surgeon perform it in an early stage of the case. Benjamin Bell met with such success. Nuck also effected a radical cure by repeating the operation a certain number of times. We are not then to relinquish all hope, even though the disorder may recur. But, one thing seems now to be quite established, namely, the impossibility of accomplishing a perfect cure, and restoring the original integrity of the eye, when once

this organ has suffered such distention, that the function of vision is destroyed.

If the surgeon prefers letting out the redundant quantity of the humours in one of the foregoing ways, an endeavour is afterwards to be made to improve the tone of the eye with corroborant applications. The eye may be bathed with cold water, a decoction of oak bark, or any spirituous aromatic collyrium.

When the disease has attained such a degree, that the sight is entirely lost, and the eyeball distended far above its natural size, it is best to give up all idea of attempting a radical cure; the humours may be discharged, and an artificial eye afterwards worn.

Scarpa places little reliance in the *paracentesis oculi* as a means of effecting a permanent cure of hydrophthalmia. Indeed, he maintains, that it can never succeed, unless the puncture, made by the trocar, excite inflammation and suppuration of the interior of the eye. The method recommended by this eminent writer, is to remove a circular piece of the centre of the cornea, about three lines in diameter. Thus, an opening is made, which at once serves for the discharge of the humours, and to excite the requisite degree of inflammation within the eye. The incision should on no account be made in the sclerotica.

The sight being irrecoverably lost, Scarpa advises surgeons to introduce a small bistoury across the apex of the cornea, at one line and a half from the central point of this membrane, whether affected with opacity or not. The little femilunar flap is then to be raised with a pair of forceps, and the incision continued into a complete circle by directing the edge of the knife upwards. Through the circular aperture, thus made in the middle of the cornea, the surgeon is gently to press out as much of the superabundant humours of the eye as is requisite to lessen the eyeball, and make it return into the orbit, so as to admit of being covered by the eyelids.

Scarpa recommends merely applying a pledget of dry lint, and a retentive bandage, till inflammation begins, which generally happens about the third or fifth day. Such remedies are now to be employed as appear best calculated to moderate the inflammation; and a bread and milk poultice is to be applied to the eyelids, and changed every two hours. When, on the commencement of inflammation, the eyeball swells so considerably, as to project from the orbit again, the prominent part is to be covered with a liniment of oil and wax, or the yolk of an egg mixed with some oleum hyperici. Either of these dressings is to be laid under the bread and milk poultice. In proportion as the internal suppuration of the eye begins, the swollen state of this organ undergoes a gradual diminution.

When the removal of a piece of the cornea, to the extent above specified, fails to excite a mild inflammation and suppuration of the interior of the eye by the fifth day, Scarpa advises us either to expose the eye to the air, or to cut away a little of the whole edge of the opening already made in the cornea, so as to bring on the kind of inflammation and suppuration essential to the cure. Scarpa *suile principali malattia degli occhi*, cap. 18.

The late Mr. Ford introduced a seton through the eyeball, for the purpose of lessening the size of the organ when affected with hydrophthalmia. *Medical Communications*, vol. i.

After operating for the relief of the present affliction, a fungus occasionally grows out of the internal part of the eye. Such an excrescence was, in one instance, destroyed by the external employment of belladonna. (*Terras, Journal de Médecine*, tom. 45.) But in case this or other means

fail in preventing the reproduction of the fungus, the surgeon is called upon to recommend the entire extirpation of the eye. See EYE, *Extirpation of*.

HYDROPTHALMION, from ἵδωρ, *water*, and οφθαλμῖος, *the eye*, a swelling which sometimes happens just under the eye, in dropical and cachectic habits.

HYDROPHYLACIA, from ἵδωρ, *water*, and φυλάξω, *I keep*; a word used by Kircher, and some others who have written in the same system, to express those great reservoirs of water which he places in the Alps, and other mountains, for the supply of the rivers which run through the several lower countries. This he makes to be one of the great uses of mountains in the economy of the universe.

HYDROPHYLAX, in *Botany*, from ἵδωρ, *water*, and φυλάξω, *a guardian, or keeper*, probably from the circumstance of its being always found inhabiting the sea shore.—Schreb. 68. Linn. Suppl. 14. Willd. Sp. Pl. v. 1. 581. Mart. Mill. Dict. v. 2. Juss. 210. Lamarck Dict. v. 3. 156. Illustr. t. 76. (Sariffus; Gært. t. 25.) Cls and order, *Tetrandria Monogynia*. Nat. Ord. *Stellatae*, Linn. *Rubiaceae*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, erect, superior, permanent, divided into four, ovate, acute, bordered, somewhat fleshy segments. *Cor.* of one petal, funnel-shaped; tube longer than the calyx; limb angulated, divided into four ovate, revolute segments; throat bearded. *Stam.* Filaments four, inserted at the summit of the tube, decurrent, erect, longer than the corolla; anthers somewhat spear-shaped. *Pist.* Germen oblong, inferior; style thread-shaped, curved; stigma bifid. *Peric.* Berry dry, ovate, compressed, having three ribs on each side, the middle one highest, with an attenuated margin, a little incurved, fungous, two-celled, with a transverse partition. *Seeds* solitary, oblong, triangular, roughish, having two furrows on the inner side.

Ess. Ch. Corolla a funnel-shaped petal. Calyx four-cleft. Capsule angulated, of two cells, with a transverse partition. Seeds solitary.

1. *H. maritima*. Linn. Suppl. 126. (Sariffus anceps; Gært. 118. t. 25. f. 4.)—Found by Koenig on loose sand by the sea, near Gudukuhr, in the East Indies.—This is the only species known. It has the habit and appearance of *Arenaria marina*, but is larger.—*Root* simple, thread-shaped, red, fleshy, sweet. *Stem* creeping, smooth, coloured, jointed, very long, furnished with obtuse, membranaceous, permanent sheaths. *Leaves* opposite, spreading, ovate, acute, entire, fleshy, shining, interspersed with small, whitish, pellucid tubercles; leaf-stalks short, sheathing the stem, and becoming, when the leaves fall, permanent sheaths. *Flowers* axillary, usually in pairs, but not opposite, erect, of a pale blue colour. *Anthers* blue.

HYDROPHYLLUM, from ἵδωρ, *water*, and φύλλον, *a leaf*, expressive of an aquatic leaf, but Tournefort censures this appellation, saying the plant grows in a rich, but not very watery soil. Miller conjectures that M. Morin gave the genus this name because, in spring, water is usually found in the cavity of its leaves.—Hence its English appellation, *Water-leaf*.—Linn. Gen. 83. Schreb. 109. Tournef. t. 16. Willd. Sp. Pl. v. 1. 814. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 1. 197. Juss. 129. Lamarck Dict. v. 3. 157. Illustr. t. 97. Gært. t. 110.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Borraginæ*, Juss.

Gen. Ch. *Cal.* Perianth scarcely shorter than the corolla, spreading, permanent, of five deep, awl-shaped segments. *Cor.* of one petal, campanulate, cloven into five, erect, obtuse, emarginate segments; nectary, a chink closed by two longitudinal converging plates, fastened to the petal, within the middle of each segment. *Stam.* Filaments five, awl-

shaped, longer than the corolla; anthers incumbent, oblong. *Pist.* Germen ovate, pointed; style awl-shaped, the length of the stamens; stigma bifid, acute, spreading. *Peric.* Capsule globose, of one cell and two valves. *Seed* solitary, round, large.

Ess. Ch. Corolla bell-shaped, having five, longitudinal, honey-bearing streaks on the inside. Stigma bifid, capsule globose, two-valved.

1. *H. virginianum*. Linn. Sp. Pl. 208. Lamarck Illustr. t. 97. f. 1.—“Leaves pinnatifid.”—Native of Virginia and Carolina, on a moist boggy soil; flowering in May and June. A hardy herb, whose *root* is fibrous, and spreading. *Leaves* rising from the root on footstalks, indented on their edges, veiny, of a shining green. *Flowers* also coming from the root, hanging down in loose clusters, rather inconspicuous. *Seeds* irregularly ovate and angular, elegantly reticulated with very minute excavations, yellowish white.

2. *H. canadense*. Linn. Sp. Pl. 208. Lamarck Illustr. t. 97. f. 2.—“Leaves lobate-angular.”—Native of Canada, and flowering in May.—Very similar to the last except in foliage, and in this respect *H. canadense* is not unlike the *Acer* or *Maple*, for its leaves are half five-lobed, smooth, with the lobes acute, slightly toothed, and having a sinus at the insertion of the footstalk.

These plants are very hardy, and should be placed in a moist rich soil.

3. *H. appendiculatum*. Michaux. Boreal.-Amer. v. 1. 134. “Very hairy all over. Radical leaves somewhat pinnatifid. Sinuses of the calyx with reflexed appendages.”—Michaux found this in mountainous woods of North America. He describes the *flowers* as in somewhat panicked clusters, of a blueish colour, their calyx having reflexed appendages, like some species of *Campanula*.

HYDROPHYSOCELE, an old term in *Surgery*, implying a hernia, in which a good deal of fluid and air is contained. The word is compounded of ἵδωρ, *water*, φυσω, *a flatus*, and κελω, *a hernia*.

HYDROPIK, synonymous with *dropical*, being the adjective from *hydrops*; which see.

HYDROPIPER, in *Botany*. See *ELATINE*.

HYDROPNEMATOCELE, from ἵδωρ, *water*, πνευμα, *wind*, and κελω, *a tumour*, a hernial swelling containing a large proportion of air and fluid.

HYDROPNEMOSA RCA, an ancient term in *Surgery*, signifying a tumour containing water, air, and any fleshy substance. The word is derived from ἵδωρ, *water*, πνευμα, *wind*, and σαφω, *flesh*.

HYDROPOTA, of ἵδρωποτος, formed of ἵδωρ, *water*, and ποτω, *drinker*; of πωω, *I drink*, in *Medicine*, a person who drinks nothing but water.

It has long been controverted among physicians, whether or no the hydropote lived longer than other persons? See *DRINK*.

HYDROPS, ἵδρωψ, of ἵδωρ, *aqua*, and ψω, *vultus*. See *DROPSY*.

Hydrops ad matulam, literally “a dropsy into the chamber-pot,” a term sometimes used to signify a *diabetes*.

HYDROPYRETOS, formed of ἵδωρ, *water*, and πυρετος, *fever*, a word used by some authors to express a malignant fever, attended with very copious sweats. Some make it the same with the sudor Anglicus, or sweating sickness.

HYDRORACHITIS, from ἵδωρ, *water*, and ραχις, *the spine*, denotes, in *Surgery*, a particular kind of tumour situated on the vertebrae, remarkable for being of a most incurable nature; and proving fatal, when it bursts or is punctured,

punctured. The case will be considered hereafter. See *SPINA bifida*.

HYDRORHODINON, formed of ἵδωρ, *water*, and ῥόδοι, *rose*; a name given by the ancients to a mixture of water and oil of roses. This, as it was at once cooling and emetic, was very much used by the ancients, to provoke vomiting after the taking of poisons.

HYDROROSATON, in the *Writings of the Ancient Physicians*, a name given to a drink made of water, honey, and the juice of roses. The proportions were four pounds of roses, five pints of water, and two pints of honey.

HYDROSA'RCA, from ἵδωρ, *water*, and σαρκίς, *flesh*, in *Surgery*, any fleshy tumour containing fluid.

HYDROSA'RCOCELE, from ἵδωρ, *water*, σαρκίς, *flesh*, and κύστις, *a tumour*, signifies a hydrocele, or preternatural accumulation of fluid in the tunica vaginalis, attended with a chronic enlargement or induration of the testicle. See **HYDROCELE** and **SARCOCELE**.

HYDROSCOPE, ἵδροςκοπιον, formed of ἵδωρ, *water*, and σκοπιον, *I consider*; an instrument anciently used for the measuring of time.

The hydroscope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom; the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out of the vertex of the cone, pointed out the hour.

Synefius describes the hydroscope at large in one of his letters. See **CLEPSYDRA**.

HYDROSELINUM, in *Botany*, a name given by some authors to smalage.

HYDROSTATIC BALANCE, a kind of balance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid.

The instrument is of considerable use in estimating the degree of purity of bodies of all kinds; the quality and richness of metals, ores, minerals, &c. the proportions in any mixture, adulteration, or the like; of all which the specific weight is the only adequate test.

The hydrostatical balance is founded on this theorem of Archimedes, that a body heavier than water weighs less in water than in air, by the weight of as much water as is equal to it in bulk. Whence, if we subtract the weight of the body in water from its weight in air, the difference gives the weight of as much water as is equal in magnitude to the solid proposed.

Having, therefore, two bodies, the one firm, the other fluid, together with the weight of each apart; to find their proportion, divide the greater by the lesser; the quotient compared to one, that is, unity, will be the antecedent of the proportion desired.

The instrument, with its apparatus, is represented *Plate X. figs. 7 and 8, Hydraulics*, and needs little description. See **GOLD**.

AB is a nice balance, turning with a small part of a grain, and furnished with a long examen D, for determining the exact horizontal position of the balance.

1. To find the specific gravity of a fluid: hang to the end B of the beam the little scale S, and to the bottom of the scale S, by a horse-hair, which is of the same specific gravity with water, the glass bubble G, which must be specifically heavier than any fluid except mercury. To the opposite end A of the beam hang a brass scale E, which is a counterpoise to the bubble G, immersed in water; but when the bubble hangs out of the water, a weight must be laid on E to keep it *in equilibrio*, which weight will be equal to what the bubble lost in water, or to a bulk of water

equal to the bubble; when rain-water is used, this weight will be a thousand grains. Then fill a cylindrical vessel I, about two-thirds with common water; and when the bubble is let into it, the beam will remain in a horizontal position, if the water be of the same specific gravity as that in which the bubble was adjusted; if it be not, there will be a variation, which is to be corrected by means of little weights for that purpose. Having thus adjusted the bubble in water, the specific gravity of any other fluid will be found by weighing the bubble in it; and since you always weigh so much of the liquid as is equal to the bulk of the bubble, if there be any difference between such quantity and the like quantity of water, it will be discovered by putting weights into the ascending scale. E. g. if red port wine be put into the vessel I, the bubble will sink, and require the addition of ten grains in the scale E, when the balance has been adjusted in rain-water, for restoring the equilibrium; which shews that port wine is lighter than rain-water ten parts in a thousand, or one hundredth part. If proof brandy be used, seventy-seven grains will be required to restore the equilibrium, and therefore brandy, or proof spirits weighs, seventy-seven parts in a thousand, or one-thirteenth part less than rain-water. But in a denser medium G would rise; and if sea-water be used, twenty-six grains must be put into the scale S to restore the equilibrium, which shews that sea-water is twenty-six parts in one thousand, or one thirty-eighth part heavier than rain water.

2. To find the specific weight of a solid; instead of the bubble, hang on the glass bucket K, *fig. 8.* which with its suspending piece H, will be *in equilibrio* with the counterpoising scale E. Having weighed the solid in air in the bucket, by counterpoising it with weights on the scale E, note its weight; but because not only the solid to be tried, but the glass bucket itself will lose of its weight when immersed in water, you must restore to the bucket the weight that it loses by being immersed, that the body in it alone may be examined: this is done by means of the piece F, which weighs just as much as a bulk of water equal to the bucket; and being slipped on the suspending piece at H, it not only restores to the bucket what it had lost by being immersed in water, but makes a scale for receiving weights, in order to restore the equilibrium to the solid contained in the bucket, and to shew how much it has lost of its weight in water. When many bodies are to be weighed hydrostatically, it is best to weigh them all in the air successively, and set down their weights before you begin to weigh them in water, because it would be troublesome to dry the bucket every time. Care must also be taken that no bubbles of air adhere to the bodies weighed in water, which would make them lighter.

Dr. Defaguliers has added a contrivance to this machine to make it more nice, see *fig. 9.* S, S, S, are three screws which serve to set the foot and stem upright; and OM is a string and plummet, whose point hanging over M, shews when the piece PC is truly vertical. There is also a piece EO, which has a slit to compare with the examen D playing in the notches Cc. Defag. Exp. Phil. vol. ii. p. 196.

Mr. Martin proposes the following construction of an accurate hydrostatical balance. AB, (see *fig. 10.*) is the foot on which it stands; CD, a pillar supporting a moveable brass plate EF, fastened to it by the screw in the knob e. In the end of this plate is fixed an upright piece IK, supporting another plate GH, which slides backwards and forwards thereon, and is moveable every way about it. In the end of this plate at H, is fixed (by a nut beneath) a wire LM, taped with a fine thread from one end to the

other; upon this moves the swan-neck slip of brafs NO, to which a very exact balance is hang at the point N; to one of whose scales P, is appended the heavy body R, by a fine horse-hair, or piece of silk S; the weight of the said body R in the air is expressed by the weights put into the scale Q to make an equilibrium therewith, which being destroyed by immersing the solid in the fluid T V, contained in the glafs W V, is again restored by weights put into the scale P. So that the weights in the scale Q compared with those in the scale P, shew at once the specific gravity of the solid R to that of the fluid T V.

For several other constructions of this instrument, designed for greater accuracy than that of the common sort, the reader may consult s'Gravensande's *Physices Elem. Math.* &c. tom. i. lib. 3. cap. 3. The specific gravities of small weights may be determined by suspending them in loops of horse-hair, or silk threads, to hook at the bottom of the scale of the common hydrostatical balance. *E. g.* if a guinea suspended in air be counterbalanced by 129 grains in the opposite scale; and upon being immersed in water, requires $7\frac{1}{2}$ grains to be put into the scale over it, in order to restore the equilibrium; we thus find that a quantity of water of equal bulk with the guinea, weighs $7\frac{1}{2}$ grains, or 7.25; by which divide 129, the weight of the guinea in air, and the quotient, or 17.793, shews that the guinea is so many times heavier than its bulk of water. Whence, if any piece of gold be tried, by weighing it first in air, then in water, and if upon dividing the weight in air by the loss in water, the quotient is 17.793, the gold is good; if the quotient be 18, or between 18 or 19, the gold is very fine; but if it be less than $17\frac{1}{2}$, the gold is too much alloyed with other metal. If silver be tried in this manner, and found to be eleven times heavier than water, it is very fine; if it be $10\frac{1}{2}$ times heavier it is standard: but if it be any less weight, compared with water, it is mixed with some lighter metal, such as tin.

In order to find the specific gravities of those bodies that are lighter than water, let any upright stud be fixed into a thick flat piece of brafs, and in this stud let a small lever, whose arms are equally long, turn upon a fine pin as an axis. Let the thread which hangs from the scale of the balance be tied to one end of the lever, and a thread from the body to be weighed, be tied to the other end. This done, put the brafs and lever into a vessel; then pour water into the vessel, and the body will rise and float upon it, and draw down the end of the balance from which it hangs; then put as much weight in the opposite scale as will raise that end of the balance, so as to pull the body down into the water by means of the lever; and this weight in the scale will shew how much the body is lighter than its bulk of water. *Ferguson's Lect.* p. 160, 8vo.

Otherwise: Take another body of a compact form, but much heavier than an equal bulk of water, so that when this body is connected with the body in question, they may both sink in water. This being prepared, ascertain the weight of the lighter body in air, and the weight of the heavier body in water. Then tie, by means of thread, both bodies together, but not so closely as to exclude the water from, or to harbour bubbles of air between them; and weigh them both in water. Now since the heavy body is partly buoyed up by the lighter body, the weight of both in water will be less than the weight of the heavier body alone. Subtract the former from the latter, and add the remainder to the weight of the lighter body in air; for this sum is the weight of a quantity of water equal in bulk to the lighter body. Therefore the weight of the lighter body in air must be divided by the last-mentioned sum, and the quotient will express the specific gravity of the lighter body.

E. g.—A piece of elm being varnished in order to prevent its absorbing any water, was found to weigh in air 920 grains. A piece of lead, which was chosen for this purpose, was found to weigh in water 911.7 grains. The piece of elm and the piece of lead were tied together, and being suspended from the hook of the scale, &c. in the usual manner, were found to weigh in water 331.7 grains, *viz.* 580 grains less than the lead alone; therefore 580 was added to 920 (*viz.* to the weight of the elm in air) and made up the sum of 1500. Lastly, 920 was divided by 1500, and the quotient 0.6133 expressed the specific gravity of the piece of elm.

In the use of the hydrostatical balance, it will be proper to observe the following general precautions. The water in which the solid is to be weighed, besides its being either distilled or rain water, must be quite clean. Its temperature, as well as that of the solid, must be as near as possible to 62° of Fahrenheit's thermometer; for which purpose the ball of the thermometer must be placed in the water, and the temperature is adjusted by the addition of hot or cold water. If the solid body be soluble in water, or if it be porous enough to absorb any water, then it must be varnished, or smeared over with some oily or greasy substance; but in that case some allowance must be made on account of the varnish, &c. When the solid is weighed in water, its upper part ought to be a little way below the surface of the water; for instance, about an inch; and it must by no means be suffered to touch the sides or bottom of the jar. Care must be had that no bubbles of air adhere to the solid under water; for they would partly buoy it up. These may be easily removed by means of a feather. The solid must be of a compact form, and free from accidental or artificial vacuities, so as not to harbour any air; for otherwise its specific gravity cannot be ascertained by weighing in water, &c. Thus a piece of silver, which is much heavier than water, may be formed into a hollow sphere, which will appear to be much lighter than water; for if this sphere were immersed in water, it would displace a quantity of water which is equal not only to the silver, but also to the space which is contained in the sphere. It is for this reason that a ship might be made of iron, or of copper, or, in short, of any substance whose specific gravity far exceeds that of water, and yet it would float as well as a ship which is made of wood, in the usual way. See *Specific Gravity*.

Hydrostatic Bellows, in *Hydrostatics*, is a machine for demonstrating the upward pressure of fluids (see *FLUID*), consisting of two thick oval boards A, (*Plate X. Hydraulics*, &c. *fig.* 11.) each about sixteen inches broad, and eighteen inches long, covered with leather, to open and shut like a common bellows, but without valves, only a pipe B, about three feet high, is fixed into the bellows at *e*; let water be poured into the pipe at C, which will run into the bellows, and separate the boards a little. Then lay three weights *b, c, d*, each weighing a hundred pounds, upon the upper board; and pour more water into the pipe B, which will run into the bellows, and raise up the board with all the weights upon it; and if the pipe be kept full until the weights are raised as high as the leather, which covers the bellows, will allow, the water will remain in the pipe, and support all the weights upon it; even though it should weigh no more than a quarter of a pound, and these three hundred pounds; nor will all their force be able to cause them to descend and force the water out of the top of the pipe. The reason of this will appear, if we consider that if a hole be made in the upper board, and a tube be put into it, the water will rise in the tube to the same height as it rises in the pipe; and would rise as high by supplying the pipe in as many tubes as the board could contain holes.

Now,

Now, suppose only one hole to be made in any part of the board, of an equal diameter with the bore of the pipe B, and that the pipe holds just a quarter of a pound of water; if a person puts his finger upon the hole, and the pipe be filled with water, he will find his finger to be pressed upward with a force equal to that of a quarter of a pound. As the same pressure is equal upon all equal parts of the board, each part, whose area is equal to the area of the hole, will be pushed upward, with a force equal to that of a quarter of a pound: the sum of all which pressures against the under side of an oval board, sixteen inches broad, and eighteen inches long, will amount to three hundred pounds; and, therefore, so much weight will be raised up and supported by a quarter of a pound of water in the pipe. Hence if a man stands upon the upper board, and blows into the bellows through the pipe B, he will raise himself upon the board; and the smaller the bore of the pipe is, the easier he will be able to raise himself; and then by putting his finger upon the top of the pipe, he can support himself as long as he pleases; provided that the bellows be air-tight. Mr. Ferguson has described another machine, which may be substituted instead of this common hydrostatical bellows: A B C D, *fig. 12*, is an oblong square box, in one end of which is a round groove, as at *a*, from top to bottom, for receiving the upright glass tube I, which is bent to a right angle at the lower end as at *i*, in *fig. 13*, and to that part is tied the end of a large bladder K, which lies in the bottom of the box. Over this bladder is laid the moveable board L, *figs. 12* and *14*, in which is fixed an upright wire M; and leaden weights N, N, to the amount of sixteen pounds, with holes in their middle, are put upon the wire over the board, and press upon it with all their force. The cross bar *p* is then put on to secure the tube from falling, and keep it in an upright position; and then the piece E F G is to be put on, the part G sliding tight into the dove-tailed groove H, to keep the weights N, N, horizontal, and the wire M upright, which is received into a round hole *e*, in the part E F. There are four upright pins in the four corners of the box within, each almost an inch long, for the board L to rest upon, in order to keep it from pressing the sides of the bladder below it close together at first. The whole machine being thus put together, pour water into the tube at top, and the water will run down the tube into the bladder below the board, and after the bladder has been filled up to the board, continue pouring water into the tube, and the upward pressure of the bladder will raise the board with all the weight upon it, even though the bore of the tube should be so small, that less than an ounce of water would fill it. Ferguson's Lectures, Supplement, 1767. p. 16.

HYDROSTATIC Instrument, Bradford's, is an invention for weighing money and discovering its defect either of weight or purity.

It consists of a thin flat brass ruler, about half a foot long; on each side of which are two graduated lines, those on the upper side marked A and W (see *Plate X. Hydraulics, fig. 15*. N° 1.) and those on the other side B and W, *ibid.* N° 2. There are also a small chain and pincers wherein to fix the piece of money intended to be weighed and proved, together with two pair of centre pins, marked A and B, *ibid.* N° 2 and 3, being the points of suspension of the rod when used; whereof the former pair A are to be used for proving all pieces of gold under thirty-six shillings value; and the other pair, marked B, for all pieces from thirty-six shillings to seventy-two shillings, or three pounds twelve shillings. Lastly, there is a sliding piece, or index C, *ibid.* N° 3, by the motion of which, backward or forward, until the point

of equilibrium is discovered, the value of any piece suspended in the pincers is found upon the graduated lines already mentioned. Of these lines, those marked A and B are called statical lines, as being calculated for weighing the piece in air, and those marked W W, are called hydrostatical lines, as serving to point out the alloy or adulteration of the piece weighed. A whole division on each line is equal to the weight or value of one shilling in gold; a half division to six-pence, and a quarter division to three-pence.

To prove a guinea: first suspend it in the pincers, and then placing the inside of the sliding-piece C to twenty-one on the line A on the upper side of the ruler, which must move freely on the centre pin marked A, and if the guinea and sliding-piece exactly balance each other, the guinea is full weight; if not, move the slider backwards or forwards until they equiponderate; when the division cut by the inside of the slider is the true weight of the gold; and if it rests for instance, at twenty and a half, then the guinea weighs only twenty shillings and sixpence. In the next place, to prove the alloy of this piece, let the slider be brought to the division twenty and a half, upon the hydrostatical line marked W, for whatever division is cut by the slider in weighing on the statical line, it must be placed at the same on the hydrostatical line adjoining. Then let the piece, together with the pincers, and the brass link whereon it is suspended, be immersed in water (*ibid.* N° 3.) as far as the notch on the said link; if then the instrument acts in equilibrium, or the piece sink deeper in the water, the guinea is standard gold; but if the slider must be moved farther backward before it will equiponderate, the guinea is adulterated. If it is alloyed with silver, allow two shillings for every penny it wants in the hydrostatical weight; and then if the number of pence the piece is deficient in weight hydrostatically, when doubled, exceed the number of shillings it weighs statically, it may be concluded to be adulterated with some baser metal than silver. However, a more speedy method of discovering whether a piece of gold be adulterated or not, without moving the slider more than once, is this: when the piece is weighed statically, bring the slider to the division on the hydrostatical line expressing its weight: and immersing the piece and pincers as before, so that the surface of the water may be exactly at the mark on the long link, if the instrument does not then equiponderate, gently lower the hand that holds the fluid, until the instrument comes to an equilibrium; at which time, if the guinea be a counterfeit, great part of the pincers will appear above the water; if a 36s. piece be tried, not only the pincers, but a small part of the coin, will appear above the surface, if the piece be counterfeit. This last method is sufficiently near the truth for common practice.

If there is occasion to weigh and prove a very small piece of gold, as a 2s. 3d. 4s. 6d., &c. the method is, to put the said pieces in the pincers, with some other piece that has been approved before; by which means the weight and alloy of the small piece may be easily discovered, as above. If the piece be above 36s. the slider is to be placed according to the divisions of the statical and hydrostatical lines on the under side of the instrument, which are fitted to the standard of the mint; by which a guinea weighs 129 grains.

HYDROSTATICAL Paradox, is a principle, which has been already stated, and in some degree illustrated and evinced under the article FLUID, and also under the article of *HYDROSTATIC Bellows*. It is so denominated, because at first view it seems to be paradoxical; but it results from the nature of fluids, which press every way alike. The paradox is this, that any quantity of water, or any other fluid, how small soever, may be made to balance and support any quan-

tity, or any weight, how great soever. Thus, water in a pipe or canal, open at both ends, always rises to the same height at both ends, whether those ends be wide or narrow, equal or unequal. And since the pressure of fluids is directly as their perpendicular heights, without any regard to their quantities, it follows that whatever the figure or size of the vessels may be, provided their heights be equal, and the areas of their bottoms equal, the pressures of equal heights of water are equal upon the bottoms of those vessels; even though the one should contain a thousand or ten thousand times as much as the other. Mr. Ferguson has illustrated and confirmed this paradox by the following apparatus. Let two vessels, (*Plate XI. Hydraulics, fig. 16.*) such as A B and C D, be of equal heights, but very unequal capacity; let each vessel be open at both ends, and their bottoms E and F of equal widths. Let the brass bottoms G and H be exactly fitted to each vessel, not so as to go into them, but for each vessel to rest upon respectively; and let a piece of wet leather be put between each vessel and its brass bottom, for the sake of keeping them close. Join each bottom to its vessel by a hinge D, so that it may open like the lid of a box; and let each bottom be kept up to its vessel by equal weights W, hung to lines which pass over the pulley P, whose blocks are fixed to the sides of the vessels at F, and the lines tied to hooks at *d*, fixed in the brass bottoms opposite to the hinges D. Things being thus prepared, hold one vessel upright in the hands over a basin on a table, and cause water to be poured slowly into it, till the pressure of the water bears down its bottom at the side *d*, and raises the weight E; and then part of the water will run out at *d*. Mark the height at which the surface H of the water stood in the vessel, when the bottom began to give way at *d*; and then, holding up the other vessel in the same manner, cause water to be poured into it; and it will be seen that when the water rises in this vessel just as high as it did in the former, its bottom will also give way at *d*, and it will lose part of the water.

The natural reason of this surprising phenomenon is, that since all parts of a fluid at equal depths below the surface, are equally pressed in all directions, the water immediately below the fixed part B *f* will be pressed as much upward against its lower surface within the vessel, by the action of the column A *g*, as it would be by a column of the same height, and of any diameter whatever; and therefore since action and re-action are equal, and contrary to each other, the water immediately below the surface B *f* will be pressed as much downwards by it as if it were immediately touched, and pressed by a column of the height A *g*, and of the diameter B *f*; and therefore the water in the cavity B D *d f* will be pressed as much downward upon its bottom G, as the bottom of the other vessel is pressed by all the water above it. Ferguson's Lectures, p. 105.

HYDROSTATICS, composed of ὑδρ, *water*, and στατις, *statics*, of στατος, *stands*, of νησι, *island*, hydrostatics being conceived as the doctrine of the equilibrium of liquors, is the doctrine of gravitation in fluids; or that part of mechanics which considers the weight or gravity of fluid bodies, particularly of water, and of solid bodies immersed in them.

To hydrostatics belongs whatever relates to the gravities and equilibria of liquors, with the art of weighing bodies in water, in order to estimate their specific gravities.

Mr. Boyle has applied hydrostatics to good purpose, in examining and proving the goodness and purity of metals, minerals, and other bodies, particularly fluids, in an express treatise, entitled "Medicina Hydrostatica."

The laws of hydrostatics, with the application of them,

see delivered at large under the articles FLUID and *Specific GRAVITY*.

Hydrostatics are frequently confounded with hydraulics, on account of the affinity of the subjects; and several authors chuse to treat of the two promiscuously. See HYDRAULICS.

The oldest writer on hydrostatics is Archimedes, who first delivered the laws of them in his book "De insidentibus humido." Marin Ghetaldus first brought his doctrine to experiment, in his "Archimedes Promotus;" and from him Mr. Oughtred took the greatest part of what he has given us on this subject. The celebrated M. Pascal has written an excellent treatise on this subject, entitled "Traité de l'Equilibre des Liqueurs et de la Pesanteur de l'Air." M. Mariotte, in a French treatise, published at Paris in 1686, "Of the Motion of Water and other Fluids," gives most of the propositions of hydrostatics and hydraulics, proved by reason, and confirmed by experiments. The Jesuit F. Tertius de Lanis, in the third tome of his "Magisterium Naturæ et Artis," lays down the doctrines of hydrostatics more amply than they are elsewhere found. F. Lamy, in the second part of his mechanics, entitled "Traité de l'Equilibre des Liqueurs," delivers the fundamental laws of hydrostatics and hydraulics; and the like is done by Dr. Wallis, in his "Mechanica." Lastly, sir Isaac Newton gives some of the sublimer matters in the second book of his Philosoph. Nat. Princip. Mathematic. For an account of other writers on this science, see HYDRAULICS.

HYDRO-SULPHURET, in *Chemistry*, a compound of sulphuretted hydrogen with alkaline and earthy bases, and likewise with metallic oxyds. The properties of the hydro-sulphurets are: that they are abundantly soluble in water, and are crystallizable; the solution is colourless as long as the action of the air is excluded; but when it is admitted, a yellow colour is soon acquired, owing to the oxygen of the atmosphere combining with the hydrogen of a portion of the sulphuretted hydrogen, while the sulphur combines with the remaining portion of it, forming a super-sulphuretted hydrogen in union with the base. The principal hydro-sulphurets are as follow: *viz.* 1. Hydro sulphuret of potash: this salt is white, and perfectly transparent, resembling the sulphate of soda by its transparency and the size of its crystals. Its taste is at first alkaline, and afterwards extremely bitter; when dry it is without smell, but when liquid it exhales a fetid odour. It attracts humidity from the atmosphere, and passes into a liquid syrup. When fluid, it gives a green colour to bodies in contact with it; it is soluble in water and alcohol, abstracting heat during the solution: with acids, it gives rise to a brisk effervescence, without depositing any sulphur. It precipitates the metallic solutions: the precipitates from different metals being of different colours and shades. 2. The properties of the hydro-sulphuret of soda are very like those just enumerated of the potash; but the nitrous and oxy-muriatic acids produce a precipitate of sulphur, owing to their decomposing the sulphuretted hydrogen, by affording oxygen to its hydrogen, while the other acids merely expel it. To distinguish the hydro-sulphuret of potash from that of soda; add a few drops of the solution of each to a solution of alumine in sulphuric acid: the potash gives rise immediately to a crystallization of alum; while that of soda has no such effect. 3. Hydro-sulphuret of ammonia is thus produced: when equal parts of sulphuretted hydrogen and ammonia, in their elastic states, are mixed together, they immediately combine; a white cloud is produced, which is condensed, and a thin, soft deposit is formed on the sides of the vessel, which

which exhales a penetrating vapour when exposed to the air : this is the hydro-sulphuret of ammonia.

HYDRŌTHQRAX. See DROPSY.

HYDROTICS, formed of *ὕδωρ*, *water*, in *Medicine*. See HYDROPIC.

HYDRUNTUM, OTRANTE, in *Ancient Geography*, the most easterly part of Italy, having a port, from which it was usual to pass over to Greece : the gulf in that place being scarcely 12 leagues broad. Near it was a cape, called "Hydrus Mons."

HYDRUS, or *Water Serpent*, in *Astronomy*, is a southern constellation, including ten stars. See CONSTELLATION.

HYDRUS, in *Zoology*, a genus of serpents lately established by Dr. Schneider, and which is designed to contain a number of those species of the serpent tribe that are of the aquatic kind, whether those which reside in fresh waters, or the marine elements; or such as indiscriminately inhabit either.

Most of the snake tribe possess the power of moving in the water without difficulty, and some, from their peculiar conformation, perform the act of swimming with much facility; but the structure of the hydrus is in an eminent manner adapted to this particular purpose, the tail being broad, flat, and compressed, like that of some kinds of fishes, and by means of which it is enabled to direct its course with equal certainty, and swim with equal ease and swiftness. Water serpents are mentioned by various writers of antiquity, as Aristotle, Ælian, and Pliny, and also by others of the middle ages, as well as those of modern times. Ælian speaks of snakes of large size, with flat tails, produced in the Indian sea, and Aristotle mentions others resembling the conger. It is, therefore, very probable that some few of the genus may have been known to them, though it is not less likely they might have confounded the muræna with their sea serpents, or perhaps even some of the terrestrial kinds of serpents, as the uninformed among the moderns too frequently denominate all those snakes "water snakes" which they happen to discover in the water; without reflecting that those snakes may have only sought shelter in the water in the moment of pursuit, or been discovered in the very instant of time when they have plunged into that element in search of prey.

Bosc, and after him other writers of credit on the tribe amphibia, reject the name of hydrus, given by Schneider; that term having been previously assigned to a tribe of vermes, the polype or hydra of Linnæus. They, therefore, since it appears desirable the genus should be retained, adopt it by the name of *Hydrophis* instead of *Hydrus*, and under this appellation it is received by the best writers at this time. Daudin, it is true, esteems the distinction too diffuse, and with the exception of a few species continued under the name of enhydris, returns the hydrus genus of Schneider to the Linnæan coluber, but his example is not followed by his own countrymen, among whom the three genera, as before mentioned, seem very generally admitted at this period.

It should be distinctly understood that Mr. Schneider does not include the whole of the water serpents under one genus; he considers their residence in the water as the characteristic only of a tribe, which he subdivides into two genera, the first of which he calls *Hydrus*, the other *Enhydris*. In both the form of the tail is alike, flat, broad, and formed for swimming, but in the shape of the scales and some other particulars they differ materially, those of the hydrus corresponding with the viper (coluber), and the enhydrus with the snake (anguis). A third genus is constituted by still later naturalists of the Hydrus colubrinus of that author, under the name of *Platurus*, this species being furnished by nature with venomous fangs like the poisonous kinds of snakes. The

genus last adverted to was supposed to consist only of a single species, but we find among the Indian serpents described by Dr. Ruffel, some other poisonous kinds, which perhaps belong to this particular genus.

Species.

* Genus *Hydrus*, Schneider. *Hydrophis*.

LATICAUDA. Pale yellowish, with transverse brown bands; tail pointed. *Anguis laticauda*, Linn. *Hydrus fasciatus*, Schneider. *Tatta Pam*, Ruffel.

The form of this species is long and slender; the head small, not broader than the neck, and covered with large scales; the neck cylindrical; the back carinated; sides declining, and belly roundish. The scales on the trunk, tail, and belly are orbicular, close and not imbricated; those on the under part of the body amount to two hundred, and are placed in two rows; those beneath the tail fifty; the teeth small. Schneider supposes this may be of the poisonous kind, as he observed a large curved fang-like tooth on each side, concealed as it were in a kind of sheath. The specimen described by Dr. Ruffel was found on the sea beach at Vizagapatam, and appeared very alert in its motions, yet when put into a vessel of sea-water to be preserved alive, in order to ascertain the effects of its bite, it very soon died. The length of this was about two feet; according to Schneider it grows to a much larger size.

BICOLOR. Body above black, beneath yellowish; tail spotted with black. *Hydrus bicolor*, Schneider. *Anguis platura*, Linn. *Nixboa Quaquecolla*, Seba. *Nalia Wablagillee Pam*, Ruffel.

A native of the Indian seas, and said by Forster to be very common near the coasts of the island of Otaheite, where it is called by the natives *Etoona-toree*, and constitutes an article of food; it is about two feet six inches long, and feeds on fish and molluscous animals, which, according to Forster, it seizes with the utmost address. The same species is found in various parts of the Pacific ocean.

CÆRULEUS. Blue, with numerous yellow bands. *Shootur*, Ruffel.

Length three feet and a half; abdominal scales three hundred and thirty-two; caudal forty. Native of India.

MAJOR. Livid, with brown decurrent bands, and hexagonal abruptly carinated scales. Shaw.

Described from a specimen in the British Museum. Its length is more than three feet; its colour pale or livid, marked throughout the whole length of the back by a series of large transverse, semi-current dusky bands; the tail banded more deeply. The length of the tail is about four inches, and the scales which cover it are of a somewhat square or lozenge form, and so disposed as to resemble in some degree those of a fish; they are all marked by an abrupt middle carina; the scales on the body are chiefly hexagonal, and are carinated in the same manner. It appears to be of the poisonous kind, as one of the teeth on each side in the upper jaw is larger than the rest, and on being examined with a lens is evidently tubular, the slit towards the end being much longer in proportion than in that of the rattlesnake. The species is a native of the Indian seas.

GRACILIS. Anterior part of the body slender, and covered with smooth ovate scales; the posterior end thicker, and covered with smooth abruptly-carinated hexagonal scales. Shaw.

Length two feet; head very small, and not of greater diameter than the neck; the tail about an inch and three-quarters in length, colour uncertain, but appears to have been banded all along the upper parts, from the head to the tail,

HYDRUS.

tail, with numerous, equidistant, brown, and somewhat obtusely pointed bands reaching almost to the abdomen, those on the small or cylindrical part of the body being continued into annuli.

CÆRULESCENS. Blueish with dusky blue decurrent bands, and white abdomen. Shaw.

A native of the East Indies, the length two feet; in appearance resembles *Hydrus major*, but the abdomen has a single and perfectly undivided row of hexagonal scales, from the throat to the beginning of the tail, of about the length of an inch in diameter, and forming a carina on that part; back marked by a carina also; tail two inches and a quarter long, and moderately broad. Colour above pale livid blue, beneath white, and marked throughout its whole length by decurrent bands of deeper blue.

CURRUS. Short, yellowish, with dusky decurrent sub-acuminated bands, somewhat confluent above. Shaw.

A native of the East Indies; the length one foot, the body compressed, and considerably thicker in proportion to its length than the species *cærulescens*; the head flattish; neck and anterior part but little thinner than the rest of the body; tail about an inch long, and of the usual form; back and abdomen carinated, the carina of the latter more obtuse. The general colour is pale yellow, with a pretty close series of deeply decurrent dusky bands from head to tail, and which are so disposed as to appear alternately confluent on the upper part of the back, more especially near the head. Described from a specimen in the British Museum.

SPIRALIS. Yellowish, with brown bands longitudinally confluent beneath; the body spirally contorted. Shaw.

An elegant species, of a slender form, and about two feet in length, the body much compressed throughout; the dorsal carina very acute, that of the abdomen with a flattened edge of scales somewhat wider than the rest, and about the fifteenth of an inch in diameter; the head small; mouth wide; scales on the head large, those on the body moderately small, ovate, and slightly carinated. The general colour is yellow, with bars of deep chestnut brown, each dilating on the abdomen; and the back from about the middle nearly to the tail is marked with a series of large, round, blackish spots. "The most remarkable circumstance in this snake (says Dr. Shaw) is the singular obliquity of its form; the body in different parts being alternately flatter on one side than the other, and the pattern completely expressed on the flattened side only; the other, or more convex side, being unmarked by round spots, and lying as it were beneath; thus constituting several alternate spiral curves." Gen. Zool.

** Genus *Enhydris*.

CASPIUS. Cinereous olive with four rows of orbicular black spots disposed in quincunx order down the back; abdomen yellow, tessellated with black. *Coluber hydrus*, Pallas.

Inhabits the Caspian sea and also the Rhine, the length about three feet; tail almost black, and terminated by a small double point, one beneath the other. The head is small, the eyes surrounded by a yellow circle; teeth numerous, small, and placed in two rows; the tongue very long and black.

ATROCÆRULEUS. Black blue; abdomen yellow, with a central longitudinal line of blue. *Hydrus enhydris*, Schneid. *Mutta Pam*, Ruffel.

Described by Dr. Ruffel as being about twenty inches in length, the colour dark blue and changeable; the yellow of the abdomen inclining to white; head small and covered with large scales; anterior part of the body slender, the

circumference of the trunk, in the thickest part, about two inches and a quarter; and the tail short, small, taper and compressed. The specimen mentioned by Dr. Ruffel was taken in an Indian lake called Aukapilly in one of the traps placed there for catching eels. It is supposed to be harmless, having no visible fangs.

CINEREUS. Ash colour; snout broad, obtuse, and black; abdomen yellowish. *Hydrus rynchops*, Schneider. *Karoo Bokadam*, Ruffel.

Inhabits India; the length three feet and a half, the thickness near the head three inches; in the middle of the body four inches and a half; the snout projecting, broader than the neck, and forming a kind of beak which is covered with small laminae, the remainder of the head, with the whole of the upper parts, beset with ovate or sub-orbicular carinated scales; eyes small and vertical; mouth moderate; teeth close set, small, irregular, and not reflex. Colour of the scaly part of the snout pale cinereous. Tail rather compressed, eight inches in length, somewhat tapering, and obtuse at the end.

PISCATORUS. Yellowish brown, with numerous round black spots united by black lines, and disposed in oblique rows. *Hydrus piscator*, Schneider. *Neeli Koca*, Ruffel.

Length two feet nine inches; circumference three inches and a half; head rather broad, ovate, and somewhat depressed, with the sides compressed; covered with large scales; tail eleven inches in length, slightly carinated, tapering very gradually, and terminating acutely; the abdomen yellowish white. The species is a native of India, and is esteemed a water snake, as it frequents the wet paddy fields; it moves swiftly, and carries its head high, with a menacing air, but is not a poisonous species, and cannot easily be irritated. When provoked it would neither hiss nor snap at a stick presented to it; nor was it provoked to bite a chicken though pecked several times by the animal. It is known to feed on fish.

PALUSTRIS. Brownish yellow, with rhomboid brown spots edged with black; abdomen pearl colour; tail above reddish white. *Hydrus palustris*, Schneider. *Paragoodoo*, Ruffel.

Resembles the last; the length more than two feet; trunk round; head broadish, oblong, and covered with large scales; tail round, about five inches and a half long and very taper; between each of the oblique rows of brown rhomboidal spots is a ferruginous line, the whole having a decussated appearance; the tail plain and immaculate. According to Dr. Ruffel, this species is not uncommon in India, frequenting the damp grounds, and the borders of tanks, and growing to a size much superior to the former.

DORSALIS. Dirty white, with a dorsal black band sinuated at the edges. *L'Enhydre dorsale*, Bosc.

The length about one foot; head ovoid; abdomen carinated. Country unknown.

*** Genus *Platurus*. Armed with venomous Fangs.

FASCIATUS. Lead colour, with broad black surrounding bands. *Coluber laticaudatus*, Linn. *Hydrus colubrinus*, Schneider. *Platurus fasciatus*, Latreille.

Native of the Indian and American seas; its general length two feet six inches, or more; the head is covered with large scales; the body cylindrical; tail flattened and somewhat dilated at the tip. This is a poisonous serpent, but the fangs are remarkably small in proportion to the size of the creature.

LANCEOLATUS. Back blue, under the belly yellowish; tail lanceolate and entirely blue.

A native of the Indian seas, and is called by the inhabitants

ants in the English settlements Hoglin; it is two feet and a half in length; the series of abdominal scales three hundred and six, and those of the tail forty-eight. This and the following species are extremely dangerous, their bite proving mortal in a few minutes.

ALBUS. White with numerous blue bands; tail obtuse.

Described by Dr. Ruffel as a native of India, under the name of Chittul. The length is three feet, the number of abdominal scales is three hundred and eight; and those of the tail forty-eight.

HYELA, in *Ancient Geography*, a river of Asia, in Bithynia, called by Pliny *Hylas*.—Also, a town of Arabia Felix. Ptol.

HYELLA, a maritime town of Magna Græcia, in Lucania, called also *Hyalé*. Strabo.

HYELLIUM, a town of Asia, in Phrygia, upon the Meander.

HYEMAL SOLSTICE, the same with *winter solstice*. See **SOLSTICE**.

HYEMANTES, in the *Primitive Church*, offenders who had been guilty of such enormities, that they were not allowed to enter the porch of the churches with the other penitents, but were obliged to stand without, exposed to all the inclemency of the weather.

HYES, in *Mythology*, a surname given to Bacchus, from the name Hye given to his mother Semelè: or, according to others, because her feast commonly happened in a rainy season; from *εω*, to rain. The Athenians worshipped Jupiter under the character Pluvialis, and erected an altar to him on mount Hymetta.

HYETUSSA, in *Ancient Geography*, a small island situated on the coast of Ionia, over-against the mouth of the Meander, and south of the promontory of Troglidium.

HYGEIA, or **HYGIEIA**, in *Mythology*, an epithet given to Minerva, as the goddess of health. Hygieia was represented as one of the four daughters of Esculapius. She often accompanies her father in the monuments of him now remaining, and appears like a young woman, commonly holding a serpent in one hand, and a patera in the other; sometimes the serpent drinks out of the patera; sometimes he twines about the whole body of the goddess.

HYGIEINE, *Ἑγίεινη*, formed of *εγω*, *found, healthy*, that branch of medicine which considers *health*, and discovers proper means and remedies, with their use in the preservation of that state.

The objects of this branch of medicine are, the non-naturals. See **AIR**, **DIET**, **EXERCISE**, &c.

Hygieine, more largely taken, is divided into three parts; *prophylactice*, which foresees and prevents diseases; *syntheritice*, employed in preserving health; and *analeptice*, whose office is to cure diseases, and restore health.

HYGINUS, pope, in *Biography*, is thought to have been a native of Athens, flourished in the second century, and was brought up as a philosopher by profession. He was elected to the office of bishop of Rome upon the martyrdom of Telesphorus about the year 140, and filled it till his death, which took place three years after. He was the zealous opponent of the doctrines propagated at that period by Valentine and Cerdo, but could not prevent them from making considerable progress. He settled and confirmed the several orders and degrees of the clergy; ordained the solemn consecration of churches, and did many other acts which were regarded, at that period, as of great importance to the interests of the prevailing religion. Moreri.

HYGINUS, CAIUS JULIUS, one of the ancient grammarians, is mentioned by Suetonius as a native of Spain, though some have supposed him an Alexandrian, and to have

been brought to Rome after the capture of that city by Julius Cæsar. He was appointed keeper of the Palatine library, and received pupils for instruction. He was intimately acquainted with Ovid and other literary characters of the age; he was said to be the imitator of Cornelius Alexander, a Greek grammarian; wrote the lives of illustrious men, which are referred to by Aulus Gellius; a volume of examples, and a copious treatise on the cities of Italy. Other works have been attributed to him: but the only pieces that have come down to us, are entitled “*Poeticon Astronomicon, de Mundi et Spheræ, ac utriusque Partium, Declaratione, lib. iv.*” and a book of fables. The best edition of these works in conjunction is contained in Munker’s “*Mythographi Latini.*” Gen. Biog.

HYGRA, of *εγρος*, *moist*, a name given by the ancients to what they called liquid plasters, in opposition to those called xeria, or dry ones. These first were a sort of liniments.

HYGROCIRSOCELE, compounded of *εγρος*, *moist*, and *κυσσοκορμη*, *ramæ varicosus*, in *Medicine*, a branch of a vein swelled with ill blood, or other humours; or a varicose tumour of some of the veins of the testes, attended with a gathering of water in the scrotum.

HYGROMETER, or **NOTIOMETER**, compounded of *εγρος*, *moist*, and *μετρον*, *I measure*, a machine, or instrument, whereby to measure the degrees of dryness, or moisture, of the air. It is also called *Hygroscope*. See the next article.

HYGROMETRY is the term used by Lambert, Saussure, and other writers to denote the science concerning the nature and quantity of aqueous vapour in the atmosphere, and its relation to certain instruments called *hygrometers*. This branch of meteorology has been greatly improved of late years, and is justly considered of importance, as being intimately connected with *hygrology*, or the science of aqueous meteors in general.

The two great objects of hygrometry are, 1st, To find what quantity of water exists in solution, or in an elastic state, in a given volume of the atmosphere, or, which is still better, in a given perpendicular column reaching to its summit; and, 2dly, To ascertain the disposition of the atmosphere on any occasion to deposit water or to absorb it, or, in more familiar language, its disposition to rain or to be fair.

The earlier philosophers had the second object chiefly in view, on account of the more immediate benefit which seemed likely to be derived from the knowledge of it; but latterly both objects have engaged the attention of those who have pursued this branch of physical investigation. Various means have been applied and instruments used under the name of hygrometers or hygrosopes, to indicate the fluctuations of moisture existing in the atmosphere. The detail of experimental enquiry may be conveniently digested under five heads; namely, 1. The alternate expansion and contraction of animal and vegetable substances, by dryness and moisture. 2. The quantity of water absorbed from the air by chemical agents having an affinity for it. 3. The quantity of water evaporated under given circumstances. 4. The cold produced by the evaporation of water; and, 5. The dew-point; or that point of temperature at or below which dew is deposited from the atmosphere upon glass or any other smooth substance.

1. *On the Expansion and Contraction of Animal and Vegetable Substances by Dryness and Moisture*.—It has been long known that animal and vegetable substances of different kinds are subject to contraction and dilatation by moisture and dryness. Mr. Boyle made experiments on ropes, by suspending weights of 50 or 100 lb. to them, which he found were raised

HYGROMETRY.

and lowered alternately by the moisture and dryness of the air. Amongst the hygrometrical substances of this kind, that have been more or less noticed, may be reckoned ropes and cords of various kinds, such as whip-cord, catgut, &c., wood, particularly deal, ivory, whalebone, hair, beard of a wild cat, and several other vegetable productions, &c. If these bodies retained the property of being affected by moisture undiminished, they would form comparable instruments for hygrometers or rather hygroscopes; but unfortunately they all in time become less sensible than at first.

We shall here give in brief detail an account of the manner in which hygrometers, consisting of the above-mentioned materials, have been constructed.

Stretch a hempen cord or a fiddle-string, as *AB* (*Plate XII. Hydraulics, fig. 1.*) along a wall, bringing it over a truckle or pulley *B*, and to the other extreme *D* tie a weight *E*, into which fit a style, or index, *FG*. On the same wall fit a plate of metal *HI*, divided into any number of equal parts, and the hygrometer is complete.

For it is a matter of undoubted observation, that moisture sensibly shortens the length of cords and strings; and that as the moisture evaporates they return to their former length; and the like may be said of a fiddle-string. The weight, therefore, in the present case, upon an increase of the moisture of the air, will ascend; and upon a diminution of the same, it will descend.

Hence, as the index *FG* will shew the spaces of ascent and descent, and those spaces are equal to the increments and decrements of the length of the cord or gut *ABD*, the instrument will discover whether the air be more or less humid now than it was at another given time.

Or thus: if a more sensible and accurate hygrometer be required, strain a whip-cord, or fiddle-string, over several truckles, or pulleys, *A, D, E, F,* and *G* (*fig. 2.*), and proceed with the rest as in the former example. Nor does it matter whether the several parts of the cord *AB, CD, DE, EF, FG,* be parallel to the horizon, as expressed in the present figure, or perpendicular to the same. The advantage of this, above the former hygrometer, is, that we have a greater length of cord in the same compass; and the longer the cord, the greater its contraction and dilatation.

Or thus: fasten a twitted hempen cord, or fiddle-string, *HW*, by one end, sustaining a weight *W* (*fig. 3.*) to an iron hook; and let the other end descend upon the middle of an horizontal board, or table, *AB*, and fit an index *I*. Lastly, from the centre *B* describe a circle; which divide into any number of equal parts.

Now, it is matter of observation, that a cord or gut twists itself as it is moistened, and untwists again as it dries. Mr. Molyneux, secretary of the Dublin society, writes, that he could perceive this alternate twisting and untwisting in a cord, by only breathing on it eight or ten times, and then applying a candle towards it. Hence, upon an increase or decrease of the humidity of the air, the index will shew the quantity of twisting or untwisting; and, consequently, the increment or decrement of humidity, or dryness.

Or thus, fasten one end of a cord or fiddle-string, *HI*, (*fig. 4.*) to a hook *H*; and to the other end fasten a ball *K*, of a pound weight. Draw two concentric circles on the ball, and divide them into any number of equal parts; fit a style, or index, *NO*, into a proper support, *N*, so as the extremity *O* may almost touch the divisions of the ball.

Here the cord or gut twisting or untwisting, as in the former case, will indicate the change of moisture, &c. by the successive application of several divisions of the circles to the index.

Or thus: provide two wooden frames, *AB* and *CD*, (*fig. 5.*) with grooves in them; and between these grooves fit two thin leaves of ash, *A E F C* and *G B D H*, so as they may easily slide either way. At the extremes of the frames *A, B, C, D*, confine the leaves with nails, leaving between them the space *E G H F*, about an inch wide. On *I* fasten a slip of brass dented, *IK*; and in *L* a little dented wheel, upon whose axis, on the other side of the machine, an index is to be put. Lastly, from the centre of the axis, on the same side, draw a circle, and divide it into any number of equal parts.

Now, it being found by experience, that ash wood readily imbibes the moisture of the air, and swells with it; and as that moisture slackens, shrinks again; upon any increase of the moisture of the air, the two leaves *A F* and *B H*, growing turgid, will approach nearer each other: and, again, as the moisture abates they will shrink, and again recede. Hence, as the distance of the leaves can neither be increased nor diminished without turning the wheel *L*, the index will point out the changes in respect of humidity and dryness.

It is to be noted, that all the hygrometers above described become sensibly less and less accurate; and, at length, undergo no sensible alteration at all from the humidity of the air. The following is much more lasting; though no hygrometer will serve for years, like a barometer and thermometer; but whatever be the substance of which it is made, will be so altered as to become in a great degree useless.

Take the manoscope described under that article, and instead of the exhausted ball *E*, (*fig. 6.*) substitute a sponge, or other body which easily imbibes moisture. To prepare the sponge, it may be necessary to wash it first in water; and when dry again, in water or vinegar, wherein sal ammoniac, or salt of tartar, has been dissolved, and let it dry again.

Now, if the air become moist, the sponge, growing heavier, will preponderate; if dry the sponge will be hoisted up, and, consequently, the index will shew the increase or decrease of humidity of the air.

In the last mentioned hygrometer, Mr. Gould, in the Philosophical Transactions, instead of a sponge, recommends oil of vitriol, which is found to grow sensibly lighter or heavier, in proportion to the lesser or greater quantity of moisture it imbibes from the air; so that being satiated in the moistest weather, it afterwards retains or loses its acquired weight, as the air proves more or less moist. The alteration in this liquor is so great, that in the space of fifty-seven days it has been known to change its weight from three drachms to nine; and has shifted an index or tongue of a balance thirty degrees. A single grain, after its full increase, has varied its equilibrium so sensibly, that the tongue of a balance, only an inch and a half long, has described an arch one-third of an inch in compass; which arch would have been almost three inches, if the tongue had been one foot, even with so small a quantity of liquor; consequently, if more liquor, expanded under a large surface, were used, a pair of scales might afford as nice an hygrometer as any kind yet invented. The same author suggests, that oil of sulphur per campanam, or oil of tartar per deliquium, or the liquor of fixed nitre, might be substituted in lieu of the oil of vitriol.

This balance may be contrived two ways; by either having the pin in the middle of the beam, with a slender tongue, a foot and a half long, pointing to the divisions on an arched plate, as represented in *fig. 6*:

Or, the scale with the liquor may be hung to the point of the beam near the pin, and the other extreme be made so long,

HYGROMETRY.

long, as to describe a large arch on a board placed for the purpose, as represented in *fig. 7.*

Mr. Arderon has proposed some amendment in the sponge hygrometer. He directs the sponge A (*fig. 8.*) to be so cut as to contain as large a superficies as possible, and to hang by a fine thread of silk, upon the beam of a balance B, and exactly balanced on the other side by another thread of silk at D, strung with the smallest lead-shot, at equal distances, so adjusted as to cause an index E, to point at G, the middle of a graduated arch, F G H, when the air is in a middle-state, between the greatest moisture and the greatest dryness. Under this silk so strung with shot, is placed a little table or shelf I, for that part of the silk and shot which is not suspended to rest upon. When the moisture imbibed by the sponge increases its weight, it will raise the index, and also part of the shot, from the table, and *vice versa* when the air is dry. Phil. Trans. N^o 479. vol. xlv. p. 96.

From a series of hygroscopical observations, made with an apparatus of deal wood, described in the Philosophical Transactions, N^o 480, Mr. Coniers concludes, 1. That the wood shrinks most in summer, and swells most in winter, but is most liable to change at spring and fall. 2. That this motion happens chiefly in the day-time, there being scarcely any variation in the night. 3. That there is a motion even in dry weather, the wood swelling in the morning, and shrinking in the afternoon. 4. The wood, by night as well as day, usually shrinks when the wind is in the north, north-east, and east, both in winter and summer. 5. That by constant observation of the motion and rest of the wood, with the help of a thermometer, one may tell the situation of the wind without a weather-cock.

He adds that the time of the year may be known by it; for in spring it moves quicker and more than in winter; in summer it is more shrunk than in spring; and has less motion in autumn than in summer.

See an account of the method of constructing these and other hygrometers in Lowthorp's Abridg. Phil. Trans. vol. ii. p. 30, &c. and plate 1. annexed. See also Phil. Trans. vol. xliii. N^o 473. p. 6, &c. vol. xlv. p. 169, and p. 184.

Dr. Hooke's hygrometer was made of the beard of a wild oat, fet in a small box, with a dial plate and an index. See his Micrographia, p. 150, &c.

An hygrometer of this kind may be constructed in the following manner. Let A B C D (*fig. 9.*) be a square brass plate, about four inches square, with a ring or circle fixed to it, graduated on the flat and the inner edge. I C represents a very light index of brass or steel, with a small cylindrical lump in its centre, into which is fastened the top of the beard of a wild oat, by a little peg, and the other end of it in another lump, about an inch under the plate, which, having a little hole under C, allows the beard of the oat to come through, in order to carry the hand, and yet keep it in its place, without hindering it to twist and untwist. There are also two wires coming down under the middle of the plate, which hold a little cross bar, making a small frame to carry the lump that holds the bottom of the beard exposed to the air. The four feet of this instrument, two of which are seen at C, D, must be about one inch and a quarter long, to keep the frame under the plate from touching any thing which the instrument is fet upon. A B, in *fig. 10.* represents the plate, F and F two of its feet, C and D the little lumps to which the wild oat-beard, C D, is fastened; *e f* and *g h* the wires supporting the piece *f h*, and all together form an open frame, to hold the lump D. The beard passes through the hole *i*, in order to carry the index I *i*, which points to the degrees on the graduated circle A B.

The following hygrometer was contrived by Dr. Hales and Desaguliers. P c p w C, (*fig. 11.*) is a piece of lignum vitæ, cylindrical at C w P, but from C w to p a truncated cone, and serewed like the fuzee of a watch, but not so taper. The length of the instrument is about a foot, the cylindrical part an inch in diameter, and half an inch long; the large part of the serew about three quarters of an inch, and the small part half an inch; at each end there are fine steel pivots, bearing on two fine conic holes in brasses in the frame that carries the instrument, that it may turn easily. A sponge, S, hangs by a silk from the cylinder of the instrument, so as to turn it by its rising or falling; a weight W, hanging from another silk *u*, coiled upon the serew C p, keeps the sponge in equilibrio. When the sponge becomes heavier, by imbibing moisture from the air, it runs down, and draws up W; but as W comes up, its strings must advance towards C w, where, hanging farther from its centre, its power will be so increased, that it will keep the sponge in equilibrio, though its weight be increased. But as the weight rises, it will shew on the scale, D D, how much the sponge is heavier, and consequently the air moister. This instrument will be made still more sensible, when its pivots are supported by four friction wheels. Salt of tartar, or any other salt, or pot-ashes, may be put into the scale of a balance, and used instead of the sponge. Defag. Exp. Phil. vol. ii. p. 300.

In an hygrometer invented and described by Mr. Ferguson, A A A A (*fig. 12.*) is a frame of wainscot or mahogany, grooved in the longest sides, to hold the pannel B B B B of white deal board, without pinching it. The pannel is about the thickness of a crown-piece, and fifteen inches long cross-wise to the grain of the wood. The middle part projects at C and C, where it is fastened into the frame by two serews; so that this part always remains in the same place, whilst the rest of the pannel expands by moist air towards both ends of the frame, and contracts towards the middle, when the air is dry. To a pin at F is fastened one end of a small flexible cord D E, and the other end goes round the pulley G, and is fixed into the bottom of its groove at *h*. One end of another small cord, I K, is fixed into the groove of the large pulley H, at *a*, going round the part *a i* H, and passing round to M, round a small pulley L, the axis of which turns in the piece O, lying above it, and serewed to the frame at C. To the end of the cord is suspended a flatish weight N. The diameters of the pullies G and L are equal, and about one-tenth of the diameter of H. The distance of the pullies G, and pin F, will determine the expansion of the pannel between F and G: which will cause the pulley, G, to turn backward, and any point in H ten times as much; and in this proportion will the weight N be raised: therefore, if the pannel extend one-tenth of an inch by moist air, the pulley L will be turned quite round. As the air grows dry, the pannel contracts, the weight N descends, and turns all the pullies the contrary way. The back of the plate A A, (*fig. 13.*) is serewed to the other side of the frame, so that the straight edge of the plate may be even with the uppermost side of the frame, and the centre B may be directly over the centre of the pulley L (*fig. 12.*), on whose axis the index B C (*fig. 13.*) is fixed, which, by moving on the graduated edge of the plate, indicates the moisture or dryness of the air. The pannel should be changed in three or four years. (Phil. Trans. vol. liv. art. 47.) Mr. Smeaton has given the construction of an hygrometer of cord: it is, doubtless, the best that has been published constituted of that substance.

Mr. Smeaton's hygrometer is exhibited in (Plate XIII. *figs. 1 and 2.*) A B C (*fig. 1.*) is an orthographic delineation of the whole instrument seen in front, with the box-cover H, which

HYGROMETRY.

defends the index, &c. from injury, and by a glass exposes the scale to view. FG in both figures represents a flaxen cord, about 35 inches long, suspended by the turning peg F, attached to a loop of brads wire at A. This cord is that which is called by net makers in London *flaxen three-threads laid*, and is between one 20th and one 30th of an inch in diameter. It is previously boiled in a solution of two penny-weights troy of common salt in one pound avoirdupoise of water, boiled till the whole is reduced to six ounces avoirdupoise. The cord soaked in this brine is dried, and then stretched, by tying three or four yards of it to two nails against a wall, in a horizontal position, and hanging a weight of a pound or two to the middle. When it has remained in this position for a week or more in a room, it will be fit for use. G, I, (fig. 2) are two loops, or long links of brads-wire, laying hold of the index KL, which is moveable on a small stud or centre K. The cord FG is kept moderately strained by a weight M, about half a pound avoirdupoise. As the cord lengthens or shortens, the end of the index passes over the scale NQ, disposed in the arc of a circle, and containing 100 equal divisions. This scale is attached to the brads sliding ruler QP, which moves upon the directing piece RR, fixed by screws to the board, which makes the frame or base of the whole; and the scale and ruler, NQP, are retained in any place nearer to or farther from the centre K, by the screw S. Fig. 3. represents in profile the sliding piece and stud I, which traverses on that part of the index next the centre K; and which can, by the two screws of the stud, be retained upon any part of the index that is made parallel, and which is done for three or four inches from the centre, for that purpose. The stud is filed to the edges like the fulcrum of a scale-beam, one being formed on the under-side, and the other upon the upper, as near as possible to one another. A hook formed at the lower end of the wire loops, G, I, retains the index by the lowermost end of the stud, while the weight M hangs by a small hook upon the upper edge. By these means the index is kept steady, and the cords strained by the weight, with very little friction or burthen upon the central stud K. Fig. 4. is a parallelogram of plate brads to keep out dust, which is attached to the upper edge of the box-cover H, and serves to shut the part of the cover, necessarily cut away, to give leave for the wire, G I, to traverse with the sliding stud (fig. 3.) nearer to or farther from the centre of the index K. In this (fig. 4.) there is a hole *a*, about one-fifth of an inch diameter, for the wire G I to pass through, in the motion of the index, without touching; *b* is a slit of a lesser size, sufficient for the wire to pass, and allow the cover to come off without deranging the end of the index; *c, c*, are two small screws applied to two slits, by which the plate slides lengthways, in order to adapt the hole *a* to the wire G I, at any place of the stud I, upon the index KL. This index is 12 inches long, four inches of which, from the extreme end, are filed so narrow, that any part of them may serve for an index to the divisions of the scale; the scale itself also slides four inches. The directing piece, RR, is parallel to a line drawn from *o* upon the scale to the centre, K, of the index; consequently, as the attenuated part of the index forms a part of a right line drawn from the same centre, whenever the index points to *o* upon the scale, though the scale be removed nearer to or farther from the centre of the index, yet it produces no change in the place to which the index points. When the divided arc of the scale is at 10 inches from the centre, which is its mean distance, then the centre of the arc and the centre of the index are coincident. At other distances, the extremes of which are eight or 12 inches, the centre

of the divisions, and the centre of the index, pointing to them, not being coincident, the index cannot move over spaces geometrically proportionable to one another in all situations of the scale; yet the whole scale not exceeding 30 degrees of a circle, it will be found, on computation, that the error can never be so great as $\frac{1}{100}$ th part of the scale, or one degree of the hygrometer.

For adjusting the instrument, take off the box-cover, and set the instrument nearly upright about a yard from a moderate fire; there let it remain, till the index sinks as low as it will go, stroking the cord occasionally between the thumb and finger downwards. When it is become stationary, raise or depress the index by means of the peg at top, till it lies over the point *o*; then remove the instrument from the fire, and with a camel-hair pencil dipped in warm water, moisten the cord, without suffering any drops of wet to fall from it till it is saturated, and the index becomes stationary. If the index lies over the degree marked 100, all is right; if not, slacken the screw S, and slide the scale nearer to or farther from the centre, till the point 100 come under the index, and the instrument is adjusted for use. The intermediate space must then be divided into equal parts. The adjustment may be repeated two or three times a year, or as often as may be judged necessary to adapt the scale to the existing capacity of the cord. If the compass of the slide be not sufficient to effect this, slacken the proper screws, and move the sliding stud I nearer to or farther from the centre of the index, as the angle, formed by the index between the points of dry and wet, happens to be too small or too large for the scale. Mr. Smeaton was led by observation to mark the point of *o dry*, *20° the mean*, *40 moist*, *70 very moist*, and *100 wet*. Phil. Transf. vol. lxi. part i. art. 24.

Other instruments of a more delicate and portable nature have since been invented. We may form an idea of the slow and gradual manner by which a cord of this kind loses its power, by the result of a series of experiments made by Mr. Dalton, and published in his *Meteorological Essays*, 1793. A piece of whip-cord, six yards long, was hung up in a room and thrown over a pulley; it was then stretched by a weight of three ounces for some months; after which an index and a scale of inches and decimals were attached to the end having the weight. A regular series of observations were made on it three times a day for two years, and once a day for three succeeding years. The room was without fire, but airy.

The results are below: the higher numbers denote greater dryness, all other circumstances being the same.

	1788	1789	1790	1791	1792
Annual means	9.33	10.77	11.21	11.59	11.92

Hence

HYGROMETRY.

Hence it appears that a cord, in these circumstances, increases every year in length, but less and less each year, and that the range of variation diminishes each year. The quantity, however, is such as to render instruments of Smeaton's construction occasionally adjusted very comparable.

Another still more simple form of this sort of hygrometer consists of a short piece of cord or cat-gut, from four to ten inches, suspended by a hook over a horizontal board; to the lower end of the cord is fixed a horizontal index having a circular graduated scale on the board. As the cord attracts moisture or the contrary, it twists or untwists, and thereby turns the index. On this principle, the Dutch toys, called weather houses, are made; one end of the index supports a small image of a man, and the other that of a woman; the former appears, or is brought out, in wet weather, and the latter in fair weather.

M. de Luc some time ago constructed an hydrometer of ivory. The part of his hygrometer which is affected by the moisture of the air, is a hollow tube of ivory *aab* (fig. 5.) two inches eight lines long, and internally two lines and a half in diameter. This tube is open at the end *aa*, and closed at *b*, terminating in a point; and the thickness of its sides, for the length of two inches six lines from the bottom, is but three sixteenths of a line: it is this thin part which does the office of an hygrometer; the remaining part of the cylinder, towards its orifice *aa*, must be kept a little thicker, in order to bear the pressure of a tube of glass, about fourteen inches long, the lower end of which is seen at *dee*. The internal diameter of this tube is about three-eighths of a line, and the outside diameter about two lines, in order that the part *gg* of a brass piece *ffgg*, through which it passes, and which is to enter into the ivory pipe, be as thick as possible. In order to hinder that part of the tube which incloses the brass piece from being affected by the variations of moisture, it is covered with a brass ferril *bbii*. These pieces are united together with gum lac or mastich, which melts by the heating of the glass and brass. M. de Luc's reason for chusing ivory for his hygrometer, is, that this matter appeared to him more proper than any other for receiving the impression of the moisture of the air, without suffering thereby any material change. The cylinder made of it becomes more capacious, in proportion as it grows moister; and this is the fundamental principle of the instrument. M. de Luc has also found, that upon letting this cylinder lie for some time in water of an uniform temperature, it swells to a certain point, after which it dilates no farther. This circumstance furnished him with a *maximum* of humidity; and, consequently, with one point of comparison in the scale of the hygrometer; and this point he has fixed at the temperature of melting ice. For measuring the differences in the capacity of this ivory cylinder, and thereby discovering its different degrees of moisture, M. de Luc makes use of quicksilver, with which he fills the cylinder, and a part of the communicating glass tube. The more capacious this cylinder is, or, which is the same, the moister it is, the lower does the mercury stand in the glass tube, and *vice versa*. Now M. de Luc has found, that the lowest point to which it can sink, is that where it stands when the ivory cylinder is soaked in melting ice: he therefore names or graduates this point 0 in the scale of his hygrometer; and, consequently, the degrees of this scale are degrees of dryness, counted from below upwards, as the quicksilver rises in the glass tube. To give these degrees a determinate length, and thus to render the hygrometers capable of being compared with each other, M. de Luc employs in constructing them such glass tubes as have been previously prepared, by being made into thermometers, and filled with mercury, so as to ascertain upon

them the points of melting ice and boiling water, and to take exactly the distance between these points by any scale at pleasure. When this is done, the bulb of this preparatory thermometer must be broken, and the quicksilver it contains exactly weighed. It is by knowing the weight of this, together with the distance between the fixed points of the thermometer, that the scale of the hygrometer is determined. *E. gr.* Let the weight of the quicksilver be one ounce, and the distance between the above-mentioned points one thousand parts of a certain scale; then suppose that the quicksilver in the hygrometer to which this tube is to be applied, weighs only half an ounce; this will give a fundamental line, consisting of 500 parts of the same scale. The fundamental line, thus found, is applied to the scale of the hygrometer, beginning at 0, and measuring it off about four times over, that the whole variation of the instrument may be comprehended. Each of those spaces being afterwards divided into 40 equal parts, gives such degrees as M. de Luc has found most convenient. In general terms, the length of the fundamental line of the hygrometer must be to the interval between the two fixed points of the preparatory thermometer, as the weight of the quicksilver in the hygrometer is to the weight of the quicksilver in that thermometer. This proportion between the scale of the hygrometer, and that of the preparatory thermometer, furnishes an easy method of correcting in this instrument the effects of heat upon the mercury which it contains. It will easily be conceived, from the construction of the scale of this hygrometer, that if its cylinder of ivory was suddenly changed into glass, the instrument would become a true thermometer, in which the interval between the points, answering to melting ice and boiling water, would be divided into 40 parts. If, therefore, a thermometer with a scale similarly divided into 40 parts between the fixed points, be placed near the hygrometer, it will shew immediately the correction to be made on that instrument for its variations as a thermometer, under particular restrictions, which M. de Luc has stated.

The part of the frame of the instrument upon which the scale is marked is immovable; so that, before observing the point at which the mercury stands, it may be pushed upwards or downwards, according as the thermometer has risen or fallen with respect to the point of melting ice; and thus the indications of the hygrometer can at once be freed from the errors which would arise from the difference in the volume of the quicksilver, on account of the different degrees of heat.

For this purpose, at the top of this scale, there is an index over-against another small scale, marked upon the unmovable part of the frame: the degrees of this small scale are eightieth parts of the fundamental line, and answering to the degrees of the thermometer on the same frame. When the index points to 0 of the small scale, the thread which indicates upon the tube of the hygrometer the point to which the mercury sunk in the melting ice, answers likewise to 0 in the scale of the hygrometer. See an elaborate account of the principles and advantages of this hygrometer, the particular process of its construction, and observations made with it by M. de Luc, in the *Phil. Trans.* vol. lxxiii. part ii. art. 38.

The instrument, with its frame, is seen in *fig. 6.* It is mounted on deal, because this wood suffers the least change in the length of its fibres. The lower part of the frame is slit through the whole length of the ivory pipe, in order that the air may circulate freely round this pipe, and the bulb of an annexed thermometer. The hygrometer is fastened in three parts, *viz.* at bottom on a small bracket, at top by a tube passing through a piece either of hard wood

HYGROMETRY.

or of metal fastened by screws, and chiefly by means of a brass wire on the neck of the brass piece, which unites the glass with the ivory pipe. This piece is laid in a small plate of a hard wood, which in that place fills a groove originally made through the whole length of the board. To prevent dust from getting through the opening of the tube, it is shut up in a small ivory case. The scale of the hygrometer is marked upon a deal slip, which slides along the groove just mentioned. This and all the other parts of the frame must be lined with paper, for marking the necessary scales, and this paper is afterwards varnished over. The scale of the hygrometer is carried to the upper point, by means of a knob fixed on a small piece of hard wood or metal screwed to the bottom of the board, and which affords a free passage to the tube of the hygrometer.

Messrs Saussure and De Luc have both successfully prosecuted their investigations in the science of hygrometry. The former of these gentlemen wrote an essay on hygrometry, which was published in 1783. In this elaborate, and in many respects excellent work, Saussure contends for the superiority of human hair, for the purpose of hygrometers. Hair, he finds, after it has been boiled in a weak alkaline lixivium, will expand by moisture nearly $\frac{1}{5}$ th of its length, and contract again by dryness; and that it is less liable to lose this effect by time than most other substances, and is moreover, from its tenuity, very quickly reduced to the present state of the atmosphere. On these accounts he gives it the preference to other substances, and constructs his hygrometer with it accordingly. The principle of the construction is to fasten one end of the hair to a fixed point, and the other to the arbor of a small wheel, which carries a fine needle at one extremity; this needle points out, upon a graduated circular arch, the hygrometric degrees. The hair is stretched by a counterpoise of three or four grains, suspended from the same arbor by a fine silk thread. A more particular description of the construction is given by the author, in reference to plate I, fig. 1, of the essays. See *Plate XIII. Hydraulics, fig. 7.*

“The inferior extremity of the hair, *a b*, is held by the mouth of the screw-pincers, *b*; these pincers, represented separately in B, terminate in a screw, which enters into the female screw at C: this screw turns continually in its supporter, and serves to raise or depress B at pleasure. The other extremity, *a*, of the hair is held by the inferior mouth of the double moveable pincers, represented separately in A. These pincers, at their lower mouth, take hold of the hair, and at their upper a fine well tempered silver wire, which is wound round the arbor *d*, which is represented separately in D F. This arbor, which carries the needle *e e*, marked E in the separate figure, is cut like a screw, and the bottom of the thread is flat and cut square to receive the silver wire fastened to *a*, and connected to the hair. I was forced to use a silver wire, because, when the hair was fixed to the cylinder and wound round it, it grew rough, and contracted a stiffness, which the counterpoise could not overcome; whereas, a well tempered silver wire always keeps the same flexibility. It was necessary to cut the arbor like a screw, in order that this wire might not be wound upon itself and thicken the arbor, nor take a situation too oblique and variable. The wire is fixed to the arbor by a small pin F. The other end of the arbor, D, has the form of a pulley, flat at the bottom, to receive a fine flexible silk thread, to which is suspended the counterpoise marked *g* in the great figure, and G in the separate figure. This counterpoise, intended to stretch the hair, acts in a direction contrary to that of the hair, and of the moveable pincers to which it is fastened. If then it is desired the hair should be stretched with a weight of four grains, it is necessary the counterpoise should weigh four grains more

than the pincers. The same arbor passes on one end through the centre of the dial, and turns in a very small hole upon a true and well polished pivot. The other end has a similar pivot, which is received in a hole made at the end of the arm *h* of the double square *b i*, H I. This double square is fixed behind to the dial by the screw I. The dial *l e e k*, divided into 360 degrees, is supported by two ears *l, l*; these are soldered to two tubes, which surround the cylindrical columnus *m m, m m*. The screws of pressure, *n, n*, pass through these tubes, and serve to fix the dial, and the arbor attached to it, to any desired height. These two columns which support the dial, are firmly fixed to the base of the hygrometer, which rests on the four screws *o, o, o, o*, by which it may be placed in a vertical position. The square column *p p*, which rests upon the farther cross bar of the base of the hygrometer, carries a box *q*, to which is fixed a kind of pencil case *r*, the vacuity of which is of the same diameter as the cylindrical counterpoise *g*. When the hygrometer is to be transported from one place to another, and some fear may be entertained that the vibrations of the counterpoise may do harm, the case is raised to receive the counterpoise which is then fixed by the screw *s*, and the box itself is fixed by another screw *t*. When the hygrometer is to act, the counterpoise is disengaged and the box lowered, as in the figure. Lastly, there is seen on the top of the instrument a piece of crooked metal *x y z*, which binds together the three columns just described. This piece is pierced in *y* with a square hole, which is convenient when the hygrometer is to be suspended.”

M. de Luc, however contends, in his “*Idées sur la Météorologie, 1786*,” that hairs, and all other animal or vegetable hygrometric substances taken lengthwise, or in the direction of their fibres, undergo contrary changes from different variations of humidity; that when immersed in water they lengthen first and then shorten; that when they are nearest the extreme of humidity, they shorten with an increase and lengthen with a diminution of humidity. These observations may be just; but the irregularities happening only in or near one extreme, and being small, may be neglected. Saussure takes his point of extreme moisture from the air confined under a glass bell, the sides of which are kept moist: De Luc objects to this as not exhibiting the maximum of moisture, and observes, that steam in an elastic state does not render bodies moist, as is proved by the experience of Mr. Watt, who found that wood, exposed to the steam of a steam-engine, was constantly dried and cracked as if exposed to the fire. This objection can scarcely apply, however, to the case. For the steam in an engine is generally some degrees warmer than the temperature necessary for its support as an elastic fluid, and a degree or two in temperature at the heat of the boiling water, have an infinitely greater effect in drying than they have at the ordinary temperature of the atmosphere. Besides, the point of extreme moisture in a hygrometer should most evidently indicate that state of the atmosphere when evaporation is at a stand, or the air is saturated with moisture without any visible deposition of water. It cannot be supposed that there is any interval between saturation and precipitation. De Luc prefers whale-bone upon the whole for an hygrometer, and of that a small thin slip cut across the grain. The description of his whale-bone hygrometer is given in the 81st vol. of the *Philos. Transac. part ii.* as follows.

“The frame will be sufficiently known from the figure (*fig. 8.*) therefore, we shall confine ourselves to the description of some particulars. “The slip of whale-bone is represented by *a b*, and at its end, *a*, is seen a sort of pincers made only of a flattened bent wire, tapering in the part that holds the slip, and pressed by a sliding ring. The end *b* is fixed to a move-

HYGROMETRY.

able bar *c*, which is moved by a screw for adjusting at first the index. The end *a* of the slip is hooked to a thin brass wire, to the other end of which is also hooked a very thin silver gilt lamina, that has at that end pincers similar to those of the slip, and which is fixed by the other end to the axis, by a pin in a proper hole. The spring *d*, by which the slip is stretched, is made of silver-gilt wire; it acts on the slip as a weight of about 12 grains, and with this advantage over a weight (besides avoiding some other inconveniences) that in proportion as the slip is weakened with lengthenings by the penetration of moisture, the spring, by unbending at the same time, loses a part of its power. The axis has very small pivots, the shoulders of which are prevented from coming against the frame, by the ends being confined, though freely, between the flat bearings of the heads of two screws, the front one of which is seen near *e*." The section of that axis, of the size that belongs to a slip of about eight inches, is represented in fig. 9, the slip acts on the diameter *a a*, and the spring on the smaller diameter *b b*.

The point of extreme dryness is obtained in both instruments by inclosing them in a receiver of air, in which is a quantity of quicklime, which absorbs the moisture from the air and instrument; that of extreme moisture is found by De Luc, by immersing the instrument in water, or at least by wetting the whale-bone with water; but it is found by Saussure as above described.

The mean height of De Luc's hygrometer, for the whole year, in London, is about 79. The mean height of Saussure's at Paris, (according to Bouvard's observations) for 1807, was 81.5', the driest 53 and the moistest 100. The monthly means shew the air to be much drier in March, April, May, June, July, and August, than in the six succeeding months, every where in high north latitude.

2. *On the quantity of water absorbed from the air by chemical agents having an affinity for it.*—Though the action of animal and vegetable fibres on the atmosphere or the vapour in it must be of a chemical nature, yet in the instruments above noticed the quantity of waters absorbed by them makes no part of their history. In some sort of bodies however, the quantity of water they absorb from the atmosphere or part with into it, is the measure of their hygrometric action, and is determined by actually weighing the body exposed to the atmosphere. A sponge, suspended from the extremity of a balance beam, is heavier or lighter according to the hygrometrical state of the air; sulphuric acid, carbonate of potash, and other bodies, attract moisture from the air in great abundance, and when saturated according to the existing state of the atmosphere, will give or take moisture with the changes of the air, which of course may be determined by the balance. This sort of instrument however, being less portable than the other, and subject to other inconveniences, has been very generally abandoned.

3. *On the quantity of water evaporated under given circumstances.*—Some philosophers, conceiving that the best way to ascertain the disposition of the atmosphere to receive moisture, is to find by actual experiment how much water is evaporated from a given surface of water in a given time, have adopted this sort of experience as the most direct and accurate method of obtaining one object of hygrometry. Supposing the labour to be no objection, the method would answer the purpose completely, were not the influence of a greater or less current of air of so much consequence in evaporation. When the hygrometers, such as have been described, indicate dry, there can be no doubt that the air is disposed to quick evaporation; and it may be concluded conversely, that when evaporation is quick, an hygrometer would point to considerable dryness. It would be

desireable to ascertain whether a direct ratio subsists between these two effects in any given temperature; and also whether a change of temperature would disturb the ratio. Some account is given of a series of experiments on evaporation under that head, and their application to the present subject is obvious; but it is unnecessary to repeat them here.

4. *On the cold produced by the evaporation of water.*—Mr. Leslie has proposed a new hygrometer, or rather a new method of finding the rate of evaporation of water in the air; it may be seen in Nicholson's Journal, 4to. vol. 2. or in the 35th vol. of the Annales de Chimie. It is founded on the principle that evaporation produces cold, and consists of a kind of air-thermometer nicely adjusted, the bulk of which, by being moistened with water, immediately cools to a lower degree in consequence of the evaporation of the water, and the more the quicker the evaporation. Hence a law might be found to indicate, from the degree of cold produced, the rapidity of evaporation. If so, it would be a convenient substitute for the method pointed out in the preceding division. The author has not yet developed the advantages of this instrument so as to bring it into general use.

5. *On the dew-point; or that point of temperature at or below which dew is deposited from the atmosphere upon glass or any other smooth substance.*—M. Le Roi was the first, according to Saussure, who made a practice to find the dew-point of the air with hygrometrical views; he used to take a glass nearly full of water; then he gradually put into it ice-cold water, till a dew was deposited on the outside of the glass, and noted the temperature of the water. This temperature may be called the dew-point. Instead of ice-water, Saussure used pounded sal-ammoniac to cool the water; and a mixture of nitre and sal-ammoniac is still better. Saussure, however, conceives this expedient insufficient to answer the purposes of an hygrometer; though he allows the value of it taken in conjunction with the others previously described. Of late Mr. Dalton has revived the practice of Le Roi, shewn the rationale of the experiment, and founded upon it a new system of hygrometry. See Manchester Memoirs, vol. 5. part 2. pages 535 and 671: also vol. 1. second series, page 252. Some account of his views may be seen under EVAPORATION.

Mr. Dalton first establishes the fact, which indeed had been ably maintained before by De Luc, that the extreme quantity and force of vapour, in a vacuum of given dimensions, are the same as the extreme quantity of force of vapour in the same volume of any kind of air, provided the temperature is the same in both cases. That is, aqueous vapour exerts just the same whether air is present or absent, and its maximum is regulated solely by the temperature, supposing water as a source always to be present. He finds experimentally the utmost force of steam in a vacuum for each temperature, from 0° to 212° of Fahrenheit or upwards. This force is expressed in inches and decimals of mercury, which it can support in a barometer. When the force of steam in the air is required, it may be found from the dew-point; as this manifestly shews the temperature at which the steam of the air begins to be condensed. For instance, suppose the dew-point is at 45°: then the extreme force of vapour of that temperature, in a vacuum or in air, is perceptible, .316 of an inch of mercury, or $\frac{1}{3}$ th of the force of the atmosphere. Or, in a given volume of air, the weight of the vapour is $\frac{1}{7}$ th of the weight of the whole, allowing .7 for the specific gravity of pure steam. Hence we see the great importance of the dew-point, as from it the quantity of steam in any given volume of atmospheric air may be determined. Mr. Dalton extends his principles still farther than this;

HYGROMETRY.

this; he not only determines the quantity of vapour in a given volume of air, as above, for the dew-point, but he finds the whole quantity of steam in a column reaching to the top of the atmosphere; he argues, that as in an atmosphere of pure steam the force of it at the earth's surface would be its weight, so in a mixture of atmosphere, till the elastic force of each at the earth's surface is the weight of the whole atmosphere of that kind. Hence, in the above instance, the weight of the incumbent aqueous vapours in the atmosphere is $\frac{1}{4}$ th of the whole weight of the atmosphere, and is equal to 4.3 inches of water. That is, if a perpendicular column of air to the top of the atmosphere had the whole of its steam (or water) precipitated to the bottom, leaving the air perfectly dry, the depth of the water so precipitated would be $4\frac{3}{4}$ inches nearly.

Thus it appears of what use is the dew-point in finding the quantity of water actually existing in the atmosphere at any time in the form of steam or elastic vapour, which is the first great object of hygrometry. But the use of the dew-point in ascertaining the other great object of hygrometry may be easily shewn. Mr. Dalton has proved, in the Essays above-mentioned, that the quantity of water evaporated from any given surface is proportional to the maximum force of vapour at the temperature which the surface has, the vapour being always understood to be in contact with water. But that if the force of steam be small, as in low temperatures, then the force of the steam already existing in the atmosphere must be deducted from the former, as having great influence in this last case, but very little in other cases where the evaporating force is comparatively large. Thus for instance, taking the dew-point at 45° as before, and assuming the temperature of the air at the same time to be 50° ; we have $.375 - .316 = .059$ for the evaporating force; but if the temperature was $54^\circ, 58^\circ$, or 62° , the evaporating force would be 2.3, or four times as great respectively. This force does not, however, increase directly with the temperature; as 5° above 45 only produce the same evaporating force as 3° above 65 would produce, or as $\frac{1}{4}$ th of a degree above 162 would produce. Hence principally arises the much greater evaporation in summer than in winter.

In the Essays above referred to, Mr. Dalton has given an abstract of a series of observations on the dew-point for Manchester, lat. $53^\circ 20' N.$, which it may be proper to subjoin.

1800. July. Mean dew-point for 21 days = 53° , highest 62° , lowest 40° .
 Aug. Mean for 11 days = 56° , but too high for the monthly mean; highest 60° .
 Sept. Dew-point above 50 for 6 days; highest 60° .
 Oct. Dew-point mostly below 52° , highest 59 .
 1801. May. Dew-point above 50° for 4 days; highest 55° .
 June. Mean for 10 days $49\frac{1}{2}$; highest $57\frac{1}{2}$; lowest 30° . *
 July. Mean for 8 days 53° ; highest 56° .
 Aug. Mean for 22 days $54\frac{1}{2}$; highest 61° .
 Sept. Mean for 14 days 54° ; highest 60° .
 Oct. Dew-point for 5 days above 50° ; highest 57° .
 Nov. Highest 54° ; lowest 22° .
 Dec. Highest 44° ; lowest 18° .

* On the 13th, great damage done to potatoes, &c. by the cold which accompanied this remarkably low state of vapour for the season. The dew-point was 46 on the 12th, and 40° on the 14th.

In order to make the observations on the dew-point subservient to the purpose of a complete hygrometer, that is, one to denote both the actual quantity of vapour in the air,

and the rate at which evaporation is going on, it is necessary to notice the temperature of the air at the time of observation. In a series of meteorological observations this would be almost matter of course. Then the rate of evaporation obtained as above would indicate the drying power of the air at the time. A series of hygrometrical observations might then be thrown into the following form. The numbers in the last column are all multiplied by 100, to make them more suitable to common notation.

Temperature of the Air.		Hygrometer.		
		Dew-point.	Correcting quantity of Water in a vertical Column of the Atmosphere.	Evaporating force.
		Inches in depth		
June 1. Morn.	50°	45°	4.30	5.9
Noon	70	45	4.30	40.5
Even.	60	45	4.30	20.8
2. Morn.	50	48	4.77	2.4
Noon	65	50	5.10	24.1
Even.	54	49	4.92	6.6

Saussure determined by some very important experiments the quantity of water in a cubic foot of air at the temperature 66 , both by abstracting the vapour from saturated air, and by saturating previously dried air. The results agree very nearly with the above theory. But when he attempted to ascertain the quantity of vapour in other temperatures, above and below, by means of his hygrometer, not by direct experiment, he did not succeed; at least the results will not agree with those deduced as above. He finds the quantities of water too large in the lower temperatures, and too small in the higher. This will be shewn by the following table.

TABLE of the Quantity of aqueous Vapour in the Atmosphere at different Temperatures.

Dew-point. Temperature.	Water in a cubic Foot of air, in Grains, according to		Whole Quantity of Vapour in a vertical Column to the Top of the Atmosphere, being condensed into Water, according to Dalton, amounts to
	Saussure.	Dalton.	
			Inches in Depth.
0°	—	.81	.88
5	—	.96	1.04
10	2.6	1.13	1.22
15	2.8	1.36	1.56
20	3.1	1.62	1.74
25	3.4	1.97	2.11

32°	3.9	2.52	2.72
35	4.1	2.78	3.00
40	4.5	3.33	3.57
45	5.0	3.98	4.30
50	5.5	4.77	5.15
55	6.1	5.58	6.02
60	6.7	6.60	7.13
65	7.4	7.76	8.38
70	8.0	9.08	9.80
75	8.7	10.72	11.58
80	9.5	12.60	13.62

In the construction of this table, the force of vapour is taken from the table in the Manchester Memoirs, vol. v. part 2, and it is supposed to result from the pressure of an atmosphere of steam, when the fourth vertical column is calculated. The specific gravity of steam is supposed to be .7, that of common air being 1. Saussure's table in his Hygrometry, 8vo, page 261, is reduced from French grains and feet to English, by multiplying by two, and dividing by three; the grains which he gives as contained in saturated air. A reduction is also made from Reaumur's scale to Fahrenheit's.

Mr. B. M. Forster has favoured us with the following description of the winding oat-beard hygrometer.

The principal differences in this hygrometer from those usually made of oat-beards are the following.

The graduated circle (Plate XIII. *Hydraulics*, fig. 2.) is numbered *completely round* instead of *half round* each way, as usual. On the top of the oat-beard, (the *avena sterilis* of Linnæus, preferred on account of its size to the common oat,) is cemented a circular piece of paper A, on which is fixed a tubular piece of straw B, which is capped with another piece of paper C: D is a support to keep the beard upright, made of card paper. On the straw tube, or little cylinder, is fastened a piece of fine lichen string, on which is hung a pea, to serve as a weight to keep the string stretched.

As the oat-beard untwists with moisture, the index (made of straw) moves the same way round as the hand of a watch, and thus moving coils the string round the straw tube or axis, by which means the number of revolutions from any time observed may be known, and thus the confusion will be avoided, which is occasioned by the index moving more than once round, which it does in passing from extreme dryness to wet.

The spring may be so placed as to wind *up* when the index moves the contrary way, that is, from moist to dry, if the maker so chuses; and in this case the circle must be numbered the contrary way from the above. The oat-beard is *fixed*, and the index is not to be turned or set to a certain point, as in the case with the common hygrometer, by a contrivance behind the case. The method of keeping a register of this hygrometer will be thus.

When on the upper part of the axis there is one coil, and the index points at - - - 6, set down 1-6.
two coils - - - - 6, ----- 2-6. &c.

If the circle be divided into 100 divisions, the reckoning will be no coil, and the hand at 10 set down 10,

1 Coil - - - 10 ----- 110,

2 Coils - - - 10 ----- 210, &c.

which, if the circle be large enough, will be a very convenient mode of registering. An account of this instrument was communicated by the inventor to the editor of the Philosophical Magazine. See vol. xi. p. 167.

Kater's hygrometer, as constructed by Mr. Thomas Jones, of Kenton-street. (See fig. 3.) The substance of which this hygrometer is composed, was discovered in India by captain Kater about the year 1800; and is the *Andropogon contortum* of Linnæus, a species of grass, and is called in the Myfore country, in the Canarese language, "Oobeena Hoeloo." It is best when gathered in the month of January, and should be thoroughly dried in the sun (in India) before it is used. While captain Kater was in India he had one made, which he used with great effect, for the refraction, during a series of observations, which he was then officially employed in making. The instrument was described in the Asiatic Researches, and was afterwards brought to England in the year 1806. Mr. Thomas Jones then made several on that plan; but it is now laid aside in consequence of a superior method which he has contrived. It may be proper to remark, that

this hygrometric substance acts in the same manner as our beard of the English oat, but it possesses much greater durability, and is exceedingly sensible, making from eight to twelve revolutions from extreme dry to extreme moist, simply of itself, without the means of an increased scale, by wheels and pinions. Each of those revolutions being divided into one hundred parts, gives the observer a scale of from 800 to 1200 parts from dry to moist, being an extent of scale which no other hygrometer possesses. The revolutions and parts are seen on a dial plate by means of two small hands. The instrument is of a cylindrical form, one inch and a half in diameter, and two inches long, extremely portable, and not in the least liable to injury in travelling in a carriage. Its sensibility is so great, that it may be truly said to be hardly ever at rest in the open air, particularly in the summer season, when the opening or shutting a door or window, or the approach of a person, is sure to be indicated. Perhaps it may not be amiss to remark, that it is sensibly affected in the hand of a person who may be in health or otherwise. The great sensibility of this instrument makes it particularly valuable where small quantities of moisture, &c. are required to be measured, in chemical or philosophical experiments; likewise for agricultural operations, and iron, steel, and cotton manufactories, &c. &c.

HYGROPHILA, in *Botany*, so named by Mr. Brown, from *ὕγρος*, wet, and *φιλία*, to love, or *delight in*, because of the attachment of this genus to a moist, marshy soil. Brown. Prodr. Nov. Hoil. v. 1. 479.—Class and order, *Didymia Angiosperma*. Nat. Ord. *Personate*, Linn. *Acanthi*, Juss.

Ess. Ch. Calyx tubular, half five-cleft, equal. Corolla ringent. Cells of the anthers parallel, unarmed. Seeds several in each cell. Partition attached to the valves.

This genus is removed from *Ruellia* on account of the ringent corolla and tubular calyx, which latter separates moreover into five deep segments, in consequence of the swelling of the capsule. *R. ringens* of Linnæus is one species, for which the Flora Zeylanica of that author, and the Hortus Malabaricus of Rheede, are, according to Mr. Brown, improperly quoted in the Species Plantarum. Another species, very nearly allied to the former, is

H. angustifolia of Brown. "Leaves lanceolate-linear, approximated in pairs, with hairy axillas. Upper joints of the stem shorter than the corolla. Found by sir Joseph Banks in the tropical part of New Holland.

These are caulescent plants, with narrow leaves, and axillary, crowded, nearly sessile flowers. The bractæas are small and fringed. Capsule sessile, its valves compressed at the back. Each seed is supported by a small prop, or elastic appendage.

HYGROPHOBIA, in *Medicine*, is sometimes used in the same sense with hydrophobia.

HYGROSCOPE, compounded of *ὑγρός*, moist, and *σκοπεω*, I observe, or consider, is commonly used in the same sense with hygrometer, which see.

Wolfius, however, regarding the etymology of the word, makes some difference. According to him, the hygroscope only shews the alterations of the air in respect of humidity and dryness; but the hygrometer measures them. A hygroscope, therefore, is a less accurate hygrometer.

HYIOTES, *ὑγιεινός*, Filiation. See ADOPTION.

HYKES, a sort of blankets, in great use among the natives of Barbary. They are woven by the women, who make no use of a shuttle therein, but conduct every thread of the woof with their fingers. One of these hykes is usually six yards long, and five or six broad, serving the Kabyle as well as Arab, both male and female, for a complete dress in the day, and for his bed and covering in the night. It is a loose and troublesome kind of garment, being frequently

frequently disconcerted, and falling on the ground, so that the wearer is every moment to be taking it up, and folding it anew round his body. Dr. Shaw (Trav. p. 286.) takes it to be much the same with the *peplus*, if not with the *toga*, of the ancients.

HYLÆA, in *Ancient Geography*, a country of Europe in Scythia.

HYLARCHIUS, formed of *ὕλη*, *matter*, and *αρχή*, *government*, or *hylarchic principle*, a word by which some authors express what they call a ruling and presiding spirit, which governs and actuates all matter. See **PLASTIC**.

HYLAS, in *Ancient Geography*, a river, fountain, and lake in Bithynia.

HYLAS, in *Biography*, a musician and a dancer, brought up at Rome, under Pylades the Pantomime, and passionately beloved by him. He was so vain of his talents, that he arrogantly challenged his master. The challenge was accepted, the day fixed, and all Rome thronged to the theatre.

The two actors had to represent Agamemnon. The young Hylas, to add to his stature, had buskins on, which made him taller than usual, and he stood a tip-toe on the stage with all his might. The Roman youth were in raptures, and applauded with unbounded fury, crying out that he was divine!

Pylades then appeared, with a noble and dignified countenance, expressing by his steps and gestures, all the different sentiments which occupied the mind of the great king. The spectators, unanimously impelled by an irresistible approbation, rapturously cried out that he had obtained the victory. "Young man," says Pylades to Hylas, "we had to represent a king who commanded twenty kings; you have made him tall, and I have made him great."

HYLE, or **HYLEG**, from *ὕλη*, which signifies *matter*, among *Alchemists*, is their first matter, or it is matter considered as produced by nature herself; called also *chaos*.

HYLEG, or **HYLECH**, in *Astrology*, an Arabic term for a planet, or for a point of the heavens, which in a man's nativity becomes, as is pretended, the moderator and signifier of life.

HYLEGIAL PLACES, among *Astrologers*, are those wherein a planet being found, is qualified to have the government of life attributed to it.

HYLLEHROG, in *Geography*, a very narrow island, about three miles long, on the Baltic, near the S. coast of Lapland. N. lat. 54° 36'. E. long. 11° 32'.

HYLLIS, in *Ancient Geography*, a peninsula, called also the "Promontory of Diomedes," a cape of Liburnia, on the Adriatic sea.

HYLOBII, or **HYLOBIANS**, compounded of *ὕλη*, which, besides *matter*, signifies also *wood*, *forest*, and *βίος*, *life*, a sect of Indian philosophers, thus denominated by the Greeks, because they retired to forests, to be more at leisure for the contemplation of nature.

HYLOPATHIANS, formed of *ὕλη*, *matter*, and *παθός*, of *πάσχω*, *I suffer*. See the following article, and **ANAXIMANDRIANS**.

HOLOZOISTS, formed of *ὕλη*, *matter*, and *ζωή*, *life*, the name of a sect of atheists among the ancient Greek philosophers, who held matter to be animated; maintaining that matter had some natural perception, without animal sensation, or reflection, in itself considered; but that this imperfect life occasioned that organization, whence sensation and reflection afterwards arose. Of these, some held only one life which they called a *plastic* nature, presiding regularly and invariably over the whole corporeal universe, which they represented as a kind of large plant or vegetable: these were called the *cosmoplastic* and *stoical* atheists, because the Stoics

held such a nature, though many of them supposed it to be the instrument of the Deity. Others thought that every particle of matter was endued with life, and made the mundane system to depend upon a certain mixture of chance and plastic or orderly nature united together. These were called the *Stratonici*, from Strato Lampfacenus, a disciple of Theophrastus, called also *Phylicus*, (Cicero, De Nat. Deor. lib. i. cap. 13.) who was first a celebrated Peripatetic, and afterwards formed this new system of atheism for himself. Besides these two forms of atheism, some of the ancient philosophers were *Hylopathians*, or *Anaximandrians*, deriving all things from dead and stupid matter, in the way of qualities and forms, generable and corruptible; and others again adopted the anatomical or *Democritical* system, who ascribe the production of the universe to atoms and figures. See on this subject Cudworth's *Intellectual System*, vol. i. book i. chap. 3. Birch's edit. 1743.

HYLOGYNÆ and **HYLOPHAGI**, in *Ancient Geography*, a people of Ethiopia, who lived near one another, and were distinguished by similar manners; they made their habitations in the trees during the night for fear of wild beasts. Dioscorus has described them.

HYMÆAS, in the *Ancient Greek Music*. See **ΕΡΜΑΥΛΙΑ**.

HYMEN, in *Anatomy*, from *ὑμῶν*, a *membrane*, a fold of membrane of various sizes in different individuals, closing to a greater or less degree the entrance of the vagina in the virgin, but not found after marriage. See **GENERATION**.

HYMEN, *Imperforate*. See **VAGINA**, *Imperforate*.

HYMEN, in *Botany*, is used for a fine, delicate skin, where-with flowers are inclosed while in the bud, and which bursts as the flower blows or opens.

The term *hymen*, in this sense, is particularly used in speaking of roses.

HYMEN, in *Mythology* and *Poetry*, a term of invocation. *Hymen*, or *Hymenæus*, is properly a fabulous divinity, supposed by the ancients to preside over marriages; and who accordingly was invoked in epithalamiums, and other matrimonial ceremonies, under the formula, *Hymen o Hymenee!*

The poets generally crown this deity with a chaplet, sometimes of roses, at other times of sweet marjoram; and represent him, as it were, dissolved and enervated with pleasures; dressed in a yellow robe, and shoes of the same colour, with a torch in his right-hand, and a flame-coloured veil in his left. Catullus, in one of his epigrams, addresses him thus:

"Cinge tempora floribus,
Suaveolentis amaraci."

It was for this reason, that the new married couple bore garlands of flowers on the wedding day; which custom also obtained among the Hebrews, and even among the Christians during the first ages of the church, as appears from Tertullian, De Corona Militari, where he says *Coronant et nuptæ sponsas*. St. Chrysostom likewise mentions these crowns of flowers; and to this day the Greeks call marriages *στειφανισμα*, in respect of this crown or garland.

HYMENÆA, in *Botany*, from *Hymen*, the god of marriage, because, as Linnæus informs us, its younger leaves cohere together in pairs throughout the night. This genus is the *Courbaril* of Plumier, who adopted that barbarous term from the inhabitants of South America, where the plant grows spontaneously. May not the similitude which its gum, when burnt, bears to the torch of Hymen, by emitting a clear flame, and grateful smell, be another satisfactory explanation of the above name?—Linn. Gen. 206. Schreb. 276. Willd. Sp. Pl. v. 2. 512. Mart. Mill. Dict.

v. 2. Ait. Hort. Kew. v. 2. 49. Juss. 351. Lamarck. Ill. Instr. t. 330. Gærtner. t. 145.—Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceae*, Linn. *Leguminosae*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, leathery; tube short, turbinate, compressed, permanent, having an oblique mouth; limb four-cleft, nearly equal, erect, deciduous; segments ovate, obtuse, two opposite ones flattish, a little broader; the two others concave, with one side narrower. *Cor.* somewhat papilionaceous, of five, nearly equal petals, inserted into the neck of the calyx; standard, the two uppermost petals obliquely ovate, obtuse, sessile, at the upper concave segment of the calyx; wings, two petals, similar, lateral, a little narrower; keel, the bottom petal, channelled or hollowed out, approximating to the wings, within the lower concave segment of the calyx. *Stam.* Filaments ten, distinct, awl shaped, erect, deflexed nearly half way down, very long, within the keel and wings, inserted into the neck of the calyx; anthers linear, affixed to the back. *Pist.* Germen fabre-shaped, compressed, standing on a stalk; style very long, taper, deflexed; stigma thickened, obliquely truncated. *Peric.* Legume very large, ovate-oblong, obtuse, of one cell, filled with a powdery pulp. *Seeds* many, ovate, imbedded in dust and fibres.

Obs. Schreber has paid great attention to the above generic character, which is considerably dilated beyond the Linnæan description.

Ess. Ch. Calyx five-cleft. Petals five, nearly equal. Style twisted inwards. Legume filled with a farinaceous pulp.

1. *H. Courbaril*. Locust-tree. Linn. Sp. Pl. 537. (Courbaril; Plum. Gen. 49. t. 36. Ceratia diphyllos; Pluk. Phyt. t. 82. f. 3.)—Native of the Well India islands, and the continent of America. A large spreading tree, its thick stem being covered with a russet bark. It is esteemed an excellent timber tree if suffered to be old before it is felled. *Leaves* in pairs, pointed. *Flowers* in loose panicles at the end of the branches, of a yellow colour, striped with purple. *Pods* fleshy, brown, shaped like the common garden bean, about six inches long and half as broad, of a purplish brown colour and woody consistence, each containing a few seeds separated by transverse partitions, and inclosed in a whitish substance, intermixed with filaments, as sweet as honey, which is eaten by the Indians with great avidity. Between the principal roots of the tree exudes a fine transparent resin, yellowish or red, which is the *Gum Anime* of our shops. This is the finest varnish known, when dissolved in rectified spirits of wine. It has been remarked that the wild-bees are very fond of building their nests in the branches of this tree. Its wood is in great request for wheel-work in the sugar-mills, particularly for cogs to the wheels, being extremely hard and tough, as well as capable of a fine polish. It is so heavy that a cubic foot of it weighs about a quarter of an hundred weight. The *Hymenæa* is a very tender stove-plant, and must constantly remain in the tan-bed. In growth it is very like the *Anacardium*, or Cashew-nut.

Willdenow has described two other species, *H. venosa* of Vahl, and *H. verrucosus* of Gærtner; the former brought from Cayenne, the latter from Madagascar, but they both nearly resemble the Courbaril, nor have we materials sufficient to decide concerning them.

HYMENÆUM, in the *Ancient Greek Music*, the nuptial song or epithalamium.

HYMENIUM, in *Botanical phraseology*, from *ὑμν*, a membrane, is used by Persoon for the membranous smooth expanded surface in which the seeds of Fungi are imbedded. See FUNGI.

HYMENODES, of *ὑμν*, membrane, and *ἰδος*, form, an epithet applied by the old authors to such urine as is found

to be full of little films and pellicles. Hippocrates also applies it to the menstrual discharges, when they are mixed with a tough viscid phlegm.

HYMENOPAPPUS, in *Botany*, from *ὑμν*, a film or membrane, and *πᾶπιος*, the seed down, so called by L'Heritier from the crown of its seed being composed of membranous leaves or scales.—Willd. Sp. Pl. v. 3. 1776. L'Herit. Monograph.—Michaux Boreal. Amer. v. 2. 103. (Rothia; Lamarck. Illustr. t. 667.) Class and order, *Syngenesia Polygamia Æqualis*. Nat. Ord. *Compositæ discoidea*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common calyx* of many leaves, set in a double row, these leaves are loosely spreading, oblong, obtuse, green and downy at the base, white above, permanent. *Cor.* compound, tubular, uniform; florets all similar, perfect, fertile, longer than the calyx, funnel-shaped, hairy on the outside; tube thread-shaped; limb five-cleft, lanceolate, acute, revolute. *Stam.* Filaments five, capillary, erect; united anthers cylindrical, tubular, five-toothed, as long as the florets. *Pist.* Germen inferior, turbinate, hairy, crowned with the seed-down, and terminated by a roundish body which the thread-shaped style perforates; stigma on the outside, bifid, revolute. *Peric.* none, except the permanent calyx. *Seeds* solitary, angulated, truncated, elevated by the disk in two concentric rows, umbilicated, villose, brown; down of 12 or 15 approximating, erect, ovate, concave, somewhat torn or entire, membranous, pellucid scales. *Recept.* naked, rather small.

Ess. Ch. Receptacle naked. Seed-down of many scales, chaffy. Calyx of many leaves, spreading.

1. *H. scabigerus*. L'Heritier Monog. cum icone.—Native of Carolina, flowering towards the end of autumn. *Root* annual, somewhat tapering, and fleshy, a little branched at the sides, of a chestnut colour. *Stem* erect, branching, angulated, rather woolly, two feet high. *Leaves* alternate; radical ones on footstalks; stem-leaves gradually sessile, bipinnatifid; segments lanceolate, acute, green above dotted with little tubercles; downy and grey beneath; spreading. *Flowers* forming a corymbus, white, very fragrant.

The publication of L'Heritier, in which this new genus is founded and delineated, is one of those monographs, of which twelve copies only were printed, mentioned in our account of that author. See L'HERITIER.—Lamarck has described the same plant under the name of *Rothia carolinensis*, in the *Journal d'Hist. Nat.* vol. i.

HYMENOPHYLLUM, from *ὑμν*, a film, or membrane, and *φυλλον*, a leaf, because the foliage of this fern is remarkable for its filmy texture. Sm. Mem. of the Turin Acad. v. 5. 418. t. 9. f. 8. *Tracts* on Nat. Hist. 256. *Fl. Brit.* v. 3. 1141. (Trichomanes; Linn. Gen. 560. Juss. 16.)—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*, Linn. Juss.

Gen. Ch. Fructifications inserted into the margin of the frond, distinct. *Involucrum* two-valved, flattish, straight, opening outwards, including the column.

Ess. Ch. Fructifications placed at the edge of the frond. *Involucrum* of two valves, opening outwardly.

Obs. "The bivalve involucrum and short column so distinct from the urn-shaped undivided involucrum, and long column or style, of the true Trichomanes," have induced Dr. Smith to establish this new genus in his dissertation on Ferns, printed by the academy of Turin.

1. *H. Tunbridgensis*. Tunbridge Filmy-leaf. Sm. *Fl. Brit.* 1141. *Engl. Bot.* t. 162. (Trichomanes Tunbridgensis; Linn. Sp. Pl. 1561.)—"Frons alternately bipinnate, decurrent, sharply ferrated as well as the involucrum. Fructifications solitary at the upper edge of the base of each general division of the frond."—A native of moist and shady

rocks which it clothes in large tufts in Wales, Westmoreland, and the north of Yorkshire, and also by Powers-court cascade near Dublin, but more especially about Tunbridge, which is its original habitat. It flowers in May and June.—*Root* creeping, capillary, wiry, throwing out fibres occasionally and producing numerous upright *fronds*, which curl backwards from drought. Their substance is extremely membranous and pellucid, appearing finely reticulated under a microscope; their segments linear, sharply serrated and furnished with a strong central rib. *Frustrifications* in the place of the first segment, each terminating its appropriate nerve and pointing upwards. *Involucrum* arising from the substance of the leaf, of two slightly concave valves, between which is a short column, beset with small, round, bivalve capsules, each embraced with an elastic ring as in the more common ferns.

2. *H. alatum*. Wing-stalked Filmy-leaf. Engl. Bot. t. 1417. (H. Tunbridgensis β. Sm. Fl. Brit. 1142.)—“Fronds tripartite, lobed, decurrent; segments linear, bluntish, entire. Main stalk and branches winged. *Frustrifications* oblong, crenate, solitary at the upper edge of the base of each subdivision of the frond.”—Gathered in the county of Kerry, by Mr. Mackay, gardener to the botanic garden at Dublin.—This rare fern manifestly differs from the last in having a larger and more compound frond, and in its *main stalk* being winged from the very bottom; but more especially in the margin of the segments being always entire, and in the *involucrum* or *calyx* being oblong and cylindrical, not obovate and compressed, except towards the summit; neither is its margin serrated or toothed, but slightly and obtusely crenate. Dr. Smith remarks of this species, “Few of our British plants have been more enveloped in doubt than this; very few could better repay the scrutiny of the curious botanist.” We are now competent to describe it as a new species, for it does not agree with the character of any *Hymenophyllum* in Dr. Swartz’s Essay on Ferns in Schrader’s Journal. Dr. Swartz has there described 20 species, but the only two British ones known may serve as a sufficient epitome of the genus. We must not omit to mention that Mr. Brown, in his Prodr. Nov. Holl. v. 1. 159, refers the *H. alatum* to *Trichomanes*.

HYMENOPTERA, in *Entomology*, an order instituted by Linnæus for the reception of those insects which have four membranaceous wings, and the abdomen of the female mostly armed with a sting. The genera are cynips, tentredo, firex, ichneumon, sphex, ammophila, scolia, thynnus, leucopsis, tiphia, chalcis, chrysis, vespa, apis, formica, and mutilla.

HYMETTIUM MARMOR. See MARBLE.

HYMETTUS, in *Ancient Geography*, a mountain of Attica, S.W. of Athens, and of the Ilius, extending from the S.W. to the N.E., at the distance of a league from the city. It was celebrated for the excellent quality of its honey, which is highly extolled by Strabo, l. ix. It was also famous for its marble. On this mountain were altars, one consecrated to Jupiter, and the other to Apollo. See Pausanias, in Attica, c. 32.

HYMN, a song, or ode in honour of God; or a poem proper to be sung, composed in honour of some deity. See ODE and SONG.

The word is Greek, ὕμνος; *hymu*; formed of the verb ὕδα, *celebro*, I celebrate.

Lidore, on this word, remarks, that hymn is properly a song of joy, full of the praises of God; by which, according to him, it is distinguished from *threna*, which is a mourning song, full of lamentation.

The hymns, or odes, of the ancients, generally consisted

of three stanzas or couplets; the first called *strophe*; the second, *antistrophe*; and the last, *epode*.

St. Hilary, bishop of Poitiers, is said to have been the first that composed hymns to be sung in churches; he was followed by St. Ambrose. Most of those in the Roman breviary were composed by Prudentius. They have been translated into French verse by Messieurs De Port Royal. The Te Deum is also commonly called a hymn, though it be not in verse; so also is the *Gloria in excelsis*.

In the Greek Liturgy there are four kinds of hymns; but then the word is not taken in the sense of a praise offered in verse, but simply of laud, or praise. The angelic hymn, or *Gloria in excelsis*, makes the first kind; the *trifagion*, the second; the cherubic hymn, the third; and the hymn of victory and triumph, called εἰσμαὶ, the last.

HYMN of Castor, in the *Musick of the Ancients*. The Lacedæmonians, in marching to battle, played on the flute what they called *Castoreum Melos*. Some authors pretend that Castor himself invented this hymn, and that from him it had its name; others that Minerva invented the hymn of Castor, and that this air served at first for the Pyrrhic dance.

HYMN of Aristotle to Hermias.

Aristotle honoured his friend and kinsman, Hermias, prince of Atarnea, with a hymn, or canticle, which is preserved in Athenæus, and in Diogenes Laertius, for which he is said to have been arraigned at a court of justice, where he was accused of impiously lavishing upon a mortal such honour and praise, as were due only to the gods.

Aristotle’s Hymn to Hermias.

“Virtue! thou source of pure delight,
Whose rugged mien can ne’er affright
The man with courage fir’d;
For thee the sons of Greece have run
To certain ills, which others shun,
And gloriously expir’d.

“When’er thy sacred seeds take root,
Immortal are the flow’rs and fruit,
Unfading are the leaves;
Dearer than smiles of parent kind,
Than balmy sleep, or gold refin’d,
The joys thy triumph gives.

“For thee the Twins of mighty Jove,
For thee divine Alcides strove
From vice the world to free;
For thee Achilles quits the light,
And Ajax plunges into night,
Eternal night, for thee.

“Hermias, the darling of mankind,
Shall leave a deathless name behind
For the untimely slain;
As long as Jove’s bright altars blaze,
His worth shall furnish grateful praise,
To all the Muse’s train.”

The offence given by Aristotle in this poem, which his enemies denominated a Pæan, seems to have been the saying that the actions of his friend would be sung by the Muses, as long as the worship of Jupiter Hofpitalis continued. Athenæus, however, did not regard it as a true Pæan, because the characteristic exclamation *Io Pæan* did not occur in any part of it.

HYMN of Battle, a kind of air which was sung by the Greeks when they advanced to battle, and began to charge instead of the shout, which was used at other times. Traces of this custom are still found amongst the Arnauts, inhabit-

ants of Macedonia, now subject to the Turks. These people, stout and bold, like their ancestors, engage with a rapid pace; the chief sings, and his troops answer, whilst they press forward with an accelerated velocity. These hymns ought to be short, and consist of short verses, set to a lively air. Horace speaks in one of his odes of a poet called Tyræus, who, in the wars of Messina, animated by his verses the Lacedæmonians to such a degree, that they thus gained a complete victory. In the time of Thucydides, however, the Lacedæmonians marched in silence to the sound of flutes, and by its cadence regulated their steps, the better to preserve their ranks. It was this, without doubt, which gave marshal Saxe the first idea of marching to time; one of the best plans that could be devised to perfect the military art.

HYMNIA, in *Mythology*, a surname given to Diana, under which appellation she was worshipped, and had a temple in Arcadia.

HYMNUS, *Lat.* *hymno*, *Gr.* a song in honour of gods or heroes. The difference between a *hymn* and a *canticle* consists in this, that the canticle more generally relates to actions, and the hymn to persons. The first songs of all nations have been canticles or hymns. Orpheus and Linus passed among the Greeks for the authors of the first hymns, and there remain among the works of Homer a collection of hymns to the gods.

We have a fine translation of the hymn of Callimachus to Apollo, by Prior, and of Homer's hymn to Venus, by Congreve.

HYNE-LOUGH, in *Geography*, the name given to a small bay on the south coast of Ireland, in the county of Cork, which lies west of Toe-head, between it and Baltimore.

HYNNERY, a town of Sweden, in the province of Smaland; 45 miles W.S.W. of Wexio.

HYOBANCHE, in *Botany*, from *ύς, ύς, a bog*, and *αγγυ, to choke or strangle*; at least so it appears by the analogy of *Orobanche*, which Linnæus certainly had in view.

Schreb. 421. Willd. Sp. Pl. v. 3. 354. Mart. Mill. Dict. v. 2. Juss. 101. Lamarck Dict. v. 3. 158.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personata*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth of seven, linear, pointed, erect leaves, as long as the corolla. *Cor.* of one petal, ringent; upper lip vaulted, emarginate; lower lip none. *Stam.* Filaments four, in pairs, inserted at the base of the corolla, of a middling length; anthers ovate, drooping, bursting on the upper side. *Pist.* Germen superior, ovate; style thread-shaped, curved at the top; stigma thickish, obtuse, emarginate. *Peric.* Capsule roundish, two-celled. *Seeds* numerous, small.

Obf. This genus is separated from *Orobanche* on account of the structure of its calyx and corolla.

Eff. Ch. Calyx of seven leaves. Corolla ringent, having no lower lip. Capsule of two cells and many seeds.

1. *H. sanguinea*. Linn. Mant. 253. (*Orobanche mauritanica*, flore purpureo; Pet. Gaz. t. 37. f. 4).—Found at the Cape of Good Hope growing parasitically on other roots. *Stem* about six inches high, quite simple, woody, imbricated with leaves which are formed of ovate, thickly imbricated, outwardly convex, smooth, obtuse scales. *Spike* terminal, villose, imbricated with bracts and flowers, which latter are solitary and sessile. In habit and structure this genus is nearly allied to *Orobanche*, but is of a blood-red colour throughout.

HYO-GLOSSUS, in *Anatomy*, a muscle of the tongue. See **DEGLUTITION**.

HYOIDES, from *υ*, and *ειδος, form*, a bone resembling

the Greek letter upsilon in its shape, and connected to the root of the tongue. See **DEGLUTITION**.

HYO-PHARYNGEUS, a name sometimes given to the middle constrictor pharyngis muscle. See **DEGLUTITION**.

HYOSCYAMUS, in *Botany*, from *ύς, ύς, a bog*, and *αυυ, a bean*. Ælian relates that if this plant be devoured by swine its effects are extremely noxious, and that the animals which partake of it will die, unless they are well drenched with water both internally and externally.—Linn. Gen. 98. Schreb. 133. Willd. Sp. Pl. 1010. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 254. Ait. Hort. Kew. v. 1. 240. Tournef. t. 42. Juss. 124. Lamarck Dict. v. 3. 327. Illustr. t. 117. Gært. t. 76.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Lurida*, Linn. *Solanæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, tubular, ventricose below, with a five-cleft, acute mouth, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical, short; limb straight and spreading, five-cleft half way down, its segments obtuse, one broader than the rest. *Stam.* Filaments five, awl-shaped, inclining; anthers roundish. *Pist.* Germen roundish; style thread-shaped, as long as the stamens; stigma capitate. *Peric.* Capsule ovate, obtuse, marked with a line on each side, two-celled, seeming to be formed of two capsules closely approximating, with a lid opening horizontally; receptacles half-ovate, affixed to the partition. *Seeds* numerous, rugged.

Eff. Ch. Corolla funnel-shaped, obtuse, irregular. Stamens inclined. Capsule with a lid, two-celled.

1. *H. niger*. Common Henbane. Linn. Sp. Pl. 257. Engl. Bot. t. 591. Woodv. Med. Bot. t. 52.—“Leaves sinuated, embracing the stem. Flowers sessile.”—Common in waste ground by the road side throughout England, more especially on a dry calcareous soil, flowering in July. *Root* annual, spindle-shaped. *Stem* branched, round. *Leaves* alternate, sessile, oblong, sharply sinuated. *Spikes* terminal, simple, recurved, accompanied with leaves. *Flowers* sessile, erect. *Calyx* pitcher-shaped, reticulated with veins. *Corolla* yellow, very gracefully pencilled with a net-work of purple veins. The whole plant is hairy, viscous, poisonous, and narcotic, except its seeds, whose oil counteracts their noxious properties. “The seeds and capsules together, smoked as tobacco, are in some places a popular remedy for the toothache, but convulsions and temporary insanity sometimes follow its use.”

2. *H. reticulatus*. Egyptian Henbane. Linn. Sp. Pl. 257. (*H. flore rubello*; Ger. em. 355. f. 5).—“Stem-leaves on footstalks, sinuated, acute; floral-leaves entire. Flowers ventricose.” Native of Crete, Syria and Egypt.—It flowers in July—This annual is very similar to the common Henbane, but differs in having its stem-leaves ovate, bent upwards, and smoother on the upper side; the floral-ones sessile and entire. *Flowers* on a very short stalk, bell-shaped, red, beautifully reticulated with dark veins; their tube swollen.

3. *H. albus*. White Henbane. Linn. Sp. Pl. 257. Ger. em. 353.—“Leaves on footstalks, sinuated, obtuse. Flowers sessile.”—Native of the south of Europe, flowering in August.—This also resembles *H. niger* in habit and structure, but the leaves are more rounded or obtuse, very soft, clothed with white hairs, as is also the stem. *Flowers* fewer; lower ones on longer stalks than the upper. *Capsule* membranaceous, ventricose at the bottom. *Seeds* numerous, small, kidney-shaped, of a whitish ash-colour.

Linnæus observed a variety of this species having the throat of the corolla coloured with dark purple and green.

4. *H. aureus*. Golden-flowered or shrubby Henbane. Linn. Sp. Pl. 257. Curt. Mag. t. 87.—“Leaves on footstalks,

stalks, bobed, dentate, acute. Flowers on stalks. Fruit pendulous."—A native of Crete and other parts of the East. It is very commonly cultivated in this country, as it flowers almost through the summer, and is extremely ornamental.—*Root* biennial (perhaps perennial.) *Leaves* roundish, acutely indented on their edges, hairy. *Flowers* at each joint of the stem, of a bright yellow colour with a dark purple base. *Style* much longer than the corolla. Alpinus and other authors make two varieties of this, differing only in size and the shade of colour in the corolla.

5. *H. muticus*. Smooth or beardless Henbane. Linn. Mant. 45. Willd. n. 5. Schumdel. Ic. t. 71.—Leaves on footstalks, ovate, acutely angled. Calyx without awns. Bractæas undivided.—Native of Egypt and Arabia.—*Stem* a foot high, erect, roundish, somewhat pubescent. *Branches* axillary, shorter. *Leaves* alternate, obtusely sinuated, acute, entire, palish. *Raceme of flowers* all directed one way, curved in at the top. *Calyx* bell-funnel-shaped, not at all spinous. *Flowers* campanulate; at first green on the outside, then whitish; on the inside very dark purple, but finally, the whole flower becomes white and unspotted. *Stamens* declining, purple, a little longer than the corolla. *Pistil* longer, declining.

6. *H. pufillus*. Dwarf Henbane. Linn. Sp. Pl. 258. (*H. pufillus aureus americanus*; Pluk. Phyt. t. 37. f. 5.)—"Stem-leaves lanceolate, toothed; floral-leaves in pairs, entire. Calyx furnished with spines."—Native of Persia.—*Root* annual. *Stem* six inches in height, brittle, hairy. *Leaves* alternate, on long hairy stalks. *Calyx* turbinate, ten-angled, nearly the length of the corolla, and broader than its tube, spiny at top. *Corolla* yellow with a black throat, divided on the lower side beyond the limb. *Stamens* declining.

7. *H. physalodes*. Purple-flowered Henbane. Linn. Sp. Pl. 258. Amœn. Acad. v. 7. t. 6. f. 1. Curt. Mag. t. 852.—"Leaves ovate, quite entire. Calyx inflated, sub-globular."—A native of Siberia, flowering in March and April. *Root* perennial. *Stems* a foot high, simple, erect, round, rough with hairs. *Leaves* alternate, heart-shaped, entire, dark-green, hairy underneath, the upper ones gradually larger. *Flowers* in bundles, terminal, of a purple colour, funnel-shaped, erect. *Stamens* a little shorter than the corolla, converging. *Style* as long as the corolla. *Stigma* capitate, emarginate, whitish. This plant seems to be *Pulmonaria hirta*, Linn. Sp. Pl. App. 1667.

8. *H. Scopolia*. Night-shade leaved Henbane. Linn. Mant. 46. Willd. n. 8. Curt. Mag. t. 1126—"Leaves ovate, entire. Calyx inflated, campanulate."—A native of Carniola, flowering in May.—*Root* perennial; *st.* nearly a foot high, forked. *Leaves* alternate, occasionally opposite, lanceolate-ovate, naked, entire. *Stalks* axillary, single-flowered. *Flowers* pendulous. *Calyx* smooth, beardless. *Corolla* bell-shaped, very similar to that of *Atropa Belladonna*, the deadly nightshade. *Filaments* hairy, straight. *Capsule* globose, of two cells.

Obs. These two last species *H. physalodes* and *Scopolia* differ from the rest in having the fruit seldom opening, and a more regular corolla.

HYOSCIAMUS Peruvianus, henbane of Peru, a name by which Dodonæus and many other authors have called the tobacco plants, more usually known by the name nicotiana.

HYOSERIS, from *ὄσος*, a swine, and *σῆσις*, a kind of lettuce, whence its English appellation swine's lettuce, or swine's succory. Linn. Gen. 404. Schreb. 531. Willd. Sp. Pl. v. 3. 1612. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 339. Ait. Hort. Kew. v. 3. 130. Juss. 169. Lamarck. Dict. v. 3. 158. Illustr. t. 654. Gærtn. t. 160. (*Taraxacaltrum*; Vail. Mem. Acad. des Sc.—ann. 1721.) Class and order,

Syngenesia Polygamia Æqualis. Nat. Ord. *Compositæ Semiflosculoſæ*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common calyx* cylindrical-angular, about eight or ten-cleft, permanent; scales lanceolate, erect, acute, somewhat keeled, equal, calyced at the base with very short close scales. *Cor.* compound, somewhat imbricated, uniform; each flower hermaphrodite; proper, of one petal, tongue-shaped, linear, truncated, five-toothed. *Stam.* Filaments five, capillary, very short; anthers united, tubular. *Pist.* Germen oblong; style thread-shaped, the length of the stamens; stigmas two, reflexed. *Peric.* none; common permanent calyx close or spreading. *Seeds* solitary, oblong, membranaceous, streaked on one side along the middle, almost the length of the calyx; the marginal ones broadest; down sessile, chaffy. *Receptacle* naked.

Ess. Ch. Calyx almost equal. Down simple, chaffy. Receptacle naked.

1. *H. minima*. Swine's succory. Linn. Sp. Pl. 1138. Engl. Bot. t. 95. (*H. mascula*; Ger. em. 288.)—"Stem divided, destitute of leaves. Flower-stalks swelling upwards."—Found in barren sandy gravelly fields, but rather sparingly, flowering in June.—*Root* annual, small, spindle-shaped. *Leaves* radical, depressed, oblong, toothed, now and then entire, rough, particularly at their edges. *Stems* three, four, or more, round, smooth, taper, and purplish at the bottom, under the flowers hollow and inflated, with here and there a few scattered, pointed, erect bractæas. *Flowers* solitary, small, lemon-coloured; florets very obtuse, and toothed. *Seeds* crowned with an elevated chaffy border.

Several species of this genus, of which Willdenow reckons eight in all, require revision, nor are the generic characters well defined. In some instances the crown of the seed is encompassed with hairs.

HYOSYRIS, a name given by Pliny and some other authors to the common knapweed, or *jacea nigra*.

HYO-THYROIDEUS, in *Anatomy*, a muscle passing between the os hyoides and the thyroid cartilage, and described in the article *DEGLUTITION*.

HYPACARIS, or *HYPACYRIS*, in *Ancient Geography*, a river of Scythia, which sprung, according to Herodotus, from a lake, and passing through the middle of the country of the Scythian Nomades, discharged itself into the Euxine sea, near the town of Carcinites, forming on the right Hylæa and the Curſus Achilles.

HYPACTIC MEDICINES, formed of *ὑπαίρειν*, *I take away*, a term used by some authors for cathartic medicines.

HYPÆA, in *Ancient Geography*, one of the islands called Stæchades, now Hieres, situated on the coast of Gallia Narbonnensis.

HYPÆPA, a town of Lydia, between the Tmolus and the Cayster.

HYPÆSIA, a country of the Peloponnesus, in Triphylia.

HYPÆTHROS, or *HYPÆTHRION*, *ὑπερθεῖον*, formed of *ὑπερ*, *under*, and *θεῖον*, *air*, in the *Ancient Architecture*, a kind of temple, open at the top, and thereby exposed to the air.

The hypæthron, according to Vitruvius, is an open building or portico, such as anciently were certain temples that had no roof or covering. Of this we have an instance, in the temple of Jupiter Olympius, built by Cossutius, a Roman architect at Athens.

Of hypæthrons, some were decastyle, others pycnostyle; but they had all rows of columns within-side, forming a kind of peristyle; which was essential to this sort of temple.

HYPALLAGE, *IMMUTATION*, a grammatical figure, whereby,

whereby, of different expressions which give the same idea, we make choice of that which is least natural and obvious; or, when there is a mutual permutation or change of cases, moods, regimens, &c.

The term is formed of ὑπαλλάττω, *I change*, composed of ὑπο and ἀλλάττω, *I change*; of ἀλλοί, *another*.

As in this instance, *Dare classibus aulicos*; instead of *Dare classes aulicas*.

HYPANA, in *Ancient Geography*, a town of Triphylia, E. of Achæron and N. of Typanæ.

HYPANIA, a town of the Peloponnesus in the Elide; probably the same with Hypana.

HYPANIS, a river of European Scythia, since named the *Bog*. According to the ancients it originated in a large lake, called the "Sea of the Hypanis."

HYPAPANTE, or HYPANTE, a name which the Greeks give to the feast of the purification of the holy Virgin, or the presentation of Jesus in the temple.

The words are Greek, ὑπᾶντε, and ὑπαπαντε, which properly signify *humble*, and *lowly meeting*; being compounded of ὑπο, *under*, *beneath*, and ἀντα, or ἀπανταν, *I meet*, of αντι, *contra*, *against*. The denominations are taken from the meeting of old Simœon, and Anna the prophetess, in the temple, at the time the child Christ Jesus was brought thither.

HYPARNA, in *Ancient Geography*, a town of Asia, in Lycia, according to Arrian.

HYPATA, a town of Greece, and one of the principal towns of Thessaly, according to Apuleius, Asia. Aur. l. i. —Also, a country of Asia, on the river Sangar.

HYPATE, ὑπάτη, in the *Greek Music*, an epithet by which the Greeks distinguished the lowest tetrachord, and the lowest string of each of the two lowest tetrachords.

HYPATE *Hypaton*, was a tone higher than the *proslambanomenos*. See *Greek SCALE* and *NOTATION*.

HYPATE *Μεσση*, ὑπάτη μεσση, the lowest string of the second tetrachord, which was also the most acute of the first, as these tetrachords were conjoint. See *CONJOINT*.

HYPATE *Prima*, in *Music*, is an interval, so called by M. Henling, whose ratio is $\frac{2}{3} = 358 \text{ S} + 7 \text{ f} + 31 \text{ m}$, or the *FIFTH*, which see.

HYPATIA, in *Biography*, a female philosopher of the Eclectic sect, was the daughter of Theon, a celebrated mathematician of Alexandria, who flourished in the fourth and fifth centuries. The talents of his daughter were cultivated with great assiduity, and she was made mistress of the different branches of polite learning, and became intimately conversant in the sciences of geometry and astronomy, as they were at that day understood. She next applied herself to philosophy, and is said to have excelled all the philosophers of her time. So high was her reputation, that she was strongly solicited to become a public preceptress in the school where Ammonius, Hierocles, and other celebrated philosophers taught: and such was her attachment to science, that she yielded to the public voice, and became an instructor in the schools. Here she explained the principles of philosophy, and endeavoured to reconcile the systems of Plato, Aristotle, and other masters. The celebrity of her name attracted scholars from all parts, and she gained the respect and admiration not only of those who formed her auditories in the schools, but the most eminent characters in Alexandria, and was even consulted by the magistrates in cases of importance. She is said, however, not to have been intoxicated by the respect which was paid to her from all quarters; that though she excelled most of the philosophers of the age in mathematical learning and science, she discovered no pride, and though she was in person exceedingly beautiful, she never yielded to

the impulse of vanity, nor ever gave occasion to the slightest suspicion against her chastity. Possessed of such extraordinary accomplishments and virtues, her house became the resort of persons of learning and distinction; but her talents excited the jealousy of mean and little minds, and the attainments to which she was indebted for her celebrity proved the occasion of her destruction. Orestes, a man of liberal education, and intimately acquainted with Hypatia, whom he frequently consulted, was governor of Alexandria; and Cyril, a bishop of great authority, but haughty, violent, and intolerant in the highest degree, filled the patriarchal chair of that city. This prelate, who perhaps did not wish to appear the avowed persecutor, infligated the populace to plunder the property of the Jews, by forcibly expelling them from Alexandria. Orestes, resenting his conduct, laid the affair before the emperor; who, declining to interfere in the dispute, the city became a scene of frequent tumults and contests between the partizans of the prelate and governor. The intimacy of Orestes with Hypatia now became a ground of jealousy to Cyril, who felt indignant that his rival should have it in his power to be benefited by her sage advice, on which account she was calumniated by the bishop's friends among the monks and Christian populace, and at length she fell a sacrifice to their malignity. Not satisfied with her life, they put her to the most extreme torture, and then treated her dead body with the utmost indignity. Hypatia was murdered in the year 415, under the reign of Theodosius II. by the consent and wishes, if not by the direct instigation, of Cyril, a bishop of what was falsely called Christianity. The Christian religion teaches every thing that is excellent, kind, and praiseworthy, and the actions of malignant priests are not to be imputed to the creed which they profess, but to the rancour of heart, which is but too frequently found in the tyrants of the world, in ecclesiastical as well as civil polity. Moreri. Enfield's Hist. Phil.

HYPATOIDE, in *Music*, a note, or air, in a low pitch.

HYPATOIDES, grave sounds. See *LEPSIS*.

HYPATON, DIATONOS. See *DIATONOS* and *SYSTEM*.

HYPÆLYPTUM, in *Botany*, a name of whose meaning we can discover nothing. Can it have been corrupted from the *Hypolytrum* of Richard and Persoon, which has a great appearance of being the same genus? For this suggestion we are indebted to Mr. Brown.—Vahl. Enum. v. 2. 283. Brown. Prodr. Nov. Holl. v. 1. 219.—Class and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juss.

Gen. Ch. *Cal.* Spike closely imbricated on all sides, with obovate concave scales, one of them to each flower; perianth of two membranous linear valves, nearly as long, and opposite to each scale. *Cor.* none. *Stam.* Filaments three; anthers linear. *Pist.* Germen superior, oblong-ovate; style one, cloven, deciduous; stigmas two or three, undivided. *Peric.* none. *Seed* solitary, naked, obscurely triangular, without any hairs at the base.

Eff. Ch. Scales imbricated every way, single-flowered. Perianth of two valves, opposite to each scale. Corolla none. Seed one, naked, beardless.

This genus is allied to *Kyllingia*, with which it agrees in habit. The species in Vahl are four;

1. *H. pungens*. "Spikes ovate-oblong. Scales obtuse. Involucrum spinous-pointed."—Supposed to be a native of South America. *Stems* two feet high.

2. *H. argenteum*. "Spikes ovate. Scales acute. Style three-cleft. Leaves linear."—Native of the East Indies and of Senegal. *Stem* a foot high. *Flowers* very white.

3. *H. sphacellatum*. "Spikes ovate. Styles two-cleft.

Leaves.

Leaves linear."—Found at Tranquebar. A foot high. Spikes whitish, brown when old.

4. *H. filiforme*. "Spikes oblong. Stem thread-shaped. Leaves bristle-shaped."—Native of Guinea. Glaucescous, six inches or more in height. Spikes dark brown when old.

The roots of all are fibrous and purple. Stems triangular, erect, without joints. Leaves two or three, channelled, rigid, rough-edged, sheathing. Involucrum mostly two-leaved. Spikes terminal, sessile.

To these Mr. Brown adds a fifth.

5. *H. microcephalum*. "Spikes ternate, nearly globose. Scales linear-wedge-shaped, awned. Involucrum of two very long leaves."—Native of the tropical part of New Holland. The stem is slender, triangular.

HYPECOUM, appears to be derived from *υπηχυειν*, to rebound, because its seed-vessels when touched by the hand burst with a crackling noise. This genus is the *υπηκοουμ* of Dioscorides, and Hypecoum of Pliny.—Linn. Gen. 66. Schreb. 90 Willd. Sp. Pl. v. 1. 704. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 1. 168. Sm. Prodr. Fl. Græc. v. 1. 107. Juss. 236. Lamarck Dict. v. 3. 160 Illustr. t. 88. Gærtn. t. 115. (Hypecoon; Tournef. t. 115.) Class and order, *Tetrandria Digynia*, Nat. Ord. *Corydalis*, Linn. *Papaveraceæ*, Juss.

Gen. Ch. Cal. Perianth small, of two, ovate, acute, erect, opposite, deciduous leaves. Cor. of four petals, the two exterior ones opposite, broader, trifid, obtuse; the two inner alternate with the others, trifid half way down; the middle segment concave, compressed, erect. Stam. Filaments four, awl-shaped, erect, covered by the middle segment of the inner petals; anthers erect, oblong. Pisl. Germen superior, oblong, cylindrical; styles two, very short; stigmas acute. Peric. Pod long, curved inwards, jointed. Seeds globose, compressed, a single one in each articulation of the seed-vessel.

Obs. The stamens of *H. erectum* appear to be tetradynamous.

Ess. Ch. Calyx of two leaves. Petals four, the two outer ones broader. Fruit a pod.

1. *H. procumbens*. Linn. Sp. Pl. 181. (Cuminum coriiculatum, five Hypecoum Clusii; Ger. em. 1067. 3.)—"Pods curved, compressed, jointed. The two larger petals obtusely three-lobed." Native of the south of Europe, and cultivated, by Gerarde, in this country, before 1597. It flowers in June and July, ripening seed in August.—Root simple, annual, fibrous. Leaves chiefly radical, much divided, pale green, with a greyish or glaucous tinge. Stems several, slender, compressed, naked at bottom, but furnished with a few leaves at the upper part, amongst which the flower-stalks appear, each supporting a small yellow flower. Pod grooved with longitudinal streaks. Seeds from ten to twenty, dark brown.—*H. patens*, Willd. Hort. Berol. t. 5, seems not different from this.

2. *H. littorale*. Willd. n. 2. Jacq. Collect. v. 2 205. Ic. Rar. v. 2. t. 309.—"Pods jointed, compressed, curved. Petals entire, the outer ones longer and linear-spatulate."—A native of dry sand on the shores of Germany.—This is scarcely more than a variety of the last, as it differs only in the leaves being shorter and more acutely toothed, with entire and paler petals.

3. *H. pendulum*. Linn. Sp. Pl. 181. (Cuminum siliquosum; Ger. em. 1067. 2.)—"Pods drooping, round, cylindrical. The larger petals obtusely three-lobed."—A native of the south of France, flowering in June and July.—Stem more slender, and standing more erect than in *H. procumbens*. Leaves also longer and narrower. Flowers smaller, appearing at the divisions of the branches, they are yellow like those of the greater Celandine, but less.

4. *H. erectum*. Linn. Sp. Pl. 181. Amn. Ruth. 58. t. 9. "Pods erect, round, torulose. The larger petals emarginate, three-lobed." Amman received seeds of this plant from Dauria, and Miller from Iltria; the latter cultivated it here before 1759. This has much the appearance of the last in leaf and flower, but its pods grow erect, and are writhed and twisted about.

5. *H. imberbe*. Sm. Prodr. Fl. Græc. n. 278.—Pods curved, compressed, jointed. All the petals beardless.—Found by Dr. J. Sibthorp in the isle of Cyprus. A figure of this species is destined for the Fl. Græca, t. 156. It has the habit of the rest.

Obs. The juice of these plants is of a yellow colour, resembling that of Celandine, and is said to have the same narcotic effect as opium.

HYPELATE, from *υπερ*, under, and *δενδρον*, a fir-tree, so named by Dr. Patrick Browne. Schreb. 730. Browne Jan. 208. Swartz Prodr. 61. Class and order, *Polygamia Monœcia* Schreb. rather *Gandria Monogynia*.

Gen. Ch. Perfect Flowers. Cal. Perianth of five (seldom four) ovate, concave, spreading, deciduous leaves, two of which are less than the rest. Cor. Petals five, ovate, a little less than the calyx, deciduous, with a nectariferous cell about the germen. Stam. Filaments eight, spreading, placed round the base of the germen, the length of the corolla; anthers ovate-cordate. Pisl. Germen globose, superior; style short, erect; stigma deflexed, triangular, three-furrowed, acute. Peric. Drupa pulpy, roundish. Seed. Nut oval, very smooth; kernel solitary. Male Flowers on the same tree, but in a distinct pasticle. Cal. Cor. and Nest. the same as in the perfect flowers, from the middle of which last arise the Stam. Filaments eight, converging at the base, either erect, reflexed or ascending, broader at the base; anthers ovate-cordate. Pisl. The triangular rudiment of a germen; style awl-shaped, very small.

Ess. Ch. Calyx five-leaved. Corolla of five petals. Stigma bent down, triangular. Drupa single-seeded.

1. *H. trifoliata*. Swartz Prodr. 61. Browne Jan. 208. (Cytisus arboreus, foliis obtusis glabris; Sloane Jan. v. 2. 33.) Found at Jamaica by the river-side under the town and on the red hills very plentifully. This tree has many trunks, each about four or five inches in diameter, covered with a smooth cinnamon-coloured bark. Branches upright. Leaves always three together at the end of a common footstalk, of a yellowish green colour, very smooth, having one middle rib, and some transverse ones. Dr. Browne observes that it is full of slender branches, and furnished with many leaves of the same texture and grain with those of *Lignum Vitæ*, but remarkably different in form and disposition. He never saw the fruit in a perfect state.

HYPENEMIUS, an epithet applied by authors to barren eggs, or such as a hen lays before she has been trod by the cock. They are also called *æphyria ova*, and had both these names from the winds being supposed to generate them.

HYPER, a Greek word used in the composition of divers terms derived from that language.

The Greek preposition *υπερ*, *hyper*, literally signifies above, beyond; and in composition it expresses some excess, or something beyond the signification of the simple word it is joined with.

HYPER, *Supra*, below. See EPI.

HYPER-ÆOLIAN, the penultima in the acute of the fifteen modes in Greek music, of which the fundamental or key-note was a fourth above the Æolian mode. Neither the hyper-æolian, nor the hyper-lydian mode was so ancient as the rest; nor is either of them mentioned by Aristoxenus;

Aristoxenus; and Ptolemy, who admitted only seven modes, comprehended neither of them in his list.

HYPERANTHERA, in *Botany*, from ὑπερ, upon, and ανθηρα, an anther, so named by Forskall, in allusion to the superior length or projection of two of the stamens. Forsk. Egypt. Arab. 67. Willd. Sp. Pl. v. 2. 535. Vahl. Symb. v. 1. 30. (Anoma; Loureir. Cochinch. v. 1. 278. Moringa; Schreb. 741. Burmann. Zeylan. t. 75. Juss. Gen. 348. Lamarck. Illustr. t. 337.) Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, in five deep segments, inferior. *Cor.* irregular, of five obovate petals, inserted betwixt the segments of the calyx: the upper one largest. *Stam.* Filaments 10, awl-shaped, unequal; anthers roundish, some of them often imperfect. *Pistl.* Germen linear, superior; style longer than the stamens; stigma simple. *Peric.* Pod long, straight, pulpy, of one cell, and three rugose, spongy valves. *Seeds* numerous, roundish, with three wings.

Ess. Ch. Calyx in five deep segments. Petals unequal, inserted into the calyx. Legume long, straight, of three valves. Seeds winged.

Obs. The last species has a bivalve legume, and seeds without wings.

1. *H. decandra*. Willd. n. 1. (Anoma Moringa; Loureir. Cochinch.)—"Flowers decandrous. Leaves bipinnate; lower leaflets ternate. Legumes somewhat octagonal."—A native of many parts of India; observed by Loureiro at Bengal. This tree is of a middling size. Branches spreading. Leaves alternate, unequally bipinnate; leaflets obovate, smooth, entire. Flowers white, in scattered panicles. Legume awl-shaped. Seeds furnished with three membranous wings, and arranged in a straight and simple order along the valves.

2. *H. Moringa*. Willd. n. 2. (Anoma Moringa; Loureir. Cochinch. Guilandina Moringa; Linn. Sp. Pl. 546. Jacq. Ic. Rar. v. 3. t. 461.)—"Flowers semi-decandrous. Leaves bipinnate, lower leaflets ternate. Legumes triangular."—A native of Ceylon and Egypt. This species very nearly approaches the last in size and habit, but its leaves are opposite, and flowers less brilliant. Legume more than a foot long, triangular, sometimes square. Seeds triangular and winged, disposed in a single row; these are the "Ben-nuts," formerly much used by perfumers for their oil, which absorbs and retains scents very powerfully.

3. *H. femidecandra*. Willd. n. 3. Vahl. Symb. v. 1. 30.—"Flowers semi-decandrous. Leaves bipinnate, simply pinnate at the top."—A native of Arabia. Leaves unequally bipinnate, consisting of six or eight pair of opposite leaflets, on short stalks, larger by degrees towards the top, remote, smooth. Flowers in paniced clusters. The common and partial flower-stalks alternate.

4. *H. cochinchinensis*. Willd. n. 4. (Anoma cochinchinensis; Loureir. Cochinch.)—"Flowers semi-decandrous. Leaves bipinnate, downy. Legumes two-valved. Seeds naked."—Found in the woods of Cochinchina. A tree about ten feet high with ascending branches. Leaves opposite, unequally bipinnate; leaflets nearly ovate, downy. Flowers white, in scattered panicles. Legume oblong, somewhat compressed, attenuated at either end.

HYPERBATON, or **HYPERBASIS**, in *Grammar* and *Rhetoric*, is a transposition, or a figurative construction, inverting the natural and proper order of the terms of a discourse.

The word is ὑπερβατον, or ὑπερβασις, derived of ὑπερβαινω, *transgredior*, I go beyond; formed of ὑπερ, ultra, beyond, and βαινω, eo, I go.

The hyperbaton, Longinus observes, is no other than a transposal of sentiments, or words, out of the natural order and method of discourse, and always implies great violence, or strength of passion, which naturally hurries a man out of himself, and distracts him variously. Thucydides is very liberal in hyperbatons.

Quintilian calls the hyperbaton *verbi transfressio*. It is of use to enliven and animate the discourse: it is very proper to express a violent passion, and represent an agitation of mind in the liveliest manner.

HYPERBIBASMUS, ὑπερβιβασμος, in *Rhetoric*, a figure which inverts the order of construction. Cornelius Nepos gives an instance of it in his life of Chabrias: "Athenienses diem certam Chabriæ præstituerunt, quam autem domum nisi redisset, &c. for ante quam."

HYPERBOLA, in *Geometry*, one of the Conic Sections, is formed by the common section of a plane and a conic surface, when the cutting plane neither meets the whole contour of the cone, nor is parallel to a plane that touches the conic surface.

A plane, such as we have just described, being indefinitely extended, will likewise cut the opposite conic surface, and the common section will be another hyperbola perfectly similar to the former one. The two curves, formed by the intersection of the same plane, with two opposite conic surfaces, are called opposite sections, or opposite hyperbolas.

For the definitions relating to the hyperbola, and opposite hyperbolas, we must refer to the article **CONICS**; as we must likewise do for the chief properties which these curves have in common with the other conic sections: in this place we intend to treat of the more noted properties peculiar to the particular curves under consideration.

1. If a parallelogram be completed by drawing parallels to the asymptotes of an hyperbola from any point in the curve, that parallelogram will be constantly of the same magnitude.

Let CA, CB (*Plate X. Conics, fig. 1.*) be the asymptotes of an hyperbola, and let two parallelograms CPMQ, Cpmq, be formed by drawing parallels to CA, CB, through M and m, any two points in the curve: these parallelograms are equal. Let two lines, GF and HK, parallel to one another, be drawn through M and m to cut the asymptotes. Then by similar triangles,

$$GM : MP :: Hm : mp,$$

$$FM : MQ :: Km : mq.$$

Therefore, $GM \times MF : PM \times MQ :: Hm \times Km : mp \times mq.$

But (*Cor. 27. Con.*) $GM \times MF = Hm \times Km.$

Therefore $MP \times MQ = mp \times mq.$

Therefore the parallelograms CPMQ, Cpmq, are equal (*23. 6. E.*)

Cor.—If MP, a parallel to one asymptote, meet the other asymptote in P, then the rectangle CP × PM is constantly of the same magnitude.

2. A triangle formed by two asymptotes of an hyperbola, and a tangent of the curve which meets them, is constantly of the same magnitude.

Let a tangent of a hyperbola cut the asymptotes CA, CB (*fig. 1.*); from the point of contact M, draw MP parallel to CB, and MQ parallel to CA; then the line TS will be bisected in M (*21. Con.*); hence it is plain that the triangle CTS is the double of the parallelogram CPMQ, and consequently the triangle is constantly of the same magnitude (1).

3. *Lemma.*—Let DE (*fig. 2.*) be parallel to AC, one side of a triangle, then the line BF, drawn from the angle opposite

HYPERBOLA.

opposite to AC, through O, the intersection of AE and DC, will bisect AC.

Let BF cut DE in G. Then, because the parallels DE and AC are cut by three lines drawn through B,

$$DE : EG :: AC : CF.$$

And because the same parallels are cut by three lines drawn through O,

$$DE : EG :: AC : AF.$$

Therefore (11. 5. E.)

$$AC : CF :: AC : AF.$$

Consequently (9. 5. E.) $AF = FC$.

4. A straight line drawn from the intersection of two tangents of an hyperbola (figs. 3. and 4.), or opposite hyperbolas, through the centre, will bisect the line drawn between the points of contact.

Let TM and TN be two lines touching an hyperbola, or opposite hyperbolas in M and N; then TC, drawn through the centre, will bisect MN. Let the line which touches the curve in M meet the asymptotes in G and H; and the line touching in N, meet the same lines in K and L; join HK and GL. Then the two triangles GCH and LCK are equal (2); take away, or add, the triangle KCH, and the two triangles KGH and KLN will likewise be equal: therefore KH is parallel to LG (39. 1. E.); and MN, which bisects HG and KL (21. Con.), will likewise be parallel to KH and GL (2. 6. E.) Now TC will bisect GL (Lem.); therefore it will also bisect MN parallel to GL.

5. If a tangent of an hyperbola meet a diameter, and an ordinate be applied to the same diameter from the point of contact; then the semi-diameter will be a mean proportional between the segments lying between the centre and the tangent, and the centre and the ordinate.

First let a tangent HB (figs. 5. and 6.) meet a transverse diameter CA, and let HF be an ordinate to the same; draw AM a tangent of the curve to meet BH in M; draw HA and CM cutting AH in O, and HF in N; join AN. Because AH is bisected in O (4), and AM parallel to HF (1. Cor. 16. Con.), it is manifest that AMHN is a parallelogram. Because AM is parallel to HF, therefore

$$CM : CN :: BA : BF.$$

And because AN is parallel to BH, therefore

$$CM : CN :: CB : BA.$$

Consequently (11. 5. E.)

$$CB : BA :: BA : BF.$$

Secondly, let the tangent HB and ordinate HF be drawn to a second diameter CA; draw the diameter CD, conjugate to CA, and therefore parallel to HF; draw also HT parallel to CA, and therefore an ordinate to CD; let HB cut CD in S.

Then (29. Con. et alternando)

$$CA^2 : CA^2 + CF^2 :: CD^2 : HF^2.$$

But, on account of similar triangles,

$$CB : BF :: CS : HF, \text{ or } CS \times HF = CF^2.$$

But, by the first case, $CS \times HF = CS \times CT = CD^2$; therefore (11. 5. E.)

$$CA^2 : CA^2 + CF^2 :: CB : BF.$$

Convertendo $CA^2 : CF^2 :: CB : CF$, or $CB \times CF : CF^2$;

$$\text{therefore } CA^2 = CB \times CF.$$

6. The difference of the squares of any two conjugate diameters of an hyperbola, is equal to the difference of the squares of the two axes.

Let CD (fig. 7.) be the transverse axis of an hyperbola, and CM any other transverse diameter, and draw the tangents BDE, PMQ, limited by the asymptotes; also draw

CR from the centre perpendicular to PQ. Then because the triangles BCE and PCQ are equal (2), the rectangles $BC \times CE$ and $PC \times CQ$ will also be equal (23. 6. E.); but,

$$\left. \begin{aligned} 2 BC \cdot CE &= BC^2 + CE^2 - BE^2 \\ 2 PC \cdot CQ &= PC^2 + CQ^2 - PQ^2 \end{aligned} \right\} (12 \ \& \ 13. \ 2. \ E.)$$

therefore $BC^2 + CE^2 - BE^2 = PC^2 + CQ^2 - PQ^2 =$

(because BE and PQ are bisected in D and M (21. Con.))

$$2 CD^2 - 2 BD^2 = 2 CM^2 - 2 MP^2. \text{ Therefore}$$

$$CD^2 - BD^2 = CM^2 - MP^2,$$

and BD is half the conjugate axis, and MP half the diameter conjugate to CM.

7. If a parallelogram be completed by drawing straight lines through the extremities of two conjugate diameters of opposite hyperbolas, so as to be parallel to the diameters themselves, that parallelogram will be constantly of the same magnitude, and equal to the rectangle contained by the two axes.

Let MN and PQ (fig. 8.) be two conjugate diameters of opposite hyperbolas, and let the parallelogram FHKG be formed by drawing parallels to MN and PQ through the extremities of the same lines; then, because HM and MK, as well as FN and NG, are all equal to PC or CQ (Def. 16. Con.); and HK and FG, both parallel to PQ, are tangents of the hyperbolas; it is plain that the four angular points of the parallelogram will be upon the asymptotes of the curves (Def. 16. Con.); therefore the triangle HCK is always of the same magnitude (2); and consequently the parallelogram FHKG, which is quadruple of the triangle, is likewise constantly of the same magnitude. And the same parallelogram is equal to the rectangle contained by the axes; because the parallelogram becomes a rectangle when the conjugate diameters MN and PQ become the two axes of the hyperbolas.

8. If NE and MF (fig. 9.), two tangents of opposite hyperbolas, be both parallel to the semi-diameter CP, and be intersected by a third tangent DEF, which cuts them in E and F; then $CP^2 = NE \times MF$: and if the semi-diameter CQ be parallel to the tangent DEF; then $CQ^2 = DE \times DF$.

Join MN, which will pass through the centre C (Cor. 18. Con.), and draw DO parallel to NE and MF, and DR parallel to MN. Then MC and CP are conjugate semi-diameters, and DO is an ordinate to MC, and DR an ordinate to PC; therefore

$$OC : CN :: CN : CL \quad (5)$$

$$\text{Convertendo et Alternando, } ON : NL :: CN : CL$$

$$\text{Componendo } OL : LN :: ML : CL$$

therefore, by similar triangles

$$OD, \text{ or } RC : NE :: MF : CS;$$

$$\text{Consequently } MF \times NE = RC \times CS = CP^2 \quad (5).$$

Again,

$$DE : EN :: CQ : CP \quad (\text{Cor. 1. 28. Con.})$$

$$DF : MF :: CQ : CP;$$

$$\text{therefore } DE \times DF : MF \times EN :: CQ^2 : CP^2$$

$$\text{and because } MF \times EN = CP^2$$

$$\text{therefore } DE \times DF = CQ^2.$$

9. Two straight lines MF and Mf (fig. 10.), drawn from any point in the curve of an hyperbola, make equal angles with the tangent MT drawn from the same point.

Let MT meet the transverse axis in T, and draw MK perpendicular to the same axis produced. Then

$$Mf^2 - MF^2 = fK^2 - KF^2 \quad (47. 1. E.)$$

$$\text{that is, } (Mf + MF) \times (Mf - MF) = fK \times (fK + KF);$$

but

HYPERBOLA.

but $Mf - MF = 2AC$ (42. Con.), $fK + KF = 2CK$;

$$\text{therefore } AC \times \frac{Mf + MF}{2} = CF \times CK:$$

$$\text{Consequently, } AC : CF :: CK : \frac{MF + Mf}{2};$$

$$\text{but (5), } CT : CA :: CA : CK,$$

$$\text{ex æquo, } CT : CF :: CA, \text{ or } \frac{Mf - MF}{2} : \frac{Mf + MF}{2}.$$

and, componendo et dividendo

$$fT : TF :: Mf : MF.$$

Therefore (3. 6. E.) MT bisects the angle fMf .

10. If MP (fig. 10.) touch an hyperbola, and MF be drawn from the point of contact to either focus; then CP , drawn from the centre parallel to MF , and limited by the tangent, will be equal to AC , half the transverse axis.

Draw Mf to the other focus, and draw fP meeting MF , produced if necessary, in H : because $fC = FC$, and CP is parallel to FH , therefore $fP = PH$: consequently, since MP bisects the angle fMF (9), $MH = Mf$ (3. 6. E.): therefore $FH = Mf - MF = AB$ (42. Con.); and $CP = \frac{1}{2}FH = AC$.

Cor. 1.—The line fP will be perpendicular to the tangent MP .

For MP , which bisects the vertical angle of the isosceles triangle fMH , will cut the base MH at right angles.

Cor. 2.—If fP and Fp be drawn from the two foci perpendicular to a tangent of the hyperbola, the points P and p will be in the circumference of the circle described upon the transverse axis as a diameter.

11. The rectangle under FP and fP (fig. 10.), two perpendiculars drawn to any tangent of the curve, is equal to the square of half the conjugate axis.

For the points P and p are in the circumference of the circle described upon the greater axis AB ; therefore if fP meet the circle again in O , the segment OPp , which contains a right angle, will be a semi-circle, and OC and Cp will be one straight line, and the triangles fCO and $F Cp$ will be equal, and $AO = pF$. But $Pf \times fO = Pf \times Fp = fA \times fB = fC^2 - CA^2 = \text{square of half the conjugate axis}$ (Def. 23. Con.).

12. A straight line TF , (fig. 11.) drawn from the intersection of two tangents of an hyperbola, or opposite hyperbolas, to one of the foci, will make equal angles with the lines MF and NF drawn from the points of contact to the same focus.

Draw Mf , Nf to the other focus, and in MF , NF , produced, if necessary, take $MQ = Mf$, and $NP = Nf$; and join Tf . Because TN bisects the angle fNF (9), and $Nf = NP$, therefore $TP = Tf$ (4. 1. E.): for a like reason $TQ = Tf$: therefore $TP = TQ$; because $PF = NF - Nf$, and $FQ = Mf - MF$, therefore $PF = FQ$ (42. Con.) Hence it is plain that the angle $TFN = \angle TFQ$ (8. 1. E.)

Cor. 1.—The angles which TF makes with one tangent, are equal to the angles which Tf makes with the other tangent.

For the triangles MTf and MTQ are equal, and the angle $MTf = \angle MTQ$; also, the angle $FTP = \angle FTQ$.

And taking the differences of these equals,

$$fTP - MTF = MTF;$$

$$\text{therefore } fTP = 2NTf = 2MTF.$$

$$\text{And } NTf = MTF$$

$$MTF = NTf.$$

Cor. 2.—If two tangents of an hyperbola, drawn from the

extremities of a chord passing through the focus, meet in T (fig. 12.); then TF will be perpendicular to the chord MN . For the angles MFT , NFT , are in all cases equal; and when MF and FN become one right line, each of the angles is a right angle.

13. If MN (fig. 12.) be any chord drawn through the focus of an hyperbola, and PQ , likewise drawn through the focus, be ordinately applied to the transverse axis, then $4MF \times FN = MN \times PQ$.

Draw MS , NR , perpendicular to the transverse axis, and NG , PH , MK , perpendicular to the directrix that corresponds to the focus F . Then (43. Conics)

$$PF : PH, \text{ or } FL :: MF : MK \text{ or } LS$$

$$(17. 5. E.) PF : PH :: MF - PF : FS;$$

$$\text{in like manner, } PF : PH :: PF - FN : FR$$

$$(11. 5. E.) \text{ and alternando, } MF - PF : PF - FN :: FS : FR.$$

$$\text{By similar triangles, } FS : FR :: MF : FN;$$

$$\text{therefore } MF - PF : PF - FN :: MF : FN;$$

$$\text{and } (MF - PF) \times FN = (PF - FN) \times MF;$$

$$\text{whence } 2MF \times FN = MN \times PF,$$

$$\text{and } 4MF \times FN = MN \times PQ.$$

14. If a tangent of an hyperbola, as DE (Plate XI. fig. 13.), intersect two perpendiculars drawn from the extremities of the transverse axis in the points D and E ; then two right lines, drawn from these points to one of the foci, as F , will contain a right angle.

Draw FM to the point in which DE touches the curve, and produce FM to S : then, because DB and DM are tangents, therefore the angle $DFM = \angle DFB$ (12). And, in like manner, because AE and EM are tangents, the angle $AFE = \angle EFS$: therefore the angle EDF is half the sum of the angles AFS and AFM , or a right angle.

Of Conjugate Hyperbolas.—It has been proved, that if MN (fig. 14.), limited by the asymptotes of an hyperbola, touch the curve in P , then MN will be bisected in P (21. Con.), and the triangle $M CN$ will be constantly of the same magnitude: whence it follows that, supposing MN to be drawn so as to make the triangle $M CN$ always of one constant magnitude, the middle point P of MN will be constantly in the curve of an hyperbola, of which CP and CQ (CQ being parallel and equal to PM) are conjugate semidiameters, and the lines CM and CN are the asymptotes. Draw MG , in the angle adjacent to $M CN$, to pass through Q ; then the triangle $M CG$ will be equal to the triangle $M CN$, and Q will be the middle of MG : therefore, according to what has been observed, Q will always be found in the curve of an hyperbola, of which MG is a tangent, and MC and CG are the asymptotes: and this hyperbola is so related to the first one, that the terminations of the second semidiameters of the one curve are in the other curve, as is plain from what has already been said. Four hyperbolas, comprehending the two we have been describing, and their corresponding opposite hyperbolas are called *conjugate hyperbolas*: such curves lie in opposite angles of the same asymptotes, and the extremities of the second diameters of two of the opposite hyperbolas are in the two remaining opposite hyperbolas.

The most remarkable properties of conjugate hyperbolas are as follows:

1. The second diameters of two of the opposite hyperbolas are all transverse diameters of the other two.

2. Two conjugate diameters of two of the opposite hyperbolas are also conjugate diameters of the other two curves.

3. If a parallelogram $FHCL$ be completed, by drawing parallels to the asymptotes through any point in one of

HYPERBOLA.

four conjugate hyperbolas, as F, that parallelogram will be constantly of one and the same magnitude.

For such a parallelogram will be equal to one-fourth of the triangle M C N, or to one-fourth of the triangle M C G, which is equal to M C N.

4. And hence, if from any point F, in one of the curves, F H be drawn parallel to one asymptote to meet the other; then $CH \times HF$ will be constantly of the same magnitude.

5. A line F K, terminated by two adjacent hyperbolas, and parallel to one asymptote, is bisected by the other asymptote.

For $CH \times HF = CH \times HK$.

It may be remarked, that while opposite hyperbolas must be regarded as two different branches of the same curve, conjugate hyperbolas are two different curves, possessing, indeed, some analogous properties, but really unconnected by the law of continuity. For, in the first place, when a plane cuts two opposite conic surfaces, it produces no more than two opposite hyperbolas, without the smallest trace of the conjugate hyperbolas. And in the next place, if we consider the hyperbola as it is determined by an algebraic equation, no such equation can be found that, preserving the same system of the co-ordinates, will comprehend all the four conjugate hyperbolas. Let the curves be defined by two rectangular co-ordinates x and y , parallel to the two axes; then if, in the equation which belongs to two opposite hyperbolas, the ordinate x be necessarily greater than y , in the equation of the two conjugate hyperbolas, the same ordinate x will necessarily be less than y ; a circumstance which plainly excludes the two latter curves from the equation that defines the two first. Again, if we define the curves by means of two co-ordinates x and y , parallel to the asymptotes, which leads to this equation, $a \times b = x \times y$; then, making x and y both positive in one of the angles of the asymptotes, they will become $-x$ and $-y$ in the opposite angles; and in the two angles adjacent to these, they will be x and $-y$, and $-x$ and y : now, the equations $a \times b = x \times y$, and $a \times b = -x \times -y$, which belong to the two opposite hyperbolas, are consistent with one another, but they are both inconsistent with the equations $a \times b = x \times -y$, and $a \times b = -x \times y$, which would belong to the conjugate hyperbolas, if the same system of the co-ordinates were preserved.

Of the Description of a Hyperbola in Plano.—1. When the transverse axis and the two foci are given (*fig. 15.*), any number of points in the opposite hyperbolas may be thus found: Take any point O, in the transverse axis produced beyond the foci, and describe a triangle upon Ff (*22. 1. E.*), that shall have its sides respectively equal to the distances of O from A and B, the vertices of the transverse axis; then the vertex of this triangle, M or m, will be in one of the hyperbolas: and in this way, may as many points in both curves be found as shall be thought necessary.

When the two axes are given, the foci may be readily found (*Cor. Def. 23. Con.*), and then the curves may be described by this method.

2. A hyperbola that has its two axes equal to one another, and the angle of the asymptotes equal to a right angle, is called an equilateral hyperbola: such a curve may be thus described, by finding an indefinite number of points. Let AB = Dd be the two semi-axes; in AB, produced either way, assume any point O, and, having drawn an indefinite perpendicular through O, cut CO in L with a circle described from the centre D with the radius CO, and set off

OP, op upon the perpendicular, each equal to CL; then will P and p be points in one of the opposite curves.

3. When the two foci f and F, and the transverse axis AB (*fig. 16.*) are given, the hyperbola may be described by the following mechanical contrivance. Provide a straight ruler, and let it be made to turn round one focus f , so as to have its straight edge fE always directed to f ; take a thread, which is shorter than the whole length of the ruler, by the length of the transverse axis AB, and having fixed one end of the thread in the other focus F, attach the other end to the extremity of the ruler at E: then if the ruler be turned round about f , while the thread is stretched tight by a pin P which slides along the straight edge of the ruler, the point of the pin will trace the hyperbola required. For the excess of fP above PF is equal to the excess of the whole ruler above the whole length of the thread; that is, to the transverse axis AB.

4. When the directrix AM (*fig. 17.*), the corresponding focus F, and the vertex V are given; from V, as a centre with the distance VF, describe a circle, and it will cut the directrix in a point, as H; for FVA cuts the directrix at right angles, and VF is greater than VA (*43. Con.*): join VH, and provide a ruler MEN, with two straight edges, making an angle equal to the angle VHA, and place it on the same side of the directrix MA with the focus F, so that the edge ME may be in the direction of MA, and the other edge EN may be turned toward F; fix one end of a thread, which is equal in length to EN in F, and attach the other end to N: then, if the thread be stretched tight by a pin P, which slides along EN, the point of that pin will describe the hyperbola required. For, draw PR perpendicular to the directrix, then PE = PF; and, because the angles MEN and AHV are equal, by similar triangles

$$PE \text{ or } PF : PR :: VH \text{ or } VF : VA.$$

Therefore P describes the hyperbola required (*43. Con.*).

Of the Area of the Hyperbola.—In the treating of the ellipse we have shewn that the area of a whole ellipse, or of any segment of it, has to the area of the whole circle described on the transverse axis, or to the corresponding segment of that circle, the same proportion that the conjugate axis has to the transverse axis; and the same reasoning by which this was proved will apply equally to any two curves whatever which have their ordinates answering to the same absciss every where in the same proportion: whence it follows, that the constant proportion of the co-ordinates will be that of the areas taken between the same limits. Now, if we suppose any number of hyperbolas to be described upon the same transverse axis, then, as it is easy to prove, the ordinates of these curves drawn to the common axis, and answering to the same absciss, will be proportional to the second axis of the several curves: and therefore, according to what has been observed, the hyperbolic areas cut off by the ordinates will be proportional to the second axis. This proposition does not, indeed, enable us to square the hyperbolic spaces: but we learn from it that the problem will be accomplished generally for all hyperbolas, if we can find the quadrature of any one in particular, as the equilateral hyperbola, which is the simplest of all.

In farther treating of the quadrature of the hyperbola, we shall consider the area contained between the curve and its asymptote, and shall begin with shewing that the spaces comprehended between the ordinates are the measures of the ratio of the absciss taken on the asymptotes; in other words, that the asymptotic spaces are the logarithms of the absciss.

1. If through F and G (*fig. 18.*) two points assumed in a hyperbola, two ordinates TH and GK be drawn parallel

HYPERBOLA.

to one asymptote to cut the other in H and K; then the hyperbolic sector FCG will be equal to the mixtilinear space FHKG.

For the triangle CFH will be equal to the triangle CGK, and when these are taken from the space CFGK, the remainders, which are the sector FCG and the space FHKG, will likewise be equal.

2. If the abscissæ CH, CK, CM, be taken in continued proportion, the asymptotic spaces FHKG, GKML will be equal.

Draw FL, CF, CG, CL, and let CG cut FH in N, FL in O, and ML produced in P. Because CH, CL, CM are in continued proportion, therefore HN, GK, and PM will also be in continued proportion. Again,

$$LM : KG :: CK : CM \text{ (Cor. 1.)}$$

by similar triangles, GK : MP :: CK : CM;
therefore LM : KG :: GK : MP.

And, because HN, KG, and PM were before shewn to be in continued proportion, therefore LM = HN. In like manner, it may be shewn that FH = PM. Therefore PL = FN, and FL will be bisected in O. Therefore every line drawn in the hyperbola parallel to FL will be bisected by the diameter CG (15. Con.): and hence it is easy to infer that the hyperbolic segment cut off by FL will be bisected by GO. And because CO likewise bisects the triangle FCL, it is plain that the sectors FCG and GCL are equal; and consequently so are the spaces FHKG and GKML, which are equal to the sectors.

3. If the ratio of the abscissæ CG and CH (fig. 19.) be equal to the ratio of the abscissæ CD and CF; then will the asymptotic spaces KGH L and EDF I, comprehended between the ordinates, be equal.

For if we take CS a mean proportional between CG and CF, it will also be a mean proportional between CH and CD. Therefore the space KGRS = space RSFI, and the space LHR S = space RSED: consequently the space KGH L = space EDF I.

4. The asymptotic spaces comprehended between the ordinates are the measures of the ratios of the abscissæ.

Let the ratio of CB to Cm be a small ratio, and suppose that of CG to CF to be an exact multiple of the ratio of CB to Cm: then, according to what has been shewn, it is plain that the asymptotic space KGF I will be the like multiple of the space ABmn. Now, the ratio of CB to Cm may be taken so small that all other ratios may be considered as exact multiples of it; and then the corresponding hyperbolic spaces will be the like multiples of the area ABmn: which proves what was proposed.

What has here been demonstrated of the abscissæ and the asymptotic spaces is exactly the same relation that subsists between numbers and their logarithms: and therefore if the abscissæ be taken to represent the series of natural numbers, the hyperbolic spaces comprehended between the ordinates will be proportional to the logarithms of the numbers.

5. Supposing the abscissæ to be given, it is proposed to investigate a series for the asymptotic space in the equilateral hyperbola.

The vertex of the hyperbola being at A, let the ordinate AB = BC = 1, BF = x, and put z to represent the hyperbolic area ABFI: between CB and CF interpose as many mean proportionals Cm, Cp, &c. as there are units in the whole number denoted by i: then, according to what has been proved, all the spaces ABmn, mNGK, &c. of which the number is i, will be equal; and therefore, the space ABmn = $\frac{z}{i}$: but, because CF = 1 + x, there-

fore Cm = $(1+x)^{\frac{1}{i}}$; and Bm x BA = $(1+x)^{\frac{1}{i}} - 1$: now when i is a very great number, and consequently Bm very small, the rectangle Bm x BA may be considered as equivalent to the hyperbolic space ABmn; therefore $\frac{z}{i} =$

$(1+x)^{\frac{1}{i}} - 1$; and $z = i \times \left\{ (1+x)^{\frac{1}{i}} - 1 \right\}$; and by expanding the radical by the binomial theorem, we get

$$z = x - \frac{i-1}{2i} \cdot x^2 + \frac{i-1}{2i} \cdot \frac{2i-1}{3i} \cdot x^3 - \&c.$$

This expression of the value of z is greater than the truth for all values of i, but it differs less and less from the truth as i is taken greater and greater; and therefore, by taking the limit to which the expression constantly approaches as i increases, we shall have accurately

$$z = x - \frac{1}{2} x^2 + \frac{1}{3} x^3 - \frac{1}{4} x^4 + \&c.$$

This is the series which Mercator invented for the quadrature of the hyperbola, and which he published (in 1667) in his Logarithmotechnia. If the area denoted by z lie on the other side of AB, and Bf = x, then it may be shewn, in the same manner as before, that $z = i \times \left\{ 1 - (1-x)^{\frac{1}{i}} \right\}$: and, by expanding and taking the limit we shall get

$$z = x + \frac{1}{2} x^2 + \frac{1}{3} x^3 + \frac{1}{4} x^4 + \&c.$$

This series, which may appear to be a very easy extension of Mercator's invention, was first given by Dr. Wallis of Oxford, in a letter to lord Brouncker, published in the third volume of the Philosophical Transactions.

The same investigation will apply to any hyperbola (fig. 20.): for preserving the same denominations as before, we still have the space ABmn = $\frac{z}{i}$; and if m denote the sine of the angle of the asymptotes, then the space ABmn = m x AB x mB = m x $\left\{ (1+x)^{\frac{1}{i}} - 1 \right\}$; therefore $z = m \times i \times \left\{ (1+x)^{\frac{1}{i}} - 1 \right\}$; whence

$$z = m \times \left\{ x - \frac{1}{2} x^2 + \frac{1}{3} x^3 - \frac{1}{4} x^4 + \&c. \right\}$$

And in like manner when the area is on the other side of the ordinate AB, we shall have

$$z = m \times \left\{ x + \frac{1}{2} x^2 + \frac{1}{3} x^3 + \frac{1}{4} x^4 + \&c. \right\}$$

It readily follows from what has been proved, that, in different hyperbolas (figs. 19 and 20.), if we take CF to CB in the same proportion, the asymptotic spaces ABFI, or the equivalent sectors ACI, will be proportional to the sines of the angles formed by the asymptotes: this supposes that BC is unit in all the hyperbolas; when this is not the case, the space of every hyperbola will be proportional to the square of BC multiplied by the sine of the angle of the asymptotes, or, which is an equivalent space, to half the product of the two axes of the curve.

It has already been remarked that the hyperbolic trapeziums, or sectors, bear the same relation to the corresponding abscissæ, that the logarithms of numbers do to the numbers themselves; and by taking m, or the sine of the angle contained by the asymptotes of a proper magnitude, the hyperbolic trapeziums or sectors will be measured by the very same numbers as the logarithms in any proposed system. Thus in the equilateral hyperbola, when m = 1, the hyperbolic spaces agree in numerical value with the logarithms

HYPERBOLA.

arithms of Napier's system; and if $m = .434294$, the hyperbolic spaces will be equivalent to the logarithms of Briggs's system, which are those contained in the tables in common use. From what has now been said we derive an easy rule for computing the area of any hyperbola by means of a table of logarithms. Let the semi-transverse axis of an hyperbola = a (fig. 20.), the semi-conjugate $AY = b$, the absciss of the transverse $CX = y$; then the ordinate $XI = \frac{b}{a} \sqrt{y^2 - a^2}$; and if XI cut the asymptotes in O and E , then $XO = \frac{b}{a} \times y$; therefore $IO = \frac{b}{a} \times (y + \sqrt{y^2 - a^2})$: now

$$IE : EF :: AY : BY, \text{ or } BC :: OI : CF;$$

therefore $\frac{OI}{AY} = \frac{OI}{b} = \frac{y + \sqrt{y^2 - a^2}}{a} = \frac{CF}{BC} = \text{value of}$

CF when BC is unit: then the hyperbolic trapezium $ABFI$, or the equivalent sector ACI , will be equal to

$$\frac{a \times b}{2} \times \text{Napier's logarithm of } \frac{y + \sqrt{y^2 - a^2}}{a};$$

or if $M = .434294$, the same space will be equal to

$$\frac{a \times b}{2M} \times \text{Briggs's logarithm of } \frac{y + \sqrt{y^2 - a^2}}{a}.$$

With regard to the area XAI , it is the difference of the triangle ICX and the sector ACI .

Napier's logarithms, which are expressed by the sectors, or asymptotic trapeziums of an equilateral hyperbola, in which CB is unit, have obtained the appellation of hyperbolic logarithms: but they do not seem to be better entitled to this name than Briggs's logarithms, which are equivalent to the sectors, or asymptotic trapeziums of the hyperbola, in which BC is unit, and the sine of the angle of the asymptotes = $.434294$. Nay, what is more, the latter sort of logarithms may be expressed by the areas of an equilateral hyperbola, as well as the former: for this purpose we have only to make $BC = \sqrt{.434294}$; and the sector ACI , or the trapezium $ABFI$, will be equal to Briggs's logarithm of the number equal to $\frac{CF}{BC}$.

6. We shall now finish what we have to say on the quadrature of the hyperbola with considering the inverse problem, for determining the absciss when the hyperbolic area is given; or, which is the same thing, for determining the number when the logarithm is given. Now, according to what has already been shewn, we have, in a hyperbola that has the sine of the angle of the asymptotes = m , $z =$

$$m \times i \times \left\{ (1 + x)^{\frac{1}{i}} - 1 \right\}: \text{ therefore } 1 + x = \left(1 + \frac{1}{i} \cdot \frac{z}{m} \right)^i;$$

and, by expanding by the binomial theorem, we get $1 + x = 1 + \frac{z}{m} + \frac{i-1}{2i} \cdot \frac{z^2}{m^2} + \frac{i-1 \cdot i-2}{2i \cdot 3i} \cdot \frac{z^3}{m^3} + \frac{i-1 \cdot i-2 \cdot i-3}{4i^3} \cdot \frac{z^4}{m^4} + \&c.$ This equation is not rigorously exact for any value of i , but it is the more nearly true, the greater is the number that i stands for; and therefore when we take the limit to which the series continually

approaches, we shall have accurately $1 + x = 1 + \frac{z}{m} + \frac{1}{1.2} \cdot \frac{z^2}{m^2} + \frac{1}{1.2.3} \cdot \frac{z^3}{m^3} + \frac{1}{1.2.3.4} \cdot \frac{z^4}{m^4} + \&c.$ And if the area z be taken on the other side of the ordinate AB ,

then, in like manner, $1 - x = 1 - \frac{z}{m} + \frac{1}{1.2} \cdot \frac{z^2}{m^2} - \frac{1}{1.2.3} \cdot \frac{z^3}{m^3} + \frac{1}{1.2.3.4} \cdot \frac{z^4}{m^4} + \&c.$

Of the Rectification of the Hyperbola.—1. Let CB (fig. 21.) the semi-transverse axis of an hyperbola, be unit, the distance of the focus from the centre $CF = e$; and consequently the semi-conjugate axis = $\sqrt{e^2 - 1} = CD$: let CP , an absciss of the transverse axis, = x ; the corresponding ordinate $MP = y$; and draw MT a tangent of the curve: then, by the property of the curve, we have

$$CB^2 : CD^2 :: CP^2 - CB^2 : PM^2;$$

$$\text{or } 1 : e^2 - 1 :: x^2 - 1 : y^2;$$

hence $y = \sqrt{e^2 - 1} \cdot \sqrt{x^2 - 1}$. Let the length of the arc BM of the hyperbola be denoted by H ; then

$$\dot{H} = \sqrt{\dot{x}^2 + \dot{y}^2} = \dot{x} \sqrt{1 + \frac{x(e^2 - 1)}{x^2 - 1}} = \frac{\dot{x} \sqrt{e^2 x^2 - 1}}{\sqrt{x^2 - 1}}.$$

If the tangent MT cut the transverse in T , then $CT \times CP = CB^2$; hence $CT = \frac{1}{x}$; and $TP = x - \frac{1}{x} =$

$$\frac{x^2 - 1}{x}; \text{ therefore } MT = \sqrt{TP^2 + MP^2} = \frac{\sqrt{(x^2 - 1)(e^2 x^2 - 1)}}{x};$$

Put $\tau = MT$, then by taking

the fluxions in the value of τ , we shall get

$$\dot{\tau} = \frac{\dot{x} \sqrt{e^2 x^2 - 1}}{\sqrt{x^2 - 1}} + \frac{\dot{x} \sqrt{x^2 - 1}}{x^2 \sqrt{e^2 x^2 - 1}};$$

therefore $\dot{\tau} - \dot{H} = \frac{\dot{x} \sqrt{x^2 - 1}}{x^2 \sqrt{e^2 x^2 - 1}};$

thus the rectification of the hyperbola is reduced to the investigation of the fluent of $\frac{\dot{x} \sqrt{x^2 - 1}}{x^2 \sqrt{e^2 x^2 - 1}}$, generated

while the absciss increases from unit to any indefinite value; for it is clear from what has been proved, that this fluent will express the difference between the hyperbolic arc MB and its tangent MT . And because a tangent of the hyperbola approaches indefinitely to the asymptote as the point of contact recedes from the vertex, we may likewise infer from what has been said, that the whole fluent generated while x increases from being equal to unit to be infinitely great, is equivalent to the excess of the asymptote above the curve, when both are indefinitely extended: this last case being the most interesting one of the problem, we shall principally have it in view in what we have farther to add on this subject.

Let $\sqrt{x^2 - 1} = \tan. \phi$, and while x increases from 1 to be infinitely great, the arc ϕ will increase from 0 to be a quadrant, or $\frac{\pi}{2}$ (π denoting 3.14159 , &c.): then $x = \frac{1}{\text{cof. } \phi}$.

$\sqrt{e^2 x^2 - 1} = \frac{\sqrt{e^2 - \text{cof. } \phi}}{\text{cof. } \phi}$; and $\dot{x} = \frac{\dot{\phi} \text{ fin. } \phi}{\text{cof. } \phi^2}$: therefore by substitution

$$\tau - H = \int \frac{\dot{x} \sqrt{x^2 - 1}}{x^2 \sqrt{e^2 x^2 - 1}} = \int \frac{\dot{\phi} \text{ fin. } \phi}{\sqrt{e^2 - \text{cof. } \phi} \phi^2};$$

and, because $\text{fin. } \phi = \frac{1}{2} - \frac{1}{2} \text{cof. } 2\phi$, and $\text{cof. } \phi = \frac{1}{2} + \frac{1}{2} \text{cof. } 2\phi$, therefore

$$\tau - H = \frac{1}{2} \int \frac{\dot{\phi} (1 - \text{cof. } 2\phi)}{\sqrt{e^2 - \frac{1}{2} - \frac{1}{2} \text{cof. } 2\phi}};$$

affume,

assume, $a^2 + b^2 = c^2 - \frac{1}{2}$, $2ab = \frac{1}{2}$; then $a + b = c$,

$$a - b = \frac{c + \sqrt{c^2 - 1}}{2}; \text{ and } a = \frac{c + \sqrt{c^2 - 1}}{2},$$

$$b = \frac{c - \sqrt{c^2 - 1}}{2}; \text{ consequently, } \sqrt{c^2 - \frac{1}{2} - \frac{1}{2} \text{ cof. } 2\phi}$$

$$= \sqrt{a^2 + b^2 - 2ab \text{ cof. } 2\phi} = \left(\text{putting } f = \frac{b}{a} \right)$$

$a \times \sqrt{1 + f^2 - 2f \text{ cof. } 2\phi}$: again, let

$\Delta = \sqrt{1 + f^2 - 2f \text{ cof. } 2\phi}$, then $\text{cof. } 2\phi$

$$= \frac{1 + f^2 - \Delta^2}{2f}; \text{ and } (1 - \text{cof. } 2\phi) = \frac{\Delta^2}{f}$$

$$- \frac{1}{2} \cdot \frac{(1-f)^2}{f}; \text{ therefore } \tau - H = \frac{1}{2a}$$

$$\int \frac{\frac{1}{2}(1 - \text{cof. } 2\phi)}{\sqrt{1 + f^2 - 2f \text{ cof. } 2\phi}} = \frac{1}{4af}$$

$$\left\{ \int \Delta \cdot \dot{\phi} - (1-f)^2 \cdot \int \frac{\dot{\phi}}{\Delta} \right\}; \text{ and, because } \frac{1}{4af} =$$

$$\frac{c + \sqrt{c^2 - 1}}{2}, \text{ and } \frac{(1-f)^2}{4af} = \frac{2(c^2 - 1)}{c + \sqrt{c^2 - 1}}, \text{ therefore}$$

$$\tau - H = \frac{c + \sqrt{c^2 - 1}}{2} \times \int \Delta \cdot \dot{\phi} - \frac{2(c^2 - 1)}{c + \sqrt{c^2 - 1}}$$

$$\int \frac{\dot{\phi}}{\Delta}$$

Now, let Δ and $\frac{1}{\Delta}$ be developed into series containing the cosines of the multiples of 2ϕ ; as thus,

$$\Delta = A^{(0)} + A^{(1)} \text{ cof. } 2\phi + A^{(2)} \text{ cof. } 4\phi + \&c.$$

$$\frac{1}{\Delta} = B^{(0)} + B^{(1)} \text{ cof. } 2\phi + B^{(2)} \text{ cof. } 4\phi + \&c.;$$

then, taking the whole fluents from $\phi = 0$ to $\phi = \frac{\pi}{2}$, we

$$\text{have } \int \Delta \cdot \dot{\phi} = A^{(0)} \times \frac{\pi}{2}, \text{ and } \int \frac{\dot{\phi}}{\Delta} = B^{(0)} \times \frac{\pi}{2}$$

with regard to $A^{(0)}$ and $B^{(0)}$, they will be found by these series, *viz.*

$$A^{(0)} = 1 + \left(\frac{1}{2}\right)^2 \cdot f^2 + \left(\frac{1 \cdot 1}{2 \cdot 4}\right)^2 \cdot f^4 + \left(\frac{1 \cdot 1 \cdot 3}{2 \cdot 4 \cdot 6}\right)^2 \cdot f^6 + \&c.$$

$$B^{(0)} = 1 + \left(\frac{1}{2}\right)^2 \cdot f^2 + \left(\frac{1 \cdot 3}{2 \cdot 4}\right)^2 \cdot f^4 + \left(\frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\right)^2 \cdot f^6 + \&c.$$

and thus we get the following value of the excess of the asymptote above the hyperbolic curve, when both are infinitely extended, *viz.*

$$\frac{\pi}{2} \times \left\{ \frac{c + \sqrt{c^2 - 1}}{2} \cdot A^{(0)} - \frac{2(c^2 - 1)}{c + \sqrt{c^2 - 1}} \cdot B^{(0)} \right\};$$

and this expression is, in most cases, very commodious for computation, because, on account of the smallness of

$$f^2 = \left(\frac{c - \sqrt{c^2 - 1}}{c + \sqrt{c^2 - 1}} \right)^2, \text{ the series for } A^{(0)} \text{ and } B^{(0)} \text{ con-}$$

verge very rapidly.

HYPERBOLA, Acute, an hyperbola whose asymptotes make an acute angle.

HYPERBOLA, Ambigens, is that which has one of its infinite legs inscribed, and the other circumscribed. See **AMBIGENAL**.

HYPERBOLA, Equilateral or Rectangular, is that wherein

the conjugate axes are equal, and whose asymptotes make a right angle. Since the parameter is a third proportional to the conjugate axis, it is also equal to the axis: wherefore if in the equation $y^2 = bx + \frac{bxx}{a}$, expressing the na-

ture of the hyperbola, you suppose $b = a$; the equation $y^2 = ax + x$ will express the nature of the equilateral hyperbola. And hence the squares of the ordinates y^2 and z^2 are to each other as $ax + x$ and $av + v$: that is, as the rectangles of the abscissas into right lines composed of the abscissas and parameter. See **HYPERBOLA, supra**.

HYPERBOLAS, Infinite, or **HYPERBOLAS of the higher kind**, are those defined by the equation $ay^{m+n} = bx^n(d+x)^n$. Hence in the infinite hyperbolas $ay^{m+n} : av^{m+n} = bx^m(a+x) : bz(a+x)$; that is $y^{m+n} : v^{m+n} :: x^m(a+x) : z^n(a+x)$. See **HYPERBOLOID**.

As the hyperbola of the first kind, or order, has two asymptotes; that of the second kind, or order, has three; that of the third four, &c.

In respect of these, the hyperbola of the first kind is called the *Apollonian* or *conical* hyperbola: it is thus called in contradistinction to the hyperbolas of the higher kinds. It is called hyperbola from *ὑπερβαλλων*, to exceed, because in this

curve the square of the ordinate or y^2 is equal to $bx + \frac{b}{a}x^2$, and therefore exceeds the product of the parameter b , by the abscissa x .

HYPERBOLA, Inscribed. See **INSCRIBED**.

HYPERBOLA, for the locus of an, see **LOCUS**.

HYPERBOLA, for the quadrature of an, see **QUADRATURE** and **HYPERBOLA, supra**.

HYPERBOLAS, Conjugated, a name given to four hyperbolas, when the first and second axes of two opposite hyperbolas are the second and first axes of two other opposite hyperbolas. See **HYPERBOLA, supra**.

Hyperbolas of all degrees may be expressed by the equation $x^m y^n = a^{m+n}$ where a is a given quantity, x an abscissa taken on the asymptote, and y an ordinate to the asymptote.

HYPERBOLEON. The hyperboleon tetrachord was the most acute of the five tetrachords in the Greek system. This word is the genitive case of the plural substantive *ὑπερβολαι*, *summits, extremes*; the most acute sounds being at the summit of the rest.

HYPERBOLE, *ὑπερβολή*, *superlatio*, formed of the verb *ὑπερβαλλων*, to exceed, in *Rhetoric*, a figure, whereby the truth and reality of things are either excessively enlarged or diminished. See **EXAGGERATION**.

The character of an hyperbole is to exaggerate or extenuate the idea of the thing spoken of, beyond the bounds of truth, or even probability. As, he ran swifter than the wind; he went slower than a tortoise, &c.

Hyperboles, says Seneca, lie without deceiving; they lead the mind to truth by fictions; they convey the sentiment intended, though by expressing it in terms which render it incredible. The hyperbole promises too much, in order to make you conceive enough. There is nothing faulty in an hyperbole, when it is *ultra fidem*, as Quintilian says, provided that it be not *ultra modum*.

Aristotle observes, that hyperboles are the favourite figures of young authors, who love excess and exaggeration; but that philosophers should not use them without a great deal of reserve.

The pitch to which an hyperbole may be carried, is a point of great delicacy; to carry it too far is to destroy it: it is of the nature of a bow-string, which by immoderate tension,

tenfion, flackens; and frequently has an effect quite contrary to that intended. Longinus.

Those hyperboles are best, which are latent, and are not taken for hyperboles. For this reason, they should scarcely ever be used but in a passion; and in the middle of some important incident: such as the hyperbole of Herodotus speaking of the Lacedæmonians, who fought at Thermopylæ: "They defended themselves, for some time, with the arms that were left them, and at last with their hands and teeth; till the barbarians, continually shooting, buried them, as it were, with their arrows." Now what likelihood is there, that naked men should defend themselves with their hands and teeth against armed men; and that so many persons should be buried under their enemies' arrows? Yet does there appear some probability in the thing, by reason it is not fought for the sake of the figure; but the hyperbole seems to arise out of the subject itself. Id.

Of the like kind is that passage of a comic poet, mentioned by Longinus: "He had lands in the country no larger than a Lacedæmonian epistle."

There are certain manners of tempering the harshness of hyperboles, and giving them an air of probability. Virgil says, that to see the fleets of Antony and Augustus at the battle of Actium, one would have taken them for the Cyclopes floating on the water: and Florus, speaking of the expedition wherewith the Romans built a number of vessels in the first Punic war, says, 'It seemed not that the ships were built by workmen, but that the trees were transformed into ships by the gods.' They do not say, that the ships were floating islands; nor that the trees were metamorphosed into ships; but only that one might have taken them to be so. This precaution serves as a kind of passport to the hyperbole, if we may be allowed the phrase, and makes it go down even in prose; for what is excused before it is said, is always heard favourably, how incredible soever it be. Bouhours. The excess in this trope is called *auxesis*; as when we say of any thing that is very high, it *reaches to the skies*: the defect or contrary extreme is termed *meiosis*; as when we say of a very lean person, *he is nothing but skin and bones, or a mere skeleton*.

HYPERBOLIC, or HYPERBOLICAL, something relating either to an hyperbole, or an hyperbola.

HYPERBOLIC Conoid. See CONOID.

HYPERBOLIC Cylindroid, is a solid figure, whose generation is given by sir Christopher Wren, in the Philosophical Transactions.

Two opposite hyperboles being joined by the transverse axis, and through the centre, a right line being drawn at right angles to that axis; and above that, as an axis, the hyperboles being supposed to revolve; by such revolution, a body will be generated, which is called the hyperbolic cylindroid, whose bases, and all sections parallel to them, will be circles. In a subsequent transaction, the same author applies the new figure to the grinding of hyperbolic glasses; affirming, that they must be formed this way, or not at all. Phil. Transf. vol. iv. p. 961.

HYPERBOLIC Leg of a curve, is that which has an asymptote, or tangent at an infinite distance.

Sir Isaac Newton reduces all curves, both of the first and of the higher kinds, into those with hyperbolic legs, and those with parabolic ones; that is, such as have asymptotes, and such as have not, or such as have tangents at an infinite distance, and such as have not. See CURVE.

HYPERBOLIC Line is used by some authors for what we call the hyperbola itself.

In this sense the plane surface, terminated by the curve

line, is called the hyperbola; and the curve line that terminates it, the hyperbolic line.

HYPERBOLIC Logarithms, or Napierian Logarithms, are a series of numbers, particularly useful in the determination and computation of fluents, arising from various problems in the higher branches of the mathematics; at the same time they have the property of common logarithms in facilitating many arithmetical operations, such as multiplication, division, extraction of roots, &c. &c.

These numbers are called hyperbolic logarithms, because they express the areas or spaces contained between the asymptote and curve of the hyperbola; those areas being limited by ordinates parallel to the other asymptote; the ordinates themselves decreasing in a geometrical progression. But this does not appear to be a proper method of denominating them, as such areas may be made to denote any system of logarithms whatever; for which reason they are now generally termed Napierian logarithms; from the name of their illustrious inventor, John Napier, baron of Merchiston, in Scotland. (See LOGARITHMS.) As we shall, under the article LOGARITHMS, enter at some length on the history of the invention, and the successive improvements of these very useful numbers; it will only be necessary, under the present article, to attend to the particular system which is the subject of our immediate consideration; by shewing, 1st, how it happened, that Napier fell upon this system, exclusively of all others; 2dly, in what respect it is inferior to that of the common logarithms, for arithmetical and trigonometrical operations; 3dly, that these numbers necessarily arise in the determination and computation of fluents; 4thly, we shall shew their application to the problems before mentioned; and lastly, present the reader with the most extensive table of hyperbolic logarithms that has yet been published; being for every number from 1 to 10,000, and each true to the eighth place of decimals.

Napier, in the construction of his logarithms, did not adapt them to the series of natural numbers 1, 2, 3, 4, 5, 6, &c. as it was not his intention to extend them to arithmetical operations in general; but he confined his labours to that circumstance which first suggested to him the necessity of the invention; and therefore he adapted his logarithms to the approximate numbers, which express the natural sines of every minute in the quadrant.

The same restricted idea was pursued through his method of constructing the logarithms. As the lines of the sines, of all arcs, are parts of the radius, or sine of the quadrant; he conceived the line of the radius to be described or run over by a point moving along it, in such a manner, that in equal portions of time it generated or cut off parts in a decreasing geometrical progression; leaving the several remainders, or lines, in geometrical progression also; while another point in an indefinite line, described equal parts of it in the same equal portions of time; so that the respective sums of these, or the whole lines generated, were always the arithmeticals or logarithms of these sines.

Thus $a z$ is the given radius on which all the sines are to be taken, and $A, 1, 2,$ &c. the indefinite

line containing the logarithms; these lines being both generated by the motion of points, beginning at A and a . Now at the end of the 1st, 2d, 3d, &c. moments or equal portions of time, the moving points being found at the places marked 1, 2, 3, &c. then will $z a, z 1, z 2, z 3,$ &c. be the series of natural sines; and $A a,$ or $(o), A 1, A 2, A 3,$ &c. will be their logarithms, supposing the point which generates

HYPERBOLIC LOGARITHMS.

generates a z to move every where, with a velocity decreasing in proportion to its distance from z ; viz. its velocity in the points 0, 1, 2, 3, &c. to be respectively as the distances z 0, z 1, z 2, z 3, &c.; while the velocity of the point generating the logarithmic line remains always the same as in the first point A, or 0. Hutton's Introduction to Logarithms.

In this state the system of logarithms was undetermined, having only supposed one condition or limitation; namely, that the logarithm of a z , or radius, should be 0, or radius itself equal to unity, which was assumed, in order to render the trigonometrical operations the more easy; but another condition was still necessary to limit the scale or system; and as the one which we have described was contrived in order to simplify the operations; so the second was assumed, in order to render the calculation of the tables as easy as possible; for which reason he supposed, that the two generating points should begin to move from A and a with equal velocities, or that the increments, as A 1, described in the first moments, should be equal; and this supposition gave at once to every number its particular logarithm, and thus he found that his logarithm of the ratio of 10 to 1 became 2.30258509, and hence it happened, that by means of these two accidental and arbitrary assumptions, Napier's system of logarithms was of that kind which we designate by hyperbolic logarithms.

It would, however, be uninteresting to the reader to follow Napier any further in his construction, as methods much more simple have been since discovered for the formation of logarithmic tables; and which shew far more distinctly the nature of those numbers; in order to the explanation of which, it will be proper to begin by defining logarithms in general: thus,

The logarithm of a number is the exponent of that power of some other number, which is equal to the first: hence, if $r^x = a$, then will x represent the logarithm of a ; and r will be the radix of the system, which it is obvious may be assumed at pleasure. If we take $r = 10$, it will be the common logarithmic system; and if r be taken = 2.7182818, it gives the hyperbolic logarithmic scale; and the reason for assigning to r the above value will be evident from the following investigation. Since $r^x = a$, we must, in order to find the logarithm of a , obtain an expression for x , in the above equation in terms of r and a ; which may be effected thus:

Let $a = 1 + p$, and $\frac{1}{x} = z$; then from $r^x = a$, we deduce

$$r = (1 + p)^z = 1 + \left(p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right) z + \frac{1}{2} \left(p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right)^2 z^2 + \frac{1}{2 \cdot 3} \left(p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right)^3 z^3 + \frac{1}{2 \cdot 3 \cdot 4} \left(p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. \right)^4 z^4 + \&c.;$$

and by making $p - \frac{p^2}{2} + \frac{p^3}{3} - \frac{p^4}{4} + \&c. = s$; we shall have

$$1 + sz + \frac{1}{2} s^2 z^2 + \frac{1}{2 \cdot 3} s^3 z^3 + \frac{1}{2 \cdot 3 \cdot 4} s^4 z^4 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} s^5 z^5 + \&c. = r; \text{ or } sz + \frac{1}{2} s^2 z^2 + \frac{1}{2 \cdot 3} s^3 z^3 + \frac{1}{2 \cdot 3 \cdot 4} s^4 z^4 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} s^5 z^5 + \&c. = r - 1; \text{ which let be}$$

put equal to q ; then by reverting the series, z or $\frac{1}{x}$ will be

$$\text{found} = \frac{q - \frac{1}{2} q^2 + \frac{1}{3} q^3 - \frac{1}{4} q^4 + \frac{1}{5} q^5 - \&c.}{s} =$$

$$\frac{q - \frac{1}{2} q^2 + \frac{1}{3} q^3 - \frac{1}{4} q^4 + \frac{1}{5} q^5 - \&c.}{p - \frac{1}{2} p^2 + \frac{1}{3} p^3 - \frac{1}{4} p^4 + \frac{1}{5} p^5 - \&c.}; \text{ and, consequently,}$$

$$x = \frac{p - \frac{1}{2} p^2 + \frac{1}{3} p^3 - \frac{1}{4} p^4 + \frac{1}{5} p^5 - \&c.}{q - \frac{1}{2} q^2 + \frac{1}{3} q^3 - \frac{1}{4} q^4 + \frac{1}{5} q^5 - \&c.} \text{ or, substituting}$$

for p and q their respective values; that is, $p = a - 1$, and $q = r - 1$, we have the following general expression for the logarithm of a ; viz. $\log. a$

$$= \frac{(a-1) - \frac{1}{2}(a-1)^2 + \frac{1}{3}(a-1)^3 - \frac{1}{4}(a-1)^4 + \frac{1}{5}(a-1)^5 - \&c.}{(r-1) - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 - \frac{1}{4}(r-1)^4 + \frac{1}{5}(r-1)^5 - \&c.}$$

which is a general expression, in terms of a and the radix r , which last may, therefore, be assumed any number at pleasure, greater or less than unity. Now as r , in every system, is a constant quantity, being always the number whose logarithm, in the system to which it belongs, is 1, the above expression may be simplified, either by assuming r equal to some particular number, and from thence finding the value of the series constituting the denominator; or, by assuming the whole series equal to some particular number, and from thence finding the value that must be given to the radix r .

By the latter of these methods the denominator may be made to vanish, by assuming the value of the series of which it consists equal to 1; in which case the logarithm of a becomes, $\log. a = (a - 1) - \frac{1}{2} (a - 1)^2 + \frac{1}{3} (a - 1)^3 - \frac{1}{4} (a - 1)^4 + \frac{1}{5} (a - 1)^5 - \&c.$; or, making again $a = 1 + p$; we have $\log. (1 + p) = p - \frac{1}{2} p^2 + \frac{1}{3} p^3 - \frac{1}{4} p^4 + \frac{1}{5} p^5 - \&c.$ and by means of the expression, $(r - 1) - \frac{1}{2} (r - 1)^2 + \frac{1}{3} (r - 1)^3 - \frac{1}{4} (r - 1)^4 + \&c. = 1$, we find $r = 2.7182818$, &c. which is the number we before stated to be the radix of the hyperbolic system.

The above is evidently the simplest form that the logarithmic series admits of; and, therefore, such as would be naturally adopted by any person, before he was aware of the advantages or disadvantages of it in other respects, when compared with a different system; and thus it was Napier first employed these numbers, although he did not know of the above method of arriving at them. But as soon as Briggs had considered the nature of their generation, and the purposes they were intended to answer, he soon convinced himself, and Napier likewise, that much advantage would arise in their application, by taking for the radix of the system of logarithms the same number, as was the radix of the scale of notation; that is, by assuming $r = 10$; by which means, the logarithm of the same digits in the same order was always constant, whether these were integral, decimal, or compounded of both; and only the index or characteristic was to be changed; and various other advantages that this method possesses over the other, will be explained under the article LOGARITHMS: we shall, therefore, only observe here, that the advantages of Briggs's system are so decisive, that Napier's would, before this time, have been forgotten, had not the invention of fluxions again called into action the dormant powers of hyperbolic logarithms.

We have already seen that the hyperbolic logarithm of $1 + p$, or of $1 + x$, by writing x instead of p , is hyp. $\log. (1 + x) = x - \frac{1}{2} x^2 + \frac{1}{3} x^3 - \frac{1}{4} x^4 + \frac{1}{5} x^5 - \&c.$

Now let it be required to find the fluent of the fluxion $\frac{\dot{x}}{1 + x}$: this in a series becomes $\dot{x} \left(\frac{1}{1 + x} \right) = \dot{x} (1 - x + x^2 - x^3 + x^4 - x^5 + \&c.) = \dot{x} - x\dot{x} + x^2\dot{x} - x^3\dot{x} + x^4\dot{x} - \&c.$; or, taking the fluents by the common rule, we have the

HYPERBOLIC LOGARITHMS.

fluent of $\frac{\dot{x}}{1+x} = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \frac{1}{5}x^5 - \&c.$

but this last series is the same as that expressing the hyp. log^r of $(1+x)$, therefore the fluent of $\frac{\dot{x}}{1+x}$ is the hyp. log. of

$1+x$. And the same rule is general for every quantity, of which the numerator is the fluxion, or any multiple of the fluxion of the denominator; these being all reducible to the same form. (See FLUXIONS and FLUENTS.) Thus we have

the fluent of $\frac{\dot{x}}{x \pm a} = \text{hyp. log. of } (x \pm a)$

the fluent of $\frac{2x\dot{x}}{a^2+x^2} = \text{hyp. log. of } (a^2+x^2)$

the fluent of $\frac{nx^{n-1}\dot{x}}{a^n+x^n} = \text{hyp. log. of } (a^n+x^n)$

the fluent of $\frac{\dot{x}}{\sqrt{x^2 \pm 2ax}} = \text{hyp. log. of } (x + \sqrt{x^2 \pm 2ax})$

the fluent of $\frac{\dot{x}}{\sqrt{x^2 \pm 2ax}} = \text{hyp. log. of } (x \pm a + \sqrt{x^2 \pm 2ax})$

the fluent of $\frac{2a\dot{x}}{a^2-x^2} = \text{hyp. log. of } \left(\frac{a+x}{a-x}\right)$

the fluent of $\frac{2a\dot{x}}{x\sqrt{a^2+x^2}} = \text{hyp. log. of } \left(\frac{\sqrt{a^2+x^2}-a}{\sqrt{a^2+x^2}+a}\right)$

the fluent of $\frac{x^2\dot{x}}{\sqrt{b^2+x^2}} = -\text{hyp. log. of } \left(\frac{1+\sqrt{1+b^2/x^2}}{x}\right)$

These are only a few of the cases in which hyperbolic logarithms are applied to the computation of fluents; and for the application of which to practice, the following table will be found very useful: it will need little or no explanation, being the same in form as the common tables of logarithms; and all that is necessary to be observed is, that as the index of the logarithm is not repeated in every column, a small dash (—) is placed over the first figure of the decimal, when any change takes place in the index. Thus, for example, the hyp. log. of 1097 is 7.00033446, the small dash indicating, that the index in that place changes from 6 to 7. If the hyperbolic logarithm of a fraction be required, we have only to subtract the log. of the denominator from that of the numerator for the log. sought: thus, the hyp. log. of

$\frac{119}{1172} = 4.77912349 - 7.06646697 = -2.28734348$; the whole of which expression is negative, whereas in the common system, the decimal part always retains a positive value, and the index only becomes negative; and this is again one of the inconveniences attending the hyperbolic system. When the natural number corresponding to any given hyp. log. is required, whether the given log. be positive or nega-

tive, it is always best to add to the given log. the log. of such a power of 10 as will bring it as near the end of the tables as possible, and then having found the natural number the same as in the common tables; divide the result by the same power of 10 for the natural number sought: the reason for which is, that the differences are too variable in the beginning of the table to be of any assistance in deducing the proportional parts. Suppose, for example, the given hyperbolic logarithm was -3.28734348 , and it was required to find the corresponding natural number. Now the hyp. log. of 10 = 2.30258509, multiply this by 5, we have $10^5 = 11.51292545$, which being added to the given log. we have $-3.28734348 + 11.51292545 = 8.22558197$. Again,

$$\begin{array}{r} \text{Nat. number to } 8.22558197 \\ \hline 8.22587090 = 3735 \left\{ \begin{array}{l} 8.22558197 \\ 8.22550309 \end{array} \right. \end{array}$$

Difference $36781 : 1 :: 7888 : .2$

hence $\frac{3735.2}{100000} = .037352$ is the natural number required.

And in this manner may the natural number answering to any given hyp. log. not in the table, be reduced to another within the limits of the table, by adding or subtracting from it such powers of 10 as are sufficient for that purpose; observing always to repeat the reverse operation after the number is obtained. And by a similar method, the hyp. log. of any number not found in the table may be reduced to another, that is, by either multiplying or dividing it by such powers of 10 as may be necessary for that purpose; only remembering to subtract or add to the logarithm thus found the logarithm of the same power of 10, as that by which the given number was multiplied or divided. This will be more evident from the following examples:

Exam. 1.—Find the hyperbolic logarithm of .7854.

First, $.7854 = \frac{7854}{10000}$; and, therefore, the hyp. log. of $.7854 = \text{hyp. log. } 7854 - \text{hyp. log. } 10^4 = 8.96877824 - 4 \times 2.30258509 = -0.24156212$, the logarithm sought.

Exam. 2.—Find the hyperbolic logarithm of 78.54.

Here $78.54 = \frac{7854}{100}$; and, therefore, the hyp. log. of $78.54 = \text{hyp. log. of } 7854 - \text{hyp. log. } 10^2 = 8.96877824 - 2 \times 2.30258509 = 4.36360806$, the log. required.

The following table of hyperbolic logarithms has been computed by Mr Peter Barlow, of the Royal Military Academy, Woolwich; and it is presumed that it will be considered as an acquisition to mathematicians: it forms only a small portion of an extensive set of mathematical tables calculated by the same gentleman; most of which are entirely new, but the slow demand that such works experience will, it is feared, prevent the appearance of this useful performance.

HYPERBOLIC Mirror. See **MIRROR.**

HYPERBOLIC Space, in the *Higher Geometry*, the area or space contained between the curve of the hyperbola, the asymptote, and the ordinate.

HYPERBOLICUM ACUTUM, a solid made by the revolution of the infinite area of the space contained between the curve of the hyperbola and its asymptote. This produces a solid infinitely long, and yet is demonstrated to be equal to a finite solid or body. See *Logarithmic CURVE.*

HYPERBOLIFORM FIGURES, are such curves as approach, in their properties, to the nature of the hyperbola; called also *hyperboloids.*

HYPERBOLOIDS, are hyperbolas of the higher kind, whose nature is expressed by this equation, $a y^{m+n} = b x^m (a + x)^n$. See **HYPERBOLA.**

HYPERBOLOID denotes also the hyperbolic conoid. See **CONOID.**

HYPERBOREAN, ὑπερβορέϊος, in the *Ancient Geography.* The ancients denominated those people and places Hyperborean, which were to the northward of the Scythians. They had but very little acquaintance with these Hyperborean regions; and all they tell us of them is very precarious, and much of it false.

Diodorus Siculus says, the Hyperboreans were thus called because they dwelt beyond the wind Boreas; ὑπερ signifying *above* or *beyond*; and Βορέας, Boreas, the north wind. This etymology is very natural and plausible, notwithstanding all that Rudbecks has said against it, who would have the word to be generally Gothic, and to signify *nobility.*

Herodotus doubts whether or not there were any such thing as Hyperborean nations: Strabo, who professed that he believed there were, does not take Hyperborean to signify *beyond Boreas*, or the north, as Herodotus understood it: the preposition ὑπερ, in this case, he supposes only to help in forming a superlative; so that hyperborean, on his principle, means no more than *most northern*: by which it appears the ancients scarcely knew themselves what the name meant by it. Strabo assigns for their habitation the country in the vicinity of the Euxine sea. Callimachus the poet places them near the Palus Mæotides. Pliny and Pomponius Mela place them behind the Rhipæan mountains, towards the icy sea. Virgil and Catullus are of the same opinion. According to Mela, Pliny, and others, they inhabited a country in which they had a day and night of six months each. Most of our modern geographers, as Hoffman, Cellarius, &c. have placed the Hyperboreans in the northern part of the European continent, among the Siberians and Samoëds: according to them the Hyperboreans of the ancients were those, in general, who lived farthest to the north. The Hyperboreans of our days are those Russians who inhabit between the Volga and the White sea. According to Clavier, the name Celtes was synonymous with that of Hyperboreans. These people, it is said, were accustomed to send the first productions of their fruits to Delos, to be consecrated to Apollo, whom they principally honoured.

HYPERCATALECTIC, ὑπερκαταλεκτικῶς, composed of ὑπερ, *over*, *beyond*, and καταλεγεῖν, *I put to the number, I add*; so that hypercatalectic denotes as much as *superadded*; in the *Greek* and *Latin Poetry*, is applied to verses which have one or two syllables too much; or beyond the regular measure. See **VERSE.**

The Greek and Latin verses are distinguished, with respect to their measure, into four kinds: *acatalectic* verses, where nothing is wanting at the end; *catalectic*, which want a syllable at the end; *brachycatalectic*, which want a whole foot at the end; and, lastly, *hypercatalectic*, which have one

or two syllables too many. These last are also called *hyper-meters.*

HYPERCATHARSIS, in *Medicine*, from the Greek ὑπερ, *supra*, and καθαρῖς, *I purge*, signifies an *over-purgation*, or excessive purging induced by medicine.

A hypercatharsis is said to take place, when the frequency of loose stools, after any cathartic has been administered, continues great, after the operation of the cathartic might have been expected to cease; or when the purging operation is very severe, being accompanied with a great discharge of serous or mucous fluids from the bowels, or with bloody evacuations. Such extreme purgation is most commonly occasioned by cathartics of a drastic nature; but we have seen it produced, in certain conditions of the constitution, by those of a milder quality, such as the crystals of tartar. In oïd and debilitated habits, violent purgatives should be employed with great caution, and only when more lenient ones appear to be altogether inadequate to accomplish the object in view; since a hypercatharsis, induced in such habits, may occasion so sudden a depression of the powers of life as may be irrecoverable. The ancients, from the paucity of their catalogue of purgative drugs, were compelled to administer the white hellebore, where an active cathartic was required; and it would appear, from the aphorisms of Hippocrates, that convulsions and death occasionally followed the hypercatharsis, which that acrid medicine produced.

The most effectual remedy for allaying the inordinate action and irritation in the bowels, in a hypercatharsis, is opium, under any form. If the strength is already considerably reduced, it may be combined with cordial and stimulant medicines, wine, and light but cordial nutriment. The absorbent and astringent substances may be advantageously united with the opiates, but are inefficacious alone; such are chalk, gum kino, the extract of log-wood, and especially the extract of catechu, which, when joined with aromatics and opium, as in the *confectio catechu* of the Edinburgh Pharmacopœia, is a very effectual foother of excessive irritation in the alimentary canal. As the irritation, thus excited, is often chiefly seated in the large intestines, the opiates may be frequently administered in mucilaginous or starch glysters with great and speedy benefit.

HYPERCHIRIA, in *Mythology*, a title of Juno, under which she was worshipped in Laconia.

HYPERCRISIS, in *Medicine*, a term used by Galen and other ancient writers to denote any immoderate critical excretion, or *super-crisis*, as it were. (See **CRISIS.**) Thus when a fever terminates by a profuse sweating or diarrhœa, the discharge being greater than the strength of the patient is able to bear, a hypercrisis was said to take place. See Galen, cap. 3. prognost.

HYPERCRITIC, compounded of ὑπερ, *supra*, and κριτικῶς, of κριτής, *judex*, of κρίνω, *I judge*; an over-rigid censor, or critic; one who will let nothing pass, but animadvert severely on the slightest fault.

HYPER-DIEZEUXTS, in *Music*, the disjunction of the two tetrachords, separated by the interval of an octave, as the tetrachord hypaton and hyperbolæon.

HYPER-DORIAN, a mode so called in Greek music, and sometimes denominated Mixo-Lyidian; the fundamental or key-note of which was a fourth above the Dorian. See **MODE.**

The invention of the hyperdorian mode is ascribed to Pythoclides.

HYPERDULIA, ὑπερδουλίαν, composed of ὑπερ, *above*, and δουλίαν, *worship*, in the *Romish Theology*, is the worship rendered to the Holy Virgin.

The worship offered to saints is called *dulia*; and that to the

the Mother of God, *hyperdulia*; as being superior to the former.

HYPERICOIDES, in *Botany*. See ASCYRUM.

HYPERICUM, ὑπερικόν of Dioscorides, as appears by his description; and the *Hypericum* of Pliny. Linnæus deduces the name from ὑπερ, *above*, and εικων, *a figure or image*, which does not seem to bring us a step nearer to its meaning. Linn. Gen. 392. Schreb. 517. Willd. Sp. Pl. v. 3. 1437. Mart. Mill. Dict. v. 2. Sm Fl. Brit. 800. Juss. 255. Tourn. t. 131. Lamæck. Illustr. t. 643. Gærtn. t. 62. (Ascyrum; Tourn. t. 131. Lamæck Illustr. t. 642.) Class and order, *Polyadelphia Polyandria*. Nat. Ord. *Rotacea*, Linn. *Hyperica*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep, nearly ovate, concave, permanent segments. *Cor.* Petals five, oblong-ovate, obtuse, spreading, obliquely twisted according to the sun's motion. *Stam.* Filaments numerous, capillary, united at the base into three or five bundles; anthers small, roundish. *Pist.* Germen superior, roundish; styles three or five, sometimes one or two, simple, distant, the length of the stamens; stigmas simple. *Peric.* Capsule roundish, the number of its cells agreeing with that of the styles. *Seeds* numerous, oblong, affixed to the central column.

Ess. Ch. Calyx in five deep segments, inferior. Petals five. Filaments numerous, united by the base into three or five sets. Capsule with many seeds.

A copious and handsome genus, chiefly European, American, or Chinese, rarely tropical. Willdenow has 88 species; 11 are now known as belonging to the British Flora. The stems are either shrubby or herbaceous, usually angular. *Roots* perennial. *Leaves* simple, opposite, sessile, entire. Whole herbage generally smooth, with glandular pellucid dots, and an aromatic scent, rarely downy. *Flowers* terminal, cymose, yellow and brilliant. *Calyx* often fringed.

Common wild species are,

H. quadrangulum, Engl. Bot. t. 370. Curt. Lond. fasc. 4. t. 52, found about ditches and rivers; *perforatum*, Engl. Bot. t. 295. Curt. Lond. fasc. 1. t. 57, more abundant in dry bushy places; and *pulehrum*, Curt. Lond. fasc. t. 56. Engl. Bot. t. 1227, which forms an elegant decoration to healthy bushy ground.

H. calycinum, Curt. Mag. t. 146. Engl. Bot. t. 2017, now known to be wild near Cork, in Ireland, is a frequent ornament to shrubberies and parks, where its ample blossoms are very conspicuous.

Several shrubby American species are cultivated with us for ornament, as the *hircinum*, remarkable for its strong fox or goat-like scent.

HYPERIDES, in *Biography*, an eminent Grecian orator, the son of Glaucippus, was born at Athens, and studied under Plato and Isocrates. He cultivated the art of eloquence, became one of the most distinguished orators of his time, and acquired that sway in state affairs which popular oratorical talents never failed to obtain in the ancient democracies. He was the steady and zealous opponent of Philip of Macedon, and his zeal caused him to be made commander of a galley, in which capacity he gained much credit by his promptness and zeal in succouring the Byzantians. When Philip threatened an invasion of Eubœa, Hyperides procured a tax to be levied for the equipment of 40 galleys, and set the example by contributing one for himself and another for his son. In the time of Alexander he was possessed of the chief influence in Athens, and when that prince demanded galleys and officers from the Athenians he opposed the grant of either. His life was fully devoted to his country. He moved distinguished honours to Demosthenes his great competitor in eloquence; but when this prince of orators was

suspected of having taken a bribe from Harpalus, he was appointed to conduct the prosecution against him. Hyperides was himself accused of having acted contrary to the laws, by procuring a decree for granting citizenship to foreigners, and liberty to the slaves, whose families he caused to be transported to the Piræus, but he justified himself on the ground of state necessity, and proved that it was not he who passed the decrees, but the alarm with which Athens was seized, and the defeat of the Charœnea. Hyperides continued his opposition to the Macedonian power after the death of Alexander; and when Antipater sent deputies to Athens, who made a high eulogy upon their master as the worthiest of men: "I know," replied Hyperides, "that he is a very worthy man, but we will have no master however worthy he may be." The approach of Antipater obliged Hyperides and the other leading characters to quit Athens, and he had an interview with Demosthenes, also a fugitive at Ægina. Departing thence, he was seeking for a safer place of refuge, when he was apprehended by Archias in the temple where he had taken sanctuary, and carried to Antipater at Cleonæ. He was put to the torture with the hope of obtaining from him some state secrets: to prevent this he is said to have bit off part of his tongue; but another account relates that his tongue was cut out by the tyrant as a punishment due to his silence. His body was left unburied till some of his relations secretly committed it to the funeral pile, and brought his ashes to Athens. Quintilian characterises the oratory of Hyperides as singularly sweet and acute, better adapted to little than to great causes. In the time of Photius 52 of his orations were extant. Gen. Biog.

HYPERIDROSIS, the distention of a part by water.

HYPERINESIS, of ὑπερ and νησις, *purgation*, a word used by Hippocrates for any excessive evacuation, but most frequently in the same sense as hypercatarrhis, an over-purging.

HYPER-IONIAN, in *Ancient Music*, one of the Greek modes, whose fundamental was one fourth above the Ionian. It is the 12th mode ascending in the scale.

HYPERIUS, GERARD ANDREW, in *Biography*, was born at Ypres in Flanders, whence he took his surname, in the year 1511. He was sent to Paris to complete those studies which he had successfully commenced in the Flemish schools. He entered on the study of divinity, which he prosecuted with much diligence till the year 1535. During the vacations he travelled much in different countries, and after he had completed his studies at Paris he spent some time at Louvain, and then visited several other German universities. These visits into heretical countries not only prevented him from being preferred in the church, but obliged him to seek the security of his person in England, which at almost every period of her history has been more or less friendly to the votaries of freedom. He lived four years in the house of Charles lord Montjoy, who settled on him a handsome stipend, which enabled him to apply himself to the pursuits of literature. During this period he embraced the opportunities offered him of visiting the universities of Cambridge and Oxford, but, alarmed at some proceedings of Henry VIII., he returned to the continent, settled at Marburg in 1542, and was appointed to the theological chair. The duties of this office he performed with great reputation 22 years. He died in the year 1564, about the age of 53. He was author of numerous works, some of which were published by himself, and the rest were given to the world after his death. They consist of "Commentaries on the Scriptures;" "Theological Disquisitions;" "Controversial Tracts;" treatises in rhetoric, logic, arithmetic, geometry, astronomy, optics, natural philosophy, &c. Hyperius, says his biographer, had

had a very clear head, and a very happy talent in conveying instruction. He was meek and polite in conversation, and delighted in social convivial intercourse. In a word, he was a man who possessed true wit and good sense, and who added to those qualities a high degree of virtue and zeal. Bayle.

HYPER-LYDIAN, in *Music*, was the most acute of the 15 Greek modes. Its fundamental was a fourth above the Lydian.

HYPERMETER, composed of $\delta\pi\epsilon\tau$, *supra*, and $\mu\epsilon\tau\rho\nu$, *measure*, in the *Ancient Poetry*, the same with hypercatalectic.

HYPEROA, a word applied by authors to the upper part, or palate of the mouth, and the basis cerebri. It properly signifies any upper place.

HYPEROCHE of *Dr. Busby*, in *Music*, (*Mus. Dict.*) is "the difference between the enharmonic and chromatic diesis," an interval, whose ratio is $\frac{2097152}{2109375} = 5 \Sigma + f$,

which is the **SEMI-COMMA** *maxime* of Rameau, see that article. A doubt, however, remains with us, as Dr. B. has quoted no author, only mentioning the ancient authors generally, nor given the ratios, whether by the term "chromatic diesis," he did not mean the least chromatic diesis of Holder, Chambers, &c. in which case his hyperoche would coincide with the hyperoche of Hensling and others below.

HYPEROCHE of *Dr. Callcott*. In perusing the additions by Dr. Callcott to the Overend MS. which we have so often quoted, we met with an interval so named, whose ratio is $\frac{16,677,181,699,666,569}{16,777,216,000,000,000} = 5 \Sigma + 2 f$, which is the **greater RESIDUAL**, see that article.

HYPEROCHE of *Hensling*, Travers, Dr. Pepusch, Overend, Dr. Callcott (*Musical Grammar*, art. 23r.), &c.

is an interval whose ratio is $\frac{3072}{3125}$, or $\frac{2^{10}3}{5^5}$, its value in *Farey's* notation being $15 \Sigma + f + m$; its common logarithm is .9925711,8968, the reciprocal of which is 74288,1032; its Euler's or binary logarithm is .024679, such being its decimal value of the octave 1: it is equal 1.37696 major commas, and to 15.157524 schismas. It is equal to the sum of the following pairs of intervals, *viz.* a diaschisma and a medius residual, a major comma and a semi-comma major of Rameau, a minor comma and a semi-comma *maxime* of Rameau, a dieze minime and a schisma, a prisma and five schismas, &c. It results, as the difference between the following pairs of intervals, *viz.* a semitone minor and an enharmonic diesis, an enharmonic diesis and a major residual, a semitone subminime and a minor comma, a major semitone and two enharmonicdieses, a chromatic diesis and a major comma, two semitones minor and a semitone major, two minor tones and three major semitones, three minor semitones and a minor tone, &c. The following three intervals also compose it by addition, *viz.* a schisma, a minor residual and a diaschisma, a schisma, a medius residual, and a major comma, &c.

If three major thirds be turned upwards, and two minor thirds and a fourth downwards, each true and without any beats on an instrument having sufficient strings, this interval will result; which, in the additions to the Overend MS. by Dr. Callcott, is designated by the Greek small ρ or ρi .

HYPEROCHE of *Ptolemy*, is an interval whose ratio is $\frac{128}{129}$, or $\frac{2^7}{3 \cdot 43}$, or 6.88806 $\Sigma + m$, and therefore not in the diatonic scale: its common logarithm is .9966202,5935, and its Euler's log = .01122725, and it is equal to .6264543 major commas. It cannot, of course, be tuned by any combinations of perfect concords, though it readily

may by calculating the BEATS which it makes. See that article.

HYPERO-PHARYNGÆI, in *Anatomy*, a name given by M. Santorini to the perystaphylo-pharyngæi muscles.

HYPEROSTOSIS, from $\delta\pi\epsilon\tau$ upon, and $\delta\sigma\tau\epsilon\omega$, a bone, in *Surgery*, any hard indolent swelling upon a bone. See EXOSTOSIS.

HYPER-OXYMURIATES. See the following article.

HYPER-OXYMURIATIC ACID, in *Chemistry*. This acid contains a greater proportion of oxygen than the oxymuriatic acid, and on that account has received its name. It may be procured in combination with potash in the following process: if a quantity of potash, with six times its weight of water, be put into one of the bottles of Woulfe's apparatus, and a stream of oxymuriatic acid gas be passed through it till the potash is saturated, crystals in the form of fine white scales fall to the bottom; these are crystals of hyper-oxymuriatic of potash, being a compound of potash and hyper-oxymuriatic acid. This acid is chiefly known in its saline combinations. These are named *hyper-oxymuriates*, and from the peculiarity of their chemical composition—the large quantity of condensed oxygen existing in them, and retained by no very strong attraction, their characters are extremely distinctive. The principal are these, they afford very pure oxygen when exposed to a red heat, detonating with great violence with inflammable bodies, either on the application of heat, or by mere percussion or trituration, and causing those bodies to burn when sulphuric or nitric acid is added to the mixture of the salt and the inflammable matter. Their taste is cool and penetrating; they are generally soluble in water, and crystallizable: the greater number of them are also soluble in alcohol. They do not precipitate any of the metallic salts; nor destroy the vegetable colours, but in small quantities they heighten them. The hyper-oxymuriatic acid contains

Oxygen	-	-	65 parts.
Muriatic acid	-	-	35
			100

The order of the affinities of the hyper-oxymuriatic acid is the following:

Potash,	Lime,
Soda,	Ammonia,
Barytes,	Magnesia,
Strontites,	Alumine.

From the hyper-oxymuriates of potash, oxygen-gas can be obtained in the greatest purity; but the most astonishing of its properties are those which it exhibits when mixed with combustibles. All combustible substances are capable of decomposing it, and in general the decomposition is attended with violent detonations. When three parts of this salt and one of sulphur are triturated in a mortar, the mixture detonates violently: the same effect is produced when the mixture is placed upon an anvil, and struck smartly with a hammer. It sometimes detonates spontaneously without any perceptible friction. Charcoal produces the same effect, though not so violent. This property led Berthollet to propose it as a substitute for nitre in the preparation of gunpowder. The attempt was made in 1788, but as soon as the workmen began to triturate the mixture of charcoal, sulphur, and the hyper-oxymuriate of potash, it exploded with violence, and proved fatal to two of the experimenters. Phosphorus detonates with this salt either by trituration or percussion, but

The quantities used should not be more than half a grain each, or there will be danger in the experiment. When this salt is triturated in a mortar with a little cotton cloth, small repeated explosions are heard similar to the crack of a whip, and if the cotton be dry and warm it sometimes takes fire. When nitric acid is poured upon a mixture of oxymuriate of potash and phosphorus, flakes of fire are emitted at intervals for a considerable time. The theory of these explosions is this. The oxygen of the acid combines with the combustible, and at the same time lets go a quantity of caloric: and trituration or percussion acts merely by bringing the particles which combine within the sphere of each other's attraction. The constituents of the oxymuriate of potash are

58.3 Acid,
39 2 Potash,
2.5 Water.

It is prepared by dissolving one part of carbonate of potash in six parts of water, and saturating the potash with oxymuriatic acid gas. When the saturation is nearly completed the oxymuriate falls down in crystals. It is purified by solution in boiling water: as the water cools, the pure hyperoxymuriate crystallizes. The crystals are to be dried between the folds of blotting paper. Hyperoxymuriate of soda may be prepared by the same process as hyperoxymuriate of potash; it crystallizes in cubes, and it produces a sensation of cold in the mouth. The other hyperoxymuriates that have been examined are those of ammonia, magnesia, lime, barytes, and strontian. See *MURIATIC Acid*, in which article an account of Dr. Davy's experiments on it, with a view to its decomposition, and the results will be given.

HYPER PHRYGIAN, in *Ancient Music*, called by Euclid hypermixolydian, was the most acute of the thirteen modes of Aristoxenus.

HYPERSARCOMA, or **HYPERSARCO'SIS**, from $\epsilon\pi\epsilon\sigma\sigma$, and $\sigma\alpha\rho\zeta$, *flesh*, a fleshy excrescence; fungous granulations; proud flesh.

HYPERTHYRON, formed of $\epsilon\pi\epsilon\sigma\sigma$, *over*, and $\delta\epsilon\upsilon\tau\epsilon\tau$, *gate*, in the *Ancient Architecture*, a sort of table used after the manner of a frieze, over the jambs of Doric doors and gates, and the lintels of windows. It lies immediately under the corona; and is, by our workmen, usually called the *king-piece*.

HYPETHRE, two rows of pillars surrounding, and ten at each face of any temple, &c. with a peristyle within of six columns. See **HYPETHROS**.

HYPHESIS, or **HOPHESIS**, in *Ancient Geography*, a river of India, called anciently by the natives *Beypaslia*; now the *Beyah*; which see.

HYPHEN, $\Upsilon\pi\epsilon\upsilon$, in *Grammar*. an accent or character, which implies, that two words are to be joined, or connected into one compound word—*As, male-administration*, &c.

Hyphens serve also to connect the syllables of such words as are divided by the end of the line.

HYPHIAUTES, **EPHIAUTES**, in *Mythology*, names given by the Greeks to certain rural divinities answering to the Incubi of the Romans.

HYPHYDRA, in *Botany*, derived from $\epsilon\upsilon\upsilon$, *under*, and $\eta\delta\omega\varsigma$, *water*, because, as Aublet informs us, it is always found growing three or four feet under the surface.—Schreb. 666. Willd. Sp. Pl. v. 4 629. Vahl. Symb. v. 3. 99. (Tonina; Aubl. Guian. 856. Juss. 443.) Class and order, *Monacia Gynandria*. Nat. Ord. *Plantæ incerte sedis*, Juss.

Gen. Ch. Male, Cal. Perianth of one leaf, deeply divided into three, obovate, concave, smooth lobes incurved at the top. Cor. none. Stam. Filaments six, capillary, long, inserted, at the angles, above the germen; anthers roundish.

Pist. Germen empty, inflated, membranous, hexagonal, truncated at the top; style capillary, the length of the stamens; stigma none.—Female, Cal. Cor. and Stam. none. *Pist.* Germen roundish, with three furrows; style triangular; stigmas three, acute. *Peric.* Capsule membranous, of one cell, and three valves. Seed solitary, ovate, streaked.

Ess. Ch. Male, Calyx three-cleft. Corolla none. Stamens six. Female, Calyx none. Corolla none. Style single. Stigmas three. Capsule of three valves, single-seeded.

1. *H. amplexicaulis*. (Tonina fluviatilis; Aubl. Guian. 857. t. 330.—Eriocaulon amplexicaule; Rottb. Surinam. 4. t. 1. f. 1.)—An inhabitant of waters at Guiana and Cayenne, flowering and bearing fruit in February. This herb puts forth many branching, scattered, erect or decumbent little stems, furnished with capillary radicles. Leaves alternate, smooth, narrow, lanceolate, acute, fringed longitudinally with reddish bristles, sessile, embracing the stem. Flowers capitate, axillary, on solitary footstalks.

HYPNOTIC, $\Upsilon\pi\alpha\sigma\iota\sigma$, derived from $\epsilon\pi\iota\sigma\sigma$, *sleep*, in *Medicine*, a remedy which promotes or induces sleep; called also *soporific* and *opiate*. See also **NARCOTICS**.

HYPNOTICUS SERPENS, the *sleep-snake*, in *Zoology*, the name of an East Indian species of serpent, called by the Ceylonefe *nintipolong*, a word importing the same sense. It is of a deep blackish brown, variegated with spots of white, and is a very fatal kind in its poison, its bite always bringing on a sleep which ends in death.

HYPNUM, in *Botany*, an ancient name for some kind of moss, formerly used in medicine. The word is supposed by Dillenius, who first adopted it for the particular genus to which it is now applied, to originate from $\epsilon\pi\iota\sigma\sigma$, *sleep*; and he justifies its application on the principle of fragrant substances, like these mosses, producing sleep. Dill. Musc. 261. Linn. Gen. 564. Schreb. 762. Hedw. Fund. v. 2. 94. Sm. Fl. Brit. 1276. Juss. 11. Lamarck Illustr. t. 874. (Leskea; Schreb. 762. Hedw. Fund. v. 2. 93. t. 10. f. 62—65.)—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Ess. Ch. Capsule ovate-oblong, from a lateral scaly sheath. Outer fringe of sixteen teeth, dilated at the base; inner a variously-toothed membrane; veil smooth.

This vast and beautiful genus differs from *Bryum*, (see that article), in no other essential character than the lateral, not terminal, situation of its female flowers. The habit, however, is widely different. *Hypnum* has usually a lax, spreading, repeatedly branched stem, whence its English name of Feather-moss, cloathing the ground to a wide extent, and being of larger dimensions than most others of this family. The species in the *Flora Britannica* are 77, and a few others have been found since that work came out. The *Species Muscorum* of Hedwig defines 83 *Hypna*, besides 35 species of *Leskea*, or *Leskia*, a genus comprehended under *Hypnum* in Flor. Brit. Yet these, making together 118, form but an inadequate catalogue of the known species, and some of them are reducible to other genera, *H. Smithii* of Dickson and Hedwig being a *Pterogonium*; and others belonging to *Hookeria*. The difference on which Hedwig founds the distinction between *Hypnum* and *Leskea* consists in the inner fringe, the teeth of which in the latter are equal and uniform, usually 16 in number, while in the former there are 16 broad teeth, with single or double intermediate ones. This distinction, however, proves not only extremely difficult to discern, but totally unnatural as to the species it brings together or separates, and by no means certain or constant in each.—See **FRINGE** of **MOSESSES**.

Hypnum is distributed into several sections.

1. Capsules erect. Shoots cylindrical.

Of this *H. pulchellum*, Engl. Bot. t. 2006, and *sericeum*, t. 1445, the latter very common on walls, roofs, banks, and trees, may serve for examples.

2. Capsules erect. Shoots compressed, the leaves being disposed in two ranks.

The only two British species here are *complanatum*, Engl. Bot. t. 1492, and *trichomanoides*, t. 1493.

3. Capsules drooping or curved. Shoots compressed, the leaves in two ranks.

Such are *denticulatum*, t. 1260; *crenulatum*, t. 1261; *serulatum*, t. 1262; and the common *riparium*, t. 2060. But *lucens* no longer remains here, being now called *Hookeria lucens*, (see *HOOKERIA*;) and there is much reason to believe the beautiful *undulatum* ought also to make one of a new genus, marked by its furrowed capsule.

4. Capsules drooping or curved. Shoots compressed. Leaves imbricated every way.

A handsome tribe, see *splendens*, Engl. Bot. t. 1424; *prolifera*, t. 1494. Curt. Lond. fasc. 1. t. 72, very common in woods, but rarely in fruit; and *pralongum*, t. 2035, also very frequent.

5. Capsules drooping or curved. Shoots cylindrical. Leaves imbricated every way.

A rather numerous section, in which we find *Alopecurum*, Engl. Bot. t. 1182, a native of shady moist rocks; *serpens*, t. 1037, very common, known by its white veil; *lutescens*, t. 1301; and the beautiful though vulgar *purum*, t. 1599.

6. Capsules drooping or curved. Leaves squarrose.

The sharp prominent leaves, projecting on all sides of the branches, give the peculiar character of this very distinct section, as in *suilans*, t. 1448; *friatum*, t. 1648; *stellatum*, t. 1302; and the great well-known *triquetrum*, t. 1622.

7. Capsules drooping or curved. Leaves curled.

In this elegant section are *rugosum*, t. 2250; *scorpioides*, t. 1039, the figure done from too young a specimen, but otherwise correct; *cupressiforme*, t. 1860; *molluscum*, t. 1327, and a near relation of the last, though much finer, the true *H. Christa castronsis*, t. 2108, recently discovered in Scotland by Mr. G. Don.

HYPO, ὑπο, a Greek particle retained in the composition of divers words borrowed from that language; literally denoting *under*, *beneath*.—In which sense it stands opposed to ὑπερ, *supra*, *above*.

HYPO-ÆOLIAN, a mode in the *Ancient Music*, called also by Euclid the grave hypo-lydian. This mode has its fundamental a fourth below the Æolian.

HYPOBOLE, from ὑπο, and βολη, *I cast*, or *Subjection*, in *Rhetoric*, a figure, so called, when several things are mentioned, that seem to make for the contrary side, and each of them refuted in order. This figure, when complete, consists of three parts; a proposition, an enumeration of particulars with their answer, and a conclusion. Thus Cicero, upon his return from banishment, vindicates his conduct in withdrawing so quietly and not opposing the faction that ejected him. Pro. Dom. cap. 35.

HYPOCATHARSIS, ὑποκαθαρσις, compounded of ὑπο, *under*, and καθαρσις, *I purge*, in *Medicine*, a too faint or feeble purgation.

HYPOCAUSTUM, ὑποκαυστος, formed of the preposition ὑπο, *under*, and the verb καυσω, *I burn*, among the Greeks and Romans, was a subterraneous place, wherein was a furnace that served to heat the baths.—Vitruvius calls it *caldarium*.

The ancients had properly two sorts of hypocausta; the one called by Cicero *vaporarium*, and by others *laconicum*, or *sudatio*; which was a large sweating bath, in which were

three brazen vessels called *caldarium*, *tepidarium*, and *frigidarium*, according to the water contained therein.

The other hypocaustum was a sort of *fornax*, or oven, to heat their winter parlours, or *cenatiuncule hyberna*.

The latter hypocaustum was called *alveus* and *fornax*; and the man that tended the fire, *fornacator*. See *BATHS*.

The remains of a Roman hypocaustum, or sweating-room, were discovered under ground at Lincoln, in 1739. We have an account of these remains in the Phil. Trans. N^o 401. sect. 29. See *Abr.* vol. ix. p. 455.

HYPOCAUSTUM, among the moderns is that part or place where the fire is kept that warms a stove, or hot-house.

HYPOCHÆRIS, in *Botany*, ὑποχæρις, an ancient name of uncertain derivation. Linn. Gen. 405. Schreb. 533. Willd. Sp. Pl. v. 3. 1620. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 840. Juss. 170. Lamarck Illustr. t. 656. Gærtn. t. 160. Class and order, *Syngenesia Polygamia equalis*. Nat. Ord. *Compositæ Semiflosculose*, Linn. *Cicboracæ*, Juss.

Gen. Ch. *Common Calyx* roundish, imbricated, swelling at the base; the scales lanceolate, acute. *Cor.* compound, uniform, imbricated, the florets hermaphrodite, equal, numerous, each with one ligulate, linear, abrupt, five-toothed petal. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen ovate; style thread-shaped, the length of the stamens; stigma two, reflexed. *Peric.* none, except the closed calyx, assuming a globose pointed shape. *Seeds* solitary, oblong. *Down* feathery, stalked. *Recept.* clothed with linear-lanceolate scales, the length of the seeds.

Eff. Ch. Receptacle chaffy. Calyx somewhat imbricated. Down feathery.

Obf. Haller, Reichard, and others have remarked, that in *H. glabra* the seeds of the circumference have sessile down. See *Fl. Brit.* 842.

Five species of *Hypochæris* are defined by Willdenow, some Linnæan ones being removed to *Seriola*. Three are natives of England; the *maculata*, Engl. Bot. t. 225, found in chalky open pastures, but rarely; *glabra*, t. 575. Curt. Lond. fasc. 3. t. 53, a native of gravelly fields, sometimes found among turnips in Norfolk, in which case it is very luxuriant; and *radicata*, Curt. Lond. fasc. 3. t. 52. Engl. Bot. t. 831, a very common weed.

The first is perennial, with a nearly solitary, rather large, yellow flower, and toothed, rough leaves spotted with black. The second is annual, smooth, with several small, pale, yellow flowers, expanding in the morning only. The third is perennial, with rough runcinate leaves, a smooth branching stem, and large flowers of a full yellow.

The other two species in Willdenow are,

1. *H. helvetica*, Jacq. Ic. Rar. t. 165, a large and handsome plant, confounded by Linnæus with his *maculata*, from which its narrower, lanceolate, unspotted leaves, perfectly simple stem swelling upward, and very large flower distinguish it. This species, found on the Alps, is delineated by Haller, Allioni, and Villars, being a favourite with alpine botanists.

2. *H. minima*, Desfont. Atlant. v. 2. 238. (*H. hispida*; Roth. Catal. v. 1. 100.) Native of Barbary, resembling *H. glabra*, but scarcely half its size, with roughish leaves and a bristly calyx.

HYPOCHEOMENOS, a person afflicted with a catact, or opacity of the crystalline lens of the eye. The term is derived from ὑποχæρις, *to suffuse*.

HYPOCHONDRIA, in *Anatomy*, from ὑπο, *under*, and χονδριος, *cartilage*, those parts of the cavity of the abdomen which are covered by the inferior ribs and their cartilages:

HYPOCHONDRIASIS.

cartilages: they are distinguished by the epithets right and left. See ABDOMEN.

HYPOCHONDRIASIS, in *Medicine*, a disorder principally characterized by an anxious and apprehensive state of mind in respect to the patient's health, and by an imaginary suffering of many morbid affections, together with a deranged state of the digestive organs.

This complaint has been known from ancient times, and has received a great variety of appellations, many of which have been derived from hypothetical views of its nature. The term *hypochondriasis*, or *hypochondriac disease*, is taken from *hypochondrium*, ὑποχόνδριον, which signifies literally *under the cartilage*, and is the name given by anatomists to the upper and lateral regions of the belly which lie under the cartilages of the false ribs. This appellation was probably given to the disease in question, in consequence of the general uneasy sensations which are experienced by hypochondriacs in these parts of the body, especially on the left side; as well as from the opinion of physicians, that the seat of these sensations, and of the disease itself, is always in some of the organs which lie in the hypochondria, and which are the stomach and spleen on the left side, and the liver on the right. The Arabians denominated the disease *Mirachia*, the word *Mirach*, in their language, signifying the abdomen or belly. The opinion, which was for a long time prevalent, that the *spleen* was principally the seat of the disorder, gave occasion to the use of the name of that viscus to denote the malady. And another supposition, that the disordered state of the mind was excited by *vapours*, arising from a collection of fæulent and offensive matter accumulated in the spleen and first passages, gave rise to the denomination of *vapours*, by which the malady has also been designated. The French call hypochondriacal persons, *malades imaginaires*, from the various imaginary evils of which they complain. The term *hyp* and *hypo*, familiarly used in this country, are obviously contractions of the Greek name.

It would be impossible to give a regular history of all the symptoms of a disease, which is ever varying and irregular in its phenomena, and includes, in different instances, almost all the painful sensations and signs of disordered functions, that are witnessed in the various complaints incident to the human frame. We must content ourselves, therefore, with delineating the peculiar features of the disorder, and enumerating some of the most remarkable circumstances that have been observed to accompany it. We might say, in a few words, that, after a series of symptoms, evincing a deranged state of the bodily health in general, but especially of the organs of digestion, which have continued for an indefinite length of time, a state of mind gradually shews itself, which is distinguished by the following circumstances; languor, listlessness, or want of resolution and activity with respect to all undertakings: a lowness of spirits, sadness, and timidity; and with respect to all future events, a dread and apprehension of the worst, or most unhappy occurrences, often upon the slightest grounds. But this apprehension is particularly directed to the state of the patient's health; he attends minutely to every change of sensation, and from every unusual feeling, though of the slightest kind, anticipates great danger, and even death itself. He supposes himself, at different times, as these sensations vary, afflicted with every disorder in succession that he has either seen, heard, or read of: and, in respect to all these feelings and apprehensions, he commonly entertains the most obstinate persuasion and belief, and is even disobliged by any person, who shall intimate that he looks well. He is fond of complaining, and tiresome in describing his maladies: never satiated with

medicines, yet constantly anxious to fly from remedy to remedy; and equally desirous of medical counsel, yet soon dissatisfied with every physician. As the disease advances, he is afflicted with most unaccountable sensations and affections, which can be only referred to his imagination.

Such, in brief, is the character of hypochondriasis. This state of mind, however, as we have just stated, is ushered in and accompanied by various symptoms of corporeal disease, which are principally referable to a disordered condition of the digestive organs, with which other organs also suffer in sympathy. Thus the person is troubled for a considerable time with flatulency, and a sense of heat and pain along the course of the œsophagus and the pit of the stomach, called heart-burn, sometimes attended with acidity and sometimes with a feeling of oiliness and rancidity, especially when eructation takes place. The air, which is evolved in the stomach, produces great distention of that organ, and this distention is always accompanied with an uneasy feeling and sense of anxiety: this wind afterwards descends into the bowels, producing croaking and rumbling noises, called *borborigmi*, and exciting pricking pains, "spasms, thumpings, and pulsations in the belly," as Maudeville describes them, which consist of slight convulsive motions of the abdominal muscles. The appetite is frequently bad, but in some cases craving, and is generally irregular in the beginning, as well as the alvine discharge. As the disorder advances the patient is generally very colicive, discharging black hardened excrement, with much pain and straining. At this time the bowels are moved with difficulty, and require strong cathartics to produce any effect: hæmorrhoids or piles, especially internal ones, accompanied with great pain, and not unfrequently with bleeding, are liable to occur. Sometimes a diarrhœa suddenly comes on; but so far from giving relief, it rather exhausts the strength of the patient, and leaves him low and dejected.

While these symptoms of indigestion prevail, others, which appear to be the direct or indirect consequence of them, are often very troublesome. There is often a weight, oppression, or tightness felt about the præcordia, with palpitations of the heart: the face is frequently flushed, and flying heats are felt even over the whole body: the head often aches, and the eyes are dim. The urine is various: it is often of a wheyish, or milky white appearance, which always announces a great weakness and disorder in the chylopoëtic viscera: at other times a pale and limpid urine is passed in large quantities, especially after any agitation of mind, or hurry of spirits. Cold sweats, which alternate with flushes of heat, fainting, giddiness, deafness, ringing in the ears, and disturbed and unrefreshing sleeps, from which the patient wakes in fright, are common symptoms in the advanced stages of the disorder. The whole nervous system is deranged. The patient generally feels a much more oppressive sensation of weakness and fatigue than is natural, considering the muscular strength which he is capable of exerting. Slight symptoms of debility, which in another person would hardly produce any disagreeable effect, for instance, sudden distention of the stomach, slight palpitation, or colic, instantly occasion all the alarming feelings of fear and apprehension, and these are accompanied with a degree of anxiety which cannot be described.

But the hypochondriac has many painful feelings in parts where no disease apparently exists, and many diseased perceptions which command his belief, and greatly add to the sum of his misery. A number of those distressing feelings are often external pains, seated immediately under the skin, and in parts which, when examined, appear to be in a sound

HYPOCHONDRIASIS.

state. Sometimes the pain is seated in the middle of one or two of the ribs; sometimes in the middle of the leg, thigh, or arm; sometimes in the back, and in various parts of the scalp. That these painful feelings are generally transmitted from impressions in the stomach and bowels, appears from this; that they are most frequent, when the patient is troubled with indigestion, flatulency, colicness, or colic: what is very remarkable, the external pain is often increased by pressure. Dr. Crichton mentions the case of a gentleman who suffered exceedingly from these false pains. If the finger was pressed upon the pained part, it generally excited spasms in the organs of respiration, and occasioned so much agony, as to make him scream aloud; after the pressure was removed, the pain ceased. These pains were constantly shifting their place, and often wandered over half the patient's body in the course of the day. Dr. Whytt, after enumerating many facts, concludes, "that faintings, tremors, palpitations of the heart, convulsive motions, and great fearfulness, may be often owing more to the infirm state of the first passages, than to any fault either in the brain or heart:" and he farther remarks, in regard to himself, "When my stomach and bowels have been out of order, and affected with an uneasy sensation from wind, I have not only been sensible of a general debility and flatness of spirits, but the unexpected opening of a door, or any such trifling unforeseen accident, has instantly occasioned an odd sensation about my heart, extending itself from thence to my head and arms, and, in a lesser degree, to the inferior parts of my body. At other times, when my stomach is in a firmer state, I have no such feelings, or at least in a very small degree, from causes which might be thought more apt to produce them." Whytt on Nervous Disorders, chap. iii.

When the disagreeable feelings, dejection of spirits, and unremitting anxiety and attention to their health and to every new sensation, have continued for an indefinite time, which is longer or shorter, according to a variety of circumstances, diseased perceptions suddenly arise, which claim the belief of hypochondriacs. It would be vain to attempt an enumeration of all the extravagant ideas which enter into the minds of such people, since they are infinitely various. Some think that their extremities and posteriors are made of glass: others that their legs are as soft as wax; some think they have no heart, others that they have no soul; others fancy that they are dead, and others that they are changed to monsters, &c. In others, the disorder verges upon melancholy, and ideal pains of poverty, persecution of enemies, secret vengeance, and calumny, haunt them perpetually: but in this case, the disease may be considered as having passed the limits of hypochondriasis, and put on the character of insanity. When hypochondriasis arises from diseased viscera, the erroneous ideas, which present themselves to the mind of the patients, generally concern their own frame. It is not very easy to trace these erroneous perceptions to the original painful, yet obscure sensations in the body, to which they owe their existence. It is only, indeed, by a long continuance of these sensations, that they become associated with the strange notions of hypochondriacism. "Nothing can be more interesting," Dr. Crichton remarks, "to a physician who is endowed with only a moderate share of the spirit of observation, than the progress of this complaint in a number of patients, especially in regard to its effects on the mind. They always struggle more or less in the beginning, with the lowness and dejection which affect them; and it is not until many a severe contest has taken place between their natural good sense, and the involuntary suggestions which arise from the obscure and painful feelings of

their diseased nerves, that a firm belief in the reality of such thoughts gains a full conquest over their judgment. A firm belief in any perception never takes place until it has acquired a certain degree of force; and as all impressions which arise from the viscera of the abdomen are naturally obscure, we see the reason why these must continue for a great length of time, or be often repeated before they can draw a person's attention from the ordinary impressions of external objects, which are clear and distinct, and before they acquire such a degree of vividness as to destroy the operations of reason." An Inquiry into the Nature and Origin of Mental Derangement, &c. vol. i. p. 202.

Dr. Crichton thus attempts to explain the fact, that the source of the mental illusion generally lies in the abdomen. "Most of the objects which surround us have been examined by several of our senses; we have compared the various sensations they have yielded, and these, therefore, become associated in our minds; so that if any external body, thus examined, be again presented to only one of our senses, the idea of all its various qualities is recalled, and we necessarily believe in their reality. The sources of almost all our perceptions, while we are in health, lie in external objects: for the nerves of the external senses are the only ones of our whole frame which convey clear impressions to the intellectual part. Hence we acquire a natural habit of ascribing all strong impressions to some external cause. In cases, therefore, where the cause of the sensation cannot be examined, a false judgment may easily arise. The languor and pain and various uneasy sensations, which a hypochondriac feels, naturally withdraw his attention from surrounding objects; and as the exercise of his judgment is weakened by the same circumstances, he does not examine the unreasonable ideas with accuracy, when they are first presented to his mind. Painful feelings are associated with melancholy thoughts; and new and uncommon feelings, upon the same principle, are ascribed to strange and uncommon causes. The weakness, therefore, which a hypochondriac feels in his limbs, makes him imagine they are unable to support him; but if they cannot do so, he concludes they must bend or break; the idea of fragility, or flexibility, however, is often derived from such substances as wax and glass, and he therefore believes that his limbs are made of some kind of similar materials." Loc. cit. p. 208.

In a word, these singular notions of the hypochondriac may be considered as arising from a long recurrence of novel and distressing sensations, connected with a morbid state of the nervous system in general, and of the mind or spirits in particular, which absorb the attention of the individual to the exclusion of common impressions: and as the perturbed and agitated mind converts every obscure impression on the sight, for instance, into visions of horrible form, of the reality of which, if the impressions continue, it conceives a firm belief; so these unusual sensations in the interior of the body become the ground-work of false and extravagant perceptions.

There is no difficulty in accounting for the ordinary suppositions of hypochondriacs, that they are affected with certain dangerous or loathsome diseases; when it is recollected, that scarcely any organ or portion of the body altogether escapes being the seat of some uneasiness or irregularity of function, which, in the watchful anxiety of the patient's mind, and his disposition to dependency, at once becomes the object of his attention and evil forebodings. Like *hysteria* in the female, this disease assumes the form, and mimics the symptoms, of almost all other diseases. When palpitations of the heart occur, with intermissions of the pulse, tightness in the chest, pulsation in the abdomen, &c. from over-distention of the stomach by food or flatulency, the hypochondriac

HYPOCHONDRIASIS.

hypochondriac immediately supposes that hydrothorax, dropy of the pericardium, aneurism of the heart or of the great artery, angina pectoris, or some such formidable disease, with which his reading or enquiries have made him acquainted, is already his lot. If, from sympathy with the same organs, the head is affected with giddiness, or pain, the eyes occasionally dim, the vision double, or otherwise incorrect, the ears affected with a ringing noise, &c. the notion of some disease fixed in the brain immediately occurs, which is at one time supposed to be hydrocephalus, at another an abscess in the brain, or some morbid adhesion among the membranes, &c. And in like manner, every other organ of the body is in its turn believed to be the seat of some fatal and irremediable malady.

While this general disturbed state of the sensations continues, the sleep is commonly imperfect and interrupted, and every variety of distressing dreams is excited; so that the patients frequently awake suddenly, with starting and in great terror, supposing themselves haunted by all sorts of monsters and visions which imagination can suggest, and suffering much from those oppressive feelings, which are comprehended under the denomination of *incubus* or *night-mare*. It is not difficult to conceive, that some of the fancies, entertained by hypochondriacs, may have originated in these dreams, and become rivetted by repetition, from the recurrence of the peculiar sensations which called forth the trains of ideas. See DREAMS.

It would be superfluous to attempt to illustrate all the various absurd notions which hypochondriacs have in different instances entertained, and the strange resolutions which they have formed in consequence; many examples of them are detailed by writers on mental derangement, of which one or two may suffice. Tulpus relates, that a painter of considerable reputation imagined that all his bones were become so soft and pliant, that they must necessarily bend like wax, if he attempted to walk, or if any hard body was struck against them. In conformity with the fears which such a notion inspired, he kept his bed during the whole winter, imagining that if he arose, his legs would be compressed by his own weight into a lump like clay or wax. (See his *Obs. Med. lib. i. cap. 18.*) Marcus Donatus has stated, that a baker of Ferrara believed he was made of butter, and on that account would not approach the oven, lest he should melt. (*Hist. Med. Rar. lib. ii. cap. 1.*) The same author has recorded the case of a person, of the name of Vincentinus, who believed that he was of such an enormous size, that he could not go through the door of his apartment. His physician gave orders that he should be forcibly led through it, which was done accordingly, but not without a fatal effect; for Vincentinus cried out, as he was forced along, that the flesh was torn from his bones, and that his limbs were broken off, of which terrible impression he died in a few days, accusing those who conducted him of being his murderers. (*ibid.*) Dr. Darwin had witnessed twice an imaginary itch, and twice an imaginary diabetes, when there was not the least vestige of either of those diseases, and once an imaginary deafness, where the patient heard perfectly well; and an imaginary venereal disease, when they have only deserved it, is a very common hallucination among modest young men. See *Zoonomia*, vol. ii. class. iii. §. 2.

Although a great majority of hypochondriacal complaints, especially of the slighter kind, even when they have continued for a considerable time, do not lead to any serious result; yet there are many instances in which the actual state of corporeal disease is ultimately demonstrated, by the termination of the symptoms in dangerous and fatal maladies; such as apoplexy, palsy, jaundice, dropy, tympany, and

pulmonary consumption; not to mention the more complete diseases of the intellect, confirmed mania, melancholy, and fatuity, in which they occasionally end. For although the morbid condition of the abdominal viscera may be but slight in the first instance, and will yield to the regimen adopted for its removal; yet diseased vascular action, when long continued, whether idiopathic or sympathetic, frequently leads to morbid structure, to great congestions, and to slow inflammation, with adhesions, effusions of lymph and serum, &c. which are the consequences of the latter. See Whytt on Nervous Disorders, chap. vi.

Causes of Hypochondriasis.—Some persons are obviously much more liable to hypochondriacal affections than others; and this *predisposition* to the disease appears to consist in a peculiarity of constitution of the nervous system, and of the digestive organs. This constitution is not always to be distinguished by external character; but it belongs more particularly to the male sex, to the advanced periods of life, and to the melancholic temperament: it is commonly original, or distinguishes the individual from his birth; and is often hereditary, having existed in his progenitors; but it may be brought on by disease, by improper aliment, and certain modes of life. The disease, however, occasionally takes place in persons of the sanguineous temperament, as we shall state immediately. With respect to the constitution of the digestive organs, it is remarked by Dr. Whytt and Dr. Crichton, that this does not consist solely in debility; since we sometimes see the appetite good, and digestion well performed, on the one hand, and, on the other, we often meet with indigestion and disordered states of the stomach and bowels, in persons who have never suffered any hypochondriasis. It is to be considered, therefore, as a peculiar sensibility of the nerves of these parts, which are readily put into an unnatural or depraved state of feeling.

The *exciting causes* are such circumstances as tend to augment or produce this derangement of the chylopoëtic viscera, and of the general state of the nervous power. Among these we may enumerate great watching; excessive fatigue; anxious pursuit of business; a sedentary life; intense application to study; excess in venery; all the depressing passions, however produced, as grief, anxiety, and fear; general repletion in respect to food, or the use of improper diet; intermitting and remitting fevers. To these most writers on the subject have added, the prevalence of a gouty humour, or the existence of atonic, misplaced or retrocedent gout; the recession of certain cutaneous eruptions; and the retention and suppression of accustomed evacuations, as the catamenia and hæmorrhoids.

The former of these causes invariably influence the digestive organs, destroy the appetite for food, and render the stomach incapable of converting that which is taken into nutriment; hence the load and oppression after eating, the torpor, sleeplessness, &c. which ensue. At the same time an extreme mobility of the nervous system is induced, especially by exhaustion, from watching, hard study, or any other continued and anxious pursuit, or where there is any severe depressing emotion of mind. These causes, therefore, at once give rise to that disturbed state of the nervous system which takes the alarm at every disagreeable or unusual sensation, and to that derangement of the organs of digestion, which, from their peculiar and universal sympathy with every other part of the body, tends to multiply those morbid sensations. Hoffmann remarks, that intense study operates in an additional way, in consequence of the posture of the student; who, in leaning forwards immediately after the stomach is distended with food, necessarily occasions a pressure upon the viscera of the abdomen, and especially upon the meseraic veins;

HYPOCHONDRIASIS.

veins; whence the circulation through the liver is impeded, and consequently congestion must take place in the various organs of that cavity. (Syst. Med. Ration. tom. 1. lib. ii. cap. 10.) This disease, therefore, has been observed to be particularly frequent in literary men. These congestions have, in fact, been found to exist in such cases. Dr. Whytt says, "in the bodies of those who have died of the hypochondriac disease, the meseraic and other veins which meet to form the *vena portarum* (the great vessel which supplies the liver), have been often found greatly distended with blood. But," he adds, "this distension of those veins, if any thing preternatural, was probably only a consequence of some obstruction of the liver, and not to be reckoned, as it has been by some authors, the cause of that distemper." (Loc. cit. chap. 5.) Obstruction by direct pressure on the *vena portæ* must occasion the same effects on the other abdominal viscera as obstruction in the liver itself; and these effects, Dr. Whytt alleges, are occasioned "by hindering the free circulation of the fluids through these parts, by affecting their nerves with an uneasy sensation, and by preventing digestion; in the liver and spleen, by impeding the secretion of bile, and, by their weight, occasioning a disagreeable sensation, not only in these, but in the neighbouring parts by sympathy; in the mesentery, by preventing the further preparation of the chyle, and its course towards the thoracic duct; in the uterus and ovaria, by disturbing the functions of these parts, and by consent affecting the stomach and bowels."

The latter causes above-mentioned, especially the previous occurrence of intermitting and remitting fevers, may give rise to hypochondriasis, by their well-known influence on the abdominal viscera, especially the liver and spleen, which they often leave in an enlarged, indurated, or scirrhus state; from which the rest of the adjoining organs will be disordered in the way just stated. The observation, that wandering gout, as it has been called, gives rise to these nervous derangements is as old as Aretæus; and Musgrave, Whytt, and others among the moderns, have borne testimony to the correctness of the observation. It is, however, only an hypothetical expression of the fact, that when a regular fit of gout has occurred, these local and varying complaints have for a time disappeared; but affords no just grounds for the supposition of a morbid humour afloat in the system. (See GOUT and HUMORAL Pathology.) And in the same manner, the relief of hypochondriacal symptoms, on the appearance of certain pustular, scurfy, or other cutaneous eruptions, has been deemed a further proof that complaints of this kind proceed from some morbid humour in the blood; a notion which we have endeavoured to refute in the articles just referred to. See Whytt, loc. cit. Musgrave de Arthritide Anomala, cap. 19.

With respect to the *proximate cause*, or the essential constituent part of the disease, almost all writers have agreed in referring it to a morbid condition of the chylopoëtic and other abdominal viscera, as we learn from the following enumeration by Dr. Whytt. "Many authors," he observes, "have ascribed this disorder in men to obstructions in the spleen, liver, and mesentery. Highmore to a vitiated constitution of the stomach. (Exercit. de passione hyster. et affect. hypochond.) Willis to an indisposition of the brain and nerves, or to a fault of the spirits. Etmüller, who confounds the hypochondriac disease, when in a higher degree, with the scurvy, has written a dissertation to prove that its seat is not in the spleen, but in the intestines, especially in that part of the *colon* which lies in the left hypochondre, in which the excrements often stagnate, and where much wind is pent up. (Opera p. 1820.) Sydenham ascribes the same

distemper to an ataxy or confusion of the spirits. (Epist. ad D. Cole.) Maudeville to a disordered chylicification, and a deficiency or paucity of the spirits. (Treatise on the hypochond. and hyster. Passions, Dial. 1. and 2.) Juncker makes the *causa proxima* of the hypochondriac affection to consist in an obstructed motion of the blood in the *vena portarum* and viscera connected with it. (Conspectus Medicinæ, p. 186.) Boerhaave derives it from an atrabiliary humour lodging in the pancreas, spleen, stomach, and neighbouring organs. (Aphorism 1098.) Hoffmann from a perverted peristaltic motion of the stomach and intestines. (Syst. Med. Rat. tom. iii. p. 3. cap. 5.) And, lastly, Dr. Cheyne is of opinion, that all great nervous disorders proceed from some glandular obstruction in the stomach, bowels, liver, spleen, mesentery, or other organs of the lower belly. (English Malady, part ii. cap. 7.)"

It may be observed, then, that the observations of physicians from early times have nearly coincided, in referring the seat of the diseased action, upon which the symptoms of hypochondriasis depend, to the viscera of the abdomen; that the very appellation of the disease is deduced from such observations; that the uneasy sensations of patients, under this disease, are principally ascribed to the same part of the body; and that the disease often terminates in actual morbid structure of the organs there contained. The manner in which disease in these organs may give rise to the singular morbid sensations in distant organs, has been briefly touched upon above; and those who wish for farther illustration, in regard to the wonderful and widely extended sympathy, which obtains between the alimentary canal and almost the whole system, will be gratified by the perusal of the first chapter of Dr. Whytt's treatise, so often referred to in this article. (See also SYMPATHY.) A very able and experienced teacher in London infers from these facts, which opinion, he alleges, is corroborated by the superior success of a particular mode of treatment, "that the proximate cause of hypochondriasis, in a curative view, consists in a sluggish and irregular state of the hepatic function." Dr. Curry's Syllabus of Lectures at Guy's Hospital, p. 199.

Diagnosis.—There is some difficulty in drawing a precise line of distinction between hypochondriasis, on the one hand, and *dyspepsia* (indigestion), *hysteria*, and *melancholia*, on the other. This arises partly from the circumstance, that these diseases have all several symptoms in common; that hypochondriasis is often combined with one or other of them; and that they sometimes reciprocally pass into each other. There are few cases of hypochondriasis in which some degree of dyspepsia is not present; but Dr. Cullen has pointed out a striking difference in the disease, as it occurs in two different temperaments, or states of the constitution: first, as it occurs in *young* persons of both sexes, in men of a *sanguine* temperament, and of a lax and flaccid habit; and, secondly, as it occurs in *elderly* persons of both sexes, of a *melancholic* temperament, and of a firm and rigid habit. "These two different cases of the combination of vapours and dyspepsia," he says, "I consider as two distinct diseases, to be distinguished chiefly by the temperament prevailing in the persons affected. As the dyspepsia of sanguine temperaments is often without vapours; and as the vapours, when joined with dyspepsia in such temperaments, may be considered as perhaps always a symptom of the affection of the stomach, so to this combination of dyspepsia and vapours, I would still apply the appellation of *dyspepsia*," &c. "But the combination of dyspepsia and vapours in melancholic temperaments, as the vapours, or the turn of mind peculiar to the temperament, are essential circumstances of the disease; and as this turn of mind is often with few or only slight symptoms of dyspepsia,

and

HYPOCHONDRIASIS.

and even though the latter be attending, as they seem to be rather the effects of the general temperament than of any primary or topical affection of the stomach, I consider this combination as a very different disease from the former, and would apply to it strictly the appellation of hypochondriasis." Dr. Cullen farther remarks, "I believe the affection of the mind is commonly different in the two diseases; in dyspepsia it is often languor and timidity only, easily dispelled; while in hypochondriasis it is generally the gloomy and rivetted apprehension of evil. The two diseases are also distinguished by some other circumstances. Dyspepsia, as I have said, is often a symptomatic affection, while hypochondriasis is, perhaps, always a primary and idiopathic disease. As debility may be induced by many different causes, dyspepsia is a frequent disease, while hypochondriasis, depending upon a peculiar temperament, is more rare." Cullen, *First Lines*, par. 1227 and 1231.

Most of the older writers consider *hysterical* and *hypochondriacal* affections as essentially the same, differing no more from each other than as the frame of the female sex, in which *hysteria* most commonly occurs, is more delicate than that of the male, which is most liable to hypochondriasis; or inasmuch as the *uterus* is supposed to be the seat of the disease in the one case, while the liver, spleen, or some contiguous viscus, is believed to be chiefly deranged in the other. The intelligent physician, Fred. Hoffmann, seems to have been one of the first to point out the difference of the two diseases, in respect to their symptoms, causes, and termination. (*Med. Rat. Syst.* tom. iii. p. 4. cap. 5. § 5 & 6.) There is this obvious difference between hysteria and the disease in question, in regard to the state of the spirits, to wit, while in hypochondriasis these are always in some degree low, inspiring the patient with a greater or less dread and apprehension with respect to the state of his bodily health; no persons, on the contrary, have a greater flow of high spirits than hysterical patients often exhibit; and the suddenness with which the symptoms change from one class to an opposite one, without any evident cause, or on the slightest imaginable, is one of the most remarkable features of the hysterical disease, not to mention the peculiar convulsive paroxysms, the *globus*, &c. which very frequently accompany the latter. See *HYSTERIA*.

With regard to the distinction between hypochondriasis and *melancholy*, an ambiguity has arisen, not only from the one occasionally degenerating into the other, but from the difference of opinion among medical men, as to the use of the terms. The generality of writers agree in confining the term hypochondriasis to those instances of dejection of spirits and gloomy apprehensions, which relate exclusively to the personal bodily health of the patient, while they appropriate the term melancholy to those cases in which the dependency and anxiety are fixed upon external relations, as the supposed loss of friends, the imaginary influence of calumny, persecution, &c. In the state of melancholy, too, the digestion is often not impaired, whereas indigestion almost invariably accompanies hypochondriasis; and it may be added, that in hypochondriasis the indigestion precedes this sorrowful state of the mind; whereas, in melancholia, when idiopathic, the state of the mind precedes, and is in a great measure unconnected with the indigestion. (Sims, in *Memoirs of Med. Society of Lond.* vol. v. p. 393.) Dr. Crichton has expressed an opinion, that it is of little utility to confine our diagnostic observations to the nature of the erroneous ideas, and he includes a much wider range in his notion of hypochondriasis. Nevertheless he subscribes in some measure to the distinctions above made, in admitting, that "when hypochondriasis arises *primarily from diseased viscera*, the erroneous ideas, which present themselves to the

mind, generally concern their own frame; but when it has *primarily arisen from melancholia*, then the morbid ideas are for the most part unnatural, or at least unreasonable fancies, either concerning other people, or their own worldly affairs." (*Vol. i. p. 201.*) These distinctions are all that are requisite with a practical view, and it is immaterial by what name we designate them, provided we avoid the confusion which an undefined acceptance of ordinary terms must occasion.

Cure of Hypochondriasis.—The method of treatment, required for the removal of hypochondriasis, must necessarily vary in different cases, according to the age, temperament, and particular symptoms of different individuals; and the attention of the physician must be directed more or less to the bodily or to the mental indisposition, accordingly as the one or the other is found to predominate. In all cases, indeed, these two indications must principally be kept in view; 1. To correct the particular dyspeptic or other morbid state of the alimentary canal, and of the organs more immediately connected with it; and 2. To occupy the mind with a variety of intertelling impressions, connected by a natural association, and thus gradually to weaken and destroy the morbid concatenation of ideas which had taken place.

So far as the bodily health is concerned, and especially that of the stomach, it might seem necessary only to have recourse to the usual remedies for *indigestion*; and that practice has generally been carried on with little distinction; but Dr. Cullen has justly pointed out some distinction which is to be made. Where the symptoms of indigestion are particularly urgent, then the same means must be resorted to for their relief, as in cases of simple dyspepsia. Thus, where excess of acidity, which, from the slow evacuation of the stomach in melancholic temperaments, often arises to a high degree in hypochondriasis, occurs, it must be obviated and corrected with the utmost care, by the use of the several antacids, and other means adapted to that purpose. (See *INDIGESTION*.) In like manner, the distress arising from flatulency, heartburn, costiveness, &c., may be alleviated by the appropriate means. (See the same article; also *CARDIALGIA*, *FLATULENCE*, and *CONSTIPATION*.) The point in regard to which Dr. Cullen suggests an important distinction in the treatment of hypochondriasis and simple dyspepsia in sanguine habits, relates to the use of corroborant medicines, to restore the tone of the stomach. "In dyspepsia," he says, "the chief remedies are the tonic medicines, which to me seem neither necessary nor safe in hypochondriasis; for in this there is not a loss of tone, but a want of activity that is to be remedied." (*First Lines*, 1239.) And he suggests, that a practice directly opposite to that employed in the case of dyspepsia is often to be followed. Cold bathing, he observes, is often highly useful to the dyspeptic, and as a general stimulant, may sometimes seem useful to the hypochondriac; but it is not commonly so to the latter; while, on the other hand, warm bathing, hurtful to the dyspeptic, is often extremely useful to the hypochondriac. Another instance, he says, of a contrary practice necessary in the two diseases, and illustrating their respective natures, is, that the drinking tea and coffee is always hurtful to the dyspeptic, but is commonly extremely useful to the hypochondriac. These observations, however, admit of many exceptions. Chalybeate mineral waters have commonly been employed in hypochondriasis, and seemingly with success. But this, Dr. Cullen justly supposes, is probably to be imputed to the amusement and exercise usually accompanying the use of these waters, rather than to the tonic power of the small quantity of iron which they contain; and that perhaps the elementary water,

by

HYPOCHONDRIASIS.

by favouring the excretions, may have a share in relieving the disease.

One of the most important parts of the medical treatment of hypochondriasis, however, regards the diminution of that torpor and sluggishness, with which the hepatic functions are performed; if this is not accomplished, the other remedies, calculated to obviate the symptoms of dyspepsia, will afford but a brief and temporary alleviation of the disorder. This degree of morbid action in the liver, may be known by attending to the state of the bowels, and of the fecal evacuations from them; by the various colour and odour of which the deficiency or morbid condition of the bilious secretion may be estimated. The most useful treatment consists in maintaining a gentle stimulant operation upon the bowels by means of mild mercurial preparations, varying them in point of strength as the torpor of the alimentary canal is greater or less.

Exercise, as it strengthens the system in general, and the chylipoetic viscera in particular, as it obviates the pressure upon those viscera, which a sedentary and studious habit occasions, and as it contributes to maintain a free and active circulation through the most minute portions of the arterial system, and thus supports the proper performance of all the functions of secretion, (see EXERCISE,) proves a particularly advantageous remedy in hypochondriasis. But it is not less useful, perhaps, by its operation on the mind, than by that upon the body, as we shall immediately explain.

The management of the mind, in hypochondriacs, has been considered by Dr. Cullen as the most important part of the treatment, and as often a nice and difficult point. But as it must be admitted, that the morbid perceptions, which characterize the disease, originate actually in corporeal disturbance; so the state of mind must be considered as a symptomatic and secondary part of the complaint. Nevertheless, as the morbid associations will be strengthened, if not in any way opposed, after they have once gained admittance, independently of any increase of the corporeal disease, they should not be treated with neglect. It must be conceded, therefore, to Dr. Cullen, that "the firm persuasion which generally prevails in such patients, does not allow their feelings to be treated as imaginary, nor their apprehension of danger to be considered as groundless;"—"such patients therefore are not to be treated either by raillery or by reasoning. It is said to be the manner of hypochondriacs to change often their physician, and indeed they often do it consistently; for a physician who does not admit the reality of the disease, cannot be supposed to take much pains to cure it, or to avert the danger of which he entertains no apprehension." Hence Dr. Cullen allows, that if the pious fraud of a placebo be admissible at any time, it seems to be in treating hypochondriacs, even with the best view to their own security and advantage; for they, ever anxious for relief and fond of medicines, will apply to every source where these are offered, and, though frequently disappointed, will still take every new drug that can be proposed to them; and thus often become the victims of empiricism and ignorance. The following observations from the able professor above quoted, seem to comprehend all that is rational in regard to the mode of occupying the minds of hypochondriacs.

"As it is the nature of man to indulge every present emotion, so the hypochondriac cherishes his fears, and, attentive to every feeling, finds in trifles light as air a strong confirmation of his apprehensions. His cure therefore depends especially upon the interruption of his attention, or upon its being diverted to other objects than his own feelings. Whatever aversion to application of any kind

may appear in hypochondriacs, there is nothing more pernicious to them than absolute idleness, or a vacancy from all earnest pursuit. It is owing to wealth admitting of indolence, and leading to the pursuit of transitory and unsatisfying amusements, or to that of exhausting pleasures only, that the present times exhibit to us so many instances of hypochondriacism. The occupations of *business* suitable to their circumstances and situation in life, if attended with neither emotion, anxiety, nor fatigue, are always to be admitted, and persisted in by hypochondriacs. But occupations upon which a man's fortune depends, and which are always, therefore, objects of anxiety to melancholic men; and more particularly where such occupations are exposed to accidental interruptions, disappointments, and failures, it is from these that the hypochondriac is certainly to be withdrawn.

"The hypochondriac who is not necessarily, by circumstances or habits, engaged in business, is to be withdrawn from his attention to his own feelings by some *amusement*. The various kinds of sport and hunting, as pursued with some ardour, and attended with exercise, if not too violent, are amongst the most useful. All those amusements which are in the open air, joined with moderate exercise, and requiring some dexterity, are generally of use. Within doors, company which engages attention, which is willingly yielded to, and is, at the same time, of a cheerful kind, will be always found of great service. Play, in which some skill is required, and where the stake is not an object of much anxiety, if not too long protracted, may be often admitted. In dyspeptics, however, gaming, liable to sudden and considerable emotions, is dangerous; and the long continuance of it, with night-watching, is violently debilitating. But in melancholics, who commonly excel in skill, and are less susceptible of violent emotions, it is more admissible, and is often the only amusement that can engage them. Music, to a nice ear, is a hazardous amusement, as long attention to it is very fatiguing.

"It frequently happens, that amusements of every kind are rejected by hypochondriacs; and in that case, *mechanical means* of interrupting thought are the remedies to be fought for. Such is to be found in brisk exercise, which requires some attention in the conduct of it. Walking is seldom of this kind, though, as gratifying to the restlessness of hypochondriacs, it has sometimes been found useful. The required interruption of thought is best obtained by riding on horseback, or in driving a carriage of any kind. The exercise of sailing, except it be in an open boat, engaging some attention, does very little service. Exercise in an easy carriage, in the direction of which the traveller takes no part, unless it be upon rough roads, or driven pretty quickly, and with long continuance, is of little advantage.

"Whatever exercise may be employed, it will be most effectual when employed in the pursuit of a journey; first, because it withdraws a person from many objects of uneasiness and care, which might present themselves at home; secondly, as it engages in more constant exercise, and in a greater degree of it than is commonly taken in airings about home; and, lastly, as it is constantly presenting new objects which call forth a person's attention." Cullen, loc. cit.

We must observe, however, in conclusion, that the exercises, thus recommended, operate perhaps equally by restoring the corporeal health, as by abstracting the attention of the mind from its erroneous perceptions. Upon the same principle, *reasoning* with hypochondriacs is commonly useless; for, as Dr. Crichton remarks, although the singular notions which they entertain may now and then be eradicated from their minds by means of a little art, there is fel-

dom any real good to be derived from this, except the disease be at the same time cured; for if diseased impressions continue to arise in the mind from the disordered viscera, other illusive notions will spring up as one set is destroyed. And we have already alluded to a fatal instance of a forcible attempt to convince a hypochondriac of his error by a mechanical proof.

HYPOCHOPHOSIS, a slight degree of deafness.

HYPOCHYMA, or **HYPOCHYSIS**, from ὑπο, *under*, and χυσι, *to pour*, in *Surgery*, the disease usually denominated a cataract, which was supposed to proceed from a humour running under the crystalline lens. See **CATARACT**.

HYPOCISTIS, in *Botany*, Tournef. t. 477. See **CYTINUS**.

HYPOCISTIS, ὑποκίστις, formed of ὑπο, *under*, and κίστις, *cistis*, in *Medicine*, a juice used in the composition of theriaca, &c.

The hypocistis is the juice of a shoot or excrescence of the same name, sprouting out from the foot of a kind of cistus, or rock-rose, which is called *ledon* or *ladanifera*; common enough in the hot countries.

The shoot grows about three or four inches high; and one, two, or three inches thick; and is somewhat bigger at top than at bottom; and is soft, succulent, of a yellowish colour, and surrounded from space to space with a sort of rings, or brownish knots. It bears a number of little bell-shaped flowers, but no leaves.

When gathered, they pound it in a mortar, and express the juice: that done, they evaporate it on the fire till it come to the consistence of a hard blackish extract, much like Spanish liquorice: then they make it up into little masses for carriage. It is a mild astringent, of no particular smell or flavour, and recommended for stopping fluxes of the belly, vomitings, and hæmorrhages; though anciently much more than at present. It is also an ingredient in some unguents.

It is sometimes used as a substitute to acacia.—Dr. Quincy says, it is the more powerful astringent of the two.

HYPOCRANIUM, in *Surgery*, signifies an abscess under the cranium, between the bone and dura mater. The term is derived from ὑπο, *under*, and κρανιον, *the skull*.

HYPOCRAS. See **HIPPOCRAS**.

HYPOCRATERIFORMIS, *Saucer-shaped*, in *Botany*, the name given by Mr. Tournefort to a peculiar sort of flowers of plants, of the general order of the infundibuliform, but not so deep and narrow at the mouth as those simply so called, but expanded into the figure of a saucer.

HYPOCRINE, or **HIPPOCRENE**. See **HELICON**.

HYPOCRISY, ὑποκρίσις, in *Ethics*, denotes dissimulation with regard to the moral or religious character.

HYPODIACONORUM FESTUM. See **CALENDARIVM festum**.

HYPO-DIEZEUXIS, in *Music*, according to Bacchius, sen. is the interval of a fifth between two tetrachords separated by a disjunction, and further by a third intermediate tetrachord. Thus there is a hypo-diezeuxis between the tetrachords hypaton and diezeumenon, and between the tetrachords synnemenon and hyperbolæon. See **TETRACHORD**.

HYPO-DORIAN, the lowest of all the modes of *Ancient Music*. It has its fundamental a fourth below that of the Dorian mode. It is said to have been invented by Philoxenus. This mode is grand, but cheerful: uniting sweetness with majesty.

HYPODROME. See **HIPPODROME**.

HYPOESTES, in *Botany*, a name given by Dr. Solander, who meant to write it *Hypoesthes*, from ὑποεστειν, *an inner vestment or covering*, expressive of the minute membranous internal calyx. Brown. Prodr. Nov. Holl. v. 1. 474.

Class and order, *Diandria Monogynia*. Nat. Ord. *Personate*, Linn. *Acanthi*, Juss.

Eff. Ch. Calyx in five equal segments, contained in a four-cleft three-flowered involucre. Corolla two-lipped. Seeds two in each cell, with an appendage at their base. Partition attached to the valves. Anthers of one cell.

A genus separated from *Justicia* by Solander and Brown, consisting of caulescent herbs or shrubs. The involucres, naturally three-flowered, though sometimes, by abortion, single-flowered, grow opposite, in axillary or terminal spikes, accompanied by leafy bractæas. The flowers are either purple or white. Within the proper calyx is a small white membranous integument.

Examples of this genus are found in the first section of Willdenow's *Justicia*, as *J. fastuosa*, Linn. Mant. 172. Vahl. Symb. v. 1. t. 1. f. tent by Koenig from Tranquebar. To this is nearly allied *J. Forskalki* of Vahl.

Mr. Brown found a new species in the tropical part of New Holland, which he denominates *H. floribunda*.

HYPOGÆUM, ὑπογαιον, formed of ὑπο, *under*, and γαια, *earth*, in the *Ancient Architecture*, is a name common to all the parts of a building that are under ground; as the cellar, butteries, and the like places.

The term hypogæum was used by the Greeks and Romans for subterraneous tombs in which they buried their dead.

HYPOGÆUM, ὑπογαιον, in *Astronomy*, is a name given to the celestial houses which are below the horizon; and especially the *inimæ cali*, or bottom of heaven.

HYPOGASTRIC ARTERY, in *Anatomy*, a name under which the internal iliac is often described, as the corresponding vein is also called the hypogastric. More commonly, however, the name is given to those continuations of the trunks of the internal iliacs, which ascend along the sides of the bladder to the umbilicus, where they take the name of umbilical. They go to the placenta. See **EMBRYO** for their description.

HYPOGASTRIC Region, is the lower portion of the abdominal cavity. See **ABDOMEN**.

HYPOGASTRIUM is the same with the **HYPOGASTRIC region**; which see.

HYPOGASTROCELE, from ὑπογαστριον, and κελειν, *a tumour*, in *Surgery*, a ventral hernia. See **HERNIA**.

HYPOGLOSSUM, in *Botany*. See **RUSCUS**.

HYPOGLOSSUS, in *Anatomy, from ὑπο, *under*, and γλωσσα, *the tongue*, the nerve of the ninth pair, so called from its situation under the tongue.*

HYPOGLOTTIS, or **HYPOGLOSSIS**, composed of ὑπο, *under*, and γλωττις, *tongue*, is a name given to two glands of the tongue.

There are four large glands of the tongue; two of them called hypoglotides, situated under it, near the venæ ranulares; one on each side of the tongue. They serve to filtrate a kind of serous matter, of the nature of saliva, which they discharge into the mouth by little ducts near the gums.

HYPOGLOTTIS, or *Hypoglossis*, in *Medicine*, denotes an inflammation or ulceration under the tongue; called also *ranula*.

HYPO-IASTIAN, in *Music*. See **HYPO-IONIAN**.

HYPO-IONIAN, the second of the modes of *Ancient Music* from the lowest: Euclid calls it hypo-iaastian, and grave Phrygian. Its fundamental is a fourth below the Ionian mode.

HYPOLÆNA, in *Botany, from ὑπο, *under*, and λαειν, *a cloak, or covering*, alluding to the short integument which invests the base of the fruit. Brown. Prodr. Nov. Holl.*

τ. 1. 251. Class and order, *Diacia Triandria*. Nat. Ord. *Calamaria*, Linn. *Restiaceae*. Brown.

Eff. Ch. Male, Cal. scales of a catkin. Perianth a husk of six leaves. Stamens three. Anthers simple, peltate.

Female, Cal. scales numerous, imbricated. Perianth a husk of six leaves, terminal, solitary. Style in two or three divisions, deciduous. Nut bony, naked, single-seeded, longer than the perianth.

A genus established by Mr. Brown, who observes, that it has the habit as well as the male flowers, of *Restia*, for which reasons, as well as on account of the want of a lobed external appendage to the perianth, he has separated it from the *Willdenovia* of Thunberg, whose fruit is similar, but its male inflorescence (not well described by Thunberg), and its habit are different.

The species are,

1. *H. fastigiata*. Stems branched, round, striated, ash-coloured; their branches somewhat level-topped. Glumes of the perianth at length oval.

2. *H. exsulca*. Stems branched, round, smooth; their branches alternate, quite simple. Glumes of the perianth roundish.

Both grow in various of the cooler parts of New Holland.

HYPOLEPIS, from ὑπο, *under*, and λεπτις, *a scale*. Perfoon Syn. v. 2. 598. The same plant as *Phelypæa sanguinea* of Thunberg and Willdenow. See PHELYPÆA.

HYPO-LYDIAN, the fifth mode of the *Ancient Music*, beginning from the lowest. Euclid calls it hypo-iatian and hypo-phrygian. Its fundamental is a fourth below the Lydian. Euclid distinguishes two hypo-lydian modes; the acute, which is that of this article, and the grave, which is the same as the hypo-zolian.

The hypo-lydian mode was proper for funeral chants, sublime and divine meditations: its invention is attributed by some to Polymnestes of Colophon, by others to Damon of Athens.

HYPOLYTRUM, in *Botany*, from ὑπο, *under*, and ελπίον, *a cover, or scale*, on account, as we presume, of the internal scaly covering of the seeds. Perfoon Syn. v. 1. 70. Class and order, *Triandria Monogynia*. Nat. Ord. *Calamaria*, Linn. *Cyperoideæ*, Juss.

Eff. Ch. "Scales imbricated every way. Seeds with an internal cover, resembling a glume of three or four valves. Stamens two or three. Stigmas one or two." Perfoon.

This is suspected to be the same genus with *Hypalyptum*, (see that article,) and even their names are perhaps originally the same. Perfoon defines three species, *H. latifolium senegalense*, and *gracile*, all communicated by M. Richard. Their definitions, however, do not accord with our above-mentioned species of *Hypalyptum*.

HYPO-MIXO-LYDIAN, a mode added by Guido d'Arezzo to the *Ancient Music* of the church: it is properly the plagal of the mixo-lydian mode, and its fundamental is the same as that of the Dorian mode.

HYPOMNEMATOGRAPHUS, ὑπομνηματογραφος, derived from ὑπο, *register*, and γραφειν, *I write*, in the *Primitive Church*, an officer who attended on the bishop, and kept a register of his consecrations.

HYPOMOCHLION, ὑπομοχλιον, formed of ὑπο, *under*, and μοχλος, *lever*, in *Mechanics*, the fulcrum of a lever, or the point which sustains its pressure, when employed either in raising or lowering bodies.

The hypomochlion is frequently a roller set under the lever; or under stones, pieces of timber, &c. that they may be the more easily lifted up, or removed.

HYPONITIS, in *Botany*, a name given by Dillenius to

a genus of plants, called by Tournefort orobanchoides. See MONOTROPA.

HYPONOMOS, in *Surgery*, from ὑπο, *under*, and νομος, *a phagedenic ulcer*, a deep phagedenic ulcer.

HYPOPHORA, ὑποφορα, in *Rhetoric*, the first part of the prolepsis: thus, in the following instance: "but some men will say, how are the dead raised, or with what body do they come?" is the *hypophora*; and, *thou fool, that which thou seest*, &c. is the *anthypophora*, or solution of the objection.

HYPOPHORA, in *Surgery*, a deep, fistulous ulcer, from ὑποφορα, to be carried underneath.

HYPO-PHRYGIAN, one of the modes of *Ancient Music*, derived from the Phrygian. Its fundamental was a fourth higher. Euclid speaks still of another hypo-phrygian mode below it; which was called with more accuracy the hypozolian mode.

The character of the hypo-phrygian mode was calm, tranquil, and proper to appease the vehemence of the Phrygian. It was said to have been invented by Damon, the friend of Pythias, and the music-master of Socrates.

HYPOPTHALMION, from ὑπο, *under*, and οφθαλμος, *the eye*, in *Surgery*, denotes a swelling, which sometimes takes place under the eye in cases of dropsy and cachexy.

HYPOPTHALMUM, in *Botany*, a name used by some authors for the *aster atticus*.

HYPOPHYLLOCARPODENDRON, in *Botany*, Boerhaave. See LEUCADENDRON and PROTEA.

HYPOPHYLLOSPERMOUS PLANTS, formed of ὑπο, *under*, φυλλον, *leaf*, and σπριμα, *seed*, are such plants as bear their seeds on the back-sides of their leaves.

HYPOPHYSIS, from ὑπο, *under*, and φυν, *to produce*, an inflammation of the eye, arising from a turning of the eye-lid inwards. See TRICHIASIS.

HYPOPIA, from ὑπο, *under*, and πιν, *the eye*, an ecchymosis just under the eye; a black eye.

HYPOPITYS, in *Botany*, Dill. Gen. 7. See MONOTROPA.

HYPOPODIUM, in *Antiquity*, a piece of furniture belonging to the bath; its use was to set or rest the feet on, as the name imports.

HYPO-PROSLAMBANOMENOS, in *Music*, the name of an additional string or sound, which Guido is said to have added to the scale of the Greeks, a note below proslambanomenos, answering to gammut or G on the first line in the base. The author of this new sound expressed it by the letter ζ, gamma, of the Greek alphabet, whence the name of gammut was derived. See DIAGRAM.

HYPOPYON, or HYPYPIUM, is a term in *Surgery*, usually signifying an abscess under the cornea, in the interior or posterior chamber of the aqueous humour. The word is compounded of ὑπο, *under*, and πιν, *pus*.

A distinction has been drawn by some writers between the case, where the matter is situated in the anterior chamber, and that where it lies in the posterior one, the latter instance being sometimes named *empyema oculi*. But since both chambers always have a free communication with each other through the pupil; since one chamber can never have much matter in it, without a part gliding into the other; and lastly, as the matter in either example may be discharged through the same opening; Richter contends, that the difference in the cases is not of much importance. Hypopyium is generally a consequence of a violent inflammation of the eye; yet unusual instances do present themselves, in which the disease comes on quite unpreceded by any degree of ophthalmia. This is said to happen particularly in venereal and scrophulous patients. A woman, in the Royal In-

HYPOPYON.

firmly of Edinburgh, had a very considerable collection of matter in the anterior chamber, accompanied with very little, or no inflammation. The matter altered its form and place according to the position of the head, and, during the day, the agitation of the body, produced by walking, mixed the matter with the aqueous humour, and rendered the whole anterior chamber turbid. Wardrop's *Essays on the Morbid Anatomy of the Human Eye*, p. 51.

Hypopyum, when it is a consequence of inflammation, can only proceed from a violent degree of it, and it commonly makes its appearance under the following symptoms. The pain is throbbing and acute, and instead of being confined to the eye-ball and upper part of the forehead extends as far as the back of the head. All on a sudden, however, upon the attack of a shivering fit, it undergoes a diminution, and it is at this period that the first drop of matter generally makes its appearance at the bottom of the anterior chamber, in the form of a semilunar whitish speck, which, in proportion as the quantity increases, gradually becomes larger, spreads upwards, covers the pupil, and at length occupies the whole of the anterior chamber. In this state, the cornea exhibits every where a white appearance. The progress of the disease is various. When the case is left to take its own course, the pain often becomes again excessively severe, and no alleviation is experienced, till the matter makes its way through the cornea, and escapes, together with the aqueous humour, and, in general, a considerable portion of the vitreous. The pain immediately abates; but the eye is irrecoverably destroyed. In favourable cases, the matter, with the aid of proper means, is entirely dispersed. Sometimes it is only partly absorbed, and a portion continues, either upon the inside of the cornea, upon the surface of the crystalline lens, or in the pupil, so as to produce either total blindness, or a material impairment of vision.

The matter of hypopyum is commonly represented to be pus; but Scarpa, the celebrated surgeon at Pavia, adopts the opinion, that it is only coagulating lymph, which is effused from the highly inflamed choroides and uvea in severe ophthalmies affecting the interior of the eye.

While the violence of the inflammation of the eye lasts, the hypopyum never fails to enlarge; but as soon as this stage ceases, and the ophthalmia falls into its second period, or that attended with local weakness, the matter in the anterior chamber receives no longer any addition, and, from that moment, is disposed to diminish. See Scarpa *Sulle Malattie degli Occhi*.

Surgical writers have recorded curious examples of a periodical species of hypopyum. A man, of a bad habit of body, became blind the first fortnight of every month. A yellowish matter, which was so thick and opaque as to conceal the iris, could always at this time be remarked in the anterior chamber. The conjunctiva was also inflamed; but not painful. On the fourteenth day of each month these complaints used to disappear, and the sight to return. (Janin *Mémoires sur l'Œil*, p. 412.) Another person was deprived of his eye-sight every morning, and, during the attack, the aqueous humour was always very turbid. The patient at the same time regularly suffered pain under the short ribs, on the right side. The paroxysm constantly terminated on a copious discharge of air being made from the alimentary canal. See Richter's *Anfangsgründe* Band 3. p. 97.

The treatment of hypopyum consists either in attempting to disperse the matter collected in the anterior or posterior chamber, or else in making an incision for its evacuation. Against the latter proceeding, as a general one, Scarpa has

urged several weighty considerations, as we shall presently notice.

The tendency of an hypopyum to diminish, as soon as the first violence of the ophthalmia is over, shews, according to Scarpa's judgment, how important it is, in order to check the progress of hypopyum, to employ the most powerful means for subduing the first severity of the inflammation of the eye. With this view, copious evacuations of blood, both generally and topically, are recommended. When chemosis prevails, the conjunctiva is to be divided. Mild aperients, blisters to the nape of the neck, little bags of emollient herbs applied to the eye, and other measures for the relief of the first stage of severe ophthalmia, are highly necessary. These will be known to have fulfilled the desired end, by the abatement of the lancinating pains in the eye, the cessation of the febrile symptoms, the restoration of the free motion of the eye, and the hypopyum no longer continuing to increase. The first measures have now answered every expectation, notwithstanding the eye-lids and conjunctiva may still be affected with a degree of redness. The lower orders of people are frequently seen in the second stage of acute ophthalmia, going about with an hypopyum, and making no complaint whatever of any of the serious sufferings always attendant on the first stage of acute ophthalmia. It is only at this crisis, or at the termination of the acute stage of violent inflammation of the eye, that the hypopyum ceases to enlarge, and begins to be absorbed, provided this salutary process be not impeded by any wrong plans.

Scarpa remonstrates against making an incision in the cornea to let out the matter; a plan which has been commonly taught by surgical authors, and which has been extensively adopted, but which most frequently gives rise to evils worse than hypopyum itself, and this, notwithstanding Richter's advice be followed, not to let out all the matter at once, and not to promote its exit by pressure or injections. Scarpa assures us, that a wound in the lower part of the cornea, how small soever it may be, most commonly re-produces the severe acute ophthalmia, and occasions a large extravasation of lymph, or matter in the chambers of the aqueous humour. Besides, after opening the cornea, the matter, if left to itself, would be several days in becoming entirely discharged, during all which time it would keep the edges of the wound asunder, and make them suppurate. In this manner the cut would be changed into an ulcer, through which the aqueous humour would escape, and in all probability a fold of the iris be protruded. Even the crystalline lens itself might fall out. No arguments in favour of the practice can justly be drawn from the successful result of certain cases, in which the hypopyum spontaneously bursts. Scarpa reminds us that there is a wide difference between the effects of a spontaneous opening into a natural or preternatural cavity of the animal body, or of one made with caustic, and the consequences of an opening made with a cutting instrument. In the two first methods the subsequent symptoms are constantly milder than in the last. Besides, the fact is, that when an hypopyum discharges itself through an ulcerated opening, it not infrequently happens that not only the aqueous humour escapes, but a prolapsus of the iris also happens.

Scarpa only admits the utility and necessity of dividing the cornea, when the coagulating lymph, or matter of an hypopyum, exists in very large quantity, and produces such distention of the eye, and such urgent symptoms, as put the patient's life into danger, besides menacing a total destruction of the affected organ.

It is maintained by this distinguished anatomist and surgeon, that as the fragments of cataracts, when pushed through the pupil into the anterior chamber of the aqueous humour, are

in time absorbed, there cannot be a doubt that the coagulating lymph, in the example of hypopium, also admits of being taken away by the absorbents, as soon as a further extravasation no longer goes on, and the lymphatics begin to recover their activity. Scarpa, therefore, inculcates that the resolution of an hypopium is the first thing which the surgeon ought to aim at in the treatment of the common form of the disease, and that the best method of doing this is to subdue the first vehemence of the acute ophthalmia by antiphlogistic remedies, and mild, emollient, topical applications.

When success attends this plan, as it does in the generality of cases, the hypopium not only ceases to enlarge, but even begins to diminish, in proportion as the violence of the inflammation abates.

Various remedies have been recommended for the purpose of dispersing the matter collected in the chambers of the aqueous humour. Montieur Janin was of opinion, that when the matter disappeared, it was not absorbed, but exuded through the pores of the cornea. His advice, consequently, was to endeavour to make the pores of this membrane as pervious as possible, by the topical employment of emollient applications, so as to promote the escape of the matter. For this object he recommends the decoctum malvæ, as exceedingly efficacious. He used to bathe the eye several times a day with this remedy, and in the intervals apply compresses wet with the same. Janin assures us, that even when both the chambers of the eye were full of matter, and the cornea seemed likely to burst, this method proved successful, the dispersion being generally effected in about twelve or fourteen days. There can be no doubt that benefit has been derived from using the decoctum malvæ, especially as Pellier and other eminent oculists confirm the accounts of the good effects of the application. But we believe with Scarpa, that it is by no means superior to several other remedies, and that every topical emollient application, if conjoined with such internal antiphlogistic treatment as is the most proper for repelling the acute stage of the severe ophthalmia, would be equally beneficial. Mere warm water is productive of quite as much good.

With respect to Janin's notion of the matter of the hypopium exuding through the pores of the cornea, the opinion is altogether destitute of foundation. Richter rightly maintains, that when an hypopium is dispersed, there are no appearances in support of such a sentiment. When blood is extravasated in the anterior chamber, and afterwards disappears, it must be by absorption, for if it exuded out of the cornea, it would be visible upon the surface or in the substance of this transparent membrane.

Woolhouse recommends, for the dispersion of a hypopium, the application of a poultice, made of the pulp of a roasted apple, and containing a small proportion of camphor. Gueria advises the use of a collyrium, composed of rose-water, muriate of ammonia, aloes, and myrrh. Mauchart speaks in favour of warm collyria, and of fomenting the eye.

We decidedly join Richter in thinking, that, as the eye is in general violently inflamed, all irritating applications must be hurtful and improper. Little benefit can be expected from any remedies which only come into contact with the eye-lids, as, for instance, Woolhouse's poultice. But, supposing the applications to act more extensively, they can hardly operate effectually upon the surfaces, by which the matter of the hypopium is secreted. Some good, however, will result from emollients, and much more may reasonably be expected from such means as tend to excite and quicken the action of the absorbents, as, for example, antimonials, aperients, bleeding, blisters on the nape of the neck, or behind the ears,

&c. These remedies not only promote the absorption of the matter, they likewise have a powerful effect in putting a stop to the inflammation.

When the first stage of severe ophthalmia has resisted the best modes of treatment, or when these have been practised too late, the matter in the chambers of the eye is occasionally so abundant, after the first stage of the ophthalmia is over, that it continues for a long while to obstruct vision. Scarpa has often seen patients, especially paupers, who, from negligence or wrong treatment, have remained a great while after the cessation of the acute stage of an ophthalmia, with the anterior chamber almost entirely filled with the glutinous matter of hypopium. When the inflammation ceases, these persons are described as wandering about the streets with great unconcern, and having no affliction but the impairment of their sight. In this second stage of ophthalmia, the hypopium cannot be dispersed, either so speedily, or by exactly the same treatment as in the first stage. In a case of this description, Scarpa recommends such remedies as are most calculated to invigorate the debilitated tone of the vascular system of the eye, particularly the lymphatics. The time necessary for the completion of this object will vary according to the patient's age and the nature of his constitution. The surgeon ought carefully to try the degree of irritability in the eye, by introducing, between the globe and the eyelids, a few drops of a collyrium, containing some sulphate of zinc, and mucilage of quince-seeds. Should the eye seem too strongly stimulated by this application, it must not be used, and little bags, filled with warm mallows and a few grains of camphor, are to be substituted for it. In the intervals the vapour of the spiritus ammoniæ comp. may be applied to the eye. A blister is also to be put on the nape of the neck. As soon as the eye will easily bear the vitriolic collyrium, this is to be employed, and its strength may afterwards be gradually increased by the addition of a few drops of camphorated spirit.

Under such treatment, the hypopium may often be observed to disappear regularly as the chronic ophthalmia is removed.

We are not, however, always to expect to be thus successful with regard to hypopium, attended either with the first or second stage of ophthalmia. When the extravasated matter strongly distends the chambers of the aqueous humour, and the cornea in particular, the most skilful treatment will sometimes not avail in preventing ulceration, opacity, and the bursting of the central part of the cornea.

When the ulcerated opening is formed, some of the matter of the hypopium escapes, and a degree of amendment follows; but the relief is only of short continuance, as a portion of the iris is soon protruded through the aperture. If, in an urgent case of this kind, the bursting of the cornea were not speedily to happen, the violent symptoms depending on the distention of the eye-ball would compel the surgeon to make an opening in that membrane. This form of the disease is described as being excessively severe, and even attended with danger. The head-ache, and pain in the eye, are frequently so grievous as to occasion delirious symptoms. According to Scarpa, the surgeon may the more readily make up his mind to practise an incision, as there is hardly any hope of saving the eye.

Should there be any reasonable chance of restoring the transparency of the cornea, and of preserving the eye, Scarpa approves of opening this membrane at its lower part, just as is done in the operation of extracting the cataract. But when no such pleasing prospect occurs, he thinks the best and quickest way of relieving the severe pain of the hypopium, is to introduce across the central point of the cornea...

near a small bitoury, so as to make a cut about one line and a half broad. The little flap is then to be raised with forceps, and removed with one stroke of a pair of scissors.

The opening, thus made, will not be liable to close like a simple incision. The fluid part of the matter immediately escapes, and rest some time afterwards, followed, sooner or later, by the crystalline lens and vitreous humour.

As soon as the operation is done, a bread and milk poultice is to be applied, and care taken to change it every two hours. At the same time such means are indicated as are most calculated to avert and diminish inflammation, and sooth nervous irritation. The eye gradually suppurates and heals, after which it is generally in a state to admit of the application of an artificial eye. See *EYE, Artificial*.

Although Scarpa sanctions the performance of an incision in the foregoing case of hypopium, which is attended with urgent, distressing, and perilous symptoms, he maintains that the practice is highly improper in common instances, for reasons already explained.

With respect to cutting out a piece of the centre of the cornea, as is advised by Scarpa, we feel persuaded that nothing can justify this proceeding unless it is decidedly certain that the eye and eye-sight are beyond recovery. In any other circumstance, the incision should undoubtedly be executed, as in the extraction of the cataract. See *CATARACT*.

HYPORCHEMA, formed of ὑπορχομαι, *I accommodate my dancing to a singing chorus*, of ὑπο and χομαι, *I dance*, in the *Greek Poetry*, a poem composed of divers kinds of verses, and of different lengths; but always very short, and full of Pyrrhic feet. This poem was composed either to be sung or played with the flute or cithara, but to regulate a dance according to the sound of voices and instruments. Proclus says, it was a dance accompanied with a song. These were, probably, the origin of the Italian *Ballata*; which see.

HYPORISMA, in *Surgery*, an aneurism.

HYPOSCENIUM, ὑποσκηνιον, in *Antiquity*, a partition under the pulpit or logeum of the Greek theatre, appointed for the music.

HYPOSCHESES, ὑποσχεσις, in *Rhetoric*, the same with division.

HYPOSPADIAS, in *Surgery, from ὑπο, *under*, and σπασ, *I draw*, a Greek name anciently given to a person, who had the orifice of the canal of the ureter not directly at the extremity of the gland. Galen applies the same name to those, the frenum of whose penis is too short, on which account it is bent in erection; this is easily remedied by cutting the ligament, and washing the wound with warm wine.*

HYPOSPATHISMUS, in the *Ancient Surgery*, an operation practised, by making three incisions in the forehead, to the very bone, about two inches long; in order to cut or divide all the vessels between those incisions. The design of the operation was to prevent defluxions on the eyes.

The word is ὑποσπασιμοις, formed of ὑπο, *under*, and σπασ, *spatula*; by reason after incisions were made they thrust a spatula all along between the pericranium and the flesh.

HYPSPHAGMA, in *Surgery*, a contusion of the eye, attended with ecchymosis; a black eye.

HYPSTAPHYLE, from ὑπο, *under*, and σφαιρα, *the uvula*, a relaxation, or elongation of the uvula.

HYPSTASIS, ὑποστασις, compounded of ὑπο, *under*, and σταμι, *I stand, I exist*, q. d. *subsistentia*, a Greek term, literally signifying *substance*, or *subsistence*; it is used in theology for *person*.

Thus some have held that there is but one nature or essence in God, but three hypostases, or persons.

The term hypostasis is of a very ancient standing in the

church. St. Cyril repeats it divers times, as also the phrase, *union according to hypostasis*. The first time it occurs in all Christian antiquity, is in a letter of that father to Nestorius, where he uses it instead of προσσωσι, the word we commonly render *person*, which did not seem expressive enough. "The philosophers, says St. Cyril, have allowed three hypostases: they have extended the divinity to three hypostases: they have even sometimes used the word *Trinity*: and nothing was wanting but to have admitted the consubstantiality of the three hypostases, to shew the unity of the divine nature, exclusive of all triplicity in respect of distinction of nature, and not to hold it necessary to conceive any respective inferiority of hypostases."

This term has occasioned great dissentions in the ancient church; first among the Greeks, and afterwards also among the Latins.

In the council of Nice, hypostasis was defined to denote the same with *essence*, or *substance*; so that it was hereby to say, that Jesus Christ was of a different hypostasis from the Father; but custom altered its meaning. See *TRINITY*.

HYPSTASIS, in *Medicine*, the sediment of the urine, or that thick heavy part of the urine which subsides and settles at bottom.

HYPSTATICAL, in *Theology*, is a term used in speaking of the mystery of the incarnation.

Hypostatical union, is a phrase used by some divines for the union of the human nature with the divine in the person of Jesus Christ.

HYPSTATICAL Principles, among the *Chemists*, and particularly the *Paracelsists*, are the three chemical elements, *salt, sulphur, and mercury*; called also the *tria prima*. See *PRINCIPLE* and *ELEMENT*.

HYPSTYNAPHE, in the *Greek Music*, the disjunction of two tetrachords separated by the interposition of a third tetrachord conjoint with both; so that the homologous or relative strings of the two tetrachords, disjoined by the hypostynaphe, have the interval of five tones, or a minor seventh between them. Such are the two hypaton and synmemenon tetrachords.

HYPSTHECA, in the *Civil Law*, an obligation, whereby the effects of a debtor are made over to his creditor, to secure his debt.

The word comes from the Greek, ὑποθηκα, *a thing subject to some obligation*; of the verb ὑποθηκαμι, *supponor, I am subjected*; of ὑπο, *under*, and τημι, *pono, I put*.

As the hypotheca is an engagement procured on purpose for the security of the creditor, various means have been made use of to secure him the benefit of the convention. The use of the pawn or pledge is the most ancient, which is almost the same thing with the hypotheca; all the difference consisting in this, that the pledge is put into the creditor's hands; whereas, in a simple hypotheca, the thing remained in the possession of the debtor. It was found more easy and commodious to engage an estate by a civil covenant than by an actual delivery: accordingly, the expedient was first practised among the Greeks; and from them the Romans borrowed both the name and the thing: only the Greeks, the better to prevent frauds, used to fix some visible mark on the thing, that the public might know it was hypothecate, or mortgaged by the proprietor; but the Romans, looking on such advertisements as injurious to the debtor, forbade the use of them.

The Roman lawyers distinguished four kinds of hypothecas: the *conventional*, which was with the will and consent of both parties: the *legal*, which was appointed by law, and for that reason called *tacit*; the *praetor's pledge*, when by the sight or non-appearing of the debtor, the creditor was

put in possession of his effects; and the *judiciary*, when the creditor was put in possession by virtue of the sentence of the court.

The *conventional* hypotheca is subdivided into *general* and *special*. The hypotheca is *general*, when all the debtor's effects, both present and future, are engaged to the creditor. It is *special*, when limited to one or more particular things.

For the *tacit*-hypotheca, the civilians reckon no less than twenty-six different species thereof.

HYPOTHECATE, from the Latin *hypotheca*, a *pledge*; to hypothecate a ship, is to pawn the same for necessaries; and a master may hypothecate either ship or goods, for relief, when in distress at sea. For he represents the traders as well as the owners; and in whose hands soever a ship or goods hypothecated come, they are liable. 1 Salk. 34. 2 Litt. Abr. 95.

HYPOTHENAR, in *Anatomy*, a name given by Winslow to two muscles of the little finger. The abductor minimi digiti is his hypohenar minor; and the adductor ossis metacarpi minimi digiti is the hypohenar metacarpi.

HYPOTHENUSE, or rather **HYPOTENUSE**, ὑποθηνυσα, *subtendens*, formed of ὑποτινω, *subtendo*, I *subtend*, in *Geometry*, is the longest side of a right-angled triangle; or that side which subtends, or is opposite to the right angle.

Thus in the triangle ABC (*Plate VIII. Geometry, fig. 100.*) the side AC, opposite to the right angle ABC, is called the hypotenuse.

It is a celebrated theorem in geometry, that in every rectilinear right-angled triangle, as ABC, the square of the hypotenuse, AC, is equal to the squares of both the other sides, AB and BC. This is particularly called the Pythagorean theorem, from its inventor Pythagoras, who is said to have sacrificed a whole hecatomb to the Muses, in gratitude for the discovery. For proof of this theorem, let AD be the square on the hypotenuse AC, and BG, BI, the two squares on the sides AB and BC: let MBH be parallel to AE, meeting GF, produced, in H; and let EA be produced to meet GH in N, and DC to meet IK in O. If from the equal right angles GAB, CAN, the angle NAB, common to both, be taken away, there will remain NAG = BAC; whence, as the angle G is also = ABC, and the side AG = AB, the sides AN and AC (= AE) are likewise equal; and therefore the parallelogram AM = the parallelogram AH (being both on equal bases and between the same parallels); which last, and consequently the former, is equal to the square BG, standing on the same base AB, and between the same parallels. By the same mode of reasoning, the parallelogram CM is = the square BI; and, consequently, the square AD (= AM + CM) = both the squares BG and BI. The same reasoning is applicable to circles or any other similar figures; *viz.* that any figure described on the hypotenuse is equal to the sum of the two similar figures described on both the other two sides.

HYPOTHESIS, ὑποθεσις, formed of ὑπο, *under*, and θεσις, *positio*, of ἔθηναι, *pono*; I *put*, in *Logic*, is a proposition or principle which we suppose, or take for granted, in order to draw conclusions for the proof of a point in question.

In disputation, they frequently make false hypotheses, in order to draw their antagonists into absurdities: and even in geometry, truths are often deducible from such false hypotheses.

Every conditional or hypothetical proposition may be distinguished into hypothesis and thesis: the first rehearses the conditions under which any thing is affirmed or denied; and the latter is the thing itself affirmed or denied.

Thus in the proposition, a triangle is half of a parallel-

ogram, if the bases and altitudes of the two be equal; the latter part is the hypothesis, if the bases, &c. and the former the thesis, a triangle is half a parallelogram.

In strict logic, we are never to pass from the hypothesis to the thesis; that is, the principle supposed must be proved to be true, before we require the consequence to be allowed. Dr. Barrow says, that hypotheses, or postulata, are propositions assuming or affirming some evidently possible mode, action, or motion of a thing, and that there is the same affinity between hypotheses and problems, as between axioms and theorems; a problem shewing the manner, and demonstrating the possibility of some structure, and an hypothesis assuming some construction which is manifestly possible.

HYPOTHESIS, in *Physics*, &c. denotes a kind of system laid down from our own imagination, by which to account for some phenomenon or appearance of nature.

Thus we have hypotheses to account for the tides, for gravity, for magnetism, for the deluge, &c.

The real and scientific causes of natural things generally lie very deep: observation and experiment, the proper means of arriving at them, are in most cases extremely slow; and the human mind is very impatient: hence we are frequently driven to feign or invent something that may seem like the cause, and which is calculated to answer the several phenomena, so that it may possibly be the true cause.

Philosophers are divided as to the use of such fictions or hypotheses, which are much less current now than they were formerly. The latest and best writers are for excluding hypotheses, and standing wholly on observation and experiment.

Whatever is not deduced from phenomena, says sir Isaac Newton, is an hypothesis; and hypotheses, whether metaphysical or physical, or mechanical, or of occult qualities, have no place in experimental philosophy. *Phil. Nat. Prin. Math. in calce.*

The Cartesians take upon them to suppose what affections in the primary particles of matter they please; just what figures, what magnitudes, what motions, and what situations, they find for their purpose. They also feign certain unseen, unknown fluids, and endue them with the most arbitrary properties; give them a subtlety which enables them to pervade the pores of all bodies, and make them agitated with the most unaccountable motions. But is not this to set aside the real constitution of things, and to substitute dreams in their place? Truth is scarcely attainable even by the surest observations; and will fanciful conjectures ever come at it? They who found their speculations on hypotheses, even though they argue from them regularly, according to the strictest laws of mechanics, may be said to compose an elegant and artful fable; but it is still only a fable. *Cotes in Præfat. ad Newton. Princip.*

HYPOTHESIS is more particularly applied, in *Astronomy*, to the several systems of the heavens; or the divers manners wherein different astronomers have supposed the heavenly bodies to be ranged, moved, &c.

The principal hypotheses are the Ptolemaic, Copernican, and Tychonic.

The Copernican is now become so current, and is so well warranted by observation, that the advocates of it hold it injurious to call it an hypothesis.

HYPOTHETICAL. *Proposition* and *Syllogism*. See **CONDITIONAL**.

HYPOTRACHELION, from ὑπο, *under*, and τραχηλος, *neck*, in *Anatomy*, denotes the lower part of the neck.

HYPOTRACHELION, in *Architecture*, is used for a little frieze in the Tuscan and Doric capital, between the astragal and annulets; called also the *colerin* and *gorgerin*.

The

The word is also applied by some authors, in a more general sense, to the neck of any column; or that part of the capital thereof below the astragal.

HYPOTYPOSIS, or *Imagery*, ὑποτύποισι, formed of the verb ὑποτύποιω, *per figuram demonstro, I show, represent, or make any thing to be seen*; of ὑπο, *under*, and τυπος, *type, image, resemblance*, in *Rhetoric*, a figure whereby a thing is described or painted in such strong and bright colours, that it does not seem to be read, or heard, but actually seen, or presented before the eye.

Such is that elegant one of Cicero, wherein he paints the barbarity of Verres: "Ipse inflammatus scelere et furore, in forum venit. Ardebant oculi; toto ex ore crudelitas emanabat. Expectabant omnes quo tandem progressurus, aut quidnam acturus esset; cum repente hominem corripit, atque in foro medio nudari ac deligari, et virgas expedire jubet. Clamabat ille miser se civem esse Romanum, &c." Such is also the picture which he has drawn of Catiline, consisting of an unaccountable mixture of contrary qualities. *Pro. Cœl. c. 5.*

The hypotyposis is frequently used by the poets, and particularly Virgil, who abounds in paintings.

This figure is peculiarly suited for drawing characters, and often affords the finest ornaments in poetry and history, as well as oratory. It is also adapted to move and interest different passions, according to the nature of the subject, and the artful management of the speaker.

HYPOXIS, in *Botany*, from ὑπο, *underneath*, and ἄνω, *sharp*, alluding, as it should seem from the generic description, to the tapering and pointed base of the capsule. *Linn. Gen. 166. Schreb. 221. Willd. Sp. Pl. v. 2. 106. Mart. Mill. Dict. v. 2. Brown. Prodr. Nov. Holl. v. 1. 288. Juss. 55. Lamarek. Illustr. t. 229. Gærtn. t. 11.*—Class and order, *Hexandria Monogynia. Nat. Ord. Coronarie, Linn. Narcissi, Juss.*

Gen. Ch. Cal. none. Cor. of one petal, superior, in six deep, equal, ovate-oblong, spreading segments, permanent. Stam. Filaments six, very short, capillary; anthers oblong, shorter than the petals. Pist. Germen inferior, turbinate; style thread-shaped, the length of the stamens; stigma three-cleft, bluntish. Peric. Capsule rather oblong, tapering at the base, crowned with the permanent corolla, and composed of three cells, not bursting. Seeds numerous, roundish, "with a lateral beak-like projection." Brown.

Ess. Ch. Corolla superior, permanent, in six deep equal segments. Capsule tapering at the base, without valves. Seeds numerous, with a lateral beak.

Obs. Mr. Brown, like Gærtner, describes the capsule as not separating into valves, which is true of some species, but the whole have not yet, in his opinion, been sufficiently examined.

Undoubted species of *Hypoxis* are,

1. *H. erecta. Linn. Sp. Pl. 439. Curt. Mag. t. 710. A native of dry pastures in North America.*

2. *H. sobolifera. Jacq. Ic. Rar. t. 372. Curt. Mag. t. 711. Found at the Cape of Good Hope.*

3. *H. ferrata. Linn. Suppl. 197. Jacq. Ic. Rar. t. 369. Curt. Mag. t. 709. Found also at the Cape.*

These are bulbous herbs, with numerous radical leaves of a lanceolate form, channelled, hairy or smooth. Stalks radical, more or less corymbose. Flowers resembling those of the English *Ornithogalum luteum*, yellow within, green underneath.

Willdenow enumerates 15 species in all, some of which are suspected to be varieties.

H. juncea. Sm. Spicil. 15. t. 16. brought by the late Mr. Frazer from Carolina, is supposed to be a starved nar-

row-leaved variety of the *erecta*, the stalks of which are single-flowered.

HYPOZOMA, in *Anatomy*, a name given to such membranes as separate two cavities.

In this sense the mediastinum is an hypozoma.

HYPPASUS of Metapontus, or Crotonia, in *Biography*, is enumerated among the disciples of Pythagoras, late in his life. Theon of Smyrna informs us, that Lafus and Hyppafus seeking celebrity, and in order to avoid the tediousness of calculation by the ratio of numbers, as Pythagoras found the proportions of intervals by means of hammers and strings, his two disciples discovered by means of different portions of water in two vases or glasses of equal size, and in unison with each other; that when one of them was half filled with water, leaving the other empty, the result was the octave 2 to 1. Then filling one vase or glass three parts full of water, and the other half full, they produced the proportion or consonance of the 5th or 3 to 2; and, lastly, four portions of water in one glass, and three in the other, produced the fourth or 4 to 3. The same proportions of consonances were still produced as in the *Syrinx* from reeds of different lengths, or by holes in the flute, or tibia.

This article has been inserted by Padre Martini without telling us that he had proved it to be true by experiment.

HYPPIAS, according to Lucian, was an excellent musician, and the first man of his time for geometry, perspective, and astronomy. He was also a great architect. A description of the magnificent baths of his construction may be read in Lucian.

HYPPOPHORBION, in the *Ancient Musical Instruments*. The Lybians, according to Pollux, invented a kind of flute called hypphorbion, because its sound resembled the acute neighing of a horse.

The hypphorbion was made of a stick of laurel stripped of its bark and pith, and served those who had the care of horses at pasture as a kind of lure or horse-call.

HYPOMACHUS, in the *Ancient Greek Music*. An eminent performer on the flute, perceiving one day at a public exhibition, that one of his disciples of ordinary talents was violently applauded by the common people, silenced him by a blow of his cane; telling him that the greatest proof of his ignorance was the being applauded by the mob.

HYPONAX was the inventor of Iambic verse, according to Athenæus, lib. 14.

HYPSEA, in *Ancient Geography*, a river of Sicily, placed by Ptolemy between Heraclea and Agrigentum, and according to this geographer, discharging itself into the sea to the south of the latter city. It is now called *Belici*; which see.

HYPSELE, an episcopal town of Egypt, W. of the Nile, in a nome of which it was the chief place, called the Hypselites nomos.

HYPsICLES, in *Biography*, an ancient mathematician who flourished in the second century, under the reigns of Marcus Aurelius and Lucius Verus, was a native of Alexandria, and a disciple of Isidorus. He was author of a work entitled "Ἀναζήσιμος, five de Ascensionibus," which was published at Paris by Mentelius, with the Optics of Heliodorus in 1657. He is supposed to be author of the 14th and 15th books of the "Elements of Geometry," which are commonly attributed to Euclid. *Gen. Biog.*

HYPsICRYMNOS, in *Ancient Geography*, a town in the vicinity of Caucasus, said by Æschylus, in his Prometheus, to have been peopled by Arabs.

HYPHILOGLOSSUS, in *Anatomy*, the same with *basiloglossus*. See *HYOGLOSSUS*.

HYPHILOIDES, from ὑψίλος, and ἰδος, *form*, the same with *hyoides*; which see.

HYPHISTARII, **HYPHISTARIANS**, ὑψισταῖοι, formed from ὑψίς, *highest*, in *Ecclesiastical History*, a sect of heretics in the fourth century; thus called from the profession they made of worshipping the most High God.

The doctrine of the Hyphistarians was an assemblage of Paganism, Judaism, and Christianity. They adored the most High God with the Christians; but they also revered fire and lamps with the Heathens; and observed the sabbath, and the distinction of clean and unclean things, with the Jews.

The Hyphistarii bore a near resemblance to the Euclites or Massilians.

HYPSPHYLLUM, in *Surgery*, an ulcer under a cicatrix or scab.

HYPUSUS, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia, N. of Megalopolis.

HYPTIS, in *Botany*, a genus named by Jacquin from ὑψίς, *refusinate*, because the limb of the corolla is turned, as it were, upon its back.—Schreb. 388. Willd. Sp. Pl. v. 3. 84. Mart. Mill. Dict. v. 2. Jacq. Collect. v. 1. 101. Juss. 449. Lamarek. Dict. v. 3. 184. Illustr. t. 507.—Class and order, *Didymia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth turbinate, permanent, divided half way down into five, lanceolate, acute, generally equal, erect segments. *Cor.* of one petal, ringent; tube funnel-shaped; throat dilated; limb spreading widely, *refusinate*; the upper lip (which is reversed as to its situation) cut into three, lateral, ovate, acute segments, the middle one roundish, concave, obtuse; the lower lip (turned uppermost) is divided half way down into two half-ovate, flat, acute segments. *Stam.* Filaments four, awl-shaped, two shorter; anthers twin, dependent. *Pist.* Germen four-cleft; style thread-shaped; stigma bifid or simple. *Peric.* none, the calyx protecting the four seeds.

Ess. Ch. Calyx five-toothed. Corolla ringent, reversed, its upper lip bifid, lower one trifid, the middle segment formed like a little pouch. Stamens declined.

1. *H. verticillata*. Willd. n. 1. Jacq. Ic. Rar. v. 1. t. 113.—“Flowers in whorls. Leaves lanceolate, toothed.”

—A native of Hispaniola. It flowers in the stoves of Europe about November or December.—This *shrub* is about ten feet high, with one or two upright stems, which are smooth, brownish-ash-coloured, round and woody; the younger branches square and herbaceous. *Leaves* opposite, on footstalks, lanceolate, acute, unequally serrated, smoothish, from three to six inches long, slightly odorous. *Whorls* on the younger branches, at each pair of leaves, sessile, six-flowered. *Corolla* white, with the segments of the upper lip purplish. *Calyx* a little hispid at the back and at the edges of the segments. *Anthers* pale yellow.

2. *H. capitata*. Willd. n. 2. Jacq. Ic. Rar. v. 1. t. 114.—“Flowers in little stalked heads. Leaves ovate, toothed.”—This is also found in Hispaniola, flowering in December.—*Stem* rather shrubby, about a yard in height, square, brown. *Branches* annual, subdivided, roughish. *Leaves* opposite; on footstalks, veined, unequally serrated, rather hairy on both sides, dark green; the lower ones wrinkled, about seven inches long. *Flower-stalks* bearing numerous white or bluish-coloured flowers collected together into a semi-globular head. The tube of the corolla is a little hairy on its outside, especially on the back of the helmet. Whole plant inodorous.

VOL. XVIII.

Willdenow refers *Clinopodium rugosum*, Linn. Sp. Pl. 882. to this genus, as well as *Clinopodium chamadrys*, Vahl. Symb. p. 3. 77; the former, under the name of *Hyptis radiata*, and the latter of *H. Chamadrys*.

HYPULUS, in *Surgery*, an ulcer under a cicatrix.

HYRAX, in *Zoology*, a genus of mammalia in the order Glires. The essential character consists in having two broad and distant fore-teeth in the upper jaw, in the lower jaw four, of a flattened form, broad, notched, and placed contiguous; grinders large, tuberculated, and ten in number (or sometimes eight); fore-feet four-toed; hind-feet three-toed; tail and clavicle none.

In the general aspect this animal bears some resemblance to the guinea-pig; the length from the muzzle to the end of the rump is about fifteen inches. The head is short, the snout blunt, blackish, and without hair; the ears oval, open, brown, and woolly; the body thick and short, and the belly prominent; the hair of the fur woolly, above or on the back brownish, mixed with longer black and a few bristles; the colour becoming grey in descending on the sides, and being towards the abdomen whitish. The limbs appear very short, the shoulders and thighs being concealed under the fur. The anterior feet are four-lobed, and each lobe is armed with a flat rounded nail; the posterior feet are only two-lobed, but have besides a toe which is furnished with a long sharp claw.

According to Schreber there are two species of the hyrax genus, one of which is found at the Cape, the other an inhabitant of Syria. In this opinion he is followed by Gmelin, who thus describes the two presumed species under the names of *Capensis* and *Syriacus*, “*Capensis*; palmarum unguibus planis plantarum unico subulato,”—and “*Syriacus*; pedibus unguiculatis.” Schreber. The species *capensis* is that above described, and is the same as the *Cavia capensis* of Erxleben, Marmotte du Cap of Buffon, and Cape cavy of Pennant. That called *Syriacus* is the animal mentioned by Bruce under the name of the “Lamb of Israel,” and which that author concludes to be the Saphan of holy writ; it seems to differ principally from the former in being about two inches longer, the body more elongated in proportion, the muzzle longer, and the fur reddish-grey. The difference between these two animals is confessedly inconsiderable, inasmuch, perhaps, as to justify an idea that they may not be specifically distinct; Sonnini is convinced they are the same, and confidently asserts it to be the only species of this genus known.

At the Cape this animal is called by the natives *kliip-daas*, or rock badger, but as its haunts are the more retired, and inaccessible parts of the mountains, its habits in a natural state are little known; it is said to form its retreat in the hollows of rocks and caverns, where it makes a litter composed of moss and leaves that occasionally serves to afford it rest or nourishment, as herbage constitutes its natural food. Some writers, and among the number Dr. Pallas, seem to believe this animal forms burrows in the earth like the marmot and the badger, but this appears improbable when we consider the flat and rounded form, as well as weakness of the toe-nails, the structure of which is very different from those of animals which we well know are destined by nature to scratch and burrow in the earth, the solitary toe nail on each of the posterior feet excepted, and this, it is supposed, is principally useful to the animal in assisting it to remove from the skin some portion of those numerous pediculi with which it is infested and tormented. The flesh of the hyrax is esteemed by the inhabitants of the Cape good eating; the Hottentots endeavour also to discover its haunts for another reason as well as that of its capture, for they collect in the

places of its retreat a particular substance supposed by them to be deposited from the urine of this animal after long exposure to the air; and which they maintain to be a sovereign remedy in many disorders; the colour of this substance when dry is blackish, and the smell offensive in the extreme.

When domesticated the Cape Iyrix becomes a familiar and interesting animal, and one susceptible of attachment. If called by any name by which it is accustomed to be distinguished, it replies in a short but sharp and piercing cry, and approaches those it knows in confidence. It dreads cold, and places itself close to the fire when it can conveniently. The disposition of this animal is remarkably timid. Those transported from the Cape into European climates have been known to subsist on bread, potatoes, fruits, and various other vegetables.

HYRCAN I., *Joux*, in *Biography*, high-priest and prince of the Jews, was the son of Simon Maccabeus. On the invasion of Judea by the Syrian governor in the year B.C. 139, he and his brother Judas led a body of troops, who entirely defeated the invaders. After his father's murder by his son-in-law, Ptolemy, he went to Jerusalem, where he was declared Simon's successor in the priesthood and sovereignty. This was in the year 135. Antiochus Sidetes laid siege to Jerusalem, but was induced to grant a peace to the Jews upon condition of their dismantling the city, and the payment of a large sum of money. Hyrcan afterwards made an alliance of friendship with Antiochus, and accompanied him in his war against Phraates, king of Parthia, in which he did much service, and after the death of Antiochus, he took advantage of the civil dissensions prevailing in Syria, made himself master of several neighbouring towns, and entirely shook off all dependence on that crown. He afterwards became the aggressor, and made considerable conquests for his country, till at length he extended his dominion not only over Palestine, but also over the provinces of Samaria and Galilee, and the Jewish state appeared with greater lustre than under any of his predecessors since the captivity. He was zealous for his religion, and attached to the sect of Pharisees, but a quarrel with that haughty and powerful body embittered the latter part of his life. He died in the year 107, and was succeeded by Aristobulus.

HYRCAN II., high-priest and king of the Jews, was eldest son of Alexander Jannæus; but at the death of his father, his mother Alexandra took the reins of government, and allotted to him the succession of the priesthood. On her decease Hyrcan was declared king, but being of a quiet and unenterprising disposition, he was quickly dispossessed of his dignities, and reduced to a private station. He was afterwards persuaded by Antipater to accompany him to Arabia, in the vain hope of obtaining the assistance of king Aretas to restore him. The Romans, gained over by Aristobulus, the brother of Hyrcan, defeated Aretas, and the two brothers at length pleaded their cause in person before Pompey. In the year 63 B.C. Hyrcan was restored to his pontifical office with the title of prince, but he was divested of royalty, and made tributary to Pompey. He lived several years under the protection of the Romans; and was very much favoured by Cæsar, but at length he fell into the hand of his nephew Antigonus, who cut off his ears, in order to incapacitate him for the priesthood. He was then carried into Parthia, where he was well treated, till he complied with an invitation from Herod to return to Jerusalem, and resume the pontificate. His honours were of short duration, being beheaded by the tyrant when he was in the eightieth year of his age. Josephus. *Univer. Hist.*

HYRCANIA, in *Ancient Geography*, a large country of Asia, situated to the south of the eastern part of the Caspian

sea, hence called the Hyrcanian sea. It had on the W. Media, on the S. Parthia, and on the E. Margiana. This country was mountainous, covered with forests, and inaccessible to cavalry. It was separated from Parthia by mount Corone. According to Ptolemy the Maxaræ, and S. of them the Chirindi, and also the Arabeni, were situated towards the sea. Its towns were Barange, Adrapfa, Casape, Aberbina, Amarusa, Sinica, Hyrcania the metropolis, Sale or Sacæ, Afmura or Afmurna, and Mausoca.

It is now well known that Timotheus, the Nestorian pontiff, who had been raised to that dignity A.D. 778, converted to the Christian faith by the ministry of Subchal Jesu, whom he had consecrated bishop, first the Gelæ and Dailanites, by whom a part of Hyrcania was inhabited; and afterwards, by the labours of other missionaries, the rest of the nations, which had formed settlements in Hyrcania, Bactria, Margiana, and Sogdia. It is also certain, that Christianity enjoyed in these vast regions, notwithstanding the violent attacks of the Mahometans, to which it was sometimes exposed, the advantages of a firm and solid establishment for a long course of ages; while the bishops, by whose ministry it was propagated and supported, were all consecrated by the sole authority of the Nestorian pontiff.

HYRCANIA, or *Hyrcanus Campus*, a country of Asia Minor.

HYRCANIA, a country of Asia, S. of Babylonia; inhabited by the Hyrcanii, who, as well as the Sacs and Cadusians, occupied that district which lay between the Tigris and the Euphrates. These people were powerful enemies of the king of Assyria; and an alliance with them was sought for by Cyrus in his war against this prince. He formed of these people 2000 cavalry, and a very considerable body of infantry; and having dispossessed the Assyrians of their garisons on the frontier of the country, Cyrus assigned them to his new allies. The Hyrcanians, who inhabited Hyrcania, on the coast of the Caspian sea, were a ferocious people.

HYRGALE, a town of Asia, in Phrygia Salutaris; situated on a river towards the northern part of this province. The chief magistrate bore the title of Archon. The worship of Cybele was established in this city; but abandoned on the introduction of Christianity. Its bishop assisted at the council of Chalcedon, in 451.

HYRIA, a town built by the Cretans, who assumed the name of Japyges Messapii. It was situated in the interior of the country between Tarentum and Brundisium. Strabo calls it Ouria, and the Latins Uria. It is now Dria.

HYRYNSELMI, in *Geography*, a town of Sweden, in the government of Ulea; 34 miles N.E. of Ulea.

HYS, a town of the Arabian Irak, on the Euphrates; 120 miles S. of Bagdad.

HYSSOP, in *Botany and Gardening*. See **HYSSOPUS**.

HYSSOP, *Common*, *Hyssopus officinalis*, in the *Materia Medica*, is a native of Siberia, and the mountainous parts of Austria, and flowers from June till September. The hyssop mentioned in the Old Testament is not supposed to be this plant, which is neither the *esof* of the Hebrews, nor the *υσσωπος* of the Greeks. It was first cultivated in England by Gerarde in 1596, and is now extremely common in our gardens. The leaves of hyssop have an aromatic smell, and a bitterish, moderately warm taste. They give out their active matter both to water and rectified spirit; the watery infusions are of a brownish or greenish yellow, and the spirituous tinctures of a blackish green colour. On inspissating the latter, the remaining extract retains its flavour, is bitterish, and very warm, and discovers a penetrating pungency, resembling that of camphor. Water, distilled from the fresh herb, is found pretty strongly impregnated with its flavour.

An essential oil is obtained from the distillation, which rises to the surface, to the quantity of about an ounce from six pounds of the leaves: this oil is very pungent, and in smell exactly resembles the hyssop.

The stimulating quality of hyssop is ascribed to the quantity of essential oil which it contains; and with a view to its aromatic and stimulant effects, Bergius recommends it as an emmenagogue and antihysteria; but it is chiefly employed as a pectoral, and has been long thought an useful medicine in humoral asthmas, coughs, and catarrhal affections: for this purpose, an infusion of the leaves, sweetened with honey or sugar, and drank as tea, is recommended by Lewis.

Hyssop is greatly commended in cases of bruises from falls, blows, &c. used externally by way of fomentations or cataplasms, or only a little bundle of the plant sewed up in a linen rag, and applied to the part. Ray gives an account from Mr. Boyle, of a violent contusion of the thigh, from a kick of a horse, which was happily cured by this herb, boiled and applied as a cataplasm. He tells us, the violent pain was almost instantly removed, and the very mark and blackness taken off in a few hours. It is also recommended as a vermifuge by Rosenstein. Woodv. Mat. Med.

Hyssop was commonly made use of, as we learn from the scriptures, in purification. Thus God commanded the Hebrews when they came out of Egypt, to take a bunch of hyssop, to dip it in the blood of the paschal-lamb, and sprinkle the lintel and two side-posts with it. (Exod. xii. v. 22.) Sometimes a little wool was added to it of a scarlet colour. So in the purification of lepers, a bunch, composed of hyssop, the branches of cedar, and red wood, was dipped in water, mingled with the blood of a bird, and with this the leper was sprinkled. (Levit. xiv. v. 4.) David also alludes to these ceremonial cleansings in his 51st Psalm, v. 7th. "Purge me with hyssop, and I shall be clean."—Cruden observes it is very probable that this plant grows to a great height in Judea, since it is said in the Gospel, that the soldiers having filled a sponge with vinegar, they put it upon a stick of hyssop and presented it to our Saviour's mouth, who was then upon the cross.

HYSSOP, *Hedge*, in *Botany* and the *Materia Medica*. See GRATIOLA.

HYSSOP, *Mountain*. See THYMBRA.

HYSSOPIC ART, a name which Paracelsus gave to chemistry, considered as the art which purifies metals, minerals, &c. in allusion to that text in the Psalms, "Purge me with hyssop, and I shall be clean."

HYSSOPUS, in *Botany*, generally taken for *ισσωπος*; of Dioscorides, derived by some from *ὕς*, to rain, or to be showered on, and *ω*, the countenance, because the dust of this plant, when dried and pulverized, was used in the Grecian sacrifices for sprinkling the head and eyes, as the Catholics now use holy water for the purpose of *crossing* themselves, and this operation was supposed to cleanse the impurities of those over whom hyssop was sprinkled. Professor Martyn more justly deduces the word from the Hebrew, *Esof*. Linn. Gen. 289. Schreb. 385. Willd. Sp. Pl. v. 3. 47. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 283. Juss. 113. Tournef. t. 95. Lamarck Dict. v. 3. 185. Illustr. t. 502.—Class and order, *Didynamia Gynnospermia*. Nat. Ord. *Ver-ticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, cylindrical, oblong, striated, acutely five-toothed, permanent. *Cor.* of one petal, ringent; tube cylindrical, slender, as long as the calyx; throat inclined; upper lip straight, flat, short, roundish, emarginate; lower lip divided into three segments, the lateral ones shorter and obtuse; the middle one crenate, obcordate, acute, with distant lobes. *Stam.* Filaments four, erect, longer

than the corolla, distant; the two upper ones shorter, but the two longer ones nearer to the lower lip; anthers simple. *Pist.* Germen four-cleft; style thread-shaped, under the upper lip, and of the same length; stigma bifid. *Peric.* none; the calyx containing the seeds, which are four in number, and subovate.

Eff. Ch. Corolla with a small middle crenate segment in its lower lip. Stamens straight, distant.

1. *H. officinalis*. Common Hyssop. Linn. Sp. Pl. 796. Jacq. Austr. t. 254.—"Spikes all leaning in the same direction. Leaves lanceolate."—A native of the south of Europe, flowering from June to September. *Root* woody, half an inch thick. *Stem* about 18 inches high, at first square, then round. Leaves sessile, the lower ones in pairs, narrow, smooth, entire, like those of lavender, but shorter. *Flowers* in whorls, from the bosoms of the leaves, continued into a spike, of a blue colour, but varying to red and white. The whole plant has a strong aromatic scent, and was cultivated in this country by Gerarde in the year 1596.

2. *H. Lophanthus*. Mint-leaved Hyssop. Linn. Sp. Pl. 796. Jacq. Hort. Vind. v. 2. t. 182.—"Flowers reflexate, lower stamens shorter than the corolla. Leaves cordate."—Native of Siberia, flowering in August and September. *Root* perennial, fibrous, sending out many square stalks, which divide into branches. *Leaves* heart-shaped, rough, pale on the under side. *Clusters* of four or five purple flowers are produced at each joint of the stem. The tube of the corolla is longer than the calyx.

3. *H. nepetoides*. Square-stalked Hyssop. Linn. Sp. Pl. 796. Jacq. Hort. Vind. v. 1. t. 69.—Stem sharply quadrangular. Flowers in close whorls. Leaves ovate.—Native of Virginia and Canada, flowering from August to October.—*Root* perennial. *Stem* erect, about four feet high. *Leaves* obliquely cordate, or ovate, serrated, acute, on short foot-stalks. *Flowers* yellow, in thick close spikes four or five inches long; upper lip of the corolla divided into two roundish segments. *Seeds* brown.

There is a variety of this species with purple stalks and flowers, the leaves on longer footstalks, and the spikes of flowers denser, but Willdenow has made a new species of it, we presume, under the name of *H. seropularifolius*. Vide Willd. Sp. Pl. v. 3. 48.

HYSSOPUS, in *Gardening*, affords a plant of the low under-shrubby kind; of which the species cultivated is the common hyssop (*H. officinalis*).

There are several varieties, as the blue-flowered, the white-flowered, the red-flowered, the long-spiked, with deep blue flowers, the curled-leaved, and the striped-leaved.

Method of Culture.—This is a kind of plant which is capable of being raised by means of seeds, cuttings, and slips.

The seeds should be sown in a bed or border of light mould, prepared for the purpose, in the spring season, being well raked in. When the plants appear, they should be thinned where they stand too close, and as soon as they are three or four inches in height, be planted out in the places where they are to grow. In the forming of edgings of this plant, the seeds may be deposited in drills run along the edges of the borders, &c. where they are to grow, being covered in about half an inch in depth.

In the two latter modes, some of the more robust side-shoots should be cut or slipped off, and planted in a shady border, or other place, in the latter part of the summer, at the distance of five or six inches from each other, water being immediately given, and occasionally repeated. The plants soon take root, when in the autumn they may be set out where they are to grow.

It is the common blue-flowered hyssop that is the kind mostly made use of, and which is commonly cultivated either in close rows, or by way of edging to beds and other parts, in which latter case the plants are kept regular and in order, by annual clippings. The rows should be about fifteen or eighteen inches apart where that method is employed, and nearly at an equal distance between the plants in the rows.

They are the young leafy shoots and flower-spikes which are usually employed, being cut as they are wanted. And the flower stems may be cut over during the summer, and be tied up in bunches for use.

Plants of the several different varieties may likewise be planted out separately, in the borders, clumps, and other parts of the pleasure grounds, in order to form small bushy plants for the purpose of ornament.

HYSTERA, a term used by some of the old writers in medicine to express the fecundines.

HYSTERALGIA, in *Medicine*, from the Greek ὑστέρησις, signifying the *womb* or *uterus*, and ἄλγος, *pain*, a term used by the nosologists to denote all the slow painful disorders of that organ.

Sauvages describes sixteen species of hysteralgia, distinguishing them by the various circumstances by which the pain is excited. Thus he includes, under this genus, the pains arising from *prolapsus* of the uterus (Spec. 1. H. *ab hysteroptosi*); from *hernia* of the same viscus (2. H. *ab hysterocèle*); from *dysmenorrhœa*, or painful menstruation (3. H. *à menostasia*); from cancer of the uterus (4. H. *cancerosa*); from ulceration and scirrhus (5 and 6. H. *ulcerosa, scirrhosa*); from pruritus in the uterus (7. H. *pruriginosa*); from a bony substance in it (8. H. *ab ossi*. See Hody, in *Philos. Transact.* vol. ix. p. 191.); from intermitting fever (9. H. *febricosa*, Morton, *Pyretologia*, p. 92.); from hysterical affections (10. H. *vaporosa*); from abscesses succeeding to inflammation of the uterus (11. H. *ex abscessu*. See HYSTERITIS); from the gradual distention of the uterus in pregnancy (12. H. *impregnatarum*); from suppression of the milk (13. H. *lactea*); from the natural contractions of the uterus after delivery, during the discharge of the *lochia*, commonly called *after-pains* (14. H. *lochialis*); from a supposed translocation of the milk to the hypogastric region (15. H. *ab sparganosi*); and, lastly, from calculous concretions formed in the uterus (16. H. *calculosa*). See his *Nosol. Meth. Class. vii. Ord. 4.* It will be observed, that some of these varieties of hysteralgia, such as those connected with the enlargement of the gravid uterus (sp. 12.) and the after-pains (sp. 14.), can scarcely be considered as diseases, unless they occur in an unusual degree of severity: while, on the other hand, some of them are extremely rare; such as the case described by Hody (sp. 8.), and the variety occasioned by the presence of calculi. The first and second species, depending upon prolapsus of the vagina and hernia, can only be relieved by mechanical means, by which the uterus may be replaced in its natural situation. (See *PROLAPSUS Uteri*, and *HYSTEROCELE*.) Ulceration and cancer of the womb constitute the most painful and distressing diseases to which the female frame is subject, and will be treated of under their proper heads. See *WOMB*.

But, in addition to these instances of hysteralgia, there are cases in which pain, referred to the uterus and its appendages, is a leading symptom, and cannot be ascribed exactly to any of the causes above-mentioned. Such pains sometimes come on a few weeks after delivery in married women, and are often dated from the last child-birth. They are most commonly accompanied by some irregularity in the menstrual discharge, generally by an increase of it, or by alternations of a bloody, with a thinner, less coloured, and

offensive evacuation. The symptoms vary a little in different cases, apparently according as the uterus itself, or its particular appendages are disordered. In general the patient complains of pains in the loins, extending round the margin of the pelvis to the groin, on one or both sides, and shooting down the thigh to the knee, or, in more severe cases, even to the foot. Sometimes the pain is more strictly referred to the uterus itself, or its neck, and the loins are scarcely affected; and sometimes it is fixed, in one side, above the ilium, as if seated in the ovarium. In one case we have seen the disease confined apparently to the ovarium and ligaments of one side, in which there was great soreness of the part, where the round ligament passes to the pubes. The stomach is frequently disordered by sympathy, and the patient complains of nausea, flatulence, and other symptoms of indigestion; and occasionally some degree of febrile action attends these complaints.

These forms of hysteralgia are by no means unfrequent, especially among the poor; and seem to originate often in some degree of chronic inflammation, and diseased secretion in the uterus, consequent on the irritations of child-birth, or produced by causes suddenly interrupting or deranging the lochial and menstrual discharges. Sometimes it is probable that they are merely the signs of incipient scirrhus.

There are no medicines which operate specifically upon the uterus. When there is clearly a feverishness connected with hysteralgia, laxatives and diaphoretics are the most useful medicines, the pain being at the same time soothed by conium, opium, humulus, or other anodynes. The tincture of the hop, or humulus lupulus of Linnæus, has sometimes appeared to afford ease in these cases, when the other narcotics had failed; but perhaps this observation is applicable to any medicine of this class. When the hysteralgia is connected with great weakness and lowness of spirits, and a considerable leucorrhœa, cordials and tonics, combined with the anodynes just mentioned, must be administered. In the case attended with pain and soreness in the course of the round ligament, the application of leeches to the groin, and the use of saline laxatives, afforded relief. In all these cases rest, or abstinence from all motion, especially from walking, seem to be beneficial; although perhaps negatively, by allowing the vessels of the part to recover their natural actions, which the erect posture and the irritation of walking tend to prevent. See *Edin. Med. and Surg. Journal*, vol. iv. p. 241.

In the volume of the *Journal*, just quoted, a case of hysteralgia is related, which continued, without one day's cessation, for twenty-six years, yet no derangement in the structure of the uterus, sufficient to account for it, was discovered after death. See p. 168.

HYSTERIA, HYSTERICUS, or *Hysterical Affection*, from ὑστέρησις, the *uterus*, or *womb*, implies literally the *uterine disease*; it denotes a state of constitution, in which a variety of spasmodic, convulsive, and painful affections occur, together with extreme variability of the spirits, and a frequent sense of suffocation, from a ball rising from the abdomen to the throat, which has been called the *globus hystericus*, and considered by some as the essential characteristic of the disease.

Other appellations have been given to the disease, with reference to its origin from the womb, especially to the convulsive paroxysms, or *hysteric fits*, which have been called *suffocation of the womb, suffocatio uteri, fits of the mother*, &c. The appellation of *vapours* has also been applied to this disease in females, as well as to the hypochondriasis in men; and from a similar notion, that it is occasioned by vapours, ascending from the *uterus*, and affecting the brain, lungs, &c.;

HYSTERIA.

&c. ; as vapours arising from the stomach, liver and spleen, were supposed to give rise to hypochondriasis.

All medical writers have admitted the difficulty of describing, in a concise manner, the various forms of this disorder, which exhibits such a number of phenomena, which rapidly appear and change, that it imitates almost every disease of the nervous class, and even several of the more fixed and organic diseases. "Dies me deficeret," says Sydenham, "si omnia, quæ adfectus hystericos gravant, symptomata enumerare velim; tam diversa atque ad invicem contraria specie variantia, quam nec Proteus lufit unquam, nec coloratus spectatur chamæleon." (Dissertatio Epistolæ ad Gul. Cole.) The most complete form of *hysteria*, however, is seen in the paroxysms, or *fits*, which occur at various periods, without any regularity. These are commonly preceded by a sense of lassitude, coldness of the feet, and a copious discharge of pale limpid urine: often by pain in the head, loins, or stomach; which latter organ, as the fits commence, is sometimes affected with vomiting. The paroxysms commonly begin by some pain and fulness felt in the left side of the belly. From this a ball seems to move, with a grumbling noise into the other parts of the belly; and, making as it were various convolutions there, seems to move into the stomach, and more distinctly still rises up to the top of the gullet, where it remains for some time, and by its pressure upon the larynx gives a sense of suffocation. There is occasionally much difficulty of breathing, and a palpitation of the heart at the onset. By the time the disease has proceeded thus far, the patient is affected with a stupor and insensibility, while at the same time the body is agitated with various convulsions: the trunk of the body is writhed to and fro, and the limbs are variously agitated; commonly the convulsive motion of one arm and hand, is that of beating with the closed fist upon the breast very violently and repeatedly. The whole of the belly, and particularly the navel, is often drawn strongly inwards; sometimes there is a violent working, or alternate rising and falling of the belly, attended with considerable noise. The *sphincter ani*, during the fit, is sometimes so firmly constricted as not to admit a small glyster-pipe, and there is at the same time an entire suppression of urine. This state continues for some time, with some remissions and renewals of the convulsive motions; but they at length cease, leaving the patient in a stupid and seemingly sleeping state. More or less suddenly, and frequently with repeated sighing and sobbing, together with a murmuring noise in the belly, the patient returns to the exercise of sense and motion, but generally without any recollection of the several circumstances that had taken place during the fit.

Such fits are very liable to recur from time to time, and during the intervals the patients are subject to involuntary motions, to fits of laughing and crying, with sudden transitions from one to the other; while sometimes false perceptions and some degree of delirium also occur, as well as all the various incongruities of the disease to which we alluded above. The preceding account is that of the most common form of the *hysteria paroxysm*; but this is considerably varied in different persons, and even in the same person at different times. It differs chiefly by having more or fewer of the circumstances above-mentioned, by the greater or less degree of violence of these, and by the different duration of the whole fit. See Cullen, First Lines, par. 1514, *et seq.*

Sydenham has enumerated the principal varieties of form, which the *irregular hysteria*, as it has been termed, assumes; or, to use perhaps a more correct expression, the principal disorders of the functions, which take place in the intervals of the paroxysms, or occur where the paroxysms do not

appear. "The disease," he says, "is not more remarkable for its frequency, than for the numerous forms under which it appears, resembling most of the distempers wherewith mankind are afflicted. For in whatever part of the body it be seated, it immediately produces such symptoms as are peculiar to that part; so that unless the physician be a person of judgment and penetration, he will be mistaken, and suppose such symptoms to arise from some essential disease of this or that particular organ, and not from the *hysterical passion*." (Loc. cit.) Dr. Ferriar, in his chapter on the "conversion of diseases," has remarked that the conversions of hysteria are very common sources of error to young practitioners, and sometimes deceive even the most experienced. "Whoever would present us with a good book," he says, "on the *fallacy of symptoms*, which is greatly wanted, must be completely master of this unaccountable disease." Ferriar, Med. Histories and Reflections, vol. ii. See also *CONVERSION of Diseases*, where the substance of that ingenious dissertation will be found.

"When the hysterical disposition is set in motion, the same author observes, it is not uncommon to find many of the different viscera attacked by it in turns, and the diseases peculiar to each counterfeited with much exactness. I have seen symptoms of paralysis, jaundice, palpitation, and nephritis, succeed each other rapidly in the same patient, while some of the characteristic marks of hysteria have been discernible, and where the unity of the disease was proved, by the disappearance of all menacing affections, on the approach of regular fits. In one case, the bowels were attacked, and the symptoms of *enteritis* were so precisely imitated, as to give much alarm for the patient's safety. I suspected the real nature of the disease, from observing that the pulse was soft and full, that the evacuations were natural, and that her spirits were agitated, even to involuntary emotions, by slight causes. This case terminated successfully, on the accession of clear hysterical symptoms. Several years ago, I attended an elderly lady, for a complaint which seemed to vibrate between apoplexy and palsy; after lying for several weeks in a state which afforded little hope of amendment, she was affected with involuntary sobbing and weeping; the complaints in her head and limbs were converted into hysterical convulsions, and she recovered completely.

"It is very common to meet with syncope, or palpitations of the heart and great vessels, accompanied with a soporific depression, or extreme dejection of strength and spirits, and converted, after deep sighing or discharge of tears, into the hysterical paroxysm. In these cases, the pulse is sometimes full and regular during the most alarming appearance of sinking, and sometimes variable to such a degree, as to exclude all conjecture, excepting that of an hysterical origin.

"I have met with several cases of hysterical hæmoptoë, in which the quantity of blood evacuated was very considerable; six or eight ounces were sometimes spit up daily, for a fortnight or three weeks successively. Most of the usual symptoms attended, which denote danger in this complaint, when it arises from other causes; but the equal moderate state of the pulse, and the appearance of some degree of *globus hystericus*, seemed to determine the nature of the complaint; a conversion accordingly soon took place to the ordinary hysterical paroxysm, and no bad consequence followed the hæmorrhage from the lungs.

"In all similar instances, the supervening hysterical paroxysm puts a favourable termination to the irregular appearances." Loc. cit.

Sydenham's account of these irregularities differs, in some respects, from the one just detailed; especially inasmuch as

HYSTERIA.

he does not generally notice the solution of the local complaint by the occurrence of the regular hysterical paroxysm, which he mentions only as one of the forms which the disease assumes. He seems to consider the copious discharge of limpid urine, as the chief characteristic of the hysterical attacks, which counterfeits other diseases; (Opera Univerſa, Edit. Lugd. Bat. 1726, p. 392. 394. 570. Wallis's Tranſlat. p. 111. 114. and 399, vol. ii.) but he looks upon this ſymptom as belonging in common to hysteria in women, and to hypochondriaſis in men.

Among the diſeaſes which he has obſerved to be counterfeited by hysteria, are *apoplexy*, when it attacks the head, which terminates in *hemiplegia*, and is chiefly ſeen in lying-in-women, after difficult parturition, attended with great hæmorrhage: the *clavus hystericus*, or acute pain in one ſmall ſpot in the head, which is often accompanied by vomiting, and *palpitation* of the heart; theſe are moſt frequent in delicate and chlorotic girls: pain in the ſtomach, colic, with porraceous vomiting, reſembling the *iliac paſſion*, terminating in *jaundice*, and always accompanied by great deſpondency; chiefly attacking women of lax fibre, who have ſuffered ſevere labours from large children: pains in the kidneys and bladder, like *fits of the ſtone*, with *ſuppreſſion of urine*; occurring in women much debilitated by previous hysterical fits, and in a bad ſtate of health; who are alſo liable to long-continued vomiting and *diarrhœa*, without pain, diſcharging green bile. He likewiſe remarks, that the diſeaſe is liable to attack the external parts and muſcular fleſh, ſometimes cauſing pain, ſometimes ſwelling, in the throat, ſhoulders, hands, thighs, and legs, more eſpecially in the laſt; which ſwelling, however, is to be diſtinguiſhed from œdema, by being greateſt in a morning, by leaving no pit after preſſure with the finger, and by commonly affecting only one leg; though its external appearance much reſembles that of œdema. But the moſt ſevere of thoſe pains, is that which affects the back. He adds, that theſe pains have this circumſtance in common, that they all leave the parts extremely fore and tender, as if they had been ſeverely beaten, ſo that they cannot bear the touch for ſome time; and that theſe pains and other ſymptoms are all preceded by a death-like coldneſs of the external parts. Diff. Epitolaris.

To conclude, the regular hysterical paroxysm ſometimes alternates with the *cataleptic* ſtate, in which the patient remains fixed in one inſenſible poſition (ſee CATALEPSY); ſometimes with a loſs of voice; with *carus*; and with various ſtates of mental derangement, as *nymphomania*, *fatuity*, &c.

Causes of Hysteria.—The *predispoſing* cauſe of this diſeaſe appears to conſiſt chiefly in a certain mobility of the nervous ſyſtem, which is almoſt peculiar to the female conſtitution, the “*variūm et mutabile, fœmina*,” more eſpecially to females of a ſanguine temperament, and of a plethoric and irritable habit. The diſeaſe, therefore, is very rarely ſeen in the male ſex, and never in the ſame exquisite degree in which it occurs in women. In the latter, it appears moſt generally from the age of puberty to that of thirty-five or forty years; very ſeldom before the firſt or after the laſt of thoſe periods; but at all ages, the time at which it moſt readily occurs is that of the menſtrual period, and it is often obviously connected with ſome irregularity or deficiency in the uterine functions; as with ſuppreſſed or difficult menſtruation, pain in the uterus, &c. It affects barren women, more than thoſe who are breeding, and therefore frequently young widows. It occurs eſpecially in thoſe females who are liable to nymphomania; and the noſtologiſts have properly enough marked one of the varieties of this diſeaſe by

the title of *hysteria libidinofa*. It is more frequent in cold than in hot climates.

The *exciting* cauſes of hysteria, which readily operate on a conſtitution pre-diſpoſed to the complaint, are eſpecially all violent paſſions, and every conſiderable emotion of the mind, particularly thoſe brought on by ſurpriſe. Some females, liable to this diſeaſe, acquire ſuch a degree of ſenſibility, as to be ſtrongly affected by every impreſſion, however ſlight, that comes upon them ſuddenly and by ſurpriſe; even by diſagreeable odours, fights, &c. An indolent life and a luxurious manner of living tend both to augment the pre-diſpoſition to the diſeaſe, and to call it into action. Any irritation, eſpecially in the alimentary canal or in the uterus, will excite hysteria; whence it often accompanies a ſtate of inanition, or emptineſs of the ſtomach from long faſting (Sydenham, *loc. cit.*); the uſe of a ſtrong emetic or purgative (*idem.*); painful menſtruation; and an immoderate diſcharge of the menſes, either in child-bed, or at other times. It is alſo occasionally excited by a prolapſus of the uterus, though more rarely; and it has been ſaid to follow the reſpreſſion or metaſtaſis of chronic cutaneous eruptions, intermittent fevers, and other acute diſeaſes.

As to the *proximate* cauſe of the diſeaſe, it may be remarked, that its paroxysms appear to begin by a convulſive and ſpaſmodic affection of the alimentary canal, which afterwards influences the brain and a great part of the nervous ſyſtem. But, as Dr. Cullen obſerves, “although the diſeaſe appears to begin in the alimentary canal, yet the connection which the paroxysms ſo often have with the menſtrual flux, and with the diſeaſes that depend on the ſtate of the genitals, ſhews that phyſicians have at all times judged rightly in conſidering this diſeaſe as an affection of the uterus and other parts of the genital ſyſtem.” Par. 1520.

He confeſſes himſelf, however, unable to explain in what manner the uterus and the ovaria are affected in the diſeaſe; how the affection of theſe is communicated with particular circumſtances to the alimentary canal; or how the affection of this part, riſing upwards, affects the brain, ſo as to occasion the particular convulſions which take place. To ſay that there is a great ſympathy between the uterine and digeſtive organs, is but to expreſs the fact in other terms; and with this general expreſſion we muſt be content at preſent.

Sydenham refers all the phenomena to the irregular motions of the animal ſpirits; which is a ſtill more hypothetical expreſſion of the fact, becauſe the very exiſtence of ſuch ſpirits is a mere aſſumption, which a better investigation has rejected as altogether unfounded. He denies that the diſeaſe is to be aſcribed “to the aſcent of malignant vapours from the corrupted ſemen or menſtruous blood in the uterus to the parts affected, as ſome authors have aſſerted; or, as others affirm, to a latent depravity of the juices, or a collection of acrid humours.” And his reaſon is very concluſive againſt the humoral pathology: “for,” he ſays, “that the cauſe of the diſeaſe does not lie concealed in any morbid matter, appears evident from this ſingle inſtance. If a ſlender weak woman, otherwiſe uſually healthy, happens, by miſtake, to be debilitated and exhauſted by a ſtrong vomit or purgative, ſhe will be infallibly ſeized with ſome one of the concomitant ſymptoms of this diſeaſe; which would, by theſe means, rather have been carried off, than occasioned, if the cauſe of it had been any preſent humour. The ſame may be ſaid of too great loſs of blood, whether it be taken away by bleeding, flows immoderately after delivery, or be diminished by inanition and too long abſtinenſe from fleſh; all which would rather be preventive than productive of hysterical diſeaſes, if the cauſe of theſe conſiſted in ſome

HYSTERIA.

some kind of morbid matter; whereas, on the contrary, they are never more certainly occasioned than by these evacuations." Nevertheless, Sydenham was unable to banish completely his prejudices in favour of the humoral pathology, although refuting it thus satisfactorily; and therefore, he maintains that "the irregular motion of the spirits generates putrid humours in the body;" and that these corrupt juices, collected in the blood, are sent to various organs, producing chlorosis, and other cachectic diseases. *Loc. cit.*

It would be quite superfluous to enter into any discussion respecting the absurd notions of the ancients, who attributed the disease either to the ascent of vapours from the uterus, producing the sense of suffocation and convulsions, or to the ascent of the uterus itself, which was supposed to roam about the abdomen at times, and, by pressing the diaphragm upwards, to give rise to the symptoms. The latter opinion seems to have been held both by the philosophers and physicians; for Hippocrates (*de Natura Mulierum*) and Plato (*Timæus*) have expressed the same notion; the latter comparing the uterus to an animal, desirous of impregnation, and wandering through the whole body. Galen's knowledge of anatomy enabled him to refute these absurdities (*de locis affect. cap. 5.*); and therefore the notion of rising vapours was adopted, and it continued to be espoused for a considerable period after the restoration of learning. For a statement of the arguments, the reader may consult Sennert. *Pract. lib. i. sect. 1. cap. 14.* and *lib. iv. part 2. sect. 3. cap. 4.* the works of Fernel, &c.

Of the Diagnosis.—The hysteric paroxysm scarcely resembles any other affection of the body, except occasionally the paroxysm of *epilepsy*; but in epilepsy, the convulsive motions are generally much more violent, and the insensibility more complete; there is foaming at the mouth, and a state of coma or profound sleep follows the fit; on the contrary, there is no *globus* rising into the throat, no agitation of the abdomen, no screaming, laughing, or crying, nor any copious discharge of limpid urine, as is common in the commencement of the hysteric fit.

The disease in general has been considered by many physicians as the same with hypochondriasis, the latter term being appropriated to it, when occurring in the male sex, and hysteria when it is found in the female. But this seems to be improper, if the symptoms of the two diseases be accurately examined. They may have, indeed, some symptoms in common; but for the most part they differ widely. Spasmodic affections occur in both; but they are generally local, confined to particular parts, and much less severe in hypochondriasis, as well as much less frequent than in hysteria. Indigestion occasionally affects hysteric patients; but they are often entirely free from it, which never happens in hypochondriacs. But the diseases are still more certainly distinguished by the temperament which they usually attack, and by the time of life at which they appear to be most exquisitely formed: youth and a sanguine temperament being most liable to hysteria, while the middle or advanced periods of life, and a melancholic temperament, are peculiarly favourable to hypochondriasis. Nor are they limited to the respective sexes; for the male sex, when youth and the sanguine temperament, exquisitely marked, concur, is not absolutely free from the attacks of hysteria; and instances of hypochondriasis in the female sex, of the opposite age and temperament, are very common.

With respect to the irregular forms of hysteria, under which it resembles many other diseases, we have already anticipated the means of forming a diagnosis. Dr. Ferriar considers the supervention of the regular paroxysm as the

principal source of discrimination: but as the disease is generally removed by this occurrence, it is desirable to detect the nature of those irregular affections at an earlier period. Besides the copious discharge of limpid urine, which Sydenham considered as the pathognomonic symptom of hysteric complaints, the same accurate observer deemed the state of the mind a valuable index of their presence; and it is obvious, from the observations above quoted from Dr. Ferriar, that he also attended to this point, and to the state of the pulse. As the most frequent exciting causes of hysteric fits are some sudden and strong emotions of the mind, whenever Sydenham was consulted by women concerning any particular disorder, which could not be accounted for on the ordinary principles of investigating diseases, he always inquired whether they were not chiefly attacked with it after fretting or any disturbance of mind; and if they acknowledged this, he concluded that the disorder was of the hysterical class, especially when the other diagnostic, copious pale urine, at the same time occurred. *Épist. ad Dom. Cole.*

Although the paroxysm of hysteria is extremely alarming to the inexperienced observer, it is scarcely ever fatal in its own form, unless when it is induced by some very violent cause; and the disorder generally disappears in the decline of life. Instances have occurred, indeed, in which it has continued to harass a patient from the commencement to the cessation of the catamenial discharge, and then ceased.

Of the Cure.—In the treatment of hysteria, as in many other diseases, considerable discrimination will be required in the application of remedies, which must be varied according to the form or degree of the complaint, to the temperament, habit of body, and condition in life, of the patient, and to the nature of the causes exciting it. Although that peculiar mobility of the nervous system, on which the disorder chiefly depends, is most frequently connected with a plethoric habit, and a purely sanguine temperament; yet this is by no means universal: for it is often observed in habits the reverse of plethoric, in which a considerable degree of debility, and a pale and phlegmatic temperament prevail. In ascribing the convulsive paroxysms of hysteria to a local plethora or turgescence of blood in the uterus, from the analogy of epilepsy and asthma, which he refers to a turgescence of blood in the vessels of the brain and of the lungs respectively, Dr. Cullen has obviously hit upon a false analogy, which will not bear him out in the explanation. For in the epilepsy and asthma, the peculiar functions of the brain and of the lungs are disordered by plethora of these organs; the functions of sense and motion, in the one case, and of respiration in the other, are almost exclusively deranged. But in hysteria, if the analogy were correct, the uterine functions should be alone or principally diseased: whereas the functions of the brain, the lungs, and the alimentary canal, are chiefly deranged, to which the supposed plethora does not extend. See Cullen, *First Lines*, par. 1523.

Whatever notion be adopted as to the pathology of the disease, the curative indications seem to resolve themselves into two; namely, *first*, in the paroxysm, to check its violence; and, *secondly*, in the interval, to endeavour to lessen or remove the predisposing and exciting causes.

The first indication will be fulfilled by different means, according to the state of the patient's habit. If she is of a robust and plethoric constitution, *blood-letting* is the most effectual antispasmodic that can be employed; and when the convulsions are severe, or long continued, with a flushing or fulness of the vessels of the face and external parts, it is the only antispasmodic that can be administered with safety.

At

HYSTERIA.

At the same time, the turgescence and activity of the blood-vessels, and the consequent over-irritation of the nervous system, may be diminished by the application of cold to the head and abdomen, or to the body in general. The use of nauseating emetics has also been recommended for this purpose. Where the plethora is not so considerable as to warrant general blood-letting, cupping from the neck, or from any part in pain, may be substituted.

But in those habits, which exhibit no marks of plethora or of considerable strength, evacuations of blood, so far from being beneficial, are extremely detrimental, and are absolutely enumerated among the causes which induce the disease. In such constitutions, the hysterical paroxysm is to be diminished or cut short by stimulant and antispasmodic medicines. Of these, opium, in its various preparations, is one of the most effectual; and its efficacy is considerably aided by a combination with the more diffusible stimulants, especially with æther and ammonia, or the volatile alkali. It is most commonly not difficult to force the patient to swallow twenty or thirty drops of sulphuric æther and of tincture of opium, in any liquid, at the commencement or during the continuance of the fit; and this is frequently followed by a speedy cessation of the spasmodic motions. Various other stimulant medicines, especially those of strong and pungent odour, may be administered with good effect under the same circumstances; such are the preparations of valerian, musk, castor, camphor, assa-fœtida, oil of amber, oleum animale, &c. At the same time, any strong impression made upon the nervous system will frequently arrest the progress of the paroxysm; as the application of any strong-smelling substance to the nostrils, such as burning feathers, and volatile salts. The stimulus of heat may likewise be resorted to for the relief of the paroxysm, when it is obstinate; and it may be applied to the whole body, by means of the warm bath; or to the lower extremities, in the way of pediluvium.

After the paroxysm is over, the means for fulfilling the second indication must be adopted, in order to prevent relapses: and as the principal predisposing cause and the leading feature of the hysterical habit, (the great mobility of the nervous system,) is connected with the opposite conditions of plethora and of inanition or debility, the first object will be to correct this predisposition, by the means adapted to the removal of the one or the other of these conditions respectively. In robust and plethoric habits, the adherence to a moderate system of living, to a light and spare diet, chiefly of vegetable matters, or weak animal broths, which may be taken in sufficient quantity to distend the stomach, and relieve the sensation of inanition, without affording a copious nutriment, must be strongly recommended. The use of strong cathartics for this purpose is deprecated by Sydenham; because the irritation of these medicines, and the sudden depletion which they occasion, when drastic, are liable to excite the paroxysms, in the mobile constitution of hysterical persons, and thus to produce the evil which it is the object of medicine to prevent. With a view to reduce the strength and fulness of the habit, the constant repetition of hydragogue purgatives is surely not advisable; but for other purposes they are requisite, and shall be mentioned presently. The gradual abstraction of nutriment is the safest method of reducing the plethoric condition, especially when combined with regular exercise. In the opposite state of constitution, in thin spare habits, the opposite method of replenishing the system by nutritious and full diet will necessarily be resorted to, attending at the same time to the use of exercise. Sydenham observes that thin and bilious habits often derive the most essential benefit from a *diet of milk*, and

that "some women have been cured of long and obstinate hysterical disorders, which had baffled all the endeavours of the physicians, by living on milk only for some time." The hysterical *colic*, he says, has especially been removed by this diet, which, being much easier of digestion than a more heterogeneous mixture of food and drink, affords less irritation to the alimentary canal. On the whole, indeed, milk, as it partakes of a middle nature between that of the animal and vegetable aliments, and being in its qualities nearly assimilated to the chyle, affords the best means of restoring strength to valetudinarians, and those of weak digestive powers, where it agrees with the individual constitution. But where the debility is not so great, a moderate quantity of animal food, with some wine or fermented liquors, will be requisite.

When the state of plethora has been corrected, or pretty free evacuations have been made, and still more particularly when the habit is spare and feeble, various tonic remedies are to be resorted to, with a view to lessen the irritability and to improve the general strength of the constitution. Among tonic remedies, the metallic medicines have been found very serviceable, and especially the various preparations of *iron*. After evacuations, and in debilitated habits without any previous evacuation, Sydenham prescribed some chalybeate medicine to be taken for thirty days, considering it one of the most effectual strengtheners. He preferred, as Baglivi, Hoffmann, and other able physicians have also done, to give the iron in substance; and as he affirms, he had never found or heard that it injured any one, who used it in this manner, so much experience had convinced him that it cures with more expedition and certainty than any of the common preparations. Dr. Cullen, however, gave the preference to the salts of iron, such as the sulphate and tartrate, and the ammoniated iron. The oxyd, which is precipitated by adding an alkali to a solution of the sulphate of iron, and is in a state of impalpable powder, is a very convenient form for exhibition. The *chalybeate waters* have been also drank with great benefit in hysterical cases; but, as has been before observed, the very minute portion of iron, contained in these waters, seems scarcely sufficient to produce those beneficial effects; and much of the advantage, gained during a course of the waters, is to be ascribed to the other concomitant circumstances, which tend to re-establish the general health; namely, the constant exercise, the early and regular hours, the cheerful society, and the various amusements, which divert the attention of the patient from brooding over her feelings. See HYPOCHONDRIASIS.

Many other tonic and corroborant medicines, both of the metallic and vegetable classes, have been employed with benefit to restore the general strength of hysterical patients. Such are the oxyd and saline combinations of zinc, the ammoniated copper, and even the nitrate of silver, which have been administered in the intervals between the paroxysms of *epilepsy* (which see). But the vegetable tonics, as being on the whole more safe, have generally had the preference; among these the *cinchona*, or Peruvian bark, stands most eminent for its strengthening qualities. Where the stomach is particularly affected, the bark may be advantageously combined with some of the more aromatic bitters, all of which possess more or less of a tonic power; such as the bark of the *cajuparilla*, the roots of gentian, and colombo, a powder or extract of the flowers of chamomile, &c. Sydenham considers the Peruvian bark as next to steel in its beneficial operation upon hysterical females, and especially in that form of it in which violent convulsions take place, and the patients beat their breasts; or, in other words, where the regular paroxysms occur with considerable violence. He likewise recom-

recommends an infusion of gentian, angelica, wormwood, centaury, orange-peel, and other bitters, in *canary*, to be taken in the quantity of a few spoonfuls three times a day.

“But,” the same intelligent physician remarks, “the best thing I have ever found for strengthening and cheering the spirits, is riding on horse-back some hours almost every day.” This exercise, indeed, appears to have been considered by Sydenham as a *panacea* in almost all chronic disorders; and, although confirmed consumption may not yield to it so readily as his observations might lead us to expect, we are persuaded, that in all diseases, in which the alimentary and chylopoëtic viscera are chiefly disordered, this mode of exercise, steadily persevered in, affords the most certain relief.

In attempting to restore the general strength, and to lessen the irritability of the nervous system, all those expedients, which are now well understood as being conducive to health, should be employed with regularity and perseverance. The forms of exercise, as well as the quantity of it, should be proportioned to the strength of the patient, and increased as the increasing strength renders it capable of being taken with slight fatigue. The clothing should also be regulated, with attention to the varying conditions of the atmosphere; and especially with care, that in chilly weather, the deviations from the mean may be always on the side of warmth; the attempts to harden the constitution, in habits extremely delicate and irritable, being as pernicious as they are absurd in principle. All anxieties and considerable emotions of the mind should be avoided, as far as possible, and the causes of them removed. And there are circumstances at times, which render it advisable to change the sexual condition of the patient, by marriage; by which the mental state in some cases may be probably relieved, and the uterus, being called upon to perform its natural functions, may likewise be restored to a more healthy condition.

From what has been said above, in regard to the deceptive forms of the irregular hysteria, when it mimics, as it were, the various organic diseases, according to the organ in which it takes its seat, we by no means wish to mislead the inexperienced into a belief, that these organs are not often seriously affected, and that active remedies are not often to be applied to them under such disorders. On the contrary, Sydenham has mentioned the hysteric apoplexy as being sometimes fatal. All that is to be understood by calling these local organic attacks *hysteric*, is, that where they occur in a constitution, in which either imperfect paroxysms of hysteria, or the great nervous mobility and variable spirit of the hysteric habit appear, in such cases the symptoms are to be considered as much less formidable than those of ordinary organic disease, and as likely to yield more readily to remedies, which therefore require to be used with less activity and vigour, and to be repeated with more caution. Whenever the individual organs and their functions are greatly disordered, it is the duty of the physician not to omit the remedies which experience has shewn to be effectual in restoring them to health in other cases; watching, at the same time, the various concomitant appearances which may indicate the peculiar state of the habit, and may lead him to discriminate the counter-indications. Such discrimination, however, is not peculiar to the treatment of hysteria; it is in all diseases requisite, and the possession and exercise of it constitute the principal characteristic of an experienced physician.

Before we conclude, we must observe, that the apprehensions which Sydenham and many other physicians have entertained, relative to the danger of using purgatives freely in hysteria, appear to have been carried to a degree far beyond what

unprejudiced observation would lead us. In this, as in many other diseases in which the alimentary canal is much deranged, a free purgation is not only safe, but most beneficial; and a considerable discharge of dark, offensive, and unnatural faeces is often thus procured. Dr. Hamilton affirms, that he has adopted this practice with great success, calling in at the same time the aid of sordid and tonic medicines, which, however, he considers as merely subsidiary. At all events, though Dr. Hamilton may have kept one indication too exclusively in view, yet the lesson which he has taught us, to unload the bowels in all these nervous cases, is doubtless extremely important. See his *Obs. on the Utility of Purgative Med.* 2d edit. chap. vii.

HYSTERICUS Lapis, in *Natural History*, a name given to an American stone, called also *lapis uterinus*, supposed to be famous for its virtues against disorders of the womb, externally applied. It is black, and capable of a fine polish.

HYSTERICUS Clavus. See *CLAVUS*.

HYSTERITIS, in *Medicine*, from *ὑστέρησις*, the *womb*, with the termination *itis*, used to denote inflammation, signifies inflammation of the womb. Sauvages, and some other writers, have employed the term *Metritis*, from *μήτρας*, also signifying the *womb* or *uterus*, to denote the same disease. *Nosol. Method. Clafs iii. Gen. 15.*

The uterus is obviously liable to suffer inflammation, like the other viscera of the body, from the common causes of inflammatory disease. In the unimpregnated state, however, it is less frequently attacked by this disorder than most of the neighbouring organs; and seldom, if ever, is thus affected, except about the periods when its vessels are in a state of increased action, in consequence of the occurrence of the menstrual discharge. At these periods, when not only the uterine system, but the constitution in general, undergoes a slight crethism, or tendency to febrile excitement, sudden exposure to cold, violent exercise, great heats, or very high feeding, occasionally bring on inflammation in the womb; more especially in females of plethoric habit, and strong fibre, who are accustomed to a system of diet above the rules of just temperance. Where the uterus has become subject to inflammation in this way, it appears often to become unfit for the office of conception, and leaves the patient childless.

The most frequent cause of inflammation of the womb, however, is the irritation or injury which it is liable to suffer during the process of parturition or abortion. When it is considered, indeed, how much pressure different parts of this organ necessarily undergo, during these processes, even by the long continued actions of the uterus itself upon the body of the child; and that, in the early part of labour, it not unfrequently occurs, that the lower segment of the uterus is protruded into the cavity of the pelvis, along with the head of the child, and in this situation is squeezed between the head and the sides of the pelvis; (not to mention the occasional necessity of using instruments;) it must be obvious that many causes of violence will be applied in a natural labour, and more in difficult and preternatural cases. Perhaps the free discharge of the *lochia*, which is a necessary consequence of the separation of the *placenta*, answers the secondary purpose of local depletion, and thus, like a copious blood-letting instituted by art, prevents the evils which would otherwise be very likely to ensue. This supposition is rendered farther probable, from the circumstance that inflammation of the uterus, when it comes on a few days after child-birth, commonly arises where the patient has been exposed to cold, by being taken out of bed too early, a practice deservedly reprobated by Sydenham,) and is connected with a suppression of the lochial discharge. See

HYSTERITIS.

Clarke's Essays on the Management of Pregnancy and Labour, &c. p. 59.

Inflammation of the substance of the uterus, when it exists simply, is tolerably well marked by its symptoms. It usually begins about the second or third day after delivery, and is first known to exist by a sensation of pain felt at the lower part of the abdomen, which gradually increases in violence, and is distinguishable from *after-pains* by its constancy. After-pains are intermittent, like the pains of labour, depending, like them, upon contractions of the uterus; but the pain of inflammation, arising from the uninterrupted action of the vessels, is necessarily unremitting. The patient complains much of any pressure applied externally to the region of the uterus; and this organ feels larger than common under the hand, as well as much harder, resembling almost a stone in firmness. Marks of constitutional affection soon appear in the increase of heat over the whole body, a white and dry tongue, thirst, head-ache, a hard, full, and strong pulse, (when the disease occurs in full habits,) and in all cases a frequency of pulse, from 100 to 120 strokes in a minute. Very soon after the attack, the stomach is usually affected with sickness and vomiting; but this symptom is not invariably present. There is commonly a considerable degree of pain in the back, shooting round the pelvis to the groins, and down the thighs. Not only the lochial discharge, but also the secretion of milk is for the most part interrupted. The bowels are variously affected; often colic in the commencement of the disease, but frequently very loose as it advances. The urine is commonly high-coloured, depositing sometimes a pink-coloured sediment, when it can be seen unmixed with the uterine discharges. It will sometimes be found, when the disease has communicated with the neck of the bladder, or when the uterus and bladder have suffered, that suppression of urine will take place, so that the catheter must be employed two or three times a day to draw it off. On the other hand, we have seen the inflammation apparently extend to the kidneys, in which case no urine was secreted for two or three days; yet the patient experienced the sensation of an urgent desire to make water, probably from the inflammation being likewise communicated to the neck of the bladder. If the inflammation is very great, it may spread to the peritoneum, covering the fundus of the uterus, and lining the cavity of the belly; in which case there is great swelling, tension, and soreness of the belly, and other new symptoms arise, such as characterize the child-bed fever, described in another place. See PERITONITIS *Puerperarum*.

In the progress of the disease, slight shiverings frequently take place at different times in the day, while the acuteness of the pain is diminished, and the face of the patient becomes occasionally flushed. These symptoms, together with the increased frequency and weakness of the pulse, mark the tendency of the disease either to suppuration, or to a dangerous failure of the vital powers. The tongue puts on a fiery red or scarlet appearance, which is often followed by aphthæ: symptoms of great general irritation succeed; and the patient is often cut off in a short time. Now and then, however, a flow of foetid lochia relieves these symptoms, the pulse becomes less frequent; the flushings more rarely appear; the tongue grows paler, and the skin, which before had been hot and dry, now relaxes and is cooler; a spontaneous diarrhœa comes on, and the patient recovers. (Clarke, loc. cit.) The case is more favourable, and the prospect of recovery greater, where these shiverings and flushings have never occurred; but where the uterus gradually becomes softer, and less tender on pressure, the lochial discharge returns in its usual quality and quantity, and the secretion of milk begins again.

Of all the acute diseases, to which women are liable in the puerperal state, inflammation of the womb appears, on the whole, to be the least fatal; partly, perhaps, because the pain and fever accompanying it, at a time when the patient is necessarily under the care of her medical attendant, speedily call for the application of remedies. When the disease destroys life, it is usually by symptoms of excessive irritation: sometimes it goes on to suppuration; but rarely, it would seem, to mortification. It is true, as Dr. Clarke observes, that mortification has been often described as occurring in the uterus; but he is satisfied from experience that this has been chiefly said to happen by persons not habituated to the examination of the bodies of women who have died in child-bed, and who have mistaken the appearance of that part of the uterus, to which the placenta had adhered, for gangrene: whereas, it is commonly only the remainder of the maternal portion of the placenta, and of the coagula of blood formed at the extremities of the large vessels of the uterus, upon the separation of the placenta; and a very little attention, by gently scraping off this substance, will detect the sound internal surface of the uterus beneath.

On dissection, after death produced by *hysteritis* in puerperal women, the uterus is commonly found very firm in its substance, but larger than when naturally contracted. Upon cutting into it, *pus* is often found, which is situated in the large veins, and not in any circumfered cavity, like that of an abscess. Inflammation is often observed running along the Fallopian tubes, and into the ovaria, which when cut open are found loaded with blood. Pus is also sometimes found in the cavity of the Fallopian tube, as well as in the substance of the ovaria, which are in some cases dilated by inflammation and matter, so as to equal in bulk a pigeon's egg. When the inflammation has existed in the uterus simply, little or no extravasated or secreted fluids have been found in the cavity of the abdomen: the peritoneal surfaces have also been discovered free from disease in some cases. In others, however, the peritonæum which covers the uterus has been observed to be partially inflamed, as well as that covering the posterior part of the bladder. Clarke, loc. cit. Baillie, Morbid Anatom. p. 364, 2d edit.

When the symptoms of inflammation of the uterus concur with the puerperal state, or severe abortion, little doubt will arise as to the seat of the disease. But when it occurs in the unimpregnated state, the symptoms may be mistaken for those of inflamed bowels, kidneys, or bladder, if not very attentively investigated. When, however, we observe a woman complaining of a burning pain, with a sense of weight and distention in the lower part of the belly, the pain being constant, fixed, and throbbing; when there is also a pain in the loins, frequently shooting round the pelvis to the groins, and down the thighs, and in addition to these, an acute fever, with sickness at the stomach, and extreme restlessness, little doubt can remain respecting the existence of inflammation in the uterus. An examination *per vaginam*, when the *os uteri* will be found extremely tender and painful to the touch, will more completely decide the matter, where it is permitted. The inflammation, however, is liable to become complicated, in this case too, by extending to the kidneys, bladder, and other contiguous parts; and a degree of strangury and *tensismus* (or fruitless desire to go to stool) is liable to occur from the mere vicinity of the uterine irritation.

Cure of Hysteritis.—As the disease, therefore, is often extended to different organs at the same time, and the symptoms must necessarily be rather complicated, the functions of all the suffering organs being in some measure deranged, an accurate distinction of the seat of the disorder is often difficult. This, however, is the less important, as the same remedies

remedies will remove the inflammation, in whichsoever viscous it may occur. Of these, *blood-letting* is the most efficacious; and, even in the puerperal state, in strong constitutions, it should be early and liberally employed. In the disease happening independent of parturition, it cannot be omitted with safety, perhaps, under any circumstances; but the repetition of it must be determined by the constitution of the patient, the violence of the symptoms, and the effect of the previous bleeding on the disease. It may frequently be found necessary a second and a third time. But in less robust habits, it will be expedient, if the symptoms, although diminished, have not been entirely removed by the first bleeding, to take away more blood by applying six or more leeches, inclosed in a basin, to the belly, or by cupping the skin of the abdomen. A *blister* may be also applied to the belly, as near the seat of the pain as may be. Dr. Clarke, however, is of opinion that these applications are not so beneficial in this affection, as in some other inflammatory disorders; and thinks that he has often observed them to increase the frequency of the pulse, and the irritation in the system at large. At the same time, the decided advantages obtained from blisters, in peripneumonies and other internal inflammations, lead him to speak hesitatingly against the general employment of them. Gentle *cathartics*, especially of the saline class, are evidently useful in the case of hysteritis, unconnected with child-birth; but in that which follows delivery, a course of purging is not to be recommended. It is always right, indeed, in the first instance, to procure two or three evacuations from the intestines; but, afterwards, it will generally be enough to preserve the regular motions of the bowels, by giving, from time to time, small quantities of castor oil, or a little rhubarb mixed with some saline purgative. Dr. Clarke states this objection to long continued purging, that it has the effect of preventing that gentle perspiration, which, if it can be produced and kept up, does more towards curing the disease than any internal remedy can effect. With a view of producing this salutary determination to the skin, small doses of antimony and opium, or the compound powder of ipecacuanha, which bears the name of Dr. Dover, with the addition of a little rhubarb, and an occasional saline draught, may be usefully administered. In case a spontaneous diarrhoea should come on, it should not be interfered with, farther than taking care that the strength of the patient be not too much reduced by it. Except where there is reason to suspect the existence of undigested or indigestible aliment in the stomach, the action of vomiting should always be avoided; inasmuch as it constantly increases the pain by the agitation which it occasions, and the pressure made by the muscles of the abdomen on the inflamed uterus.

It is scarcely necessary to add, that, during the whole course of the disease, every thing heating and stimulating should be cautiously avoided; that the food of the patient should be of a mild and digestible nature, consisting of liquid and vegetable substances, and her drink watery and diluent, every sort of animal food, and of fermented and spirituous liquors, being abstained from.

As hysteritis occurs, both connected with and independent of parturition, particularly in those who indulge in full diet, and in the use of heating food and liquors; so the prevention of the disease must depend principally upon temperance and regularity in this respect. In the former case, this end may be obtained by attention to the proper management of the woman both before and during labour.

If the diminution of pain, and the accession of shiverings, announce the commencement of suppuration, little, it is to be feared, can be done by medicine. Under such circumstances, a great proportion of patients will be carried off. The

most favourable tendency of the suppuration will be, when the pus is in the veins of the uterus, or in the Fallopian tube; that it may escape into the cavity of the uterus. The only means within the power of the physician, in this case, are to recommend a milk-diet, or some other light and nutritious aliment, and to soothe the irritation and pain by moderate doses of narcotic medicines.

HYSTERIUM, in *Botany*, a name given by Perfoon and others to a species of Fungi, composed of various species, amongst which is the *Lichen pulicaris* of preceding authors, but this name will probably not be retained.

HYSTEROCELE, in *Surgery*, a rupture, or hernia, containing the uterus. The term is derived from ἵστῆρα, *the womb*, and κελῆ, *a tumour*. See **HERNIA**.

HYSTEROCYSTICA ISCHURIA, a retention of urine, arising from the pressure of the uterus upon the bladder.

HYSTEROLITHUS, formed of ἵστῆρα, *womb*, and λίθος, *stone*, or *Cunulithus*, in *Natural History*, a stone thus called, from its resemblance to the external parts of generation of the female sex. This is a species of helmintholithus in the Linnæan system. These stones are found in great abundance near the castle of Braubach, upon the Rhine, on the confines of the landgrave of Hesse.

HYSTEROLITHUS is also a name given by Ol. Wormius (*Museum*, p. 83.) to the cast or inside impression of a sort of Anomia shell, as Dr. Woodward states in his *Letters on the Method of Fossils* (p. 10.), and thus shews the absurdities of the tales which had been related of this stone. This species of anomia occur with mytilites, in argillaceous rubble-stone, or slate. Kirwan's *Geo. Essays*, p. 244.

HYSTEROLOGY, ἵστῆρολογία, signifying a *discourse inverted*, in *Rhetoric*, a species of hyperbaton, or a vicious manner of speaking, wherein the natural order of things is inverted; called also by the Greeks ἵστῆρον ποταμῶν; *q. d.* putting the first thing where the last should be.

Thus Terence uses *valet & vivit*, for *vivit & valet*. And Virgil *moriamur & in media arma ruamus*, for *in media arma ruamus & moriamur*. Quintilian exposes this fault, lib. xi. cap. 2. where he says, *quadam—turpiter convertuntur, ut si peperisse narres, deinde concepisse; in quibus, si id quod posterius est dixeris de priore tacere optimum est.*

HYSTEROPHORUS, in *Botany*. See **PARTHENIUM**.

HYSTEROPOTMI, ἵστῆροπότμοι, in *Antiquity*, the same with deuteropotmi.

HYSTEROPTOSIS, in *Surgery*, a bearing down of the uterus.

HYSTEROTOMIA, from ἵστῆρα, *the womb*, and τομῆς, *a section*, the operation of cutting through the parietes of the abdomen into the uterus, for the purpose of extracting the fœtus, a proceeding sometimes necessary: the Cæsarian section.

HYSTEROTOMOTOCY, ἵστῆροτομοσία, an operation more usually called the Cæsarian section.

HYSTRIX, in *Zoology*, a genus of mammalia, in the order Glires, the fore-teeth in which are two in number, and cut off obliquely; the grinders eight; toes either four or five; and the body covered with spines and hair. These constitute the porcupine genus of English writers.

Species.

CRISTATA. Anterior feet four-toed; posterior pair five-toed; head crested; tail short. S. G. Gmelin. *Hystrix capus cristato*, Brill. *Hystrix*, Gesner, &c. *Stachelschwein*, Ridinger. *Porc-épic*, Buff. *Crested porcupine*.

The length of this species is about two feet; the head long and compressed; the snout short and obtuse; the upper lip cleft to the nostrils; eyes small, and black; ears oval,

broad, and short; tail conic and spinous; feet short; hair between the spines cinereous; the spines long, stout, smooth, and annulated with black and white. The longest of these spines, and also the bristles of the neck, it is able to erect at pleasure. This animal is found in Asia, Africa, and the south of Europe, as Italy and Spain; it burrows in the earth, where it forms a number of convenient apartments, with a single entrance. During the day time the porcupine remains in its burrows; which it leaves at night in search of fruits, roots, herbs, and other vegetables of which its food consists. When frightened it rolls itself up like the hedgehog, and presents its formidable armament of spines, for it has no other means of defence, but this is alone sufficient to repel the temerity of most animals that venture to attack it. The porcupine brings from two to four young at a litter, is easily tamed, and the flesh is reputed excellent for the table. There appear to be several varieties of the common porcupine.

PREHENSILIS. Feet four-toed; tail long, prehensile, naked at the end beneath. Schreber. *Hylrix Americanus*, Briss. *Cuandu Brasiliensis*, *Lusitanis Ourico caeliens*, Mareg. *Brasiliensis porcupine*.

A native of the woods of Brazil, New Guinea, and New Spain. This species climbs trees, feeds on fruits and small birds; grunts like the swine, rolls itself up, sleeps in the day, is easily tamed, and is taken for the sake of its flesh, which is esteemed an article of food. The length of the body is about fifteen inches; the tail seven inches; the whiskers are long and white; feet cinereous; claws strong and black. A supposed variety, with the tail longer and spines shorter, (*Hylrix longius caudatus*, *brevioribus aculeis*,) is described by Barrer. Fr. équin. The animal called *Hoitzlacuatzin*, seu *Tlacuatzin*, by Hernandez and Nieremberg, is presumed by Gmelin to be another variety of this kind; it has the tail short and thick; a third kind is said to be smaller than the common Brazilian porcupine, and has the head white.

MEXICANA. Tail long, prehensile; hind feet four-toed; spines nearly concealed among the long hair. *Mexican porcupine*.

Length eighteen inches; tail nine inches; body dusky. This kind inhabits Mexico.

DORSATA. Interior feet four-toed; hind feet five-toed; back spinous. Schreber. *Hylrix pilosus Americanus*, Cateby. *Cavia Hudsonis*, Klein. *Ursen*, Buffon. *Hudson's-bay* or *Canadian porcupine*.

Inhabits North America; the body is rusty brown above; tail beneath white at the tip; and the spines nearly concealed among the hair. This animal is nearly the size of the hare; it digs holes under trees, and feeds on fruits and the bark of the juniper. The Canadian porcupine is sometimes found entirely white.

MACROURA. Feet five-toed; tail very long; spines clubbed or jointed. Schreber.—*Porcus aculeis sylvestris*, Seba.

The ears in this species are short and naked; the tail the length of the body, the tip crowned with a tuft of long, knotted, silvery hairs; body short and thick; ears short and naked; and the eyes large and bright. Inhabits the woods of the islands in the Indian ocean.

HYTH, or **HITH**, a port, wharf, or little haven, to embark or land wares at. Such is *Queen-hith*, &c.

HYTHE, or **HITHE**, in *Geography*, a market town and one of the principal Cinque Ports, is situated in the parish of Saltwood, hundred of Heane, and county of Kent, England. Its name signifies, in Saxon, a port or haven; and it was anciently of far greater importance, as a maritime

town, than at present. Leland says, "it hath bene a vere great towne yn length, and conteyned iiii paroches, that now be clene destroued; that is to say, St. Nicolas parochie, Our Lady parochie, St. Michael's parochie, and our Lady of Westhithie."—And again—"to cownt from Westhithie to the place wher the subitans of the towne ys now, ys ii good myles yn length al along on the shore." He mentions a fire in the reign of Edward II, which destroy'd nearly four hundred houses, and was followed by a pestilence; so that the town was greatly diminished. In the beginning of the next century, it again suffered much by simular visitations. At the time of the maritime survey, in the reign of Elizabeth, there were 122 inhabited houses in Hythe, and persons "lacking habitation" ten: its shipping consisted of "seventeen traivellers, at five tuns; seven shoters, of fifteen tuns; three crayers, of thirty tuns; and four crayers, of forty tuns." Since this survey, the haven has been wholly lost, and the sea beach is now nearly three quarters of a mile from the town. According to the returns under the act of 1801, the number of houses in Hythe was 217; that of inhabitants 1365. The houses are chiefly comprised in one long street, running parallel with the sea; but having two or three lesser ones branching off at right angles. The civil government of the town is vested in a mayor, twelve jurats, and twenty-four common-council-men; by whom, together with the freemen, the representatives are elected; the number of voters being about 180. The first return of barons to parliament from this port, was in the forty-second year of Edward III. The church occupies a very elevated situation on the acclivity of the hill above the town. It is built in the form of a cross, with a tower at the west end, and appears to have had originally another tower, rising above the roof, from the intersection of the nave and transept. The west tower, with the south end of the transept, was rebuilt between the years 1748 and 1751, at which time the whole church underwent a general repair. Near the altar, on the south side, but partly concealed by the wainscoting, are four beautiful stone seats, with trefoil heads, and a range of circles and quatrefoils above them. The church-yard commands a fine view of the sea, and coast of France. Near the middle of the principal street are the court-hall and market-place; and in one of the streets leading towards the beach, on the opposite side, is a small theatre. In this parish are two hospitals, or alms-houses, of ancient foundation; the one called St. John's, the other St. Bartholomew's. The former was founded for lepers previously to the year 1336, but at what particular era is uncertain; the other was built by bishop Hamo Noble, surnamed De Hythe, from his having been born in the town; and his deed of foundation, which is printed in the *Registrum Rossense*, describes it as "erected on the spot where he and his ancestors first had their origin." Besides the Martello towers that have been recently erected along this coast, there are several small forts on the beach in this vicinity, which were built shortly after the commencement of the last war. On the heights immediately above Hythe are extensive ranges of barracks for infantry, erected since the beginning of the present century; and near these are numerous mud-wall cottages for the wives and families of the soldiers. Other barracks, of a temporary kind, are within the town. Hythe is distant from London 67 miles; and has a weekly market on Thursday.

About one mile north-west from Hythe stands Saltwood castle, the original foundation of which has been attributed to the Romans, though probably on insufficient authority. Kilbarne says, that it was erected by Oesc, son of Hengist; and Grose states that "on examining these ruins, every stone of them evidently appears to have been laid by the Nor-

mans." This last assertion is not only disproved by historical authorities, but is demonstratively erroneous; as the principal buildings now standing are of a much later date, and in a different style of architecture. Hasted states that it was rebuilt by Henry de Essex, baron of Ralegh, and standard-bearer to Henry II. Archbishop Courtenay, who was promoted to the see of Canterbury in the fifth year of Richard II., expended great sums in rebuilding this castle, to which he annexed a park, and made it his usual place of residence. The site of this castle was well chosen; the walls encircle an extensive area, of an elliptical form, surrounded by a very broad and deep moat, partly natural, and partly artificial.

The entrance into the first court was by a gateway, now in ruins, defended by a portcullis: the outer walls were strengthened by several circular and square towers, all of which are dilapidated.

About half a mile from Saltwood, westward, is Sandling, the new seat of William Deedes, esq. who has built here a large mansion, under the direction of Bonomi, on a hill which commands fine views of the sea, and yet looks down on its own demesne, consisting of wooded valleys, and replete rural scenery, possessing many beauties. Hasted's Kent, vol. iii. Beauties of England and Wales, vol. viii.

I and J.

I

I, The ninth letter of the English alphabet, may be considered both as a vowel and a consonant; agreeably to which two different powers, it has two different forms; though, since the vowel and consonant differ in their form as well as sound, they may, as Dr. Johnson observes, be more properly accounted two letters.

The Hebrews call the *j* consonant *jod*, יוּד, from יָד, *hand* and *space*; because it is supposed to represent the hand clenched; so as to leave the space underneath void. With them it was pronounced as the consonant *y*, as it still is among the Germans, and some other people. The Greeks had no *j* consonant, and for that reason used their vowel *i* instead of it, as coming the nearest in sound. The letter *i* was used as a consonant among the Latins. In English *j* consonant has invariably the same sound with that of *g* in *giant*; and serves to mollify that of the vowels; as in *Jesu*, *just*, *joyful*. *I* vowel varies in its sound: in some words it is long, as *fine*, *thine*, &c. In others short, as *fin*, *thin*. Prefixed to *e*, it makes a diphthong of the same sound with the soft *i*; or double *ee*, in *field*, *yield*, except in *friend*, which is pronounced *frend*. Subjoined to *a* or *e*, it makes them long, as *fail*, *nigh*; and to *o* makes a mingled sound, which approaches more nearly to the true notion of a diphthong, or sound composed of the sounds of two vowels, than any other combination of vowels in the English language, as *oil*, *coin*. The sound of *i* before another *i*, and at the end of a word, is always expressed by *y*. Johnson.

The vowel *i*, according to Plato, is proper for expressing fine and delicate, but humble things; on which account that verse in Virgil,

"Accipiunt inimicum imbrem, remisque fatiscunt,"

which abounds in *i*'s, is generally admired.

The vowel *i* was the only vowel which the Romans did not mark with the dash of a pen, to shew when it was long; instead of which, to denote it long, they used to make it bigger than ordinary, as in *Piso*, *Vivus*, &c. According to Lipsius, they often repeated it when it was to be long,

J A B

as in *di*. They sometimes also denoted the length of this letter by adding *e* to it, and turning it into a diphthong, as *divēi* for *divi*, *omnēis* for *omnis*, &c.

I, in *Grammar*, *ik*, Gothic, *ic*, Saxon, *ich*, Dutch, is a pronoun personal. By Shakspeare **I** is more than once written for *ay*, or *yes*: *e g.*

"Did your letters pierce the queen?"

— **I**, sir; she took 'em and read 'em in my presence,
And now and then an ample tear trill'd down."

I, in *Logic*, denotes a particular affirmative proposition.

I was anciently a numeral letter, and signified a hundred, according to the verse.

"I. C. compar erit, et centum significabit."

I, in the ordinary way of numbering, signifies one; and when repeated, it signifies as many units as it is repeated times. When put before a higher numeral, it subtracts itself, as **IV**, **IX**, &c. but when set after it, it is added as often as it is repeated; as **VI**, **XI**, **VIII**, **XIII**, &c.

In abbreviatures and ciphers, **I** frequently represents the whole word *Jesus*, whereof it is the first letter.

Neither the long nor the short **I**, the consonant *ja*, nor the vowel **I**, is the initial of any technical term in *Music*.

I, in the *French Coinage*, characterizes the money of Limoges.

JA, in *Geography*, a town of Sweden, in East Bothnia; at the mouth of the river *Jafari*; 12 miles N. of *Ulea*.

JA, *St. St. Ja*, or *St. Agatha*, a town of France, in the department of the *Sesia*, situated on the *Naviglio*, containing five churches. N. lat. 43° 22'. E. long. 8° 8'. See *St. AGATHA*.

JAATSURO, a town of Japan, in the island of *Nippon*; 65 miles N.W. of *Jedo*.

JAB, a town of Africa, in the kingdom of *Woolli*, situated on the river *Gambia*.

JABA, a town of Africa, in *Bambarra*, on the *Niger*. N. lat. 13° 15'. W. long. 4° 45'.

JABADII

JABADII INSULA, an ancient name given to Sumatra, according to M. D'Anville, though others have supposed it to be Java. Ptolemy speaks of this island and says, that it abounded with gold. He calls the capital Argentea, the position of which seems to correspond with that of Achen.

JABAJAHITES, a sect among the Mussolmen, who, according to Ricaut, teach, that God is not perfectly wise; that his knowledge does not extend to every thing; and that time and experience have furnished him with the knowledge of many things whereof he was before ignorant. Thus, say they, not being apprised from all eternity of every event that shall happen in the world, he is now obliged to govern it according to the chance and occurrence of those events.

JABARABA, in *Geography*, a town of Brazil, in the government of Minas Geraes; 32 miles S. of Villa Rica.

JABARIANS, a sect of Mahometans, in direct opposition to the *Kudavians*, distinguished by denying free agency in man, and ascribing his actions wholly to God. They take their denomination from Al Jabr, which signifies necessity or compulsion, because they maintain that man is necessarily and inevitably constrained to act as he does, by force of God's eternal and immutable decree. Some of these, who are more rigid in their opinion, are called *pure Jabarians*, and others, who are more moderate, are called *middle Jabarians*. The former will not allow men to have any power at all; asserting that man can do nothing, and that he is destitute of power, will, or choice, as much as an inanimate agent. They assert also, that rewarding and punishing are the effects of necessity, and they also say the fame of the imposing of commands. This was the doctrine of the "Jahmians," the followers of Jahm Ebn Safwan, who likewise held that paradise and hell will vanish, or be annihilated, after those who are destined to these habitations shall have entered them, so that at last there will be no existing being besides God. The moderate Jabarians ascribe some power to man, but such as has no influence on the action. As to those who grant the power of man to have some influence on the action, which influence is called "acquisition," some will not allow their being denominated Jabarians; whereas others reckon them in the number of middle Jabarians, and contend for the middle opinion between absolute necessity and absolute liberty, attributing to man acquisition or concurrence in producing the action, or in consequence of which he gains commendation or incurs blame; and they make the "Asharians" a branch of this sect. To the middle or moderate Jabarians, belong the "Najarians," whose founder Al Hafan Ebn Mohammed al Najar taught, that God created the actions of men, both good and bad, and that man acquired them, and that man's power had an influence on the action, or a certain co-operation, which he called "acquisition," agreeing in this respect with Al Ashari; and the "Derarians," the disciples of Derar Ebn Amra, who also held that men's actions are really created by God, but that man really acquired them. The Jabarians also say, that God is absolute Lord of his creatures, and may deal with them according to his own pleasure; so that if he should admit all men without distinction into paradise, it would be no partiality, or if he should cast them all into hell, it would be no injustice, concurring in this respect with the Asharians. Sale's *Prel. Disc.*

JABBEE, in *Geography*, a large town of Africa, in the kingdom of Bambarra, having in it a Moorish mosque, and situated on the Niger; 55 miles S.W. of Segou. N. lat. 13° 59'. W. long. 3° 21'.

JABBUAH, a town of Hindooستان, in the circar of Banwalah; 25 miles S.S.E. of Tandla.

JABEZ, or **JABESH-GILEAD**, in *Scripture Geography*, a city in the half-tribe of Manasseh beyond Jordan, situated in

Gilead, at the foot of the mountain so called. Eusebius places it six miles from Pella towards Gerasa.

JABI, or **YABBAH**, a district of Africa, on the Gold Coast, situated to the east of Anta, the soil of which is rich and fertile; but the gold obtained here is adulterated.

JABIRU, or **JABRU-GUACU**, in *Ornithology*, the *MYC-TEREA Americana*; which see.

JABLONOW, in *Geography*, a town of Poland, in the palatinate of Braclaw; 64 miles N.W. of Braclaw.

JABLONOWSKY, **JOSEPH ALEXANDER VON**, in *Biography*, a Polish prince, who devoted himself chiefly to the sciences, and, for the sake of improvement, made several tours through Germany and France. When the troubles broke out in Poland he resigned his senatorial dignity, left the country, and took up his residence at Leipzig, where he distinguished himself not only as a friend and protector of science, but as a man of great literary acquirements. He founded a society which was named after himself, and assigned a liberal sum for the purpose of distributing premiums to the authors of the best answers to questions proposed on various literary subjects. This society still exists, holds its meetings at Leipzig, and occasionally presents the world with the fruit of its labours. The prince died in 1777, at the age of sixty-five. His works are, "The Lives of twelve Generals:" written in the Polish language: "A Treatise on the Slavonic Poetry," and some pieces of a similar nature. *Gen. Biog.*

JABLONSKI, **DANIEL ERNEST**, was born at Dantzic in the year 1660: he was educated partly at Lissa and partly at Frankfort on the Oder. He spent some time in his maturer studies at Holland, and from thence he went to England, and took all the advantages which the university of Oxford could afford him. On his return to his native country in 1683, he was admitted to the ministry, and appointed pastor of the reformed church at Magdeburg. After some successive changes he was at length appointed to be minister to the court of Berlin. He was extremely anxious to promote an union between the Calvinists and Lutherans, and to introduce into Prussia a constitution of church government resembling that of the English establishment: but his well-meant efforts proved ineffectual. He was not however disheartened by want of success, but directed all his attention to the same subject twelve years afterwards. Some account of the measures taken in this business will be found at the end of Dr. Maclaine's translation of Mosheim's *Ecclesiastical History*. To this account is annexed "A Plan of Ecclesiastical Discipline and Public Worship," drawn up by Jablonski, and several original papers. In 1706, M. Jablonski received the diploma of doctor of divinity from the university of Oxford. In 1718 the king of Prussia nominated him counsellor of the Consistory, in 1729 member of the Directory of the reformed churches, and in 1733 president of the Academy of Sciences at Berlin. He died at the age of eighty, in 1741. He was author of a great number of works, chiefly theological, but his most important were, 1. "Biblia Hebraica, cum Notis Hebraicis et Lemmatibus Latinis ex recensione, et cum Præfatione Latina, D. E. I." 2 "Jura et Libertates Dissidentium in Religione Christiana in Regno Poloniæ et Magno Ducatu Lithuaniz, ex legibus Regni, et aliis Monumentis authenticis excerpta." Moreri. Mosheim.

JABLONSKY, **CHARLES GUSTAVUS**, private secretary to the queen of Prussia, and a considerable naturalist, began his career, as an author, by the publication of "A Syllem of all known indigenous and foreign Insects," arranged according to the Linnæan system, and intended as a continuation of Buffon's *Natural History*. The share which Jab-
lonsky

lonfsky had in this work extends only to the seventh sheet of the third part, relating to butterflies. His illness prevented him from continuing a work that demanded much labour and attention. It was carried on by Mr. Herbst, a clergyman at Berlin; who also continued another work on the description of the *Scarabæi*, begun by Jablonsky. Our author died in the year 1787, at the age of thirty-one, to the regret of his friends, who had high expectations from his talents and great assiduity. Gen. Biog.

JABLONSKY, JOHN THEODORE, brother of D. Ernest, was born at Dantzic in 1654. He was educated partly at Amsterdam, and partly at Berlin, from whence he was sent to the Gymnasium of Königsberg, and then to Frankfort on the Oder. In 1680 he made a tour through Germany, Holland, and England, and in 1687 he accompanied the princess of Dessau to Poland, where he remained till the death of the prince Radzivil, the husband of his patroness. He was now appointed secretary at the court of the duke of Saxe-Barby, and in 1700 was elected secretary to the Academy of Sciences at Berlin, then newly established. In 1715 he accompanied on his travels, in the capacity of tutor, Frederic William, hereditary prince of Prussia, and upon his return was appointed a counsellor of state. He died in 1731, leaving behind him a great number of very learned works, among which was "A General Dictionary of Arts and Sciences;" which was afterwards augmented and improved by J. J. Schwabe, professor of philosophy at Leipsic. Gen. Biog..

JABLONSKY, PAUL ERNEST, son of Daniel Ernest, was born at Berlin in 1693. His great talents were discovered at an early period, and having studied at Frankfort, and acquired a deep knowledge of theology and the Coptic language, he was admitted among the royal candidates; and at the king's expence made a literary tour through Germany, Holland, England, and France. In the course of his travels he had an opportunity of improving himself in the Coptic, particularly by consulting the different works in that language at Leyden, Oxford, and Paris. In 1720 he was appointed professor of philosophy, and preacher to the reformed congregation of Frankfort on the Oder: in 1722, public professor of theology, and afterwards member of the Academy of Sciences at Berlin. He died in the month of September, 1757. He was author of many learned and theological works; and was by his labours of much service to biblical literature. Two of his principal pieces were "Rhempha Ægyptiorum Deus ab Israelitis in Deserto cultus," and "Pantheon Ægyptiorum, sive de Diis eorum Commentarius."

JABLUNKAU, in *Geography*, a town of Silesia, in the principality of Teschen, on the river Elbe, with an adjoining fort; 11 miles S.S.E. of Teschen. N. lat. 49° 32'. E. long. 18° 48'.

JABOK, or JABEOK, in *Scripture Geography*, a brook on the other side of Jordan, whose spring was in the mountains of Gilead. It fell into Jordan, near the sea of Tiberias, south; and separated the land of the Ammonites from Gaulonitis, and that of Og king of Basan. Gen. xxxii. 42 to 43.

JABOLPOUR GURRAH, a town of Hindooistan, in Gurry Mundella; 28 miles E.N.E. of Gurrâh.

JABOROSA, in *Botany*, a name given by Jussieu from the Arabic appellation of the Mandrake, *Jaborose*, with which the plants in question agree in habit, and almost, as Jussieu himself hints, in genus. Juss. 125. Willd. Sp. Pl. v. 2. 1016. Lamarck. Illustr. v. 2. 11. t. 114. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped,

in five nearly equal segments, permanent. *Cor.* of one petal, tubular, much longer than the calyx; tube nearly cylindrical; limb in five acute, somewhat spreading, segments. *Stam.* Filaments five, short, flat, inserted into the upper part of the tube, and scarcely extending beyond its orifice; anthers erect, heart-shaped. *Pist.* Germen superior, roundish; style thread-shaped, the length of the tube, erect; stigma capitate, with a small point. *Peric.* and *Seeds* unknown.

Eff. Ch. Corolla tubular. Stamens inserted into the top of the tube. Stigma capitate. Berry?

1. *J. integrifolia*. Lamarck. Illustr. t. 114.—Leaves elliptic-oblong, slightly toothed.—Native of Buenos Ayres, where it was gathered by Commerfon, from whose specimens alone, of this and the following species, any thing is known concerning them in Europe. They appear to be perennial herbaceous plants, of the size of a primrose, with several radical rather downy leaves, without any stem. *Flowers* on simple radical stalks, shorter than the leaves, the tube an inch and a half long, rather slender.

2. *J. runcinata*. Lamarck. n. 2.—Leaves lyrate. Tube of the corolla somewhat bell-shaped.—Gathered by Commerfon near Monte Video. Its lyrate, deeply toothed leaves, and shorter bell-shaped flower, much like that of *Atropa Belladonna*, sufficiently distinguish it from the preceding.

JABOTAPITA. See OCHINA.

JABOTI, in *Zoology*, the name of a remarkable species of tortoise found in America. The shell of this species is black, and has many hexangular figures marked upon it; the head and legs are brown, variegated with spots of a dusky greenish hue. The liver of this species is accounted a very delicate food.

JABOU, in *Geography*, a country of Africa, W. of Benin.

JABRIN, a district of Arabia, S.W. of Hadsjar, abounding with salt.

JACA, a town of Spain, in Aragon, at the foot of the Pyrenées, on the river Aragon; the see of a bishop suffragan of Saragossa. This ancient town, which has a citadel built in 1592, was formerly the capital of Aragon, as it is now of a district, comprehending nearly 200 towns and villages; 45 miles N. of Saragossa. N. lat. 42° 29'. W. long. 0° 41'.

JACA, in *Natural History*, the name of a kind of nut, very common in China, which is reckoned the largest of all yet known. It is produced from the trunk of the tree, as if the branches, however large and strong, were not able to bear it; its shell is so strong, that there is occasion for an ax or hatchet to open it; and within are innumerable cells or vesicles, containing a pulp of a yellow colour, which surrounds a kernel like the chestnut, that is exceedingly sweet when ripe.

JACAMACIRI and JACAMAR, in *Ornithology*. See *ALCEDO Gallula*.

JACANA. See *PARRA Jacana*.

JACAPA, or JACAPU. See *TANAGRA Jacapa*.

JACARAY, in *Geography*, a town of Brazil, in the government of St. Paul; 50 miles N.E. of St. Paul.

JACARE, in *Zoology*. See *LACERTA Alligator*.

JACARINI, in *Ornithology*. See *TANAGRA Jacarina*.

JACCA, in *Ancient Geography*, a town of Spain, in the interior of the country of the Vasconi. Ptol.

JACCATRA, in *Geography*, one of the empires of the island of Java, bounded on the E. by that of Cheribon, and to the W. by the kingdom of Bantam. It was formerly governed by its own kings; but the last of these, having been subdued by the arms of the Dutch East India Company in the year 1619, they have ever since possessed it by the right of conquest, as sovereigns. It is under the immediate

immediate government of the governor-general and the council of India, and all the Javaneſe of Jaccatra are therefore born the company's ſubjects. Before this revolution, Jaccatra was the capital of the empire, but Batavia, which is built near the former, is now the chief place. The Preanger lands are diſtricts which did not formerly belong to the kingdom of Jaccatra, but which have been united to the company's poſſeſſions ſince the year 1677; and the adminiſtration of them is divided between Batavia and the reſidency of Cheribon. The whole country of Jaccatra, with the Preanger lands, is 110 Dutch miles in circumference, and comprizes 30 diſtricts, containing together 33,914 families, or 203,384 inhabitants; of which the diſtrict of Batavia alone includes 19,469 families, or 116,814 inhabitants. Hence it appears, that the other diſtricts are much leſs populous, ſo that a great extent of excellent land remains uncultivated and neglected, and that which is tilled is owing to the indultry and perfeverance of the Chineſe, who are ſettled here. The depopulation of Jaccatra has been chiefly owing to the conqueſts of the company, which having taken the capital and defeated the army of Bantam, carried away the inhabitants into the latter kingdom; in conſequence of which Jaccatra remained for a conſiderable time nearly in an uninhabited ſtate. Since the year 1753, however, the population has here been conſiderably augmented. Jaccatra is watered and fertilized by ſeveral rivers, of which the largeſt are the Sadani, or the river of Tangerang, and that of Crawang, which deſcend from the inland mountains, and flow into the ſea in a northerly direction. The river of Tangerang runs into the ſea, not far from the point of Ontong Java, and near its mouth the company have a ſmall port called the "Kwal." This river gives part of its water to a canal that ſupplies the canals and moats of the city of Batavia; but the greater part is furniſhed by other rivers. The productions of Jaccatra are principaly coffee, ſugar, and rice; likewiſe indigo, cotton, yam, turmeric, and cadjung, or lentiles, from which laſt oil is preſſed. In 1778 there were ſold in Holland the following articles, being productions of the colony of Jaccatra; viz. 2,000,000lbs. of ſugar, at 4 ſtivers; 2,000,000lbs. of coffee, at 11 ditto; 500,000lbs. of pepper, at 17 ditto; 100 leaguers of arrack; 10,000lbs. of candied ginger; cotton-yarn to the amount of 200,000 florins, and indigo to the amount of 1000 florins. This may be taken as the annual quantity of what Jaccatra is able to furniſh for Europe, and the gain upon theſe articles is conſiderable, as none of them coſt much; the pepper and coffee nearly $2\frac{1}{2}$, and the ſugar $1\frac{1}{2}$ ſtivers per pound. Of ſugar, the company farther diſpoſe every year full four millions of pounds weight in Japan, Surat, Malabar, and other eſtabliſhments, from which they likewiſe make conſiderable profits; and about the ſame quantity, 400,000lbs. is exported in private trade, together with immense quantities of arrack, rice, and other articles. Stavorus's Voyage to the Eaſt Indies, &c. vol. iii.

JACCHAGOGI, *Ἰακχάγογος*, in *Antiquity*, thoſe who carried the ſtatue of the hero Jacchus in proceſſion, at the celebration of the Athenian feſtival called *Eleuſinia*. They had their heads crowned with myrtle.

JACCHUS, in *Zoology*. See SIMIA.

JACEA, in *Botany*. See CENTAUREA.

JACI, in *Geography*, a ſmall well built and populous town of Sicily, in the valley of Demona, where a great quantity of ſilk is manufactured. It was formerly called Aeis. (See ACIS.) The modern town is ſituated far higher than the ancient city, if we judge from its actual elevation above the level of the ſea, and the number of ſtrata of lava which are diſcovered in deſcending the flight of ſteps, leading from

this town to the Caricatore, which is below it; 12 miles N N.E. of Catania. N. lat. 37° 40'. E. long. 15° 15'.

JACINA, a river of Naples, which runs into the gulf of Squillace, N. lat. 38° 57'. E. long. 17°.

JACINTH, in *Botany*. See HYACINTHUS.

JACK, in *Falconry*, ſignifies the male of birds of ſport. See FALCON and HAWK.

JACK, or Pike, in *Ichthyology*. See ESOX Lucius.

JACK, in *Mechanics*, is an inſtrument in common uſe for railing heavy timber, or very great weights of any kind. See Plate XXX. *Mechanics*, fig. 1.

But as the wheel-work of this engine is incloſed in the ſtrong piece of timber C B, the inſide of it is repreſented in fig. 2, where the rack A B muſt be ſuppoſed at leaſt four times as long in proportion to the wheel Q, as the figure repreſents it; and the teeth, which will be then four times more in number, to be contained about three in an inch. Then if the handle H P be ſeven inches long, five turns of it; i. e. five times 22 inches, or 110 inches, will be the velocity of the power, whilſt the weight raiſed by the claw A, or depreſſed by the claw B, moves one inch: for as the pinion of the handle has but four leaves, and the wheel Q twenty teeth, there muſt be five revolutions of the handle to turn the wheel once round, whoſe three-leaved pinion R will, in that revolution, juſt move the rack three teeth, or one inch. This might have been alſo known without feeling, or even knowing the number of the teeth of the wheel and pinions, by meaſuring a revolution of the handle in fig. 1; and comparing the ſpace gone through by it with the ſpace gone through by the end A or B. This machine is ſometimes open behind from the bottom almoſt up to the wheel Q, to let the lower claw, which in that caſe is turned up as at B, draw up any weight. When the weight is drawn, or puſhed ſufficiently high, it is kept from going back by hanging the end of the hook S, fixed to a ſtaple, over the curved part of the handle at b.

JACK is alſo the name of a well known engine uſed for turning a ſpit: the weight is the power applied; the friction of the parts, and the weight with which the ſpit is charged, are the force to be overcome; and a ſteady uniform motion is maintained by means of the fly. See the conſtruction of this engine more particularly explained and illuſtrated by a figure, under the article *MECHANICAL powers*.

JACK, *Smoke*, is an engine uſed for the ſame purpoſe with the common jack, and is ſo called from its being moved by means of the ſmoke or rarefied air; aſcending the chimney, and ſtriking againſt the tail of the horizontal wheel A B, (fig. 3.) which being inclined to the horizon, is moved about the axis of the wheel, together with the pinion C, which carries the wheels D and E; and E carries the chain F, which turns the ſpit. The wheel A B ſhould be placed in the narrow part of the chimney, where the motion of the ſmoke is ſwifteſt, and then the greateſt part of it muſt ſtrike upon the ſails. The force of this machine depends on the draught of the chimney, and the vehemence of the fire.

JACK, in a *Ship*, is a ſort of flag or colours, diſplayed from a maſt erected on the outer end of a ſhip's bowſprit. In the Britiſh navy the jack is nothing more than a ſmall union flag, compoſed of the interſection of the red and white croſſes; but in merchant-ſhips this union is bordered with a red field. See FLAG.

JACK is uſed alſo for a horſe or wooden frame to ſaw timber upon; for an inſtrument to pull off a pair of boots; for a great leathern pitcher to carry drink in; for a ſmall bowl that ſerves as a mark, at the exerciſe of bowling; and for a young pike.

JACK, a *Muſical* implement in a virginal, ſpinnet, and harpſichord;

harpsichord; it is a small machine, usually made of pear-tree wood, in which is a tongue, armed with a quill. This tongue moves on a rivel, and when the quill has struck the string, by the jack being thrown up with the key, on the end of which it rests, if the finger is taken off, it returns to its place under the string, and the tongue, thrown back by passing the string, is forced into its perpendicular situation by the spring of a bristle behind it.

JACK-Arch, in *Architecture*, is an arch of one brick thickness.

JACK-Head, in *Hydraulics*, a part sometimes annexed to the forcing-pump. See **PUMP**.

JACK-in-a-Box, in *Botany*. See **HERNANDIA**.

JACK by the Hedge. See **ERYSIMUM**.

JACK-Daw. (See **CORVUS MONEDULA**.) This bird is very mischievous to the farmer and gardener, and is of such a thievish disposition, that he will carry away much more than he can make any use of. There is a method of destroying this bird by a particular sort of springe, which is much practised in some parts of England, and is so useful, that it ought to be made universal. The method is this: a stake of about five feet long is to be driven firmly into the ground, and made so fast that it cannot move, and so sharp pointed at the top, that the jack-daw cannot rest upon it. Within a foot of the top there must be a hole bored through it, of three quarters of an inch in diameter; through this hole is to be put a stick of about eight inches long, then a horse-hair springe or noose is to be fastened to a thin hazel-wand, and this brought up to the place where the short stick is placed, and carried with it through the hole; the remainder being left open under that stick. The other end of the hazel-rod is to be put through a hole in the stake near the ground, and fastened there; the stake is to be planted among the jack-daw's food, and he will naturally be led to fettle on it; but finding the point too sharp, he will descend to the little cross stick; this will sink with his weight, and the springe will receive his leg, and hold him fast.

JACK-Daw, Purple. See **GRACULA QUISCALA**.

JACK-Ketch, is a name given by the populace to the common hangman.

JACK-in-a-Lantern. See **IGNIS FATUUS**.

JACK-Snipe, in *Ornithology*. See **SCOLOPAX GALLINULA**.

JACK Wanbafium, in our *Old Writers*, a kind of defensive coat-armour, worn by horsemen in war, not made of solid iron, but of many plates fastened together; which some persons by tenure were bound to find upon any invasion.

JACK, Wood, a sort of stool made use of for sawing or cutting wood upon.

JACK ALL, in *Zoology*, the name of a creature of the dog-kind, the *canis aureus* of Linnæus, called by authors *lupus aureus*, the gold-coloured wolf, and by the modern Greeks *spilachi*. See **AUREUS**.

JACKSON, JOHN, in *Biography*, was born at Senfey, near Thirst, in Yorkshire, in 1686. He was educated at Doncaster, under Dr. Henry Bland, afterwards head-master of Eton school. From Doncaster he went to Cambridge, and was entered, in 1702, of Jesus college. Here he took his degree of B. A. and quitted the university in 1707, and engaged himself as private tutor in the family of a gentleman of Derbyshire. In the following year he was ordained, and soon after obtained the rectory of Rossington, which had been reserved for him, by the corporation of Doncaster, after the death of his father. In 1714 he commenced his career as author, by publishing three letters in defence of Dr. Samuel Clarke's "Scripture Doctrine of the Trinity," under the name of a country clergyman. This work was the means of introducing him to the notice of Dr. Clarke,

who was anxious to procure for him some preferment in the church. In 1714, Mr. Jackson engaged in the Bangorian controversy, and proved an able defender of bishop Hoadly, in the cause of liberty. In 1716 he engaged in a controversy with Dr. Waterland, in defence of the sentiments maintained by Dr. Clarke. He pursued the subject still farther in a correspondence with Mr. Whiston, by which he was led to determine never more to subscribe to the thirty-nine articles. In consequence of this resolution, he lost, about the year 1724, the hopes which he had been led to entertain of a prebendary of Salisbury, which bishop Hoadly refused to give him without subscription. This refusal was so extraordinary, especially as it came from Hoadly, and as the law did not make subscription necessary, that the prelate was censured for it by his best friends. Whiston exclaimed, "how consistent this was with his own notion of liberty of conscience, or with that Christian freedom, of which he was always an advocate, I do not well understand." Upon the death of his friend Dr. Clarke, in 1729, Mr. Jackson was presented to the mastership of Wigton's hospital, in Leicester, by the duke of Rutland, which place he filled, till his death, with much reputation and credit, candidly admitting into the house persons of different religious persuasions, even some who had been violent partizans against him. Mr. Jackson next appeared as an author in defence of human liberty, or the liberty of the will, in opposition to Anthony Collins, who had published a pamphlet in behalf of the doctrine of necessity: he also wrote in justification of human reason; and in defence of the Christian religion, in opposition to Tindal's work, entitled "Christianity as Old as the Creation." His other smaller treatises we shall pass over, though very useful and important in the controversies and discussions of the period in which the author flourished. In 1752 he sent his great work into the world, entitled "Chronological Antiquities, or the Antiquities and Chronology of the most ancient Kingdoms from the Creation of the World, for the Space of Five thousand Years." This work, the result of much studious application, and very extensive reading, consisted of three volumes 4to., was well received by the literati of our own country, and was translated into the German language. He had other works in view, particularly an edition of the New Testament in Greek, with scholia in the same language; this he meant to have accompanied with all the various readings which he had collected, but the infirmities of age prevented him from accomplishing his designs. He died in 1763, in the 78th year of his age. He was a man of deep and very extensive learning, particularly in Greek and Roman literature, and his industry was indefatigable. He was the avowed friend of civil and religious liberty, and was never afraid of avowing the truth on any subject, although he was fully sensible of the obloquy and temporal losses to which such conduct would expose him. *Biog. Brit.*

JACKSON, THOMAS, was born at Witton, in the county of Durham, in the year 1579. Having obtained a good classical education, he was entered of Queen's college in the year 1595, and in the following year he was, on account of his great merit, unanimously elected a scholar of Corpus Christi college, notwithstanding the utmost interest was made for another candidate. He took his degrees in regular course, and was at length chosen vice-president of his college several years successively. He first obtained a benefice in his native country, which, in a short time, he relinquished for the vicarage of St. Nicholas, in Newcastle-upon-Tyne. He was in sentiment a rigid Calvinist, and was much admired and followed as a preacher. Being afterwards appointed chaplain to Dr. Nale, bishop of Durham, that prelate was the

means of making him a convert to Arminianism. In 1650 he was elected president of Corpus Christi college, on which occasion he resigned the vicarage in Newcastle, and soon afterwards was nominated chaplain in ordinary to his majesty, and collated to the vicarage of Witney in Oxfordshire. In 1635 he was made a prebend of Winchester, and in 1638 he was promoted to the deanery of Peterborough. He died in 1640, leaving behind him a character for a solid and penetrating judgment, and for extensive and sound learning. His works are numerous, but wholly theological; the principal of them consist of "Commentaries on the Apostle's Creed," in twelve books. His works, thirty years after his decease, were collected and published in three volumes folio, to which is prefixed the life of the author. Biog. Brit.

JACKSON, WILLIAM, an eminent musical composer, was a native of Exeter, in Devonshire. He was pupil of the celebrated Travers, and may be said to have imbibed no small portion of that composer's spirit. It must be allowed that Jackson possessed a considerable share of intellectual ability, and evinced on many occasions a very distinguished taste for the fine arts. His judgment in general was sound; genius will not be denied him, and when genius, judgment, and taste are united in the same person, we are entitled to expect an approximation to human excellence. At the same time it must be confessed, that these qualities were strongly alloyed by a mixture of selfishness, arrogance, and an insatiable rage for superiority.

In many of his musical compositions he has displayed traits of novelty, but these are not the most estimable of his productions. The "Elegies," the best of his works, possess superior melody, for which we may allow him credit; but the harmony of these is in some measure derived from his old master; that is, they are constructed upon the model of that composer's canzonets. Indeed, many of Jackson's early compositions favour much of the spirit and contrivance of Travers.

Jackon's fame, in a great measure, may be said to be founded in his judgment of selection with regard to poetry; though he sometimes took unwarrantable liberties with his author, in order to accommodate the lines to his music.

Perhaps no composer copied less from others than Jackson, yet at the same time it must be admitted that he was a palpable plagiarist. His most interesting and novel melodies are too frequently associated with common passages that have existed almost from the origin of music; the descent of four notes in the diatonic order is sufficient to illustrate our meaning. Jackson's peculiar fort existed in giving an elegant and plaintive melody to elegiac poetry. In constituting harmony, without rendering the middle part or parts of a composition destitute of melody, Jackson stands unrivalled.

This is no trivial praise, when it is known that, before his time, composers were, and are at present, very defective in this part of their art.

It was a defect in Jackson's music, that his melody would suit any species of plaintive lines: few of his compositions displayed the art of mingling expression with melody, and preserving the latter in its purity. His "Fairy Fantasies," not yet published, evince more congruity than any others of his works.

Jackon paid his court to the graphic muse, but never looked at nature, believing, that by copying other masters, he might at last arrive at excellence. His great model was his friend Gainsborough, whose colouring and composition he constantly endeavoured to imitate, sometimes with a degree of success which induced him to lay a false claim to the merit of originality. But had he succeeded in even

equalling that great artist, his pictures would not have spoken the language of nature; the man who merely copies another, either in music or painting, can never be considered a great artist; he can only be a faint echo, and ranked among the *servum pecus imitatorum*.

Jackon's literary works, though not of the highest order, possess genius. He wrote "Thirty Letters on various Subjects," 8vo. "The Four Ages, and other Essays," 8vo. "Treatise on the present State of Music." Also some papers in the essays of the Exeter Society. He produced eighteen musical publications, consisting of "Hymns, Songs, Canzonets, Elegies," and an "Ode to Fancy," &c.

Jackon was elected organist of St. Peter's cathedral, Exeter, in 1777, and continued in that situation till his death, in 1803.

Though his general mode of living was temperate, yet he thought that a still greater abstinence would prolong his existence. He latterly dined on milk-porridge, and drank water. This experiment was fatal. His habit necessarily became impoverished, and his existence terminated in a dropsy, at the age of 73.

JACKSON, in *Geography*, a county of America, in Georgia, containing 7736 inhabitants, of whom 1400 are slaves.—Also, a county of Tennessee, in Mero district.

JACKSON, *Port*, a bay or harbour on the E. coast of New Holland, so called by lieutenant (afterward captain) Cook, who discovered it in May 1770, and found that it had good anchorage. This is one of the noblest harbours in the world, extending about 14 miles in length, with numerous creeks and coves. On the south of this, at a spot called Sidney cove, a settlement for transported criminals was fixed. Jackson lies three leagues N. of *Botany-bay*; which see. See also *NEW HOLLAND*.

JACKSON'S *River*, a head-water of James's river, in Virginia, which rises in the warm spring mountains, and runs S.W. through the valley, until it is joined by Carpenter's creek, when the river assumes the name of Fluvanna, and flows S.E. About $\frac{1}{2}$ of a mile from its source, it falls over a rock 200 feet into the valley below. It is near half as high as Niagara, but only 12 or 15 wide.

JACKSONBORO, a post-town of America, in Scriven county, Georgia; 670 miles from Washington.

JACKSONIA, in *Botany*, so named by Mr. Robert Brown, in memory of the late Mr. George Jackson, F.L.S. a man of the most excellent and amiable character, devoted to the science of botany, to which, under the auspices of his patron and friend, A. B. Lambert, esq. he has rendered several important services. The improved style of the Botanical Repository, for some time past, though far short of what he wished, is owing to his care, and he has furnished a paper in the tenth volume of the Linnæan Society's Transactions, on a new genus of Decandrous Leguminous plants, named *Ormosia*. Many manuscripts evincing his learning and scientific skill remain in the hands of Mr. Lambert. Mr. Jackson died of a rapid decline Jan. 12, 1811, aged 31, and was interred on the 16th in St. George's burying-ground, Mary-le-bone. He was a native of Aberdeen.—Brown in Ait. Hort. Kew v. 3. 12.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, nearly equal, acute segments. *Cor.* papilionaceous, of five petals. Standard inversely heart-shaped, about equal to the calyx. Wings rather longer, obtuse, with a tooth on their upper side near the base. Keel of two petals, of the size and shape of the wings. *Stam.* Filaments ten, awl-shaped, distinct, equal, ascending deciduous; anthers roundish. *Pisil.* Germen nearly sessile, oval; style awl-shaped, slender;

slender; stigma simple, obtuse. *Peric.* Legume ovate or oblong, somewhat swelling, of one cell and two valves, downy on their inside. *Seeds* two, roundish, without any appendage.

Eff. Ch. Calyx in five deep, nearly equal, segments. Corolla papilionaceous. Style awl-shaped. Stigma simple. Legume of one cell, downy within. *Seeds* two, without any appendage.

Of this genus, whose habit is slender and resembling that of Broom, two species are defined in an unpublished sheet of the third volume of the *Hortus Kerwenfis*, kindly communicated to us by Mr. Brown, that the memory of his friend might as soon and as widely as possible be commemorated. These are,

1. *J. scoparia*. Brown MSS.—“Stem arborefcnt, without thorns. Branches angular. Clusters terminal.”—Native of New South Wales, from whence it was sent to Kew garden by Mr. George Caley, in 1803. This is the plant mentioned in Sims and Kœnig’s *Annals of Botany*, v. 1. 511, which the author of the essay there printed, and of the present article, for want of the fruit, could not then venture to determine. Its *branches* have the aspect of a *Spartium*, and are somewhat silky, leafless, much branched, and angular. *Flowers* yellow, in scattered short clusters. Specimens were long ago sent from Port Jackson, by Dr. White.—This species is kept in the green-house, and flowers from June to August.

2. *J. spinosa*. Brown MSS. (*Gompholobium spinosum*; Billard. Nov. Holl. v. 1. 107. t. 136.)—“Stem shrubby. Branches spinous, spreading, twice or thrice forked, angular. Bractæas very short, closely pressed to the top of the flower-stalk.”—Native of the south-west coast of New Holland, from whence it was sent to Kew, by Mr. Peter Good in 1803, and is kept in the green-house, flowering most part of the summer. The *stem* is much branched, rigid and spinous, without leaves. *Flowers* stalked, usually in pairs. Billardiere says the seeds are from two to four, and kidney-shaped.

Several more species of *Jacksonia* are destined to appear in Mr. Brown’s *Prodromus Fl. Novæ Hollandiæ*, with which, we presume, the above specific characters are contrasted. S.

JACKSONSBOROUGH, in *Geography*, a small post-town of South Carolina, on the W. side of Edisto river, about 35 miles W. of Charleston.

JACKTALL, a town of Hindoostan, in Dowlatabad; 12 miles N.W. of Ramgur.

JACMEL, a jurisdiction and sea-port town on the S. side of the island of St. Domingo. This jurisdiction, in the French part of the island, contains three parishes, remarkable for the goodness of its soil, and the abundant crops of coffee. The town is situated on the S. side of the neck of the south peninsula; 6 leagues westward of Cayes de Jacmel, or 13 S.W. of Port-au-Prince, and 53 E. of cape Tiburon. N. lat. 18° 21'. W. long. from Paris 75° 2'.

JACMEL, *Cayes de*, a town and parish on the E. side of the stream of its name; the parish is bounded E. by the plain on the Spanish part, at the foot of the mountains of Bahoruco, 80 leagues square, fit for any kind of cultivation.

JACO, a river of Brazil, which runs into the Atlantic. S. lat. 17° 25'.

JACO, in *Ornithology*. See PSITTACUS *Eriothacus*.

JACOB, in *Scripture History*, the son of Isaac and Rebecca, was born in the year B. C. 1836. He was twin-brother of Esau (see Gen. xxv. 25.), of a meek peaceable disposition, domestic in his habits, inclined to a pastoral life, and the favourite of his mother; whereas, Esau was of a more fierce

and turbulent temper, fond of hunting, and, in consequence of his masculine active spirit, the object of his father’s partial affection. Jacob derived his name from the manner of his birth, as he came into the world holding his brother’s heel, which, in Hebrew, is expressed by *אָקָב*, whence *אָקָב*, *he supplanted*, a term indicating some events that occurred in the progress of his years, and of which we have already given a brief account under the article Esau. It is needless minutely to detail the particulars of his future history, as they are recited in the book of Genesis, to which the reader is referred. Here we find, that in order to avoid the threatened effects of his brother’s displeasure, incurred as we have already related under the article Esau, Jacob was sent by his mother to her brother Laban. In his journey he had a vision of a peculiar nature, which brightened his prospects, and induced him to form pious and laudable resolutions. On his arrival at Padan-Aram, he was hospitably received by his uncle Laban; and in a little while he conceived an affection for Rachael, his youngest daughter. In order to obtain Laban’s consent to their marriage, he agreed to serve him seven years; but at the close of this period of service, Leah, the eldest sister, was substituted for Rachael; and he contracted to serve Laban for a second term of years, upon condition of obtaining the first object of his affection. Upon the expiration of this term he married Rachael; and during his abode with Laban, he was singularly prosperous. At length his situation became intolerably grievous, and he determined to return with his wives and children, and the property he had acquired, to his own country. Availing himself of an opportunity which Laban’s absence afforded, he prepared for his journey; and he had proceeded so far before his departure was known, that Laban was seven days in pursuing him before he could overtake him. Upon their interview on mount Gilead, Laban remonstrated and Jacob justified the measure which he had adopted. Rachael, however, before her departure, had contrived to purloin her father’s *teraphim* (which see); and Laban, in his remonstrance with Jacob, complained of the robbery. Jacob, unapprized of the fact, consented to an examination of every tent, and declared that the individual, who was guilty of the robbery, should be put to death. Rachael contrived to elude the search; and Laban, apprehending that his charge was unjust, inclined to measures of conciliation. Accordingly, he proposed to Jacob terms of alliance, and that a monument should be erected as a testimony of it to future ages. Jacob acquiesced: a pile of stones was reared, called by Laban, in the Syriac tongue, *Jagar-Sahadutha*, and by Jacob, in Hebrew, *Gilead*; both signifying the heap of witness. The treaty was concluded with a sacrifice and a feast; and Laban, having embraced and blessed Jacob and his family, set out on his return to Padan-Aram. Jacob, as he pursued his journey, began to entertain apprehensions of the unappeased resentment of his brother Esau; and notwithstanding the conciliatory measures he had adopted, he soon found that his brother was advancing to meet him with an armed force, and with seeming purposes of hostility. Having recommended himself by an act of devotion to the divine protection, he prepared a costly present for his brother. At this time he was favoured with a prophetic vision, which served to allay his fears and to animate his resolution; and from a circumstance that occurred on this occasion, he obtained the name of “Israel,” signifying a man who has prevailed with God; and this became afterwards the name of his posterity. Having joined his family after this vision, he advanced to meet his brother, who received him in the most kind and affectionate manner, and invited him to settle in his neighbourhood. Jacob, however, could not easily

dismiss his apprehensions of danger, and chose rather to take up his abode near Shechem, where he purchased ground, on which he built an altar to the Lord. A circumstance of a very distressing kind occurred, for an account of which we refer to the history, which made it necessary for Jacob to remove from the vicinity of Shechem; and whilst he was deliberating whither to direct his course, he was instructed to erect an altar to God at Bethel, a place where he had received early assurances of the divine protection and favour. Having erected an altar at this place, he set out on his journey to his father; but in the way he was severely afflicted by the loss of his beloved wife Rachael, who died in childbirth of her son Benjamin. Soon afterwards he arrived at Mamre, and continued there till his father's death. At this time Joseph, being about 17 years of age, became the object of jealousy to his brethren; who, meditating his destruction, determined at length to sell him to a troop of Ishmaelites, and to feign a story, with which they imposed upon the afflicted father, of his having been torn to pieces by some wild beast. After the lapse of some years, Jacob received the consolatory news of Joseph's being still alive, and in a station of high honour and power at the court of Pharaoh. (See JOSEPH.) The news, we may well imagine, transported him beyond measure, and he fainted in the arms of his sons who communicated it. As soon as he could be persuaded that the report was true, and found himself surrounded by the presents of his son, and by the chariots of Egypt, which were to convey him and his family thither, he prepared for his journey, and in his way stopped at Beer-sheba, to offer sacrifices to God, thus expressing his gratitude and his desires of continued protection and blessing. Having received assurances of divine favour, he pursued his journey with pleasure; and, as he approached the borders of Egypt, he received a message from Joseph, requesting him to meet him in the land of Goshen, situated between the Red sea and the Nile, which was a fruitful territory, and adapted to his pastoral life. The interview between the patriarch and his son Joseph is best conceived by a mind of virtuous sensibility. Having obtained leave of Pharaoh to settle in the land of Goshen, Joseph conducted his father and family thither; and here they prospered and multiplied. Jacob lived 17 years in Egypt; and when he apprehended that his life was drawing to a close, he obtained a promise from Joseph that his remains should be carried to Canaan, and deposited with those of his progenitors, Abraham and Isaac, in the cave of the field of Machpelah, which Abraham had purchased. When he was dying, he adopted the two sons of Joseph, Manasseh and Ephraim, as his own; declaring, that in the division of the promised land they were to receive a double lot, and to be considered as the heads of two distinct tribes. Having delivered to his sons, who were collected round him, his dying predictions of the events that should happen to their several descendants in future times, and which exactly corresponded to the patriarch's declarations, Jacob expired, at the age of 147 years, in the year B. C. 1689. Joseph faithfully fulfilled his promises with respect to the burial of his father; and Pharaoh testified his respect for Joseph by contributing in various ways to the pomp of the funeral procession. After having deposited the remains of their father in the cave of Machpelah, Jacob's sons returned to Egypt, where they and their posterity remained till the time of the *Exodus*. See EXODUS. Genesis, ch. xxv.—4. Anc. Un. Hist. vol. ii. p. 248. &c. &c. Calmet's Dict. Bib. art. *Jacob*.

JACOB, JOHN, in *Biography*, was a native of Zulpha, and in the year 1641 he filled the post of principal joiner to the king of Persia. He was celebrated for his skill in mechanism,

and was author of many useful inventions. Having an opportunity of visiting Europe, he formed a complete idea of the art of printing, and upon his return to Ispahan he succeeded in erecting a press, and cut for himself matrices for the necessary types. The first specimens of his typographical art were in the Armenian language, and consisted of the epistles of St. Paul, and the seven penitentiary psalms. He would have proceeded with the other parts of the bible; but his progress alarmed the copyists, who excited such a clamour against him that he was obliged to lay aside the undertaking. He was a Christian in religion; but on account of his very extraordinary talents he was permitted to hold a post which was never before occupied but by a Mahometan. His sovereign would gladly have enrolled him among the followers of the prophet, but no offers of preferment, however tempting, could prevail on him to renounce Christianity. Moreri.

JACOB, HENRY, celebrated as the founder of the first independent or congregational church in England, was a native of Kent, and received his academical education at St. Mary's hall, Oxford. Having entered into holy orders, he was made precentor of Corpus Christi college, and afterwards obtained the benefice of Cheriton in Kent. In the year 1604 he published "Reasons taken out of God's Word, and the best of human Testimonies, proving the Necessity of reforming our Churches of England." The publication of this, and of another work, against what was falsely called "learned preaching," drew down upon him the persecution of bishop Bancroft, and to avoid his wrath he fled to Holland. At Leyden he met with Mr. Robinson, with whom he had frequent conferences, and became a convert to the Brownist principles, since known by the name of independency. In Holland he published several treatises, and upon his return he avowed a design of setting up a separate congregation upon the model of those in Holland. This, in a short time, he carried into effect, and thus laid the foundation of the first independent congregational church in England. He was elected pastor of the church, and continued with his people till the year 1624, when, being desirous of entering on a more enlarged sphere of usefulness, he went to Virginia, where he soon afterwards died. He was author of many publications which were highly esteemed in his day. Neal's Hist. Puritans.

JACOB, HENRY, son of the preceding, was born in the year 1609. He received the greater part of his education at Leyden, and made a wonderful progress in philological and oriental learning. He was patronized first by the earl of Pembroke, and then by archbishop Laud. By the influence of the latter he was appointed "focius grammaticalis" in Merton college, a post which had not been occupied for more than a century, and the duties of which required him to be reader of philology to the juniors. He became fellow of his college, and acted some time as amanuensis to Mr. Selden. In 1648 he was expelled from his fellowship and college by the parliamentary visitors; and being destitute of the means of subsistence he came to London, where his friend Mr. Selden contributed to his support. He was never an economist either with regard to his little property or his health, and by intense application to his studies he died, at Canterbury, at the early age of 44. He left behind him many very learned pieces, particularly "Græca et Latina Poemata." Gen. Biog.

JACOB, a performer on the establishment of the Royal Academy at Paris, a scholar, on the violin, of Gavigné, who likewise taught that instrument, according to the principles of his master, by which he acquired reputation. He published, in 1769, a new musical grammar, in which he wrote
down

down the doctrine of the Abbé la Cassagne, concerning the reduction of all clefs to one; calling his book l'Unckfier, a plan which he had stolen from our countryman, Salmon, as Dumas had done before, and others of his countrymen since. Salmon's "Essay for the Advancement of Music, by reducing all Clefs to one," was published in 1672, to which there was no valid objection but the rendering all previous compositions obsolete. See SALMON and CLEF.

JACOB, *St* in *Geography*, a town of the duchy of Stiria; seven miles W. of Fridburg.—Also, a town of Stiria; six miles N.E. of Marburg.—Also, a town of Tyrol; eight miles S. of Landeck.—Also, a town of Sweden, in the government of Abo; 10 miles E. of Abo.

JACOB'S CREEK, an eastern water of Youghiogany river, in Westmoreland county, Pennsylvania. Six miles W. to Monongahela river there is a carrying place from the Youghiogany, opposite to the mouth of this creek.

JACOB'S LADDER, in *Botany*. See POLEMONIUM.

JACOB'S STAFF, a mathematical instrument for taking heights and distances; the same with the cross-staff.

JACOBLEA, in *Botany*. See SENECIO.

JACOBÆAN LILY, in *Botany*. See AMARYLLIS *Formosissima*.

The name was given by the Spaniards, because this flower resembles, in size, colour, and shape, the red crosses worn by the knights of the order of St. James, embroidered on their habits, as may be seen by some of their portraits brought into this country.

JACOBÆASTRUM. See OTHONNA.

JACOBÆOIDES. See OTHONNA.

JACOBBAZZI, DOMINIC, in *Biography*, an Italian cardinal, was born at Rome in the year 1443. Having fixed upon the ecclesiastical life, he applied himself to the study of the canon law and theology, and became so eminent for his proficiency in these sciences, and for his talents as a man of business, that he was employed by pope Sixtus IV., and five of his successors, in the management of several important affairs. He rose rapidly in the church; by pope Julius II. he was made vicar of Rome, and president of the university in that city; he was likewise put in possession of several bishoprics, and at length, in the year 1517, he was elevated to the rank of cardinal by pope Leo X. He died about the year 1527, when he was 84 years of age. He was author of "A Treatise concerning the Councils," which was originally published at Rome in 1538, in folio. It forms the 18th volume of father Labbe's "Collectio Maxima Conciliorum," and renders that collection extremely valuable.

JACOBIN, in *Ornithology*. See LOXIA *Molucca*.

JACOBINE, the name of a particular species of pigeon, called by Moore the *columba cyria cucullata*. (See COLUMBA *Cucullata*.) It is generally called the jack, for shortness. It is, when genuine and of the true breed, the smallest of all pigeons. It has a range of feathers inverted quite over the hinder part of its head, and reaching down on each side of the neck to the shoulders of the wings, which forms a kind of friar's hood, from whence the bird has its name. This species has also a short bill, and a pearly eye. The colour is various in the feathers; there are reds, yellows, blues, blacks, and mottles; but whatever is the general colour, the head, tail, and flight, are white. Some pigeons of this species are feather-legged, others are not.

JACOBINS, a name given in France to the religious who follow the rule of St. Dominic, on account of their principal convent, which is near the gate of St. James, in Latin Jacobus, at Paris; and which, before they came possessed of it in the year 1218, was an hospital of pilgrims, dedicated to the said saint. (See DOMINICANS.) Others maintain, that they have been called Jacobins ever since they were

established in Italy; because they pretended to imitate the lives of the apostles.

They are also called *friars predicants*, or *preaching friars*.

JACOBINS, a term of reproach applied soon after the French Revolution to those who actually were, or who were suspected to be attached to the French interest.

JACOBITES, in *Ecclesiastical History*, a sect of heretics, who were anciently a branch of the Eutychians, and are still subsisting in the Levant.

They were so called from Jacobus, James, of Syria, called Albardai, or Baradæus, who was one of the heads of the Monophysites, or sectaries who owned but one nature in Jesus Christ.

This poor monk revived the cause of the Monophysites by his activity and diligence; and when he died bishop of Edeffa, A.D. 588, he left this sect in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. The laborious efforts of Jacob were seconded in Egypt, and the adjacent countries, by Theodosius, bishop of Alexandria.

The Monophysites were a sect of vast extent, comprehending the Armenians, Copts, and Abyssinians: and the denomination of Jacobites is commonly used in an extensive sense, as comprehending all of them, except the Armenians; but it more strictly and properly belongs only to those Asiatic Monophysites, of which Jacob Albardai was the restorer and chief. All the patriarchs of the Jacobites assume the denomination of Ignatius.

As to their faith, all the Monophysites, both Jacobites and others, follow the doctrine of Dioscorus touching the unity of nature and person in Jesus Christ. See MONOPHYSITES.

JACOBITES, in England, is a term of reproach bestowed on such persons as disallow of the revolution by king William, and still assert the rights, and adhere to the interests of the abdicated king James, and his line.

JACOBS, LUCAS, in *Biography*, a painter, born at Leyden, and therefore commonly known by the name of Lucas Van Leyden. In the year 1494 he made the entrè of life, and as he grew up was instructed by his father, Hugh Jacobs, in the art of painting. Afterwards he became the pupil of Cornelius Engelbrecht, and had acquired considerable reputation as a painter, and also as an engraver, when he arrived at the age of manhood.

His style is of the dry Gothic school of Germany, of which Albert Durer is the leader; close upon whom followed Jacobs, with nearly as much merit as a painter, though not his equal by far in invention. The attempt to copy the model closely is in the works of the latter as evident as in those of the former, and his draperies have the same character. Both are imperfect and meagre in lines; but sometimes, where they copied the large flowing dresses of the church, they are broad and have much majesty. His feeling of expression is of a low and vulgar cast, and oftentimes mere grimace; but it must be acknowledged that he and Albert were far above their contemporaries in Germany.

The works of this master are numerous; but he is perhaps better known by his prints, engraved by himself with great ingenuity, from a great number of his pictures in Leyden, Amsterdam, Vienna, &c. &c. He died in 1533, at the age of 39.

JACOBESHAGEN, in *Geography*, a town of Pomerania; 16 miles E. of Stargard. N. lat. 53° 25'. E. long. 15° 30'.

JACOBSON, JOHN CHARLES GOTTFRIED, in *Biography*, was born at Elbingen in 1726. He studied at Leipzig, but in consequence of an unfortunate duel he was obliged to leave that.

that place, and entered into the service of the elector of Saxony. He afterwards enlisted in a regiment of infantry at Berlin, and during a two years' residence in that city he diligently frequented the different manufactories and workshops, and between the years 1773 and 1776 published his "Description of all the Cloth Manufactories in Germany," in four volumes octavo. He was indefatigable in his pursuits, and besides his own publications he assisted Sprengel in his "Collection of the Arts and Handicrafts," and Nicolai in his "Description of Berlin." In 1778 he was actively engaged in military affairs, but after the campaign of this year he obtained a discharge, and began his "Technological Dictionary of all useful Trades, Arts, Manufactures, &c." which was published in parts between the years 1781 and 1784. In the latter year he was appointed inspector of all the royal manufactories in the kingdom of Prussia; he died in 1789. He was author of "A Description of all the Linen, Cotton, and Woollen Manufactures in the Prussian States," in 4 vols. and he had begun a "Compendium of Technology," when death put an end to his labours. Gen. Biog.

JACOBSTADT, in *Geography*, a sea-port town of Sweden, in the government of Wala, with a convenient port. N. lat. 56 41'. E. long. 22 36'.

JACOBUS, a gold coin, worth twenty-five shillings; so called from king James the First of England, in whose reign it was struck. We usually distinguish two kinds of Jacobus, the *old* and the *new*; the former valued at twenty-five shillings, weighing six penny-weights ten grains; the latter, called also Carolus, valued at twenty-three shillings; in weight five penny-weights twenty grains.

JACOPONE DA TODI, in *Biography*, an Italian poet of the 13th century, was born at Todi, of the noble family of Benedetti, or Benedettoni. He was brought up to the profession of the law, in which he practised, obtained a fortune, and lived in every respect as a man of the world. A serious accident which befel his wife, and occasioned her death, led him to reflection, and he immediately devoted himself to religion. He entered the order of the Franciscans: to receive the humiliation of contempt he counterfeited folly, and succeeded so well, that his baptismal name of Jacopo was changed into the nick-name of Jacopone. The rigour of his superiors surpassed his own voluntary mortifications, and for a slight offence he was thrust into a noisome dungeon, where he is said to have composed one of his most rapturous canticles of divine love. He underwent greater sufferings from the resentment of pope Boniface VIII., on account of some reflections thrown out respecting the evils brought on the church by that pontiff. He was closely imprisoned, and allowed no other sustenance than bread and water. He survived his liberation but three years, and died in 1306. His "Spiritual Canticles" have given him a place among the Italian poets. Of this work the best edition is that of Venice, in 1617. Moreri.

JACPOE, in *Geography*, a town on the W. coast of the island of Borneo. S. lat. 0 14'. E. long. 109 21'.

JACQUELOT, ISAAC, in *Biography*, was born at Vassy, in Champagne, in the year 1647. He was educated for the ministry and as soon as he had arrived at man's estate he was appointed his father's colleague in the church of his native place. After the revocation of the edict of Nantz he retired to Heidelberg, and from thence he removed to the Hague. His talents as a preacher acquired for him a high reputation, and he was solicited by the king of Prussia to become his minister at Berlin; to which he readily acceded, and enjoyed a handsome pension from his majesty till his death in 1708. He was author of many works, among which are "Dissertations on the Existence of God;"

"Dissertations on the Messiah;" and "A Treatise on the Inspiration of the Sacred Books." He wrote and published "A Criticism on the Picture of Socinianism," written by Jurieu, which exposed M. Jacquetot to a bitter persecution.

JACQUES, FRERE (*Friar JAMES*), whose surname was BAULOT, or BEAULIEU, a celebrated lithotomist, and a man of singular character, was born, in 1651, at a village in Franche-Comté, where his father was a poor labourer. At the age of sixteen he was seized with an inclination to travel. The education, which he had received, did not extend beyond writing and reading; but he had an ardent desire for other knowledge, and a propensity, which he felt for the practice of surgery, was put in the way of gratification, by himself becoming a patient in the hospital of his province. During his convalescence, he applied himself with great assiduity to assisting the sick, and learned to bleed. He soon afterwards enlisted in a regiment of cavalry, in which he served some years, and became acquainted with an Italian empirical surgeon, named Pauloni, who had become famous for cutting for the stone, and curing ruptures. Having procured his discharge, at the age of twenty-one, Jacques attached himself to this empiric, and travelled with him five or six years, in various countries, as an assistant. At length feeling himself equal to undertake the practice without a director, he quitted Pauloni, and began to act for himself in the villages and country towns of Provence, taking no more recompence for his services, than just sufficed for his humble maintenance. After having practised his art eight or ten years, he put on a monastic habit, in 1690, or 1691, but not of any particular religious order, and took the name of *frere* Jacques, by which he was ever afterwards distinguished. He now visited the larger towns; especially Marseilles, and went also into other provinces, where he chiefly operated upon the poor; but, among the persons of rank whom he cut, was a canon of Paris, who recommended him to visit the metropolis, and gave him letters of introduction. He arrived at Paris in August 1697, and was ordered to perform his operation on the dead body in the presence of the physicians and surgeons of the Hôtel-Dieu. But although one or two of these officers gave a preference to his operation, prejudice and envy prevailed, and he was not allowed to practise it on the living body. He, therefore, quitted Paris in October of the same year, and went to Fontainebleau, the residence of the court, where the success of his operation, in the presence of the principal medical men, obtained him a reputation, which led to a second visit to Paris; where he is said to have been unsuccessful in a large proportion of his operations, and was taxed with extreme ignorance of anatomy, as well as of the art of surgery in general, so that he refused, it was alleged, to pay much attention to the wound, saying, that "it was sufficient that he had removed the stone; God would heal the patient." Time and experience, however, taught him better; and he employed proper dressings and treatment. His name spread throughout Europe as the most successful lithotomist of his time; and between the years 1688 and 1714, he visited Holland, Geneva, Flanders, and the principal cities, performing an immense number of operations with various success. When at Paris, in 1703, he performed his operation on the marshal de Lorges, who died on the following day, and he quitted that city in some disgrace, resolved never to return. He was much honoured by the magistrates of Amsterdam, who caused his portrait to be engraved, with the inscription, "Frater Jacobus de Beaulieu, Anachoreta Burgundus, Lithotomus omnium Europæorum peritissimus;" and above it, this motto, as a justification of some of his failures,

failures,—“*Quia non omnes convalescunt, non idcirco nulla medicina est.*”—The celebrated surgeon and anatomist, *Rau*, opposed him, however, with acrimony; but did not refuse to borrow from him his method, which, with some improvements, constituted the *lateral operation*, afterwards brought to perfection in England by *Chefelden*. In the course of his travels, *Frere Jacques* was called to Vienna to be consulted for the emperor *Joseph*; and at Rome, he was received with great honour by the pope. But tired at length with wandering about, he sought his native village: his parents were dead; and, having distributed some money among his nephews, he chose a quiet retreat near *Befançon*, with a view of finishing his days in retirement and tranquillity. And after a sojourn of a few weeks, he died, in December 1714, at the age of sixty-nine, with all the tokens of sincere piety. *Frere Jacques*, though in some measure chargeable with the temerity of ignorance, was a man of genius and of an elevated mind, and deserves to rank among the improvers of an useful art. He published an account of his method of operating, in 1702, in a pamphlet of eight pages; and it was reprinted by *M. Morand* in the second part of his “*Opuscules.*” *Eloy. Dict. Hist.—Gen. Biog.*

JACQUIER, FRANCIS, a very learned ecclesiastic and mathematician, was born at *Vitry*, near *Paris*, in 1711, and died at *Rome* in 1788. He was one of the editors of what is generally known in this country as “*The Jesuits’ edition of Sir Isaac Newton’s Principia.*” This edition, which was published in four thin volumes in 4to. in the year 1760, is illustrated with a perpetual commentary, for the benefit, as the editors avow, neither of the very learned, nor of those who are wholly unskilled in mathematical science. *Jacquier* was author of several works written in the Italian language.

JACQUINIA, in *Botany*, so named by *Linnaeus*, in honour of the celebrated *Nicholas Joseph Von Jacquin*, professor of botany at *Vienna*, born at *Leyden* in 1727, who was early distinguished by the publication of his history of American plants, as he has since been by numerous very splendid works. This venerable author is, as far as we know, still living at *Vienna*, and has an only son, *Joseph Von Jacquin*, who resided for some time in England about twenty years ago, and treads in his father’s steps.—*Linn. Gen. 101. Schreb. 137. Willd. Sp. Pl. v. 2. 1064. Mart. Mill. Dict. v. 2. Jacq. Amer. 53. Ait. Hort. Kew. ed. 2. v. 2. 5. Juss. 151. Lamarck. Illustr. v. 2. 45 t. 121.—Class and order, Pentandria Monogynia. Nat. Ord. Sapete, Juss. Myrsineae, Brown.*

Gen. Ch. Cal. Perianth inferior, of five roundish, concave, permanent leaves. *Cor.* of one petal; tube bell-shaped, inflated, longer than the calyx; limb in ten roundish segments, of which the five inner ones are shorter. *Stam.* Filaments five, awl-shaped, inserted into the receptacle; anthers arrow-shaped. *Pist.* Germen superior, ovate; style the length of the stamens; stigma capitate. *Peric.* Berry roundish, pointed, of one cell. *Seed* solitary, roundish, cartilaginous.

Ess. Ch. Corolla in ten segments. Stamens inserted into the receptacle. Berry with one seed.

Obs. The germen contains the rudiments of several seeds, one of which only, for the most part, comes to perfection. Hence the embryo, naturally erect, becomes transverse from the a tered position of the seed in ripening. See *Brown’s Prodr. v. 1. 533.*

Five supposed species of *Jacquinia* are defined by *Willdenow*, but of these one is indicated by *Mr. Brown* as a new genus, belonging to a very different order, the *Rubiaceae*. This is *J. venosa* of *Swartz’s Prodr.*, omitted either by accident or design, in his *Flora Ind. Occid.* The place of

this, however, is supplied by a new species from the second edition of the *Hortus Kewensis*. They are all shrubby or arborescent, with rigid, smooth, entire, scattered leaves on short stalks, each with a pair of minute, awl-shaped, intra-foliateous, deciduous stipulas, not always discernible. Flowers terminal, racemose or solitary, white, yellow, or orange-coloured, on smooth stalks.

1. *J. arborea*. *Vahl. Eclog. Amer. fasc. 1. 26. Willd. n. 1.*—Leaves obovate, somewhat wedge-shaped. Branches even; the lowermost quaternate; upper ones forked.—Found by *Mr. Ryan* in the island of *Montserrat*, on the sea coast in one place only, near the road called *New Windward*. A tree from four to 20 or 30 feet high, the trunk from six to eight inches thick, the branches scarcely swelling under their subdivisions, in which character and its greater size only it differs from the following, and they ought surely to be considered as mere varieties.

2. *J. armillaris*. *Linn. Sp. Pl. 272. Jacq. Amer. 53. t. 39.*—Leaves obovate, somewhat wedge-shaped. Branches swelling under their subdivisions; whorled below; forked above. Clusters many-flowered.—Native of the *West Indies*. A handsome shrub, seldom more than four or five feet high. Leaves two inches long, emarginate, sometimes with a minute point. Flowers about 20 in a cluster, the size of lily of the valley, white, smelling like *jasmine*. Berry as big as a pea, reddish orange. The *Indians* are said by *Jacquin* to make bracelets of the seeds, whence the specific name, and the leaves to intoxicate fish if thrown into the water.

3. *J. aurantiaca*. *Ait. Hort. Kew. ed. 2. v. 2. 6*—Leaves obovate or lanceolate, with spinous points. Clusters of few flowers.—Discovered in the *Sandwich islands* by *Mr. Archibald Menzies*, by whom it was introduced into the *Kew garden* in 1796. It is kept in the stove and flowers most part of the summer. The upper leaves of each branch resemble those of the two foregoing, but the lower ones are smaller and almost lanceolate; every one of them is tipped with a rigid spine. The branches and stalks are slightly downy. Flowers orange-coloured, only three in the cluster of the only specimen we have seen, which is preserved in the *Bankian herbarium*.

4. *J. ruscifolia*. *Linn. Sp. Pl. 271. Jacq. Amer. 54. Ait. Hort. Kew. ed. 2. v. 2. 6.* (*Fruticulus foliis rusci stellatis; Dill. Elth. v. 1. 148. t. 123. f. 149.*)—Leaves all lanceolate, with spinous points. Flower-stalks simple.—Native of *South America*. Found by *Jacquin* in mountainous woods at the *Havannah*, flowering in *January* and *February*.—A rigid shrub, three feet high, with narrow, coriaceous, spinous-pointed leaves, whose form is like the lower leaves of the species last mentioned. The stalks are single-flowered, recurved as the fruit ripens.

A large variety, as it appears to be, of this species, received by *Miller* from *Carthage*, and called by that author in his *Dictionary Ruscus frutescens*, is preserved in the *Bankian herbarium*. Its larger leaves somewhat approach those of the *aurantiaca*, but the flower-stalks are simple.

5. *J. linearis*. *Linn. Sp. Pl. 272. Jacq. Amer. 54. t. 40. f. 1.*—Leaves linear, with spinous points. Flower-stalks simple, reflexed.—Native of the sea-shore near *Port-au-Prince* in *Hispaniola*, bearing flowers and fruit in *January*. *Jacquin*. Much smaller than any of the foregoing, with leaves scarcely more than an inch long. Flowers small, white, inodorous, on slender reflexed stalks.

JACRAH, in *Geography*, a town of *Bengal*; 35 miles S. of *Burdwan*.

JACTITATION of *MARRIAGE*. See *MARRIAGE*.

JACULATOR, or *SHOOTING-FISH*, in *Ichthyology*, is a species

a species of the *chatodon* in the Linnæan system, or the *CHÆTODON Rostratus*; which see.

JACULGONG, in *Geography*, a town of Hindoostan, in Dowlatabad; 18 miles S. of Oudighir.

JACULUM, or JACULUS, in *Zoology*, the name of a species of serpent, (the *ANGUIS Jaculus*;) found in Rhodes, and some other places, and more usually called *Acontias*; which see. It is found in Egypt, with the abdominal scales somewhat broader.

JACULUS. See *DIPUS Jaculus*.

JACUPEMA, in *Ornithology*, the name of a Brazilian bird of the pheasant kind, nearly as large as the common European hens. Its feet are of a fine red; it is a very well tamed fowl, and is easily kept tame. It has its name from the noise it makes, which is, *jacu, jacu, jacu*. Margrave. See *PENELOPE cristata*.

JACURSO, in *Geography*, a town of Naples, in Calabria Ultra; 8 miles W. of Squillace.

JACURUTU, in *Ornithology*, the *Bubo Magellanicus*. See *STRIX Bubo*.

JACUSI, in *Geography*, a town of Japan, in the island of Nippon; 25 miles N. E. of Achila.

JACUT, in the *Natural History of the Arabians*, is generally supposed to be the name of the ruby only; and it is owing to this, that among the gems used by the Arabian physicians in medicine, the ruby is supposed to have been most of all in esteem, as the name jacut oftener occurs in their writings than that of any other of the gems.

JACUT-AGA, is the name of an officer in the court of the grand seignior. He is one of two eunuchs who have the care of the treasure.

JACZIN, in *Geography*, a town of Poland, in Galicia; 3½ miles S.W. of Halicz.

JACZINOW, a town of Galicia; 52 miles S. of Halicz.

JADDESSES, is the name of an inferior order of priests in Ceylon, who have the care of the chapels appropriated to the genii, who form a third order of gods among these idolaters. These priests are applied to by the people in a time of disease or calamity, who offer a cock on their behalf to appease the anger of the demons.

JADE, in *Natural History*. See *NEPHRITIC Stone*.

JADEL, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 20 miles N.W. of Rabba.

JADERA, in *Ancient Geography*, a town and colony of Liburnia, placed by Pliny 160 miles from Pola. We find references to it in the medals of Claudius and Justinian.

JADEVAR, in *Geography*, a town of Hindoostan, in Vissapour; 15 miles S.E. of Raibaug.

JADGEREM, or JAGEROM, a town of Persia, in the province of Chorassan. N. lat. 36° 23'. E. long. 55° 42'.

JADJAPOUR, a town of Bengal; 33 miles S.S.E. of Moorshedabad.

JADISPOUR, a town of Hindoostan, in Bahar; 21 miles W. of Arrah.

JADO, a town of Japan, in the island of Nippon; 5 miles S.E. of Meaco.

JADREKA, in *Ornithology*. See *SCOLOPAX Limosa*.

JADUNATPOUR, in *Geography*, a town of Hindoostan, in Bahar, on the Soane; 20 miles W.S.W. of Rotasgur.

JAEGERSPREIS, a town of Denmark, in the island of Zealand; 22 miles N.W. of Copenhagen.

JAEI, a town of Hindoostan, in the circar of Nagore; 16 miles N.E. of Nagore.

JAEN, a province of Spain, from which the king of Spain takes the title of king of Jaen, whence it is called a kingdom, and having been a kingdom in the time of the

Moors, till it was annexed to the crown of Castile: it is now comprehended under the government of Andalusia, and forms one of its divisions. It is about 60 miles from N. to S. and about as much from E. to W., itself mountainous and surrounded with mountains, which afford mines of lead, copper, and silver, and which separate it from the kingdoms of Cordova, Toledo, Murcia, and Granada. The river Guadalquivir divides it from the kingdom of Seville. The valleys of this province are merely such as have been formed by torrents of water; and the decomposition of the hills, not contiguous or connected, have at different periods produced those gaps and passes, which now form the roads in this petty kingdom, once the domain of a Moorish chieftain, and for a long period the theatre of chivalry, honour, and love. In the centre of this rugged kingdom, about ¼ of a league from the town of Linares, is a small plain situated in the most elevated part of the country, which affords an extensive prospect, comprehending Jaen the capital, as well as Andujar, Baeza and Ubeda. The hills at the extremity of this place are pierced like a sieve, with innumerable shafts and excavations, supposed to be the work of the Moors, from which they supplied the neighbouring states with silver, copper, and lead. The common or wild cummole is so common here, that the whole kingdom might be stocked with it; here is also plenty of game. The principal towns of this small kingdom are Jaen, Baeza, Ubeda, Caçorla, and Cañona.

JAEN, the capital of the above kingdom, is said by some to have been the Oningi of Pliny, and the Oringi of Livy, and, according to others, the Menteiffa of the Romans. It is situated at the foot of a mountain of mixed marble, at the top of which the ruins of its antique castle are visible, a league from the river Guadalbeva, and two from the Guadalquivir. It is surrounded by walls, flanked with towers; contains some squares, one of which is spacious, and is formed by pleasant houses. It is well supplied with water, which is distributed by fountains in the squares, streets and houses. This city is the see of a bishop, suffragan of the archbishop of Toledo: its diocese contains two cathedral chapters, two collegiate chapters, seven arch-priests, and 438 parish churches. Besides the cathedral, which is a noble structure, and parish churches, Jaen has a great number of monasteries and nunneries, and two hospitals. The chapter of the cathedral is composed of eight dignitaries, 21 canons, 21 prebendaries, and 30 priests who serve the church. This city is the residence of the intendant of the province: it has a criminal judge, and a lord mayor for the administration of justice, a municipality composed of a determinate number of regidores, a board of economy, and a population of about 30,000 persons. Jaen was taken from the Moors by Ferdinand II. king of Castile, in 1243. It was formerly rich and commercial, and had a great number of silk manufactories; but these became almost extinct at the end of the 16th and beginning of the 17th century. An attempt was made to revive them about the middle of the 18th century; but few of them are now remaining. The environs of Jaen are extremely agreeable, abounding with delightful fertile valleys, and furnishing great quantities of corn, hemp, flax, pasture, and exquisite fruits. The lands belonging to the town yield the same productions, in still greater plenty: they are particularly planted with trees of every kind, and as there is no deficiency of mulberry trees, the silk-worm is raised; but it is an object very much neglected; 45 miles E. of Cordova. N. lat. 37° 53'. W. long. 3° 51'.

JAEN de Bracamoros, a province of South America, in the viceroyalty of New Granada. It is the most southern of the viceroyalty, and was subdued by Pizarro about the

year

year 1540. In the mountains is found some gold; and the plains produce cotton, excellent chocolate, and tobacco.

Jaen de Bracamoros is also the name of a town, the capital of the above province, which was founded in the year 1549 by Diego Palomino. It is situated in the jurisdiction of Chaca-Inga, on the N. shore of the river Chinchipe, at its conflux with the Maranon, and is the residence of the governor. It lies in about $5^{\circ} 25'$ S. lat. and its longitude is nearly that of Quito. It contains between 3 and 4000 inhabitants, who are for the most part Mestizos, with some Indians, but very few Spaniards.

JAEPOUR. See JYENAGUR.

JAERSBORG, a town of Denmark, in the island of Zealand; 5 miles N.N.W. of Copenhagen.

JAFÄ, a territory of Arabia, surrounded by Aden, some part of the Imam's dominions, and the extensive province of Hadramaut. It is fertile, and abounds particularly in coffee and cattle. It was formerly under the dominion of the Imam; but in the end of the 17th century the inhabitants revolted, and became independent. They are governed at present by three sovereign princes, who have conquered also a part of Hadramaut. These princes are, the sultan of Refles, who resides at Medsjeba, the sultan of Mofaka, who takes his title from the place of his residence, and the sultan of Kara, who resides in a castle upon the mountain of Kara. One of these sultans of Jafa likewise possesses Schahr, a sea-port town, from which incense, inferior in quality to that of India, is exported. Niebuhr.

JAFÄTIN ISLANDS, a cluster of small islands in the Red sea, near the coast of Egypt. N. lat. $27^{\circ} 10'$. E. long. $33^{\circ} 50'$.

JAFERI, a town of Persia, in Chorasan; 75 miles N.N.W. of Badkis.

JAFFA, YAFFA, YAFA, or YAFFÉ, the ancient *Joppa*, was formerly a considerable sea-port on the Mediterranean, and the only port which the Jews had on that sea. It was seated on a high hill, which commanded a full prospect of the sea on one side, and of a fertile country on the other. On the S. it had the town of Jamnia, on the N. Cæsarea Palestina, and on the E. Rama or Ramula. During the holy war, this city, so often mentioned both in the Old and New Testament, was so entirely ruined, that it had scarcely any buildings left besides the old castle, situated on an eminence above it, and another near the sea. The present town has been neatly rebuilt with stone, but on account of the inequality of its situation the streets are paved in steps. It is walled, and has two principal gates and a smaller one; the latter and one of the former yet remain; the other is shut up. It is commanded by an eminence on the N. within musket shot, where Ali Bey, when he besieged it, pitched his camp. Although it has a good wharf, ships cannot come up to it; nor has it any port or secure place of anchorage. This port, which is formed by a pier, and at present choked up, might be cleared out, and made to contain vessels of 300 tons burden each. At present ships are obliged to cast anchor out at sea, at nearly a league's distance from the shore; where they are by no means safe, the bottom being a bank of rock and coral, which extends as far as Gaza. Yafa is the port at which the rice sent from Damietta to Jerusalem, the merchandize for a small factory at Ramla, and the commodities from the various ports on the coast of Syria, are landed. Here also the pilgrims from the Morea and Constantinople arrive; and here the spun cottons of Palestine, and other articles of trade, conveyed by sea, along the coast, are shipped. Although in its present state it does not deserve mention as a sea-port, or place of strength, it is capable of being made one of the most im-

portant on the coast, on account of two springs of fresh water which are within its walls, on the sea-shore, and which enabled it to make an obstinate resistance during the late wars. The air, formerly deemed insalubrious, has, by the draining of some adjacent marshes, been rendered perfectly healthy; and before the two late sieges, it was one of the most agreeable towns on the coast. Its environs were a continued forest of orange and lemon trees, citrons and palms, which here first begin to bear good fruit. The country at a greater distance abounded with olive trees as large as walnut trees: but in the sieges undertaken by Ali Bey and his successor Mahomed Abu-dhahal, the Mamlouks cut them down and used them for fire wood. It has thus lost its greatest convenience and ornament: but it was impossible to deprive it of the rivulets that water its gardens, and nourish the young suckers, which have already begun to shoot. This town has three small convents of Christians, Armenian, Greek, and Roman Catholic, and a few Jews. Yafa is one of the three appanages, or "Melkana," into which Palestine is divided, the other two being Loudd and Gaza. The former belongs to the Walda, or Sultana-Mother; and is held by an Aga, who pays to her 120 purfes. For this he receives the whole miri and poll-tax of the town, and some adjacent villages. But the chief part of his revenue arises from the custom-house, as he receives all the duties on imports and exports. The government is now mild; and the population, gradually increasing, may be estimated at 6 or 7000 souls. Jaffa, in the year 1799, was taken by the French, though not without considerable difficulty and bloodshed, but they held possession only 40 days. According to sir R. Wilson the conquest was followed by a massacre of 3800 prisoners, four days after the surrender of the town; and he informs us that 580 French soldiers, sick in the hospital, were poisoned with opium by command of the French general Bonaparte; 40 miles S. of Acre, and 40 miles N. of Gaza. N. lat. $32^{\circ} 2'$. E. long. $34^{\circ} 53'$. Volney's Travels, vol. ii. Browne's Travels, p. 359.

JAFFIERABAD, a town of Hindoostan, in the country of Berar, and cirar of Aurungabad, 40 miles N.N.E. of Aurungabad. N. lat. $20^{\circ} 22'$. E. long. $76^{\circ} 25'$.—Also, a town of Hindoostan, on the coast of Guzerat, and next to Diu, a place of the greatest trade on this coast. The town is surrounded by a wall for its defence. In a river near this town are found very large oysters. N. lat. $20^{\circ} 56'$. E. long. $70^{\circ} 36'$.—Also, a town of Bengal; 6 miles N.W. of Islamabad.—Also, a town of Oude; 7 miles S.E. of Hajypour.

JAFFIERGUNGE, a town of Bengal; 40 miles E.S.E. of Dacca.

JAFFNA, the capital of the district of Jafnapatam in the island of Ceylon, stands at the distance of some miles from the sea, but communicates with it by means of a river navigable with boats. The river falls into the sea near Point Pedro, where are a fort and harbour. The fort of Jaffna was given up by the Dutch to the British troops, as soon as they appeared before it. It is small, but exceedingly neat and well built. The Pettah, or Black Town, without the walls, which is of a quadrangular figure, is large and more populous than that of Trincomalee. Since Columbo was taken possession of by the English, several Dutch families have quitted it, and taken up their residence in the vicinity of Jaffna; as this latter place is much cheaper and better supplied with all the necessaries of life, several of which are scarcely to be procured in the other parts of the island. The inhabitants of Jaffna consist of a collection of various races. The greatest number consists of Malabars of Moorish extraction, who are divided into several tribes, known by the names of Lubbahs, Belalas, Mopleys, Chittys, Choliars, and a few Brahmins; they

they are distinguished by wearing a little round cap on their close shaven heads. There is also a race of Malabars found here somewhat differing in their appearance from those on the continent. These different tribes of foreign settlers greatly exceed in number the native Ceylonefe in the district of Jaffna. The Malabars are employed in manufacturing cotton, cloths, &c. The Chittys and Lubbahs trade in cloths, calicoes, handkerchiefs, &c. and go backwards and forwards to the continent to carry on this trade. The Lubbahs are Moors and Mahometans. The Belaias are numerous; they are chiefly husbandmen and attend to tillage and rearing cattle. These are extremely litigious and quarrellsome; and, although professed Christians, they observe scarcely any of the ordinances of our religion. They are in some measure Pythagoreans; and say when a child is born lame, blind, or dumb, that it was formerly the soul of a person, who must have deserved this punishment by his actions in a former state. They are extremely superstitious, and attached to many of the rites of Paganism.

The Choliars and Chivias do the hard work; are porters, palankeen bearers, and water carriers; though some are descended from the higher order, and will only carry the great men. The Panias and Pariars are the fishermen, as also the Mokkeuas. The Nallouas are the blackest of all the tribes. They gather the toddy from the cocoatrees, make arrack, tend the cattle, and are labourers and Coolies. The Pariars are accounted the lowest and most despicable. All these in some measure partake of the Ceylonefe customs and habits of life, mingled with their own. They inhabit various parts of the north-west coasts of Ceylon.

At Jaffna there is also a number of handicraftsmen, such as goldsmiths, jewellers, joiners, and makers of all different parts of household furniture. They are very expert in their respective operations; particularly that race known in this island by the name of Portuguese, who surpass all the rest in the beauty and dexterity of their workmanship.

JAFFNOO, a kingdom of Africa, bounded on the N. by Sahara or the great desert, on the E. by Ludamar, on the S. by Kasson, and on the W. by Geduma. N. lat. 15° to 15 40'. W. long. 7° 40' to 9°.

JAFFRAY, a post-town of America, in Cheshire county, New Hampshire, on the S. side of the great Monadnock mountain, six miles N. of the Massachusetts line; incorporated in 1773, and containing 1341 inhabitants. Here are found red and yellow ochre, alum, vitriol, and black lead in great quantities: and also buck-bean or menyanthes, reckoned useful in Medicine.

JAFFRYGUNGE, a town of Bengal; 43 miles N.E. of Purneah.

JAFNA. See **JAMNIA**.

JAFNAPATAM, a district of Ceylon, comprehending an oblong peninsula in the northern extremity of the island, almost cut off from the rest by a branch of the sea, which penetrates across the island, except that a small strip of land remains, which is nearly inundated at high water. This district looks directly towards Negapatam on the Coromandel coast, and is considered as the most healthy in the island: a circumstance which is ascribed to its being surrounded almost on all sides by the sea, by which means the violent hot winds from the continent of India are cooled in their passage. The fields, clothed with verdant pasture, exhibit a convincing proof of the temperate nature of the climate. Fruits, vegetables, game, and poultry abound every where in this district; and it seems that the atmosphere differs in some respect or other from that conti-

guous to other parts of the island; as it is only in the tract which lies between Point Pedro and Jaffna that sheep have been ever reared with success. The articles of commerce produced here are of no great value; the cinnamon and pepper being of an inferior kind to that which grows in the S.W. of the island. Jafnapatam was once a kingdom by itself, but was divided into several provinces. It is very populous, and has a great number of villages and churches, for all the various denominations of its inhabitants. The four lesser provinces contained in it are Beligame, Tennermarche, Waddermarche, and Patchiapalle. The Dutch built a church in 1658 at Telipoli, near a shady and pleasant grove. Several very good villages lie along this district, with churches and school-houses for educating the native children. The passage from Point Pedro to Negapatam on the opposite coast is usually made by boats in a few hours. The king of Jafnapatam built a small fort here against the incursions of the Moors and Malabars. It was taken by the Portuguese in 1620, and lost by them in 1658. This was the last station retained by them in the island.

Dependent upon the district of Jaffna, and at a small distance in the sea to the north-west of Point Pedro, are several small islands, which the Dutch named from their own native cities, Delft, Haarlem, Leyden, and Amsterdam. These islands they employed in breeding horses and cattle, as from their excellent pasture they are better adapted to this purpose than any part of Ceylon. The English government continues the same system. The horses are bred under the superintendance of officers appointed for the purpose, and, when at proper age, are disposed of on account of government. Percival's Ceylon.

JAFRABAD, a town of Persia, in the province of Irak; 20 miles E.S.E. of Sava.

JAG, in *Mining*, signified formerly a drove or number of pack-horses, used for carrying ore, lead, &c.; and hence the carriers of ore for hire in Derbyshire are still called *jaggers*, although carts and waggons have long been substituted for pack-horses in this district. Jag or join of ale, is also a term among the miners here for a quantity of ale sent for by a party of them at their work.

JAGA, in *Geography*, a town of Africa, in the country of Kasson, on the south side of the Senegal. N. lat. 14°.

JAGA Calanda, a town of Africa, in the kingdom of Matamba; 70 miles N.W. Sta. Marin de Matamba.

JAGA Cocoda, a country of Africa, S. of Benguela.

JAGAMI, a town of Japan in the island of Niphon, 80 miles N.W. of Meaco.

JAGANABATTA, a town of Bengal, 42 miles S.W. of Burdwan. N. lat. 22° 35'. E. long. 87° 50'.

JAGANATH, in *Hindoo Mythology*, a name of Vishnu and of Krishna; more generally applied to the latter, who, under the designation of Jaganatha, or lord of the universe, has a very celebrated temple dedicated to him in the territories of the raja of Berar. It is situated in the province of Cuttaek, near the sea-shore in the bay of Bengal, and is annually visited by an immense concourse of pilgrims. It is said that all sects of Hindoos venerate the sanctity of this sacred temple, and resort thither in expiation, by ablutions, prayers, alms, and austerities, of sin, or in the hope of spiritual or temporal advantage; it may, however, be concluded that the pilgrims are chiefly of the sect who exclusively worship Krishna as the deity; which sect is called Gokalaitha; Gokal being another of Krishna's names. The extreme care with which Hindoos avoid eating with an individual of an inferior tribe, or partaking of food so prepared, is a well known fact; but an exception from its generality is said to obtain at Jaganath, where the high and low, the Brahman and the

Pariar, affociate and eat together. In the late war between the English and the Mahratta confederates, this temple, with the greater part of the province in which it is situated, fell into the hands of the former; but of course suffered no profanation: on the contrary, its sanctity was guarded with more than native vigilance; immunities were extended to pilgrims, and their approach to its holy precincts greatly facilitated. A similar policy at the sacred city of Benares has now for many years operated very favourably on the English character. While under Hindoo government, a heavy toll was imposed on the entrance of individuals, and this toll or tax was arbitrary, in reference to the supposed wealth of the visitor. This, as may be supposed, gave rise to much vexation and injustice. Its abolition was a very popular measure, and has contributed, among other causes, to render Benares one of the most populous and wealthiest cities in the world. See **BENARES**.

JAGARESTÉ, in *Geography*, a town of Thibet; 180 miles N. of Fyzabad. N. lat. 29° 38'. E. long. 81° 30'.

JAGARNAUT, a town of Hindoostan, in the province of Cuttack, famous for a grand pagoda, which lies a few miles E. of Chilka lake, and close on the sea-shore. (See **JAGANATH**.) It is an excellent sea-mark, on a coast that is perfectly flat and uniform. It has no claim to great antiquity; but major Rennell supposes, that it succeeded the temple of Sumnaut in Guzerat, which was destroyed by Mahmood in the 11th century.

JAGAS, or **GIAGAS**, savages of Africa, in the kingdom of Congo, (which see,) of whose cruel practices Cavazzi has given an account, that would be hardly credible, if it were not well authenticated. The women often expose their own children to wild beasts. Some of the Jaga princes take pleasure in eating young women, and their favourite dish is a fœtus cut from the womb; and a princess is said to have been so fond of her gallants that she ate them successively. The laws of the Jagas, called "quixillas," present a horrible code of vice and cruelty, being certainly the only rational code ever enacted for these brutal purposes. Their most delicious beverage is warm human blood. Indeed, the cruelty of the Jagas surpasses all description. Queen Zinga tore her own son from her breast, and bruising him in a mortar, formed a horrible banquet, which continued to be made in the same manner of the bodies of babes. Being regarded as a sovereign charm, the Jaga chieftain, Cassangi, used to have a young woman killed every day for his table; and she was often selected, who had passed the night in his bed. Zinga ordered that all her officers, before they proceeded on an expedition, should exercise the conjugal mysteries in public, in the midst of a solemn assembly with the wife or concubine, who was the most favourite object of their love. The slaves among the Jagas die in a certain expectation of a similar but happier existence in another world; and it is esteemed an act of generosity to kill a beautiful female at the tomb of a friend: the Singhillas, or priests and magicians, are singularly despotic, and while they enforce the laws on others, esteem themselves free from their observance. As after a battle the bodies are claimed, each warrior is understood to wound in a particular part that he may select his prey. The women, by the account of the author above cited, are as ferocious as the men, and delight to cleave the skull and suck the warm brains of the slain. Five or six strong men will at once destroy and share a captive, by cutting where their portions begin, and tearing him in pieces. But the above relation affords a sufficient specimen of their savage manners and conduct.

JAGERNDORF, in *Geography*, a principality of Silesia, originally part of Troppau, and now established as a distinct

principality in favour of duke Nicholas V: but ceded, at the peace of Berlin in 1742, by Maria Theresa, queen of Hungary and Bohemia, to Frederick II. of Prussia.—Also, the capital of the above principality, situated on the Oppa, containing two churches and a convent; 12 miles N.W. of Troppau. N. lat. 50°. E. long. 17° 40'.

JAGERSBURG, a town of Brandenburg, in the New Mark; 15 miles E. of Arenswald.—Also, a town of Hesse-Darmstadt; 13 miles S.S.W. of Darmstadt.

JAGHAUS, a town of Germany, in the Tyrol; 14 miles N.W. of Schwaz.

JAGHIRE, a term in India, which denotes a grant of land from a sovereign to a subject, revocable at pleasure; but generally, or almost always for a life rent. Hence are derived "jaghiredars," or holders of jaghires: their titles to their possessions being nominally during their life-time only, though some of them in the Mahratta state have long since become hereditary. This term "Jaghire" is applied to the East India company's lands in the Carnatic, extending from Madras to the Pullicate lake, northward; and to Alem-parvé, southwards; and westward, beyond Conjeveram: that is, about 108 British miles along shore, and 47 inland, in the widest part. This Jaghire is understood to be held in perpetuity. It contains about 2440 square miles; and its revenue is reckoned at about 150,000*l.* per annum.

JAGIPOUR, a town of Hindoostan, in Bahar, on the left bank of the Ganges; 48 miles E.S.E. of Hajypour.

JAGNEVO, a town of European Turkey, in Servia; 8 miles S. of Pristina.

JAGNIDE, *Ital.* See **HYAGNIS**.

JAGO, in *Geography*, a town of Africa, in Guinea, on the river Formosa; 70 miles from the sea.

JAGO, *St.* the capital of the kingdom of Chili. See **SANTIAGO**.

JAGO, *St.* a town of the island of Cuba, which was formerly its capital, but of late much reduced from its former splendour, is situated at the distance of 269 leagues from Havannah, in a hilly country, subject to slight earthquakes. It lies near the south coast, on a bay, about six miles from the sea: the haven is spacious and secure, the entrance being by a channel two leagues in length, defended by a castle at the extremity. The women are regarded as the most handsome in the island. It is the see of a bishop, suffragan of St. Domingo. N. lat. 20° 15'. W. long. 75° 32'. See **CUBA**.—Also, a town of Mexico, in the province of Guaxaca; 45 miles E.S.E. of Guaxaca; which see.—Also, a river of Mexico, which runs into the Pacific ocean, N. lat. 22° 30'. W. long. 106°.—Also, a town of New Mexico, in the province of New Leon.—Also, a town of California; 120 miles W. of Loretto.—Also, a town of Paraguay; 154 miles S. of Assumption.—Also, a river of Peru, which runs into the Pacific ocean, N. lat. 1° 20'.

JAGO, *St.* or *Santiago*, the chief of the Cape Verd islands; it is one of the most fertile and best cultivated, about 40 British miles in length, by 20 in breadth. Although it has many mountains, it has been reckoned the most unhealthy of these islands. The people are generally black, or of a mixed colour; a few of the better rank excepted. The principal production of this island is cotton; and the chief fruits are grapes, plantains, citrons, lemons, oranges, musk and water melons, limes, guavas, pomegranates, quinces, custard-apples, papas, and other tropical fruits. Its animals are cows, horses, asses, mules, deer, hogs, goats, and black-faced monkeys with long tails. Of the feathered birds there are cocks, hens, ducks, Guinea hens, parroquets, parrots, pigeons, turtle-doves, crab-catchers, curlews, and many of them valuable for their plumage. The population of this

island is estimated at about 12,000 persons. When it was visited by sir George Staunton in November, 1792, in his voyage to China, the island was in a state of absolute famine. Little or no rain had fallen there for three years before, the rivers were almost entirely dry: the surface of the earth was in general destitute of any herbage; the greatest part of the cattle had already perished, not less through drought than want of food. Of the inhabitants many had emigrated, and many were famished to death. The plains and fields, formerly productive of corn, sugar-canes, or plantains, nourished by regular falls of rain, now bore little semblance of vegetation. Of the island of St. Jago, the south-west side only had any appearance of volcanic formation. About two miles from Praya bay is a very high hill, altogether composed of clay and sand, on which appeared not the least marks of the action of fire. About six miles, near the road, from the town of Praya to that of St. Jago, is another hill, almost entirely composed of rich iron stone, of a deep blue or purple colour, formed of clay, calx of iron, and siliceous earth. In the rocks opposite the governor's house, near Praya, are several narrow perpendicular veins of white spar. The beach is covered with a fine siliceous sand. The Portuguese maintain no force at St. Jago, capable of insuring a proper respect to their flag there; and so far are they from drawing any revenue from the place, that supplies are sent to it from Portugal. A trade for slaves from Africa is established at St. Jago; and that trade is a monopoly to the crown. The governor derives his chief profit from the sales of cattle to the ships which call there; and of the amount of these sales he claims a moiety. Such is the state of the inhabitants, that they altogether depend for a supply of whatever their own island cannot afford, upon vessels casually stopping there. They set little value upon money, which might long lie useless in their hands; preferring to barter whatever they have to sell, for a return, principally of corn or clothing, rather than any quantity of specie that would be offered to them. The water obtained here is neither good nor easy to be had. The chief towns are St. Jago and Praya. N. lat. 15° 4'. W. long. 23° 40'.

JAGO, St., Ribera, or Riveira, a town of the above-mentioned island, and formerly its capital, is situated in the bottom of a vale, between an elevated plain, on the boundary of which is a fort in ruins, which was originally designed to defend the steep descent towards the town, and a high hill opposite to it. This vale seemed to have been scooped out by the force of a violent torrent, rolling along with it great rocks which stood in its passage, and emptying itself with them into the sea. There a small, irregular, and unsafe harbour was formed by these rocks, while the current itself is diminished into a stream, so small and sluggish, that it cannot clear its mouth from the sands which the tide throws in, and by which it is almost choked up. On each side of this little stream are remains of dwellings of considerable solidity and size; and the fragments of glass lustres, still hanging from the ceilings of the principal apartments, denote the elegance or riches that were once displayed in this now deserted place. It had formerly 300 houses built of rough stone, a church, and a convent. But sir George Staunton, who visited it in his "Embassy to China" says, that not above half a dozen families remained in it; the rest had abandoned it, or perished. He adds (vol. i. p. 135.) here was still, however, an attempt at a slight manufactory of striped cotton slips, the same as are made in other parts of the island, for the use of the Africans on the Main, who pay for them in slaves, elephants' teeth, and Arabic gum. The governor now resides at Porto Praya, which is frequented by the ships that, for commercial or other purposes, touch at this island. See PORTO PRAYA.

JAGO de los Caballeros, St., a town of the island of Hispaniola; 90 miles N. of St. Domingo. N. lat. 19° 36'. W. long. 70° 52'.

JAGO de Compostella, St. See COMPOSTELLA.

JAGO del Estero, St., a town of South America, capital of the country of Tucuman, and see of a bishop; situated on the banks of the Dolce, which is here large and navigable for vessels of burthen, and which affords great plenty and variety of fish. The town contains about 300 houses, or 500 families, and is destitute of walls, ditch, or other fence. The inhabitants are mostly mestizos and mulattoes, of a dark yellow complexion, indolent and sickly from the heat of the climate, and more addicted to pleasure than labour. Surrounded with forests, and situated on a plain, the town suffers from a stagnation of air. It has hardly 300 men fit for bearing arms. The women, who are generally handsome, are troubled with swellings or wens in the throat. The adjacent country produces plenty of wheat, rice, barley, and all sorts of fruits, particularly figs and raisins. The forests, which yield abundance of game, are infested with tigers and other beads of prey; 650 miles N.N.W. of Buenos Ayres. N. lat. 27° 46'. W. long. 65° 12'.

JAGO de Gutagaya, St., a town of Peru, in the diocese of La Plata, and chief town of the jurisdiction of Chicas, under the government of Buenos Ayres; 80 miles S. of Potofi.

JAGO de Leon, St., See CARACCAS.

JAGO de los Montanas, St., a town of South America, in Quito; 10 miles N.W. of St. Francisco de Borja.

JAGO Sanabes, St., a town of South America, in the province of Buenos Ayres, on the Parana; 25 miles S. of Corrientes.

JAGO de los Valles, St., a town of Mexico, in the province of Gualteca, on the river Panuco; 60 miles S. of Panuco. N. lat. 22° 40'. W. long. 100° 36'.

JAGO de la Vega, St. See SPANISH TOWN.

JAGO de Veragua, St., a town of Mexico, and capital of Veragua, situated in a fertile country, abounding with maize, plantains, &c. and plenty of cattle. It contains an elegant hospital, and is the seat of a governor, whose authority extends over 14 towns and villages; 110 miles S.W. of Porto-Bello. Nat. lat. 8° 40'. W. long. 81° 46'.

JAGO, St. Military Order of. See ST. JAMES of the Sword.

JAGODINA, in Geography, a town of European Turkey, in Servia, on a small river, which runs into the Morava; 60 miles S.E. of Belgrade. N. lat. 45° 15'. E. long. 20° 56'.

JAGOLEEAH, town of Bengal; 21 miles N.N.E. of Calcutta.

JAGOTPOUR, a town of Hindoostan, in Oude; 16 miles N. of Manickpour.

JAGOVAT, a town of Persian Armenia; 12 miles N. of Erivan.

JAGRA, or *JAGGERY*, a name given to a peculiar species of sugar, prepared from the cocoa-nut. This is prepared in Ceylon from a liquor called "toddy," procured, by incision, from the top of the tree where the leaves shoot up; a slit is made in this part of the tree with a knife over night, and a "chatty," or earthen pot, suspended from the branches so as to receive the juice, which immediately begins to distil, and continues to do so till next morning, when the pot is removed. This liquor, when drank before the heat of the rising sun has caused it to ferment, is very wholesome and cooling, and operates as a gentle purgative. But upon being fermented it becomes intoxicating; and in this state is well known to the European soldiers, who use it in large quantities when they cannot procure the arrack distilled from it. Arrack in Ceylon is wholly made from toddy, and whole woods of

the cocoa-tree are employed for the purpose of procuring it. A barm or yeast arises from this process, equal to that which is procured from our malt liquor employed in the preparation of whisky. The toddy is likewise made into vinegar, and yields a species of coarse black sugar known by the above name.

JAGRA, or *Giarra*, in *Geography*, a country of Africa, producing plenty of rice, cotton, and corn, a little S. of the river Gambia; about 50 miles from the sea.

JAGRAH, a town of Hindoostan, in the circar of Nagore; 15 miles N. of Nagore.

JAGRENATPOUR, a town of Bengal; 10 miles N.W. of Purneah.—Also, a town of Bengal; 20 miles W. of Islamabad.—Also, a town of Hindoostan, in Bahar; 65 miles S.S.E. of Hajypour.

JAGUA, a town of the island of Cuba; 85 miles W.S.W. of Havannah.

JAGUACAH-GUACU, in *Ornithology*, the name of a Brazilian bird of the king-fisher kind, called by the Portuguese *papa péixe*. See *ALCEDO Alcyon*.

JAGUARA, in *Zoology*. See *FELIS Onca*.

JAGUARACA, in *Ichthyology*, the name of a Brazilian fish, in many things resembling the scorpius of the Mediterranean. It is of the size of the fresh-water perch, and its mouth is very large, but without teeth. It is caught among the rocks, and is a very well tasted fish. Margrave.

JAGUARETE, in *Zoology*. See *FELIS Dicolor*.

JAGUILMA, in *Ornithology*, a species of *Pittacus*; which see.

JAIL. See *GAOL*.

JAIL-Fever, in *Medicine*. See *FEVER* and *TYPHUS*.

JAHANABAD, in *Geography*, a town of Bengal; 20 miles S. of Burdwan. N. lat. 22° 55'. E. long. 87° 55'.

JAHANAGUR, a town of Bengal; 10 miles W. of Kishenagur.

JAHEDHIANS, a sect of Mahometans, the followers of Amru Ebn Bahr, surnamed Al Jahedh, a great doctor of the Môtazalites, and much admired for the elegance of his compositions, who differed from his brethren in imagining that the damned would not be eternally tormented in hell, but would be changed into the nature of fire, and that the fire would of itself attract them, without any necessity of their going into it. He also taught that if man believed God to be his Lord, and Mohammed the apostle of God, he became one of the faithful, and was obliged to nothing further. Of the Koran, he used to say it was a body, which might sometimes be turned into a man, and sometimes into a beast; seeming to agree with the notion of those who assert the Koran to have two faces, one of a man, the other of a beast; thus probably intimating the double interpretation which it will admit of, according to the letter, or the spirit.

JAHI, in *Geography*, a town of Asiatic Turkey, in Nalolia; 16 miles N.N.E. of Angura.

JAHNU, in *Hindoo Mythology*, is called the father of the Ganges, from an extravagant story of an austere sage, named Jahnu, having been disturbed at his devotions by the intrusion of the river. In anger he swallowed the whole stream, but, relenting, poured it forth again from an incision in his thigh, or, according to others, from his ear. Ridiculous as this wild story may seem, it has probably some historical allusion, for it is generally admitted that both the history and science of the Hindoos are veiled in mythological fables, taken literally by the people, the Brahmans only possessing a knowledge of their real import. This fable of Jahnu is frequently alluded to in Hindoo writings, and affords considerable scope for poetical exuberance. Moor's Hindoo Pantheon.

JAHNUVI, a name of the river Ganges, or Ganga, as it

would be more properly written. The river obtained this appellation, which means the offspring of *Jahnu*, from the circumstance above mentioned.

JAHUPICE, in *Geography*, a town of Poland, in the palatinate of Braclaw; 48 miles S.E. of Braclaw.

JAICZA, a town, with a castle, of European Turkey, in Bosnia, near the river Pliva; 26 miles S. of Banjaluka.

JAICZI, a town of Great Bucharia, on the Jihon; 36 miles S. of Bokhara.

JAIMINI, in *Philosophy*, the founder of a school in India, professing tenets similar in many parts to those taught by Socrates. Jaimini inculcated the unity of the deity, rejecting the stories, so generally received by many sects of Hindoos, of the incarnations of deities. He maintains that the great powers and attributes of the deity Brahma, Vishnu, and Siva (personifications, of creation, preservation, and destruction), were men, who, through righteousness, attained a high degree of perfection, and were endowed by the deity with qualities approaching to his own attributes. His followers call this doctrine Purva Mimansa, distinguishing it from another branch of Jaimini's philosophy called Vedanta, between which discrimination is not easy. (See *VEDANTA*.) Mimansa is the general name for the philosophy of Jaimini, which is upheld by many learned Hindoos. It teaches the eternity of the elements, and of the universe; that bodies are only a compound of atoms, and not produced from one substance; that man is a free agent; that rewards and punishments hereafter differ in degrees, according to virtue or sin. The transmigration of the soul is also a tenet in the Mimansa philosophy. See *MIMANSA*.

JAINA, the founder of a sect, whose tenets have spread very extensively over India. By some authors the sect of Jaina, or Jina, as it is sometimes written, is supposed to be a subdivision of that of Budha, or Boodha (see *BOODHA*), while others contend for its originality and antiquity over most other of the sects into which the Hindoos are theologically subdivided. Between the Jainas and the Brahmans, a degree of malignity appears to have existed formerly, greater than is now any way discernible. Abu'l Fazel, in the *Ayin Acbaree*, a work written about the year 1600, A.D. has the following passage: "From the most ancient times down to the present, the learning and wisdom of Hindoostan have been confined to the Brahmans and the followers of Jaina; but ignorant of each other's merits they have a mutual aversion. Krishna, whom the Brahmans" (of his own sect, he should have added, for it is not true of them universally) "worship as God, the Jainas consider as an infernal slave; and the Brahmans carry their aversion so far as to say, that it is better to encounter a mad elephant than to meet a man of this persuasion." This mutual malignity led to the horrible excesses of religious persecution, inflamed by the jealousy of rivalry, and the baser feelings of hatred and revenge.

In these conflicts the Jainas are related to have suffered most disastrously from the superior prowess and address of the Brahmans and their adherents, who destroyed the temples, books, &c. of their ill-fated opponents, expelling the remains of the sect to the confines of India. Such, however, is the tenacity of heresy, cemented, as it were, by persecution, that the followers of Jaina are now found to have re-established themselves in the more central parts of the peninsula of India, where the mildness of their manners and tenets appears to gain them proselytes and respect. It is, however, on the western coasts of the hither peninsula that this interesting people have of late been most noticed by travellers. In the provinces of Kanara and Myore, particularly in the former, Jainas in considerable numbers now freely

freely practise the ceremonies of their religion, and unmo-
 lested indulge in their whimsical, and extravagantly inoffensive
 propensities. Their leading tenet is "the sin of depriving
 any animal of life," and in obedience to this humane pre-
 cept, they not only abstain wholly from animal food, but
 some among the stricter individuals will not drink water
 until it hath been boiled; it being deemed less criminal to
 kill the animalculæ than to destroy them in their stomachs.
 Others carry a broom to sweep the ground on which they
 tread or sit, lest they inadvertently crush an insect. The
 Jainas are the sect who endow the hospitals for animals and
 reptiles, that have attracted the attention of several tra-
 vellers. These hospitals are called Pinjri-pala, meaning an
 enclosure of protection, and afford it to almost every de-
 scription of animal, monies more especially; weevils and
 other diminutive reptiles are nursed in these receptacles of
 ill-directed charity. The Jainas are deists in doctrine; they
 worship one supreme being under the denomination of Ar-
 hang Paramatma, which in the Sanscrit language means
 the supreme soul; they reject the polytheism and incar-
 nations of the orthodox Hindoos, but they honour, almost to
 deification, twenty-four holy persons whom they call Ary-
 huntas, of whom images are made and placed in their tem-
 ples. Of these Aryhuntas, or Tirthunkaras, as they are
 otherwise denominated, Rishaba Deva is the first in point
 of time and veneration. To him are ascribed the existing
 books of their laws, religion, and morals: of these sacred
 persons and books lids are given, with many curious par-
 ticulars respecting the Jainas of Guzerat, in Moor's Hindoo
 Infanticide. All the Aryhuntas have the common deno-
 mination of Deva, meaning divine, or God-like, appended
 to their names. Among the Jainas the division into tribes
 or *castes* is not observable as among other Hindoos; Yati
 and Sravaka being their only distinctions. The former are
 a sort of priest, or rather spiritual preceptor, who read and
 expound to the Sravakas or laity, the Sastras or scriptures
 of the Jaina faith. The Yatis are devoted to religion from
 their infancy, and are admitted to this distinction after a due
 course of study and piety. They profess celibacy and ab-
 stinence, reciting a verse said to comprize their duties:
 "that person who keeps his five senses under subjection is a
 Yati;" this denotes the Yati with the Jainas to be equi-
 valent to a Saniasy among the orthodox Hindoos. (See
 SANIASY.) The Yati lives by charity; he may not dress
 his food himself, nor eat while the sun is below the horizon;
 roots of all sorts, honey and butter unclarified, are prohi-
 bited; all kinds of grain, vegetables, and fruit, produced
 above ground, with milk and ghee, or butter clarified, are
 lawful food. The Yati is supposed to have renounced the
 world and all sensual gratifications; he affects a contempla-
 tive indifference, performing no offices of mourning or re-
 joicing. The Yati performs no religious rites; he is merely
 an ascetic and spiritual guide. The Sravakas resort to
 some sects of orthodox Brahmans for the performance of
 marriage, funeral, and other ceremonies. See SRAVAKA
 and YATI.

The Jainas, like the other Baudhas, or adherents of Budha,
 are addicted to gigantic sculpture. In the province of
 Kanara is a colossal figure of Jaina-deva, of a magnitude un-
 equalled perhaps by any now in existence. Of this statue
 major Moor has given a description and a plate in his Hindoo
 Pantheon. It is upwards of seventy feet in height, and
 being situated on an eminence, called Indra-giri, or the hill
 of Indra, is seen in all directions from a distance of twelve
 or fifteen miles. Major Moor's print is taken from a sketch
 in the collection of lord Wellington, who has visited the
 statue, and judged that the hill on which it now seems to

stand, was once considerably higher, and that it has been
 cut away, leaving only the figure; a mode of sculpture
 similar, although under different circumstances, to the sub-
 terranean excavations of Elephanta, Kenoreh, and other
 temples. It is, major Moor observes, difficult to conceive
 how in any other mode such a mass of stone could have been
 so situated, its magnitude precluding the supposition of con-
 veyance and erection. Other colossal figures of the Jainas
 of Kanara are described and represented in the Hindoo Pan-
 theon; also a very beautiful obelisk, 52 feet in height, the
 shaft of one stone, in front of one of their temples, indi-
 cating a degree of taste and refinement in architectural sci-
 ence, that could scarcely be expected under the political
 and theological discouragements to which the persecuted
 Jainas are believed to have been subjected. One singularity is
 strikingly observable in all the images, colossal or dimi-
 nutive, of the Baudhas and Jainas; they have woolly frizzled
 heads, and many of them thick lips; such as might be
 expected in Africa, but altogether dissimilar to the features
 and lank hair of the Hindoos. See on the subject of this
 article Asiatic Researches, vol. ix. Moor's Hindoo Pan-
 theon. Moor's Hindoo Infanticide.

JAINAD, in *Geography*, a town of Hindoostan, in the
 circar of Mahur; 38 miles N. of Neermul.

JAIRE, Str. a town of France, in the department of
 the Leman; 15 miles S.E. of Geneva.

JAK in *Jakko*, a town of Africa, on the Ivory coast.

JAKA, a kingdom of Africa, 500 miles from the sea,
 with a capital of the same name, on the S. side of the Se-
 negal.—Also, a town and district of Africa, on the Ivory
 coast.

JAKAI, a town of Circassia; 45 miles W. of Eski-
 kefek.

JAKIN, a town of Africa, in the kingdom of Adra,
 on the Slave coast, where the English and Dutch had fac-
 tories, till they were driven away by the king of Dahomy.—
 Also, a river which separates the country of Adra from
 Benin, and runs into the sea at Grand Popo.

JAKIRA, a town of Africa, on the Slave coast; 10 miles
 S. of Assom.

JAKOBHAVN, a Danish settlement in Greenland.

JAKOWIZINA, a town of Russian Poland, in the pala-
 tinate of Braclaw; 36 miles W.N.W. of Braclaw.

JAL, a town of Persia, in the province of Mecran; 210
 miles N. of Kidge.

JALA, a small island in the Atlantic, near the coast of
 Africa. N. lat. $11^{\circ} 45'$.

JALAC, a town of Nubia, at the conflux of the Ta-
 cazé and Nile; 240 miles S. of Sennaar. N. lat. $17^{\circ} 50'$.
 E. long. $34^{\circ} 10'$.

JALALABAD, a town of Candabar, in the country
 of Cabul, on the river Kameh; 60 miles E.S.E. of Cabul.
 N. lat. $34^{\circ} 6'$. E. long. $69^{\circ} 45'$.—Also, a town of Hin-
 doostan, in the circar of Schaurunpour; 26 miles from
 Schaurunpour.

JALALGUNGE, a town of Bengal, and principal place
 of the province of Bajoohow; 25 miles N.N.E. of Goragot.
 N. lat. $25^{\circ} 28'$. E. long. $82^{\circ} 30'$.

JALALPORUM, a town of Hindoostan, in the circar
 of Schaurunpour; 20 miles N.N.W. of Merat.

JALAMLAM, a town of Arabia; 35 miles S. of
 Mecca.

JALANGHI-LIMAN, a town of Asiatic Turkey, in
 Natolia; 12 miles S. of Smyrna.

JALAP, in the *Materia Medica*, so called from the name
 of the country, viz. Chalapa, or Xalapa, a province in New
 Spain, between La Vera Cruz and Mexico, whence it is
 brought,

brought, the root of a species of the convolvulus, or the convolvulus with variable leaves, foot-stalks with single flowers, and a tuberous root. Botanists have differed much with respect to the official jalap plant; Linnæus, following Cluſius, Plumier, Tournefort, and others, first referred it to the *Mirabilis*; but in the second edition of his *Materia Medica*, he adopts the opinions of Ray and Müller, in considering it a convolvulus; and, indeed, after the account given of this plant by Dr. Houlton, no reasonable doubt can remain on this subject.

The mechoacan and this are reckoned of a species; and therefore as this is sometimes called *mechoacana nigra*, that goes as often by the name of *jalapium album*.

As jalap does not appear to have been known to the ancients, it has its place in medicine only since those parts of America, which produce it, have been traded to by the Europeans. It is said to have been first brought to Europe about the year 1610.

The jalap roots are brought over in thin transverse slices, and also whole, of an oval shape, solid, hard, and heavy; of a blackish colour on the outside or cortical part, and internally of a dark greyish, with several black circular striæ; the hardest, darkest coloured, and those which have the most of these resinous veins, are the best. This root has scarcely any smell or taste; but to the tongue and the throat it manifests a slight degree of pungency.

The medicinal activity of jalap resides principally, if not wholly, in the resin, which, though given in small doses, occasions violent tormina. The gummy part bears an inconsiderable proportion to the resinous, and is found to have little or no cathartic power, but as a diuretic it is extremely active.

In doses of a scruple, or half a dram, it is an effectual and safe purgative, very rarely occasioning any severe gripes or nausea. Jalap is an excellent purgative in dropical and other cases, in which serous humours are to be evacuated. Jalap, in large doses, or when joined with calomel, is recommended as an anthelmintic and a hydragogue; and from its general efficacy in dropics was called "*Panacea Hydropticorum*." Hossman thought it particularly improper and unsafe to administer this medicine to children; but Dr. Cullen observes, that if jalap be well triturated before exhibition with a hard powder, and the crystals of tartar are the fittest for the purpose, it will operate in lesser doses than when taken by itself, and at the same time very moderately, and without griping. Except, he says, when given in very large doses, I have not found it to be heating to the system; and if it be triturated with a hard sugar, it becomes, in moderate doses, a safe medicine for children, which in this form they will readily receive, as the jalap itself has very little taste. But it should not be administered, says Geoffroy, in acute fevers, nor to persons of dry and hot constitutions; for in such cases, it is liable to the same mischiefs as other acid purgatives, and will sometimes bring on heat and inflammations in the viscera.

The preparations of jalap in use with us are a tincture, an extract, and a resin. The tincture is made by macerating eight ounces of jalap root powdered in two pints of proof spirit for 14 days, and straining. The extract is prepared by first drawing a tincture from the powdered root with rectified spirit, in the proportion of a pound of the root and four pints of the spirit, macerating the root in the spirit for four days, and pouring off the tincture; then boiling the residuum in ten pints of water, until it be reduced to two pints; then strain the tincture and decoction separately, and let the former be distilled, and the latter evaporated until each begins to grow thick. Lastly, mix the extract with

the resin, and reduce it to a proper consistence. Let the extract be kept in a soft state fit for forming pills, and in a hard state so that it may be reduced to powder. This extract may be taken by itself in doses of twelve grains, or more. Jalap root, digested in as much rectified spirit as will cover it to the height of about four fingers, gives out the greatest part of the resinous matter in which its activity resides, and tinges the menstruum of a yellowish brown colour. On inspissating the filtered tincture to about one-half, and adding to the remainder a proper quantity of water, the liquor becomes milky, and on standing deposits the pure resin. This preparation, by itself, irritates and gripes much, without proving considerably purgative; but thoroughly triturated with testaceous or other powders, or with soap, or ground with almonds, or powdered gum arabic, and made into an emulsion with water, or dissolved in rectified spirit, and mixed with a proper quantity of syrup, that the solution may bear being diluted with watery liquors without precipitation, it purges, in doses of eight or ten grains, as effectually, and, for the most part, as mildly as the jalap in substance. Lewis's *Mat. Med.*

The Edinburgh college directs the exhibition of jalap in powder, with twice its weight of crystals of tartar. The dose of the simple powder is commonly from one scruple to two; of the compound powder it may be double this quantity, which is nearly equal to 10 or 15 grains of the extract, or about two drams of the tincture. Woodv. *Med. Bot.*

After all the preparations the chemists have invented for this root, the best way of giving it is in substance. Mr. Bolduc, in his analysis of it, found, that when he separated its saline and its resinous parts, by making extracts of it, first with spirits of wine, and then with water, that the saline or watery extract was much larger in quantity than the other, but that it purged weakly; and that the resinous extract, though it operated in a small dose, was yet a very rough medicine; so that the best way of using them was together, and that nature gave us the medicine ready prepared. *Mem. Acad. Par. 1701.*

However, others have observed, that the extracts of jalap appear preferable to the root in substance, not only on account of the dose being rendered smaller by the rejection of the woody parts, but likewise as being more uniform and certain in strength. Lewis.

Many fraudulent chemists, when jalap is dear, have a trick of putting scammony, which is of itself almost all resin, among it, and sometimes gamboge; by which means they can afford to sell it cheaper than the price it can be honestly made for. But their most curious cheat is in mixing it with the common black resin; two parts of the latter to one of the former. But this may be known by putting it into rectified spirit, which will again dissolve the resin of jalap, but not touch the other. The virtues are the same with those of the root, but it works rougher, because all substances stick to the coats of the intestines, so as to occasion much pain and uneasiness; for which reason this is corrected with sugar, cream of tartar, or the like; by which means it is brought into the same state as nature presents it in the root. For some purposes, indeed, where the form is required to be small, as often in administration to children, this is most convenient. Its dose is from three grains to one scruple.

Jalap possesses a fermenting power in a considerable degree, and is said to be used with this intention by brewers and distillers.

JALAPA, in *Botany*. See CONVOLVULUS and MIRABILIS.

JALASJARVI, in *Geography*, a town of Sweden, in the government of Wafa; 40 miles E.N.E. of Christine-fstadt.

JALEA, a town of Asiatic Turkey, in Natolia; 12 miles S.W. of Adramitti.

JALEH, a kind of raft of a particular construction, used in navigating some of the rivers in India, particularly the Cabul or Kameh, on which some of the emperors have made voyages down this river from the neighbourhood of Jalalabad, 60 or 70 miles below Cabul, to Pafhawur. As no embarkations of the hollow kind are in use, it seems to prove that the navigation is interrupted by rapids; for there can be no doubt but that the body of water in the Kameh is sufficient to carry boats.

JALEMGORY, in *Geography*, a town of Hindoostan, in the circar of Sollapour; 18 miles E. of Sollapour.

JALEMUS, *Ἰαλέμιος*, or JALEMIA, in *Antiquity*, a kind of mournful song used upon occasion of death, or any other affecting accident; such as the Linos was among the Greeks, and the Maneros among the Egyptians. (See *SONG*.) Hence the Greek proverbs had their original, *ἰαλέμιος οὐκ ὀστέρως*, or *ψυχοτερός*, i. e. *more sad or colder than a jalemus*; *ἢ τῆς ἰαλέμιος ἐγχεαπτεός*, *worthy to be ranked among jalemus'es*. Mem. Acad. Inscript. tom. xiii. p. 554.

JALI, in *Geography*, an island in the Grecian Archipelago, about five miles in circuit; four miles S.E. of Stanchio.—Also, a town in the island of Borneo; 70 miles N. of Negara.

JALIGNY, a town of France, in the department of the Allier, and district of La Palisse; 15 miles S.E. of Moulins. The place contains 482, and the canton 8114 inhabitants, on a territory of 280 kilometres, in 12 communes.

JALLA, a town of Hindoostan, in Bahar; 18 miles N.N.W. of Durbungah.

JALLACOTTA, a town of Africa, in the country of Tenda; 10 miles W. of Tenda. N. lat. 13°. W. long. 12° 9'.

JALLAIS, a town of France, in the department of the Mayne and Loire; 7 miles N. of Chollet.

JALLAS, a river of Spain, which runs into the Atlantic, N. lat. 42° 59'. W. long. 9° 12'.

JALLINDAR, a circar of Hindoostan, in the country of Lahore, of considerable extent, between the rivers Setledge and Beyah.—Also, the capital of this district; 30 miles E. of Lahore. N. lat. 31° 16'. E. long. 75° 25'.

JALLOFFS, or YALLOFFS, a people inhabiting an extensive interior territory of Africa, between the rivers Gambia to the south, and the Senegal to the north and east; or between about 14° and 16° N. lat. and 13° and 15° W. long. Of these people little certain is known; but they are represented as of an exceeding black, and more beautiful complexion and more regular features than the inhabitants of the neighbouring countries.

JALONKADOO, an extensive country of Africa, lying between Guinea on the S.W. and Manding on the N.E. and containing either the springs or first courses of the rivers Niger and Senegal, and also of several other streams which form the Boki, Furkoomah, Wonda, Koloro, &c. It is between the parallels of 11° and 12° N. lat. and 6° and 9° E. long.

JALLYNE, a town of Bengal; 20 miles W. of Nagore.

JALOAN, a town of Hindoostan, in the circar of Gohud; 10 miles N.N.E. of Kooch.

JALOAR, a town of the Carnatic; seven miles N. of Ootatore.

JALONITZA, a town of European Turkey, in Wala-

chia, on a river of the same name; 95 miles S.W. of Iffmail.

JALOUR, a large town of Hindoostan, situated on a mountain difficult of access, in the country of Agimere, and circar of Sirowy; 63 miles W.N.W. of Oudipour. N. lat. 25° 15'. E. long. 73° 40'.

JALOWKA, a town of Lithuania, in the palatinate of Troki; 24 miles S. of Grodno.

JALPUG, a lake of European Turkey, in Bessarabia, 30 miles long, and from three to five broad, communicating with the Danube, and receiving water from a river called by the same name at Tabak; 15 miles W. of Iffmail.

JALYSUS, or JALISSUM, in *Ancient Geography*, a town situated on the N.W. coast of the island of Rhodes; founded, according to Herodotus, by the Danaides, and fortified on occasion of the Peloponnesian war.

JAM, a town of Greater Bucharica; 10 miles S. of Samarcand.

JAM, or *Jamb*, in the language of our lead-miners in Mendip, a thick bed of stone, which hinders their work when they are pursuing the veins of ore.

JAMA, in *Geography*, a river of Peru, which runs into the Pacific ocean, S. lat. 9° 10'.

JAMACAI, in *Ornithology*. See *ORIOLOUS Jamacaii*.

JAMADA, in *Geography*, a town of Japan, in the island of Xicoco; 20 miles W. of Ovtli.

JAMADAGNI, in *Hindoo Mythology*, is the father of Parafu Rama, by his wife Runeka. (See *RUNEKA*.) He was a pious Brahman, who, in his retirement, was entrusted by Indra with the charge of Surabhi, the wonderful cow, which granted every desire, hence named also Kam-denu. (See *SURABHI*.) On a particular occasion he entertained the raja Diruj in so magnificent a stile as to excite his astonishment, until he learned the secret of the inestimable animal possessed by his host. Impelled by covetousness, or rather heart-hardened by the gods, who willed the raja's punishment should appear to be the immediate result of that base passion, the raja demanded the cow from the holy Brahman; and on refusal resorted to stratagem and force, which ended in the death of Jamadagni, but not in success with respect to the cow, which disappeared. Jamadagni is stated to be descended from Bhrigu the son of Brahma, and is one of the seven Rishis, the immediate offspring of the creative power. Meor's Hindoo Pantheon. See *RISHIS* and *MENUS*.

JAMADSUKURI, in *Geography*, a town of Japan, in the island of Nippon; 50 miles S.W. of Nambu.

JAMAGA, a town of Japan, in the island of Ximo; 22 miles E. of Udo.

JAMAICA, an island of the West Indies, discovered by Christopher Columbus in his second expedition to the New World, May 3, A. D. 1494, retaining its original name. The early Spanish historians for Jamaica wrote Xay-maca, which in the language of the nation is said to have signified "a country abounding in springs." Columbus having at first named the island "St. Jago," Oldmixon, and some other writers, erroneously suppose that Jamaica was the augmentative of James. It was not, however, till about nine years after its first discovery that he had an opportunity of acquainting himself further with the island; in consequence of a storm which compelled him, on the 24th of June 1503, on his return to Hispaniola from Veragua, to seek refuge in a small harbour on the N. side, called to this day "Don Christopher's Cove." About seventeen years elapsed after the Spaniards had first fixed themselves in Hispaniola before they seem to have entertained any serious design of sending forth a colony to take possession of Jamaica; and the neglect of it was probably owing to its producing
neither

neither gold nor silver. At length, however, Diego, the son of the much injured Columbus, and the heir of his fortunes, instituted a memorable process against his sovereign before the council of the Indies at Seville, and obtained from this court a decision in favour of his pretensions. The council pronounced him hereditary viceroy and high admiral of all the countries and islands discovered by his father. Diego, thus sanctioned in his proceedings by the high authority of this court, embarked, with a splendid retinue, for his government of Hispaniola, to which the king had reluctantly appointed him; determined at the same time to enforce his pretensions. In July 1508 he arrived at Hispaniola, where he found two persons actually invested by the king with two separate governments, that comprehended the whole continent discovered by Christopher Columbus, including also the island of Jamaica. Diego, thus deprived of his rights, strenuously contended for the exclusive privilege of nominating, in particular to the governments of Veragua and Jamaica, the prior discovery of both these countries being a circumstance of universal notoriety. For securing his claim to Jamaica he sent thither, in November 1509, Juan de Esquivel with about 70 men. Under this gallant and equally humane commander, the natives were induced to submit without effusion of blood, and prosecuted their labours in planting cotton, and raising other commodities which yielded great profit. After a few years he died, and was succeeded by governors of a very different character, who contributed to destroy the inhabitants and to desolate the island. Sixty thousand of the wretched natives, on the most moderate estimate, were exterminated by the Spaniards; so that not a single descendant of either sex appeared to be alive when the English took the island in 1655, nor perhaps for a century before that period. It is said, indeed, that a small remnant of the ancient Indians exists on the S. side of the island of Cuba, in a little town called St. Jago de Cuba, or Iwanee, and that these have adopted the manners and language of the Spaniards. Diego Columbus, who died in his native country in 1525 or 1526, left issue three sons and two daughters; his eldest son Don Lewis succeeded to his father's honours and extensive claims; and in 1545, upon a compromise of a contest with the emperor, obtained a grant of the province of Veragua and the island of Jamaica. As he and his brothers died without issue, his sister Isabella, who was married to the Count de Gelvez, a Portuguese nobleman of the house of Braganza, became sole heiress of the Columbus family, and by her marriage conveyed all her rights to the house of Braganza, in whose possession they remained till the year 1640, when they reverted by forfeiture to the crown of Spain, in consequence of the revolution, which placed John, duke of Braganza, on the throne of Portugal. From circumstances recited in minute detail by Mr. Boyan Edwards, it appears that during the protectorate of Cromwell, the Spaniards had been guilty of several aggressions in the West Indies, and that the protector, in seeking redress, manifested a regard to justice by his moderation and temper. An appeal was at length made to force; and a powerful armament was equipped, which miscarried at Hispaniola, but succeeded at Jamaica, which was captured by the English forces in May 1655. At this time the whole number of white inhabitants on the island, including women and children, did not exceed 1500: and not one hundredth part of the plantable land was in a state of cultivation. The number of negroes, who had been first introduced from Africa by the Spanish settlers after they had exterminated the original proprietors, nearly equalled that of the whites, at the time of its capture. The principal exports of the Spanish planters, notorious for their sloth and pe-

nury, consisted, besides cacao, of hog's lard and hides, which supplied the few ships that touched at their ports with provisions, in barter for European manufactures; and this constituted the whole of their commerce. After the capture of the island, until the restoration of Charles II., the English in Jamaica remained under military jurisdiction, although it appears to have been the intention of Cromwell to have established a civil government in the island on very liberal principles. After the restoration of Charles II., the Buccaneers, who resorted to this island, and who contributed by their wealth and industry to its settlement and opulence, received from the king every kind of encouragement and protection; and people of all professions, and from all parts of the British empire, now resorted to Jamaica. In 1661 the king appointed D'Oyley, chief governor of the island; and he was ordered to release the army from military subordination, to erect courts of judicature, and, with the advice of a council, to be elected by the inhabitants, to pass laws suitable to the exigencies of the colony. These events may be considered as the first establishment of a regular civil government in Jamaica after the English had become masters of it. Soon after D'Oyley desired to be recalled, and lord Windsor was appointed in his room with instructions to publish, on his arrival, a royal proclamation, in which, for the settlement of the country, allotments of land were offered under such terms as were usual in other plantations, with such further privileges and immunities as the grantees should reasonably require. The proclamation contained other declarations, which have been always considered, by the inhabitants of Jamaica, as a solemn recognition and confirmation by the crown of those rights which are unalienable from a subject of England, and of which, so long as he maintains his allegiance, emigration for the benefit of the state cannot, and ought not to divert him. These rights and privileges were further secured by the American treaty, concluded and signed at Madrid in the month of June 1670. Such, however, were the want of integrity and steadiness, characteristic in too great a degree of Charles II., that in the beginning of 1678, Jamaica was involved in the troubles of this reign. A new system of legislation was adopted for this island similar to that of the Irish constitution under Poyning's act; and the earl of Carlisle was appointed chief governor for the purpose of enforcing it. A body of laws was prepared by the privy council of England; and a bill was offered to the assembly for settling a perpetual revenue on the crown. In future the heads of all bills (money bills excepted) were to be suggested in the first instance by the governor and council, and transmitted to his majesty to be approved or rejected at home; they were then to be returned under the great seal in the form of laws, and passed by the general assembly, which was to be convened for no other purpose than that and the business of voting the usual supplies; unless in consequence of special orders from England. The assembly rejected the new constitution with indignation. No threats would frighten, no bribes could corrupt, nor arts nor arguments persuade them to consent to laws that would enslave their posterity. In consequence of this opposition, the assembly had their deliberative powers restored to them, and sir Thomas Lynch was appointed captain-general and chief governor in the room of lord Carlisle. The English government claimed a return from the people of Jamaica for having relinquished an oppressive and pernicious project; but the assembly, averse from subjecting their country to a permanent and irrevocable tax, determined to pass their supply bills from year to year, according to their usual custom. The ministry, influenced by a kind of vindictive policy, advised the sovereign to waive the confirmation of the laws, and to

JAMAICA.

suffer the administration of justice in the island to remain on a very precarious foundation. In 1728 a compromise was happily effected. The assembly consented to settle on the crown a standing irrevocable revenue of 8000*l.* per annum on certain conditions, to which the crown agreed. The principal of these conditions are as follow: *viz.* that the quit-rents arising within the island, then estimated at 1460*l.* per annum, should constitute a part of such revenue; that the body of their laws should receive the royal assent; and that all such laws and statutes of England, as had been at any time esteemed, introduced, used, accepted, or received, as laws in the island, should be and continue laws of Jamaica for ever.

Jamaica is situated in the Atlantic ocean, about 4000 miles S.W. of England; having Hispaniola, at the distance of 30 leagues, to the E.; the island of Cuba, about the same distance, N.; the gulf of Honduras, W.; and Carthagena, on the great continent of South America, S. at the distance of 145 leagues. The centre of Jamaica lies in about 18° 12' N. lat., and about 76° 45' W. long. The climate, though much mitigated by various causes, is extremely hot, with little variation from January to December; the days and nights are nearly equal, the longest and shortest day differing no more than about two hours with little twilight; and it is twelve at noon in London, when it is about seven in the morning in Jamaica. The north and south sides of the island, which are separated by a vast chain of mountains, extending from E. to W., differ greatly from each other. Columbus, when he first discovered Jamaica, on the northern side, and perceived that part which now constitutes the parish of St. Anne, was struck with admiration at the novelty, variety, and beauty of the prospect. At a small distance from the shore, the country rises into hills with gentle acclivity, which are separated from each other by spacious vales and romantic inequalities; and is beautifully covered with groves of pimentos, forming by their deeper tints a charming contrast to the verdure of the subjacent turf. The soil is in general a chalky marl, which produces a close turf, as smooth and even as the finest English lawn, and in colour much brighter. No part of the West Indies abounds with so many delicious streams; every valley having its rivulet, and every hill its cascade. On the southern side of the island the scenery is of a different nature; its predominant feature being grandeur and sublimity, whilst the other side presents variety and beauty. Amidst precipices and inaccessible cliffs, however, there are vast plains, clothed chiefly with extensive cane-fields. To the inequalities of surface that distinguish this island, it is owing that, although the soil in many parts of the island is deep and very fertile, yet the productive land is but of small extent, in proportion to the whole. That which is actually cultivated is of a middling quality, and requires labour and manure to make it yield liberally.

Jamaica is 150 miles in length, and at a medium about forty miles in breadth. Calculating from these data, the island, if it were a level country, would contain 3,840,000 acres; but allowing for that great part of it which consists of high mountains, and supposing, at a moderate estimate, the increase on that account to be $\frac{1}{10}$ th more, or 240,000 acres, the total is 4,080,000 acres. Of these no more than 1,907,589 were, in November 1789, located, or taken up, by grants from the crown; and consequently, upwards of one-half of the lands is considered as of no kind of value, the expence of taking out a patent being of no great account; and of the located lands, Mr. Edwards supposes that little more than one million is at present in cultivation. In sugar plantations, including the land re-

served in woods, for the purpose of supplying slaves, timber, and fire-wood, or appropriated for common pasturage, all which is commonly two-thirds of each plantation, the number of acres may be stated at 639,000. Of breeding farms, called "pens," the number is about 400, and allowing to each 700 acres, the whole amount is 280,000; and the space allowed to the minor productions, as cotton, coffee, pimento and ginger, &c. including even the provision plantations, may be estimated at no more than one-half of the extent assigned to the pens. The result of the whole is 1,059,000 acres, leaving upwards of three millions an unimproved, unproductive wilderness. The mountains, however, are generally covered with extensive woods, containing excellent timber; such as the lignum vitæ, log-wood, iron-wood, pigeon-wood, green-heart braziletto, and bully-trees, all of which are to a great degree heavy, as well as compact and impenetrable. Some of these are necessary in mill-work, and would be highly valuable in the Windward islands. Of softer kinds, for boards and shingles, the species are innumerable; and there are many beautiful varieties for cabinet-work; and among these we may enumerate the bread-nut, the wild-lemon, and the well-known mahogany. Jamaica is not only abundantly wooded, but well watered; the number of its rivers being reckoned at above 100. It has also a variety of medicinal springs. Formerly, it is said, the Spanish inhabitants had mines both of silver and copper; but the present occupiers employ their industry more profitably on the surface than in digging into the bowels of the earth. The most important of its present natural productions are sugar, indigo, coffee, and cotton. The several species of grain cultivated in this island are, maize, or Indian corn, producing usually two crops in the year, and sometimes three; Guinea-corn, producing one crop in the year, planted in September, and gathered in January following, yielding from 30 to 60 bushels an acre; and various kinds of calavances, a species of pea; and rice, but in no great quantity. The island abounds also with different kinds of grass, of excellent quality: the artificial grass, called "Scot's grass," grows spontaneously in moll of the swamps and morasses of the West Indies; and it is so productive, that a single acre of it will maintain five horses for a whole year. The "Guinea-grass" is next in importance to the sugar-cane, as the grazing and breeding-farms are chiefly supported by it. Hence arises the plenty of horned cattle, both for the butcher and planter; which is such, that few markets in Europe furnish beef of better quality, and at a cheaper rate, than that of Jamaica. Mutton also is cheap and good. The seeds of the Guinea-grass were brought from the coast of Guinea, as food for some birds which were presented to Mr. Ellis, chief justice of the islands. The several kinds of kitchen-garden productions, that are known in Europe, thrive in the mountains of this island; and the markets of Kingston and Spanish town are supplied with cabbages, lettuces, carrots, turnips, parsnips, artichokes, kidney-beans, green peas, asparagus, and various sorts of European herbs, in the greatest abundance. Other indigenous productions that may be classed among the esculent vegetables, are plantains, bananas, yams of several varieties, calalaa (a species of spinach), eddoes, cassavi, and sweet potatoes. Among the more elegant fruits of the island we may reckon the anana or pine-apple, tamarind, papaw, guava, sweet-sap, cashew-apple, custard-apple, cocoa-nut, star-apple, grenadilla, avocado-pear, hog-plum, pindal-nut, nesbary, mammee, mammee-sapota, Spanish gooseberry, prickly pear, and some others, for which Jamaica is probably indebted to the bounty of nature. For the orange, the lemon, lime, shaddock, vine, melon, fig, and pomegranate, the West India islands are perhaps obliged to their

their Spanish invaders. The cinnamon has been lately introduced, and the mango is become almost as common as the orange. In 1773 a botanic garden was established in Jamaica, and in 1782 its valuable exotics were much increased.

This island is divided into three counties, *viz.* Middlesex, Surry, and Cornwall, which see respectively; and these three counties include twenty parishes, in which are eighteen churches and chapels; each parish being provided with a rector, and other church officers, and the presentation to each living being lodged with the governor or commander-in-chief. The supreme court of judicature for the whole island is held in the town of St. Jago de la Vega, the capital of the county of Middlesex, in which court the chief justice of the island presides, whose office is worth about 3000*l.* per annum. The assistant judges are gentlemen of the island, commonly planters, who receive for their attendance no recompence. From this court an appeal lies in civil actions for 300*l.* or upwards to the governor and council, as a court of error. Assize courts are also held every three months, in Kingston for the county of Surry, and in Savanne-la-Mar for the county of Cornwall. The governor, or commander-in-chief is chancellor by his office, and presides solely in that high department; he is also the sole ordinary for the probate of wills and granting letters of administration. The office of enrollments, or of secretary of the island, which is an office of record, is important and lucrative; it is held by patent from the crown, and exercised by deputation. Its emoluments exceed 6000*l.* sterling per annum. The provost-marshal-general is also an officer of high rank and great authority, and held by patent from the crown. This acting officer is high-sheriff of the whole island, and his legal receipts have been known to exceed 7000*l.* sterling a-year. The office of clerk of the supreme court is also held by patent, and exercised by deputation: some years ago its value exceeded 9000*l.* currency. There are several other lucrative appointments, held by patent or commission; and it is computed that not less than 30,000*l.* sterling is remitted annually by the deputies in office within the island to their principals in the mother country. The legislature of Jamaica is composed of the captain-general or commander-in-chief, of a council nominated by the crown, consisting of twelve gentlemen, and a house of assembly, containing 43 members, who are elected by the freeholders. All bills passed in this assembly have the force of laws as soon as the governor's assent is obtained; but the power of rejection is still reserved in the crown.

The revenues of the island are partly *perpetual* by an act of the year 1728, and partly *annual*, depending on grants of the legislature. The revenue law may raise about 12,000*l.* per annum, of which 8000*l.* is particularly appropriated, and the surplus is applicable to the contingent expences, in aid of the annual funds. The governor receives 2500*l.* per annum out of the 8000*l.* fund: and a further salary of 2500*l.* is settled upon him, during his residence in the island, by a special act of the legislature. The annual funds may amount to 70,000*l.*, of which about 40,000*l.* is a provision for granting an additional pay to the officers and soldiers of his majesty's forces stationed for the protection of the island. The current coins in Jamaica are Portugal pieces of gold, called the half-johannas, valued in England at 36*s.* each; which pass, if of full weight, at 55*s.* Spanish gold coins current are doubloons at 5*l.* 5*s.* each, and pistoles at 26*s.* 3*d.* Silver coins are Spanish milled dollars at 6*s.* 8*d.* and so in proportion for the smaller parts of this coin: the lowest coin is called a *bitt*, equal to about 5*d.* sterling. A guinea passes for 32*s.* 6*d.* The number of white inhabitants was computed

in 1780 at 25,000; but having since increased, Mr. Edwards supposes that, including the troops and sea-faring people, their number may be fixed at 30,000. The freed negroes and people of colour were computed in 1788 at 500 in each parish on an average; which makes 10,000 exclusive of the black people called Maroons. These amount to about 1400. Of negroes in a state of slavery, the precise number in 1787 was 210,894, and including those who are fraudulently not returned, this number may be augmented to 250,000. The whole number of inhabitants of every description is therefore estimated at 291,400. Mr. Edwards reports, from the books of the inspector-general of Great Britain, that the trade of Jamaica, in 1787, employed 400 vessels, containing 78,862 tons, navigated by 8845 men; that the total value of the exports from the island to various parts from January 5th, 1787, to January 5th, 1788, amounted to 2,136,442*l.* 17*s.* 3*d.*; and that the total value of the imports amounted to 1,496,232*l.* 5*s.* 4*d.* or by certain allowances necessary to be made, to 1,648,018*l.* 14*s.* 4*d.* sterling. Jamaica, says Mr. Edwards, had now nearly attained the meridian of its prosperity. The total of sugar plantations in all the parishes of the island are stated by this author to have been, in 1789, 710, and the number of negroes employed in them 128,798. The number of its coffee plantations has very considerably increased; for in 1774 the export of coffee was 654,700*lbs.*, and in 1790, 1,783,740*lbs.* The exports consist of sugar, rum, molasses, pimento, coffee, cotton wool, indigo, ginger, cacao, tobacco, mahogany, logwood, hides, and several miscellaneous articles. The imports consist of British manufactures, foreign merchandize from Great Britain, salted provisions from Ireland, formerly negroes from Africa, salted cod, &c. from the British colonies in America; from the United States, Indian corn, wheat flour, rice, lumber, slaves, &c. in British ships, from Madeira and Teneriffe wine: Mr. Edwards gives the following statement of the value of this island, considered as British property:—250 negroes at 50*l.* sterling each, amounting to 12½ millions; the landed and personal property to which these negroes are appurtenant, (including the buildings,) are moderately reckoned at double the value of the slaves themselves; making 25 millions in addition to the 12 millions 500 thousand before stated; and in further addition the houses and property in the towns, and the vessels employed in the trade, are valued at one million 500 thousand pounds more: amounting in the whole to 39 millions of pounds sterling. Edwards's Hist. West Ind. vol. i.

JAMAICA, a township of America, in Windham county, Virginia, watered by several branches of West river, and containing 263 inhabitants.—Also, a post-town and capital of Queen's county, New York, on the W. part of Long island, containing a Presbyterian, Episcopalian, and Dutch church, an academy, and nearly 100 dwelling-houses: 12 miles E. of New York city; the whole township contains 1661 inhabitants.—Also, a town of Africa, in the island of York, built by a Mulatto, the son of an Englishman, where the English have a factory.

JAMAICA *Pepper.* See PIMENTO.

JAMAICA *Wood.* See BRAZIL.

JAMALGUNGE, a town of Bengal: 42 miles S. S. E. of Dinagepour.

JAMAMA, or IMAM, a town of Arabia, the capital of a district in the province of Ned-sjed, situated on a river, which runs into the Persian gulf, and famous for being the birth-place of a prophet, named Moseilama, who existed before the days of Mahomet. N. lat. 25° 5'. E. long. 46° 8'.

JAMANASSIRO, a town of Japan, in the island of Niphon; 65 miles N. W. of Jedo.

JAMARD, in *Biography*, an ingenious and worthy ecclesiastic, who was, before the Revolution, a canon regular of St. Genevieve, prior of Roquefort, member of the Academy of Sciences, Belles Lettres, and Arts at Rouen; and who published in 1769, at Paris, in 8vo. "Recherches sur la Theorie de la Musique," or an Enquiry into the Theory of Music. The work is purely theoretical, and strictly confined within the limits of harmonics, or division of the musical scale. The author has, unluckily, given offence to the patriotic musicians of France, still exclusive admirers of Lully and Rameau, by the following reflection. "It is astonishing that the Italians, who adhere strictly to no regular system or theory of sound, should compose better music than we do, who are in possession of such excellent principles of harmony;" but M. Laborde, strongly attached to the old school, by no means admits the fact. "In the first place, so far from granting that the Italians produce better music than we (the French) it is certain, on the contrary, that our's, with respect to harmony, is much superior to that of the Italians, and that we allow their superiority in nothing but the musical drama, or opera, which is not tied down to such rules as music properly so called, nor regarded in general as amenable to the laws of counterpoint.

"In the second place, it is necessary to observe, that almost all the Italians compose by rote and by feeling, according to the method of their several schools. Very few of them have ever studied the theory, or have the least idea of the principles on which it is founded. We must allow, however, that this is the case with most practical musicians, they seem to think theory a science totally independent on practice. There is no practice, however, safe or exempt from error but by the knowledge of the principles of harmony, and the rules that flow from those principles. We will allow, if you please, that the Italians are superior to us in melody; but they must grant that we are their masters in harmony, and that we write in a manner much superior to them in accuracy, purity, and elegance." All this is very fine and honourable to France, but will the rest of Europe subscribe to M. Laborde's decisions? and will it be believed that no good music ever has been composed or can be, by persons unacquainted with Rameau's system of the fundamental base? or that all the great masters of Italy who have produced such admirable works were ignorant of harmony? But we must not forget M. Jamard's theory in this discussion. This ingenious author has not only pushed calculation by the division of the monochord into all the diatonic, chromatic, and enharmonic intervals; but to the most minute shades of sound possible; even to the warbling of birds, the sliding the finger up and down the string of a violin, or the incalculable tones of speech. The worst that can be said, perhaps, of this labour is, that its use and application are not obvious. But a serious objection by nice ears will be urged against the author's making so imperfect an instrument as the French horn the guide and umpire of the diatonic scale, of which the 4th and 6th are so intolerably false and out of tune, that "the ploughman whistling o'er the furrow'd land" would not deform his wild melody by such a scale. But though the *whole* system of M. Jamard may be inadmissible and impracticable, as much ingenuity and science are manifested in these calculations as could possibly be expected from a mere mathematician, totally unacquainted with practical music and its effects.

JAMAS, in *Geography*, a town of Japan, in the island of Ximo; 12 miles S.W. of Udo.

JAMATA, a town of Japan, in Nippon; ten miles W.S.W. of Jedo.

JAMBA, in *Ancient Geography*, a town of Asia, in Ba-

bylonia, according to Ptolemy, situated near a marsh towards Arabia Deserta.

JAMBA, in the *Mythological Romances of the Hindoos*. This is the name of a bear with whom Krishna and others of their deified heroes had adventures; ridiculous, if taken literally, but reasonably imagined to be merely a veil for physical or scientific facts. See JAMBAVANTA.

JAMBAVAN, or JAMBHUVAN, the name of a bear exhortated by Vishnu, as related in the legends of the Hindoos, for the purpose of aiding Rama in the wars of Lanka or Ceylon. On this occasion most of the gods and demigods of the Hindoo pantheon were called upon by Vishnu to assist Rama, himself indeed incarnate, against the giant king Ravana, as detailed at great length in that curious poem the Ramayana, by Valmiki, which has not yet been translated. See RAMAYANA and RAVANA.

JAMBAVANTA. In the Sni Bhagavata, or Life of Krishna, allimated by the Hindoos as the eighteenth Purana (see PURANA), a number of adventures are related in which a bear acts a conspicuous part under the name of Jambavanta. In Vishnu's anantara, or incarnation in the person of Rama, a bear likewise under nearly the same name is introduced. Some astronomical allusions are imagined to be hidden under these sylvan allegories. Krishna is the sun, he attacks and overcomes the bear, retiring with the daughter of his adversary: this may refer to the sun's approach to, and receding from, the northern tropic; Jambavanti being, it is supposed, a personification of Urfa major.

JAMBAVANTI, a female bear, daughter of Jambavanta, espoused by Krishna, as related with many similar apparently idle tales, in the Puranas and other romances, sacred and profane, of the Hindoos.

JAMBEAUX, among our *Old Writers*, armour for the legs. The word is French, from *jambe*, the leg.

JAMBEK, in *Geography*, a town of Sumatra, which is the capital of a state, and situated on a large river, both of the same name; the town is distant from the sea on the eastern side of the island about 60 miles. This was formerly a place of considerable note, and both the English and Dutch companies had establishments there. The trade consists in gold dust, pepper, and canes, but it is now esteemed of little importance; the gold being mostly drawn to the western coast across the country. S. lat. 1° 24'. E. long. 103° 39'.

JAMBER, a small island in the Atlantic, near the coast of Africa. N. lat. 10° 21'.

JAMBIA, in *Ancient Geography*, a town of Arabia Felix, on the Arabic gulf, according to Ptolemy. It was situated near the Elanitic gulf.

IAMBIC FOOT, or IAMBUS, in *Metre*, consists of two syllables; the first, short; the second, long ~; as "χ~" *preces, around*.

"Syllaba longa brevi subiecta vocatur iambus,
Pes citus." Hor de Art. Poet. 251.

Several derivations of this word are given by ancient authors, but none of them have much probability. (See Schol. on Hephæstion, p. 157 and 169. edit. Gaisford. Etym. Magn. Sch. on Nicander. Euitath. on Od. 11. p. 1684. Diomedes, p. 473.) The most probable one is from *ἰαμβός*, to aim at, or attack. Aristotle (Poet. § 4. Windstanl.) and Strabo (l. 9. § 10.) derive it from *ἰαμβίζω*, to satirize; but I cannot find that this word was ever used before the invention of iambic verse; or that in later authors it was ever used without some reference to it. When Gorgias said that Plato *καλλῶς ὁδὸς ἰαμβίζω*, he meant that he

IAMBIC VERSE.

could defame as well as a writer of iambics; and with the same allusion he called him *another Archilochus*. (See Athen. 11. 505. d.) The passage in which *ἰαμβοποιήσας* occurs in Aristot. Poet. (§ 22, see Tyrwhitt's note,) has been misunderstood by all his commentators. It should be read *ὄν Ευκλείδης ὁ ἀρχαῖος (δικακάρδης τὸν ποιητὴν) ὡς ῥαδίον ποιῆσαι, εἴ τις ὁλοσύνῃ ἐκτίθειν ἐξ ὁπόσου βολύται· ἰαμβοποιήσας ἐν αὐτῇ τῇ λέξει*; that is, *having made an iambic verse in the very expression*. It is more probable, therefore, that *ἰαμβοποίησις* was derived from the verse, than the verse from it.

Iambic Verse, is that which consisted principally of iambic feet. The Greeks used a great variety of forms of this verse, either separately, or intermixed with other verses. (See Schol. on Hephaest. p. 167.) It was measured by dipodia or double feet. When they used therefore a single iambic foot as a verse, it was called

Iambic Monometer Brachycatalectic, for which was used any foot of two syllables, except a trochee. Soph. *Æd. Col.* 117. 149. *El.* 856. 867. edit. Brunck.

An *Iambic Mon. Catal.* consisted of an amphibrach or a bacchius. (Soph. *Aj.* 873. 897. 1205. *El.* 1237. 1253. *Æd. Col.* 123.) This was sometimes intermixed with iambic trimeters. Soph. *Æd. t.* 1468. *Trach.* 865. *Æd. c.* 1271.

Iambic Monom. called also an *iambic basis*, consisted of two iambic feet; and admitted, instead of the first iambus, a tribrach, or a spondee, or a dactyl, or an anapaest. Eur. *Phœn.* 312. *Or.* 979. *Soph. El.* 127. 1232. *Æsch. Suppl.* 278. *Perf.* 1043. (See Burney's Pref. to *Æsch.* p. 16.) Aristoph. *Nub.* 1103. *Ach.* 276. It is prefixed by Anilophanes (*Eq.* 380. 455. 939.) to an iambic dimeter catal. at the end of a system of iambic dimeters.

Iambic Monom. Hypercat. or *Iambic Penthemimer*, admitted the same varieties in the first foot. Eur. *Hec.* 919. *Soph. Aj.* 599. *Æsch. Perf.* 641. (See Burney, p. 25. and 80.) The last syllable was either long or short.

Iambic Dimeter Brach. admitted a tribrach also in the second foot. *Soph. El.* 857. 1246. *Æd. t.* 667. 696. *Arist. Eq.* 386. *Pind. Ol.* 4. ult. *Pyth.* 8. *Str.* 8. *Isthm.* 7. *Str.* 8. See *Herm. Comm. de Pind. Metr.* v. 3. p. 216. *Heyn.*

Iambic Dim. Cat. called by the Scholiast on Nicander *Heniambic*. (Gaisford, p. 246.) *Soph. El.* 1241. 1262. *Aristoph. Ach.* 1223. He often closes a system of dimeters with this verse (*Eq.* 381. 456. 940.), and often intermixes them. (*Ach.* 1010. 1039.) In the second place he generally preserves an iambus (*Herm. de Metr.* p. 145.); but he has a tribrach in *Ach.* 1039; and an anapaest, *Nub.* 1104. The *Anacreontic verse* is referred by Hephaestion to this metre. It consisted of two different systems; in one of which the first foot was always an anapaest; in the other, either an iambus or a spondee; and in his genuine odes, no other variety was, I think, admitted. The last syllable was common. Both of these have been considered by others as *Ionici a majore*, with an anacrusis of one or two syllables. (See *Herm. de Metr.* p. 348.) This metre occurs with an anapaest in the first place, in Eur. *Cycl.* 493—511. *Soph. Ph.* 1176, 7. *El.* 1067, 8. 1079, 80.

Iambic Dimeter.—The tragedians admitted an iambus or a spondee indifferently in the first and third places of this verse, and a tribrach in the three first, and a pyrrhic in the last (*Soph. Ant.* 853—5. 872—4. 952, 3. 963, 4. *Eur. Or.* 978. 982. *Æsch. Prom.* 159—161. 178—180. *Sept.* 982, et seq. *Pind. Ol.* 4. *Ep.* 3. *Nem.* 1. 1.): but when many of these verses were united together in a system, as was often done by the writers of comedy, the measure was continued to the end of the system; the last syllable, there-

fore, was not common, but the fourth foot admitted the same varieties as the second; according to this scheme,

υ	—	υ	—	/	υ	—	υ	—
υ	υ	υ	υ	/	υ	υ	υ	υ
υ	—	υ	—	/	υ	—	υ	—
—	υ	υ	—	/	—	υ	υ	—

Aristoph. Eq. 367—379. 443—454. 911—938. *Ach.* 1040. 1192. 1209. *Lythist.* 260—3. (*Herm.* p. 144. *Gaisford.* p. 243—5.)

Iambic Dim. Hypercat. *Eur. Or.* 975. *Soph. Ant.* 338. 349. *Æsch. Prom.* 431. *Pind. Ol.* 6. 1. 7. 5. *Bacchylides*, fr. 7. and *Biaf. fr.* 4. *Brunck.* And with an anapaest in the third place. *Pind. Pyth.* 8. *Ep.* 1. The third verse of the *Alcæic ode* was in this metre. Alcæus seems always to have used an iambic in the third seat. See *Bentley* on *Hor. Od.* 2. 19. 15.

Iambic Trim. Brachycat. *Eur. Or.* 976. 1398. 1448. 1451. *Soph. Ant.* 587. *Æd. t.* 1339. *Pind. Nem.* 8. *Ep.* 6.

Iambic Trim. Cat.—This is ascribed to Archilochus by Hephaestion. *Archil. fr.* 24. *Brunck.* *Eur. Phœn.* 301. *Or.* 1365. *Soph. Æd. t.* 865. 889. *Theocrit. Epigr.* 18. *Br. Anal.* Phalæus has an epigram in this verse. *Anal.* 1. 421.

Iambic Trimeter, is the metre of this kind most commonly used; and it consisted of three iambic dipodiae.

“ Iambus ipse sex enim locis manet
Et inde nomen inditum est Senario;
Sed ter feritur; hinc Trimeter dicitur,
Scandendo binos quod pedes conjungimus.”
Terentianus Maurus.

It is so nearly allied to prose, that Aristotle (*Rhetor.* 3. 1. 9. 3. 8. 4. *Poet.* § 4.) and Demetrius Phalereus (§ 43. see also *Cicer. Orat.* § 189) have observed, that many iambic verses were uttered in common conversation; and they are frequently to be met with in the works of Greek prose authors. From this circumstance it was well suited to the *fermo pedestris* of satire, to which purpose it was applied by its inventor Archilochus. (See *Hor. Art. Poet.* 79. and *Od.* 1. 16. 2. and 22. *Epist.* 1. 19. 24.) The same circumstance made it also peculiarly applicable to dramatic composition.

“ Hunc Socci cepere pedem, gravesque Cothurni,
Alternisque aptum sermonibus, et populares
Vincentem strepitus, et natum rebus agendis.”

Hor. *Art. Poet.* 80.

See also *Cicer. Orat.* § 191.

A pure iambic verse would consist of six iambic feet; as

Ἐπὶ σχολῇ πάρεστι, πᾶσι Μουσίου.
Dion. Hal. *de Compos.* § 17.

but necessity obliged the first writers to admit other feet, which was chiefly done in the first, third, and fifth places.

“ Tardior ut paulo graviorque veniret ad aures,
Spondeos stabiles in jura paterna recepit,
Commodus & patiens; non ut de sede secunda
Cederet, aut quarta socialiter.”—

Hor. *Art. Poet.* 254.

The few fragments of Archilochus and Solon which remain, have a spondee in the first and third places much more frequently than an iambic; and they seem to have used them indifferently in the fifth. Archilochus also affords two instances

IAMBIC VERSE.

In the *satiric fable* the same licence was probably allowed as in the comedies. In the single drama which remains, a dactyl is not to be found in the fifth place, nor an anapaest in the third; unless Pierfon's conjecture on v. 28. be admitted.

The earliest *iambographi*, or writers of iambic verses, Archilochus, Solon, and Simonides, used a spondee or an iambus indifferently, as has been before observed, in the odd places; but were very sparing in the use of feet of three syllables. The "Poem upon Women," which was written perhaps by some Simonides of more recent date, has a tribrach once, in the first, second, and fifth places, and an anapaest once in the third. Lycophron has admitted a tribrach in the third place (v. 1164. ed. Reichard., and fourth (700. 991.), and with part in a proper name in the second and fourth (520. 874. 1046). He has ten or eleven dactyls in the third place, but an anapaest only in a proper name (720. 930. 952.); for in v. 634. τ should be expunged. See Herm. de Metr. 150, who asserts that the iambographi never admit a dactyl or anapaest. Brunck. Soph. Œd. c. 371. Porson. præf. to Hec. p. 19.

Another kind of iambic trimeter much allied to this, was the *Choliambicus*, *Glaudus*, or *Seazon*, called also *Hipponaæus*, from Hipponax, who is said to have first used it. He applied it to the same purpose of severe satire, and bitter invective, as Archilochus. (Leonid. Epigr. 97. Alcæus, Ep. 18. Philipp. Ep. 83. Demetr. Phal. § 325. Eustath. on Od. 11. p. 1684. Cic. de Nat. Deor. 3. 38. Hor. Epod. 6. 14. Ovid. Ibis, 523.) The distinguishing characteristic of it was a spondee in the sixth place. The varieties which it admitted, as far as we can collect from the fragments of Hipponax, Babrius, and others which remain, were according to the following scheme.

$$\begin{array}{cccccccccccc} \cup & - & \cup & - & / & \cup & - & \cup & - & \cup & - & \cup & - & - & - \\ \cup & \cup & \cup & \cup & / & \cup & \cup & \cup & \cup & \cup & / & \cup & - & - & - \\ - & - & - & - & & - & - & - & - & - & & - & - & - & - \\ \cup & \cup & - & & & \end{array}$$

Of these the anapaest was very rarely used, and the dactyl not frequently. (Bentley on Phalaris, p. 433—6. Gaisford on Heph. p. 251—8.) These verses were sometimes called *Mimiambi*. (Terentianus Maurus. A. Gell. 15. 25. 20. 10.) Joh. Stobæus has preserved several of them from *Herodes in Hemiambi*, which ought perhaps to be changed to *Mimiambi*. (See Casaub. on Athen. 1. cap. 17.) This metre was sometimes used by Callimachus. See his Fragments, collected by Bentley, 83—98.

When the fifth foot was also a spondee, the verse was called *ισχυριστικός*. (See Tyrwhitt's Babrius, p. 13.) This was principally used by Ananias (or, as he is called by Athenæus, Ananius), but was occasionally intermixed with the other by Hipponax and Babrius. See also an epigram on Hipponax, by Theocritus.

Iambic Trimeter Hypercat. Aristoph. Lysistr. 1297. Thesm. 988. It occurs in Æsch. Chæph. 321. 352, according to Burney's arrangement; and in Pind. Ol. 3. 6. and Nem. 9. 11 according to Hermann.

Of Iambic Tetrameter Brachycat. which is mentioned by the Scholiast on Hephæstion, I find no example.

Iambic Tetrameter Catal., called also *Hipponaæus*. (Sch. on Aristoph. Plut. 253. Hephæstion. Marius Victorinus. See Gaisford, p. 246.) This was very frequently used by the comic writers, and had a pause at the end of the fourth foot, though the word frequently did not end with it. It admitted, in the first, third, and fifth feet, the same varieties as in the same feet of the comic trimeter; and, in the second

and sixth, the same as in the second and fourth of the other. The fourth foot could only be an iambus or a tribrach; and in the seventh an iambus only was allowed, except in the case of a proper name, when an anapaest was admitted in either place. Aristoph. Ran. 905—970. Nub. 1034—1084. Thesm. 531—573. Lysistr. 539, 540. Porson, præf. to Hec. p. 39. Monthly Rev. Sept. 1789, p. 253, note.

Iambic Tetrameter. A verse of Alcæus in this metre is quoted by Hephæstion, and his Scholiast. Boiscus of Cyzicus is said to have first used it. It was not used by the Greek dramatists. Hermann, p. 181. Gaisford, p. 245.

Iambic Tetrameter Hypercat. The Scholiast on Hephæstion produces a verse in this metre, and says that the measure of iambic verses was extended still further; but the examples which he cites are made up of shorter verses of Archilochus joined together.

The Romans do not appear to have made use of so great a variety of iambic verses as the Greeks. I will enumerate those which were most commonly used by them.

Iambic Monometer Hypercat. occurs occasionally in the tragedies which are ascribed to Seneca. (Œd. 411. 415. 732.) An anapaest and a spondee were used in the first place:

Iambic Dimeter Catal. Seneca, Med. 849—878. Œd. 485. Plant. Mort. 1. 2. 19.

Iambic Dimeter. Seneca uses a system of these verses in Agam. 759—784. In the first foot he has admitted a spondee and a dactyl; in the third, a spondee; and the last syllable is common. He has an anapaest in the first and fourth, Œd. 414. Plautus (Mort. 1. 2. 25. 26. 49. 50.) and Terence (Andr. 1. 2. 5. 1. 5. 5. 8. 17. 3. 3. 5. 3. 4. 26.) use a spondee and anapaest in every foot but the last, and a dactyl also in the two first. Hermann (de Metr. p. 146.), Virgil (Catal. 5.), Horace (Epod. 1—10), Martial (1. 50. 3. 14), and Seneca (Med. 771—786.), have used this verse alternately with the iambic trimeter. Horace (Epod. 14, 15.) has intermixed it with hexameters, and Martial (1. 62.) with seazons. Besides the iambic and spondee, an anapaest and dactyl are admitted in the first place by Martial, and a tribrach by Horace, who once uses a dactyl also in that situation. The second was always an iambus or tribrach. The spondee was the most common foot in the third, but an iambus is occasionally used, and Martial and Seneca have sometimes an anapaest.

Iambic Dimeter Hypercat. This is the third verse of the Alcaic ode, which Horace always uses in this form, preserving a spondee in the third place $\cup - \cup - / - - \cup - / \cup$

Iambic Trimeter Brachycat. Seneca Œd. 719, 720. 731. 733, 4. 736. Agam. 596. He admits a spondee and anapaest in the first place, and a spondee in the third, fourth, and fifth.

Iambic Trimeter Catal. Horace uses this metre (Od. 2. 18.) with a cæsura in the middle of the third foot. As it follows a trochaic dimeter catal., and the syllable preceding the cæsura is either long or short, this verse may be considered as an asynartete consisting of an iambic penthemimer, and an ithyphallic. A spondee was allowed in the first place, and a tribrach in the second. In Od. i. 4, the same meter occurs with the same cæsura, and a long syllable always before it. As it is joined with an asynartete, compounded of a dactylic tetrameter, and an ithyphallic, it may properly be considered as an asynartete here also.

Iambic Trimeter. In the tragedies of Seneca, an iambus, tribrach, spondee, dactyl, anapaest, and proceleusmatic were admitted in the first place, and the four first of these in the third, which received an anapaest also, though rarely, and.

only in words of four syllables. In the second and fourth, an iambus, or a tribrach only, was admitted. In the fifth place an iambus is found only in five verses, and a dactyl only in four; the verse ending, in both cases, with a word of four syllables; and a tribrach only in three, and contained by one word. (See AVANTIUS.) An anapæst and a spondee were admitted indifferently in this place; but it is observable that the anapæst is always contained in one word, with or without an elision of the last syllable, except in eight places where a pyrrhic is found followed by *est*, or *se*. The only exceptions to this rule are in *Here. Oct.* 406. 757, and *Oct.* 393, which may be all made regular by an easy transposition. The anapæst in *nescio quid*, which occurs five times, is not an exception, as that expression was considered as one word.

Plautus and Terence in the first four feet use an iambus, spondee, dactyl, tribrach, anapæst, and proceleusmatic. In the fifth, a spondee, dactyl, and anapæst. The third and fourth feet were very rarely allowed to be single words, which would have thrown the arsis on the last syllable of the words; and whenever this happened, they were careful to have the preceding syllable short. (See Bentley on Terence.) Phædrus uses the same licence as the comic writers, excepting that he does not admit a proceleusmatic.

Catullus in *Carm.* 4. 20. 29; Virgil in *Catal.* 3, 4; and Horace in *Epod.* 16. (where he uses this metre alternately with hexameters), admit no foot but the iambic, except a pyrrhic at the end, from the last syllable being common. In other places where this verse is used alone, as Catullus, 52, Horace, *Epod.* 17, or with alternate dimeters, a spondee, anapæst, and dactyl were admitted in the first and third places; a spondee and anapæst in the fifth; and a tribrach in the second, third, and fourth.

The scæzon is used not unfrequently by Catullus; by Virgil, *Catal.* 2. 7; and by Martial very frequently. Virgil admits no foot of three syllables, and Catullus very rarely. Martial has the same variety as in the regular trimeter in the four first feet; and in the second and fourth he admits also occasionally an anapæst. In this metre the fifth foot, among the Latins, was almost invariably an iambus, though a spondee may be found there in Martial. 1. 67. 13.

Iambic Trimeter Hypercat. Seneca *Agam.* 612. *Plant. Aul.* 2. 1. 3. 2. *Stich.* 1. 1. See *Herm. de Metr.* 169—175.

Iambic Tetrameter Catal., called also *Septenarius*. Catullus, 25. Terence, *Andr.* 4. 2. *Eun.* 3. 4. 3. 5. *Hee.* 2. 2. 5. 2. *Plaut. Ani.* 3. 3. *Mil. Gl.* 2. 4. *Mort.* 1. 3. In all the feet of this verse, but the fourth and seventh, the same variety was allowed as in the trimeter. In the fourth, Bentley (on *Hee.* 2. 2. 10.) admits in Terence only an iambus; but in *Eun.* 3. 5. 55. his own edition has an anapæst, and in *Hee.* 5. 2. 24, a proceleusmatic, in that situation. Plautus has sometimes admitted in the fourth a tribrach and an anapæst, and sometimes seems to have considered the verse as an asynartete, and therefore admits a pyrrhic and an hiatus before the cæsuræ. (*Ani.* 3. 3. 61.) In the seventh, a spondee, dactyl, and anapæst were used. See *Herm. de Metr.* p. 177—181.

Iambic Tetrameter. This metre was also used very frequently by the comic poets. The cæsuræ was either at the end of the fourth foot, or in the middle of the fifth. In this latter case, all the six feet first admitted the same variety as the comic trimeter. In the former the fourth foot was generally an iambus. The seventh foot might be a spondee or an anapæst. The eighth was always an iambus. (*Ter. Andr.* 1. 2. 1. 3. *Eun.* 3. 5. 5. 8. *Phorm.* 2. 1. *Plautus, Bacchid.* 4. 9. *Amphitr.* 3. 4.) The verses quoted by

Cicero (*Tusc.* 1. 44.) from an old tragic poet, and which he calls *Septenarii*, were referred to this metre by Scaliger, Gerh. Vossius, and lately by Hermann. Bentley was of opinion that this verse was never used by the Latin tragedians. See *Herm. de Metr.* p. 181—186.

N.B. The editor is indebted for the two preceding valuable articles to the Rev. Mr. Adams, vicar of Hildeshead, Essex.

As a poetical foot consists of a certain number of syllables which constitute a distinct part of a verse, so a bar of an air in music contains a certain number of notes of different lengths which are reducible to long and short syllables: an hexameter verse consists of six of these feet, a pentameter of five; an iambic foot has one short and one long syllable: as $\Theta\sigma$, $\lambda\sigma\gamma\alpha$, *potens, amas.*

In ancient music, says Rousseau, there were two kinds of iambic verse, one of which was only recited to the sound of instruments, whereas the other was sung. It is not easy to comprehend what effect the accompaniment of instruments could have on simple recitation; and all that we can reasonably conclude is, that the most simple manner of pronouncing Greek poetry, or at least iambics, was to musical tones, and very much resembled singing.

IAMBICE, in the *Musical Instruments of the Ancients*. Among the stringed instruments of the ancients mentioned by J. Pollux, we find one called iambice; and Musonius, "de luxu Græcorum," says that it was a kind of triangular cithara, invented by Ibycus.

JAMBlichus, in *Biography*, an ancient philosopher, who was a native of Syria, and educated at Babylon. Upon Trajan's conquest of Assyria, he was reduced to a state of slavery; but recovering his liberty, he afterwards flourished under the reign of the emperor Antoninus. His treatise in the Greek language, entitled "Babylonia de Simonidis et Rhodanis Amoribus," and consisting of 16 books, is said to have been lodged in MS. in the library of the Escurial, and destroyed by fire in the year 1671. A fragment of it was preserved by Leo Allatius, accompanied with his own Latin version, in his *Selections from the MSS. of Greek Rhetoricians and Sophists*, Rome, 1641, 8vo.

JAMBlichus was also a native of Chalcis in Cælo-Syria, and flourished about the beginning of the fourth century. He received his first instructions from Anatolius, president of the Peripatetic school at Alexandria; and afterwards became a disciple of Porphyry. He was eminently versed in the mysteries of the Plotinian system, and taught it with such reputation and success, as to attach to his school a great number of disciples. Although he was much inferior to Porphyry in eloquence, he commanded the reverence of his followers by high pretensions to theological powers. In the exercise of these powers, which he professed to acquire by an intercourse with invisible beings, he astonished the credulous, and obtained the name of "the most divine and wonderful teacher." His reading was extensive, but his style was inaccurate and inelegant; and he took great liberty in borrowing from others, and particularly from Porphyry. This charge of plagiarism is alleged against Jamblichus by Kutter, Vossius, Gale, Mosheim, and other learned men; but Dr. Lardner does not perceive any ground for it. This impartial and candid writer is of opinion, that Porphyry and Jamblichus found the same stories in au-
thors

thors more ancient than themselves, whom they both transcribed, and sometimes almost word for word. He adds, that most of the things related by these two authors concerning the wonderful works ascribed to Pythagoras are so trifling, and so manifestly fabulous, that he cannot believe they intended to oppose them to the miracles of Jesus Christ. The miracles of our Saviour, says Lardner, are all great and awful, related by credible witnesses, with all the circumstances of credibility: the trifling and fabulous accounts of Pythagoras cannot be set in competition with them. It is sufficient disparagement to those proud and learned philosophers that they gave credit to the Pythagorean fables. We need not reproach them with an intention to oppose them to the miracles of Jesus Christ. "The Life of Pythagoras;" "An Exhortation to the Study of Philosophy;" "Three Books on Mathematical Learning;" "A Commentary upon Nichomachus;" "Institutes of Arithmetic;" and "A Treatise on the Mysteries of the Egyptians, Chaldæal Assyrians;" are all the writings of Jamblichus now extant. The most esteemed editions of the above-mentioned works are those "De Myst. Ægypt. Chald. et Assy. necnon et alii Tractatus Philosophici," printed by Aldus, at Venice, 1497, fol.; "De Myst. Ægypt. necnon Porphyrii, Epistola, &c. Gr. and Lat. ex Interpretatione et cum Notis Thonæ Gale," Oxon, 1678, fol.; and "De Vita Pythag. Liber. Gr. and Lat. ex emendatione et cum notis Ludolphi Kusteri;" Amster. 1707, 4to. From St. Jerome we learn that Jamblichus wrote copious comments on the precepts of Pythagoras, commonly called "the Golden Verses;" and the emperor Julian, who holds him in equal estimation with Plato, cites a treatise on the sun, from which he has made many extracts. Fabricius mentions another work of Jamblichus, not now extant, entitled "Of Images;" or "Of the Divinity of Images;" of which Photius has given some account. The design of Jamblichus, it is said, in this work, is to shew the divinity of idols, which he calls images, and that they are filled with the divine presence, and are fallen down from Jupiter, &c. In support of this opinion he relates many incredible stories. This work of Jamblichus is confuted by Philoponus. The time and place of his death are uncertain; but there is reason for believing that he died before Constantine, and probably about the year 333.

The school of Jamblichus produced many Eclectic philosophers, who were dispersed through various parts of the Roman empire. The immediate successor of Jamblichus was Ædesius of Cappadocia. Fabr. Bib. Græc. vol. iv. and vol. vi. Brucker's Hist. Philos. by Enfield, vol. ii. Lardner's Works, vol. viii.

JAMBlichus, another Platonic philosopher, who was a native of Apamea, in Syria, flourished during the reign of the emperor Julian, who was much attached to him, and very freely corresponded with him. This philosopher is said to have been poisoned under the reign of the emperor Valens. This Jamblichus has been confounded with the former by many writers, though they lived at very distant periods, and the works of the one have been ascribed to the other. This Jamblichus was the friend of Alypius, wrote with him on the subject of music, and composed the history of that great musician's life.

JAMBlici SAL, in *Medicine*, a kind of salt prepared with sal ammoniac, and several aromatic ingredients, such as pepper, ginger, thyme, origanum, and the like; it has its name from its reputed author Jamblichus, and is supposed by many old writers to be an excellent medicine for concocting the crude humours, and gently producing stools. It was taken

fasting in the quantity of half a spoonful, either alone or in a poached egg, or mixed with any liquor.

JAMBO, or JANBO, in *Geography*, a sea-port town of Arabia Felix, in the province of Hedsjas, on the coast of the Red sea; 72 miles S.W. of Medina. N. lat. 24° 5'.

JAMBOLIFERA, in *Botany*. See CALYPTRANTHES.

JAMBON, in *Geography*, a river of the island of St. Vincent, which runs into the sea; five miles S. of Young Point.

JAMBON, in *Natural History*, a name given by authors to a kind of sea-shell, resembling a ham of bacon. It is a species of *pinna marina*.

JAMBOS, in *Botany*. See EUGENIA.

JAMBS, among *Carpenters* and *Bricklayers*. See JAUMS.

JAMBU, in *Ornithology*. See COLUMBA *Jambu*.

JAMBU, the name of a Brazilian species of partridge, of which there are two species. They are of a dusky yellow colour, and are equal to the European partridges in the delicacy of their taste. Margrave.

IAMBUS, ἰαμβος, in the *Greek* and *Latin Prosody*, a poetical foot, consisting of a short syllable followed by a long one: as in

— — — —
 ὄσθ, λείγυ, Δει, μέας.

"Syllaba longa brevi subjecta vocatur iambus," as Horace expresses it; who also calls the iambus a swift, rapid foot, *pes citus*.

The word, according to some, took its rise from Iambus, the son of Pan and Echo, who invented this foot: or, perhaps, who only used sharp biting expressions to Ceres, when afflicted for the death of Proserpine. Some rather derive it from the Greek ἰος, *venenum, poison*; or from ἰαμβίζω, *maledico, I rail, or revile*; because the verses composed of iamбусes were at first only used in satire.

The invention of this kind of verse is ascribed by Horace to Archilocus:

"Archilochum propria rabies armavit iambo."

Art. Poet.

See IAMBIC *Foot*.

JAMDRO, or PALTÉ, in *Geography*, a lake of Thibet, of such extent that it is said to be about 300 miles in circumference, or to require to encompass it 18 days journey of 20 miles each. By the Lama's map the circumference is only 150 British miles. According to the description of Giorgi, it has in the middle a range of hills and isles; or, according to the Lama's map, one large island, encircled by a lake from three to eight miles wide. The island is said to be about twelve leagues in diameter, and the trench that every where furrounds it is about two leagues broad. On the south of the island is the convent of the great female lama, Turcapamo, who was adored as a deity, and received with supreme pomp when the visited Lassa, which is about three days journey, or about 24 miles N. of the lake. On the north of the lake stands Cambala, a mountain of great height, and at a distance of seven miles runs the river Sampo, or Burrampoot, which is here 500 feet wide. N. lat. 28° 50'. E. long. 90° 45'.

JAMENGIAN, a town of Persia, in the province of Farfistan; 42 miles W.S.W. of Schiras.

JAMES, ST., in *Scripture Biography*, denominated "The Elder," by way of contradistinction to the subject of the next article, was the son of Zebedee, a fisherman upon the lake of Galilee, and of Salome, who is supposed by Theophylact and others to have been related to our Lord. As he is always mentioned first, except in Luke, ix. 28. he was probably

probably older than his brother John. Of the call of James and John to be stated attendants on our Lord's ministry, we have an account in Matt. iv. 21, 22. Mark, i. 19, 20. Luke, v. 1—10. These two brothers were distinguished by the appellation of "Boanerges," or sons of thunder, not by way of reproach, as Cave has erroneously intimated, but as an honourable anticipation of the resolution and courage with which they would openly declare the truths of the Gospel, as soon as they were made acquainted with them. It appears that after they were enlisted in the number of our Lord's disciples, they were admitted into a peculiar intimacy with their Master, and attended him on some of the most interesting occasions in the course of his ministry. At the resurrection of Jairus's daughter, at our Lord's transfiguration on the mount, and in the scene of his last agony, James was present; and he was one of the four apostles to whom Christ delivered his prediction concerning the previous calamities and ultimate destruction of Jerusalem. James appears to have been eminently diligent and zealous in fulfilling the commission which in common with the other apostles he had received, or of announcing the character and pretensions of their Master through various parts of Judea, which were afterwards the scenes of his personal ministry. On some occasions, however, both he and his brother John, indulging a resentment, and also an ambition which were inconsistent with the nature of Christ's kingdom and the mild spirit of his religion, subjected themselves to the just reprobation of their Master. When they wished to command fire from heaven to destroy the Samaritans for refusing them the accommodation which they solicited, he reproaches them with not knowing what manner of spirit actuated them; and when, apprehending his kingdom to be temporal, they bespoke stations of dignity and influence when it was established, he corrected their mistaken views, checked their inordinate ambition, and forewarned them of the trials and sufferings that awaited them. After the resurrection of Christ, James retired into Galilee, but soon returning to Jerusalem, he was witness of his ascension, and participated of the extraordinary gifts communicated to the apostles on the day of Pentecost. His subsequent activity in preaching the Gospel to the Jews drew upon him the particular notice of the enemies of the Christian cause; and in the year 44. Herod Agrippa, himself a Jew, and desirous of engaging the attachment of the Jewish people, caused James to be apprehended and to be beheaded with a sword; thus rendering him the first among the apostles who became a martyr for Christ and his religion. It has been said by Gaspar Sanctius, and also by others, that this James planted the Gospel in Spain; but this account is inconsistent with the history in the Acts, none of the apostles having left Judea so soon; nor is the opinion founded on the testimony of any ancient writer of good credit; and it is now given up, though once defended by Baronius, both by him and other popish writers. See the Four Gospels and the Acts. Lardner's Works, vol. vi.; or Supplement to the Credibility, ch. ix.

JAMES, ST. denominated "The Less," partly by way of distinction from the former, and probably also on account of his stature, an apostle of Christ, was the son of Alphaeus, or Cleophas, and frequently called the Lord's brother. Some suppose the reason of this appellation to have been, that he was the son of Joseph by a former wife; but according to others he was thus called, because his father married Mary, sister to our Lord's mother, so that they were in reality cousins; and, therefore, in conformity to the latitude with which the Jews applied the terms brother

or sister, they were denominated brethren. That he was an apostle is evident from a great variety of passages in the New Testament, though it does not appear when his designation to this office took place. He was honoured by our Lord with a separate interview soon after his resurrection (1 Cor. xv. 7.); he was distinguished as one of the apostles of the circumcision (Acts, i. 13.); and soon after the death of Stephen, about the year 36, he seems to have been appointed president or superintendent of the Christian church at Jerusalem, to have resided in that city, to have presided in the council held there in the year 49 or 50, and to have maintained a character which commanded the respect of all who knew him, and entitled him to the appellation of "The Just." But notwithstanding the high opinion that was generally entertained of his character, his life was terminated by a premature and violent death. Hegesippus, cited by Eusebius, has detailed the circumstances attending it. Having made a public declaration of his faith in Christ, the Scribes and Pharisees excited a tumult among the Jews, which began at the temple; or at least they availed themselves of a general disturbance, however it might have originated, and demanded of James an explicit and public declaration of his sentiments concerning the character of Christ. The apostle, standing on an eminence in the temple, whence he could be heard by the assembled multitude, avowed his faith and maintained his opinion, that Jesus was the Christ or expected Messiah, and that his doctrine furnished sufficient instruction how men might be saved. The Jews were exasperated, and the Scribes and Pharisees, repenting of their conduct in extorting from the apostle such a testimony to Jesus, caused him to be precipitated from the battlement of the temple upon which he stood, and then to be stoned, because he was not killed with the fall. St. James, kneeling down, prayed earnestly to God on behalf of those who were thus maltreating him; but they persisted in their violent and savage treatment of him, till at length one of them struck him with a long pole, which put an end to his life. According to Hegesippus, this event happened about the time of the Passover, which was probably that of the year 62. At this time Festus is supposed to have been dead, and Albinus his successor was not arrived: so that the province was without a governor. Such a season left the Jews at liberty to gratify their licentious and turbulent dispositions; and they were very likely to embrace it; and we may therefore very reasonably place this event at that juncture. Of Josephus's account we have not availed ourselves, because several learned men have suspected it to be an interpolation. Bishop Pearson, however, who seems to admit the genuineness of the whole passage of Josephus, placed the death of James in the year 62; and it is now the general opinion among learned men that James died about that time. For an account of the epistle addressed to the twelve tribes scattered abroad, comprehending all Jews both in Judea and out of it, and justly ascribed to the apostle James, we refer to the article EPISTLE. As for other works that have been attributed to him, such as the Πρωτοεὐαγγέλιον (Proto-euangelion), inserted in Greek and Latin in Fabricius's Cod. Apocryph. New Test., and a "Liturgy," bearing his name, they are evidently not of his writing. The former is manifestly supposititious, and the latter bears internal marks that it belongs to a later period than the apostolical age. Lardner's Works, vol. vi. or Supplement to Credib. ch. xvi. Cave's Hist. Lit. vol. i.

JAMES, a deacon. Bede informs us that, when Paulinus was bishop of the Northumbrians, his deacon, named James, acquired great fame for his skill in the church song.

This

'This must have been about the year 620, soon after the conversion of the Saxons by Austin: when Paulinus was translated to Rochester, deacon James was left at York, to instruct the ecclesiastics in the Roman method of chanting.

JAMES I. king of Scotland, of the house of Stuart, son of Robert III. by Anabella Drummond, was born in the year 1394. In 1405 his father determined to send the young prince to France, in order that he might escape the dangers to which he was exposed from his uncle the duke of Albany, but in endeavouring to avoid one peril he fell into another; being taken by an English cruiser, he and his whole suite were carried prisoners to the Tower of London. Here the young prince received an excellent education, to which Henry IV. of England was remarkably attentive, thereby making some atonement for his injustice in detaining him. Robert died in the following year, and James was proclaimed king, but during the remainder of the reign of Henry IV. and the whole of that of Henry V., he was kept in confinement, with a view no doubt of preventing the strength of Scotland from being united to that of France against the English arms. At length, under the regency of the duke of Bedford, James was restored to his kingdom, having been full eighteen years a prisoner in this country. James was now thirty years of age, well furnished with learning, and a proficient in the elegant accomplishments of life, and dextrous in the manly exercises, which at that period were in high estimation. He married Joanna Beaufort, a lady of distinguished beauty, descended from the royal family of England, and on his return to Scotland he had much trouble to reduce the public affairs to order. During the regency of the duke of Albany and his son, many of the most valuable possessions of the crown had been alienated, and the licentiousness of the great, sanctioned by the authority and example of the chiefs, seemed to set at defiance all restraints of law and justice. James instantly caused the whole of the family of Albany and their adherents to be arrested. The latter were chiefly discharged; but the late regent, his two sons, and his father-in-law, he caused to be convicted, executed, and their estates to be confiscated to the crown. Whether these proceedings were founded in justice cannot now be ascertained, but it is certain the king himself presided as judge, and as the verdicts in Scotland are decided by a majority of votes, it would scarcely be difficult for a judge and a king to obtain his wishes whether founded in equity or not. James is also charged with entrapping a number of Highland chiefs by hospitality, entertaining them in his castle, and in the midst of their hilarity causing the gates to be shut upon them; a fact which proves that he was not over scrupulous in the means of maintaining his authority. His political ability was displayed in a less exceptionable manner by the enactment of many good laws in his parliaments, which much improved the state of society in the kingdom where they could be executed. His desire of improving the revenues of the crown led him to many acts of tyranny, which rendered him odious to his nobility. In 1436 he gave his daughter Margaret in marriage to the dauphin of France, and sent with her a splendid train and a vast body of troops. The English, who had in vain attempted to prevent this union by negotiation, now endeavoured to intercept the Scotch fleet in its passage, but they missed their object, and the prince's arrived in safety at Rochelle. James, exasperated at this act of hostility, declared war against England, and summoned the whole array of his kingdom to assist in the siege of Roxburgh; which, however, he abandoned upon an intimation of a conspiracy being formed against himself by his own people. He now retired to the Carthusian monastery of Perth, which he had himself founded, where he lived in privacy, which, instead of

preventing, facilitated the success of the plot formed against his life. The chief actors in this tragedy were Robert Graham, and Walter, earl of Athol, the king's uncle. The former was actuated by revenge for the sufferings of some of his family, the latter by the hope of obtaining the crown for himself. The assassins obtained by bribery admission into the king's apartments; the alarm was raised, and the ladies attempted to secure the chamber-door; one of them, Catharine Douglas, thrust her arm through a flap, making therewith a sort of bar, in which state she remained till it was dreadfully broken by the force of the assailants. The instant they got admission they dragged the king from his concealment, and put him to death with a thousand wounds. He left one son and five daughters. James was a poet as well as a sovereign, and his works, descriptive of the manners and pastimes of the age, became extremely popular, and are still read with delight by those who can relish the northern dialect. His private character was amiable, and he possessed qualities that would have obtained for him high respect in any condition; his improvements in the laws and police of his country, and his attempts to abolish anarchy, entitle him to respect, though in some instances his eagerness for reform led him to tyranny.

James, an accomplished but unfortunate prince, is said by all the British historians to have been a skilful musician; and it is asserted, that he not only performed admirably on the lute and harp, but was the inventor of many of the most ancient and favourite Scottish melodies. Where this prince acquired his knowledge in music is not ascertained; but it is probable that it was in France, in his passage home from which country he was taken prisoner by the English. Before the Reformation we hear of no music being cultivated in Scotland but plain-song, or chanting in the church; nor afterwards, for a long time, except psalmody.

The genuine and ancient Scots melodies are so truly national, that they resemble no music of any other part of Europe. They seem to have been wholly preserved by tradition till the beginning of the last century, when a collection of Scots songs was published by a Mr. Thomson of Edinburgh, for which there was a very large subscription; and in February, 1722, a benefit concert was advertised for the editor, to be terminated at the desire of several persons of quality, with a Scottish song. To this publication and concert may be ascribed the subsequent favour of their national, singular, and often touching melodies, south of the Tweed.

Tassoni, indeed, (lib. x. cap. 23.) tells us, that "James I. king of Scotland, had not only composed sacred music, but invented a new species of plaintive melody different from all others; in which he has been imitated by the prince of Venosa; who," he adds, "in our times has embellished music with many admirable inventions." This assertion greatly increased our desire to examine works in which so many excellencies were concentrated; particularly as we had long been extremely desirous of tracing the peculiarities of the national melodies of Scotland, from a higher source than David Rizzio. But in a very attentive perusal of all the several parts of the whole six books of the prince of Venosa's madrigals, we were utterly unable to discover the least similitude or imitation of Caledonian airs in any one of them; which, so far from Scots melodies, seem to contain no melodies at all; nor, when scored, can we discover the least regularity of design, phraseology, rhythm, or, indeed, anything remarkable in these madrigals, except unprincipled modulation, and the perpetual embarrassments and inexperience of an amateur, in the arrangement and filling up of the parts.

Buchanan, among other historians, has drawn the character

rafter of James I. of Scotland at full length; and among many other particulars, mentions his being excellently skilled in music; more indeed, he adds, than was necessary or fitting for a king: for there was no musical instrument on which he could not play so well, as to be able to contend with the greatest masters of the art in those days. Buch. *Res. Scotie*. Hist. lib. x. sect. 57.

And in the continuation of Fordun's Chronicle (*Scotichronicon*, vol. iv. p. 1323.), is a character of James I. which ranks him equally high as a musician. And in Hector Boethius is an eulogium upon him, which we shall give in the dialect of the country, from the translation of that historian by Bellenden. "He was well lernet to fight with the sword, to just, to turnay, to worfyl, to sing and dance, was an expert musician, richt crafty in playing baith of lute and harp, and findry other instruments of musik." This polished and ingenious prince may have added some melodies to the tunes of his country, imitating the national style; but, in general, the old and genuine Scots tunes seem still more ancient than even the time of James I., who being a good musician, had he been the original inventor of melodies, would have made them accord more to the rules of composition built on the scale of Guido, which was well known all over Europe at the time when this monarch was in existence. And, indeed, however singular and pleasing these airs may be, they are drawn from so imperfect a scale, and so frequently begin in one key and end in another, that we cannot help thinking they were produced before the scale of Guido was formed. (See *OSSIAN*.) It seems as if national tunes might be called *traditional*, and the general music of Europe *cultivated*.

JAMES II. son of the preceding, was in his seventh year when his father was murdered: this was in the year 1437. The custody of the youthful monarch, and the administration of government, devolved upon sir Alexander Livingstone, and the chancellor Crichton, while Archibald, earl of Douglas, and duke of Touraine, was declared lieutenant-general of the kingdom. Discord, the natural attendant upon such a government, arose among these great men, and the affairs of the nation fell into disorder. Crichton and Livingstone were perpetually at variance, till the desire of freeing themselves from earl Douglas produced a reconciliation between them. They invited him, his brother, and his chief confidant to Edinburgh, and while sitting at a sumptuous dinner, they were all three seized at the royal table, and were immediately murdered. Lord Douglas's son, within three years of this catastrophe, procured the proscription of Livingstone and Crichton, his own family he restored to all their former dignities, and the principal offices of the state were given to his friends and relations. In 1449 James was married to Mary, daughter of the duke of Guelderland, and almost as soon as he could be said to act for himself, he began to be jealous of the vast power and influence of the Douglas family. The earl, aware of his own danger, negotiated an asylum at the court of England, and at the same time entered into a bond with the earls Crawford and Ross, and other noblemen, mutually to support each other against their common adversaries. The knowledge of these facts was soon communicated to the king, who summoned the earl to his court. The haughty lord refused to comply till he should be assured of protection under the great seal. The form was readily complied with, but it was no safeguard against the meditated treachery. James received him with apparent cordiality, and invited him to supper. After the repast, he demanded of his guest the bond entered into with the earls of Crawford and Ross; this he nobly refused, and the king with his own hand stabbed him. From this period James was perpetually harassed by attempts made against his peace

by the earl's family, and in 1456 a rebellion was excited by Donald, lord of the isles, in connection with an invasion from the English. He defeated his enemies, and in his turn, in 1460, resumed hostilities, and laid siege to Roxburgh castle. Here he was killed by the accidental bursting of a piece of artillery. He was then in the prime of life, being not quite thirty years of age. He had already surmounted the difficulties which arise from youth and from violence of temper, to which he was subject, but which he had subdued, and there was every prospect of a wife and prosperous reign. He left three sons and two daughters.

JAMES III. king of Scotland, succeeded to the crown when he was only eight years old, on the death of his father in 1460. The care of his person was given to his mother, while the chief management of the government devolved on lord Evandale, the chancellor, and James Kennedy, bishop of St. Andrews. The death of the good prelate, in 1466, proved a public misfortune, by delivering the young king into the power of flattering and mercenary courtiers. In 1468 a marriage was contracted between James and Margaret, daughter to Christian I. king of Sweden, Denmark, and Norway. For the marriage portion, the Orkney and Shetland isles were pledged, and they ever after remained under the dominion of Scotland. This marriage took place in July, 1469, and James took upon himself the reins of government. His character, as it opened, displayed weakness, indolence, and caprice: he had an attachment to literature and the fine arts, as they were then understood; his mind was, however, unfortunately biassed towards despotism, but accompanied with lenity. He was esteemed pious and devout, but did not scruple indulging his avarice by alienating ecclesiastical benefices to laymen. In 1477 an unhappy quarrel took place between the king and his two brothers, the duke of Albany and the earl of Mar: the former made his escape from the Edinburgh castle in which he was confined, but the earl of Mar was accused of employing magical practices against the king's life: of this crime he was convicted and made a close prisoner, in which situation he shortly died, but whether by a fever or by more violent means is not known. The king gave great offence to his nobility, by selecting as his favourite and chief confidant, Cochrane, a mason and architect, whom from that state he elevated to the vacant earldom of Mar. During an invasion of the English, which James endeavoured to repel, Cochrane was seized and hanged, and the king himself made prisoner by his own nobles. The English proceeded as far as Edinburgh, when an accommodation took place; the king was liberated and resumed the reins of government. Some succeeding years were marked with little else than misgovernment on the part of the king, and progressive discontents among the nobles; till in 1488, a confederation of the great broke out into open rebellion, the objects of which were to dethrone and imprison James, and place his son on the throne. After various attempts at pacification, in which the king shewed an evident unwillingness to shed the blood of his people, he resolved to commit his fortune to the decision of a battle, from which he was obliged to seek safety by flight; in crossing a rivulet his horse started and threw him; though stunned he was not dangerously hurt, and was carried by his attendants to a neighbouring mill, where some of his enemies, recognizing his countenance, cruelly murdered him. He left three sons.

JAMES IV. was in his sixteenth year when he was forced into a contest with his father, and whose murder elevated him to the crown in 1488. Though urged by the ambition of his nobles to the unnatural step of open rebellion, he did not easily forgive himself the steps which he had taken. One of his first feelings after he had ascended the throne, was remorse

remorse for his unfilial and disloyal conduct, and it is said, that as there was no superior earthly tribunal to which he was amenable, he condemned himself to wear an iron chain round his body as a punishment which he had justly incurred, and that he added a new link to its weight for every succeeding year of his life. The victorious barons, less scrupulous with regard to the bloody deed in which they had been engaged, were anxious only for security for the future; and obtained a declaration in parliament of their innocence with respect to the late king's death, and other slaughters, which were imputed to his own perverseness and deceit; and a subsequent parliament in 1490 was instrumental in healing the feuds and animosities of parties, and restoring internal tranquillity. The king contributed much to this desirable end by the impartial administration of justice. The qualities of his mind and heart were well calculated to obtain for him the respect and attachment of his people in every situation and rank of life. For many years he maintained a strict peace with Henry VII. of England, till at length he offended that monarch by adopting the cause of Perkin Warbec, who came strongly recommended to him by the court of France. War was excited on this account for a short time, but the love of peace, which was ever uppermost in the mind of Henry VII. soon put an end to all national differences. Though James, on this reconciliation, abandoned the cause of Perkin, he had too high a sense of honour to give him up. In 1503 he married Margaret, the daughter of Henry, an event which, in the issue, produced the union of the two kingdoms under one crown, though at the distance of two centuries from this marriage. In subsequent parliaments James caused several very useful laws to be enacted which led to the improvement of the country, nor was he less anxious to render Scotland respectable with regard to foreign potentates. In the reign of Henry VIII. he was engaged in warfare with England: after several predatory incursions from both parties, James entered England at the head of a hundred thousand soldiers, and made himself master of many castles and other strong holds. At one of these he formed an attachment to a lady of exquisite charms, the power of which he could not resist. He forgot the importance of time to the career of his army, and remained several days in a state of inactivity, during which, from a concurrence of unfortunate circumstances, his vast army was reduced by desertion to less than thirty thousand. These, dispirited by the conduct of their king, were brought to contend with an almost equal number at Flodden Field, in Northumberland, under the earl of Surrey. The battle was fought on the 9th of September, 1513: prodigies of valour were displayed on both sides; the king rallied his troops again and again, as if ashamed of the amours which had brought him into such a state of peril; he was determined to shew himself the man and the hero; wherever there was most danger, there was James, till he fell mortally wounded; this circumstance, and the darkness of the night, put an end to the conflict. With the monarch were slain his natural son, the archbishop of St. Andrew's, twelve earls, and a multitude of the highest rank among the nobility and gentry of the kingdom. Scotland, says the historian, can reckon few more fatal days than that of Flodden Field. The body of the dead king fell into the hands of the conquerors, who carried it to the monastery of Sheene, near Richmond, where it was interred. James IV. was slain in the forty-first year of his age, and the twenty-sixth of his reign. He was succeeded by

JAMES V. his son, an infant not two years old. His minority passed in that contention of parties which commonly attended such a period in Scotland. When, however, he arrived at an age to be allowed to manage the

affairs of government, his character displayed itself in decided features. In his youth he had witnessed the disorders which a powerful and lawless aristocracy had inflicted upon his people, and he was now the constant and determined foe of the nobility. While he depressed the powerful, he raised and favoured the low, so as to obtain and merit from his people the appellation of "King of the Poor." No object was nearer to James's heart than the suppression of those bands of freebooters whom the licence of the times had suffered to range uncontrolled in the remote parts of the country. He even exposed his person in expeditions against these marauders, whom he treated with unrelenting rigour. After reducing the borders and highlands to order, James paid a visit to the isles of his dominions, and held courts of justice in the Orkneys and Hebrides, to the terror of the tyrannical chieftains of those regions. In 1537 he married the sister of the king of France, who lived but a few months. In the same year he incurred the stain of cruelty in causing the son of lord Forbes to be beheaded for treason upon very slight and unsatisfactory evidence, and still farther by the burning of the beautiful and heroic lady Glamis, sister of the earl of Angus, for the imaginary crime of witchcraft practised on his own person. James had contracted a partiality for the French court, and married for a second wife Mary, daughter of the duke of Guise, an union which probably enforced his propensity to severe measures against the Protestants, who began to appear in great numbers in Scotland, and of whom several nobly suffered death in defence of their opinions. Henry VIII. was desirous of joining James with himself in opposing the pretensions of the Roman see, and sent an embassy into Scotland to persuade him to enrich himself with the spoils of the monasteries. In some respects James was willing to listen to the proposals of the English monarch, but French influence was too powerful, and he afterwards sent an excuse to Henry for the breach of his engagement, which provoked that prince so much, that it was imagined a war between the two kingdoms would ensue. Hostilities were actually commenced, and James was urged, as well by the king of France as by his own clergy, to pursue some advantages, which he at first gained, into the enemy's country; but his army were evidently ill affected to their monarch, remonstrated against the design, and in the event of an attack some time after, suffered themselves to be taken prisoners, or deserted from their colours without a struggle. James, already depressed by the loss of his two infant princes, was now overwhelmed with anguish, shame, and despair. He retired to Falkland, and shewed every symptom of declining health. So lost was he to any thing that might interest his feelings, as a man or sovereign, that when news was brought him of the birth of a daughter, he took no other notice of the event than to say, "The crown came with a girl, and will go with a girl." He expired December 14, 1542. The reader is referred for farther information relating to the foregoing kings of Scotland, to Pinkerton's history of that country, and to Henry's History of Great Britain.

JAMES I. of England, and the VIth of that name of Scotland, was son of Mary, queen of Scotland, by her cousin Henry, lord Darnley. He was born at Edinburgh castle in June, 1566, at the exact time when his mother was at open variance with her husband, and had fixed her affections on the earl of Bothwell. The young prince was committed to the charge of the earl of Mar, who with much fidelity did his duty, and kept him out of the hands of Bothwell. In the following year Mary was forced to resign the crown, which was placed on the head of her infant son. He was solemnly crowned at Stirling, and thenceforth all public acts ran in his name. He was educated by the celebrated

Buchanan while he was at Stirling castle; his progress in school-learning was rapid, and he manifested talents which presaged the future great man: but he became the prey of flatterers, who instilled into his youthful mind the most pernicious maxims of the plenitude of regal authority, and urged him to unpopular measures, which in 1582 produced a conspiracy of the nobles against him, who took possession of his person at Ruthven castle. From thence he was conveyed to the palace of Holyrood-house, and treated with much external respect, while in reality he was held in the utmost restraint. A new confederacy of other nobles produced his liberation, and he put himself under the sway of his favourite the earl of Arran, who was violent and unprincipled, and who carried on measures of severity against the nobles of the former conspiracy, and against the clergy who favoured them. He contrived to engage the mind of the young king with a constant round of amusement, and he himself exercised with unlimited sway all the regal authority, and by his insolence and rapacity rendered himself universally odious. Queen Elizabeth of England had long employed her arts to maintain a party in the country, which policy was become more necessary on account of her conduct to its queen. Though James had hitherto been induced to treat his mother very irreverently, yet when her life appeared to be in imminent danger, from the sentence pronounced against her by an English court of judicature, he felt himself bound to interfere, and wrote a menacing letter to Elizabeth on the occasion. He also applied to other courts for their assistance, and assembled his own nobles, who promised to stand by him in preventing or avenging such an injustice. When he learned the fatal catastrophe, he rejected with a proper spirit of indignation the hypocritical excuses of Elizabeth, and set about preparations for hostilities, but cooler reflection on his own resources, which were inadequate to the purposes of carrying on a serious war, and reflecting also on the necessity he was under of keeping on terms with England to secure his succession to the crown, of which he was the presumptive heir, he resolved to resume a friendly correspondence with the English court. It is to the honour of James that one of the first acts of his full majority, in 1587, was an attempt to put an end to all family feuds among the nobility, and personally to reconcile them with each other at a solemn festival in Holyrood-house. When the invasion of England was resolved upon by Philip, king of Spain, he put his kingdom into a state of defence, resolving to support the queen against her enemies. His people also were zealous for the preservation of Protestantism, and entered into a national bond for the maintenance of true religion, which was the origin and pattern of all future engagements of the kind, under the name of solemn leagues and covenants. After the glorious defeat of the Armada, Philip, in revenge of the conduct of James, stirred up a conspiracy of some Popish lords in his kingdom, which was discovered by Elizabeth, and when it broke out into open rebellion, was instantly crushed by the king at the head of a body of troops. The conspirators were treated with lenity, which James ever shewed towards the Catholics, and which brought the sincerity of his own professed faith into question, though it probably proceeded partly from mildness of temper, and partly from timidity. Though he was probably satisfied of the errors of popery, he was fond of the splendour of ecclesiastical hierarchy, and bore a rooted antipathy to the republican model of Presbyterianism.

In the year 1589 he married Anne, daughter of Frederic, king of Denmark, and as contrary winds prevented her coming to Scotland, he went to fetch her, and having consummated the marriage, he passed the winter in a series of

feasting and amusements at Copenhagen. On his return he was frequently in danger from conspiracies against his life, particularly from those excited by the earl of Bothwell. In the year 1600, while the country was in a state of unusual tranquillity, a very extraordinary event took place, the nature and causes of which were never discovered. While the king was upon a hunting excursion, he was accosted by the brother of Ruthven, earl of Gowrie, who, by a feigned tale, induced him and a small train to ride to the earl's house at Perth. Here he was led to a remote chamber on pretence of having a secret communicated to him, where he found a man in complete armour, and a dagger was put to his breast by Ruthven, with threats of immediate death. His attendants were alarmed and came to his relief; in the end Gowrie and his brother were slain, and the king escaped unhurt. As Elizabeth advanced in age, the English nation began to look with more confidence to James as their future king, and many persons of consequence held a secret correspondence with him on the subject. In 1603, on the death of the queen, James was proclaimed her successor. He took an affectionate leave of his countrymen, and proceeded, amidst the acclamations of his new subjects, to London. One of his first acts was to bestow a profusion of honours and titles upon the great men, as well of his own country as those of England. Within a very short period, and at a time of apparent general tranquillity, a conspiracy was discovered for subverting the government and raising to the throne Arabella Stuart, a near relation of the king's, by the family of Lenox, and defended equally from Henry VII. "Every thing," says Hume, "remains still mysterious in this conspiracy, and history can give us no clue to unravel it." The principal actors in it were lord Grey, a Puritan; lord Cobham, a thoughtless man, of no fixed principle; and sir Walter Raleigh, a philosopher, and supposed to be a freethinker. What cement could unite men of such discordant principles in so dangerous a combination; what end they proposed, or what means they had proportioned to an undertaking of this nature, have never yet been explained, and cannot easily be imagined. A conference held at Hampton-court in 1604, between the divines of the established church and the Puritans, afforded James a good opportunity of exhibiting his skill in theological controversy, and the ill will he bore to popular schemes of church-government. Although the king had distinguished himself in his own country by lenity to the Roman Catholics, yet those of that religion in England were so much disappointed in their expectations of his favour, that a most atrocious plot was formed by the zealots of that party to blow up the house of lords at the first meeting of parliament, and with it the king, queen, and prince of Wales, and all the principal nobility and gentry of the kingdom, and then to set upon the throne the young princess Elizabeth, and establish the Catholic religion. This plot was fortunately discovered on the eve of the designed execution, and the principal persons in it suffered the punishment due to their crimes. In 1611 he remonstrated with the Dutch states, on account of their permitting Arminus Vorstius to hold a professorship in one of their universities. He was deemed by James a heretic, and he carried his point in getting him removed. His next object was to reduce Ireland to a settled form of law and government. In 1612 a putrid fever carried off his son Henry, a prince who was, on account of his many promising virtues, the hope and darling of the nation: and in the following year the princess Elizabeth was married to Frederic, elector palatine.

We do not pretend in these biographical sketches to enter into the minutæ of each reign, nor to record all the transactions that relate to the prince himself, but we must not omit

omit to mention the odium which James brought on himself by patronising his favourite Robert Carr, who, in prosecution of his lascivious designs, was guilty of the most atrocious acts. No circumstance, however, in James's reign was more unpopular than his treatment of the celebrated Sir Walter Raleigh; after the detection of the conspiracy already referred to, he was tried and capitally convicted, but being relieved, he was kept thirteen years in prison. In 1615 he obtained by bribery his release from prison, but the king would not grant him a pardon. He went out on an expedition with the sentence of death hanging over his head; he was unsuccessful in his object, and on his return the brutal king ordered him to be executed on his former sentence. (See RALEIGH.) James is supposed to have been more influenced to this deed by the court of Spain than by any regard to justice. The influence of that court on James appeared soon after in his negotiations for marrying his son prince Charles to the infant. The object was, however, not attained, and he afterwards married him to the French princess Henrietta, with the disgraceful stipulation, that the children of that marriage should be educated by their mother, a bigotted papist, till they were thirteen years of age. As he advanced in years he was disquieted by a concurrence of untoward circumstances. The dissensions of his parliament were very violent, and the affairs of his son-in-law, the elector palatine, now king of Hungary, also were in a very disastrous state. He had undertaken the cause of the Protestants of Germany, but instead of being the arbiter in the cause of others, he was stripped of his own dominions. In his defence, James declared war against the king of Spain and the emperor, and sent troops over to Holland to act in conjunction with prince Maurice for the recovery of the palatinate; but from mismanagement, the greater part of them perished by sickness, and the whole enterprise was defeated. Oppressed with grief for the failure of his plans, the king was seized with an intermitting fever, of which he died in March 1625. He left two children, Charles, his successor, and Elizabeth, the wife of Frederic. It would be difficult, says Hume, to find a reign less illustrious, yet more unspotted and unblemished, than that of James in both kingdoms. James possessed many virtues, but scarcely any of them pure or free from the contagion of neighbouring vices. His learning degenerated into pedantry and prejudice, his generosity into profusion, his good nature into pliability and unmanly fondness, his love of peace into pusillanimity, and his wisdom into cunning. His intentions were just, but more adapted to the conduct of private life than to the government of kingdoms. He was an encourager of learning, and was himself an author of no mean genius, considering the times in which he lived. His chief works were "Basilicon Doron;" and "The true Law of free Monarchies;" but he is more known for his adherence to witchcraft and demoniacal possessions in his "Demonology," and for his "Counterblast to Tobacco." Hume's Hist. Robertson's Hist. of Scotland.

The accession of James to the crown occasioned no immediate benefit to science or refinement in the polite arts; as the country he quitted was still less polished than that in which he arrived. Nor does it appear that this prince, either from nature or education, was enabled to receive any pleasure from music; however, early in his reign, the gentlemen of his chapel, assisted by the influence and solicitation of several powerful noblemen, who pleaded their cause, severally obtained an increase of ten pounds to their annual stipend.

An entry is made of this event in the cheque-book of the Chapel Royal, signed, not only by five of the great officers

of state, but by the subdean, chaplains, and gentlemen of the chapel then living.

Among these petitioners there is but one name, that of Edmund Hooper, which ever appears afterwards in the lists of musicians eminent for composition or performance, except Bird, Bull, and Gyles, who had distinguished themselves in the preceding reign.

Anthems, maques, madrigals, songs, and catches, seem to comprise the whole of our vocal music for the church, the stage, and the chamber, at this time. And with respect to instrumental productions under the title of "Fancies, &c." as they were chiefly composed for lutes and viols, which are now laid aside, if they had been replete with genius and learning, justice could not have been done to them in the performance. Luckily the chief part of them are of so artless and insipid a kind, that no loss would accrue to judicious and reasonable lovers of music by their utter annihilation.

Elway Bevin and Orlando Gibbons were the best, and almost the only good composers during the reign of James I. if we except those which the reign of queen Elizabeth had produced, and who embellished during a few years her successor's reign. See BEVIN, and ORLANDO GIBBONS.

JAMES II king of England, and the VIIIth of Scotland, second son of Charles I. by Henrietta of France, was born in October 1633, and immediately declared duke of York. (See CHARLES I. and II.) After the capture of Oxford by the parliament army in 1646, he was carried to London, and placed under the care of the duke of Northumberland, but in 1648 he contrived to make his escape, and in the following year joined his mother at Paris. At the age of twenty he served in the French army under the celebrated Turenne, and acquired a great reputation. He afterwards entered into the Spanish army in Flanders, under the prince of Condé, and thus he advantageously passed his exile in acquiring military experience, and the reputation of spirit and prowess suited to his birth. At the restoration of his brother, James took the command of the fleet as high-admiral; and he was married to Anne Hyde, daughter of lord Clarendon. (See HYDE.) Maritime and commercial affairs engaged the duke's attention, and he was at the head of an African company, when, in 1664, he took a part in promoting a Dutch war for the supposed interests of trade. He had been made commander-in-chief of a powerful fleet, and obtained a signal victory over the Dutch under admiral Opdam. Opdam's own ship was blown up in the action, and nineteen of his fleet were sunk or taken, with the loss of a single vessel on the part of the English. The duke was in the thickest of the fight, and three of his friends, men of high rank, were killed by his side. The conduct of Brouncker, his gentleman of the bed-chamber, brought suspicion on the duke. Without the knowledge of his master, and while he was asleep, this man gave orders to slacken sail, though in pursuit of the enemy; but as he was not punished for his orders, nor even dismissed from his office till the matter was agitated in the house, the duke himself was accused by his enemies of being privy to the orders issued by his servant. After this he had no farther share in the naval actions of that war. In 1671 the duchess of York died, leaving two daughters, Mary and Anne, who came to be successively queens of England. Before her decease she openly declared herself a convert to the Roman Catholic religion, which had been secretly that of the duke many years, and was now openly avowed by him. In the Dutch war of 1672, the duke of York was again placed at the head of the fleet, a furious engagement ensued, in which the

earl of Landwick, who was second in command, was blown up, and the duke's own ship was so much shattered, that he was obliged to shift his flag to another. At length the Dutch retired, and were not pursued, the loss being nearly equal on both sides. By an act of parliament, papists were now excluded from all public employments, and the duke was obliged to resign his command. (See *TEST ACT*.) After this he used every endeavour to introduce the Catholic religion into England. In 1677 the duke's eldest daughter, Mary, was married to the prince of Orange, an alliance which gave universal satisfaction to the nation. Both Mary and Anne had been brought up in Protestant principles, to which they stedfastly adhered. During the proceedings occasioned by the supposed Popish plot, the duke of York, in 1679, by his brother's advice, withdrew to Brussels. A bill was afterwards brought in and carried through the house of commons to exclude the duke from the succession to the throne; it was, however, rejected by the lords. In 1681 he was sent to Scotland to hold a parliament as king's commissioner; but his conduct on this occasion exposed him to the imputation of cold unrelenting tyranny, and the manner in which he treated the remnant of the covenanters was cruel in the extreme. Having returned to London, he set out for Scotland a second time, but the frigate in which he embarked struck upon a sand-bank off the coast and was lost. The duke escaped in a barge, and is said to have shewn more anxiety to save his dogs and his priests, than several persons of quality who were with him, and who were left to perish. Among those who were preserved on this occasion was Churchill, afterwards the illustrious duke of Marlborough, at that period one of the duke's favourites. During the remainder of Charles's reign, the duke had much influence in government, and was forward in promoting all the severe measures which were acted at that period. More than once the king felt himself called on to check his impetuous rigour, warning him of the probable consequences of such rashness. "Brother," said he on a particular occasion, "I am too old to go again on my travels; you may if you choose it." At this time the king was meditating some important changes in public measures; he had formed the plan of a new administration, resolved to dismiss those servants who were hated by the people, and to throw himself entirely on the good will and affections of his subjects; but amidst these truly wise and virtuous designs, he was seized with a fit, which carried him off in a few days, leaving his brother in possession of the crown and kingdom. From the moment of his succession to the throne, James seems to have pursued with steady determination two objects, *viz.* of rendering himself absolute, and of introducing the Roman Catholic religion into his dominions. He began his career in government by going openly, with the ensigns of his dignity, to mafs, though at that time it was an illegal meeting. He also shewed an intention of carrying the prerogatives of the crown as high as possible, and beyond the true constitutional limits. A rebellion, excited in favour of the duke of Monmouth, the late king's natural son, shewed the temper of James in its true light. The stability of his throne would have been strengthened by the suppression of this rebellion, had not the severity of his measures produced a hatred which was greater than the terror which it inspired. Monmouth paid his life as the penalty of his futile attempt. Of his followers many were put to death on the field, when they had no means of resistance in their power, and not a few suffered in cold blood by martial law with circumstances of savage brutality. As if not satisfied with the ferocity of his soldiery, James called to his assistance, in the bloody work, the more ferocious and superlatively cruel Jefferies, whose
