It is scarcely necessary to remark to the English reader, that the word *plague*, in the preceding passages, of course signifies only the spot or disease; and implies nothing pestilential or infectious. The word, in the Septuagint, is *ἀκαθάρτης*, *plaga*, (a stroke); the latter of which is used in the Vulgate.

It is by no means clear, indeed, that this form of leprosy was actually contagious, or was even deemed contagious; although so much care was enjoined by the law in the examination of the symptoms, and the expulsion of the diseased from the camp was strictly commanded, in case the existence of

of the true leprosy were ascertained. For in the first place, no apprehension of the communication of the disease by infection is any where expressed; the leprosy person is said to be *unclean*. But other circumstances, where no contagion or communication of disease could be suspected, were said, in like manner, to render a person unclean; and the law enjoined, in these cases also, a temporary separation of the person from society, and similar rites, offerings, and ablutions, at the time of being declared clean before the priest. (Levit. chap. xv.) Thus any issue or discharge from the body, the occurrence of the catamenia in women, child-bearing, &c. all rendered a person *unclean*, and equally subject to separation and the subsequent ceremonies. It would seem, therefore, that the loathsome and foul nature of the disease, which inspired this people with a similar horror and disgust to that which is felt towards a corpse ("tanquam nihil à cadavere differentes;" Josephus Antiq. Judaicæ. lib. iii. chap. x. see also Numbers, chap. xii. ver. 12.) was the principal reason for the severity of the law of exclusion, which was ordained against lepers. For we are informed by Josephus himself, that, so far from being supposed to be capable of infecting those about them with their disease, "lepers, in many countries, not only mix in society, but are even held in high estimation; so far from being banished, or looked upon with contempt, they are honoured, in warlike expeditions, with military dignities, and with offices of trust in the administration of public affairs; neither are they excluded from the places of public devotion." (Loc. cit.) The scriptures, indeed, furnish us with an example of the high situation of a leper, in the person of the Syrian general, Naaman, who was in great favour with his king. And even among the Israelites themselves, it would seem that the exclusion of the leprosy was not very rigidly enforced. For we find Gehazi, the servant of Elisha, still in the employment of the prophet, and conversing even with the king, after the leprosy had been inflicted on him "and his seed for ever;" (see 2 Kings, chap. v. and vi. and again chap. viii. v. 4.) to say nothing of the four lepers sitting at the gate of Samaria, who afterwards returned to communicate the news of the desertion of the Syrian camp. (Ibid. chap. vii.) And in after times the leprosy had free access to Christ, and joined in the crowds that followed him. (St. Matthew, chap. viii.) They were also inhabitants of the towns and villages; for Jesus was "in the house of Simon the leper, in Bethany." Ibid. chap. xxvi. v. 6.

These facts, then, afford more than presumptive evidence, that the Hebrew leprosy, the *leuce*, or *vitiligo alba*, was not a contagious disease, any more than the white fealy leprosy, which is common in our own time. And there is much reason for believing, that even the tuberculated leprosy, or elephantiasis, was equally void of contagious qualities, as we shall presently state, notwithstanding the strong assertions to the contrary among the ancients. We have already observed, however, that the latter was considered as a consequence of the white leprosy in many instances, or as the same disease, in a more severe degree; for the lepra was said to change into elephantiasis (Galen. de Tremor. præter Nat. cap. 13.) and this author also mentions two cases, in which, on the contrary, elephantiasis was changed into lepra by a particular mode of treatment. Galen, de Simplic. Med. Fac. lib. xi.

Little can be said, that shall possess any interest, respecting the treatment of the *leuce*, or Jewish leprosy. It was generally deemed an incurable disease in ancient times, and is almost unknown, we believe, at present in Europe. It still, perhaps, appears occasionally in Iceland, and other northern regions, as a precursor, or as a modification of the

elephantiasis, according to the observation of a late intelligent traveller in the island just mentioned. He states, that he saw a woman affected with a horrible disease, which is there called *Lilibræu*, by which her face was so corroded as to present a most disgusting spectacle. "Her legs and hands," he adds, "were swollen to an enormous size; these latter being also covered with a *thick and almost white skin lying in great wrinkles.*" (Hooker's Journal of a Tour in Iceland, p. 186.) The thickened and rugous skin, with the ulcerations of the face, belong to elephantiasis; while the morbid *vitiliginis* is characteristic of leuce. Mr. Hooker also expresses his opinion, that this disease was not contagious. No light has been thrown upon this disease by a still later traveller in the same island, who has recounted the symptoms of elephantiasis, as commonly given in books, and apparently added nothing from personal observation. (See Mr. Holland's Paper on the Diseases of Iceland, in the *fir G. Mackenzie's "Tour"* in that island, just published. Dec. 1810.) Professor Hensler mentions a case, which he once saw for a few minutes, and which appears to have resembled that mentioned by Mr. Hooker. "The whole countenance was puffed up; the cuticle was of a dirty white, or whitish-grey colour, dry and shrivelled; but soft to the touch, as if distended with a watery fluid; with fissures here and there, from which some exudation took place." The cuticle also exhibited some furfuraceous and powdery exfoliations. Hensler remarks, that the comparison (applied by Aaron to his sister Miriam, in Numbers, chap. xii. v. 12.) of such a person to a dead and macerated *fatius*, is a most happy illustration of the appearance. ("Let her not be as one dead, of whom the flesh is half consumed, when he cometh out of his mother's womb.") The physician who attended the patient, seen but once by Hensler, compared the appearance of the skin to that of thick, stiff, dried leather; it was so thick, that an experienced surgeon made several attempts to open a vein, without success, in various parts of the body. There was great swelling, stiffness, and tension of the eyelids, with a frequent ophthalmia, and great sensibility to light. A thick and fetid crust covered the scalp. She was twice so nearly cleared of the leprosy, so as to go out of doors again; the first time by large doses of conium with sublimated mercury; the second, by tincture of cantharides, after antimonials and mercurials had increased the symptoms. A third time she was improving much, under the use of small doses of arsenic, which, however, was necessarily omitted, and she ultimately died. (Hensler vom Abendländischen Aufsatz 3<sup>er</sup> Abchnitt. § 11. p. 351.) It is worthy of remark, that the leprosy, in this case, suspended a pulmonary consumption, the symptoms of which never afterwards returned.

Of the *causes* of this form of leprosy, we shall say nothing, until we come to treat of the leprosy of the middle ages.

With respect to the *leprosy of houses and of clothes*, mentioned in the Mosaic code, it is probable that the expression was merely analogical, the spots and discolourations which appeared upon the walls and articles of apparel being looked upon as resembling the leprosy spots; while, at the same time, as they were most probably the consequence of humidity, the appearance of them might either actually accompany, or precede and prognosticate, diseases in the inhabitants of the houses and wearers of the garments. (Levit. chap. xiii. and xiv.) It is no where said that the disease, called leprosy, is capable of being communicated to the inhabitants or wearers, in these cases; but that it is unclean. The garments were ordered to be burnt, and the stones to be taken away, and replaced by others, or the house ultimately

## LEPROSY.

to be destroyed, when, after certain inspections by the priest, the greenish or reddish spots in them continued.

**Leprosy of the middle ages.** The history of Europe, from the sixth to the fifteenth century, is scarcely less full of the descriptions of the physical distresses of the people, occasioned by famine, pellence, and diseases of the most loathsome and fatal kind, than of the political and moral evils which beset them. Among the maladies of those times, leprosy, under all the forms to which the term has been applied, appears to have existed so generally and unceasingly, as to have claimed a more universal attention than even the plague itself. It was one of the first subjects, on which the active benevolence of the early Christians exerted itself, and ultimately it absorbed a very large proportion of the wealth of Christendom, which was appropriated by the donations of the pious to the maintenance and relief of those who were afflicted with it. These immense charities, however, were at length administered under great abuses, and afford no accurate grounds upon which to calculate the extent of the prevalence of the malady.

In investigating the history of the disease in the middle ages, we shall probably find it sufficiently clear that the elephantiasis, or tubercular disease, (the *Lepros* of the translators of the *Arabians*;) was the principal form against which the precautionary laws were framed; but that almost all cutaneous diseases were popularly considered as of a leprosy nature; that, in fact, many mistakes were committed, and many wilful deceptions practised, by which other diseases were confounded with elephantiasis; and that its disappearance from Europe is probably the result of the amelioration of the moral and physical condition of society, which the progress of civilization and science has brought about.

The general opinion, which was prevalent among the Greeks and Romans, that leprosy diseases originated in Egypt, is in some measure confirmed by the particular consideration given to them in the first history of man; and the more copious and distinct description of these diseases, subsequently given by the Arabian physicians, as well as the accounts published by travellers in more recent times, (see those of Prosper, Alpinus, Tournefort, Niebuhr, Bruce, &c.) who witnessed their frequent occurrence in that and the neighbouring countries, have led to a common belief, that the infection was brought into Europe, in the eleventh century, by the armies that returned from the crusade. But independently of the doubts, which may be entertained, in respect to the contagious nature of *elephantiasis* and *leuc*, there is sufficient evidence recorded, especially among the transactions of the saints, in proof of the prevalence of leprosy in the west, at a much earlier period. Lepers are mentioned in many public acts, according to Muratori (*Antiquit. Ital. Med. Aevi. r. ii. diss. 16.*), in the sixth century; and Gregory of Tours speaks of a place, where these unfortunate persons were accustomed to wash themselves, as well as of a hospital appropriated for them. Gregory the Great, in the same century, likewise alludes to the subject, and particularly mentions one leper, "quem densis vulneribus morbus elephantinus defecerat." In the following century, Rhotaris, king of the Lombards, published an edict against lepers, by which they were considered as dead in the law, and enjoined not to come near to found persons, but to spritz them of their approach, by making a noise with a wooden clapper. There was a river near Atri, in Lombardy, famous in those times for the cure of leprosy; whence, in the eighth century, the Lombards were considered as a filthy leprosy people: and the wise pope Sylvester, upon the plea of leprosy, dissuaded the king of

France from marrying a Lombard princess. So early as the eighth century, St. Othmar, in Germany, and St. Nicholas de Corbie, in France, instituted leprosy houses, which had been already numerous established in Italy. King Pepin, in 757, and Charles the Great, in 789, issued ordinances, by which the marriages of lepers were dissolved, and their association with the healthy prohibited. In the life of St. Athanasius, in the ninth century, lepers are also mentioned; and indeed, in general, the acts of the saints, compiled by the Bollandists, are replete with examples of the malady, throughout Europe, in the middle ages; even in the life of St. Antoninus, so early as the fourth century, a case of leprosy, "horrendissima elephantia lepra," is mentioned. Muratori, *loc. cit.*: also Raymond, *Histoire de l'Elephantiasis*, p. 107; Henfler, *über den Aufsatz*, p. 211.

These facts imply the general prevalence of leprosy in Europe, long antecedent to the Crusades. It is clear, however, that many severe diseases afflicted Europe to a much greater extent, and with augmented virulence, about the period when those fanatical expeditions were executed, or rather from the tenth to the sixteenth centuries, than before; and, among the rest, the leprosy appears to have been everywhere prevalent. Every country abounded with its hospitals, established for the exclusive relief of lepers, although the number of these institutions has been probably exaggerated. Several authors have, by an error in translation, quoted Matthew Paris (*Hist. Angl. ad annum 1244*) for an assertion, that *nineteen thousand* lazarettos existed in Christendom; but that author only states, that the hospitals were, at that period, possessed of 19,000 *manors*. "Habent hospitalarii novem decim millia maneriorum in Christianitate." It is affirmed, however, that Lewis VIII., king of France, made bequests, in the year 1227, to two thousand *leproseries* within his own kingdom. (Raymond, *loc. cit.* 106. *Collect. des Hist. de France*. Du Cange, *Gloss. voc. Lazari*.) In this country, there were a great number of these establishments. It is affirmed, that the city of Norwich alone contained five. (Sprengel, *Geschichte in Theil*, p. 491; who quotes Hutchinson, in the *Polit. Mag.* for Feb. 1789, p. 93.) The most extensive institution of this kind was in Leicester-shire, at a place thence called Burton-Lazars; it was founded in the reign of king Stephen, and dedicated to the Virgin and St. Lazarus, and became possessed of immense riches; so that all the inferior lazaretto-houses in England were in some measure subject to the master of it, as he himself was to the master of the lazars at Jerusalem. (See Nichols's *Hist. of Leicester-shire*.) In London there were six, according to Becket, the largest of which was that of St. Giles, without Temple Bar.

Moreover, the general existence of leprosy diseases is farther evinced by the creation of an order of knighthood, which sprung from the singular combination of military ardour with a zeal for the religion of peace, so prevalent in those times. In the parable of the rich man and the poor man covered with ulcers, recorded in the New Testament, the latter was mentioned by the name of Lazarus; whence the devout disposition of the times invented a St. Lazarus, whose name was given to the order of knighthood, and who was deemed the tutelary saint of the leper-houses, and of each individual leper. So far, indeed, did the mistaken piety of the age extend, that not only was every man, who returned from Palestine affected with foul sores, deemed a saint, *Lazarus*; but was particularly recommended to the devout, as one under the special punishment of God, for the benefit of his soul. Wherefore pious persons of the highest rank believed that they could bring themselves no greater

favour in the eyes of the Deity, than by their attention to these holy sufferers, by washing, killing, and even licking their wounds. Not only priests and archbishops, but even kings are recorded to have performed this nauseous piety at certain seasons. King Robert of France, and Louis IX., have been particularly mentioned as practising these ceremonies. (Du Cange. voc. *Lazarus*. Joinville Hist. de St. Louis. Sprengel, Geschichte, ii. 489, &c.) The knights of St. Lazarus had the double duty assigned them of holy warriors and attendants upon lepers; and the lazarettos were placed generally under their controul. Lepers, indeed, were admitted into the order, and the master of it was also required to be a leprosy knight. (Möchlen de Medicis equalitri dignitate ornatis, p. 56. quoted by Hensler.) The immense wealth, which they accumulated, became at length, however, a temptation to the rapacity of some sovereigns; and Philip V., especially, accused all the hospitaliers in France of high treason, by conspiring with the Turks and Jews, seized their property, and ordered them to be burnt. Sprengel, loc. cit. Mezeray Hist. de France, ii. p. 71.

We may observe, by the way, that the application of the name of Lazarus to every thing relating to leprosy, affords another proof of the very vague manner in which the subject has been generally considered. For not only was the disease of Lazarus not termed leprosy by the divine speaker of the parable; but the statement that his body was "covered with sores," neither represents the picture of the Jewish leprosy, nor of the elephantiasis, nor yet of the lepra of the Greeks. (See a learned diss. by Fred. Hoffman, "De Morbo Lazari," in his works, Supplem. tom. iii. p. 553.)

In all the towns, where lazarettos were established, medical officers were appointed by the police, to examine all persons, who were supposed to be affected with leprosy, previous to their seclusion in those receptacles; indeed, where no such establishments existed, huts were erected a little way out of the towns (where also the hospitals were generally placed) for each individual leper. The rules and edicts, with regard to the conduct of the lepers, were, as far as the circumstances admitted of it, nearly copied from the Mosaic laws. It is obvious, however, from the writings of those physicians, who held the office of examiners after the revival of learning, and indeed it was avowed by them, that the tubercular leprosy, or elephantiasis, was the disease, to the detection of which their inquiries were particularly directed. The earliest writers, who appeared in the dawn of modern learning, (and several of whom added original observation to what they borrowed from Avicenna, and the other Arabians,) described the elephantiasis under the appellation of lepra. (See the works of Guid. de Cauliaco; Gul. de Saliceto, and the Compendium Medicinæ of our learned and able countryman, Gilbertus, who lived about the reign of Edward I., and has left a description of leprosy, so full and minute, as to evince a considerable share of personal observation, notwithstanding the charge of plagiarism from the monk, Theodorick, which Dr. Friend enforces against him.) Greg. Horst, who was one of the appointed examiners at Ulm, in Bavaria, at the end of the sixteenth century, has left us the particulars of the examination, usually practised by himself and his colleagues, when summoned by the magistrates for that purpose. After the preliminary questions relative to the age and family of the person brought before them, they examined him respecting the existence of the disease in his parents and progenitors; his habits of life and his associates, with a view to the probability of contagion; his peculiar temperament, and previous state of health, and particularly as to the sup-

pression of customary evacuations; and then as to the climate, soil, habitation, and diet, to which he had previously been accustomed. They then questioned him, *seriatim*, as to the state of all the functions, mental and corporeal: and lastly, denudatis partibus omnibus, they examined the whole body, with a view to ascertain the presence or absence of the following external symptoms. First they inspected the head, to see whether the hair was beginning to fall off; whether that of the beard was becoming softer and thinner; and that of the eye-brows and eye-lashes was disappearing; and whether, when the hairs were pulled up by the roots, a part of the skin was brought away with them; whether the eyes were round and grim, the ears acuminated, the lips thick, the nose tumefied externally, the nostrils internally stuffed and ulcerated, the face unequally swelled with tubercles, and of a livid red hue? Whether the veins under the tongue were enlarged with tubercles, as if varicose? Whether the skin was unctuous, so that water ran off it, or there were under it tubercles nearly without sensibility, especially behind the ears, and on the extremities? Whether the skin was rough, like that of an unfeathered goose, or affected with horrid fissures, and *rugæ*, resembling the hide of an elephant, or covered with warts, like the *grandines* of swine, or affected with *morphea*, *impetigo*, or a dry and incurable *scabies*? Whether there were any nodes about the joints? Whether the muscles of the extremities, especially about the thumbs, were emaciated? Whether the nails were incurved? Whether the skin was sensible to the puncture of the surgeon's needle? Whether there were offensive ulcers, with a bad habit of body, especially ulcerations and fissures in the fingers and toes? and whether the voice was hoarse and obtuse? They then drew some blood, for the purpose of examining it. "These symptoms being present," says the author, "we deem the disease elephantiasis, and decree that the patient, inasmuch as he is affected with an incurable and contagious lepra, is to be separated from all communion with the healthy." Gregor. Horstii Obs. Med. lib. vii. Obs. xviii. Epit. J. H. Hopfner.

It is obvious, however, from the acknowledgment of Horst himself, as well as from the concurring observations of several physicians before his time, that the elephantiasis was by no means the only disease of the kind admitted into the lazarettos. He goes on to observe, that where the tubercles of the face, the thick lips, acuminated ears, flattened nose, round eyes, (the essential symptoms of elephantiasis) are absent; yet where the patients are affected only with a dry and foul scabies, with pustular eruptions, fissures, and branny exfoliations, which constitute the *psora* of the Greeks; or even with great itching, emaciation, ulceration, and exfoliations of thicker scales, affecting also the head and face, which are the *lepra* of the Greeks; nevertheless they are sent to the lazarettos, if they are poor, for the means of subsistence. "Hence it happens," he adds, "that here, and elsewhere, very few instances of real elephantiasis are found in the lazarettos, whilst many are there, affected only with an obnoxious *psora* or *lepra Græcorum*." We have also the direct testimony of an able observer, Van Foreest, (better known by his Latin appellation, Forestus,) who practised at Alcmæra and Delft, in the middle of the sixteenth century, and who has also left an account of the mode of examination of lepers, adopted by himself, that a very small proportion of the persons, who wandered about the Low Countries, as lepers and beggars, were true lepers; but were merely affected with scabies, or some external derangement of the skin. "Nay," he says, "not one in ten of them is truly a leper, or afflicted with the legitimate elephantiasis." And he adds the authority of a physician at the Hague, who had, with

## LEPROSY.

with him, lamented the carelessness or ignorance of the public examiner at Harlem, by whom a great number, (*quem plurimi*), who were the subjects of some ordinary cutaneous eruption, were declared leprous. (See Forelli, *Observ. Chirurg. lib. iv. Obs. vii. Schol.*) But, above all, Riedlin, who was physician to the leper-house at Augsburg, affirms that, out of *fifty-nine* cases, he saw but one which was elephantiasis, and that in a slight degree; all the rest were instances of the *psora* and *lepra* of the Greeks. (See Shroock, *Misc. Ann. 1669, p. 61*, and Hensler, *loc. cit.*) It is probable, moreover, that in addition to all the ordinary cutaneous diseases, which were thus denominated leprosy, the *scurvey* itself (we mean the true *scorbutus*, which was formerly so well known in our fleets, and which appears to have been not unfrequent in the middle ages, during periods of scarcity and famine) was confounded with the fame disease. This idea was thrown out by Hoffmann. "Quando mecum perpendo hodierni veri scorbuti symptomata, vix mihi temperare possum, quin, iis cum additionibus elephantiacorum collatis, scorbutum leviozem elephantiasos esse speciem asseram; at inde miram morborum pro diversa regionum ac aeris constitutione mutationem considerem. Sed transeat hæc conjectura, digna quæ penitus investigetur." (*De Morbo Lazari, § v.*) Prof. Sprengel also suspects that those forms of leprosy, which have been called *mal de la rosa* in Asturia, and *pellagra* in Lombardy, were scorbutic (*Gesichte der Arzneykund, ii. 486.*); and many analogies between the two diseases are pointed out by Raymond. *Hist. de l'Elephant. p. 118, et seq.*

These leprous complaints began to decline in number and violence, in Italy, about the end of the sixteenth century, and in France and Europe, in general, in the sixteenth. In the middle of the sixteenth century, indeed, the tubercular disease, elephantiasis, was almost unknown in Italy. For Ant. Beniveni, who died very old at the beginning of the sixteenth, observes, that he once saw at Florence a stranger affected with elephantiasis; a disease, he says, almost never seen (in his time) in Italy, and almost unknown to physicians. At the beginning of the sixteenth century, Alex. Benedetti and Joh. de Vego omit the tubercular leprosy from the list of diseases, mentioning it only cursorily, and not from experience; but the latter speaks fully of morphaea, impetigo, baras, alopecia, *mal morto*, and other diseases that have been classed with leprosy. (Hensler, *loc. cit.*) About the middle of the sixteenth century, Francis I. ordered the number of lepers in each lazaretto, or *maladrerie*, to be reported, and after appropriating a sufficient sum for their support, ordered the remainder of their revenues to be given to the grand almoner, for general use. In the seventeenth century, leper-houses were still continued, (though similar measures had been generally adopted since the decline of the disease throughout Europe,) and were greatly abused by the admission of beggars, and idle vagrants of all descriptions, who employed every species of trick to imitate leprosy, or to produce appearances of cutaneous disease. The elephantiasis itself, however, still occasionally appeared, of which several recorded cases are referred to by Hensler. Some writers, indeed, have supposed, that the changes, which took place from the close of the sixteenth century downwards, were rather changes of names than an actual disappearance or diminution of leprosy; and that the *venereal disease*, which was first noticed at that period, was in fact the leprosy with a new appellation. Indeed, some authors actually denominated the *morbus Gallicus*, or syphilis, a leprosy; as Campanella, who treats of it among other leprous diseases, under the title of *lepra Gallica*. (See his *Med. Prædict. lib. vi. cap. 23.*) But although the secondary

symptoms of syphilis might be mistaken for leprosy, or called leprous, in common with other ulcerations and cutaneous affections, in a considerable number of instances, and for some time; yet, as the learned and able Astruc, after Leonicens and others, has shewn, there were so many points of obvious and decided difference, in the symptoms and progress of the two diseases, as rendered such a confusion to any great extent improbable. (See Astruc, *de Morb. Vener. vol. i. lib. i.*) Nevertheless, when we reflect upon the unvarying adherence to ancient authority, which characterized the profession for centuries after the revival of learning; and when we consider, that the measles and small-pox, for instance, were deemed the same disease, including also scarlet fever, so late as the time of Diemerbroeck (see his *Tractat. de Variolis et Morbillis, cap. 13.*); we shall readily conceive, how slow the early physicians would be in acknowledging a new disease, which had not been mentioned by the Arabians, and with what facility they might confound it with the old, under a denomination so vaguely interpreted, as that of leprosy.

At all events, we are entitled to infer, from the preceding view of the subject, that, during the middle ages, most erroneous notions prevailed respecting the leprosy; and that the terrors of the ancients, respecting the contagious and unclean nature of *leuce* and *elephantiasis*, were transferred almost indiscriminately to every chronic cutaneous disease, whether scaly, scabby, pustular, or ulcerous, contagious or non-contagious, which then occurred. And as we are now well acquainted with the latter classes of disease, (although, from causes to be mentioned immediately, they may be much less frequent than formerly), as we know that all the forms of scaly disease, such as the modifications of lepra, psoriasis, ichthyosis, and pityriasis, to use Dr. Willan's nomenclature, as well as the running tetters, or impetigines, the vesicular eruptions, herpes, miliaria, and pompholyx, and the lichens, prurigo, &c. among the papulous affections, are all void of any infectious quality; we must be satisfied, on the one hand, how mistaken was the charity, which erected thousands of hospitals, and appropriated immense treasures, for the maintenance of those who were affected by these disorders, and for the fancied security of the healthy; while, on the other, we see the cruelty and absurdity of the regulations and ceremonies, which were instituted in regard to such patients, somewhat after the manner of those enjoined in the thirteenth chapter of Leviticus, for the Jewish lepers. In fact, a person affected with the real or supposed leprosy, was treated like a dead body: funeral obsequies were performed, and masses said for the benefit of his soul. The whole is thus described by a French writer.

"A priest, clothed in a surplice and stole, repaired with the cross to the leper, who was prepared for the ceremony. The holy minister began by exhorting him to bear patiently, and in a spirit of resignation and penitence, the incurable affliction with which God had stricken him; he then besprinkled the sufferer with holy water, and conducted him to the church. Here the leper put off his ordinary clothes; and, having put on a black habit prepared for the purpose, fell on his knees before the altar, between two trestles, and heard mass; after which he was again sprinkled with holy water. This ceremony, it will be remarked, differed very little from that which is usually performed at funerals. While the leper was conducted to the church, the same verses were sung as at burials, and after the mass, which was also the same as that which was performed for the dead, the *libera* was sung, and the leper was then conducted to the house destined for him. When he had arrived, the priest again exhorted and consoled

consoled him, and threw a shovel-ful of earth on his feet. The hut (where there was no lazaretto) was small, and was furnished with a bed and bedding, a vessel for water, a chest, a table, a chair, a lamp, a towel, and other necessaries. He was presented with a cowl, two shirts, a tunic, and a robe called *houffe*, a little cask, a funnel, a rattle (*des cliquettes*), a knife, a stick, and a girdle of copper.

"Before the priest quitted him, he interdicted him from appearing in public without his leper's habit and naked feet; from going into churches, mills, or where bread was cooking; from washing his hands and clothes, &c. in the wells and brooks; from touching any commodities that he desired to purchase at market, except with a stick, in order to point out the article wanted; and from entering houses, or taverns, for the purpose of purchasing wine, as he had only the privilege of remaining at the door, of asking for what he required, and receiving it in his little cask. He was farther enjoined not to draw water, but with a proper vessel; never to reply to the questions of any one who met him on the road, unless he was to *leeward*, in order that the inquirer might not be infected by his breath, and the contagious odour exhaling from his body; never to place himself in narrow roads; never to touch children, nor to give them any thing which he had touched; never to appear in public meetings; and never to eat or drink with any but lepers. In short, these wretched people were regarded as dead among the living: their children were not baptized at the fountains; and the water employed at their baptism was thrown into lonely places. When a leper was sick, the priest administered the sacrament to him, and extreme unction; and when he died he was buried in his hovel, or in the place of interment appropriated for the leprous." See *Ogé's*, *Abregé de l'Hist. de Bretagne*, prefixed to the *Diction. de Bretagne*.

In most places these miserable outcasts were allowed to enter the towns, near which their hovels or lazarettos stood, at certain times of the year, especially about Easter and Christmas. The following law existed at Marseilles. "Prænti constitutione firmamus deinceps observandum, quod nulli Leprosi seu Mezelli, *divites vel pauperes*, possint vel debeant stare infra Massiliam, nec conversari deinceps, nisi tantum per xv dies ante pascha, et per viii dies ante Natale Domini, &c." (*Stat. Massil. lib. v. cap. 15.*) When they walked, or came into a town, they made a noise with their rattles, to warn passengers of their presence. In short, their situation was truly melancholy. The ties of marriage were dissolved, where one of the parties only was affected; but they were allowed to marry when they could find a leprous companion. They were, indeed, allowed the usufruct of property; but they could neither transfer nor inherit it: they were deemed to have suffered a civil death, and to be "hors de la loi mondaine." See *Hensler*, loc. cit. § 4. *Sprengel*, loc. cit. p. 491-2. *Raymond*, p. 112.

Yet not only were these laws executed against multitudes who were affected with cutaneous diseases, neither properly leprous nor contagious; but it is even very questionable whether the true tubercular elephantiasis itself, any more than the less formidable *baras alba*, or *lucca*, were actually contagious. We have already stated the reasons which tend to disprove the infectious nature of the latter. (See *LEPROSY of the Jews*.) The evidence against the probability of contagion, in the case of elephantiasis, rests partly upon the facts, which are casually mentioned, in more ancient times; and partly upon those which have been more carefully and correctly ascertained nearer to our own. The observations of *Aretæus*, which have been echoed by almost

all succeeding writers, are given with an appearance of terror, excited rather by an acquiescence in the popular belief, than from any actual knowledge of the fact. When we descend to the early ages of Christianity, we find these terrors perpetuated by the laws respecting lepers, which were at once the effect and the cause of a continuation of the popular opinions; but at the same time, we find kings and bishops mixing familiarly and frequently with these very objects of legal proscription, and condescending to offices which require the closest contact with their persons, not only without any expressions of apprehension, but without any one recorded instance of the disease being so communicated: we find, too, that for a term of several days, during certain fairs and festivals, these infected people are actually allowed to mix in the towns; facts which stand in direct contradiction to the traditional prejudices and laws upon the subject.

Defending, still farther, to the period when learning and observation had again enlightened the minds of men, we find these very prejudices and laws extending equally to a numerous tribe of cutaneous disorders which we know are not contagious, as to the elephantiasis; an error which must render the accuracy of the opinion, as to the contagious quality of the latter, exceedingly questionable. At the same time we discover the contention between observation and pre-conceived opinion in the minds of the learned, which almost breaks forth in the admission of the truth. Thus *Fernel*, who adopted the common notion of its contagious quality, admits, nevertheless, that from all the observations he has been able to make, he has never discovered a case which proved its existence (*De Morb. Occult. lib. i. cap. xii.*); and *Forestus*, *Fabricius*, *Plater*, &c. who still held the popular opinion, expressing their astonishment at seeing the daily commerce between the leprous and healthy, even in married persons, without any communication of the disease; so that they are compelled to ascribe its origin to certain qualities of the air and the diet.

When we come to the evidence of our own times, we have still more convincing testimony of the non-contagious nature of the tubercular leprosy. *Dr. Thomas Heberden*, still retaining somewhat of the prejudices of education, when speaking of the cases of the disease which he saw at *Madeira*, says, "Notwithstanding the just abhorrence which every one entertains of this loathsome disease, it certainly is not so contagious as is commonly imagined;" and then he relates his observations, which prove that it is *not* at all contagious. "For I have never heard of any one," he adds, "who has contracted the distemper by contact of a leper; and, on the contrary, I not only am a daily witness of communication between lepers and other people, without the least ill consequences, but know several instances where a leprous husband, married to a sound wife, has cohabited with her for a long series of years, and had several children by her, without her having contracted the least symptom of the disorder, although the children have inherited it; and *vice versa* between a leprous wife and sound husband." (*See Med. Transf. of the Coll. of Phys. vol. i. p. 32.*) Still more recently, *Dr. Adams* has investigated the nature of elephantiasis, in the same island, where there is still a lazaretto, near *Funchal*; and his observations not only confirm those of *Dr. Heberden*, as to the non-contagious nature of the disease; but they also shew that other mistakes, which originated probably in the terrors of the imagination, when the disease had acquired the appellation of *Satyriasis* (from the acuminate ears, flattened nose, and rugous front); namely, that so far from being possessed with a *libido inexpugnabilis*, the pro-creative appetite and power are gradually destroyed, if the disease arise in the age of manhood, and

## LEPROSY.

never developed if it commence before that of puberty. See Adams on Morbid Poisons, 2d edit. chap. 18.

It is true, that about the middle of the 18th century, Dr. Hillary had described the elephantiasis as occurring in the West Indies, with all the characteristics attributed to it by the ancients. But the description of that learned physician is but too obviously a transcript of the account given by Aretæus, uncorrected by his personal observation. (See his Obs. on the Dis. of Barbadoes.) In this the learned writer affords but one example, among a long series of medical scholars, in whom authority but too often dimmed the eye of observation, or distorted its view.

If the leprosy of the middle ages, then, were not contagious, whence did it originate and spread so widely? Probably the hint thrown out by Forelius, Plater, and others, and more fully developed in the excellent treatise of Raymond, already often quoted, may afford an adequate explanation of the fact; to wit, that the uncultivated and marshy condition of the soil; the consequent humid and miasmatic condition of the atmosphere; the salt, putrid, indigestible aliment, and the frequent scarcity even of that which the physical and political disorders of the times produced; the insalubrious condition of the towns and habitations, both in respect to bad situation, want of cleanliness, and other pernicious circumstances; in short, these combined evils, which appear to have existed in those times and countries where the leprosy, among other frequent and distressing maladies, prevailed, were, in all probability, the sources from which these cachectic diseases sprung.

It has been satisfactorily shewn, from a review of the domestic history of the times, in which frequent and fatal epidemics have raged, how much these were connected with the circumstances just enumerated (see EPIDEMIC, and HEALTH); and it is interesting to trace the diminution, and ultimately the total disappearances of these pestilences, in proportion to the amelioration of those physical and moral evils; and to discover, that while the happiness and comforts of man are extended by the advancement of civilization, the worst diseases that harass and shorten life are at the same time nearly extinguished. (See the excellent Obs. on the Increase and Decrease of different Diseases, by Dr. Heberden; also, Ann. Med. Register and Review.) If we turn from the febrile plagues to the more chronic maladies which are the subject of the present article, we find that they have generally gone hand in hand. (See SCURVY, LEONIS SACER, ERGOT, &c.) The history of the *furury*, in particular, affords an analogical illustration of the influence of the circumstances alluded to, in producing many of the loathsome symptoms enumerated among those of leprosy; especially the desquations of the skin, the swellings of the limbs, the ulcerations, fungous excrescences, fetid discharges, gangrenes, and loss of joints and limbs—appearances as hideous as any of those ascribed to leprosy.

Now, this disease has been banished from our fleets within the last half century, solely by the substitution of wholesome and digestible aliment, and by the adoption of ventilation and internal cleanliness; it has, in like manner, been subdued in Germany, and those parts of the north of Europe, where it prevailed fatally in the time of the Romans, in proportion as agriculture and the arts have changed the face of that once marshy and uncultivated region, and obtained a regular supply of nutritious and wholesome food.

If our space would admit of a review of the physical and political circumstances of the times, in which leprosy diseases have been so extensively prevalent, it would be easy to adduce ample proof that, from the beginning of history, these maladies have occurred under such states of society;

and that they have commonly visited, almost exclusively, those classes of society who were most exposed to the influence of those circumstances; namely the poor. Lower Egypt has, from the earliest antiquity, been subject to these diseases, and from the extensive inundations occasioned by the overflowing of the Nile, can never be rendered a dry or salubrious country. The ancient historians concur in their descriptions of its heavy and misty atmosphere, furcharged with vapours. (Strabo, lib. xvii.) The inhabitants ate a glutinous sort of bread made of the roots of the *lotus*, &c.; and used much fish in every fate; and having few trees, they had no wholesome fruits to conjoin with their diet. But how much more imperfectly the Hebrews were nourished in their long march through the wilderness of Arabia is obvious, and indeed recorded; to which all the insalubrious circumstances of a camp were added. Perhaps no combination of circumstances could be conceived more favourable, as well to the production of frequent pestilences, as to the excitement of those cachectic states of the body, in which scorbutic and leprosy affections originate, than the soil and marshes of an uncultivated land, the fordes and miasmata of an immense encampment, frequent scarcity of provisions, fatigue, and universal public anxiety and dissatisfaction, for the quelling of which the great leader had recourse to supernatural means.

It appears from the account of Prosper Alpinus, a professor of Pavia, who visited Egypt late in the sixteenth century, that both the lepra and elephantiasis of the Greeks were common among the poor at that period; and he attributes them to the causes above-mentioned. "They are compelled through poverty," he says, "to drink muddy and semiputrid water; they eat the flesh of camels and beef, and fish salted and half putrid, caught in the marshes and lakes; but they principally live upon a sort of cheese, immoderately salted and semiputrid, which is sold at a very low price." (De Medicina Ægyptiorum, lib. i. cap. xiv.)—a diet very much resembling that formerly used on ship board in long voyages; when, as we have been informed, the salted provision, which had been sometimes two years in casks, emitted an almost intolerable stench during its maceration, before being cooked.

Without attempting to trace the progress of leprosy diseases, in connection with the physical and political derangements in various countries, (a satisfactory sketch of which the reader will find in Raymond's treatise,) we shall merely exemplify this view of the subject by a slight notice of the state of Europe in the middle ages, when leprosy and pestilence of every species prevailed. From the fifth century, when the empire at length fell under the repeated assaults of the northern invaders to the tenth, the finest parts of Europe lay in a state of desolation, little cultivation was practised, all the arts were neglected or lost, and clothing, habitations, and food were alike insufficient and unwholesome; and for three centuries more this desolation was increased, if possible, by the incessant wars that were waged. There were fourteen plagues in the fourteenth century, with intervals of but six years between each; and frequent famines. The food consisted, even in England at a later period, of much salted provision, especially in the winter, and of a hard and black bread, chiefly of rye, to the scarcity of which corn, rather than to its *ergoted* or diseased condition, the *ignis sacer*, *malus ardens*, and other similar maladies, should doubtless be attributed. So little were vegetables cultivated, indeed, or gardening understood, even in the sixteenth century in this country, that, in the year 1509, queen Catharine could not procure a salad, till Henry sent to the Netherlands, and engaged a gardener to come over to raise

raise the proper articles here. (Northouck's *Hist. of Lond* book. i. chap. 7.) How totally delitute of such diet must the people in general have been at a much later period! See *HEALTH of London*.

In short, in whatever country an uncultivated soil, a marshy surface, and a humid atmosphere have been found, together with a diet generally consisting of a staled, semiputrid, insufficient, or indigestible aliment, and composed chiefly of animal flesh or fish, with a small proportion of nutritious vegetable matter; there, from the earliest times, human life has been shortened by the multiplication of pestilential fevers and cachexias of a leprous and scorbutic nature. Therefore, as Raynold observes, even if the ecclesiastical writers of the middle ages had left us no records of the history of such maladies; the history of the soil, of the circumstances of the times, and of the food generally used, would afford an incontestible monument of the existence of leprosy.

Of the *cure*, or of the attempts to remedy a disease which was generally admitted to be incurable, it would be futile to enter into any detail. The treatment of those forms of cutaneous disease, which were classed with the elephantiasis, will of course be described under their respective heads.

LEPSIA, in *Ancient Geography*, an island in the sea of Rhodes, near the coast of Caria. Pliny.

LEPSINA, in *Geography*, a town of European Turkey, in Livadia, anciently called "Eleusis" of which considerable ruins remain; 12 miles N.W. of Athens. See ELEUSINIA.

LEPSIS, in the *Greek Music*, is a name given to one of the rules of the ancient melœpeia, called also sometimes, *cutbia*; by which the composer discerns in which of the three systems of sounds he should place his melody:—in the grave part of the scale, called *hypatoides*; the acute, called *netoides*, or the mean, called *mesoides*. See MELOPEIA and USUS.

LEPSTI, in *Geography*, a town of European Turkey, in the province of Macedonia, in the gulf of Saloniki; 12 miles S. of Jenitza.

LEPTA, in *Botany*, so called from λεπτός, *slender*, or *minute*, from the remarkable diminutiveness of its flowers. Loureir. Cochinch. v. 1. 82.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Hederaceæ*, Linn. *Vites*, Juss.

Gen. Ch. Cal. Perianth inferior, spreading, small, divided into four ovate segments. *Cor.* Petals four, somewhat triangular, furrowed, inflexed, twice as long as the calyx. *Stam.* Filaments four, awl-shaped, inflexed, inserted into the receptacle at the angle of the base of the petals; anthers ovate, two-celled. *Pist.* Germen superior, roundish, four-furrowed; style scarcely any; stigma obtuse. *Peric.* Berry four-lobed, lobes ovate, slightly confluent towards the centre, single-seeded. *Seeds* roundish.

Ess. Ch. Calyx four-cleft, inferior. Corolla of four triangular petals. Berry four-lobed, four-celled, each cell containing a seed.

1. *L. triphylla*. Loureir. Cochinch. A native of woods in Cochinchina, and called by the natives Cay Mat.—This tree is about ten feet high, and exceedingly branched. *Leaves* ternate, lanceolate, entire, waved, smooth. *Flowers* white, very small, in compound, small, axillary clusters.

We are acquainted with this plant from Loureiro's account only, which approaches so nearly to many different things, that we dare not offer any conjecture respecting it. The habit of this genus very much resembles that of *Cissus*, but the character of its fruit appears to be essentially different.

LEPTADENIA, from λεπτός, *slender* or *sharp*, and ἀδή, *adans*, a gland, expressive of the contracted acute termination of the masses of pollen, which makes a very peculiar

part of the generic character. Brown *Asclep.* 23. Mem. of the Wernerian Soc. v. 1. 34.—Class and order, *Pentandria Digynia*. Nat. Ord. *Convolv.*, Linn. *Apocincæ*, Juss. *Aclepiadæ*, Brown.

Ess. Ch. Corolla somewhat wheel-shaped; tube short; orifice crowned with five scales, standing between the segments; limb bearded. Crown of the filaments wanting. Anthers unconnected, simple at the top. Masses of pollen erect, attached by their base, contracted and pellucid at the summit. Stigma pointless. Follicles . . . . .

Mr. Brown has examined three species, reducible to this genus, in the Banksian herbarium, none of which are yet described, nor has he named or defined them specifically. One was gathered by Forkall. They are all natives either of the East Indies, or of Africa. They appear to be perennial, herbaceous, climbing plants, clothed with a greyish, impalpable, powdery down. *Leaves* flat, opposite. *Umbels* between the footstalks, sometimes cymose. *Stigma* minute.

LEPTANTHUS. See HETERANTHERA.

LEPTASPIS, from λεπτός, *slender*, and ἀσπίς, a shield, a genus of grasses, separated from *Pharus* by Mr. Brown in his *Prodr.* Nov. Holl. v. 1. 211, on account of the peculiar ovate concave outer valve of the corolla; but its habit and inflorescence are so like *Pharus latifolia*, that the author himself candidly expresses his doubts of the propriety of this measure. One species was found by sir Joseph Banks in the tropical part of New Holland; another comes from the Molucca Isles.

LEPTAUREA. See ZOGIA.

LEPTIS MAGNA, in *Ancient Geography*, a town of Africa, on the sea-coast, in the Syrtic region, at the S.E. extremity of that which was particularly denominated Tripolis; not far to the E. of the river Cinyphus. It was also called Neapolis. Leptis was a Roman colony, and in process of time became episcopal. See LEMPTA.

LEPTIS PARVA, *Lempta*, a town of Africa, on the sea-coast, S.E. of Adrymetum, about a mile in compass. Some ruins of the ancient town remain. See LEMPTA.

LEPTOCARPUS, in *Botany*, from λεπτός, *slender* or *sharp*, and καρπός, *fruit*, the minute seed or nut being pointed with the permanent base of the style. Brown. *Prodr.* Nov. Holl. v. 1. 250.—Class and order, *Diocia Triandria*. Nat. Ord. *Tripetaloides*, Linn. *Junci*, Juss. *Raffines*, Brown.

Gen. Ch. Male. *Cal.* of several coriaceous, keeled scales, either fasciculated or imbricated, each one or two-flowered. *Cor.* Petals six, membranous; the three inner ones thinner and narrower. *Stam.* Filaments three, flattish; anthers simple, peltate.

Female, on a separate plant, *Cal.* and *Cor.* as in the male. *Pist.* Germen superior, roundish; style solitary, thread-shaped; stigmas two or three, oblong, downy, acute. *Peric.* Nut small, roundish, not burbling, tipped with the base of the style, with one cell and one kernel.

Ess. Ch. Male. Calyx/scales clustered or imbricated. Petals six. Anthers simple, peltate.

Female, Cal. and Cor. as in the male. Style one. Stigmas two or three. Nut crustaceous, single-seeded, crowned with the base of the style.

A genus of hard rushy plants, of nearly the same description as *Lepidospenna*; see the conclusion of that article; but more akin to the Linnæan *Rellio*, from which it differs in having a simple single-seeded nut, instead of a capsule with two or three cells and as many valves. The stems are generally quite simple, leafless, but clothed with sheaths split at one side. Flowers either in tufts, or in spike-like catkins. Mr. Brown thinks those which come under the

first description may hereafter be separated from the latter. Examples of *Leptocarpus*, are *Reslio distachyos* of Rottboll's Icones 8. t. 3. f. 5, and *Schoenodum tenax* of Labillardiere, Nov. Holl. v. 2. t. 229, the female plant.—Seven species are defined as natives of New Holland, and there are supposed to be several at the Cape of Good Hope, besides the above *Reslio*, and *R. imbricatus* of Thunberg.

LEPTOCEPHALUS, in *Ichthyology*. See MORRIS.

LEPTODECARHOMBIS, a name given by Dr. Hill to some prismatic varieties of selenite. See GYPSUM.

LEPTOMERIA, in *Botany*, named by Mr. R. Brown in allusion to its slender habit; from *λεπτός*, slender, and *μερίς*, a portion or share. Brown Prodr. Nov. Holl. v. 1. 353.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Calycifloræ*, Linn. *Elaeagni*, Juss. *Santalaceæ*, Brown.

Gen. Ch. *Cal.* Perianth superior, of one leaf, in four or five deep, widely spreading, permanent segments, internally coloured. *Cor.* Petals none. Nectary glandular, crowning the germen, in four or five lobes. *Stam.* Filaments four or five, awl-shaped, shorter than the calyx, inserted into the base of each segment; anthers roundish. *Pist.* Germen inferior, ovate; style very short; stigma depressed, of from two to five rays. *Peric.* Drupa ovate, more or less juicy, crowned with the calyx. *Seed* solitary.

Ess. Ch. Calyx of one leaf, wheel-shaped, superior, bearing the stamens. Nectary glandular, crowning the germen, four or five-lobed. Stigma divided. Drupa of one seed.

Eight species are defined by Mr. Brown, as natives of New Holland. They are slender branched shrubs, with scattered minute leaves, or none at all. Flowers minute, white, reddish or green; generally spiked, with a small deciduous bractea to each; sometimes axillary, without bracteas. The genus is akin to those species of *Thegium* which grow at the Cape of Good Hope, but differs in its glandular nectary, which is either of one piece, lobed, crowning the germen, or composed of glands, each of which stands at the base of one of the segments of the calyx. Three of the species have a starry five-rayed acute stigma, and five-cleft, spiked, bracteated flowers; among which is *L. Billaudieri*, (*Thegium drupaceum*; Labill. Nov. Holl. v. 1. 68. t. 93.) from Van Diemen's land, a slender much-branched shrub, six feet high. One, *L. acerba*, found at Port Jackson, has a two-lobed obtuse stigma, four-cleft flowers, and no leaves. The remaining four have a drier drupa, a notched blunt stigma, and five-cleft flowers, and all grow on the south coast of New Holland.

LEPTOS LIBANOTIS, in the *Materia Medica of the Ancients*, a name given by some of the Greek writers to the small frankincense, that is, such as came to their hands in small flakes, broken from the larger masses in the gathering or packing up. This was also called *manna thuris*, the manna of frankincense, the word *manna* being of old used to express any thing formed of granules, or small pieces. The ancients esteemed this *leptos libanotis*, or *manna thuris*, when pure, beyond any other kind, for they always valued that frankincense most, which was driest and most brittle; and such only as was so, could break off in these small flakes. The medicine, however, soon became subject to adulteration, and lost its credit; for the dust of the frankincense being allowed to be put up among this *manna thuris*, Dioscorides tells us, that in his time people, greedy of gain, had found the way to adulterate it, by adding, instead of this genuine dust, the sifted powder of the resin of the pine-tree. See FRANKINCENSE.

LEPTOSPERMUM, in *Botany*, so named by Forster, from *λεπτός*, slender, and *σπέρμα*, seed, because the numerous

seeds are remarkably small and slender. Forst. Gen. 36. t. 36. f. f—l. Smith Tr. of Linn. Soc. v. 3. 260. Willd. Sp. Pl. v. 2. 948. Ait. Hort. Kew. ed. 2. v. 3. 181. Juss. 323. Lamarck. Dict. v. 3. 405. Illustr. t. 423. Gærtn. t. 35.—Class and order, *Scandria Monogynia*. Nat. Ord. *Heperidea*, Linn. *Myrti*, Juss.

Gen. Ch. *Cal.* Perianth half-superior, in five deep, ovate-oblong, or roundish, often coloured segments. *Cor.* Petals five, with claws, roundish, equal, twice the size of the calyx, and much longer than the filaments. *Stam.* Filaments numerous, inserted into the calyx, awl-shaped, incurved, shorter than the corolla; anthers small, roundish, two-lobed. *Pist.* Germen half-inferior, turbinate; style simple, columnar, erect, about the length of the filaments; stigma capitate, umbilicated, undivided. *Peric.* Capsule roundish, coated in the lower part, of three, four, or five cells, and as many valves, bursting at the upper part, the partitions from the middle of each valve, opposite to each calyx-tooth. *Seeds* numerous, linear, somewhat angular, tapering at each end, very small, inserted into the central column.

Ess. Ch. Calyx five-cleft, half-superior. Petals five, longer than the filaments, furnished with claws. Stigma capitate. Capsule of three to five cells. Seeds angular.

Obs. *L. ambiguum* only has the filaments longer than the corolla.

This genus of New Holland shrubs was confounded by Dr. Solander with *Philadelphus*, and by Gærtner, Forster, and others with *Metrofideros* and *Melaleuca*. The former is distinguished from it by having the style deeply four-cleft, with simple stigmas, the petals broad at the base and sessile, leaves opposite and deciduous, and the habit indeed altogether unlike; *Metrofideros* differs in its simple stigma, extremely long thread-shaped filaments, and more dilated habit, in which characters *Melaleuca* accords with the latter, with a few exceptions as to habit in the foliage of some species, but differs from it and from *Leptospermum* in the polyadelphous stamens.—The species of the genus before us are rigid, branched shrubs, of rather humble, sometimes prostrate, growth, aromatic when bruised; their leaves alternate, small, entire, evergreen; flowers numerous, usually solitary, white, often with a purple tinge about their organs of impregnation. The following are all at present known to us.

1. *L. scoparium*. New Zealand Tea, or common South-sea Myrtle. Andr. Repof. t. 622. (*L. squarofum*; Gærtner. v. 1. 174. t. 35. *Melaleuca scoparia*; Linn. Suppl. 343. Forst. Prodr. 37. Pl. Efc. 78. Schrad. Sert. Hannov. 25. t. 15. *Philadelphus scoparius*; Soland. in Ait. Hort. Kew. ed. 1. v. 2. 156. Tea plant; Cook's Second Voyage, v. 1. 100. t. 22.)—Leaves ovate, sharp-pointed, obscurely three-ribbed. Calyx smooth; its teeth membranous and coloured.—Native of the coast of New Zealand, where it was discovered by sir Joseph Banks and Dr. Solander, and was thought by captain Cook to have been very serviceable to the health of his crew. Its infusion or tea is pleasantly aromatic and fragrant; if not suffered to stand too long, in which case it becomes bitter. Mixed with an equal quantity of the New Zealand Spruce, (see DACRYDIUM,) it was found to make excellent and highly palatable beer, of the most salutary qualities, the *Dacrydium* being too astringent alone. This plant, raised at Kew from seed in 1772, is easily kept in our green-houses, and is covered in summer with elegant white blossoms, whose calyx-teeth, filaments and style are purplish. In New Zealand it becomes a small tree. The leaves are numerous, scattered, ever-green, small, nearly sessile, entire, sharp-pointed, rigid, smooth,

## LEPTOSPERMUM.

smooth, dotted, paler beneath, more or less ovate, but varying extremely in length and breadth, so that the two varieties indicated by authors are by no means distinctly marked, and the gardeners make many more, which are equally evanescent. The *capsule* is hard and woody, permanent on the old branches long after the seeds are dispersed, as in most New Holland plants of this family.

2. *L. stovefcens*. Yellowish South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 262. Willd. n. 3. Brown in Ait. Hort. Kew. ed. 2. n. 2. (*L. Thea*; Willd. n. 2. *Melaleuca Thea*; Schrad. Sert. Hannover. 24. t. 14.)—Leaves linear-lanceolate, obtuse, without lateral ribs. Calyx smooth; its teeth membranous, coloured, naked. Native of New South Wales. It was procured from thence for Kew garden, by sir Jos. Banks, about 1787. The *branches* are longer, and more flexible, than in the former; *leaves* narrower, longer, almost linear, inclining to elliptic, and pointless. *Petals* white, often with a purple tinge, turning yellowish in drying. The *calyx-teeth* are coloured, that is, whitish, not green; which Willdenow, in copying the character, has omitted, and this caused the same omission in Hort. Kew.

3. *L. attenuatum*. Fine-branched South-sea Myrtle. Sm. n. 3. Willd. n. 4.—Leaves linear, slightly lanceolate, acute, three-ribbed. Calyx clothed with silky hairs; its teeth membranous, coloured, nearly naked.—Native of New South Wales, sent to Kew by sir Jos. Banks in 1795. Its slender habit, and narrow acute *leaves* distinguish this from both the former. The *flowers* moreover are smaller, often two together, their stalks, *germen*, and base of the calyx clothed with silvery, silky, rather spreading hairs. *Petals* and *calyx-teeth* white. It blossoms from May to July.

4. *L. grandifolium*. Large-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 6. 299.—Leaves lanceolate, sharp-pointed, obscurely five-ribbed, downy beneath. Calyx hairy; its teeth membranous and coloured.—Sent from Port Jackson, New South Wales, in 1795, by Dr. White to Mr. Lambert. It is larger than any of the foregoing in all its parts; the *leaves* above an inch long, and near a quarter of an inch broad, lanceolate inclining to obovate, with a small prominent sharp point; shining and smooth above, except when young; paler, opaque, dotted, downy, and marked with two slight lateral ribs, on each side the principal one, beneath. *Flowers* large, white and handsome, sessile and solitary at the ends of the short lateral leafy branches. The back of their *calyx-teeth*, as well as the *germen*, is covered with long, white, shaggy hairs.

5. *L. trinerve*. Silky South-sea Myrtle. (*L. lanigerum*; Willd. Sp. Pl. n. 5. *Melaleuca? trinervia*; White's Voyage, 229. t. 24.)—Leaves lanceolate inclining to obovate, three-ribbed. Calyx silky; its teeth leafy, permanent.—Native of New South Wales; *Dr. White*. This has much the habit of the last, but is in all its parts only about half the size. The *leaves* vary in breadth, and are more or less obovate. The *germen*, with the *calyx* and its teeth, are entirely clothed externally with beautiful, close-pressed, silky or filvery hairs. *Petals* white.

6. *L. lanigerum*. Hoary South-sea Myrtle. Brown in Ait. Hort. Kew. ed. 2. n. 4. Sm. Tr. of Linn. Soc. v. 3. 263. (Philadelphus laniger; Ait. Hort. Kew. ed. 1. v. 2. 156.)—Leaves oblong or obovate, obscurely three-ribbed, somewhat hairy. Calyx clothed with long shaggy hairs.—Native of Van Diemen's land, and of New South Wales. In the Transf. of the Linn. Soc. this was confounded with the last, but Mr. Brown has corrected that mistake. The present species has the *germen* and whole *calyx* remarkably hoary with long spreading hairs, not silky with close or erect

ones. The *leaves* when young are more or less hairy, and the young *branches* downy. The scales of the flowering *buds* appear also to be larger and more permanent, imbricated, elliptical, and externally hairy.

7. *L. parvifolium*. Small-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 263. Ait. Hort. Kew. ed. 2. n. 5.—Leaves obovate, imbricated, ribless. Young branches and calyx clothed with spreading hairs; teeth membranous, coloured, naked.—Sent to us from New South Wales by Dr. White in 1795. It is said to have been communicated to Kew garden by sir Jos. Banks in 1789. The *leaves* are not a quarter of an inch long, numerous, imbricated, either obovate or exactly elliptical, blunt, flat, thickish, without any rib, dotted, smooth, on short pale smooth stalks. *Flowers* terminal, solitary, small, white. *Germen* and base of the *calyx* clothed with spreading hairs, but the teeth are naked, roundish and coloured. The younger branches are rough with coarse, long, spreading hairs.

8. *L. imbricatum*. Imbricated South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 6. 30.—Leaves obovate, imbricated, ribless. Branches and calyx smooth; teeth membranous, coloured, naked, keeled.—Gathered at Port Jackson, New South Wales, by Mr. David Burton, and communicated to us by sir Jos. Banks in 1797. It greatly resembles the last, but the copious little *leaves* are still more strikingly imbricated, especially on the long lateral *branches*, which moreover are smooth, as well as every other part. The *flowers* are extremely small, standing two or three together about the end of each branch; their *germen* and *calyx* perfectly naked; the teeth of the latter sharply keeled, which in *L. parvifolium* are only a little convex.

9. *L. arachnoideum*. Cobweb-flowered South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 263. Gærtn. v. 1. 174. t. 35. f. 3.—Leaves awl-shaped, sharp pointed. *Branches* hairy. *Germen* and calyx entirely clothed with long spreading hairs.—Native of New South Wales. The *stem* is stout, apparently of humble growth, with numerous, short, zigzag, leafy, hairy, lateral, compound branches. *Leaves* crowded, awl-shaped, sharp-pointed, smooth, dark-green, about half an inch long, channelled above, convex beneath, resembling some slender kind of juniper. *Flowers* small, solitary, terminating the short subdivisions of the branches, and remarkable for the very long and fine white spreading hairs, like a spider's web, which clothe the *germen* and whole calyx. It is a stranger to our gardens.

10. *L. juniperinum*. Juniper-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 263. Venten. Malmalf. t. 89.—Leaves linear-lanceolate, sharp-pointed. Young branches silky. Calyx smooth; its teeth membranous, coloured, naked.—Native of New South Wales. Mr. Fairbairn raised it in Chelsea garden about the year 1790. This is an upright bushy *shrub*, whose young branches are clothed with silky hairs. The *leaves* are larger, and still more like juniper, than those of the preceding; silky when young. *Flowers* numerous, white, solitary at the ends of the very short, lateral, axillary, leafy shoots. *Germen* depressed, smooth as well as the *calyx* and its teeth, which are broad and coloured.

11. *L. trilobulare*. Three-celled South-sea Myrtle. Venten. Malmalf. t. 88.—Leaves linear-lanceolate, sharp-pointed. Calyx silky; its teeth coloured, minutely fringed. Stamens fifteen. Capsule of three cells.—Native of New Holland. We know it only by the plate and description in M. Ventenat's superb Jardin de la Malmaison. The habit and foliage are much like the last. *Branches* downy and reddish. *Germen* rather more elongated, clothed with short silky down, as are also the *calyx-teeth*, which are fringed, and

coloured of a purplish red. *Petals* white. *Stamens* but fifteen, and cells of the fruit only three.

12. *L. baccatum*. Pulpy-fruited South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 264. (*L. juniperifolium*; Cavan. Ic. v. 4. 18. t. 331. f. 2.)—Leaves linear-lanceolate, sharp-pointed. Bractæas smooth. *Germen* and calyx-teeth downy. Capsule with a pulpy coat.—Native of New South Wales, sent to Kew garden by sir Jos. Banks in 1790. A low depressed rigid shrub, with the habit and foliage of our English dwarf variety of the juniper. *Flowers* much like some of those last described, but their *germen* and whole *calyx* with its teeth are clothed with white cottony, rather than silky, hairs. The *germen* is closely enveloped in smooth, somewhat fringed, concave bractæas, which, being taken for the *germen* itself, caused an error in the original description of this species; but indeed that part becomes smooth as it ripens into fruit, as well as very thick and pulpy. The *petals* are yellowish in the dried plant, but probably white when recent, like *L. flavescens*. Cavanilles's synonymy seems rightly applied in Hort. Kew. though he describes the *calyx* as smooth. The *fruit* in our plant, as well as his, has five cells.

13. *L. ambiguum*. Hook-leaved South-sea Myrtle. Sm. Tr. of Linn. Soc. v. 3. 264. Exot. Bot. v. 1. 115. t. 59. (*Metrofideros corifolia*; Venten. Malmaif. t. 46.)—Leaves linear-lanceolate, recurved at the point. Calyx nearly smooth; its teeth leafy, lanceolate, naked. *Stamens* longer than the corolla.—Native of New South Wales, sent to Kew garden by sir Jos. Banks in 1791. It forms a handsome bushy evergreen shrub, blossoming plentifully in the green-house in summer. The *branches* are downy. *Leaves* numerous, crowded, dark-green, channelled, dotted, bluntish, recurved at the tip, often roughish. *Flowers* white, with very numerous spreading *stamens*, that are peculiar in this genus as being longer than the *corolla*, yet not near so long as in *Metrofideros*, and the capitate *stigma* stamps our plant a *Leptospermum*, which the habit altogether confirms. Ventenat describes the *germen* as of three cells only; we find four or five, so that this character appears variable.

14. *L. virgatum*. Wand-like South-sea Myrtle. Forst. Gen. 36. Willd. n. 12. (*Melaleuca virgata*; Linn. Suppl. 343. Forst. Prodr. 37.)—Leaves opposite, linear-oblong, bluntish. Stalks axillary, three-flowered.—Gathered by Forster in New Caledonia. As Willdenow has admitted this into *Leptospermum*, we would not leave it out, notwithstanding the reasons given in Tr. of Linn. Soc. v. 3. 265; which strongly induce us to think it a decadrous *Bacca*. The *stamens* are ten. *Leaves* opposite, whereas in every certain *Leptospermum* they are alternate. The umbellate *flower-stalks* too are not natural in this genus.

15. *L. pubescens*. Downy Twisted South-sea Myrtle. Willd. n. 6. See Tr. of Linn. Soc. v. 3. 263.—Leaves elliptic-obovate, downy, twisted, with a small recurved point. *Germen* and calyx-teeth downy.—Native of New Holland, common in gardens. We subjoin this as a species taken up by Willdenow from the Linn. Transf. but whose limits we have not yet fully determined. It does however seem distinct enough from *laniger* and *trinerose*, as well as from all the rest. Much more light is to be expected relative to all the species of this genus from the sequel of Mr. Brown's Prodrömus, and we therefore leave these two last species for future determination, especially as the *pubescens* is not received into the second edition of Hort. Kew.—For similar reasons we leave unnoticed the three species figured in Cavanilles, t. 330 and 331, which most probably are referable to some of the above; but his plates and descriptions are insufficient to de-

termine which, and would therefore still be useless, if by any means determined.

LEPTOSTACIYA, from λεπτός, slender, and σταχυς, a spike of flowers, elegantly applied by Mitchell to the *Phryma* of Linnæus, and retained by the latter as the specific name. See PHRYMA.

LEPTOSTACIYA, from λεπτός, slender or narrow, and σταχυς, the mouth, expressive of the narrow orifice of the capsule. Brown. Tr. of Linn. Soc. v. 10. 320.—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Ess. Ch. Capsule oblong, without furrows, terminal. Lid hemispherical, without a beak. Fringe a simple, flat, annular, undivided membrane, from the inner coat.

All the four known species of this genus are natives of the southern hemisphere. They are mosses of a densely tufted mode of growth, with upright, branched, perennial stems. Leaves moderately spreading in every direction, broadish, entire, revolute, with a strong midrib, and a terminal hair, which is suspected by Mr. Brown to be sometimes branched. Fruit-stalk terminal. Capsule either erect or drooping; tapering at the base into an inversely conical apophysis; much contracted at the mouth. Veil smooth and naked, deciduous.

1. *L. inehuanus*. Tr. of Linn. Soc. v. 10. 320. t. 23. f. 2.—Leaves obovate, obtuse. Capsule drooping, obovate-oblong.—Found by Mr. Brown in Van Diemen's land, upon rocks and stones at the east side of Table Mountain, near the summit, in 43 south latitude, and from 3000 to 3500 feet perpendicular above the sea. This moss is two or three inches high. *Stems* but little branched, leafy in the upper part, densely clothed with rusty down below. *Leaves* rather concave, very minutely dotted or reticulated, tipped with a twisted hair  $\frac{1}{4}$ th the length of each leaf. *Fruit-stalk* brown, smooth. *Sheath* at the base accompanied below by numerous abortive pistils and capillary, jointed, succulent threads.

2. *L. erectum*. Leaves oblong-parabolic, obtuse. Capsules oblong, erect. Found by Mr. Brown on the east coast of New Holland, in a mountainous part of the country, growing on rocks near the banks of the rivers Hawkebury and Grose. *Stems* about as tall as the former, simple or branched, clothed with rusty down in their lower part, leafy above. *Leaves* crowded, a little incurved and close-pressed by drying, each tipped with a purple hair. *Fruit-stalk* elongated, brown, smooth. *Capsule* straight. The lid had fallen off.

3. *L. gracile*. Leaves ovate-oblong, rather pointed; terminal hair half their length. Capsule oblong, straight, drooping.—Gathered by Mr. Archibald Menzies, at Dusky bay in New Zealand. The *stems* are densely tufted, somewhat branched, about an inch high, thickly clothed with rusty down in their lower part. *Leaves* yellowish-green, dotted, close-pressed when dry, pellucid, strongly revolute, with a very thick rib, and a smooth terminal hair. *Fruit-stalk* near two inches high, slender, tawny, with a sheath at the bottom, the summit very slender and drooping. *Capsule* nearly pendulous, a quarter of an inch long, slender, straight, slightly swelling in the middle, of a dark opaque brown. Lid very small, obtuse, of a still deeper brown.

4. *L. Menziesii*. Leaves oblong-lanceolate, acute; terminal hair a quarter their length. Capsule cylindrical, drooping, recurved.—Discovered by Mr. Menzies at Statenland in 1787. We, as well as Mr. Brown, are indebted to him for fine specimens of this and the last. The *stems* of *L. Menziesii* are half an inch or more in height, mostly simple, with dense rusty fibres and roots. *Leaves* bright yellowish-green, crowded, finely dotted, wavy and close-

pressed when dry, with a shortish terminal hair. *Fruit-stalk* about an inch high, solitary, erect. *Capfulæ* light brown, smooth, one-third of an inch long, drooping, cylindrical, singularly recurved, with somewhat of a turgid appearance. *Lid* very small; after it is fallen the white, membranous, very delicate fringe becomes distinctly visible.

Mr. Brown with good reason suspects *Bryum macrocarpum* of Hedwig, Crypt. v. 3, t. 10, may belong to this genus. If so, there is an error in the delineation of its fringe; and it will prove the only known species whose leaves are tipped with a branched hair.

LEPTUM, in *Antiquity*, a small piece of money, which, according to some, was only the eighth part of an obolus; but others will have it to be a silver or brass drachm.

LEPTURA, in *Entomology*, a genus of Coleoptera: the antennæ are setaceous; palpi four, and filiform; wing-cafes tapering towards the tip; thorax slender and rounded. Those of the Linnæan lepturæ which have the lip entire, constitute the genus *Donacia* of Fabricius; and such as have the lip bifid form a part of the lepturæ of that author; for the latter do not exclusively consist of those insects which, according to the Linnæan character, belong to leptura; leptura abbreviata of Fabricius, for example, is *neocydalis* major of Linnæus, and leptura variegata, the Gmelinian *neocydalis* variegata. Most of the Linnæan tribe are furnished with legs of pretty considerable length; run with much speed and activity; and are found on flowers.

## Species.

AQUATICA. Golden; posterior thighs clavated and dentated. Fabr. *Leptura aquatica*, Linn. *Leptura aquatica spinosa*, Degeer. Donov. Brit. Inf. *Donacia dentata*, Hoppe.

The colour of this species varies from reddish, or brassy, to green; the antennæ blackish, with pale testaceous at the joints; head with a line down the middle; thorax grooved; body beneath downy; legs obscure, testaceous. Common in Britain, and other parts of Europe, on aquatic plants, particularly the nymphæa.

SIMPLEX. Golden; thighs simple. Fabr.

A European species, perhaps *leptura aquatica mutica* of Degeer.

FASCIATA. Golden; wing-cafes with a purple longitudinal band. Herbt. *Leptura aquatica fasciata*. Degeer.

Inhabits watery places in Europe. The thighs sometimes armed with teeth.

MICANS. Posterior legs bidentated; flanks simple; wing-cafes glossy-violet. Hoppe.

Allied to *L. aquatica*, and inhabits the same places.

HOLOSERICÆ. Shining-green; antennæ and legs fulvous, black; posterior thighs dentated. Herbt.

An European species, found in damp fields, &c.

PALUSTRIS. Blackish-violet; antennæ and legs chestnut; posterior thighs dentated. Herbt.

A native of Pomerania; found in marshes.

CINEREA. Cinereous, speckled with coppery. Herbt. Inhabits with the former.

MARGINATUS. Posterior thighs one-toothed; wing-cafes golden; margin and spot at the base rufous; abdomen and legs silvery. Hoppe.

On aquatic plants in Germany.

NYMPLÆÆ. Posterior thighs dentated; thorax and wing-cafes coppery; body cinereous, downy. Fabr.

A native of Europe, on the leaves of the nymphæa alba. The head is coppery; antennæ and mouth black; body beneath silvery-brown.

SAGITTARIÆ. Posterior thighs one-toothed; wing-cafes

green-golden, minutely punctured and truncated; abdomen and legs golden. Hoppe.

Antennæ blackish; thorax wrinkled and furrowed.

VIOLACEÆ. Deep black, and somewhat brassy; wing-cafes obscure, violet; abdomen sanguineous. Pallas.

Size of leptura aquatica, and inhabits Siberia.

ÆNEÆ. Posterior thigh armed with one tooth; wing-cafes brassy, equal, rounded; abdomen and legs brassy. Hoppe. *Leptura ænea*, Linn.

Native of Europe.

BICOLOR. Golden; thorax above, with the wing-cafes, green, the latter with stripe of impressed dots; posterior thighs dentated. Linn. Mus. Lest.

An European species.

FUSCÆ. Posterior thighs with a single tooth; body brown; wing-cafes striated and punctured; mouth, antennæ, and legs rufous. Linn.

Inhabits with the former.

CRASSIDÆ. Posterior thighs unarmed; body green-bronzed, beneath cinereous, brassy; wing-cafes striated with punctures, and marked with transverse small lines; mouth, antennæ, and legs rufous. Linn.

Native of Europe.

RUFESCENS. Posterior thighs dentated; body reddish-bronze; beneath cinereous-bronze; wing-cafes striated, punctured with crenated wrinkles. Linn.

Inhabits Germany and Sweden.

NITIDA. Posterior thighs toothed; body shining-green gold; wing-cafes striated and punctured, with crenated wrinkles, and a broad, common, purple-green fillet; abdomen, antennæ, and legs gold. Linn.

Native of Europe.

CÆRULÆ. Posterior thighs dentated; body blue; wing-cafes striated, punctured with crenated wrinkles; antennæ brassy. Linn.

Inhabits Europe.

CLAVIFÆ. Posterior thighs unarmed; body brassy; abdomen covered with silvery down. Fabr.

Native of Germany, on aquatic plants.

FASCICULATA. Body black; posterior legs long; thighs unarmed; the flanks with a tuft of long feathers. Fabr.

Inhabits Cayenne; the body very slender, with a silvery gloss beneath.

LINEARIS. Posterior thighs unarmed; wing-cafes linear, truncated, shining-brassy; legs somewhat testaceous. Hoppe.

A species found in Europe; antennæ blackish; abdomen cinereous.

HYDROCHARIS. Posterior thighs unarmed; wing-cafes cinereous, glossy, rounded at the end; body and legs cinereous. Hoppe.

Native of Germany; the antennæ cinereous.

MICRONATA. Posterior thighs unarmed; body above livid; beneath, head, and antennæ black; thorax with two divergent lines; wing-cafes spinous at the end. Hoppe.

VULGARIS. Posterior thighs unarmed; body silvery-green; wing-cafes striated and punctured, with crenate wrinkles, and a broad, common, purple-green fillet; head, abdomen, and legs silvery-ash.

## \*\* Lip bifid.

UNIPUNCTATA. Black; wing-cafes rufous, with a black dot in the middle. Fabr.

Inhabits about Dresden.

HASTATA. Deep black; wing-cafes red; tip and future in the middle black. Fabr. *Stenocorus niger*, &c. Geoffr.

Native of the southern parts of Europe. Segments of the abdomen with silvery down at the edge.

## LEPTURA.

- BIPUNCTATA.** Black, villous; wing-cafes livid, with a black dot in the middle. Fabr.  
 Inhabits Siberia.
- TOMENTOSA.** Thorax villous and golden; wing testaceous, with the tip black. Geoff.  
 Head and antennæ black; wing-cafes smooth, slightly notched at the tip; abdomen covered with silvery down; tail emarginate; legs black.  
 Native of France.
- MELANURA.** Black, wing-cafes reddish or livid, the future and tip black. Schæff.  
 Inhabits Europe on flowers.
- LÆVIS.** Black; wing-cafes and legs livid, future, and tip of the wing-cafes black. Fabr. *Leptura futuralis*.  
 Antennæ black; body clothed with silvery down. Native of Europe.
- LIVIDA.** Black; wing-cafes testaceous and without spots; legs black. Herbit.  
 Wing-cafes rounded at the tip, and scarcely emarginate. Native of Germany.
- VILLICA.** Ferruginous; antennæ, wing-cafes, and breast brown. Schæff., &c. Fabr.  
 Inhabits Europe; first joint of the antennæ rufous.
- MERIDIANA.** Thorax somewhat spinous; wing-cafes fastigate; breast shining. Schæff.  
 Male blackish, female testaceous; legs of the larva long. A native of Europe.
- STRIGILATA.** Black; wing-cafes testaceous, with a blackish fillet. Fabr.  
 Native of Sweden.
- EMARGINATA.** Black; wing-cafes purple, tip black, and emarginate. Fabr.  
 Inhabits Cayenne, the abdomen bidentated at the end; segments shining silvery at the base.
- SANGUIOLENTA.** Black; wing-cafes sanguineous. Linn. Fn. Su. *Leptura dubia*, Scop.  
 Native of Northern Europe.
- RUBRA.** Black; thorax, wing-cafes, and shanks purple-red. Linn.  
 Inhabits Sweden.
- TESTACEA.** Black; wing-cafes testaceous; shanks rufous; thorax rounded behind. Fabr.  
 Found in the north of Europe, and is supposed to be the male of the former.
- REVESTITA.** Testaceous; wing-cafes, breast, and antennæ deep black. Schreber.  
 Native of Germany.
- PUBESCENS.** Black, with cinereous down, rib of the wing testaceous at the base. Fabr.  
 Inhabits Sweden.
- VIRENS.** Silky greenish; antennæ varied with brown and green. Oliv.
- SMARAGDULA.** Silky greenish; antennæ and legs black. Fabr.  
 Inhabits Sweden.
- ATRA.** Body entirely deep black. Oliv. Fabr. *Leptura ethiops*, Poda.  
 Legs sometimes testaceous; abdomen with white silky down.
- HUMERALIS.** Black; shoulders and abdomen ferruginous. Fabr.  
 Native of Germany.
- SCUTELLATA.** Black; scutel white. Fabr.  
 Inhabits Italy.
- SUTURATA.** Cinereous; wing-cafes testaceous, with a black future. Fabr.
- Found in Germany; the antennæ testaceous, with black tip; legs rufous, the joints black.
- EXCLAMATIONIS.** Black; wing-cafes with a yellow line down the middle, and a dot at the base. Fabr., &c.  
 A small species found in Sweden.
- LURIDA.** Ferruginous; wing-cafes testaceous. Fabr., &c.  
 Inhabits deserts of Hircania.
- FEMORATA.** Black; thighs rufous at the base. Fabr.  
 Found in Saxony.
- RUFICORNIS.** Black; antennæ and legs rufous. Fabr.  
 Native of Italy. Body covered with yellowish down.
- MARGINATA.** Black; margin of the wing-cafes and hind shanks rufous. Fabr.  
 Inhabits Norway.
- NIGRA.** Wing-cafes tapering; body black, polished; abdomen red. Schæff.  
 An European species.
- PRAEUSTA.** Body covered with golden down; head and tip of the wing-cafes black. Fabr.  
 First joint of the antennæ ferruginous; legs red. Native of Europe.
- QUADRIMACULATA.** Black; wing-cafes testaceous, with a black ring. Oliv.  
 Native of Germany.
- 4-GUTTATA.** Brown; wing-cafes black, with two ferruginous dots at the base. Fabr.  
 Inhabits Saxony.
- ROSTRATA.** Dull brassy; legs yellow. Fabr.
- SUBSPINOSA.** Black; wing-cafes testaceous, with four black bands, the first punctured; antennæ and legs yellow. Fabr. &c.  
 Perhaps the female of the last. Head black, with a fulvous frontal band; wing-cafes emarginate; three segments of the abdomen yellow. Native of Germany.
- AURULENTA.** Black; fore and hind margin of the thorax golden; wing-cafes testaceous, with four simple black bands. Fabr.  
 Inhabits Germany; segments of the abdomen edged with white.
- DUBIA.** Black and somewhat villous; wing-cafes testaceous, dotted with black; legs black. Fabr.  
 Native of Siberia. Allied to *Leptura attenuata*.
- SEXGUTTATA.** Black; wing-cafes with three yellow spots. Fabr.  
 Inhabits Germany. Herbit.
- QUADRIFASCIATA.** Black; wing-cafes testaceous, with four indented black bands. Linn. *Leptura octomaculata*, Degeer. *Cerambyx fasciatus*, Scop.  
 Native of Europe.
- 3-FASCIATA.** Black; wing-cafes with three yellow bands, the first interrupted. Fabr.  
 Antennæ pale ash, with the base black; first band on the wing-cafes composed of two dots, the second with a small tooth, the third lunated. Inhabits Sweden and Germany.
- RETICULATA.** Black; wing-cafes testaceous at the base, reticulated with yellow, and tipped with black. Fabr.  
 Native of Italy. The antennæ black; joints at the base yellow; legs rufous, with black joints.
- SERICEA.** Green-blue; wing-cafes somewhat fastigate. Fabr.  
 This and the seven following inhabit Europe.
- COLLARIS.** Thorax globular, and with the abdomen red; wing-cafes black. Fabr.
- VIRGINEA.** Thorax globular and black; wing-cafes violet; abdomen rufous. Oliv.

## LEPTURA.

**CARBONARIA.** Black; wing-cafes testaceous; tipped with brown. Linn.

Native of Africa. Antennæ yellowish at the base; thorax and wing-cafes smooth.

**LUTEICORNIS.** Yellow; thorax with two black lines; wing-cafes with four black bands. Fabr.

Inhabits Carolina. Head and antennæ yellow; legs yellow; posterior thighs with a black ring.

**4-PUSTULATA.** Black; wing-cafes with two remote ferruginous spots. Fabr.

Native of Sweden.

**8-MACULATA.** Black; wing-cafes livid, with four black spots. Schæff.

An European species.

**INTERROGATIONIS.** Black; wing-cafes yellow, with a longitudinal curved black line, and four marginal spots. Linn. Donov. Br. Inf.

Native of the northern parts of Europe.

**MARGINELLA.** Blackish; future of the wing-cafes, two marginal spots, and tip yellow. Fabr.

An inhabitant of Italy.

**6-MACULATA.** Black; wing-cafes testaceous, with three indented black bands, the anterior one a little interrupted. Schæff. &c.

Native of Europe.

**7-PUNCTATA.** Black; thorax testaceous, with a black dot; wing-cafes testaceous, with seven black dots. Fabr.

Small, linear; head with a large frontal testaceous spot; abdomen testaceous; legs black. Native of Hungary.

**12-MACULATA.** Black; wing-cafes yellow, with six large black spots on each. Fabr.

Native of Siberia.

**ATTENUATA.** Wing-cafes tapering, yellow, with four black bands; legs testaceous. Schæff.

Inhabits Europe; abdomen entirely black, or rufous, with the tip black.

**CALCARATA.** Black; wing-cafes tapering, yellow, with four black bands, the first punctured, second interrupted; posterior shanks bidentated. Herbit.

**NIPELLA.** Black; wing-cafes testaceous; anterior shanks rufous. Linn.

**ERYTHROPUS.** Black; legs red; base of the thighs, tips of the shanks, and ends of the legs black. Linn.

**5-MACULATA.** Black; antennæ annulated with black; legs and wing-cafes testaceous, the latter with five black spots and three bands. Linn.

**FUSCA.** Brown, with golden down; base of the antennæ testaceous; fore thighs and shanks testaceous, the former with four testaceous bands, the latter testaceous at the base. Linn.

**MORIO.** Thorax orbicular; body entirely black and polished. Fabr.

Native of Sweden.

**CERAMEYCIFORMIS.** Black, with whitish down; wing-cafes yellowish, with five black spots and a line in the middle. Herbit.

Found in Hungary and Austria.

**RUSSICA.** Black, with whitish down; wing-cafes yellowish, with five black spots and a line in the middle. Herbit.

Inhabits Russia.

**LÆVIS.** Black, beneath silky; antennæ yellowish-brown; anterior legs ferruginous. Herbit.

Native of Pomerania.

**SOLSTITIALIS.** Black; antennæ ferruginous at the base;

legs and wing-cafes yellow, the latter edged with black. Herbit.

Inhabits Prussia.

**4-NOTATA.** Black, with yellowish down, beneath with whitish; antennæ brown at the base; thighs ferruginous at the base; wing-cafes punctured with two orange spots. Herbit.

Same country as the preceding.

**SPLENDIDA.** Black, with yellow down; wing-cafes glabrous at the tip; legs fulvous; antennæ brown, with ferruginous base. Herbit.

Inhabits Germany.

**PLUMIPES.** Brown, punctured; thighs subclavated; hind-legs very long, the shank; rufous at the tip. Pallas.

Country unknown.

**RUFIPES.** Black; legs rufous; thighs black at the base. Schaller:

Native of Germany.

**OCTO-MACULATA.** Black; wing-cafes testaceous, with six black spots and tip. Schaller.

Inhabits Saxony.

**SCIALELLI.** Brown; base of the shells with four rufous spots. Schaller.

Inhabits Germany.

**PUMILA.** Brown; anterior legs testaceous, the thighs black above. Schaller.

Native of Saxony. A rare species, found on rhamnus catharticus.

**USTULATA.** Black; thorax and wing-cafes testaceous, tipped with black; legs testaceous.

Inhabits Germany on flowers.

**PARISINA.** Black; base of the antennæ and thighs reddish. Thunb.

Oblong, narrow. Inhabits Germany.

**BIPUSTULATA.** Wing-cafes black, striated with dots, and marked with two testaceous spots. Thunberg.

Inhabits Upsal.

**SCOPOLI.** Abdomen and thorax at the posterior margin red; wing-cafes testaceous, pellucid, and attenuated; tip and margin below the middle black. Scop.

**NIGRIPES.** Black; wing-cafes dull yellow-testaceous; legs black. Gmel. Degeer, &c.

Country unknown.

**VERNA.** Black; anterior shanks fulvous. Müll.

Native of Denmark.

**MACULOSA.** Black; wing-cafes livid-testaceous; antennæ spotted with black. Degeer.

Country unknown.

**LUNCLATA.** Black; thorax with a narrow yellow band behind; wing-cafes with two ferruginous lunules. Swederus.

Inhabits the Cape of Good Hope.

**BICOLORATA.** Pale ferruginous; eyes, wing-cafes, wings, and tail above black. *Leptura bicolor*, Swederus.

Native of America.

**VITTATA.** Pale testaceous; antennæ annulated with fulvous; wing-cafes dotted with black, with four yellow stripes. Swederus.

Inhabits America.

**10-PUNCTATA.** Black; thorax subglobular; wing-cafes with ten dots. Lepech.

Inhabits Ural.

**VARIA.** Villous, hoary; thorax subglobular; wing-cafes black with white dots, and four interrupted bands. Lepech.

Same country as the former.

**VIRIDIS.** Greenish; thorax somewhat ovate, with two darker lines; and the black back. Lepelet.

Native of Siberia.

**NIPTENS.** Thorax globular, and with the abdomen black, with yellow shining down; wing-cafes black, with four broad yellow bands; legs ferruginous. Forster.

Inhabits North America.

**BILINEATA.** Blackish-brown; thorax with two yellowish lines; wing-cafes with scattered dots. Scop.

Found in Carniola.

**CERULEA.** Blue; anterior flanks rufous. Scop.

Native of Italy.

**SQUALIDA.** Black; wing-cafes testaceous at the base and inner margin. Scop.

Same country as the former.

**BIPARTITA.** Black; thorax ferruginous with a black line; wing-cafes with a common ferruginous spot. Schrank.

This and the two following are natives of Germany.

**FERRUGINEA.** Black; wing-cafes ferruginous, with a broad patch of black. Schrank.

**LAMBDA.** Black; wing-cafes with three white bands. Schrank.

**MACULATA.** Black, with yellow downy spots; thorax globular; antennae half as long as the body. Geoffr.

This and the five following are inhabitants of France.

**NÆVIA.** Black, with yellow down; wing-cafes with two black glabrous spots. Geoffr.

**PUNCTULATA.** Blackish; head and thorax red, dotted with black. Geoffr.

**STRIGOSA.** Yellow downy; wing-cafes with three narrow black bands. Geoffr.

**GALLICA.** Blue; flanks rufous; thorax subglobular. Geoffr.

**CRASSIPES.** Deep black; thighs thick and rufous. Geoffr.

**BIMACULATA.** Rufous; thorax cylindrical; wing-cafes dotted, with a spot and waved line of white. Müll.

Inhabits Europe.

**VILLOSA.** Black, villous; thorax cylindrical, with pale longitudinal line. Müll.

Native of Denmark.

**LEPTURUS,** in *Botany*, from  $\lambda\epsilon\upsilon\tau\acute{o}\varsigma$ , slender, and  $\rho\upsilon\tau\tau\alpha$ , the tail of an animal, a genus of grasses, established by Mr. Brown, Prodr. Nov. Holl. v. 1. 207, and so called from its long slender cylindrical spike. It is founded on *Rottbolla repens*, Forst. Prodr. 9. u. 50, with a question whether *R. incurvata* of Linnaeus and Fl. Brit., as well as *R. filiformis* of Roth, may not belong to the same. The chief difference between *Lepturus* and *Rottbolla* seems to lie in the joints of the spike being single-flowered in the former, two-flowered in the latter; for in the detail of the florets, respecting the presence or imperfection of the parts of impregnation, this tribe of grasses, and indeed all grasses, are to be trusted with great caution.

**LEPTURUS,** in *Ichthyol.* The name is of Greek origin, and is formed of  $\lambda\epsilon\upsilon\tau\acute{o}\varsigma$ , slender, and  $\rho\upsilon\tau\tau\alpha$ , a tail, expressing that the fish bearing this name has a very long and slender tail. See *TRICHLURUS lepturus*.

**LEPTURUS,** in *Ornithology*. See *PHÆTON æthereus*.

**LEPUS,** the Hare, in *Astronomy*, a constellation of the southern hemisphere; whose stars in Ptolemy's catalogue are twelve; in that of Tycho thirteen; in the Britannic catalogue nineteen. See *CONSTELLATION*.

**LEPUS Aquæ,** the water-hare, in *Ornithology*, a name given to the crested diver, or colymbus of America, which is the same species with the large European kind, though

described by many authors as a different bird. It has the name of the *sea-hare* or *water-hare*, from its great nimbleness in the water. It is caught with much difficulty; and the Mexicans have a thousand fabulous stories about it. See *COLYMBUS cristatus*.

**LEPUS,** in *Zoology*, a genus of the order of Glires, in the class of Mammalia, the characters of which are that the animals of this genus have two fore-teeth in each jaw; in the upper jaw is a second inner row of fore-teeth, which are considerably smaller than the outer or primaries; the fore-teeth have each five, and the hind-feet four toes. These animals are very timid; they live on vegetable food; and they use the hind-feet in walking as far as the heel, running by a kind of leaps, or repeated bounds. They have either exceedingly short tails, named *cuts*, or none at all.

\* With tails.

1. *L. Viscacia, Vizcacha, Viscachos*, the Peruvian hare, with a longish tail, beset with bristles. Molin. Hist. Nat. Chil. Hares of this species inhabit the plains and bases of mountains in the colder parts of Peru and Chili. The fur is of a mouse colour, and so fine and soft, that, in the time of the Incas, it was woven into cloth for the Peruvian nobles, and is that employed for bonnets by the Chilese. In habit and manner this species resembles the rabbit, and digs holes under ground, in which are two contiguous chambers, one in which it sleeps, and the other, which is lower, is employed for eating its provisions, that are collected in the night; the tail is bushy, and much longer than that of any other species, and in general it turns up and is used as a weapon of defence.

2. *L. Timidus*, common hare, has a very short tail, the ears longer than the head, and black at the ends. Of this there are two varieties, viz. the horned common hare, *L. timidus cornutus*, having slightly branched horns, an animal probably fabulous; and the yellow common hare, *L. timidus melinus*, of a straw colour, of the same size with the hare, and running like it. Cook's Voy. iii. Pennant's Quad.

This species inhabits the whole of Europe, and more plentifully in Bulgaria; in the northern parts of Persia, Japan, Ceylon, and almost the whole of Asia; in Egypt and Barbary; in North America, and even in Chili. The hare is very timid, very quick in its sight and hearing, and very swift, particularly in running up hill; when hunted it runs circularly, gradually lessening the circuit, and often doubling back parallel to its path, and leaping through a great interval at the turn, in order to throw off the dogs. (See *Hare HUNTING*.) The hare feeds only by night, and chiefly on the twigs and bark of shrubs and young trees. It is hunted for sport with dogs or hawks, and, in India, with some species of the cat genus. It is said to be found of the found of a drum; it is much infested with fleas; it does not burrow, but makes a kind of nest, called by sportsmen a "form," among bushes or long grass; its urine is fetid, which it takes care not to discharge in its nest. It does not pair, but breeds often in the summer and spring, the male pursuing the female, when in season, by the scent; after going 30 or 31 days, the female brings three or four at a litter; and as hares are very lascivious, superfecundation is not uncommon. It is about two feet in length, when full grown between eight and nine pounds in weight, sometimes, though rarely, twelve; the head is oblong or oval; the ears long and tipped with black, the eyes large, prominent, and black, placed much outwards, and provided with a nictitating membrane, which remains open when the animal is asleep; the upper

## L E P U S.

lip is divided; the snout furnished with long white whiskers, the chin white; the fur on the face, back, and sides white at the roots, black in the middle, and tawny red at the ends; the breast and throat are reddish; the belly is white; the tail is black above and white beneath; the hind thighs are long, thick, and fleshy, with a cavity on each side at the pubes; the feet are thickly covered with hair on the soles. This animal is fond of birch, parsley, and pinks. Its flesh was forbidden by the Druids, but much esteemed by the Romans. For other particulars, see HARE.

3. *L. Variabilis*, varying hare, *Alpine hare*, has a very short tail, the ears shorter than the head; the whole fur becomes white in winter, except the tips of the ears, which remain black. Of this species there is a variety, called the *L. variabilis hybridus*, or spurious varying hare, the sides of which only turn white in winter. This species inhabits the coldest and most hilly parts of Europe and Asia, as Scotland, Norway, Lapland, Russia, Siberia, Kamtschatka, Greenland, and in America, about Hudson's bay, and Labrador. The spurious variety is a mixed breed, between the varying and common species, sustaining a partial change of colour, and found only in the southern and western parts of Siberia. In autumn the varying hares sometimes collect in flocks of 5 or 600: driven from the mountains of Russia and Siberia, they migrate in quest of subsistence into the lower country, and return in spring. The flesh of this species is harder, drier, and less flavoured than that of the common kind. It never mixes with the common species, but keeps on the tops of the highest hills; it does not run swiftly, but when pursued, takes shelter in the clefts of rocks; is easily tamed and very frolicsome; fond of honey and sweatmeats; it eats its own dung before a storm; changes to white in September, and recovers its grey colour in April; and it is subject to these changes when kept in a warm room; in Greenland, it is always white. Penn. Quad. Arctic Zool. Forster. Phil. Trans. lxii.

4. *L. Niger*, the black hare, has a very short tail, fur entirely black, or very dark tawny, the whole year, and inhabits Siberia, and the government of Cassan. It is much larger than the common kind, and very glossy.

5. *L. Americanus*, American hare, Hudson's bay hare, Hudson's bay quadruped, Phil. Trans. lxii. with the tips of the ears and tail grey, has a very short tail. The hind legs are a half longer than the body; the tips of the ears and tail grey. This species inhabits North America. In New England, Canada, and farther north, this species acquires a long, silky, silver-white coat of fur during winter, the edges of the ears only remaining grey: to the south it retains the whole year a short fur of an ash colour, mixed with rusty and black, on the neck and body, the legs pale-ash colour, and the belly white. It is smaller than the common hare, shelters in hollow trees and under fallen timber, and breeds once or twice a year, producing from five to seven at a litter; the fore legs are proportionally shorter, and the hind legs considerably longer than those of the common kind.

6. *L. Talai* of Buffon, Baikal hare of Pennant, the Daurian hare of Erxleb, the *cinclus leporinus* of J. G. Gmelin, has a short tail, and the edges of the ears black. This species inhabits the country beyond the lake Baikal, in the desert of Gobi or Cobi, and as far as Thibet. This is larger than the former species; in summer of much the same colour with the varying hare, and in winter a little paler; the legs are smaller and the hind legs longer; the tail longer than that of a rabbit, but shorter than that of the common hare, and like that black, especially at the root. It does not burrow, runs straight forward when pursued,

and shelters in the holes of rocks. Its flesh is white, like that of the rabbit.

7. *L. Minimus*, Chilese hare, has a very short tail, and the ears of an uniform colour. Molina H. N. Chl. This species inhabits the kingdom of Chili. It is small, not exceeding the size of a small rat; its body is of a conical form, its ears are small and sharp-pointed, its snout is lengthened, the fur is fine and very short; the flesh is white and good for food. It resembles the domestic rabbit in variableness of colour, in its prolific quality, producing almost every month six or seven young ones at a time; and in Chili it is domesticated.

8. *L. Capensis*, Cape hare, has a bushy tail, as long as the head, and red feet. It inhabits the country three days' journey from the Cape of Good Hope; dwells in the fissures of rocks, and does not burrow; about the size of a rabbit, and probably the same animal that is mentioned by Adanson as found in Guinea, which, he says, is smaller than the common kind, with a colour between that of a rabbit, and has white flesh.

9. *L. Cuniculus*, common rabbit, has a very short tail, almost of the same colour with the body, ears black at the points, and hind legs shorter than the body. Of this species there are the following varieties, viz. *cuniculus ferus*, or wild rabbit, of a brownish-grey colour; *cunic. domesticus niger*, of an uniform black colour; *cun. domesticus albus*, of an uniform, white colour, with fiery red eyes; *cun. domesticus variegatus* pied tame rabbit, of a pied or mottled black and white colour; *cun. domesticus argenteus*, silvery tame rabbit, of a silvery grey or ash-colour, with tawny feet. This species inhabits naturally the warmer parts of Europe, Asia, and Africa; it is not a native of Britain, but has subsisted in a wild and tame state in this country for several ages. It occupies principally dry sandy soils, in which it forms long winding burrows; confining itself to these holes in the middle of the day, and wandering in the evening, night, and morning, in search of food. It feeds on all kinds of green vegetables and grain. Its flesh is white and much esteemed. The female breeds six or seven times in a year, going 30 or 31 days with young, and bringing from four to eight at a litter: it acquires its full size in six months, and lives about eight or nine years; the male is very voracious, and apt to destroy the young; rabbits are preyed upon by hawks, badgers, and polecats, and are caught by means of terriers, nets, and ferrets. Numbers of them are bred in a wild state in places set apart for the purpose, called "warrens," and many are bred in houses in a domestic state. The wild variety is of a brown ash-colour, having the upper part of the tail black, and the under part white. The fur of the silvery variety is valuable.

10. *L. Saecatus*, hooded rabbit, Russian rabbit, has a double fold of the skin behind the head, and another under the throat. This animal's habitat is unknown. It is described by Mr. Pennant, from a drawing in the British Museum by Mr. Edwards, and called by him a Russian rabbit, but it is unknown in that empire.

11. *L. Sericus*, Angora rabbit, is covered with long, waved, silky hair. The Russian rabbit is reckoned by Gmelin a variety of this. It inhabits Angora in Asia Minor, and is exceedingly beautiful on account of its fine, white, silky fur, which is a valuable article in commerce.

\* \* Having no Tail.

12. *L. Brasiliensis*, Brazilian hare, named "Tapeti" by the natives, has very large ears, no tail, and, for the most part, a white ring or collar round the neck. (Pallas Cliv.) This species inhabits South America and Mexico; it is of

the same colour and magnitude with the common hare, but darker, with similar large ears; in its general appearance it resembles the rabbit. It lives in the woods, does not burrow, and its flesh is good food.

13. *L. Puffinus*, calling-hare of Pennant, has no tail, triangular ears, white at the edges; the upper parts of the body are dark-brown, mixed with blackish-grey, and the under parts lairy. (Schreber.) This species inhabits the southern extremity of the Ural mountains, about the Irtifich and the funny hills to the south of the Altaic chain. It feeds chiefly on the flowers and bark of the *Cytisus fupinus*, *Rubnia frutescens*, *Cerastium pumila*, and *Malus sylvestris*; digs holes in dry places, amid bushes, and leads a very retired life, near its burrows, which are long and intricate, with a very small entrance. These animals are discovered by their voice, which is very loud and sonorous, like the piping of a quail, and may be heard at a great distance; it is repeated at short intervals, three, four, or even six times, mostly at night and morning, and never in winter or bad weather. This species is gentle, and easily tamed; it sleeps little, drinks frequently, and is most active in the night season; its pace is not quick, but by leaps.

14. *L. Alpinus*, Mountain hare, Alpine hare of Pallas, &c. *Multa Daurica*, or Daurian weasel, has short rounded ears, and no tail, is of a bright bay colour, with brown ears and hind feet. (Schreber.) This animal inhabits the Altaic chain of mountains, to the extremity of Asia, and beyond the Lena and Yenisei, occupying the most rugged and inaccessible shelves of the mountains, burrowing in the clefts of the rocks, or living in the hollow trunks of decayed trees. Its voice or cry resembles a loud whistle. The mountain hare is preyed on by fables and Siberian weasels, and is much infested by the *Oestrus leporinus*, a species of gad-fly, which lodges its eggs in their skins, and often destroys them. This species varies in size from seven to nine inches in length, and weighs from  $1\frac{1}{4}$  pound to four ounces.

15. *L. Ogotona*, the Ogotona hare, or Mongolian weasel, has oblong, oval, somewhat pointed ears, of the same colour with the body, which is pale grey; but it has no tail. (Schreber.) It inhabits the mountains beyond the lake Baikal, and all Mongolia, especially the great desert of Cobi; dwelling sometimes in rocky places, among stones, or forming in the sand with two or three entrances. Its voice is sharp and clamorous; it feeds chiefly on the bark of the *Pyrus baccata*, and on the suckers of the dwarf elder, and in spring on various herbs which grow on the sandy soil. It is nimble, and scarcely capable of being tamed; it is preyed upon by various species of the weasel tribe, by the Manul cat, hawks, wood-peckers, and owls; it differs from the calling and mountain hares, chiefly in size, being about  $6\frac{1}{2}$  inches long. It procreates in spring, and the young ones are fully grown by the end of June.

LEPYRODIA, in *Botany*, λεπυροδία, *scaly*, so called on account of the inner scales at the base of each flower. Brown Prodr. Nov. Holl. v. 1. 247.—Class and order, *Dioecia Triandria*. Nat. Ord. *Tripetaloides*, Linn. *Junci*, Juss. *Raffiaceae*, Brown.

Eff. Ch. Flowers either dioecious or hermaphrodite. Petals six, nearly equal, prominent, with one or two scales at their base, within the proper scale of the spike, or catkin.—Male, Stamens three. Anthers simple, peltate. A rudiment of a pistil. Female, Styles three. Capsule of three cells, three-lobed, bursting at the prominent angles. Seeds solitary.

This genus is very near *Elegia*, Linn. Mant. 2. 162, (which was afterwards sunk in *Raffia*), but differs in the

presence of inner scales to the flowers, and in the male flowers being like the female, with nearly equal petals, as well as in having the sheaths of the stem permanent, not separating just above their base, and in the smaller size of the spathe. The *Calorophus* of Labillardiere nearly answers to the above character, but is a totally different plant.

1. *L. gracilis*. Stems somewhat branched. Sheaths tight. Spike compound; its lower branches rather distant. Three outer petals shortest.—Gathered by Mr. Brown at Port Jackson, New South Wales.

2. *L. stricta*. Stems perfectly simple. Sheaths tight. Spike compound; its branches rather crowded. Petals all nearly equal.—Native of the fourth coast of New Holland.

3. *L. fœrscifera*. Stems perfectly simple. Sheaths lax. Spike compound; its branches imbricated, divided. Three inner petals smallest. Found at Port Jackson.

4. *L. hermaphrodita*. Stems perfectly simple. Sheaths lax. Spikes nearly simple. Flowers hermaphrodite.—Found on the fourth coast of New Holland.

Our account of this genus is entirely taken from Mr. Brown's work, with some slight difference in terms, according to what we have used in the articles LEPTOCARPUS and LEPIDOSPERMA.

LERANG POINT, in *Geography*, a cape on the N. coast of the island of Java. S. lat.  $6^{\circ} 37'$ . E. long.  $111^{\circ} 27'$ .

LERAY, a town of France, in the department of the Cher, and chief place of a canton, in the district of Sancerre; 8 miles N. of Sancerre. The place contains 1109, and the canton 6544 inhabitants, on a territory of 170 kilometres, in 7 communes.

LERCHEA, in *Botany*, was so named by Linnæus, as a tribute of respect to the botanical acquisitions and publications of John James Lerche, principal physician to the Russian armies, who was born at Potsdam in the year 1703, and who died at St. Petersburg in 1780. He published a description of certain plants growing at Afrachan, and in the provinces of Persia which border on the Caspian sea. This tract is printed in the 5th vol. of the New Transactions of the Academy Naturæ Curiosorum, Appendix 161. 206. He also furnished an account of the *Nymphaea Nelumbo* of the Caspian sea. Haller mentions that Lerche made many curious observations on the agriculture and botany of the countries through which he travelled.—Linn. Mant. 155. Schreb. 453. Willd. Sp. Pl. v. 3. 586. Mart. Mill. Dict. v. 3. Jurl. 421.—Class and order, *Monadelphica Pentandria*. Nat. Ord. unknown.

Gen. Ch. Cal. Perianth of one leaf, tubular, five-toothed, permanent. Cor. of one petal, funnel-shaped; tube longer than the calyx; limb five-cleft, nearly erect. Stam. Filaments scarcely distinct from the tube of the germen; anthers five, oblong, placed upon the tube of the germen. Pist. Germen superior, somewhat ovate, terminated (within the corolla) by an obtuse tube; style within the tube of the germen, thread-shaped, the length of the stamens; stigma two or three, rather obtuse. Peric. Capsule somewhat globose, turulose, of three cells, sometimes only two. Seeds numerous.

Eff. Ch. Calyx five-toothed. Corolla funnel-shaped, five-cleft. Anthers five placed on the tube of the germen. Style single. Capsule of three cells and many seeds.

1. *L. longicauda*. Linn. Syst. Veg. ed. 14. 610. Mant. 256. There is no figure of this solitary species of *Lerchea*, which is a native of the East Indies, and a shrub of irregular growth, furnished with straggling jointed branches. Leaves opposite, on foot-stalks, lanceolate, smooth, entire, a foot in length. *Stipulas* sword-shaped, shorter than the leaf-stalks.

stalks. *Spike* terminal, slender, a foot high; *flowers* remote, scattered, small.

The above description is entirely taken from the works of Linnæus, the only person who ever saw the plant. No trace of it is to be found in his herbarium, yet it is to be presumed the specimen exists somewhere in his collection, probably without a name.

LERENZA, in *Geography*, a town of New Granada; 25 miles N. of Tunja.

LERGE, a town of Sweden, in West Gothland; 4 miles N. of Gothenburg.

LERI, JOHN DE, in *Biography*, a French Protestant minister, was born at La Margelle, a village in Burgundy, and professed his academical studies at Geneva. In 1556 he was selected to accompany two ministers, on a mission to join an intended colony of the reformed religion in Brazil, under the protection of admiral de Coligny. On their arrival, they found their project so involved with difficulties, that Leri returned to France in the following year, having endured astonishing hardships during his voyage. He afterwards was admitted to the office of the ministry, and exercised it at La Charité, at the time of the massacre of St. Bartholomew, when he was obliged to make a very hasty escape to the town of Sancerre. It was during the memorable siege of this place that he was granted a passport from marshal de la Châtre, permitting him to retire wherever he pleased; he went to Bern in Switzerland, where he was received in the most kind and hospitable manner by M. de Coligny, son of the admiral. In 1574 he published an interesting "History of the Siege of Sancerre;" giving an account of the transactions of that siege, and of the horrors of famine to which the Protestants submitted in defence of their religion, and all that was dear to them, which was widely dispersed, and went through many editions. In 1577 he published an account of his voyage to Brazil. He died at Bern in 1611, greatly regretted by all who knew him. Bayle. Moreri.

LERIA, in *Ancient Geography*, an island of the Ægean sea; one of the Sporades, according to Strabo.—Also, a town of Spain, in the Tarragonensis, and in the interior of the country of the Edetani. Ptolemy.

LERIDA, in *Geography*, anciently called *Ilerda*, a town of Spain, in Catalonia, distinguished in ancient and modern history for the great events which have rendered it memorable. It was the capital of the country of the Ilergetes long before the first invasion of Spain by the Romans, and had its own particular princes. In the plains of Lerida Scipio gained a signal victory over Hanno, the Carthaginian general, A.U.C. 537. It was, likewise, under the walls of this town that Julius Cæsar conquered the lieutenants of Pompey, A.U.C. 705. The beauty of its situation and the fertility of the country attracted the attention of the Romans; and as soon as they had made a conquest of it they planted colonies there, and gave it the title of "Municipium Ilerdense." This town, having fallen under the dominion of the Goths, embraced the Christian religion, and was the seat of a celebrated council held here A.D. 528, or 524. A council held here in 546 is remarkable for two of its canons: one prohibiting ecclesiastics from shedding human blood, and another permitting the communion to be administered to magicians when they are dying. After the conquest of the Moors, it became at first subject to the caliphs of Damascus, and afterwards to the Moorish kings of Cordova; but its own governor erecting the standard of rebellion and usurping the supreme power, it had a separate king. In 1149, Raymond Berenger, the last count of Barcelona, who had just ascended the throne

of Aragon, took Lerida from the Moors, and from that time it formed a part of Catalonia.

This town is situated on the declivity of a hill, at the top of which the castle stands, on the right and west bank of the river Segra, which bathes the walls of it. It is long, narrow, almost triangular, close, and ill built. It has one tolerable street, a quarter of a league in length, but, like the others, narrow and ill paved. A quay, lately built, extends through the whole length of the town, which forms a kind of promenade for the inhabitants. Their number is about 18,000. It is an episcopal see, suffragan to Tarragona. Its diocese includes 150 parishes; Lerida itself has one cathedral chapter, four parishes, eight convents of monks, three of nuns, one hospital, and one college. The town has a civil and military governor, a small garrison, and an alcade-major for the administration of justice. Its university, established in 1300, by James II., king of Aragon, was suppressed by Philip V. at the commencement of the eighteenth century. The cathedral is the only edifice in Lerida that claims attention. Lerida formerly carried on a trade in salt-fish, which has wholly failed. Its present commerce is confined to the exportation of some productions of the land, chiefly fruits and pot-herbs; great quantities of which are sent to Urgel and Aragon. The adjacent country is very fertile, and valuable on account of the variety and abundance of its produce; consisting of wheat, oats, flax, hemp, oil, wine, beans, and all kinds of excellent fruits and pot-herbs. The country is intersected with canals supplied by neighbouring rivers, and is skilfully and carefully watered. Some silk-worms are also bred here, but in no great number; 62 miles E. of Saragossa. N. lat. 41° 29'. E. long. 0° 25'.

LERIKA, a town of Swedish Lapland; 100 miles W.N.W. of Tornea.

LERILLON, a small island in the Grecian Archipelago, near the N. coast of the island of Lero.

LERIN, a town of Spain, in Navarre; 15 miles E. of Estello.

LERINA, in *Ancient Geography*, *Lerins*, an island of the Mediterranean, upon the coast of Gallia Narbonensis, S.W. of Nicæa. Strabo, who calls it "Planasia," from its form and situation, says that it had a garrison.

LERINS, in *Geography*, a name given to two small islands in the Mediterranean, near the coast of France, about six miles S. of Antibes; called "St. Marguerite" and "St. Honorat;" near these are some other islets.

LERMA, a dismantled town of Spain, in Old Castile, on the Arlanza; 23 miles S. of Burgos.—Also, a town of Mexico, in the province of Yucatan; 12 miles S. of Campeachy.

LERNA, in *Ancient Geography*, a lake or marsh, now called "Molini," in the Argolide, a little N. of Genesum. It is rendered famous by the fable of the defeat of the hydra with many heads, which retired hither and was killed by Hercules. The people of the country pretend that near this lake Neptune ran away with Proserpine; in memory of which event were annually celebrated the mysteries consecrated to Ceres: and hence these mysteries were denominated the "Lernæan mysteries." Near the lake was a wood consecrated to this goddess, which commenced at mount Pontinus. Pausan. Corinth. l. ii. c. 36.

LERNÆA, in *Zoology*, a genus of the class Vermes, and order Mollusca, which is characterized by Linnæus as having an oblong, somewhat cylindrical and naked body; tentacles or arms two, or sometimes three on each side and round, by which it affixes itself to any substance; two ovaries projecting like tails from the lower extremity. They are without eyes.

eyes, and are very troublesome to fish, adhering very firmly to them, chiefly to the gills and fins. There are fifteen species, which we shall briefly enumerate.

## Species.

**BRANCHIALIS** is one of the largest, being about two inches in length. The body is round and flexuous, the mouth is lateral, and feated between three slightly branched horns. It inhabits the northern seas, and is found adhering to the gills of cod-fish. It is used as food by the Greenlanders. Müll. Zool.

The body of this species is hollow, membranaceous, thicker before and behind; dull white, dirty red. The neck is long, tubular, and filiform; tail ending in a perpendicular groove; ovaries two, composed of long twilted cirri.

**CYPRINACHA**. Body cylindrical, clavate behind; thorax forked; tentacula lunate at the tip. It has four tentacula, two of them lunate at the tips; it is only about half an inch long, and of the thickness of a small straw; the body is rounded, of a pale greyish-white, glossy on the surface, and somewhat pellucid; it is thrust out of a kind of sheath at the base, which is of a white colour, and a thick skin; towards the other extremity of the body there are three obtuse tubercles, one of which is much larger than the rest. It is found on the sides of the bream, carp, and roach of our ponds and rivers, in abundance.

**SALMONEA**, or *Salmon loafe*. Body obovate; thorax inversely heart-shaped; tentacula two linear and approaching each other. It is rather more than half an inch long, and is found, as its name imports, adhering to the salmon about its gills. Barbut.

The body is pale and soft, head small, oblong, rather convex, with two horizontal lips; the upper one is armed with two rigid moveable hooks, the lower short, bifid; abdomen inversely ovate; ovaries round, granulate within, and as large as the whole body.

**ASSELLINA** has a lunated body, and cordated thorax, and is found in the gills of cod-fish and ling. Barbut.

**HUCHONIS**. Body knotty; two tentacula; ovary double and united behind; is found in the gills of the salmo hucho, in northern lakes and rivers. The body is clear white and somewhat cartilaginous.

**CLAVATA**. Body cylindrical, subinuate and tripled beneath the tip and snout. Müll. It is found in the fins, gills, and eyes of the Perca Norvegica.

**UNCIATA**. Body rather heart-shaped; snout simple, curved, and the mouth terminal. Müll. It is found on the gills and fins of cod-fish in the Greenland seas. The body is soft, pale, with a longitudinal groove down the middle of the back; the ovaries are rounded and thickened towards the tip.

**GOBINA**. Body rhomboid; it has two arms before and two behind, all of which are nodose; the head is armed with two curved horns. Shaw. Müll. It inhabits the gills of the Cottus gobio, or Miller's thumb, and is nearly three quarters of an inch in length.

Body bluish-white; head roundish, with two incurved horns; the mouth is placed between the horns, and is furnished with three lips; the tentacula are angular, curved, knotty; intestines translucent above; tail bifid; ovaries spiral, round, subulate.

**RADIATA** has a square depressed body, with three pair of arms and four horns. Müll. It is found in and about the mouth of the *Coryphæna rupestris*, in the Greenland seas. It is rather more than an inch in length; whitish or cinereous, and rough with hardish tubercles; the sides a little

crenate; head depressed, rounded, and covered with numerous papillæ; ovaries large, oboval.

**NOIOSA**. Body square tuberculate; with two very short arms beneath on each side. Müll. Shaw. It inhabits about the mouth of the Perca Norvegica.

Body soft, pale cinereous, convex above, and concave beneath, with four hard white tubercles in the middle of the back, and five white teeth on each side; head rounded, and divided by a break in the middle.

**CORNUTA**. Body oblong, with four straight emarginate arms; head fubovate. Shaw. Müll. It is found on some species of the Pleuronectes.

Body covered with a pellucid skin; front with two horns and a single tooth; the mouth has two feelers; ovaries brown, and its eggs are of a tawny colour.

**PECTORALIS**. Head orbicular; hemispherical; abdomen obovate, with a terminal truncate papilla. Müll. Shaw. It is found on the gill and pectoral fins of the flounder, or Pleuronectes flesus, and other species of the same genus.

Body white, diaphanous, covered with small blackish spots; the crown has two falciform projections; snout conic, truncate, with four minute horns, two short spines, and two feelers near the third conic spine. Two tentacula, not curved; ovaries two, rather narrow, sub-annulate, and of equal diameters.

**LOTÆ**, found on the gills of the *Gadus lota*, has four unequal ovaries; the mouth has two hooks; four cruciate appendages.

**CYCLOPTERINA**. Body round, flexuous, with a double orifice in the middle of the snout; snout terminated by three horns, divided into three parts. It inhabits a species of the Cyclopterus, or Lump-fish.

Body resembles the branchialis above described, but the horn is slender, turned up and entire at the tip; tail is narrower, with two convex lobes on each side; ovaries simple, spiral, and nearly five inches long when extended. There is another variety which is rather less and has greenish ovaries.

**PINNARUM** is of a reddish colour; head cylindrical and rostrate on the fore-part; it has two tentacula, which are lunate, and bifid at the tip. It is found on the dorsal fins of the *Gadus barbatus*.

Body depressed, fleshy, grooved on the back, with a cylindrical arm placed on the fore-part of the back, concealed in a groove; the ovaries long and cylindrical.

**LERNEB**, in *Geography*, a town of Algiers; 20 miles S. of Tipa.

**LERO**, anciently *Lero*, or *Leros*, an island of the Grecian Archipelago, N.N.W. of that of *Calamo* (which see). Strabo says that it was formerly inhabited by a colony of Milesians. It is about eight miles long, and two broad. It has a good harbour and a few coves, and also high mountains, in whose bosoms mines and quarries of marble might be worked; its soil is ungrateful, and its inhabitants are under the necessity of seeking succours abroad by navigation and traffic. N. lat. 37° 12'. E. long. 26° 35'.

**LERONA**, a town of Italy, in the Orvietan; 7 miles N.W. of Orvieto.

**LEROT**, or *Garden Squirrel* of Buffon, in *Zoology*. See *MYOXUS Nitela*.

**LE ROY le veu**, a form of words, by which the royal assent is signified by the clerk of the parliament to public bills; to private bills this assent is expressed by *soit fait comme il est désiré*.

**LE ROY s'avoiera**. By these words to a bill, presented to the king by his parliament, is understood his absolute

denial of that bill in a more civil way; and the bill thereby becomes wholly null and void. See ROYAL, and PARLIAMENT.

**LERVADILLA**, in *Geography*, a town of Spain, in the province of Leon; 12 miles S. E. of Ciudad Rodrigo.

**LERWIA**, or **LERWEE**, in *Zoology*. See ANTELOPE *Lervia*.

**LERWICK**, in *Geography*, a sea-port town, situated in a parish of the same name, on the east side of the Mainland of the Shetland Isles. It is distinguished as the seat of the courts held by the sheriff-depute of this shewartry, and as the general rendezvous of all the vessels employed in the whale-fishery. The harbour is one of the safest and largest in Great Britain. It is formed by the island of Bressay, and is particularly commodious from the circumstance of having two entries, one from the south, and another from the north. On the outside of the north entrance is a sunk rock, which is called the Unicorn. It derived its name from the Unicorn man-of-war, which was sent in pursuit of the earl of Bothwell, when that nobleman fled to Shetland. As this vessel appeared at the mouth of the fourth entry, before her approach was discovered by the earl, he with difficulty escaped by the north passage. The Unicorn eagerly pursued, but having no pilot on board, she struck upon this rock and was wrecked. The town of Lerwick is about half a mile in length, and is irregularly built, but contains several excellent houses. Near the north end is a small fortification, called Fort Charlotte. It is usually garrisoned by a party of invalids, and serves to protect the north entry of the harbour. About a mile and a half from the town are the remains of two ancient Danish castles. The parish extends about six miles along the coast, but at no point is more than one in bread h. The surface of the ground is for the most part rocky and mountainous. Immediately upon the shore, however, there are many very fine arable fields, the soil of which, though light and sandy, possesses considerable fertility. The population of the whole parish, according to the parliamentary returns in 1800, amounted to 1706 persons; about 900 of whom are resident in the town. Sinclair's Statistical Account of Scotland, vol. iii. communicated by the Rev. James Sands.

**LESARA**, a small island in the Baltic, E. of Aland. N. lat. 60° 18'. E. long. 20° 19'.

**LESBIAN CYNAMIUM**. See CYNAMIUM.

**LESBIUM MARMOR**, a name given by the ancients to a species of marble of a bluish-white, sometimes used for the vases and other ornamental works, but principally in the walls of public buildings.

**LESBONAX**, in *Biography*, a native of Mitylene, who flourished in the first century of the Christian era, was a disciple of Timocrates, afterwards became a teacher of philosophy in his native city, and obtained a great number of scholars. He was author of many books of philosophy, and Plotinus says he had read sixteen orations written by him. Two of these, it is supposed, have reached modern times, and were first published by Aldus, in his edition of the ancient orators, in 1513. They were afterwards published by Henry Stephens, with the orations of Æschines, Lyfias, and others. They were also published, in 1619, by Gruter. Lesbosax is said to have been the author of a treatise "De Figuris Grammaticis." He left a son named Potamon, an eminent rhetorician at Rome, in the reign of the emperor Tiberius. So sensible were the magistrates of Mitylene of his merits, and of the utility of his labours, that they caused a medal to be struck in his honour: one of which was discovered in the fourth of France about four-

score years ago, and an engraving of it published in 1744, by M. Cary, of the Academy of Marseilles. Moreri.

**LESBOS**, in *Ancient Geography*, now called *Metelin*, an island of the Grecian Archipelago, situated N. E. and S. W. and occupying in its length the port of the gulf of Adramyttium, on the coast of Asia Minor. It extended in latitude from 39° 5' to 39° 30', S. E. of the island of Lemnos. It is said, that the Pelagi first settled themselves in this island under the conduct of Xanthus, son of Triopus, king of the Pelagi, driven from Argos, who passed from Lycia to this island, called Iffa, and named by him Pelagia. Seven generations after this time, the inhabitants perished in the deluge of Deucalion, or rather in an inundation that overwhelmed this island. It was then left desolate. In process of time Maccareus, an inhabitant of Ionia, afterwards denominated Achaia, formed an establishment in this island. This prince was accompanied with Ionians and some other people of different nations. Lesbos, it is said, came hither some time after Maccareus, his progenitor.

Eustathius, in his Commentary on the third book of the Odysee, says, that this island contained five towns, viz. Lesbos, whence it derived its name, Antilla or Iffa, Pyrrha, Methymna, and Mitylene, whence this island has been since called Mitylene and Metelin. This last town was the capital. Lesbos, originally governed by rulers chosen among its own inhabitants, became afterwards subject to the dominion of foreign tyrants. It successively passed under the dominion of the Persians, and then under that of the Greeks, till its liberty was restored to it by Alexander the Great. This liberty it preserved till the time of Pompey, who reduced it into the state of a Roman province; continuing, however, for some time to Mitylene its ancient privileges. The Crusaders next established themselves for a certain period, and the Genoese were masters of it when the empire of the East fell into the hands of the Turks. It was on this occasion that Mahomet II. ten years after the capture of Constantinople, equipped a considerable fleet in order to subdue it. Mitylene, Methymna, and most of the places of this island had been well fortified; the knights of Rhodes succoured it; and the inhabitants, who knew the cruelties committed by the Turks at the capture of Constantinople, were all disposed to defend their lives. The Ottoman forces, although very considerable, would undoubtedly have miscarried against thousands of heroes, if these heroes had not been betrayed by the treachery of Lucco Gattiluso, who thought of obtaining the sovereignty of the island by delivering it up to Mahomet. Accordingly, he persuaded his cousin Gattiluso to sign a shameful capitulation. However, as a recompence for the treachery of the one, and for the weakness of the other, Mahomet caused them to be cruelly put to death a short time after. Lesbos gave birth to several persons of distinction; among whom we may reckon Alceus, a lyric poet, who long declaimed against tyranny; Sappho, the celebrated poetess, whom antiquity has placed among the Muses, and who, by an unfortunate passion, was impelled to precipitate herself from the promontory Leucates; Theophrastus, a disciple of Plato and Aristotle; Pittacus, whom Greece reckons among her sages, and who, more ardently desirous of the happiness of his fellow-citizens than of his own, conceived and executed the project of usurping power in order to restore liberty to his country; and lastly, Potamon, born at Mitylene, a distinguished rhetorician, who lived at Rome under Tiberius. This latter, wishing to return to his country, and there establish a chair of eloquence, obtained from Tiberius letters, in which it was expressly mentioned, that whoever should dare to insult Potamon, would insult in his person the emper-

peror himself. We might also mention, in more modern times, the two brothers, Barbarossas, sons of a porter, who from simple sailors, became famous pirates, and were afterwards, in succession, sovereigns of Algiers. The younger, appointed high admiral by Soliman I, is more known than his brother in the history of the Ottoman empire. For an account of the present state of Lesbos, see METELIN.

LESCAILLE, JAMES, in *Biography*, a Dutch printer and poet, born in 1610, was descended from a family of distinction and much consideration at Geneva, which took refuge in Holland on account of some persecution. By profession he was a printer and bookseller, and gained great reputation by the beauty and accuracy of various editions of books which he published. He was in high estimation as a poet, and was noticed by the emperor Leopold. He died in 1677, leaving behind him a daughter, Catherine, born in 1649, and so distinguished by her poetical talents, that she was called the Dutch Sappho. Her brother-in-law, Ranck, published, in 1728, a volume of her works, which contains seven tragedies, besides other pieces. She died in 1711. Moreri.

LESCANO, in *Geography*, a town of Spain, in the province of Guipuzcoa; 9 miles S.S.W. of Tolosa.

LESCAR, a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the district of Pau; 3 miles N.W. of Pau. Before the revolution, it was the see of a bishop, suffragan of Auch. The place contains 1885, and the canton 7823 inhabitants, on a territory of 177½ kilometres, in 15 communes.

LESCHERES, a town of France, in the department of the Upper Marne; 9 miles S. of Joinville.

LESCIVER, a town of Persia, in the province of Irak; 201 miles W. of Hamadan.

LESCZYN, a town of Poland, in Volhynia; 24 miles N. of Berdicow.

LESDIGUERES, FRANCIS DE BONNE, *Duke of*, in *Biography*, was born of an ancient family, in the Upper Dauphiné, in 1543. He was brought up to the military profession, and acquired, while he was yet a young man, so much reputation for skill and true courage, that he was chosen by the Calvinists of his native province their leader, after the death of Montbrun. Soon after the command devolved upon him, he took a number of provinces, and at length the capital of Grenoble. This was in the year 1590. When the duke of Savoy, taking advantage of the disturbances in France, projected an invasion of Provence and Dauphiné, Lesdigueres, who acted as an independent commander, covered the latter province with his arms. He now sent to court to demand the government of Grenoble, which Henry IV. could not grant him, as he had, by the advice of his council, reserved it for a Catholic; the envoy being refused his request, he applied to the council assembled, "Gentlemen, if you do not think it proper that my master should have this government, you should think of the means of taking it from him." This energetic answer was not displeasing to the king, who was glad to be under the necessity of promoting a general of the Protestant persuasion. Lesdigueres was, from this time, appointed lieutenant-general of the king's armies in Piedmont, Savoy, and Dauphiné, and by his vigilance and activity disappointed all attempts of the duke of Savoy, who was accustomed to call him the fox of Dauphiné. When that prince was constructing a strong fort on the French territory, Lesdigueres was reproached by the king for allowing it, to which he replied, "Your majesty has occasion for a good fortress to bridle that of Montmelian. Since the duke of Savoy is willing to build one at his ex-

pence, let him do it: I engage, as soon as it is completed, and furnished with cannon and ammunition, to take it from him." He performed his promise, and his services were rewarded, in 1608, with the staff of a marshal of France, and his estate of Lesdigueres was erected into a dukedom and peerage. In the succeeding reign he saved his old antagonists, the duke of Savoy, when attacked by the armies of Spain. In 1620, when the civil war was renewed, he received great offers from his party, the Calvinists, to accept the post of commander-in-chief, but he preserved his fidelity to the king, and accompanied him into the field. Upon the death of the constable of France, nothing but his religion stood in the way of his succeeding to the high office, and this obstacle he removed by abjuring the Calvinistic creed. The patent which conferred upon him the office, gave as a reason for his appointment, that it was on account of "his having been always victorious, and never vanquished." Having apostatized from his creed, probably for the sake of honours and wealth, of which he was exceedingly avaricious, he did not hesitate to take the command against his party, and was uniformly successful in the service, till his death, in 1626, when he had attained to the age of eighty-four. Notwithstanding his defects, Lesdigueres had a great mind: while leader of the Calvinists, his principal domestic was bribed to assassinate him: the plot was discovered, and taking the man aside, he ordered him to arm, at the same time he armed himself: "Since you have promised," said he, "to kill me, try to do it now, and do not forfeit your character for valour by an act of cowardice." The man threw himself at his feet, confessed his crime, and the general not only pardoned, but continued to employ him.

LESIGNA, in *Geography*, a town of France, in the department of the Aude; 11 miles W. of Narbonne.

LESINA, anciently *Pharos*, an island in the Adriatic, between Brazza and Corzola Nigra, about 44 miles long, and 5—8 broad, lying from W. to E. in N. lat. 43° 30'. In the highest parts it is rocky and barren, but nevertheless contains some good land, yielding abundance of corn. Its principal productions are also wine, oil, figs, almonds, saffron, honey, aloes, oranges, wool, cheese, and salt. Marble, in great quantities, is found on the island. Salt-fish is the chief article of commerce. Its capital is *Lefina*; which is a small, fortified town, at the bottom of a bay near Cape Pellegrino, the see of a bishop, and residence of a governor, with a capacious and safe harbour. The number of inhabitants is reckoned about 1200; 20 miles S. of Spalatro. N. lat. 43° 5'. E. long. 16° 50'.—Also, a town of Naples, in Capitanata, the see of a bishop, suffragan of Benevento, on a lake of the same name communicating with the Adriatic; almost totally destroyed in 1627 by an earthquake; 26 miles N.W. of Manfredonia. N. lat. 41° 59'. E. long. 14° 30'.

LESKAU, a town of Bohemia, in the circle of Pilsen; 7 miles E. of Plau.

LESKEA, or LESKIA, in *Botany*, an Hedwigian genus of mosses, named by its author in his *Hist. Nat. Museum Frondosorum*, v. 2. 93, in memory of his friend Leske, professor of Economy at Leipzig, and afterwards of Nat. Hist. at Marburg, who died in 1786, aged 35. This genus is by British botanists united to *Hypnum*, as agreeing therewith entirely in habit, and differing only in a very minute and uncertain character of the inner fringe, which is furnished with 16 simple teeth, instead of double or compound ones. See FRINGE OF MOSSES, and HYPNUM.

LESKEN, in *Geography*, a town of Prussia, in Pomerania; 6 miles N.N.W. of Marienburg.

LESKIRCH, a town of Tranlyvania; 14 miles W. of Fogaras.

LESKNITZ, or LESNITZ, a town of Silesia, in the principality of Oppeln; 18 miles S.E. of Oppeln. N. lat. 50° 25'. E. long. 13° 6'.

LESKO, a town of Austrian Poland, in Galicia; 48 miles S. of Lemberg.

LESKOVETZ, a town of European Turkey, in Bulgaria; 84 miles W.N.W. of Sophia.

LESLEY, JOHN, in *Biography*, bishop of Rofs, of an eminent family in the northern part of Scotland, was born in 1527. He was educated at Aberdeen, and was presented, in 1547, with a canonry in the cathedral of that city. Having obtained this preferment, he spent some years at the French universities, and took his degree of doctor of laws at Paris. In 1554, he returned to Scotland, and, taking orders, was appointed official and vicar-general of the diocese of Aberdeen. He took a most active part against the reformation, which was now taking root in Scotland; and appeared as a principal champion of the Roman Catholic party, in a disputation held between them and the reformers at Edinburgh, in 1560. When the young queen Mary was invited to return and assume the reins of government, he was sent over by the Catholics to persuade her to throw herself into the arms of the Popish party. He embarked with her at Calais in 1561; and soon after her arrival was created one of the senators of the college of justice, and privy-counsellor. Shortly after this, he was nominated to the see of Rofs. He did not confine his labours to the duties of the church, but was appointed by the queen to collect and revise the subsisting laws of the realm; and the collection printed at Edinburgh in 1566, called the black acts of parliament, from being in the black letter, was the result of its labours. When the unfortunate queen had taken refuge in England from the fury of the covenanters, and commissioners were appointed by queen Elizabeth to examine the dispute between her and her subjects, the bishop of Rofs was one of those whom Mary chose for the defence of her cause. When reasoning and argument were found to be ineffectual, he joined in conspiracies, for her deliverance, which were dangerous to the person and government of Elizabeth. He urged the duke of Norfolk to those designs which proved his ruin, and was himself involved in considerable danger: he was taken into custody, his papers searched, himself committed to the Tower, treated with the utmost rigour, threatened with capital punishment, and, after a long confinement, set at liberty, on condition that he should leave the kingdom. He accordingly went into the Netherlands, and employed himself in the most pressing solicitations to the kings of France and Spain, the German princes, and at length to the pope, in order to obtain Mary's liberation. He published several books in her defence, and in vindication of her right and title to the crown of England. In 1579, he was appointed suffragan and vicar-general of the archbishopric of Rouen; but on making his visitation of the diocese he was seized, imprisoned, and forced to purchase his liberty by a high ransom. In 1593, he was nominated to the bishopric of Constance. When there was no hope left him of returning to his own country, he retired to a monastery near Brussels, where he died in 1596. He was a man of learning, an able statesman, and a faithful servant and subject of his sovereign: his principal works, as an author, are, 1, his history, entitled "De origine, moribus, et rebus gestis Scotorum," in ten books: of these the last three books are dedicated to the queen, to whom they were presented in English, before their publication in Latin: and, 2, a geographical work, entitled "Regionum et Insularum

Scotiz Descriptio." Gen. Biog. Robertson's Hist. of Scotland.

LESLIE, JOHN, an Irish prelate in the 17th century, was born in the north of Scotland, and received the early part of his education at Aberdeen. From this place he was sent to Oxford to complete his studies. He afterwards visited Spain, Italy, Germany, and France for farther improvement, and made a proficiency in polite literature, as well as in the abstruse branches of learning. He was so great a master of the Latin, that it was said of him when in Spain "Solus Lælius Latine loquitur." He continued abroad twenty-two years, became conversant in courts, and procured the favour and friendship of many foreign princes: and on his return he was honoured with the patronage of Charles I., who admitted him into his privy-council, in which he was continued by Charles II. after the restoration. In the church of Scotland he was preferred to the bishopric of Orkney, and was translated, in 1633, to Raphoe, in Ireland. Here he built a stately palace in the form of a castle, which was found of great utility in the civil wars, as it sustained a siege, with the bishop as a kind of commander, who was, in fact, the last person who maintained the struggle in defence of the royal cause in those parts. After the restoration, he was preferred to the bishopric of Clogher. He died in 1671, being upwards of an hundred years old, and having worn the mitre more than fifty years. He wrote many curious and very learned works, which he designed for publication, but which were destroyed, together with his valuable library and MSS., the fruits of many years collection, in the civil wars. Biog. Brit.

LESLIE, CHARLES, second son of the preceding, was educated in grammar-learning at Inniskilling, and, in 1664, was admitted a fellow commoner of Trinity-college, Dublin, where he took his degrees. Upon the death of his father he came over to England, and entered himself of the Temple, at London. He soon abandoned the study of the law for that of theology, and was, in 1680, admitted into holy orders. In 1687, he was made chancellor of the cathedral church of the diocese of Connor. About this time he made himself extremely obnoxious to the Popish party in Ireland, by a zealous opposition to their doctrines, and by an earnest attachment to the Protestant religion, which he endeavoured to propagate by every means in his power. The Papists, encouraged by the reigning prince, James II., aimed at engrossing civil as well as spiritual offices; and a high-sheriff of their party was appointed for the county of Monaghan. Mr. Leslie, as a magistrate, and as conversant with the law of the land, was applied to with regard to the legality of the appointment: he instantly decided that it would be as illegal for the people to permit the sheriff to act, as it would be in him to attempt it. The magistrates, at the next quarter-sessions, inquired if the sheriffs were legally qualified, to which he replied, that "he was appointed by the king, and was of the king's religion." The answer to this was, that they boldly agreed to commit him for intrusion and a contempt of the court. Mr. Leslie, notwithstanding his attachment to the law of the land, had imbibed the doctrines of passive obedience and non-resistance, which so warped his understanding, that, at the revolution, he refused to take the oaths to William and Mary. He was, in consequence of this conduct, deprived of his preferments; and in 1689 withdrew with his family into England. Here he employed his pen in support of the cause and the party which he embraced, and was esteemed one of the ablest champions which the non-jurors had. He published an answer to the "State of the Protestants in Ireland, under the late King James's Government," by bishop, afterwards

archbishop, King. He published a weekly paper, entitled "The Rehearal," consisting of dialogues on the affairs of the times: this was continued six or seven years, when the papers were collected and published together; and it was said by bishop Burnet, that the same thread of the argument is pursued through them all, against the lawfulness of resistance in any case whatever, deriving the source of government wholly from God. Mr. Leflie wrote against Deists, Jews, Papists, Socinians, and Quakers: all his writings he afterwards collected, excepting an illiberal piece against the learned Tillotson, and published in two volumes folio. The frequent visits which he made to the continent, rendered him obnoxious to the British government; and the hatred of him was much increased by a piece, entitled "The hereditary Right of the Crown of England asserted," of which he was the reputed author. He went to Bar-le-Duc to attempt the conversion of the son of James II. to the Protestant religion, in the hope that he might one day be settled on the throne. Towards the close of queen Anne's reign, he took much pains in recommending him as her successor. The attempt was made in vain; and after the rebellion of 1715, he retired with the young Pretender to Italy. In 1721, he made up his mind to return and die in his native country; and his friends implored the protection of government, which was granted. He died at his own house in Glafough, in the county of Monaghan. He was unquestionably a man of extensive learning and great merit, and distinguished by his piety, humility, and integrity. Biog. Brit.

LESNEVEN, in *Geography*, a town of France, in the department of Finistère, and chief place of a canton, in the district of Brest; 13 miles N.E. of Brest. The place contains 2030, and the canton 16,024 inhabitants, on a territory of 167½ kilometres, in 10 communes. N. lat. 48° 34'. W. long. 4° 14'.

LESNICA, a town of Lithuania, in the palatinate of Minsk; 48 miles N.E. of Minsk.

LESNIOW, a town of Poland, in Volhynia; 18 miles S. of Lucko.

LESNO, a town in the duchy of Warfaw; 35 miles S. of Posen.

LESANDELOR, a town of Asiatic Turkey, in Cararamania; 40 miles S.S.W. of Cogni.

LESPARRE, a town of France, and principal place of a district, in the department of the Gironde; 11 miles N.N.W. of Bourdeaux. The place contains 800, and the canton 15,247 inhabitants, on a territory of 542½ kilometres, in 18 communes. N. lat. 45° 19'. W. long. 0° 50'.

LESPÉDEZA, in *Botany*, so named by Michaux, in compliment to his friend and patron Lefpedez, governor of Florida, who was very favourable to his botanical expedition through that country, though it does not appear that the governor himself was a botanist. Michaux Boreali-Amer. v. 2. 70.—This genus differs from *Hedyfarum*, see that article, in its legume, which is elliptical and turgid, smooth, of one cell, with a solitary seed. The stigma moreover is said to be capitate and somewhat conical.—The leaves are mostly ternate, rarely simple.—It appears to be a good genus, and merits further examination, for its species will probably be found rather numerous. Examples are *L. fissiflora*, (*Hedyfarum junceum*; Walter Carolin. 184. *Medicago virginica*; Linn. Sp. Pl. 1096.) a native of Virginia and Carolina: and *L. polyblacha*, Michaux, t. 40, (*Hedyfarum hirtum*; Linn. Sp. Pl. 1055.), found in Carolina and Georgia. The habit is slender and shrubby. Flowers small, purplish, in longish stalked spikes.

LESSANITZ, in *Geography*, a town of Bohemia, in the circle of Kaurzim; eight miles S.E. of Prague.

LESSAY, a town of France, in the department of the Channel, and chief place of a canton, in the district of Coutances; 11 miles N. of Coutances. The place contains 1503, and the canton 13,644 inhabitants, on a territory of 260 kilometres, in 13 communes.

LESSEE, a law term employed in leasing land, to signify the tenant. See LEASE.

LESSEES, a term used by sportsmen for the dung of a wild boar.

LESSINES, in *Geography*, a town of France, in the department of the Jemappe, and chief place of a canton, in the district of Tournay; situated on the river Dender, and celebrated for its linen manufacture; 23 miles W.S.W. of Brussels. The place contains 3037, and the canton 14,708 inhabitants, on a territory of 115 kilometres, in 11 communes.

LESSING, GOTTHOLD, EPHRAIM, in *Biography*, was born at Kamenz, in Pomcrania, in 1729. Having received the early part of his education partly at home, and partly at a boarding school, he was admitted, at the age of twelve, to the free-school of Meissen, where he remained five years, and laid in a stock of Greek and Latin. Some odes of Anacreon, which he translated at this school, were afterwards published in his works. His removal to the university of Leipzig opened a new scene to him; he paid little attention to the lectures of the professors, but studiously sought out the company of the students most distinguished for talents, and bold and singular opinions. He became a frequenter of debating clubs, and was not surpassed by any person in the societies in the originality of his sentiments, and the acuteness with which he defended them. After he had spent three years at the university, his father, who could ill bear the expence, urged him to take orders, or to pursue some profession by which he might support himself. He declined this reasonable proposal, and set about translating, and original compositions for the stage. After many changes, and much roaming about, he went to Gottenburg, where he took his degree of Master of Arts, with a view to a professorship at Gottingen, but he still continued to find support by literary employment, which consisted in translations, compilations, and some original pieces. He was a great proficient in the game of chess, a circumstance that introduced him to the acquaintance of Moses Mendelsohn; and the printer Nicolai made the third of a literary trio, who mutually sharpened each other's intellectual faculties, and influenced each other's opinions. Ramlcr the lyric poet, Sulzer the critic, and Sufimilch the satirical writer, were occasionally of their parties, and Germany perhaps could not then boast of conversations more literary and enlightened. In conjunction with Nicolai and Mendelsohn, he undertook a periodical work, entitled "The Library of Belles Lettres," which was a kind of review of works in polite literature, with original correspondence. In 1760, he was elected a member of the Academy of Berlin, and soon after was appointed secretary to general Tauenzier; his income at this period was considerable, which he spent liberally upon his relations and friends. His military associates gave him a taste for high play, which he found arguments to justify. In 1762, he accompanied his general to the siege of Schweidnitz; but after the peace, he was introduced to the king of Prussia, and then resumed his literary occupations at Berlin. Though he produced many works, yet they were not the source of much profit, and, in 1769, his circumstances were so narrow, that he was obliged to sell his library for support. At this critical juncture he met with a generous patron in Leopold, heir-apparent to the duke of Brunswick, through whose means he was appointed librarian at Wolfenbuttel.

battle. One of the fruits of this very desirable situation was a periodical publication, entitled "Contributions to Literary History," containing notices and extracts of the most remarkable MSS. The "Contributions" were made the vehicle of "Fragments of an anonymous Writer discovered in the Library at Wolfenbuttle," which consisted of direct attacks upon the Christian revelation. They occasioned a great commotion among the German theologians, and would not have been printed but for the interference of prince Leopold with the licensers of the press. In 1778 they were suppressed. Lessing, from his rising fame, and connection with prince Leopold, with whom he went on a tour to Italy, was so distinguished among the German literati, that several potentates of that country made him offers of an advantageous settlement. Nothing, however, would lead him to break his connection with his liberal patron the prince of Brunfwick, who, by his accession in 1780 to the sovereignty, was enabled to augment his favours towards him. His latter publications were "Nathan the Wise;" a second part of the same drama, entitled "The Monk of Lebanon;" and "A Dissertation on the Education of the Human Race." He died at Hamburg in the month of February, 1781. Monthly Mag.

LESSOE, in *Geography*, an island of Denmark, in the Scagerrack, nine miles long, and from one to four wide; within are some small villages, and about it some islets; about 12 miles from the coast of Jutland. N. lat. 57° 17'. E. long. 11°.

LESSOE, a town of Norway, in the province of Aggerhus; 145 miles N.N.W. of Christiania.

LESSON, in the *Manege*, is used for any piece of instruction in that art, whether given to the scholar or the horse.

LESSONS, among *Ecclesiastical Writers*, portions of the holy scripture, read in Christian churches, at the time of divine service.

In the ancient church, reading the scriptures was one part of the service of the catechumens, at which all persons were allowed to be present, in order to obtain instruction.

The church of England, in the choice of lessons, proceeds as follows; for the first lesson on ordinary days, she directs, to begin at the beginning of the year with Genesis, and to continue on, till the books of the Old Testament are read over, only omitting the Chronicles, which are for the most part the same with the books of Samuel and Kings, and other particular chapters in other books, either because they contain names of persons, places, or other matters less profitable to ordinary readers.

The course of the first lessons for Sundays is regulated after a different manner. From Advent to Septuagesima Sunday, some particular chapters of Isaiah are appointed to be read, because that book contains the clearest prophecies concerning Christ. Upon Septuagesima Sunday Genesis is begun, because that book, which treats of the fall of man, and the severe judgment of God inflicted on the world for sin, best suits with a time of repentance and mortification. After Genesis, follow chapters out of the books of the Old Testament, as they lie in order; only on festival Sundays, such as Easter, Whitunday, &c. the particular history relating to that day is appointed to be read; and on the Saints days, the church appoints lessons out of the moral books, such as Proverbs, Ecclesiastes, Ecclesiasticus, &c. as containing excellent instructions for the conduct of life.

As to the second lessons, the church observes the same course both on Sundays and week-days; reading the gospels and Acts of the Apostles in the morning, and the epistles in the evening, in the order they stand in the New Testa-

ment; excepting on faints days and holy days, when such lessons are appointed, as either explain the mystery, relate the history, or apply the example to us.

LESSONS for the *Virginal, Spinet, and Harpsichord*, have undergone great changes in the denomination and arrangement of their movements, from the time of queen Elizabeth to the present. In that prince's virginal book, now in the possession of viscount Fitzwilliam, we find *pavana* in general to be the slow movement, and *galliarida* the quick. Now and then a *fantasia*, a *coranto*, and a *gigg*; but as single movements, not parts of a suite of lessons. *Preludium*, or prelude, frequently occurs without leading to any other movement; as does *passamezzo*, *alman*, *toccata*, once; but the rest are chiefly old tunes with variations. These pieces are all written on a staff of six lines.

*Lady Nevil's Virginal Book*.—This lady was a pupil of our admirable countryman Bird; and all the lessons in her book, a thick quarto, are of his composition. They are admirably transcribed by John Baldwyne, a singing-man of Windsor, and a celebrated copyist of that time, 1591.

Its contents are; "My lady Nevil's *grounde*, with eight variations. *Qui passe*, four variations. March before the battle, 12 military movements. Old tunes varied. *Groundes* and *fancies*, with 18 pavans, and two lessons of *voluntaire*, all neatly written on four-staved paper of six lines.

Thus far all our music for keyed-instruments was in MS. But in the reign of James I. the following book appeared in print, still on six-lined paper. "Parthenia, or the Maidenhead of the first Musicke that ever was printed for the Virginals; composed by three famous Masters; William Byrde, Dr. John Bull, and Orlando Gibbons, Gentlemen of his Majesty's most illustrious Chapel. Dedicated to all the Masters and Lovers of Musick." The pieces in this collection seem to follow in *suits*, of which the first is of Bird's composition; as *preludium*, *pavana*, *galliarido*, all in G minor; then a prelude, and a *galliarido* in C; and a *pavan*, and two *galliaridos* in G, by the same.

The next author in the collection is master doctor Bull, whose pieces are arranged in the following order, "A pavan and two *galiards* in A minor; prelude, pavan, and *galiard*, in G major; two *galiards* in D minor." Orlando Gibbons' pieces have little connection, being a *galliarido* in C natural; a *fantasia* in four parts, in A minor; a pavan in do; the queen's command in C, and a *preludium* in G. This book was again engraved on copper in 1651, fol.

The title of Handel's two sets of lessons is in French, and the movements of each *suit* have the same denominations as many French composers of lessons had long used in Louis XIVth's time; as prelude, allemande, courante, gigue, with sometimes adagio, farabande, allegro, and air with *doublers*, or variations, which include all the technica of the first book.

In the second book, he has prelude, aria con variationi, minuet, chacone, and gavotta. The movements of the second book are of a lighter kind than those of the first, as the first and third set of Corelli's sonatas are called "Suonate da Chiesa," and the second and fourth sets, "Suonate da Camera."

Scarlatti's lessons are almost all single pieces, and we believe Alberti's were the first harpsichord lessons published in England, that were called sonatas. "Suonate da Cimbalo," which, without accompaniments, is still the general title of what used to be called lessons.

LESSOR, a legal term applied to the landlord, proprietor, or person who lets the land. See LEASE.

LESTANO, in *Geography*, a town of Italy, in the Friuli; 15 miles W: of Udina.

LESTI, a town of Sweden, in the government of Wafa ; 54 miles E. of Jacobitad.

LESTIBUDESIA, in *Botany*, named in honour of M. Lestiboudis, a French naturalist. Aub. d. Petit Thouars, *Plant. Ins. Afric. v. 1. 53. t. 16.* Brown. *Prodr. Nov. Holl. v. 1. 413.*

This genus is separated from *Celofia* only on account of its stigmas, which are three or four, slender and recurved, instead of being capitate or two-lobed. It includes *Celofia paniculata* and *trigyna* of Linnaeus, with some others, but Mr. Brown hints that it is probably not a natural genus, nor established on sufficient grounds. His *L. arborescens*, the only species mentioned as found in New Holland, was gathered by sir Joseph Banks in the Tropical part of that country. It has a shrubby twining stem ; elliptic-oblong, somewhat pointed, smooth leaves ; terminal as well as axillary panicles ; and three stigmas, which, according to Dr. Solander's remarks, are deeply emarginate. The manner in which the fruit bursts has not been observed.

LESTIGUANO, in *Geography*, a town of Etruria ; 27 miles W. of Volterra.

LESTOFF. See LAVESTOFF.

L'ESTRANGE, SIR ROGER, in *Geography*, was a great lover of music, and a performer. His family, one of the most ancient in Norfolk, were always great patrons of music, and musicians. Jenkins was frequently an inmate at Hunston, where, during the seventeenth century, when times were tranquil, professors and dilettanti frequently assembled to sing madrigals, and make use of several chests of viols in the performance of fancies in six parts, by the best composers of the times.

LESTRIGONS, in *Ancient Geography* and *Fabulous History*, inhabitants of Sicily towards the S.E., who are represented to have been a ferocious people. It is reported that they took Elpe, the daughter of Polyphemus the Cyclop, by force from Ulysses, who had seized her and was running away with her, and returned her to her father. If we may credit the poets, both the Lestrignons and the Cyclopes were real cannibals, who devoured fix of Ulysses's companions. The learned Bochart will have the rise of this fable to be, that the Lestrignons were anciently called Leontini, a name derived from their barbarous and cruel manners ; " à Leon-tinis moribus."

LESTWITHIAL, in *Geography*. See LÆSTWITHIAL.

LESZAISKO, a town of Austrian Poland, in Galicia ; 28 miles N.W. of Przemysl.

LET-Fall, in *Sea Language*, the word of command for putting out a sail, when the yards are aloft, and the sail is to come down from the yard ; but when the yards are stricken down, then the sail is loosed below, before they hoist the yard.

*Let-fall* is not properly said of top-fails, because they lie on the top ; and therefore the word for them is, *Heave out your top-fails*. Nor can it be applied to the mizen ; for the word is, *Strike the mizen and set it*. So that in strictness the term *let-fall* belongs only to the main-fail, fore-fail, and sprit-fail, when their yards are hoisted up aloft.

*Let-in*, in *Ship Building*, is the letting of one thing into another for support or security, as the beams into the clamps, carlings into the beams, &c. by scores being cut to receive them.

LETAC, in *Geography*, a cape on the W. coast of the island of Jersey ; six miles N.W. of St. Aubin.

LETALA, a town of Sweden, in the government of Abo ; 30 miles N.W. of Abo.

LETHAIS, a town of Mingrelia, on the Black sea ; 10 miles N. of Anaghia.

LETHAM, a town of Scotland, with a market, in the county of Fergus ; five miles E. of Forfar.

LETHARGY, in *Medicine*, ληθαργος, ληθαργια, signifying literally an *indolent forgetfulness*, (defidia obliviosa) from ληθη and αργος, is commonly used to denote an incessant and irresistible sleepiness, accompanied by an impaired state of the memory, but without delirium.

The lethargy is, in fact, a minor degree of apoplexy, and originates from the same causes, and implies a similar state of pressure on the brain, the common centre of the nervous energy, as occasions that disease. Various denominations have been given to lethargic complaints, according to the difference of the degree of severity, and some nosologists have treated of these varieties as distinct species of disease. Sauvages, for instance, has three genera of sleepy affections, *Lethargus*, *Cataphora*, and *Carus*. The cataphora he defines, a state of somnolency, from which the patient may be easily roused, without fever, delirium, or loss of memory ; the lethargy, a soporose state, from which the patient may be easily roused, accompanied with the greatest torpor of the memory and imagination, and with fever ; and *carus*, a profound sopor without snoring ; for when the snoring is present, he denominates it apoplexy. (See his *Nofol. Method. Clafs iv. Ord. 5.*) But it is obvious, as Dr. Cullen long ago observed, that these various appellations and definitions designate the same disease, in different degrees of severity ; we may, therefore, refer to the article APOPLEXY for a general view of the nature of the malady. We may observe, at present, that it originates from some *compression* upon the substance of the brain, by which its functions are impeded, and its influence on the system at large, through the medium of the nerves, obstructed ; that such compression may be occasioned by fractures of the skull, when the fractured portion of the bone is depressed inwards ; from tumours within the head ; from over-dilatation of the blood-vessels of the brain ; or from fluids effused in or upon the brain ; but that the most frequent of all these causes of compression is a plethoric state, or an accumulation and congestion of blood in the venous vessels of the head, operating, according to its degree, in producing over-dilatation or effusion.

Lethargic complaints may, therefore, both precede and succeed actual apoplexy, and are not unfrequently the forerunners of a fit. From this consideration, the importance of obviating their progress in the outset, before a rupture of the vessels of the brain, or actual effusion, takes place, must be obvious ; for, however impracticable it may be to remove the fluids so effused, or to occasion their absorption, so as to preserve the life of the patient, or to save him from an incurable palsy, if he survive ; yet, in the previous state of mere plethora of the vessels of the brain, the proper remedies may be employed with every prospect of removing the lethargic symptoms, and warding off the impending danger. The plethora may be corrected by general evacuations by blood letting, if there is an imminent threatening of apoplexy ; or by local evacuations by means of leeches, scarification, and cupping, blisters, or issues, where the danger is less imminent. At the same time, the alvine excretions should be promoted by proper laxative medicines, the diet should be light, and rather spare, and unstimulating, consisting of a large proportion of vegetable matter ; and fermented liquors of all kinds should be very sparingly taken, or altogether discarded. Exercise in the open air should be regularly performed in, and the hours appropriated to sleep shortened. In a word, a lethargy is to be considered as an impending apoplexy, or an apoplexy already begun, and to be treated accordingly. See APOPLEXY.

LETHE, ληθη, in *Ancient Mythology*, one of the five rivers

rivers of hell, signifying oblivion or forgetfulness; its waters, according to poetic fiction, having the peculiar quality of making those who drank them entirely forget every thing that was past; or, according to Virgil, "longa potant obliviam vite."

**LETHE.** *Letb*, or *Lathz*, a measure or portion of land, making one of the ancient divisions in England.

King Alfred divided England into counties, as it stands at present; those counties he subdivided into hundreds or tithings. The hundred was a division, wherein were a hundred officers to secure the peace; the *lathe* or *lathe* comprehended three or four of these hundreds.

**LETHE** was also the jurisdiction of a viscount: or a kind of assize, held once a year in each village, about Michaelmas. Whether this was instituted by Alfred, or not, is a question.

**LETHERS**, in *Geography*, a town of Hindoostan, in the circar of Sumbulpour; 16 miles W.N.W. of Sumbulpour.

**LETHRABERG**, or **LADREBERG**, a town of Denmark, in the island of Zealand; four miles S.W. of Roefchild.

**LETHUM**, in *Ancient Mythology, was distinguished by the Roman poets from *mors*, or death. See Petronius Arb. ver. 263.*

Mr. Spence conjectures, that by Lethum they meant that general principle, or source of mortality, which they supposed to have its proper residence in hell; and by *mors*, or *mortis*, the immediate cause of each particular instance of mortality on our earth. The poets give him a robe, but mention his arms being exerted out of it, as reaching at his prey. They hint at his catching people in a net, and his hunting them as they did beasts, within his toils. They represent Lethum as nearly related to Sleep; and Valerius Flaccus, in particular, acquaints us that they were brothers. Val. Flac. viii. ver. 74. Spence's Polymetis, p. 261. 263.

**LETI, GREGORY**, in *Biography*, was born at Milan in 1630. He received his education at the Jesuits' college at Cosenza, and afterwards passed some years in an unsettled ita'e, manifesting a strong repugnance to the ecclesiastical profession, which was propoled to him by his uncle the bishop of Aquapendente. Falling in company, at Genoa, with an officer of the Calvinistic persuasion, he became a convert to the reformed religion, and openly avowed it at Lausanne. He went to Geneva in 1660, married there, and settled as a man of letters. His talents were held in such estimation, that the right of citizenship was presented to him gratuitously; but his temper was so sarcastic, as to involve him in great troubles, and in 1680 he retired to England. Here he was favourably received; a pension was granted him, and he was promised the office of historiographer; but before he obtained it, he was ordered to quit the kingdom on account of some freedom which he had exercised in a work entitled "Teatro Britannico." He went to Amsterdam, became acquainted with the celebrated Le Clerc, who married his daughter, and obtained the title of historiographer of that city. Leti was a most industrious writer; his works are said to amount to a hundred volumes. Most of them are historical, but they are frequently destitute of truth, and cannot be relied on unless supported by other authority than the dictum of the writer. All his works are written in Italian, in a lively style, but diffuse and void of taste. His best productions are the lives of Sixtus V.; Charles V.; queen Elizabeth; Philip II.; and Cromwell. He died suddenly in the year 1701.

**LETI**, in *Geography*, a small island in the East Indian

sea, near the island of Timor. N. lat. 8 28'. E. long. 127° 15'.

**LE FLING**, a town of Brandenburg, in the New Mark; five miles E. of Cultrin.

**LETNA**, a river of Russia, which runs into the Viatka, at Podreskoi.

**LETSCHKOM**, or **ODISCH**, a town of Asiatic Turkey, and capital of Mingrelia; the residence of the chief and see of a Greek archbishop; 60 miles N. of Cotatis.

**LETTER**, or **LETTERBACH**, a town of Bavaria; 11 miles N. of Bamberg.

**LETTER, LITERA**, a character either in print or writing, by which any people have agreed to express one of the sounds, used in conveying their thoughts to each other in speech.

Letter is by some defined a simple uncompounded sound of the voice, that cannot be subdivided into any more simple, and generally marked with a particular character.

But it must be owned that, strictly speaking, a letter is not the sound itself, but rather the sign of a sound; for γράμμα, *litera*, is derived from γράμμαται, of γράφω, *to write*; and *litera* is formed from *litus*, the participle of *linere*, *to smear*, or *mark*; whence *oblitterare* signifies *to blot out*.

Where a sign or character does not express a sound entirely simple, but one resolvable into several, it is not so properly a letter as an abbreviation, containing in itself as many letters as its power does simple sounds. This is evident in the Latin  $\mathcal{C}$ ,  $x$ , and the Greek  $\xi$ ,  $\downarrow$ ,  $\tau$ , &c. which are composed of  $c$ ,  $l$ ,  $k$ ,  $s$ ,  $x$ ,  $s$ ,  $\sigma$ ,  $\tau$ , &c.

On the contrary, a simple sound, though expressed by several characters, is yet to be esteemed one letter; for *ib*, *ph*, are single letters; as much as  $\phi$ ,  $\theta$ , and *f*.

The letters, *f*, *g*, *b*, *k*, *q*, *x*, *y*,  $\omega$ , were unknown to the ancient Romans, as is proved by Daufquius in his Orthography, where he traces the origin of the several letters. See F, G, H, &c.

Grammarians distinguish letters into *vowels* and *consonants*; into *mutes*, *diphthongs*, *liquids*, and *characteristics*. See each of these terms respectively.

The Hebrews divide their letters into *guttural*, as *a*, *b*, *cb*, *gn*, *aleph*, *he*, *cheth*, *hain*, expressed by א, ב, ג, ד, ה, ו, ז, ח, ט, י, ק, ל, מ, נ, ס, ע, פ, צ, ק, ר, ש, ת; *dental*, as *z*, *s*, *tz*, *r*, *sh*, *zain*, *famech*, *tsade*, *resch*, *schin*, expressed by כ, פ, צ, ק, ר, ש, ת; *labial*, as *b*, *m*, *u*, *ph*, *beth*, *mem*, *vau*, *phe*, expressed by the word ב, פ, מ, ו, פה; *lingual*, or those chiefly formed by the tongue, as *d*, *t*, *l*, *n*, *th*, *daleth*, *teth*, *lamed*, *nun*, *thau*, expressed by ד, ת, ל, נ, ט, ז, טו, טז, טז; and *palatal*, as *g*, *i*, *c*, *k*, *ghimel*, *jod*, *cap*, *koph*, expressed by ג, י, כ, ק, פ.

Printers distinguish their letters into capital, majuscule, initial, or upper-case letters, which serve for the titles of books, proper names, &c.; and minuscule, small, or under-case letters; which are again divided, according to their size, into *pearl*, *nonpareil*, *picca*, *greatprimer*, *cannon*, &c.

They have also their flourished letters, engraven on wood or metal, which take place of the illumined letters of the ancient manuscripts.

There are letters of various sizes, or bodies; each of which, again, are sometimes cast with the Roman, sometimes an Italic, and sometimes an English, or Black letter face. There are also bodies with Greek, Hebrew, Arabic, the music face, &c.

Letters make the first parts or elements of grammar, constituting the subject of *orthography*; an assemblage of these composes *syllables*, of those *words*, and of these *sentences*. See each under their titles.

The alphabet of every language consists of a certain number of these letters, which ought to have a different sound, figure, and signification. See ALPHABET.

As the difference of articulate sounds was intended to express the different ideas of the mind, so one letter was originally intended to signify only one sound, and not, as at present, to express sometimes one sound, and sometimes another: which practice has brought a great deal of confusion into the languages, and rendered the learning of the modern tongues infinitely more difficult than it would otherwise have been. This consideration, together with the poverty of all the known alphabets, and their want of some letters to express certain sounds by, has occasioned several attempts towards an universal alphabet, to contain one enumeration of all such single sounds or letters as are used in any language. A thing of very considerable use; a specimen of which is given us by Mr. Lodwick, in the Philosophical Transactions. See *Universal CHARACTER*.

According to Crinitus, Moses invented the Hebrew letters; Abraham the Syriac and Chaldee; the Phœnicians those of Attica, brought into Greece by Cadmus, and thence by the Pelagians into Italy; Nicofrata the Latin; Isis the Egyptian: and Uphilas, about three hundred and seventy years after our Saviour, those of the Goths. Yet as to the first letters, what they were, who first invented them, and among what people they were first in use, there is still room to doubt; however, setting aside conjectures and prejudice, the business of antiquity seems to lie between the Egyptians and Chinese. Philo attributes the first invention of letters to Abraham; Josephus, St. Irenæus, and others, to Enoch; Babilander, to Adam; Eusebius, Clement Alexandrinus, Corn. Agrippa, &c. to Moses; Pomponius Mela, Herodian, Rufus Festus, Pliny, Lucan, &c. to the Phœnicians; St. Cyprian, to Saturn; Tacitus to the Egyptians; and some to the Ethiopians.

The Egyptian mummies and obelisks prove a great antiquity on the side of the hieroglyphics; but if the Chinese chronology may be credited, their characters are much more ancient than those of the Egyptians. The Chinese make Fohi, the first of their kings, supposed by many learned and judicious writers to have been no other than the patriarch Noah, the inventor of their letters, and compute him to have lived two thousand nine hundred and fifty years before Christ, during all which time they pretend to have certain and written accounts in their books. If this holds true, their character must be older than Moses by fourteen hundred years, and even prior to Menes, the first king of Egypt, by five hundred years; so that the Chinese letters appear to be the most ancient of that kind; and the book Yekim, said to be written by Fohi, the most ancient book.

But as China is so remote, and had so little communication with these parts of the world, we may reasonably make another enquiry into the original of letters in the hither parts of Asia, Egypt, and Europe. Here, indeed, the Egyptians seem to have the best title. It is more than probable, from the obelisks, &c. that their hieroglyphics were the first manner of writing, and the original characters in these parts, as being prior to Moses; and were made, at least in great measure, while the Israelites were slaves among them, and consequently not well qualified for inventions so very curious and judicious.

To this source the learned bishop Warburton ascribes the origin of alphabetical writing among the Egyptians: for as philosophy advanced, and their learned men wrote much, the exact delineation of hieroglyphic figures became too tedious and too voluminous; and they, therefore, by degrees

perfected another character, which he calls the running hand of hieroglyphics, resembling the Chinese characters, which being at first formed only by the outlines of each figure, became at length a kind of marks. See HIEROGLYPHICS.

This running character was denominated by the ancients *hieroglyphical*, and led to the compendious use of letters by an alphabet, which method of writing, as the ancients inform us, was invented by the secretary of an Egyptian king, and first used for secrecy in the conveyance of letters of state, whence it was called epistolary writing: but afterwards letters became common, and, as he observes, hieroglyphics secret and mysterious. This political alphabet, he adds, soon occasioned the invention of a sacred one, used by the priests, and called *hierogrammatical*. But the precise time of the invention of Egyptian letters cannot be so much as guessed at, because hieroglyphics continued in use long after letters had been found out: it is certain that they were very early, because the invention of them was ascribed to their gods. Bishop Warburton farther conjectures, that Moses brought letters with the rest of his learning from Egypt, and that he both enlarged the alphabet, because the Hebrew alphabet which he employed in the composition of the Pentateuch is considerably fuller than that which Cadmus brought into Greece; and altered the shapes of the letters, reducing them into something like those simple forms in which we now find them, in order to prevent the abuse to which they would be liable as hieroglyphic marks and symbolic images. He argues, that, considering the importance of letters among the Hebrews, with regard to the integrity of their religion, if God had been the immediate author of them, Moses would have recorded the history of their invention, as the best sanction to their use and best security from the danger of hieroglyphic writing, to which this people, so fond of Egyptian manners, were very powerfully inclined. Divine Legation, vol. ii. p. 1. 124, &c. See also on this subject Sharpe's Origin of Languages, p. 56, &c.

Many of the fathers, and some learned men among the moderns, have imagined that the knowledge of alphabetic writing was either supernaturally imparted to our first parents, or discovered very soon after the Creation by the efforts of their own powers. Others have supposed that alphabetical letters were introduced very early after the deluge, about the time of the dispersion of mankind, to which period the records of the Chaldean astronomy very nearly extend. Mr. Shuckford, who supposes that they were invented both in Assyria and Egypt, conjectures that the great project of Babel, next to the building of the tower, was the improvement of language, by dissolving the monosyllables, of which the first language of mankind consisted, into words of various lengths, in order to obtain new sets of names for new things; and that a project of this kind might gradually lead to the invention of alphabetical letters. Con. of Sacred and Prof. Hist. vol. 1. p. 248.

But to these conjectures it may be replied, that we have no authentic relation of any alphabetic character before the flood; the account of the inscription upon pillars by the first Mercury from Manetho, or of Seth mentioned by Josephus, being too fabulous to deserve credit. Besides, if they had been in use among the patriarchs after the deluge, many occasions occur, in which they would not have been omitted: and as we have no account of the use of alphabetic characters in epistles or contracts, or for other purposes to which they would naturally be applied, we may infer that they were not known. To which we may add, that none of the revelations of God to the patriarchs, were enjoined to be recorded till the giving of the law. Others have ascribed the invention of letters to the

Arabs,

Arabs, before the time of Moses; but when we consider the rudeness of their lives and manners, this opinion is by no means probable: and, therefore, the greater number of writers among Jews and Chirilians, both ancient and modern, have contented themselves with tracing their origin to Moses, supposed to be the same with the Egyptian Thoth or Hermes, mentioned in the history of that nation; alleging that God taught him the use of alphabetic letters, in the exemplar of the two tables, written, as the text assures us, with the finger of God; which words can be understood to mean only that they were written by a divine order and direction, as is evident by comparing Exod. xxiv. 27, 28. and ch. x. 4. It has been said by some of the advocates of this opinion, that the elements of language were thus supernaturally revealed to Moses upon the first arrival of the Israelites before Horeb, but that their characters, with the arrangement of them, might be left to his discretion. But it seems more probable, that letters were at this time well known to the Israelites, as God thought fit to deliver the first elements of their religion in that kind of writing: more especially as the history of so momentous a circumstance is not recorded; a circumstance, the memory of which would have been one of the greatest barriers against idolatry. From the Israelites, it is supposed this art of alphabetical writing passed to the Syrians, and from them it was communicated to the Phœnicians and Egyptians: though it seems probable that it was of a more ancient date among the latter than the time of the decalogue, or the delivery of the law on mount Sinai.

Sir Isaac Newton, in his Chronology, allows the Midianites, sprang from Abraham by his concubine Keturah, to have instructed Moses in the knowledge of writing.

Nevertheless, whether Cadmus and the Phœnicians learnt letters from the Egyptians, or from their nearer neighbours of Judea and Samaria, is a question; since some of the books of the Old Testament, being written in letters, is more likely to have given them the hint, than the hieroglyphics of Egypt. But when or wheresoever the Phœnicians learnt this art, it is generally agreed, that Cadmus, the son of Agenor, first brought letters to Greece; whence, in the following ages, they spread over the rest of Europe.

Herodotus, in his fifth book intitled Terpichore, informs us, that those Phœnicians who accompanied Cadmus into Greece, and settled there, among many other arts and sciences, introduced into that country the knowledge of letters, which the Greeks, in his opinion, were ignorant of till that time: their first letters were such as were in use among the Phœnicians; but some time after they altered them a little, both with regard to their make and sound; which alteration some have supposed to have been the change of the Hebrew characters into those that were afterwards called the Samaritan; and as at that time many of the neighbouring parts were inhabited by such as were originally Ionians, who also had received their letters from the Phœnicians, they mixed the one with the other; and hence those characters were termed Phœnician, because they were brought out of Phœnicia into Greece. Herodotus also adds, that he saw at Thebes, in Bœotia, in the temple of Imenian Apollo, three tripods, that had inscriptions upon them in Cadmean letters, which very much resembled the Ionic. The time of this expedition of Cadmus into Greece, is fixed by Sir Isaac Newton to about the 1045th year before Christ. The number of letters which Cadmus brought into Greece, according to Aristotle, as cited by Pliny, was eighteen; but according to Plutarch and Pliny himself, sixteen; to which Palamedes, in the time of the Trojan war, added four, and Simonides four; so that the Greek alphabet was gradually

perfected. The alterations and improvements introduced into Greece have led some writers to ascribe the invention of the alphabet to the Greeks; that, thus, Vossius de Arte Gram. lib. i. cap. 10. asserts, that Cecrops, who was much older than Cadmus, was the first author of the Greek letters; and others ascribe them to Lincus, or to Palamedes. (Diod. Sic. lib. iii. Tacitus, lib. xi. cap. 14.) But the more general opinion of the ancient writers is that they were derived from the Phœnicians and Egyptians. Diodorus (lib. v.) says expressly, that they were invented by the Syrians, and communicated by them to the Phœnicians, who changed the form of the characters brought into Europe by Cadmus. Pliny, (Nat. Hist. lib. vii. cap. 56.) says, that he is of opinion, that they were Assyrian, though he acknowledges that others thought they were invented by the Egyptians, and that Mercury was their first author. Diodorus, (lib. ii.) ascribes the invention of them to the same person; and likewise Plutarch Sympof. lib. xx. cap. 3. and Cicero de Natura Deorum, lib. iii. And the era of this invention is computed by chronologers to be as early as the year of the world 2054, and before the incarnation 1950 years. The Greeks retained the names and orders of several of the oriental or Cadmean letters, though they altered the form of them; and there are seven letters, viz. Γ, Δ, Η, Κ, Α, Ρ, Τ, whose original figures were retained by the Greeks with little variation. As to the Latins, all writers agree, that they received their letters from the Greeks, being first taught the use of them by some of the followers of Pelafgus, who came into Italy about 150 years after Cadmus came into Greece; or by the Arcadians, whom Evander led into these parts about 60 years after Pelafgus. Pliny (lib. vii. cap. 56.) and Solinus imagined the Pelafgi to have been the first authors of the Latin letters; but Tacitus (lib. xi. p. 131.) was of opinion, that the first Italians were taught letters by the Arcadians; and Dionysius Halicarnassus (lib. iii.) expressly affirms the same thing. That the Latin letters were derived from the Greek seems very probable from the similitude which the ancient letters of each nation bore to one another. Tacitus (Annal. lib. xi.) observes, that the shape of the Latin letters resembled that of the most ancient Greek ones; and the same observation was made by Pliny, lib. vii. cap. 58. and confirmed from an ancient table of brass inscribed to Minerva. Scaliger Digress. ad Annum Euseb. 1617, and Vossius, lib. i. cap. 24, 25. have adopted and supported the same opinions. See those citations in Shuckford's Conn. vol. i. p. 223, &c.

Thus we find, that Greece was the centre from which the rays of science shot into the western world; and the barbarous nations which penetrated into Italy towards the close of the Roman empire, carried arts and learning back into the North; or the knowledge of letters might be introduced among the northern nations from the borders of Asia, in an earlier age. (Sharpe's original Powers of Letters. Observations on Alphabetical Writing, 1772.) Rudbecks, who, in his Atlantica, claims the glory of all inventions, from all other nations, for the Swedes, maintains, that the Ionians had letters before Cadmus; that at the time of the siege of Troy, the Greeks had but sixteen letters, whereas the Phœnicians had twenty-two; whence he concludes, that it was not either Cadmus, or the Phœnicians, who taught this art to the Greeks. But, because the ancient northern nations had just sixteen letters, like the Greeks, he concludes the Greeks must either have taught them to the people of the North, or have learnt them of them. But because the form and make of the Runic letters is more artless and coarse than that of the Greek letters, he concludes, that these last must be derived from the former; taking

taking it as a principle, that those who derive any thing from another, polish and improve it. He even asserts, that by the golden apples, which Hercules was obliged to steal, meant be understood the letters in use among the Hyperboreans.

There are few things on which there has been so much written as on the original Hebrew letters. Origen, Eusebius Cæsariensis, St. Jerom, &c. have made it the subject of their enquiry. See HEBREW and SAMARITAN.

The art of joining letters to form words, and of combining the one and the other an infinite number of different ways, is a secret unknown to the Chinese. Instead of the alphabetical letters, they at first, like the Egyptians, used hieroglyphics; they painted, rather than wrote; striving, by the natural images of things drawn on paper, to express and communicate their ideas to one another.

To remedy the inconveniences of this method, they changed, by little and little, their manner of writing, making it more simple, though less natural. They even invented several characters, to express things that did not come within the reach of painting to represent: as voice, smell, thoughts, passions, and a thousand other objects that have no body or figure. From several simple strokes they afterwards framed others more compound; and in this manner multiplied the letters and characters to infinity, contriving one, or more, for every word.

This multitude of letters seems the source of that ignorance which we find among the Chinese; their whole lives being spent in learning their letters, they have no time to apply themselves to the study of things, but think themselves very learned when they are able to read. There are scarcely any of them that know all their letters; they think it is a great progress they have made, when, after forty or fifty years hard study, they are able to understand fifteen or twenty thousand. But the generality of their learned men come short of this. Father Le Compte is of opinion, that the greatest doctor among them never understood half of their letters well; for the whole number he reckons eighty thousand. This is a prodigious inconvenience to foreigners, of which the missionaries in that country make loud complaints.

Among the Chinese letters, there are some now almost worn out of use, and only preserved out of respect to antiquity. There is a second class, much less ancient than the former, only used in public inscriptions. A third, much more regular and beautiful, used in printing, and even in ordinary writing. However, as the strokes are to be distinctly formed, they cannot be written with any expedition. For this reason, they have invented a fourth kind, where the strokes, being closer, and less distant from each other, allow them to be written with more ease and readiness; and this they call the *running letter*. See CHINESE *Tongue*.

The Americans had no letters before the discovery of that country by the Spaniards. The Acaanbas engrave their memorable events and epochs on stones and metals; their songs supply the rest. In Peru and Chili, to keep an account of their goods and chattels, and to preserve the memory of their particular affairs, the Indians have recourse to certain knots of wool; which, by the variety of their colours and ties, serve instead of characters, and writing. The knowledge of these knots, which they call *quipos*, is one of their great sciences; but which is always kept as a secret, and never revealed to the children, till the fathers think themselves at the end of their days. See on the subject of this article LANGUAGE, GRAMMAR, and WRITING.

LETTERS, or *Literal Notation*, in *Music*. The Greeks

used all the twenty-four letters of their alphabet as musical characters; and these not sufficing for all their modes and genera in their natural state, were sometimes used as capitals, sometimes small; some entire, some mutilated; some doubled, and some inverted; to the amount of 1620 notes. See ALYSIUS, and NOTATION.

LETTER, *Domonical*. See DOMINICAL.

LETTER, *Double*. See DOUBLE.

LETTER, *Final*. See FINAL.

LETTER, *Cuttural*. See GUTTURAL.

LETTER, *Foundery*. See FOUNDERY.

LETTER, *Founders' Furnace*. See FURNACE.

LETTER, *Founders' Mould*. See MOULD.

LETTER, *Labial*. See LABIAL.

LETTERS, *Numeral*, are those used, instead of ciphers, to express numbers.

The Roman numerals are, C, D, I, L, M, V, X; which are all formed by describing a circle, and drawing two lines through it, crossing each other at right angles in the centre. See CHARACTER.

LETTER, *Nundinal*. See NUNDINAL.

LETTER is also a writing addressed and sent to one. See EPISTLE.

By 9 Geo. I. cap. 22. amended by 27 Geo. II. cap. 15. knowingly to send any letter without name, or with a fictitious name, demanding money, &c. or threatening, without any demand, to kill or fire the house of any person, is made felony without benefit of clergy. And by 30 Geo. II. cap. 24. persons sending letters with or without a name, or with a fictitious name, threatening to accuse any one of a crime punishable by law with death, transportation, pillory, or any other infamous punishment, in order to extort money or goods, shall be punished at the discretion of the court by fine and imprisonment, pillory, whipping, or transportation for seven years.

LETTERS of *abolition* were formerly granted by an abbot, to release any of his brethren from the obligation of subjection and obedience, and to make them capable of entering into any other religious order.

LETTER of *attorney*, in *Law*, a writing authorizing an attorney to do some legal act in our stead: as, to give seisin of lands, to receive debts, to sue a third person, &c. And letters of attorney are either general or special. West. Symb. par. 1. stat. 7 R. II. cap. 13.

The nature of this instrument is to give the attorney the full power and authority of the maker, to accomplish the act intended to be performed. Sometimes these writings are revocable, and sometimes not so; but when they are revocable, it is usually a bare authority only; and they are irrevocable, when debts, &c. are assigned to another; in which case the word irrevocable is inserted.

LETTERS *claus*, or *close*, are opposed to *letters patent*. See CLOSE ROLL.

LETTER of *credit*, among *Merchants*. See CREDIT.

LETTERS *communicatory*. See LITERÆ *communicatorie*.

LETTER of *exchange*. See BILL and EXCHANGE.

LETTER of *licence*, in *Trade*, an instrument or writing granted to a man who has failed, or broke, signed and sealed by his creditors; which letter usually gives a longer time for payment: so that the debtor, having such an assurance, may go about his business, without fearing an arrest.

LETTERS of *mart*, or *marque*, are letters under the privy seal, granted to the king's subjects; empowering them to take, by force of arms, what was formerly taken from them by the subjects of some other state, contrary to the law of mart. Letters of *marque*, in the British dominions, are to be

be granted by the admiralty; and they empower the commander of a merchant ship or privateer to cruise against and make prizes of the enemies ships and vessels, either at sea, or in their harbours. See *MARQUE*.

*LETTER missive*, in the *Election of a Bishop*. See *BISHOP*.

*LETTER missive*, in *Chancery*. If a peer is defendant in this court the lord chancellor sends a letter missive to him, to request his appearance, together with the copy of the bill; if he neglects to appear, then he may be served with a subpoena; if he continues still in contempt, a sequestration issues out immediately against his lands and goods, without any of the mesme procees of attachments, &c. which are directed only against the person, and therefore cannot affect a lord of parliament. The same procees issues against a member of the house of commons, except that the lord chancellor does not send him any letter missive.

*LETTERS patent*, or *overt*, are writings sealed with the great-seal of England, whereby a man is authorized to do or enjoy any thing, which of himself he could not do. They are so called, on account of their form; as being open with the seal affixed, ready to be shewn for the confirmation of the authority given by them; and usually directed or addressed by the king to all his subjects at large, thus, and in some other respects, differing from close letters. See *CLOSE ROLLS*.

Common persons may grant letters patent; but they are rather called patents, than letters patent; yet for distinction, those granted by the king, are sometimes called letters patent royal.

Letters patent conclude with *teste meisiso*; charters with *hinc testibus*. See *PATENT*.

*LETTERS of respite*, letters issued out by a prince, in favour of honest unfortunate debtors, against too rigorous creditors, whereby payment is delayed for a certain term.

The use of these letters is very ancient. Cassiodorus observes, they were in use in the time of Theodorick, king of the Goths; others will have them introduced towards the end of the eleventh century, by pope Urban II. in favour of those who went on the croisades.

They are still in use in France and some other countries, and take their name, à *respirando*, because they give the debtor a breathing time.

St. Louis granted three years respite to all who made the voyage of the Holy Land with him.

*LETTERS circular*, *dimissory*, *frank*, *monitory*, *pacific*, *papal*. See the several adjectives.

*LETTERS of safe-conduct*. See *SAFE-conduct*.

*LETTÈRE*, in *Geography*, a town of Naples, in Principato Citra, the see of a bishop, suffragan of Amali; 12 miles W.N.W. of Salerno. N. lat. 40° 43'. E. long. 14° 20'.

*LETTERED*, *LETRADOS*. See *LITERATI*.

*LETTERKENNY*, in *Geography*, a township of America, in Franklin county, Pennsylvania; containing 1497 inhabitants.

*LETTERKENNY*, a post-town of the county of Donegal, Ireland, situated on the river Swilly, over which it has a bridge. It is 113 miles N.W. from Dublin.

*LETTERN*, from *Letrinum*, the reading desk in ancient churches, &c., from which the epistles and gospels of the liturgy were read. The desks for the former frequently represented the prophet Moses with his horned countenance, those for the latter an eagle, the well-known emblem of St. John the Evangelist.

*LETTE*s, a people of Russia, derived from the Slavi and evincing a near affinity with the Vendi. Originally they were one people with the Lithuanians; as is evident from

the identity of their language and even of their names. In the middle ages the following denominations are used without distinction; *viz.* Letthnia, Letthovia, Lithavia, Liffonia, Lottavi, Litthvini, Letthovini, Letthvani, Lettoner, &c. Probably, says Tooke, the Lettes obtained their particular name from their first homelace. In the circle of Valk, not far from the town of Vendra, a river named Letta takes its rise; this river is called in Lettish "ta Lette," and a Lette is in their language Latvis, a man living by the river Lette. Till towards the end of the twelfth century Livonia or Lettland was entirely unknown to the German historians; it is mentioned only by Danes, Swedes, and Russians. By the two former on occasion of their piracies, and by the Russians for denoting their dominion over that country. Although Nestor, the oldest and most authentic Russian annalist, does not expressly mention the Lettes; this may possibly be owing to their not being at that time a particular nation distinct from the Lithuanians. It appears unquestionable from many testimonies, that the district inhabited by the Lettes on the Baltic already belonged to Russia in the earliest periods of its monarchy; it nevertheless appears that Livonia had then no settled constitution, nor was bound to the parent state by any firm political tie. (See *LIVONIA*) The homestead of the Lettes is not the whole of Livonia, but only a part of it which is called Lettland, consisting of four of the nine districts or circles into which Livonia, or the present vice-royalty of Riga, is divided; the remaining five circles being inhabited by Esthonians. Besides, the Kures in Courland, Semigallia, and the bishopric of Pilten are true Lettes; by whom, in part, the Lettish language is spoken in the greatest purity; and these people are mostly degenerated in Polish Livonia, where they are mixed with Poles and Russians. The number of them at present cannot be properly ascertained; but in the vice-royalty of Riga alone, there were upwards of 226,600 Lettes, according to the last census. At present they are no longer known as a separate people; they were mingled by imperceptible degrees, and at last blended with the Lettes, the Esthes, and the Coures, as they are usually called, the Lettonians, the Esthonians, and Courlanders. The Lettes, or Lettonians, are represented as a people always peaceable, industrious, hospitable, frugal, and of a somewhat better disposition than the Esthonians; and they inhabited the greater part of the Venden district, and extended themselves even into Dorpat, and hence it is that the chronicles mention the Lettes in Ungarnia. Their origin has been at one time sought for among the Grecian, and at other times among the Sarmatian tribes. By their language, however, it is perceived, that they bear an affinity with the Courlanders, or Coures, and that they are properly of Lithuanian, or in general of Slavonian origin. At present they occupy two districts, which both together are after them called Lettland. By the augmentation which they received from the Liefs, now reckoned with the Lettes, the Venders, the Lettgallians, and the Esthonians, they are more numerous than they were in the twelfth century. The Lettes call themselves Latwertis.

Both Esthonians and Lettonians, admitting many exceptions, are addicted to intemperance. Without beer and brandy they have no conception of pleasure. The aged in particular are hard drinkers, and continually smoke tobacco. They derive also a great part of their pleasure from singing and music. At their work in the field, as well as at their play, the girls are always singing. The most usual instrument with both nations is the bag-pipe, made by themselves, and sounded in proper time, in two keys, with great dexterity. The miserable horizontal harp, and the fiddle, which

which the Lettes are very fond of at all their festivals, were first introduced among them by the Germans. They are also very fond of dancing. Among their favourite summer pastimes is the swing; and this diversion, for which there is accommodation in every village at every house of entertainment, is in high vogue in Easter. In hot weather swimming is much practised by persons of all ages and sexes; and the boors without exception are passionately fond of scalding hot-baths. Infidelity towards their masters, distrust, a disposition to cheat and steal, and such like, are the vices to which they are addicted, and they certainly take their rise from the slavery in which they are held. They rarely rob one another; but they are very ingenious in devising means to impose upon their masters. Against them they have frequently risen in rebellion. Lying, cursing, and swearing are very current among them. Of their religion we shall only say, that when they were heathens, they were much given to superstition. Their paganism, it is said, was very similar to that of the Celts and ancient Germans. They had no temples, and acknowledged only one God, whom they adored under various names. They performed their religious rites in the open fields, on the top of a mountain, near a spring, or under the shade of a tree; and reckoned these places sacred. They believed in inferior deities, to whose care and government certain regions were allotted, and whom they much feared to offend. They had a god Thou, to whose influence they ascribed all aerial phenomena. Of the places and groves, where the ancient Lieflanders, as well as Eithonians as Lettonians, were accustomed to perform the holy rites of paganism, many, notwithstanding the strict orders that have been issued for their demolition, still remain, and they testify towards them an awful reverence. Offerings of wood, wax, yarn, bread, &c. are still in use among them, by laying them on the holy places, or cramming them in the hollows of aged trees. Springs and rivers likewise have their shares of these unbloody sacrifices. At their secret idolatrous assemblies, the keeping up of the fire, into which they throw all sorts of offerings, is still a principal observance. In Liefland they had idols, but no proper idol temples. The religious rites of the Celts and Lieflanders seem very much to resemble one another. Among both the Lettes and the Eithes many remains of heathenism are still observable; although in the twelfth century the Liefs, and afterwards the Lettes, were brought to the profession of Christianity by the Germans; and a part of the Eithes by the Danes. Tooke's View, &c. vol. 1.

**LETTING FARMS**, in *Rural Economy*, the practice of providing proper tenants for them, which is a business effected by different methods in different districts, as by private agreements, by proposals, and by public auction, to the highest bidder; all of which are liable to objections in some degree, but the first of these modes probably the least of any. See **FARM**.

**LETTONIA**, in *Geography*, a province of Russia, now included in the government of Riga. See **LETTES**, **LIVONIA**, and **RIGA**.

**LETTOWITZ**, a town of Moravia, in the circle of Brunn; 20 miles N.N.W. of Brunn.

**LETTUCE**, in *Botany and Gardening*. See **LACTUCA**.

**LETTUCE**, *Hart's*. See **SOW'S Thistle**.

**LETTUCE**, *Lamb*. See **VALERIANA**.

**LETTUCE**, *Will*. See **PRENANTHES**.

**LETTUCE**, in *Agriculture*, the name of a plant of the esculent kind, cultivated in the field in some districts for its use in feeding sows and pigs in the summer season. It is stated in the Calendar of Husbandry, that the writer first observed the sowing of lettuces for hogs practised in a pretty regu-

lar system, on the farm of a very intelligent cultivator (not at all a whimsical man) in Sussex. He had, every year, an acre or two which afforded a great quantity of very valuable food for his sows and pigs. He adds, that "it yields milk amply, and all sorts of swine are very fond of it." And he suggests, that "the economical farmer, who keeps many hogs, should take care to have a succession of crops for these animals, that his carts may not be for ever on the road for purchased grains, or his granary opened for corn oftener than is necessary." To raise this sort of crop, "the land should have been ploughed before the winter frosts, turning in by that earth 20 loads of rich dung per acre, and making the lands of the right breadth, to suit the drill-machine and horse-hoes, so that in this month (March) nothing more may be necessary than to fearily the land, and to drill the seed at one foot equi-distant, at the rate of four pounds of seed per acre. If half an acre or even a rood be tried near the farm-yard, the advantage, it is supposed, will not be inconsiderable."

Where the stock of swine is large, it may be proper to drill half an acre or an acre of lettuce in April, the land having been well manured and ploughed as directed above, being also scuffed in February and March, and well harrowed, repeating it before drilling. And at this period "the crop which was drilled in March (a succession being essentially necessary) should be thinned in the rows by hand, to about nine or ten inches asunder. If this necessary attention be neglected, the plants draw themselves up weak and poor, and will not recover it. Women do this business as well as men. When about six inches high, they should be horse-hoed with a scarifier or scuffler," having the hoe about four inches, or at most five inches, in width. With this sort of green food some kind of meal, or other dry meat, should be combined, as without it, it is apt to prove very laxative, and of course injurious to the animals. See **HOG** and **SWINE**.

**LEITZKAW**, in *Geography*, a town of Prussia, on the Vistula; 14 miles S.E. of Dantzic.

**LEITZNIG**, a town of the duchy of Holstein; six miles S.S.W. of Segeberg.

**LEVANDIS Millium Expensis**. See **EXPENSIS**.

**LEVANGHE**, in *Geography*, a small island near the E. coast of Ithria. N. lat. 45° 1'. E. long. 15° 52'.

**LEVANT** signifies any country situate to the east of us, or the eastern side of any continent or country, or that on which the sun rises.

**LEVANT**, or *Titus*, one of the Hæres islands, on the Mediterranean, near the coast of France. N. lat. 43° 4'. E. long. 6° 34'.

**LEVANT**, in *Matters of Commerce*, &c. is generally restrained to the Mediterranean seas; or, rather, to the country on the eastern part of it; or the coasts of Asia, and especially Asiatic Turkey, from Alexandria in Egypt to the Black Sea, including the islands of Cyprus, Rhodes, and the Archipelago.

Hence, our trade thither is called the *Levant trade*; and a wind that blows from thence, out of the Straits mouth, is called a *Levant wind*.

France was the first nation that made treaties of commerce with the Porte. The fleur de la Foret signed them in 1535; in the name of Francis I. and thereby obtained many privileges in favour of that kingdom; which they alone enjoyed, until the Venetians, the English, the Hollanders, and at length the Genoese, likewise obtained particular privileges for themselves.

**LEVANT Measures**. See **MEASURE**.

**LEVANT**, *Bale of the*. See **BOLE**.

LEVANT and *Coubant*, in *Law*, is, when cattle have been so long in another man's ground, that they have lain down, and risen again to feed, which, in general, is held to be one night at least. See DISTRESS.

LEVANTINE VALLEY, or *Valle Leventina*, in *Geography*, a valley of Helvetia, subject to the canton of Uri, and situated S. of St. Gothard, watered by the Tesino, and inhabited chiefly by Italians. It is supposed to retain by its name, traces of the "Leponiti," the ancient inhabitants of the surrounding regions. Its length, from the summit of the passage on the St. Gothard, is about eight leagues; the breadth is very inconsiderable. The lower part is extremely populous, rich in pasturage, and produces much hemp and flax. In the vicinity of the lofty mountains adjacent to it, the climate is various, and the country subject to much rain. To prevent the rain from damaging the crops, the inhabitants suspend and dry the corn and grass, on bars supported by two high poles about 15 feet asunder. The houses are entirely of wood, and externally appear like Swiss cottages; but a neglect of cleanliness proves the vicinity and greater similarity to the Italians. The Tesino is here joined by the Bromio, a torrent which takes its rise in mount Uccello, or the Vogelfberg, near Splagen; a bridge over it is the boundary of the two bailiwages of the vallies Levantine and Polese, and leads into that of Riviere. The valley now becomes perfectly flat, and of course subject to violent inundations; the few villages are scattered on the sides of the steep mountains; all below is desolate. Offogne, the residence of the bailiff, consists only of a few houses.

LEVANTO, a town of the Ligurian republic, on the coast of the Mediterranean; eight miles W. of Spezza.

LEVANZO, a small island in the Mediterranean, near the W. coast of Sicily; about nine miles W. of Trapani. N. lat. 38° 5'. E. long. 12° 24'.

LEVARE, ANTI-PHONON, in the *Musæ* of the *Romish Church*, is to begin or open the first note of an anthem.

LEVARI FACIAS, in *Law*, a writ directed to the sheriff for levying a sum of money on a man's lands and tenements, who has forfeited his recognizance; in virtue of which the sheriff may seize all his goods, and receive the rents and profits of the lands, till satisfaction be made to the plaintiff; but this writ has now given way to the remedy by *elegit*. There is also a *levari facias damna disseisitoribus*, for the levying of damages, wherein the disseisor has been formerly condemned to the disseise; and also a *levari facias residuum debiti*, to levy the remainder of a debt upon lands and tenements, or chattels of the debtor, where part has been satisfied before. And farther, a *levari facias quando vicecomes returnavit quod non habuit enforceos*, commanding the sheriff to sell the goods of the debtor which he has taken, and returned that he could not sell.

LEVARLOW, in *Geography*, a town of Poland, in the palatinate of Lublin; 40 miles S.S.W. of Lublin.

LEVASCHEVA, a town of Russia, in the government of Olonetz, on the W. coast of the lake Latcha; 16 miles S.S.W. of Kargapol.

LEVATIO ARIETUM. See ARIETUM.

LEVATOR, in *Anatomy*, a name given to various muscles, which have the effect of drawing parts upwards, or elongating them.

LEVATOR ani, is a muscle connected with the inferior extremity of the intestinal canal. See INTESTINE.

LEVATOR anguli oris, is a muscle of the lips, described under DEGLUTITION.

LEVATOR communis labiorum, is the same with the levator anguli oris.

LEVATORES cælarum, are the commencements of the external frons of intercollicular muscles. See INTERCOSTAL.

LEVATOR labii superioris et alæ nasi, a muscle common to the upper lip and the wing of the nose. See DEGLUTITION.

LEVATOR labii superioris proprius, is a portion of the former, sometimes described as a distinct muscle.

LEVATOR labii inferioris, is the same with the levator menti.

LEVATOR menti, is a small muscle situated in the chin, and described with the muscles of the lips in the article DEGLUTITION.

LEVATOR oculi, a name sometimes given to the superior straight muscle of the eye. See EYE.

LEVATOR palati molliis, a muscle of the soft palate described in the article DEGLUTITION.

LEVATOR palpebræ superioris, a muscle of the orbit belonging to the upper eye-lid. See EYE.

LEVATOR scapulae, a muscle of the scapula, called also angularis, and, by Dumas, trachelo-scapulien. It is situated in the upper part of the back, and on the lateral and posterior part of the neck; it extends from the superior angle of the scapula to the transverse processes of the four first cervical vertebrae. It is elongated, flattened, and broader below than above. Its external surface is covered below by the trapezius, above by the sternocleidomastoideus, and in the middle by the skin. The internal surface covers the serratus superior pollicis, the sacro-lumbalis, the transversalis colli, and the splenius. The edges present nothing remarkable; the posterior is longer than the anterior, and covers a part of the upper edge of the rhomboideus.

The inferior extremity is attached to the superior angle of the scapula, to the upper part of its basis, and to the internal portion of its upper edge. From this point the muscle passes upwards and forwards; it grows narrower, and is soon divided into four portions, which are at first united together by cellular tissue, but afterwards separate to be attached to the points of the transverse processes of the four first cervical vertebrae. These portions are often connected to the splenius and scalenus posterior. Sometimes the levator scapulae has only three portions fixed to the three first vertebrae of the neck; that which is attached to the atlas is larger and longer than the others, which diminish successively in size and length downwards.

It is tendinous at its attachments, and fleshy in other parts. The posterior fibres are longer than the anterior; a fasciculus of fibres is sometimes added to its front edge from the first rib.

The name of this muscle has led to a notion that it elevates the shoulder; and it has been called *musculus patientie*, from the supposition, that it acted in shrugging the shoulders. In truth it rather depresses than elevates this part; it draws the superior angle of the scapula upwards and forwards, but then the bone is rotated in such a way that its anterior angle, forming the shoulder joint, is depressed. It is assisted by the pectoralis minor. If the trapezius act in conjunction with it, the shoulder will be elevated. Supporting the shoulder to be fixed, it will incline the head and neck backwards, and towards its own side.

LEVATUM. See TERRIS & *Catalis tennis ultra debitum*.

LEUBITZ, in *Geography*, a town of Hungary; eight miles S. of Podolicz.

LEUBUS, a town of Silesia, in the principality of Wohlén, on the Oder, near which is a celebrated Cistercian

abbey, founded at the commencement of the 11th century; nine miles S.W. of Wohlen.

**LEUCA**, in *Ancient Geography*, a small town of Italy, in the country of the Salernini, and in the vicinity of the Japygian promontory. Strabo.—Also, a town of Asia Minor, on the confines of Ionia and Æolia. Pomponius Mela places it near Phocæa, in the gulf of Smyrna; and Pliny places it near Phucæa, on a promontory which was formerly an island. Diodorus Siculus says, that Leuca was situated between Cumæ and Clazomene.

**LEUCACANTHA**, in *Botany*, a name used by Dioscorides, and the other Greek writers, for the *acacia* tree, which produces the gum arabic, but it was also used for a kind of prickly plant, called also *angaila* by some of the Arabians; as being a plant whose roots were knotted and jointed. These joints were separated and dried, and then used in medicine as cardiacs and carminatives, under the names of *hank* or *hunken*. They were of a very agreeable aromatic smell, and very little taste; and the ancients always preferred such of them as were yellow and light, rejecting those which were heavy and white, and which wanted smell. It is not well known at this time what these roots were; but it is necessary, in order to the right understanding the works of the ancients, to know that there were such roots; and that though called by the same name with the gum arabic tree, they were of a very different nature.

**LEUCACHATES**, in the *Natural History of the Ancients*, the name of an agate, not a peculiar species, but only a particular appearance of the lead-coloured agate, called *phallobates*.

**LEUCADENDRON**, in *Botany*, from λευκός, *white*, and δένδρον, *a tree*, expressive of the hoary or silvery whiteness for which the fruit and smell of the species is remarkable. The name seems to have originated with Hermann, who communicated to Plukenet the Silver-tree of the Cape, under the appellation of *Leucadendros Africana*, for which Linnæus, in his *Classes Plantarum*, adopted it; but afterwards, in his *Genera*, applied this name to another tribe of the same order, and subsequently sunk both in *Protea*. Mr. Brown has restored the original *Leucadendron*. Silver-tree. Brown Tr. of Linn. Soc. v. 10. 50. (Conocarpo-dendra; Boerh. Lugd.-Bat. ed. 2. t. 175. 197. 200. 202—4.)—Class and order, *Dioecia Tetrandria*. Nat. Ord. *Aggregata*, Linn. *Protea*, Juss. *Proteaceæ*, Brown.

Gen. Ch. Male. Cal. Common Perianth imbricated, of numerous, unequal, single-flowered scales. Cor. Petals four, equal, linear, cohering in their lower part, revolute at their extremities, downy externally. Stam. Filaments four, short, inserted into the petals; anthers linear, of two cells, bursting lengthwise. Pist. imperfect, or none.

Female. Cal. like the male; its scales permanent, dilated and hardened. Cor. like the male; bearing abortive stamens. Pist. Germen superior, sessile; style simple, straight, rigid, terminal; stigma oblique, club-shaped, emarginate, rather hispid. Peric. none, except the permanent woody calyx, whose scales are sometimes confluent. Nut solitary, concealed by the scales of one seed.

Eff. Ch. Male. Calyx imbricated; its scales single-flowered. Petals four, bearing the stamens.

Female. Calyx imbricated, permanent. Petals four. Stigma oblique, club-shaped, emarginate, rather hispid. Nut of one seed, concealed by the hardened scales of the calyx.

Thirty-eight species of this noble genus are defined by Mr. Brown, all natives of southern Africa, near the Cape of Good Hope, where they usually grow in moist stony or

fandy places, about rivers, and, as far as we know, in no other part of the world. A few of them have long been cultivated in the greenhouses of Europe, but the greater part are only known in the herbariums of the curious. One of the finest collections of this whole natural order was procured from the Cape by Mr. Niven, for his patron G. Hibbert, esq. to whose liberality we are indebted for specimens of the whole.

The habit of *Leucadendron* is arborescent or shrubby, but sometimes tortuous and depressed. Leaves flat, linear, lanceolate, or obovate. Heads of flowers often yellow, not large, but frequently accompanied by very large, spreading, dilated, pilulif bractæas, which are highly ornamental.—Examples are

*L. argenteum*. (*Protea argentea*; Linn. Sp. Pl. 1. 37. Gærtn. t. 51. Lamarec Illustr. t. 53. f. 1. Conocarpo-dendron; Boerh. t. 195. Argyrodendros africana, foliis fericis et argenteis; Commel. Hort. v. 2. 51. t. 26.)—Arborescent. Leaves lanceolate, silvery; their edges, as well as the branches, hairy. Inner bractæas shorter, downy. Corolla of the male silky.—This splendid tree, growing about the bases and sides of mountains at the Cape, soon attracted the notice of the first European visitors, and was brought into the Dutch gardens, from whence probably it came to England early in king William's reign. The flowers are not ornamental, nor are they scarcely ever seen here, but the silvery splendour of the leaves is unrivalled; they are three or four inches long, sessile, lanceolate, acute, entire, spreading in every direction, clothing the branches in great abundance. Flowers solitary, terminal.—The whole style is permanent in this and four other species only.

*L. Levifanus*. Brown n. 9. Berg. Cap. 20. (*Brunia Levifanus*; Linn. Sp. Pl. 28. B. foliis oblongis incanis, &c.; Burm. Afric. 267. t. 100. f. 2, male plant. *Protea Levifanus*; Willd. Sp. Pl. v. 1. 526.)—Leaves obovate or spatulate, very blunt; smooth when full grown. Branches hairy. Heads of male flowers sessile. Seeds pointless, invelted with long hairs.—Grows in sandy heathy plains near the Cape. The stem is abruptly branched. Leaves numerous, upright, about half an inch long, entire. Flowers in little round yellow heads, without any prominent bractæas.

*L. corymbosum*. Berg. Cap. 21, male plant. (*Protea corymbosa*; Thunb. Diss. de Proteâ, n. 28. t. 2, male plant. Andr. Repof. t. 495, female.)—Leaves linear-awl-shaped, imbricated, smooth. Scales when in fruit acute, recurved at the points. Seeds somewhat compressed, inversely heart-shaped, hairy at the edge. Found at several places near the Cape. Much akin to the last in its flowers, but the leaves are totally different, resembling the narrow foliage of an *Erica* or *Diosma*. The young branches are purplish, whence it used to be called by gardeners, before it blossomed, *Protea purpurea*. Mr. Brown observes that each sex has four glands, or nectaries, at the base of the germen, which our last-described wants.

*L. concolor*. Brown n. 15. (*Protea globosa*; Andr. Repof. t. 307. Suns in Curt. Mag. t. 878, both male plants. P. itrobilina; Schrad. Sert. Hannov. t. 1, female.)—Leaves spatulate-oblong, with a callous point; smooth when full grown; the floral ones of the same colour. Branches downy. Scales of the fruit obtuse, fringed; woolly at the base.—Found near the Cape. Said to have been first raised in England by Messrs. Lee and Kennedy. This belongs to a handsome tribe of species, whose large heads of yellow flowers are encompassed by large spreading floral leaves or bractæas, which in most are coloured, but in this agree in hue with the foliage, and like that are about

two inches long, and nearly one broad, with red callous tips.

*L. grandiflorum*. Brown n. 16. (*Eurypernum grandiflorum*; Salisf. Parad. t. 105.)—Leaves obovate-oblong, with a callous point; smooth when full grown; the floral ones coloured. Branches very minutely downy. Scales of both sexes ovate, bluish, smooth, coloured.—Gathered on mount Wynberg at the Cape, by Mr. Niven, who sent it to Mr. Hbbert. It is larger and handsomer than the last, having splendid whitish *bractææ*, resembling the petals of some fine polyanthus flower.

*L. stridum*. Brown n. 21. (*Eurypernum falcifolium*; Salisf. Parad. t. 75. *Protea conifera*; Andr. Repof. t. 541.)—Leaves smooth, linear, with an awl-shaped point. *Bractææ* ovate, acute, coloured, longer than the flowers. Scales of the fruit dilated, rounded, smooth. Seeds without wings, dotted.—Native of moist stony places, about rivers, at the Cape, according to Dr. Roxburgh. Mr. Niven seems to have introduced this pretty species to our gardens, which is distinguished by its narrow leaves, copious and ornamental, though small, flowers, whose *bractææ* are white and pointed.—This species is nearly allied to *Protea pallens* and *conifera* of Linnæus and other authors, the former of which appears to be the male, and the latter the female, of Mr. Brown's *L. adfendens*.

*L. abietinum*. Brown n. 31. (*Protea tetrefifolia*; Andr. Repof. t. 461.)—Leaves all thread-shaped, channelled, bluish, smooth, spreading, curved slightly upwards. Scales of the fruit united by their lower part; distinct and two-lobed above.—Frequent about the Cape. A humble *Strub*, with numerous spreading fir-like green leaves, the uppermost of which, unchanged, encompasses the little yellow heads of female flowers, instead of *bractææ*. The heads of male flowers are smaller, and more elevated.

**LEUCADIA, ST. MAURE**, in *Ancient Geography*, an island, or rather a peninsula which was attached to Epirus by a straight isthmus, about 100 paces long and 600 broad. Upon it was situated the town of Leucas, on the summit of a mountain towards the N.E. Homer places here three towns, viz. Neriton, Croeyla, and Agylia. On the site of the first of these towns the Corinthians built that already mentioned; Leucas is now an island, the isthmus having been separated from the continent. Thus Ovid describes it:

“Leucada continuam veteres habuere coloni  
Nunc freta circumant.”

It was a tradition that unfortunate lovers made choice of this promontory for precipitating themselves into the sea. On this promontory Apollo had a temple. See **ST. MAURE**.

**LEUCANTHEMUM**, in *Botany*, from *λευκον*, white, and *ανθος*, a flower, has been the appellation of several plants of the compound radiated kind, whose rays are white; and now remains as the specific name of the common English *Chrysanthemum leucanthemum*, Great Ox-eye, or Moon Daisy.

**LEUCARUM**, in *Ancient Geography, a place of Great Britain, on the route from Caleva to Uococonium, according to the Itinerary of Antonine. It is supposed to be the same with the Leacomagus of the anonymous of Ravenna. It lies between Scadum Nunniorum and Bomiun, and is supposed to be near Gatenbury. Camden, Gale, and Baxter, imagine that Leucarum was situated where the village of Locharnum or Lochorlands, on the bank of the river Locher in Glamorganshire. But this seems to be at much too great a distance from the other stations of Cluseborough and Axbridge.*

**LEUCAS**, in *Botany, so named by Burmann and Brown,*

in allusion to the downy whiteness of its flowers, *λευκος*; being an ancient Greek name for some herb, now unknown to us, so called on account of its whiteness. *Burm. Zeyl.* 140. *Brown. Prodr. Nov. Holl. v. 1. 504.* *Ait. Hort. Kew. ed. 2. v. 3. 409.*—Class and order, *Didymia (Cymnosperma. Nat. Ord. Verticillate, Linn. Labiate, Juss. Brown.*

**Gen. Ch.** *Cal.* Perianth inferior, of one leaf, tubular, oblong, with ten ribs; permanent; its orifice unequally toothed, with from six to ten teeth. *Cor.* of one petal, ringent; tube cylindrical; upper lip vaulted, bearded, undivided; lower longer, in three segments, the middle one largest, often notched. *Stam.* Filaments four, concealed by the upper lip, two of them longer than the rest, anthers of two oblong divaricated lobes. *Pist.* Germen superior, four-cleft; style the length and position of the filaments; stigma eleven, acute, its upper segment shortest. *Peric.* none, except the permanent calyx. *Seed.* four, oblong, triangular.

**Ed. Ch.** Calyx wh ten ribs; unequally toothed. Upper lip of the corolla bearded, undivided; lower longer, three-cleft; the middle segment largest. Lobes of the anthers divaricated. Upper segment of the stigma shortest.

1. *L. zeylanica*. Ceylon Leucas. (*Phlomis zeylanica*; Linn. Sp. Pl. 820. Jacq. Ic. Rar. t. 111? *Herba ad irationis*; Rumph. Amboin. v. 6. 39. t. 16. f. 1.)—Leaves lanceolate, slightly serrated. Whorls nearly terminal. *Bractææ* fringed. Calyx oblique, with ten nearly equal teeth.—Native of the island of Mauritius; as well as of Java, and other parts of the East Indies. The root is annual. *Stem* square, downy, leafy, about a foot high, branched from the bottom in a corymbose bushy manner. *Leaves* opposite, about an inch and half long, scarcely half an inch broad, lanceolate, bluish, finely downy, veiny, wavy, or bluntly serrated, tapering at the base into a short footstalk. *Whorls* dense, axillary, one or two at the top of each stem or branch, furnished by leaves, and accompanied by several linear-lanceolate, acute, downy, strongly fringed *bractææ*. Calyx downy, swelling upwards; its orifice oblique, fringed with ten, nearly equal, small spinous teeth. *Corolla* twice as long as the calyx, white, hairy externally, especially the upper lip.

2. *L. lavenderifolia*. Lavender-leaved Leucas. (*Leonurus indicus*; Linn. Sp. Pl. 817. *Phlomis zeylanica* 2; Syst. Veg. ed. 13. 450. Willd. Sp. Pl. v. 3. 123.)—Leaves linear-lanceolate, nearly entire. *Bractææ* linear, downy. Calyx oblique, with seven teeth; the uppermost largest.—Native of the East Indies. Linnæus had it from Burmann. He first described it as a *Leonurus*, but afterwards corrected it with his *Phlomis zeylanica*, of which last he had but a very imperfect specimen. The present is distinguished by its much longer, and nearly, if not quite, entire leaves; the whorls are more numerous; *bractææ* more linear, downy, but not fringed; and the calyx is essentially different, having but seven, and those very unequal, teeth. *Corolla* much like the last. It is hard to say whether Jacquin's and Rumphius's synonyms belong to this or the *zeylanica*, for they neither of them teach any thing essential, but Jacquin's leaves certainly most resemble the present. The three figures of Plukenet, cited doubtfully by Linnæus, do not well accord with either.

3. *L. martinicensis*. West Indian Leucas. (*Phlomis martinicensis*; Swartz. Prodr. 88. Willd. Sp. Pl. v. 3. 123. *Ph. caribæa*; Jacq. Ic. Rar. t. 110. Swartz. Ind. Occ. v. 2. 1009.)—Leaves ovate-oblong, serrated, downy. *Bractææ* brittle-shaped, fringed. Whorls globose. Calyx incurved, with ten teeth; the uppermost longest.—Native of Brazil.

and the West Indies, from whence Mr. Masson sent seeds to Kew in 1781. *Root* annual. *Stem* branched, two or three feet high. *Leaves* stalked, an inch and half long, oblong, more or less ovate, hairy above, more downy and paler beneath, bluntish, strongly ferrated; entire and tapering at their base. *Whorls* numerous, axillary, dense, many-flowered, and nearly globose, with narrow, strongly fringed or bristly *bracteas*. *Calyx* curved forward, downy, with strong green ribs and white reticulated spaces between; its orifice bordered with ten spinous, all rather unequal, teeth, of which the upper one is twice or thrice as long as the rest. *Corolla* small, white, brown in decay.

4. *L. urticifolia*. Nettle-leaved Leucas. (Phlomis urticifolia; Vahl. Symb. v. 3. 76. Willd.)—"Leaves ovate, ferrated, hoary. *Bracteas* awl-shaped. *Calyx* obliquely truncate, membranous, with nine teeth."—Native of Arabia Felix, and the East Indies.—"*Root* annual. The plant resembles *Ph. indica* of Linnaeus (our *Leucas indica*), but the *stem*, as well as *leaves*, are not downy, but hoary with extremely minute hairs. The *leaves* are of the same colour on both sides, deeply ferrated, flat not rugged, downy underneath. *Calyx* rather small."—We know this merely from the above authority.

5. *L. indica*. East Indian Leucas. (Phlomis indica; Linn. Sp. Pl. 820.)—"Leaves ovate, ferrated, very downy beneath. *Bracteas* linear, hairy. *Whorls* globose. *Calyx* oblique, with one three-toothed lip."—Native of the East Indies. The seeds were sent to England by M. Thouin in 1789. *Root* annual. *Leaves* stalked, ovate, two inches long and one broad, ferrated, downy above, but whiter and softer beneath. *Corolla* very hairy. *Calyx* much enlarged and elongated after flowering, its forepart extended into an upright, oblong, ribbed and reticulated lip, with three spinous teeth at the extremity; the opposite or upper side of the orifice being short, with three or four very minute teeth.

6. *L. decemdentata*. Ten-toothed Leucas. (Stachys decemdentata; Fort. Prodr. 91. Phlomis decemdentata; Willd. Sp. Pl. v. 3. 124.)—"Leaves oblong, ferrated; contracted at the base. *Whorls* without *bracteas*. *Calyx* with ten teeth."—Native of the Society Islands. "*Stem* herbaceous, downy. *Leaves* stalked, an inch long, rather acute, ferrated, downy. *Whorls* somewhat stalked, destitute of *bracteas*. *Calyx* bell-shaped, with ten furrows, and ten awl-shaped teeth, alternately smaller. Tube of the *corolla* rather longer than the *calyx*; upper lip erect, undivided, very hairy; lower smooth, in three deep segments." Willdenow.

7. *L. biflora*. Two-flowered Leucas. (*L. foliis rotundis ferratis, flore albo*; Burm. Zeyl. 140. t. 62. f. 1. *Phlomis biflora*; Vahl. Symb. v. 3. 77. Willd. Sp. Pl. v. 3. 124.)—"Leaves ovate, ferrated. Flowers axillary, solitary, opposite. *Calyx* with ten regular teeth."—Native of the East Indies. A slender downy or rather hairy plant, with the habit of a *Stachys* or *Sideritis*. *Leaves* about half an inch long, stalked, ovate, bluntish, with five or six serratures at each side. *Flowers* nearly sessile, without *bracteas*. *Calyx* funnel-shaped, hairy, strongly ribbed, with ten sharp taper teeth, of which the five intermediate ones are rather shorter than the others. *Corolla* twice the length of the *calyx*, white, downy.

8. *L. chinensis*. Chinese Leucas. (Phlomis chinensis; Retz. Obs. fac. 2. 19. Willd. Sp. Pl. v. 3. 125.)—"Leaves ovate, ferrated, clothed with silky down. Flowers whorled, stalked. *Calyx* with ten teeth."—Native of China. "*The stem* is shrubby, with square hispid branches. *Leaves* opposite, ovate and somewhat heart-shaped, stalked, fer-

rated, clothed with silky down. *Whorls* axillary, of five or six flowers, on stalks. *Calyx* funnel-shaped, with ten furrows and ten awned teeth. *Corolla* white, its upper lip compressed, hairy externally, especially the margin; lower three-lobed, nearly naked."—Retzius.—It is to be presumed the *calyx*-teeth are regular, probably five rather the shortest as in the last. We have never seen this species, and it stands here on Mr. Brown's authority. Retzius's account of the compressed upper lip should, however, make it a *Phlomis*.

9. *L. moluccoides*. Wing-flowered Leucas. (Phlomis moluccoides; Vahl. Symb. v. 1. 42. t. 14. Willd. Sp. Pl. v. 3. 125. Clinopodium fruticosum; Forst. Egypt.-Arab. 107.)—"Leaves ovate, ferrated, finely downy. Flowers whorled, stalked. *Bracteas* linear-lanceolate. Lower segment of the *calyx* dilated, rounded, membranous, ribbed, obscurely toothed.—Gathered by Forkall in Arabia, on the hills of Hadie. One of his specimens in ripe seed, and Vahl's figure in flower, fully authorize us in referring this plant also to *Leucas*, though Mr. Brown has not mentioned it. The *stem* is shrubby, five or six feet high, with roundish downy branches. *Leaves* stalked, strongly ferrated; rough and punctate above; paler and very downy beneath; an inch or more in length. *Whorls* many-flowered, stalked, with downy *bracteas*, cut into many deep, linear, or somewhat lanceolate, segments. *Flowers* white, the size of *Laminium album*, hairy, their lower lip, according to Forkall, convex, three-lobed, the middle lobe broad, long, and heart-shaped, which agrees with the generic character, but is not properly represented in Vahl's plate, though indicated in his description. The *calyx* is very peculiar, and really two-lipped; the upper lip small, ovate and acute; the lower very large, especially when in seed, spreading, rounded, scarious, with seven or eight hairy ribs, and numerous reticulated veins; the margin wavy, or slightly toothed, not awned nor spinous; the tube is hairy, and has ten strong ribs. We can see nothing of the lateral lobes mentioned by Vahl, and indeed he seems, in his description and figure, to have been bewildered between the lower lip of the *calyx* and that of the *corolla*.

10. *L. glabrata*. Smooth Leucas. (Phlomis glabrata; Vahl. Symb. v. 1. 42. Willd. Sp. Pl. v. 3. 126.)—"Leaves ovate, ferrated, slightly hairy. Flowers whorled. *Bracteas* minute, bristle-shaped, smooth. Lower segment of the *calyx* elongated, three-toothed. Hairs of the stem deflexed.—Gathered in Arabia by Forkall, amongst whose plants it was found without a name. Vahl describes it as "herbaceous, the *stem* acutely angular, its angles and joints rough with reverted hairs. *Leaves* stalked, spreading, ovate, bluntly ferrated, entire at the base, acute, slightly hairy, about an inch long. *Whorls* remote, of six or eight flowers. *Bracteas* minute, in four deep, bristle-shaped, rather pungent, smooth segments, yellowish at the extremity, but one-fourth so long as the *calyx*; which is bell-shaped, smooth, with ten furrows, its orifice oblique, the lower lip being elongated, with three equal bristle-shaped teeth, the upper with seven teeth. *Corolla* like the last."

11. *L. flaccida*. Flaccid Leucas. Brown. Prodr. Nov. Holl. v. 1. 505.—"Leaves ovate, membranous, nearly smooth, as well as the *calyx*, which has ten equal teeth. *Whorls* many-flowered."—Gathered by sir Joseph Banks in the Tropical part of New Holland.

It will readily be perceived that the great diversity and irregularity of shape in the *calyx* of the different species, directly militate against the Linnaean division of *Didynamia Angiospermia*, into genera whose *calyx* is more or less exactly five-cleft, and others in which it is two-lipped; but

*Leucas* is not on that account the less natural a genus, and this very irregularity is its striking character. How far it might be possible or eligible to separate from it the species with a strictly regular calyx, may be worthy of future consideration. Mean while it had best stand in the first of the above sections, as not being regularly or properly two-lipped, as well as on account of its affinities.—*Phlomis alba*, Vahl. Symb. v. 1. 43, should seem also to belong to *Leucas*, though the calyx has but five teeth, but we have never had an opportunity of examining it.

*LEUCAS Delphinus*. See DELPHINUS.

*LEUCASIA*, in *Ancient Geography*, an island of the Tyrrhenian sea, upon the western coast of Italy, in the gulf of Paestum, according to Strabo and Mela.

*LEUCASPIS*, a port of Africa, in the gulf of Libya. Ptolemy.

*LEUCATA*, a promontory of Gaul, in the Mediterranean; now called "Cap de la Franqui."

*LEUCATE*, or *LEUCATAS*, a promontory of Asia, in Bithynia, and one of those which formed the gulf called "Assacenus Sinus," according to Pliny.

*LEUCATE*, in *Geography*, a town of France, in the department of the Aude; situated on the N. side of a large lake of the same name; 17 miles S. of Narbonne. N. lat. 42° 54'. E. long. 3° 7'.

*LEUCE*, or *ACHILLIS INSULA*, in *Ancient Geography*, an island in the Euxine sea, at the mouth of the Boryithenes. Strabo says, that it was consecrated to Achilles. Sallust, in his Fragments, says that it was of small extent and desert; and that it was famous for a temple, and for the statue and burying-place of Achilles.

*LEUCE*, a small island on the N. coast of the isle of Crete; according to Diodorus Siculus.

*LEUCÆ*, λευκῆ, in *Medicine*, a term nearly synonymous with the *vitiligo* of the Latins, signifies a leprous affection of the skin, of a white colour, with a loss of sensibility in the parts affected, the hair at the same time becoming white, and falling off.

The latest Greek physicians consider the *alphas* and *leucæ* as the same diseases essentially, differing only in degree, and not in kind. The *alphas* they describe as a superficial disease, in which the surface of the skin becomes white, but no farther change takes place: whereas the *leucæ* penetrates below the surface, affecting the flesh, and being much more difficult to heal. They ascribe it to an error in the assimilatory powers, in consequence of which a phlegmy or pituitous and viscous blood is generated, which is incapable of being converted into a proper red flesh, but produces a sort of flesh like that of locusts, and other crustaceous animals: the hairs, at the same time, turn white, and fall off, and the skin becomes smooth and bright, and the parts lose their sensibility; so that they may be pricked with needles, without suffering any uneasiness. In a word, the disease, thus described, is a species of *elephantiasis*, and appears to have been the same thing with the leprosy of the Jews. The Arabians properly call it the *white albaras*: nevertheless, with the later Greeks, they consider it as differing only in degree from the white *albopak*, (or *morphea*, as it has been called by the Latin translators,) which is the *alphas* of the Greeks. Hippocrates, however, seems to distinguish the *leucæ* from the *alphas*: for he observes that the latter should be considered as an external blemish, rather than as a disease; but he speaks of the *leucæ* as a distemper of the most fatal kind. (De Affection. sect. 5.) It would appear, therefore, that the word *alphas* denotes a modification of the scaly disease, the *lepra Græcorum*, and perhaps also an incipient *leucæ*; and that *leucæ* is a variety, a precursor, or a

stage of the *elephantiasis*. In this light Dr. Willan, in his able treatise on cutaneous diseases, considers them. (See that work, p. 124—126.) Celsus has classed the *alphas* and *leucæ*, together with the *melas*, (which differs from the *alphas* only in the blackish colour of the scaly spots,) under one generic term, *vitiligo*: at the same time, he points out the affinity of the *alphas* and *melas*, and the peculiar and distinct features of the *leucæ*. The two former, he says, are commonly a little rough, and not continuous, but dispersed in drops, as it were, here and there: sometimes, indeed, it spreads more extensively, but leaves interstices of the skin unaffected. They are the same in all respects, with the exception of colour. "The *leucæ*," he adds, "has some resemblance to the *alphas*; but it is whiter, penetrates deeper, and the hairs are white and downy. They all three spread, but with different degrees of rapidity in different individuals. The *alphas* and the *melas* appear and disappear in some persons at irregular periods; but the *leucæ* does not readily quit a person whom it has once attacked. The two first are not very difficult of cure: but the last is scarcely ever removed; and if it is at any time alleviated, yet the natural colour of the skin is never entirely restored." (Celsus, de Re Med. lib. v. cap. xxviii.) He then states the observations in regard to the prognosis, which are repeated by the Greek physicians; namely, that if we would ascertain whether the disease be curable or not, we should prick or scratch the skin with a needle. "If blood issues, which generally happens in the two former, the case is remediable; but if a white humour appears, it will not admit of a cure, and therefore we must make no such attempt." (Loc. cit. Compare also Aetius, Tetrabib. iv. ferm. i. cap. cxxxiii. Aëtarius, Meth. Med. lib. ii. cap. xi. Paul. Ægineta, de Re Med. lib. iv. cap. v.) The impaired sense of feeling in the parts is mentioned as an additional symptom of the irremediable state of *leucæ*, by the last named authors. See also Forelius Obs. Chirurg. lib. v. obs. iii.

The appellation of *leucæ* is derived either from λευκός, *leucos*, white, or from λευκή, *leuca*, the white poplar tree, the whiteness of the bark and leaves of which has perhaps been supposed to resemble the condition of the skin in the disease above described. See Gorter. Definit. Med. See also LEPROSY.

*LEUCELECTRUM*, a name given by some authors to that sort of amber which is white and opaque, and usually of a fatty look.

*LEUCHARS*, in *Geography*, a town of Scotland, in Fifeshire, near the German ocean. In 1801 the number of inhabitants was 1687; 6 miles N. of St. Andrews.

*LEUCHTENBERG*, a town of Bavaria, and capital of a landgraviate, to which it gives name; 36 miles E. of Nuremberg. N. lat. 49° 35'. E. long. 12° 11'.

*LEUCHTERSHAUSEN*, a town of Germany, in the margravate of Anspach, on the Altmühl; 7 miles W. of Anspach.

*LEUCI*, in *Ancient Geography*, a long chain of mountains in the isle of Crete, so called from their whiteness, being covered for a great part of the year with snow. They are now known by the names of Madura and Specia.

*LEUCISCUS*, in *Ichthyology*. See DACE.

*LEUCITE*, *Leuzit*, *Wern. Amphigène*, Häüy. *Vesuvian* or *white garnet*, Kirw. *Vulcanit*, *leucolite*, *granatine* (sort of some mineralogists).

Its colour is commonly greyish or yellowish-white, seldom ash-grey, milk-white, or greenish and reddish-white, passing into flesh and tile-red.

It occurs in grains, but most frequently in round crystals

of twenty-four trapezoidal planes, (*Amphigène trapezoidal*, Häuy, p. 147. f. 62.) or, as the form is defined by Werner, low double eight-sided pyramids, in which the lateral planes of the one are set on the lateral planes of the other, while the summits are flatly acuminate each by four planes placed on the alternate edges. They are more or less regular; sometimes perfectly so, at other times rather rounded on the edges. They are crystallized all around, and imbedded. Their size varies from very small to middle-sized; crystals of more than one inch in diameter are, however, seldom seen. No other modification than the trapezoidal has been hitherto observed.

The surface of the grains is rough, and dull or weakly glimmering; that of the crystals glistening and smooth, not striated, as in the garnets of the same form; there are, however, sometimes minute rents seen to run parallel to the short diagonal of the trapezoidal planes. Externally they are glistening, internally shining, with vitreous lustre rather inclining to resinous.

Fracture imperfectly and flat conchoidal, sometimes inclining to foliated; fragments indeterminate angular, more or less sharp-edged.

It occurs commonly slightly translucent, but also nearly transparent, and rarely with perfect transparency.

The leucite is hard in a low degree, scratching glass with difficulty: it is brittle, and easily frangible. Specific gravity, 2,461, Karsten; 2,464, Kirwan; 2,468, Briffon; 2,457 (from Vesuvius), and 2,490 (from Albano near Rome,) Klaproth.

It is infusible before the blowpipe without addition: with borax it melts into a light brown, transparent glass.

The leucite was first analysed by Klaproth, who discovered in it a considerable portion of vegetable alkali; a substance till then unsuspected to form a constituent of mineral substances. Vauquelin's subsequent analysis completely agrees with that given by Klaproth.

Mean of different Analyses.	Klaproth.	Vauquelin.
Silica	54	56
Alumine	24	20
Potash	21	20
Lime	-	2
Loss	1	2
	100	100

Leucite occurs particularly in lava, and also in rocks belonging to the fletz transformation of Werner. It should however be observed, that what has been described by several authors as leucite in basalt, trapp, &c. is nothing but cubic zeolite (analcime of Häuy). Faujas, Elnark, and others have fallen into this error.

Many places have been mentioned where leucite is found; but the best authenticated locality is that of the neighbourhood of Naples, and of Rome. They are found in immense quantities in the mountains of Albano, Tivoli, Caprarola, Viterbo, Aquapendente, Civita Castellana, and Borghetto, where they are seen enveloped in lava, often accompanied by mica, vesuvian, and hornblende.

Von Buch, Salmon, Patrin, and others, are of opinion, that the leucite crystals were formed in the lava when still in a fluid state; Dolomieu and Werner, on the other hand, consider them as having pre-existed in the rocks that were afterwards converted into lava. The idea of other mineralogical writers, who look upon these crystals as being garnets altered by volcanic fire, is now deservedly exploded.

Häuy's name of *amphigène* is derived from the double origin

of the leucite, with regard to its primitive form, which may be either the cube or the rhomboidal dodecahedron.

LEUCOCROTTA, in *Natural History*, the name given by many authors to a beal, supposed to be the swiftest of all creatures in the world: others have called it leucrocotta, but the true name is leocrocotta.

LEUCOGÆA, a name by which some authors have called the substance, more usually known by the name of morochthus, and called in English, French chalk, or Brinon chalk.

LEUCOGRAPHIS, the name used by some of the ancient writers, for the substance commonly called morochthus, or French chalk.

LEUCOBIUM, in *Botany*, a name adopted from the ancient Greek authors, who nevertheless differ about their *species*. That of Theophrastus appears to be the Linnæan *Galanthus*, whilst that of Dioscorides is doubtless, from his short account, the *Cheiranthus*, or Stock. The present genus is nearly allied to *Galanthus*, and having been called *Narcisso-Leucobium* by Tournefort, Linnæus adopted the above generic name. Snow-flake.—Linn. Gen. 160. Schreb. 215. Willd. Sp. Pl. v. 2. 30. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 352. Ait. Hort. Kew. ed. 2. v. 2. 211. Juss. 55. Lamarck. Illustr. t. 230. (Narcisso-Leucobium; Tournef. t. 208.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Sp. Sp. Sp.*, Linn. *Narcissi*, Juss.

Gen. Ch. *Cal. Sp. Sp. Sp.* oblong, obtuse, compressed, opening at the flat side, withering. *Cor.* bell-shaped, spreading; petals six, equal, ovate, flat, coalescing at the base; their tips thickish and straight. *Stam.* Filaments six, brittle-shaped, very short; anthers oblong, obtuse, quadrangular, erect, distant, bursting in the upper part. *Pist.* Germen inferior, roundish; style mostly club-shaped, obtuse; stigma setaceous, erect, acute, longer than the filaments. *Peric.* Capsule turbinate, of three cells and three valves. *Seeds* numerous, roundish.

Obf. *Leucobium autumnale* and *triciphyllum* have a thread-shaped style.

Ess. Ch. Corolla superior, bell-shaped, of six equal petals, thickened at their summit. Stigma simple. Stamens equal.

1. *L. vernum*. Spring Snow-flake. Linn. Sp. Pl. 414. Curt. Mag. t. 46. Jacq. Fl. Austr. t. 312.—Spatha single-flowered. Style club-shaped.—A native of moist woods and shady places in various parts of Italy, Switzerland, Germany, and the south of France. It flowers in the early spring; its specific name indeed is indicative of this circumstance. *Bulb* oblong, smaller than that of the *Dafodil*. *Leaves* flat, darkish-green, about four or five in number, broader and longer than those of the *Snow-drop*. *Stalk* radical, angular, hollow and channelled, furnished towards the top with a whitish spathe, opening at the side, from whence the flower proceeds. *Corolla* rather large, its petals white, tipped with green. The plant has an agreeable fragrance, something like *Hawthorn*.

2. *L. asivum*. Summer Snow-flake. Linn. Sp. Pl. 414. Engl. Bot. t. 621. Curt. Lond. fasc. 5. t. 23. Jacq. Austr. t. 203.—Spatha many-flowered. Style club-shaped.—First determined to be a native of this island by Mr. Curtis, who found it growing between Greenwich and Woolwich, as well as in the Isle of Dogs. It has since been gathered in many other parts of England, particularly Wiltmoreland, Suffolk, and Berkshire, flowering in May. *Root* a roundish bulb. *Leaves* numerous, erect, a foot and half in length, obtuse, keel'd, bright-green. *Stalk* radical, as long as the leaves, compressed. *Sp. Sp. Sp.* lanceolate, erect. *Partial stalk* solitary and single-flowered. *Flowers* pendulous, white; petals

petals tipped with green. *Antbers* obtuse, burbling by two pores at the summit. *Capsule* elliptical, three-celled. *Seeds* globular, large.

The plant is entirely without smell, but is extremely ornamental, and may be often seen in rustic gardens.

3. *L. autumnale*. Autumnal Snow-flake. Linn. Sp. Pl. 414. Curt. Mag. t. 960. Redouté Liliac. t. 150. f. 2.—*Spatha* many-flowered. Style thread-shaped.—A native of Spain and Portugal, flowering, as its name imports, in the autumn. *Bulb* thickish, of many glutinous coats, covered with a white membrane. *Stalk radical*, about six inches in height, reddish-brown, mostly bearing two or three white, pendulous, inodorous flowers, red at their base. *Leaves* capillary, springing up after the plant has flowered. Curtis however says that in specimens which were sent from Gibraltar, the leaves appeared at the same time with the flowers, though considerably shorter than they afterwards grew.

4. *L. trichophyllum*. Bristle-leaved Snow-flake. Brot. Lufit. p. 1. 552. Redouté Liliac. t. 150. f. 1.—*Spatha* two-leaved, many-flowered. Style thread-shaped.—Gathered on the sandy plains of Barbary, flowering in the midst of winter. *Leaves* thread-shaped, membranaceous. *Stalk radical*, sheathed by the leaves at its base, thread-shaped, five or six inches high. *Flowers* from two to four, pendulous, white, occasionally tinted with red on the outside.

Redouté regrets that he could not call this *hyemale*, as the name of *trichophyllum* had previously been applied by Renaulmius to the last species, to which indeed this is closely allied. The specific name of *hyemale* would have been particularly desirable on account of carrying on the analogy of nomenclature with the three other species. It is greatly to be wished that botanists who give new names to plants would well consider such analogies.

For *L. strumosum*, Ait. Hort. Kew. ed. 1. 407. t. 5, see STRUMARIA.

LEUCOIUM, in *Gardening*, comprehends plants of the bulbous-rooted flowery or perennial kind, of which the species cultivated are the great spring snow-drop (*L. vernum*); the summer snow-drop (*L. æstivum*); the autumnal snow-drop (*L. autumnale*); and the many-flowered Cape leucium (*L. strumosum*). The first has an oblong bulb, shaped like that of the daffodil, but smaller; the leaves are flat, deep green, four or five in number, broader and longer than those of the common snow-drop; the scape angular, near a foot high, hollow, and channelled; towards the top comes out a whitish sheath, opening on the side, out of which come out two or three flowers, hanging on slender peduncles; the corolla is much larger than that of the common snow-drop; and the ends of the petals are green. They appear in March, and have an agreeable scent, not much unlike those of the hawthorn.

The flowers, which at first sight resemble those of the common snow-drop, are easily distinguished by the absence of the three-leaved nectary. They do not come out so soon by a month. The first is called by Mr. Curtis the spring snow-flake.

In order to distinguish the second sort from the galanthus, Mr. Curtis names it the summer snow-flake; and in gardens it is commonly known by the name of the great summer snow-flake, and the late or tall snow-drop.

*Method of Culture*.—These plants are readily increased by off-sets from the roots, which should be separated from the old roots about every third year, in the summer season, as soon as their leaves begin to decay, in the same manner as other bulbous roots. See BULBOUS ROOTS.

They are also capable of being increased by seeds, which

should be sown in the latter end of August, in a border of light bog-earth. The plants should remain in this situation till the second summer, and be then taken up at the proper period, and planted in beds, till they begin to flower, when they should be removed into the borders. In this way they are three or four years before they flower. But by much the best method is to procure the roots from the nurseries, and plant them in the beginning of the autumn, in an eastern or northern border, where the soil is of a boggy quality, in patches of three or four together, in the fronts, putting them in to the depth of about three or four inches.

The off-sets should be planted out in beds a year or two after being taken off, till fit to be set out for flowering.

A soft loamy soil, or a mixture of loam and bog-earth, are the most suited to their healthy growth. The last sort requires protection in the house, with other Cape bulbs.

By planting them in the different aspects mentioned, a longer succession of flowers may be produced.

They are very ornamental in the fronts of the borders, or the sides of the lawns, and other parts near the house, or other public situations.

LEUCOIUM *Indicum* et *lucum*. See STOCK Gilly Flower.

LEUCOIUM *Bulbosum*. See LEUCOIUM, *supra*.

LEUCOLIBANON, in the *Materia Medica* of the Ancients, a name given to the white olibanum, or frankincense, which they carefully distinguish from the reddish or yellowish olibanum. This was also called *argyrolibanum*, or the silver-coloured olibanum; and the yellow one *chalcolibanum*. This latter word is used in the Apocalypse of St. John, and is misunderstood so far, as to be translated brasa, and supposed to be a kind of brasa from Mount Lebanon. See CHALCOLIBANON and FRANKINCENSE.

LEUCOLITHOS, in *Natural History*, a name given by some of the Greek writers to the pyrites argenteus, or silvery pyrites. The ancients had a great opinion of these fossils in diseases of the eyes; they used all the kinds of pyrites, or marcasite, after calcination, for this purpose; but as they distinguished four kinds of them, they attributed these virtues, in different degrees, to the different kinds; therefore they had recourse to so many peculiar names for distinguishing them; and the white kind was called leucolithos, to distinguish it from the dusky one called the iron pyrites, and the deeper and paler yellow kinds, called the gold and brassy marcasites.

LEUCOMA, Λευκομα, among the Athenians, signified a public register of the whole city, in which were written the names of all the citizens, as soon as they came to be of age to enter upon their paternal inheritance.

LEUCOMA (derived from λευκος, white), signifies, in *Surgery*, a whitish opacity of the cornea. Professor Scarpa, of Pavia, has made some interesting remarks on this case in his "Osservaz. sulle Principali Malatien degli Occhi." He informs us, that the albugo and leucoma are very different from what has gone under the name of the nebula of the cornea, since they are not the consequence of a slow chronic inflammation of the eyes, accompanied by a varicose state of the veins, and an extravasation of a thin milky serum into the texture of the delicate layer of the conjunctiva spread over the cornea; but are either produced by a violent acute ophthalmia, wherein a dense coagulable lymph is effused superficially or deeply into the substance of the cornea itself, or else are occasioned by wounds, or ulcers attended with loss of substance. Albugo strictly denotes the first of these cases; leucoma the last, particularly when the scar, or opaque spot, occupies the whole or a considerable portion of the cornea.

A recent albugo, remaining after the subsidence of a violent

violent acute ophthalmia, is of a clear milky colour; but when inveterate, it puts on a chalky or pearl colour, and in this frequently appears to have no vascular connection with the rest of the cornea, occasioning no uneasiness, and being incapable of being absorbed.

Provided the texture of the cornea be not disorganized by the coagulable lymph extravasated in a case of recent albugo, the opacity may often be dispersed by employing, in the first stage, general and local bleeding, internal antiphlogistic medicines, and emollient applications; and in the second stage, mild astringents and corroborants. These last, as soon as the inflammation is subdued, excite the action of the absorbents, by which vessels the opaque extravasated lymph, forming the albugo, is to be removed.

But although a recent albugo may often be dispersed, this object cannot be so easily effected when the disease has existed a long while, in which case the absorbents have frequently lost their activity, and the structure of the cornea become so disorganized, that this membrane must for ever remain opaque at the part affected. According to Scarpa, the circumstances favourable to the cure are a recent state of the disease without disorganization of the cornea, or of the delicate layer of the conjunctiva spread over it, and the patient being young, as at this period of life the absorbents are most capable of action. Scarpa assures us, that he has seen many examples in children, where the specks, left on the eye after a violent ophthalmia, have spontaneously disappeared in the course of a few months.

The following local remedies Scarpa has found most serviceable, both to recent and inveterate cases of albugo. A collyrium, composed of two scruples of sal ammon., four grains of ærugo, and eight ounces of aqua calcis. These are to stand for twenty-four hours, and the liquor then be filtered for use. An ointment, consisting of the subsequent ingredients. R Tutia f. p. ʒj Aloes f. p. Calom. ā ʒi grij. Butyr. recent. ʒʒ. M. Janin's ophthalmia ointment, and the gall of ox, thence, pike, and barbel, applied to the cornea with a hair-pencil, are also favourably spoken of. When the eye was too irritable to bear the preceding application, Scarpa sometimes used with advantage the oil of walnuts, somewhat rancid. Two or three drops were introduced into the eye every two hours, and the plan followed up for several months. He has likewise found the juice of the lesser centaury, mixed with honey, a good application.

How unpromising soever things may seem, the surgeon is to persist in the trial of remedies, at least three or four months, before the case is to be set down as absolutely incurable.

Scraping and perforating the cornea, and forming an artificial ulcer upon it, are all unavailing expedients in cases where the albugo or leucoma is in a state that Scarpa terms inveterate and coriaceous, such measures being the invention of persons quite ignorant of the structure of the cornea, and the principles upon which its transparency is to be restored.

LEUCOMENAS, in *Ichthyology*, a name by which some have called the smaris, a small fish caught in great plenty in the Mediterranean.

LEUCOPETALOS, in *Natural History*, the name of a beautiful stone described by Pliny, as being of a fine gold yellow, variegated with white.

LEUCOPETRIANS, in *Ecclesiastical History*, the name of a fanatical sect which sprang up in the Greek and Eastern churches towards the close of the twelfth century: the fanatics of this denomination professed to believe in a double Trinity, rejected wedlock, abstained from flesh, treated with

the utmost contempt the sacraments of baptism and the Lord's supper, and all the various branches of external worship, placed the essence of religion in internal prayer alone, and maintained, as it is said, that an evil being, or genius, dwelt in the breast of every mortal, and could be expelled from thence by no other method than by perpetual supplication to the Supreme Being. The founder of this enthusiastic sect is said to have been a person called Leucopetrus, and his chief disciple Tychicus, who corrupted, by fanatical interpretations, several books of scripture, and particularly St. Matthew's gospel. Mofheim.

LEUCOPHÆA ANTELOPE, in *Zoology*. See ANTELOPE *Leucophaea*.

LEUCOPHAGIUM, a name given by some physicians to a sort of medical aliment good in consumptions, and other general decays. It is composed of sweet almonds macerated in rose-water with the tender flesh of a capon, all being finally boiled together to a pulp, capable of being passed through a sieve.

LEUCOPHLEGMATIA, in *Medicine*, from λευκος, white, and φlegμα, pituita, phlegm, a term applied to the droplets of the skin, or anasarca, in consequence of the very pallid hue of the skin and complexion under such circumstances.

Dr. Cullen remarks, that the terms *anasarca* and *leucophlegmatia* have been commonly considered as synonymous; but some authors have proposed to consider them as denoting distinct diseases. The authors who are of this last opinion, employ the name of *anasarca* for that disease which begins in the lower extremities, and thence gradually extends upwards; while they term that *leucophlegmatia*, in which the same kind of swelling appears, even from the beginning, very generally over the whole body, and in which there appears to be a greater deficiency of the blood; such as occurs after profuse hæmorrhages, or other great evacuations. The distinction, however, is principally verbal. See ANASARCA, and DROPSY.

LEUCOPHRA, in *Zoology*, a genus of the class Vermes, and order Infusoria: this worm is invisible to the naked eye, and every where ciliate. There are eight species, of which four are found in the waters or marshes of our own country.

#### Species.

CONFLICTOR. Spherical, sub-opaque, with moveable intestines; it is found in clear water; is of a yellowish colour, with dark edges, and filled with very minute molecules in perpetually violent agitation. This animalcule is described and figured in Adams' Essays on the Microscope. It is said to be rather a heap of animalcules than a single individual, is larger than most species of the vorticella, perfectly spherical, and semi-transparent. It rolls at intervals from right to left, but seldom removes from the spot where it is first found. In proportion to the number of molecules above-mentioned, which are accumulated on one side or the other, the whole mass rolls either to the right or left; it is then tranquil for a short time, but the conflict becomes more violent, and the sphere moves the contrary way in a spiral line. It is a fine object for the microscope, but requires to be observed with much attention. When the water begins to fail, the little creatures assume an oblong, oval, and even cylindrical figure; the hind part of some being compressed into a triangular shape, and the transparent part ebbing as it were from the intestines, which continue to move with the same violence till the water wholly fails, when the molecules are spread into a shapeless mass, which soon vanishes,

and the whole shoot into a form, having the appearance of crystals of sal-ammoniac. See Adams, p. 500.

**VESICULIFERA** is ovate with vesicular interlines. This animalcule is a sort of mean between the orbicular and oval, very pellucid, with a defined dark edge, and inside containing some very bright vesicles or bladders. The middle frequently appears blue, and the vesicles seem as if set in a ground of that colour. The accounts given of this animalcule by Spallanzani and Müller differ in some respects; the latter, however, admits that he once saw an individual like those described by Spallanzani.

**ACUTA.** The oval leucopha, which is round, with a black point at the edge.

**FLUXA.** Sinate, kidney-shaped; body oblong, yellowish, obtuse on one part, the other produced into a cone, and generally filled with molecules.

**ARMILLA.** Round, annular; body thickened above and bent like a ring.

**CORNUTA.** Inversely conic, green, opaque. This animalcule has a resemblance to certain species of the vorticella, and requires to be observed some time before its peculiar characters can be ascertained: the body is composed of molecular vesicles, of a dark green colour, for the most part it is like an inverted cone, the fore-part being wide and truncated, with a little prominent horn, or hook, on both sides; the hind-part is conical, ciliated, the hairs exceedingly minute; those in the fore-part are three times longer than the others, and move in a circular direction. The hinder part is pellucid, and sometimes terminates in two or three obtuse pellucid projections. The animalcule will at one moment appear oval, at another reniform, and ciliated at the fore-part; but at another time the hairs are concealed. When the water which contains it evaporates, it breaks and dissolves into molecular vesicles. It is found late in the year in marshy grounds. See Adams, Pl. 25.

**HELICLIATA.** Cylindrical, obtuse on the fore-part, the hind-part furnished with a double crested organ, which it can thrust out and draw in at pleasure. To the naked eye it appears like a white point; intestines visible by a microscope, when it seems a cylindrical body; the fore-part obtusely round, the middle rather drawn in, the lower part round, but much smaller than the upper part. With a lens of pretty high power the whole body is found to be ciliated.

**NODULATA.** Ovate-oblong; depressed, with a double row of tubercles. This species is found in the intestines of the *Lumbricus terrestris*, and *Nais littoralis*; it is very pellucid, shining like silver, and is propagated by a transverse division; it is of an oval shape when young, and growing more oblong with age; it is truncate at the tip.

**LEUCOPIPER,** in the *Materia Medica*, a name by which some authors have distinguished the white pepper.

**LEUCOPOGON,** in *Botany*, so named by Mr. Brown, from λευκος, *white*, and πικρον, *a beard*, on account of the white erect hairs on the upper side of the segments of the corolla, very conspicuous even in dried specimens. Brown. Prodr. Nov. Holl. v. 541. Ait. Hort. Kew. ed. 2. v. 1. 323. (Perejia; Cavan. Ic. v. 4. 29.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Eparicidez*, Brown.

Gen. Ch. *Cal.* Perianth interior, of seven leaves, erect, permanent; the five innermost equal, lanceolate, concave; two outer ones ovate, opposite, much shorter. *Cor.* of one petal, funnel-shaped, limb in five spreading equal segments, longitudinally bearded on the upper side, with dense, erect hairs. Nectary glandular, surrounding the base of the germen. *Stam.* Filaments five, thread-shaped, equal, inserted into the tube; anthers incumbent, oblong, bursting length-

wise, rising just above the tube. *Pist.* Germen superior, roundish; style short, columnar; stigma obtuse. *Peric.* Drupa more or less succulent, or sometimes dry when ripe, sometimes crustaceous. *Nut* of from two to five cells, with one or two pendulous seeds in each.

Eff. Ch. Outer calyx of two leaves. Corolla funnel-shaped; its limb spreading, longitudinally bearded. Filaments included in the tube. Drupa of from two to five cells.

In the *Prodromus* of Mr. Brown, so rich in botanical novelties, we find the definitions of forty-eight species of this new genus, which he has separated from the *Styphelia* of preceding writers; retaining in the latter such plants only as have four or more leaves to their external calyx; a more elongated and cylindrical corolla, with five internal tufts of hair near the bottom, the limb revolute as well as bearded; filaments prominent; and a rather dry drupa, always of five cells.

*Leucopogon* is divided into five sections, of each of which we shall give some examples.

1. *Spikes axillary, many-flowered. Drupa juicy.* Six species.

*L. lanceolatus.* Brown n. 1. (*Styphelia lanceolata*; Smith Bot. of New Holland, 49; excluding the synonyms from both authors.)—Spikes drooping, aggregate. Fruit oval, of two cells. Leaves lanceolate, flat; many-ribbed beneath; with three furrows above. Branches smooth.—Sent dried from Port Jackson, New South Wales, by Dr. White, in 1793. The living plant we believe has never been brought to this country; *L. lanceolatus* of the new edition of Hort. Kew. being certainly *Styphelia parviflora* of Andr. Repof. t. 287; *S. Cnidium*, Venten. Malmaif. t. 23, which appears to us a very different species, rather agreeing with the characters of *L. apiculatus*, Brown n. 7.—The true *lanceolatus* is a larger shrub, with copious, slender, leafy, round branches, usually quite smooth, sometimes very minutely downy; the young ones reddish, becoming angular and striated when dried. Leaves scattered, slightly spreading, sessile, lanceolate, flat, sharp-pointed, entire, smooth, above an inch, but rarely approaching to two, in length, a quarter of an inch broad; of a full rather glaucous green above, and marked with three fine, often obsolete, furrows, from the base to the middle; the under side paler, with numerous, branching, parallel ribs. *Stipulas* none. *Spikes* clustered about the ends of the branches, spreading or drooping, nearly the length of the leaves, slender, loose, many-flowered, the common stalk slightly downy. *Flowers* small, white, sessile. *Bractees* solitary under each flower, ovate, concave, ribbed, downy-edged, of the size and exact appearance of the two outer calyx-leaves, placed contrary to them, permanent. Inner calyx-leaves twice as long as the outer, and smoother, rather shorter than the tube of the corolla, whose limb is reflexed, with a tolerably dense, but not very white beard, at least in the dried specimen. *Drupa* of two cells, oval, twice as long as the inner calyx-leaves, crowned by the style, which is about a third of its length.

*L. verticillatus.* Brown n. 6.—Spikes mostly terminal, aggregate; drooping when in fruit. Drupa of five cells, five-sided. Leaves interruptedly clustered, somewhat whorled, oblong-lanceolate, taper-pointed. Gathered by Mr. Brown on the southern coast of New Holland. We have what answers to his description from King George's sound, on the west coast, communicated by Mr. Menzies. It is much larger than the preceding. Leaves from two to three or four inches long, and three quarters or more broad, somewhat roughish to the touch, marked on both sides with five ribs, besides innumerable oblique lateral ones beneath;

four or five growing together in a sort of whorls. The lateral branches are also often whorled. Spikes much as in the last, but longer. Bractæas ribbed, smooth, twice as large as the outer calyx-leaves.

2. *Spikes axillary, sometimes terminal, of three or more flowers. Calyx and bractæas coloured. Drupa rather dry. Leaves not heart-shaped.* Fourteen species.

*L. apiculatus.* Brown n. 7. (*Styphelia parviflora*; Andr. Rcpof. t. 287? *S. Gnidium*; Venten. Malmalf. t. 23?)—Spikes terminal, somewhat aggregate, of five to seven flowers. Bractæas lanceolate, rather larger than the outer calyx-foales. Leaves lanceolate-oblong, erect, slightly concave, callous-tipped, smooth at the edges. Drupa crustaceous, turbinate, depressed, shorter than the calyx.—Gathered by Mr. Brown on the south coast of New Holland. He observed a smooth variety and a downy one, which he suspects may be distinct species.—The above characters most minutely answer to the above plant of Andrews, raised from New Holland seeds, and to be seen in several greenhouses, flowering in May. It is a small *shrub*, with apparently deciduous, rather glaucous leaves, hardly an inch long, smooth, with little, dense, upright, usually solitary, terminal spikes, of pretty snow-white flowers.

*L. revolutus.* Brown n. 13.—Spikes mostly terminal, aggregate, of four or five flowers. Calyx and bractæas minutely downy, the latter half the size of the outer calyx-foales. Leaves rather spreading, linear-oblong, obtuse, with a blunt callous point; convex and rough above; smooth and furrowed beneath; the edges reflexed and naked. Branches finely downy. Drupa dry, obovate, with five cells.—Found by Mr. Brown on the south coast of New Holland, and by Mr. Menzies at King George's sound. It is not very unlike the last, but the leaves are smaller, more spreading, and rough on the upper side with minute points. The flowers are larger, and very conspicuous for the long white hairiness of their segments.

*L. ericoides.* Brown n. 17. (*Styphelia ericoides*; Smith Bot. of New Holl. 48. *Epacris spuria*; Cavan. Ic. v. 4. 27. t. 347. f. 1.)—Spikes copious, axillary, solitary, of three or four flowers. Leaves oblong-linear, spreading, sharp-pointed; recurved at the edges; roughish above. Bractæas pointless. Inner calyx-leaves membranous. Drupa dry, angular.—Native of New South Wales, and of Van Diemen's land. A bushy *shrub*, with leaves scarcely half an inch long, almost every one of which is accompanied by a much shorter axillary spike of three or four flowers. The segments of the corolla are straight and sharp, looking reddish (as Cavanilles describes them) when dry, elegantly bearded with white hairs, which, as the flowers open, seem to form a dense web in the mouth of each.

To this section also belong, among others, the *Styphelia*, tab. 64, 65, 66, 67, of Labillardiere.

3. *Spikes axillary or terminal. Leaves heart-shaped. Calyx and bractæas membranous or leafy.* Five species.

*L. amplexicaulis.* Brown n. 21. (*Styphelia amplexicaulis*; Rudge Tr. of Linn. Soc. v. 8. 292. t. 8.)—Spikes axillary and terminal, spreading, stalked, longer than the leaves, which are heart-shaped, pointless, clasping the stem; minutely downy beneath; recurved and fringed at the edge. Branches hairy. Drupa lenticular, of two cells.—Found near Port Jackson. The stems are several from one root, mostly simple, round, reddish, clothed with fine horizontal hairs. Leaves spreading, near an inch long, half an inch wide, with many ribs. Calyx and bractæas smooth, acute. Segments of the corolla recurved, very hairy. Drupa compressed, oblique.

*L. difflans.* Brown n. 23.—Spikes terminal, aggregate,

zigzag. Flowers distant. Leaves ovate, somewhat heart-shaped, deflexed, pointless, minute; convex above; downy beneath. Drupa crustaceous, obovate, flat-topped, of five cells.—Gathered at King George's sound by Mr. Menzies, to whom Mr. Brown, like ourselves, was indebted for specimens. The branches are long, clothed with numerous little reflexed convex leaves. Spikes very peculiar, being long, slender, with remarkably zigzag, downy stalks. Bractæas heart-shaped, concave, ribbed, permanent. Calyx-leaves very broad. Segments of the corolla recurved, very densely bearded.

4. *Spikes terminal. Calyx and bractæas rather leafy. Drupa dry. Leaves not heart-shaped.* Eight species.

*L. microphyllus.* Brown n. 26. (*Petroja microphylla*; Cavan. Ic. v. 4. 29. t. 349. f. 2.)—Spikes clustered, of few flowers. Leaves of the calyx pointed, half membranous. Bractæas leafy, ribbed. Leaves oval, flat, obtuse, pointless; of the same colour on both sides. Drupa crustaceous, of one or two cells.—Native of the neighbourhood of Port Jackson. A pretty little *shrub*, with minute, rather imbricated, smooth, thickish leaves. The little spikes of flowers, clustered about the ends of each branch, form round heads. The inner leaves of the calyx are narrow, acute, smooth, and thin. Segments of the corolla thick, recurved, very densely covered with white hairs, as in *L. difflans*, and indeed the generality of the species.

5. *Stalks axillary, two-flowered; here and there only single-flowered; in which case there are several bractæas. Drupa dry.* Fifteen species.

*L. acuminatus.* Brown n. 37.—Stalks very short, erect, mostly two-flowered. Leaves nearly upright, linear-lanceolate, very sharp, flat, with a bristly point; their margins rough, finely toothed.—Found by Mr. Brown in the tropical part of New Holland, as are six others of this section, one of them, *L. ruscifolius*, having been discovered there by sir Joseph Banks. Most of the rest are natives of Port Jackson, but none of them have come under our inspection.

This is, on the whole, a very elegant as well as natural genus, and it is to be regretted that only one of the species has hitherto been made known to our cultivators of curious plants. The plummy whiteness of the flowers gives a striking and peculiar aspect to the whole.

LEUCOPSIS, in *Zoology*, a genus of the Hymenoptera order, of the class Insecta. The mouth is horny with short jaws; the mandible thick and three-toothed at the tip; the lip, which is longer than the jaw, is membranaceous, and emarginate at the tip; it has four feelers, short, equal, and filiform; antennæ short and clavate; thorax with a long lanceolate scale beneath; wings folded; sting reflexed and concealed in a groove of the abdomen. There are four species, all foreign insects; three found in the fourth of Europe, and one in Tranquebar.

#### Species.

GIGAS. Black; thorax with two dorsal yellow dots; abdomen sessile, with four yellow bands. It inhabits France; the wings are dusky; hind-thighs with numerous teeth.

DORSIGERA. Abdomen sessile, black, with two yellow bands, and a dot between them. It is found in Italy, Switzerland, France, and some parts of Germany. Head is black; thorax gibbous, black with a double transverse yellow line; abdomen compressed and grooved on the back; sting double, as long as the abdomen, and reflexed back into the abdominal groove; legs yellow, spotted with black; hind legs toothed, with a black spot. This beautiful insect is figured in Adams' work on the microscope; the drawing was taken from a specimen in her present majesty's cabinet of insects.

There is one also in the cabinet of Linnæus, now in the possession of our very able coadjutor, Dr. Smith, P. L. S. It appears at first sight like a wasp, to which genus the folded wings would have referred it, had not the remarkable sting or tube on the back have prevented it. It is thought to be a species between, and uniting the sphæx and wasp, in some degree partaking of the characters of both. The antennæ are black and cylindrical, increasing in thickness towards the extremity; the joint nearest the head is yellow; the head is black; so also is the thorax, encompassed with a round yellow line, and furnished with a cross one of the same colour near the head. The scutellum is yellow; the abdomen black, with two yellow bands, and a spot of the same colour on each side between the bands. The anus and the whole body, when viewed with a low magnifier, appear punctuated, and the points, when examined carefully, seem to be hexagonal, and in the centre of each hexagon a small hair is seen.

**PETIOLATA.** Black; abdomen petiolate ferruginous; the petiole with a yellow dot each side. It is found in Tranquebar. The thorax is elevated, with two yellow streaks before; under the scutellum is a yellow dot; the second segment of the abdomen is edged with yellow, and the tail is black; legs black edged with yellow; wings black.

**CELOGASTER.** Abdomen sessile; scale of the thorax half as long as the abdomen. It is found in some parts of Germany. The thorax has a yellow band behind, and the eyes are black.

**LEUCORRHEA,** in *Medicine*, λευκορροία, literally signifying *fluor albus*, or *white flux*, is a disorder of the uterus or its passages, from which a whitish or pale coloured fluid is discharged, accompanied by pain in the loins, considerable loss of strength, and a weakly aspect. It is commonly expressed by the appellation of "*the whites*" by the patients, or is simply called "a weakness."

Every serous or puriform discharge from the vagina has been comprehended under this appellation: it is obvious, however, that such discharges may be various, and may proceed from various sources. They may proceed more especially from the vessels of the uterus itself, or from those of the vagina only. In the latter case, which is probably not a very common occurrence, the cause of the excretion must be purely local: it sometimes happens during the period of pregnancy. In these instances, there must be either a local weakness and relaxation of the parts, or some irritation may exist or have been applied, so as to excite the mucous glands, the secretion from which serves to lubricate the parts, to pour out their fluids in an unusual quantity. The existence of little aphthous ulcerations within the labia sometimes gives rise to such a discharge, in which case there is also a considerable degree of soreness and tenderness in the parts; and the use of those instruments, called pessaries, has been said to produce a fluor albus, from the pain and irritation which they occasion.

In general, however, the discharge of leucorrhœa proceeds from the same vessels of the uterus itself which pour out the catamena. This inference may be deduced from the following circumstances. In the first place, the leucorrhœa is most common in those women who are subject to an immoderate flow of the menses. Secondly, it appears principally, and often exclusively, a little time preceding, and again posterior to the menstrual discharge; the latter diminishing in proportion as the leucorrhœa is increased, or seeming to be converted into the leucorrhœa. Thirdly, the leucorrhœa often continues after the period when the catamena have altogether ceased, and frequently shews a considerable tendency to a periodical recurrence. And lastly,

it is commonly accompanied with the same local and constitutional symptoms as an excessive flow of the menses; such as paleness of the countenance, a feeble pulse, an unusual debility on taking exercise, a hurry of the breathing from even moderate exertion; and at the same time the back becomes pained by any continuance in the erect posture, the extremities are frequently cold, and some œdema affects the feet in the evening. The debility also manifests itself by affections of the stomach; such as loss of appetite, flatulence, and other symptoms of indigestion; by palpitations of the heart, with frequent sensations of sinking and fluttering about the epigastric region, and even actual syncope; and by a depression of spirits, and a weakness of mind liable to strong emotions from slight causes, especially when operating suddenly; in a word, by all the train of distressing symptoms which have been denominated *nervous*. The inference, that the discharge is uterine, is farther confirmed, when it is observed, that it had neither been preceded nor accompanied by any symptoms of a local affection of the vagina; and that it had not appeared soon after communication with a person who might be suspected of giving infection; nor had, from the first appearance, been accompanied with any inflammatory affection of the pudenda.

The last observation applies particularly to the diagnosis of the discharge of leucorrhœa and that arising from venereal infection; a point which is worthy of more particular consideration. It is very easy to distinguish a simple leucorrhœa from a recent gonorrhœa; for besides the general debility, and the nervous symptoms above-mentioned, which frequently accompany the former, the colourless nature of the discharge, which only thickens, without staining the linen, and the absence of all heat and scalding on passing the urine, together with the cessation of the discharge at the time of menstruation, sufficiently characterize the leucorrhœa; whilst in the gonorrhœa there is itching, inflammation, and heat of urine, the orifice of the urinary passage is prominent and painful, there is frequent irritation to make water, and the discharge stains the linen of a yellow or greenish colour. But it must be remembered, that the discharges from the vagina, which have been denominated leucorrhœa, are sometimes opaque and of a yellowish colour, and sometimes accompanied with a degree of ardor urinae and inflammation of the external labia. This may happen in women of bad habit of body, or where there is ulceration in the vagina or uterus; but in both these cases the discharge is of a sanious nature, and very offensive; and in the latter is commonly accompanied with severe pains in the region of the uterus, and extending from the loins round the pelvis to the groins, and even down the thighs. The discharge is sometimes fo acrimonious, in these instances, as to inflame and excoriate the passages. In the herpetic or aphthous affection of the orifice of the pudendum, there is heat of urine with the discharge; but the discharge is very scanty, and the labia extremely tender and sore, so as scarcely to admit of sitting, except upon a soft seat; which does not take place either in proper leucorrhœa, or in gonorrhœa in general. In many cases, the circumstances of the patient, which render it either impossible or in the highest degree improbable that any infectious connection can have taken place, will of course admit of no hesitation in the decision; and it is often upon these circumstances alone that the practitioner is obliged to depend in forming his opinion.

The *causes* of leucorrhœa are chiefly to be sought for among those agents and circumstances, which tend to produce a debility of the system in general, or of the uterus in particular. Of the former kind, are imperfect diet, fatigue, anxiety, and much watching; the practice of suck-

ling children too long; damp, clofe, and uncleanly habitations; caufes which chiefly operate among women of the lower clafs. To thefe may be added, the almoft total want of proper exercife, living too much in warm chambers, and drinking much of warm enervating liquors, fuch as tea and coffee, which influence principally women of better ftations. The fources of local debility to the uterine fyftem itfelf are many; fuch as blows, bruises, and falls; frequent abortions, or frequent child-bearing without nurfing, difficult and tedious labours, profufe difcharge of the catamenia, or of the lochia after delivery; venus immodica; &c.

On the other hand, the effect of leucorrhœa, efppecially when it has continued long, is, in many cafes, to prevent conception and occafion barrennefs; or, if conception take place, to produce a fucceffion of mifcarriages; not to mention the conftitutional and nervous derangement already defcribed. However, if the leucorrhœa be moderate, and be not accompanied with any confiderable overflow of the catamenia, it may often continue long without inducing any great degree of debility; and it is only when the difcharge has been very copious, as well as conftant, that its effects in that way are very remarkable.

The means of cure will confift of thofe expedients which contribute to ftrengthen the general habit, and the uterine fyftem locally. The fyftem generally is to be fupported by all thofe means which regimen, diet, and medicine contribute; namely, by light and nutritious diet; by moderate exercife, by fome means of geftation, as in a carriage, on horfeback, or failing (the exercife of walking, both from the conftant erect pofture, and the action of the mufcles, being liable to produce irritation, and to augment the uterine difcharge); by the ufe of the tepid or cold bath, according to the ftrength of the patient, and the feafon of the year; by drinking the chalybeate mineral waters; or by taking fome of the preparations of iron in the way of medicine, efppecially the muriated tincture, or the fulphate, together with the cinchona, or other vegetable tonics. The mineral acids are fometimes beneficial under the fame circumftances.

The uterus itfelf and its connections may be ftrengthened either by direct local applications, or by internal medicines, which are commonly determined to the urinary paffages, and from the vicinity of thefe are often communicated to the uterus. Thefe laft mentioned medicines are cautharides, turpentine, and balfams of a fimilar nature; by which the difeafe has often been relieved or even cured. The former clafs includes a variety of astringent lotions and injections, by which the difcharge may alfo be often diminiſhed, and in young women, when the complaint is recent, entirely cured. Thus the parts may be wafhed twice or three times a day with a weak folution of the acetite of lead, or of alum, in rofe water; or an infufion of rofe leaves, or of green tea, or the chalybeate mineral waters, make very proper lotions: or thefe liquors may be thrown into the vagina twice a day, through an ivory pipe, by means of the elaftic gum. But in general injections are unwillingly ufed, unlefs when the difeafe is inveterate. When the matter difcharged is acrimonious, and inflames and excoriates the parts, or excites very troublefome and painful itching, the greateft relief is obtained by keeping the parts clean and cool, removing the acrimonious matter frequently by bathing with cold water, or with any of the above-mentioned astringent liquors.

Dr. Hamilton remarks, that women have, in many inftances, been cured of the moft obftinate habitual fluor albus by giving fuck. See his Treatife on Midwifery, pt. i.

chap. i. p. 68. See alfo Cullen, Firft Lines, § 985. Leake on the Chron. Dif. of Women.

LEUCORIDIUS, in *Ornithology*, a name by which fome have called the platea, or ſpoonbill, a very remarkable kind of ftork or heron.

LEUCORYX, ANTILOPE or *Antelope leucoryx*, in *Zoology*, the Gazella Indica, having angular horns, of Nov. Com. Petrop. xiii. 470. l. 10. f. 5. Oryx of Oppſan, Cynæg. ii. v. 445, leucoryx of Pennant, is a ſpecies of Antelope, which has very long, ſlender, upright, taper, ſharp-pointed horns, very ſlightly bent backwards and annulated at the baſe; the body being of a milk-white colour. It inhabits the iſland of Gow Bahreia, in the bottom of the Perſian gulf, near Baſſora. It is about the ſize of a Welch runt or ſmall cow; the head is large and broad, with a thick broad noſe, like that of a cow, and ſomewhat flouching ears; the body is thick and clumsy, and the whole is of a pure white except the middle of the face, the ſides of the cheeks, and the limbs, which are tinged with red: the tail is longiſh, and is tufted at the end with a brush of hairs; the horns are of a black colour. Dr. Pallas mentions a horn, apparently belonging to this animal, or ſome ſpecies nearly reſembling it, which was found in a foſſile ſtate, in Siberia. The female comes into ſeaſon in autumn, and brings forth in ſpring.

LEUCOSCEPTRUM, in *Botany*, a new genus named by Dr. Smith, is derived from λευκος, white, and ſκεπτρος, a ſceptre, on account of its elegant ſceptre-shaped ſpike of white flowers. The author of this genus remarks that “it has the habit of a *Buddleia*, but belongs to the ſecond ſection of *Vitices* in Juſſieu, near *Verbena*; and ſhould, along with *Verbena*, ſtand near *Mentha* in the Linnæan ſyſtem.”—Sm. Exot. Bot. v. 2. 113.—Clafs and order, *Didymia Gynnoſpermia*. Nat. Ord. fee above.

Eff. Ch. Corolla unequal, in four ſegments; the uppermoſt deeply cleft. Calyx five-cleft. Stamens declining, much longer than the corolla, parallel. Seeds four.

1. *L. canum*. Hoary *Leucosceptrum*. Sm. Exot. Bot. t. 116.—This is the only ſpecies known, and was gathered by Dr. Buchanan in the woods of Upper Nepal, where it flowers in December, and is called *Mufſola* by the Navars. The branches are obtuſely quadrangular, compressed, clothed with fine, denſe, whitifh pubeſcence. Leaves on ſhortiſh, downy footſtalks, oppoſite, elliptical, pointed and tapering at both ends, bluntly ferrated, veiny; green and naked above; white and downy beneath. Spike terminal, ſolitary, ſeſſile, erect, cylindrical, denſe, many-flowered. Bractææ ſmall, in four rows, oppoſite, each common to many flowers. Calyx tubular, downy; its margin obtuſe, unequally five-cleft. Corolla longer than the calyx, with a ſhort tube; the limb in four, very unequal, obtuſe ſegments, of which the uppermoſt is deeply divided; the lowermoſt, or lip, large, concave, and entire. Stamens declining, parallel, thread-shaped, ſmooth; the two longeſt double the length of the lip. Anthers roundiſh, two-lobed, yellowiſh. Germen ſuperior, four-lobed. Style declining, as long as the longer ſtamens, with a ſlove, acute ſigma. Seeds four, truncated, naked, in the bottom of the calyx.

This is one of the numerous ſplendid plants ſent by Dr. Buchanan, from the mountains of Nepal, to Dr. Smith, which fo greatly enrich the work whence the above deſcription is chiefly taken.

LEUCOSPERMUM, fo named by Mr. Brown, from λευκος, white, and ſπερμα, the ſeed. Brown Tr. of Linn. Soc. v. 10. 95. Ait. Hort. Kew. ed. 2. v. 1. 195. (*Leuca-dendron*; Salif. Parad. t. 116. Proteæ, ſect. 3, pitillius capitatis; Linn. Mant. 2. 191.)—Clafs and order, *Tetrandria Monogynia*.

*Monogynia*. Nat. Ord. *Aggregate*, Linn. *Protea*, Juss. *Proteaceae*, Brown.

Gen. Ch. *Cal.* Common Perianth of numerous single-flowered scales, collected into a head, either permanent and hardened, or membranous and deciduous. *Cor* Petals four, irregular, linear; three of them cohering by their lower part; the fourth separate and narrower. *Stam.* Filaments four, short, inserted into the petals; anthers linear, concealed by the petals, of two cells, bursting lengthwise. *Pist.* Germen superior, sessile, roundish; stigma cylindrical, rigid, deciduous; stigma swelling, smooth, somewhat oblique. *Peric.* Nut tumid, smooth, single-seeded.

Eff. Ch. Petals four, unequal, three of them cohering by their lower part. Anthers sunk in the hollows of the upper part of the petals. Style deciduous. Stigma swelling, smooth. Nut superior, sessile, tumid, smooth.

Eighteen species are defined by Mr. Brown, all natives of southern Africa, about the Cape of Good Hope, growing for the most part in dry, sandy, rather elevated situations. Eight of them are cultivated in the Royal Garden at Kew. The whole are divided into two sections; the first having a rounder head of flowers, whose calyx-scales are permanent, becoming somewhat hardened, of which description are fourteen species; the remaining four have a flatter common receptacle, with narrow deciduous scales, of which the innermost are very thin and chaffy. All are *shrubs* of rather humble growth, rarely arborecent; many of them downy or hairy. *Leaves* either entire, or furnished with callous teeth at the extremity. *Flowers* yellow, in terminal heads.

An interesting specimen of this genus is

*L. tomentosum*. Brown. n. 13. Ait. Hort. Kew. n. 7. (*Protea tomentosa*; Willd. Sp. Pl. v. 1. 514. Linn. Suppl. 118. P. candicans; Andr. Repof. t. 294.)—Style nearly the length of the corolla. Stem erect. Leaves linear or wedge-shaped, downy, three-toothed. Calyx-scales lanceolate, nearly equal to the tube of the corolla.—This is said to be very rare in England. Mr. Masson sent it from the Cape to Kew in 1789, and Messrs. Lee and Kennedy raised it from seed the year following. The whole *shrub* is clothed with fine short down of a glaucous hue, the *stem* rather hairy. *Leaves* two inches long, various in breadth, spreading, coriaceous, dilated outwards, bluntly and unequally three-toothed at the end. Heads of *flowers* produced in August and September, terminal, solitary, sessile, about the size of a walnut, variegated with orange and yellow, their scales tipped with dark brown. Few of the Proteaceous tribe are more difficult to increase by cuttings.

LEUCOSTAPHYLOS, a name given by some authors to the water-elder, or opulus.

LEVE, *Fr.* in *Music*, the *up*, an unaccented part of a bar in beating time. See ARSIS, and ACCENT, in *Music*.

LEVEL, a mathematical instrument used for drawing a line parallel to the horizon, and continuing it out at pleasure; and, by this means, for finding the true level, or the difference of ascent or descent between several places, for conveying water, draining fens, placing the surfaces of floors, &c. level, and for various other purposes in agriculture, architecture, hydraulics, surveying, &c.

The word comes from the Latin *libella*, the cross beam that forms the brachia of a balance, which, to be just, must stand horizontally.

There is a great variety of instruments of this kind, differently constructed, and constituted of different materials, according to the particular purposes to which they are ap-

plied, as the carpenters' level, masons' level, balance level, mercurial levels, surveying and spiral levels. But, however their construction may vary, they may be all referred to the following three classes: *viz.* 1. Those in which a vertical line is determined by a suspended plumb-line, or a balance weight, and the horizontal position is shewn by a line perpendicular to it. 2. Those which determine a level line by the surface of a fluid. 3. Spirit-levels, which point out the horizontal direction by a bubble of air floating in a fluid contained in a glass tube. For the purposes of agriculture, those of the improved water, air, spirit, and foot kinds are most commonly used.

Those of the first kind, depending upon the plumb-line, are very common, but not very accurate: the simplest form is that of two rulers, united together in the form of the letter L; they must be exactly perpendicular to each other: then if a plumb-line is suspended from the top of the vertical ruler, and the edge thereof be made to coincide with the plumb-line, the other ruler must be horizontal. This, when applied to the top of a wall, a beam, or floor, will shew if they are horizontal. This is the kind of level used by artificers: sometimes it is found like the letter A, of three rulers, the plumb-line being suspended from the vertex, and the two legs set on the surface to be levelled. The line hangs opposite to a mark, made on the middle of the cross ruler, when the feet are on the same level. Besides these there are many other forms. For an instrument of this kind, see *Plate IV. Surveying, fig. 5.*

LEVEL, *Plumb*, or *Pendulum*, that which shews the horizontal line by means of another line perpendicular to that described by its plummet, or pendulum.

It consists of two legs, or branches, joined together at right angles, whereof that which carries the thread or plummet is about a foot and a half long. This thread is hung towards the top of the branch, at the point 2. The middle of the branch where the thread passes is hollow, that it may hang free every where but towards the bottom, where there is a little blade of silver, whereon is drawn a line perpendicular to the telescope. The said cavity is covered by two pieces of brass, making, as it were, a kind of case, lest the wind should agitate the thread; for which reason the silver blade is covered with a glass G, to the end that it may be seen when the thread and plummet play upon the perpendicular. The telescope 1 is fastened to the other branch, or leg, of the instrument, and is about two feet long, having a hair placed horizontally across the focus of the object-glass, which determines the point of level, when the string and plummet hang against the line on the silver blade.

All the accuracy of this instrument depends on the telescope's being fitted at right angles to the perpendicular. It has a ball and socket, by which it is fastened to its foot; and is said to have been the invention of M. Picard.

Here we may introduce an account of other levels constructed on the same general principle. For the *foot-level*; see *Foot-level*.

LEVEL, *Artillery-foot*, is in form of a square, having its two legs, or branches, of an equal length; at a juncture of which is a little hole, whence hangs a thread and plummet, playing on a perpendicular line in the middle of a quadrant; it is frequently divided into 90 degrees, or rather into twice 45 degrees from the middle. See *fig. 6.*

This instrument may be used on other occasions, by placing the end of its two branches on a plane; for when the thread

thread plays perpendicularly over the middle division of the quadrant, that plane is assuredly level.

To use it in gunnery, place the two ends on the piece of artillery, which you may raise to any proposed height by means of the plummet, whose thread will give the degree above the level.

*LEVEL, Carpenters' and Paviors'*, consists of a long ruler, in the middle whereof is fitted, at right angles, another somewhat bigger, at the top of which is fastened a line with a plummet; which, when it hangs over a fiducial line at right angles with the base, shews that the said base is horizontal.

This and the masons' level, though very common, are esteemed the best for the practice of building, though the operations by them can only be short.

*LEVEL, Gunners'*, for levelling cannons and mortars, is an instrument represented in *Plate IV. Surveying, fig. 7*, consisting of a triangular brass plate, about four inches high: at the bottom of which is a portion of a circle, divided into  $45^\circ$ , which number is sufficient for the highest elevation of cannons and mortars, and for giving (not the greatest) range. On the centre of this segment of a circle is screwed a piece of brass, by means of which it may be fixed, or moved, at pleasure. The end of this piece of brass is made so to serve for a plummet and index, in order to shew the different degrees of elevation of pieces of artillery. This instrument has also a brass foot to set upon cannon or mortars, so as when those pieces are horizontal, the whole instrument will be perpendicular.

The use of this level is obvious, and consists in placing the foot thereof on the piece to be elevated; in such manner as that the point of the plummet may fall on the proper degree: this is what they call *levelling* the piece.

The most curious instrument for the use of the artificer, was lately invented by the very ingenious colonel Congreve, of the royal artillery; having the following qualifications *viz.*

1. It will find the inclination of any plane, whether above or below the horizon.
2. By applying it either to the cylinder, or outside of any piece of ordnance, angles of elevation or depression may be given to the 60th part of a degree, with less trouble than the common gunners' quadrant, which only gives to the 4th part of a degree.
3. It will give the line of direction for laying either guns or mortars to an object above or below the horizon.
4. It will find the centre of metals of any piece of ordnance.
5. With it, a point may be found in the rear of a mortar-bed, in the vertical plane of the mortar's axis; consequently a longer line of sight is given for directing them to the object than the usual way.
6. It answers all the purposes of a pair of callipers, with the advantage of knowing (to the 100th part of an inch) diameters, whether concave or convex, without the trouble of laying the claws upon a diagonal scale.
7. On the sides of the instrument are the following lines, *viz.* equal parts, solids, planes, and polygons, logarithms, tangents, versed sines, sines and numbers, plotting scales, and diagonal scale of inches for cutting fuzes by.
8. In the lid of the instrument-case is a pendulum to vibrate half seconds. It is likewise of singular use in surveying; as, 1. It takes horizontal angles to the 60th part of a degree.
2. Vertical angles.
3. Levels.
4. Solves right-angled plane triangles.
5. Oblique-angled plane triangles.
6. Answers all the purposes of a protractor, with the advantage of laying down angles exactly as taken in the field. N. B. Captain Jordane's ingenious instrument answers nearly the same purposes.

*LEVEL, Masons'*, is composed of three rules, so joined as

to form an isosceles triangle, somewhat like a Roman A; at the vertex whereof is fastened a thread, from which hangs a plummet, which passes over a fiducial line marked in the middle of the base, when the thing to which the level is applied is horizontal; but declines from the mark when the thing is lower on one side than the other.

*LEVEL, Balance, for Surveying*, consists of a telescope or ruler with sights, and another ruler fixed perpendicularly to the middle of it, in the form of T, with a weight at the lower end. The whole is suspended by a thread, or upon centres, similar to a scale beam, and the weight of the vertical leg makes the sights or telescope assume the horizontal position. Its advantage is, that it adjusts itself to the level line, which can be transferred to any distant object, by observing it through the sights or telescope. It is necessary to enclose it in a box or case to avoid oscillation from the wind. This instrument is convenient, but not very accurate.

Another balance level, called the "reflecting level," is of French invention, ascribed to M. Cassini. A telescope or ruler, with plain sights, is suspended vertically; a mirror is fixed just before the object glass, being inclined at an angle of  $45^\circ$  with the axis of the telescope. Now as the telescope hangs vertical, and the mirror bends the rays at a right angle, they will of course be horizontal. The telescope must be provided with a diagonal eye-piece, to bend the rays again horizontal, for the convenience of observation. Other modifications of this principle by Messrs. Grandjean and Geulfaens may be found, in the volumes of the *Machines approuvées par l'Académie*. They are to be considered as more ingenious in theory, than applicable to practice.

A balance level, invented by Mr. Richard Drew, is described in the 25th volume of the *Transactions of the Society of Arts*. It consists of a tube, provided with sights at both ends, and suspended from a point considerably above its centre of gravity. It has a sliding weight, adjustable by a screw, to place the tube truly horizontal. This is, perhaps, the best kind of balance level which has appeared.

To the second class of levels belongs the *water level*. This shews the horizontal line by means of a surface of water, or other liquid: founded on this principle, that water always naturally places itself *level*.

The most simple is made of a long wooden trough, or canal, whose sides are parallel to its base; so that being equally filled with water, the surface thereof shews the line of level. This is the *chorobates* of the ancients, described by Vitruvius, lib. viii. cap. 6.

The masons frequently employ this, where they would make the top or courses of a wall truly level: they form the trough by a ridge of mortar or clay stuck round on all sides on the top surface of the wall; and filling the trough, thus formed, with water, they can measure if it is equally deep in all parts.

This sort of level is also made with two cups fitted to the two ends of a pipe three or four feet long, about an inch in diameter; by means of which the water communicates from the one to the other cup; and this pipe being moveable on its stand, by means of a ball and socket, when the two cups become equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass, three or four inches long, fastened to each extreme of the pipe with wax or mastic. Into the pipe is filled some common or coloured water, which shews itself through the cylinders, by means of which the line of level is determined; the height of the water, with respect to the centre of the earth, being always the same in both cylinders.

linders. This level, though very simple, is yet very commodious for levelling small distances:

Another water level is a glass tube, bent into the form of U, having a cup at the top of each leg. This being mounted on a pedestal, and filled with water, or other fluid, it will, from the principles of hydrostatics, stand at the same level in both cups; and by looking through the glass, any distant objects which appear to coincide with the surface of the water, in both cups, will be on the same level with them.

A *reflecting level* is, that made by means of a pretty long surface of water, representing the same object inverted, which we see erect by the eye; so that the point where those two objects appear to meet, is in a level with the place where the surface of water is found. This is the invention of M. Mariotte.

Of a similar nature are the mercurial levels, but they are furnished with two small sights, provided with cross-hairs: these float upon the surfaces of the fluid in the cups, the cross-hairs of each being equally distant from the surface. A line seen through the sights will be parallel thereto, and consequently horizontal. One of these by Alexander Keith, esq. is described and illustrated by drawings in the 2d volume of the Edinburgh Transactions, p. 14, &c. from which we shall here subjoin the following extract. *Fig. 8. (Plate IV. Surveying.)* is a section of the instrument formed of mahogany or boxwood. A, A, are two oblong square cavities connected together by a narrow close channel, running from the bottom of the one to the other. B, B, are two grooves hollowed out of the wood, in order to contain the sights, &c. They are shut up by a lid, which turns upon a screw-nail at the centre C, as may be seen more distinctly from *fig. 11.*

*Fig. 9.* D, D, are the two sights, the one with a small hole, the other with a cross-hair. These sights are erected upon two pieces of ivory or hard wood, which are shaped nearly of the dimensions of the cavities A, A, but so much smaller as to enter without touching or rubbing on the sides. Mercury is poured into the two holes A, A, till they are about half full; the two pieces of ivory which support the sights are put into the cavities, and float on the surface of the mercury.

*Fig. 10.* is a perspective view of the instrument when the sights are floating upon the mercury; and *fig. 11.* is another view of it, when the sights are taken out and the lid is open.

As the two cavities communicate with each other, the surface of the mercury in both is always upon the same line of level; and consequently, if the two sights are once accurately adjusted, they will ever after point out the true level, without requiring any after adjustment.

When this instrument is to be used, it may be laid on any horizontal surface, and the sights will immediately become an exact level. It may also be fixed on a tripod as the spirit-level; or it will answer equally well, if it is affixed to the top of a single stake, which is sharpened at the point so as to be pushed into the ground. If it is to be used as a pocket-instrument, it may be made of seven inches length, being about double the dimensions of the annexed draught. A common walking cane forms a very convenient support. It is affixed to the cane by means of a brass pin E, which passes through the hole G, and through the eye or hole of the walking stick; and a brass nut F, screwing to the male-screw of the brass pin, keeps them firm together. The two grooves B, B, contain the two sights and brass pin, when not in use. Two corks, covered

with thin leather, fitted into the holes A, A, confine the mercury, when the instrument is to be transported; or, in case the mercury is found to escape, it may be poured into a small case, made of lignum vitæ, like a tooth-pick case; and this may be stopped with a cork, and made to fit into one of the grooves.

The advantages of this instrument over the spirit-level are: 1st, It requires no adjustment, consequently two observers, though otherwise not equally accurate, must make the same observation. 2dly, With this, the level of twenty different places may be taken during the time required to adjust the spirit-level for one observation. 3dly, The nicety of the spirit-level depends upon the small curve of the glass-tube, in the choice of which no rule can be laid down; neither is any thing gained, in point of exactness, by lengthening the spirit-tube above three or four inches. But every instrument of this kind is of one standard; and the further the two sights are removed from one another, the more any error is diminished. 4thly, This instrument can be made perfectly just, without taking any observation, or comparing it with another level. In order to do this, let the floats on which the sights rest, be of the same dimension and weight, and let the cross-hair and eye-hole be of one height, and without farther adjustment, they will point out the true level.

To the third class of levels belongs the *spirit level*, called also the "*air level*," which is more accurate than any other kind, and is most extensively used. The invention of this instrument has been ascribed to M. Thevenot. Others have attributed this application of a bubble of air to Dr. Hooke. The instrument consists of a cylindrical glass tube filled with spirits of wine, except leaving in it a small bubble of air: its ends are hermetically sealed to keep in the fluid. This bubble, being the lightest of the contents of the tube, will, by the laws of hydrostatics, always run towards that end of the tube which is most elevated; but when the tube is perfectly horizontal, the bubble will have no tendency towards either end. The tube is not strictly cylindrical within, though it bears that appearance; it is slightly curved, the convex side being upwards, and by this means the bubble will rest in the middle of the tube when it is horizontal, but approaches either end which is elevated above the other. The simplest form of a spirit level for fixing any plane truly horizontal, consists of a glass tube of the above description, called a bubble tube, fixed into a block of wood, as at A B, *fig. 1. of Plate V. Surveying.* The lower surface D E of the block is made flat; and when the bubble C stands between two scratches marked on the glass at *a b*, the line D E is horizontal. The method of making it correct is this; the tube is first fitted into the block, the lower edge, D E, of which is placed on a bench or table as nearly horizontal as can be determined, so that the bubble stands between the scratches *a, b*. The level is now reversed, that is, the end D is put where E was at first. In this position, if the bubble stands in the middle, it proves the level to be correct, and the table horizontal; but if it runs to either end of the tube, it shews that end to be too much elevated: suppose it B, for instance; this end of the tube must therefore be let deeper into the wood, or the surface D E rectified to produce the same effect: one-half the error must be compensated by this means, and the other half by rectifying the table or support; for D E, the level, must now be reversed again to verify these corrections; and when they are so made that the bubble stands at *a b*, either way, the level is correct.

To illustrate this more plainly, see *fig. 2*, which represents a section of a bubble tube; but, for elucidation, is shewn as

if curved much more than they are ever made. Suppose the convex or upper surface of the tube to be a segment of a large circle B C D, from the laws of hydraulics it is plain, that the bubble of air, being the lightest body in the tube, will certainly occupy the highest point of the circle at C; and the two points B, D, being equally distant therefrom, will be in the same horizontal line B E D. The larger the radius of the circle D B, so will the level be the more sensible of any deviation from the horizontal, because the bubble will have to traverse a greater distance along the tube, in proportion to any partial elevation of either end. The numerous spirit levels applied to the delicate astronomical instruments made by Mr. Troughton, and described in our articles CIRCLE, EQUATORIAL, TRANSIT, &c. are, in general, formed by grinding the inside of the tube to a circle of near 400 feet radius. In a level of this kind, the elevation of one minute of a degree, of the line B E D, will produce a motion of three inches of the bubble; therefore a second will be 1-20th of an inch, and may be determined to the greatest precision. For common purposes, the bubble tubes have a much more rapid curvature, and are proportionably less sensible, which is very proper, because the bubbles of such delicate levels can never, in common use, be brought to stand at all steady, from the bending of the floors, and tremors of the supports they are applied to. The application of the bubble tube has been shewn in numerous instances in the articles above-mentioned; but the instrument denominated the spirit-level, for surveying, remains to be described here. The most simple form is a ruler of brass, having a bubble tube fixed down upon the middle of it; at each end of the ruler a sight is erected, through which the observer views any distant object, whose level is to be ascertained. This instrument is fitted upon a support with three legs, and has a ball and socket, by which the ruler and sights can be turned about in all directions, until the bubble shews it to be horizontal. The instrument in this form, which is the original, is so extremely inconvenient for use, that it is totally unfit for the delicate observations necessary for setting out canals, and other works, where the conveyance of water is concerned, and is therefore but very little used, except in levelling for roads, where an error is of slight importance. After having described some progressive improvements in this instrument, we shall proceed to the description of the level with telescopic sights, which is universally employed for the above purposes.

The *air-level*, with sights, is an improvement of the simple *air-level* already described; which, by the addition of more apparatus, becomes more commodious and exact.

It consists of an air-level (Plate VI. *Surveying*, fig. 1.) about eight inches long, and seven or eight inches in diameter, set in a brass tube, with an aperture in the middle. The tubes are carried in a strong, straight ruler, a foot long, at whose ends are fixed two sights, exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass, crossing each other at right angles; in the middle whereof is drilled a very little hole, through which a point on a level with the instrument is described. The brass tube is fastened on the ruler by means of two screws; one whereof, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards the level. The top of the ball and socket is rivetted to a little ruler that springs; one end whereof is fastened with screws to the great ruler, and the other end has a screw 5, serving to raise and depress the instrument, when nearly level.

This instrument is yet less commodious than the following one, because, though the holes be ever so small, yet

they will still take in too great a space to determine the point of level precisely.

*LEVEL, Air, with telescopic sights.* This level, represented in Plate VI. *Surveying*, fig. 2, is like the last; with this difference, that, instead of plain sights, it carries a telescope, to determine exactly a point of level at a good distance.

The telescope is in a little brass tube, about fifteen inches long, fastened on the same rule as the level. At the end of the tube of the telescope marked 1, enters the little tube 1, carrying the eye-glass and a hair horizontally placed in the focus of the object-glass 2; which little tube may be drawn out, or pushed into the great one, for adjusting the telescope to different sights. At the other end of the telescope is placed the object-glass; the screw 3 is for raising or lowering the little fork carrying the hair, and making it agree with the bubble of air when the instrument is level; and the screw 4 is for making the bubble of air agree with the telescope. The whole is fitted to a ball and socket.

M. Huygens is said to have been the inventor of this level; which has this advantage, that it may be inverted, by turning the ruler and telescope half round; and if then, the hair cut the same point that it did before the turn, it is a proof the operation is just.

It may be observed, that one may add a telescope to any kind of level, by applying it upon, or parallel to, the base, or ruler, when there is occasion to take the level of remote objects.

For the method of adapting a level to the meridian telescope, see TELESCOPE.

Mr. Hadley has contrived a spirit-level to be fixed to a quadrant for taking a meridional altitude at sea, when the horizon is not visible. See the description and figure of it in the Phil. Trans. N° 430, p. 167, &c. or Martyn's Abridge, vol. viii. p. 358, &c. See also the method of preparing and using a water level, and a mercurial level, annexed to Davis's quadrant, for the same purpose, by Mr. Leigh, in Phil. Trans. N° 451. p. 413, or Abr. vol. viii. p. 360, &c.

*LEVEL of M. Huygens's Invention* consists of a telescope, *a*, (Plate VI. *Surveying*, fig. 3.) in form of a cylinder; going through a ferril, in which it is fastened by the middle. This ferril has two flat branches, *b b*, one above and the other below; at the ends of which are fastened little moving pieces, which carry two rings, by one of which the telescope is suspended to a hook at the end of the screw 3; and by the other, a pretty heavy weight is suspended in order to keep the telescope in equilibrio. This weight hangs in the box 5, which is almost filled with linseed oil, oil of walnuts, or other matter that will not easily coagulate, for more aptly setting the balance of the weight and telescope. The instrument carries two telescopes, close and very parallel to each other, the eye-glass of the one being against the object-glass of the other, that one may see each way without turning the level. In the focus of the object-glass of each telescope, must a little hair be framed horizontally, to be raised or lowered as occasion requires, by a little screw. If the tube of the telescope be not found level when suspended, a ferril or ring, 4, is put on it, and is to be slid along till it fixes to a level. The hook on which the instrument is hung, is fixed to a flat wooden cross; at the ends of each arm of which there is a book, serving to keep the telescope from too much agitation in using, or in carriage. To the said flat cross is applied another hollow cross, that serves as a case for the instrument; but the two ends are left open, that the telescope may be secured from the weather,

ther, and always in a condition to use. The foot of this instrument is a round brass plate, to which are fastened three brass ferrils, moveable by means of joints, wherein are put flaves: and on this foot is placed the box.

In the portable *spirit-level*, the tube is properly set in brass, and fixed by means of screws in a small brass trough, the bottom of which is ground very straight. The ferrils are useful to place the bubble in such a position that the lower surface of the trough may be parallel to a tangent supposed to be applied to the middle point of the curve of the level. The adjustment is effected without much difficulty, by placing the level on an adjustable plane, and then reversing it. If the bubble stand accurately in the same position between two marks made on the tube in both situations of the level, it follows, that neither end of the plane nor of the lower surface of the frame of the level is elevated; or, in other words, that every surface to which the level may be applied, and on which the bubble stands in the position here mentioned, is horizontal.

This easy praxis may be effected in various ways, according to the nature and figure of the instrument of which the position is to be determined; but the accuracy of the result will depend upon the sensibility of the level; that is to say, the space passed over by the bubble for every minute or second of the quadrant, and the certainty with which, under circumstances precisely similar, it shall arrive at the same position. In the best levels the curve must be circular; for in such the bubble will move with more activity, settle itself with more certainty, and describe equal spaces by equal changes of inclination. An ordinary good spirit-level will exhibit a movement of upwards of half an inch for each minute of inclination, and alter the position of its bubble by a change of five seconds, or less. In such a tube the radius of the curve will be about 150 feet. But extraordinary levels are much more delicate. De Lalande speaks of a level filled with ether, the bubble of which passed over fourteen inches by equal spaces of one-tenth of an inch for every second. The radius of this curve was consequently 1719 feet; or near one-third of a mile.

The tubes of spirit-levels are selected by trial. If a long piece of tube be nearly filled with ardent spirit, and corked at the ends, the run of the bubble may be tried with a suitable instrument called the level-trier, throughout the whole length on all sides. By this means it may be known whether, and in what parts, it may be desirable to divide the tube for the purposes of filling and closing. It is remarkable that these tubes in general prove either good throughout, or good for nothing; for it seldom happens, where one good level can be taken, that the remainder is unserviceable. A respectable mathematical instrument-maker assures us, that he finds it a good practice to go to the glass-house and cause the tubes to be drawn without suffering them to be turned round.

But the most regular and accurate levels are obtained by grinding the inside of the tube. For this purpose, a cylindrical piece of wood is turned so as to go easily through the portion of tube intended to be ground. It is then worked in the tube with water and fine emery in the usual way. As soon as the polish has by this means disappeared on one side, the tube is cleaned, filled, and tried; and accordingly as its figure proves to be more or less straight or curved, the grinding is either repeated or discontinued. Some operators polish the inside again after grinding; but this has not been found to increase their sensibility.

From the great delicacy of the spirit-level, compared with the few observations here presented on the plumb-line,

the former instrument may appear greatly to deserve the preference. Astronomers are not however agreed on this point. When a spirit-level is adjusted by reversing, at a certain temperature, and both ends of the bubble marked, it may be allowed that the instrument may be successfully applied to use. But if the temperature be raised, the spirit will expand, and of course the bubble will become shorter. Whence it appears necessary that a division and adjusting piece should be applied, from experiment, to ascertain the true station of the bubble at different temperatures; and even this application seems scarcely adequate to supply the place of repeated adjustments. The variation of the bubble will differ according to the quantity of spirit contained in the tube. In two good levels, of nearly the same magnitude and figure, we found it amount to one-fifth of an inch for every ten degrees of Fahrenheit. The bubble therefore may be one inch longer in winter than in summer, which in these individual levels amounts to near one-third of the summer length. The curvature of a spirit-level will also vary from unequal temperature; such, for example, as may arise from one end of the tube being touched or breathed upon, while the other end is left at the original temperature. The error from each of these causes may amount to several minutes, as is easily shewn by trial; but we do not find that the presence or absence of sunshine causes any perceptible difference. It is probable that the rays may not speedily alter the temperature, on account of the transparency. And with regard to these three last sources of error, it must be allowed that they are easy to be avoided, and indeed not likely to be present in the operations of accurate observers.

We have, in *Plate V. Surveying*, given figures of two levels by the most celebrated makers, the late Mr. Jesse Ramsden, and another by Mr. Troughton: of the former, A B, *fig. 3*, is the telescope, having the spirit-level C D fitted in a brass tube, fixed beneath it. The telescope is supported at its ends by resting on angular notches in two pieces of brass, Y 1, Y 2, called the *wyes*, from their resemblance to that letter. It is held in the angles of the wyes by a clip r r, shutting down over each and pinned fast. The wyes are supported on a brass bar E E, the middle of which has a large circular aperture in it, to receive a compass needle. A bottom plate a a, being screwed under this aperture in the bar, and a glass cover fitted over it, forms the compass-box F, in which the magnetic needle turns round. The bottom a a of the compass-box has a long axis fastened to it, which is fitted into the dome of the circular plate G, and also passes through a spherical ball, shewn by the dotted lines to be screwed fast to the underside of the dome of the plate. Upon this axis, the telescope-level and compass-box turn round horizontally; the ball, just mentioned, is received in a corresponding cavity in the socket R, which is part of the plate H. By this ball and socket the two plates G and H are united, but not confined to be parallel, though they are called the parallel plates. Four screws (two of which are seen at I K) pass through the plate H, and their heads support the plate G, which can, by means of them, be placed horizontal, (and consequently the axis fixed in it vertical,) though the lower plate is not horizontal, which will depend upon accident, as it is supported on three legs set on the ground, and may therefore partake of its inclination. The legs are not shewn in *fig. 1*, but are the same as those seen in *fig. 3*, at L M N: they are all jointed into the same piece of brass O, which has a large screw on the top of it, entering a female screw in the interior of the projecting part R, *fig. 3*, of the plate H. When

## L E V E L.

flut up, the three legs form one round flaff, and are secured for carriage by rings put on them: when opened out, they make a very firm stand on the ground, though it be ever so uneven. These being the chief parts of the instrument, we have only to notice the contrivances for adjusting every part to perform accurately. The mill-headed nut *d*, at the top of the telescope, being turned, thrusts forth a tube *e*, contained within the external tube of the telescope, and carrying the object glass, which is by this means adjusted to its focal distance, so as to see an object distinctly at any distance. The telescope has two wires in the eye-end at *f*/*g* crossing each other perpendicularly: it is by intersecting these the object is viewed. The eye-piece, *L*, of the telescope slides in its tube to adjust the focal distance of the eye-glasses. That these wires may be seen distinctly, the level is suspended from the telescope at one end by a screw *D*, which adjusts it parallel to the axis or line of sight of the telescope. At the opposite end *C* is another screw adjustment, to make it parallel in the direction sideways, that is, in the same vertical plane with the axis of the telescope. The *Y* 2 is supported in a socket *M*, and can be raised or lowered by the screw *N*, to make the level and telescope truly perpendicular to the vertical axis represented by the dotted lines. The screw *O* is for turning the axis about to direct the telescope to any object: it operates upon a ring or clump of brads *P*, which encloses, and is fixed to, the axis when the screw *S* is turned, but when this screw is slack, the clump releases the axis, that the telescope may be turned round readily, to bring the desired object into the field of view: then by screwing *S* the telescope is made fast, but may still be turned a small quantity by the screw *O* to direct it exactly to the object.

The compass contained in the bar *E E* is for taking bearings of any object; but as its use is not connected with the operations of levelling, and has been fully described under the article CIRCUMFERENTOR, we refer to that article.

Previous to taking any levels by this instrument, the adjustments should all be verified by the observer; for though they are ever so accurately done by the maker, they are not to be depended upon after the instrument has been carried about, or used; and for this reason they are all so contrived, as to be done with care in the open air. The process is as follows: open the three legs, and set them firmly upon the ground, placing the parallel plates *G* and *H* as nearly horizontal as can be guessed.

1<sup>st</sup>. *Adjust the level C D to be parallel to the telescope* in the following manner: Open the clips *r*, *r*, which confine the telescope in the wyes, and turn the screw *N* till the bubble comes into the middle, as is shewn by two scratches on the glass tube. Now lift the telescope gently out of the wyes, and reverse or turn it end for end, and if the bubble stands where it did before, all is right; if it goes to either end, observe how much it is from the centre, and by turning the screw *N* depress the end towards which the bubble runs, (or, what has the same effect, elevate the other end,) until the bubble returns one-half the quantity of its error. Now by the screw *D* alter the level the other half the error; if these halves were correctly estimated, it will be right, as is proved by the bubble standing right on returning the telescope to its original position. If not right now, the adjustment must be repeated till the bubble stands right either way, which proves the level and the telescope to be exactly parallel; the two cylindrical parts of the telescope, where the wyes receive it, being made precisely the same diameter.

2<sup>dly</sup>. *To make the cross-wires in the telescope intersect each other in the axis or line of collimation thereof.*—The eye-piece *L* being drawn out to see the wires distinctly, direct the telescope to any distant object, and by the nut *d* adjust the focal distance to see it clearly: select some straight line in the distant object, as the side of a window, &c. Then by the screws *N* or *O*, one elevating the telescope, the other moving it sideways, and by turning the telescope in its wyes, bring one of the cross-wires to coincide with the straight line of the distant object, without regarding the level. Now turn the telescope half round on its own axis, as it lies in the wyes; and if the cross-wire is truly in the axis it will not appear to have changed its position; but if it has, the wire must be moved, by turning an opposite hair of the four screws at *f*/*g*: by these move the wire across the field of view one-half of the error, and by the screws *N* or *O* turn the telescope back the other half. The other wire is now done in the same manner, by observing its coincidence with a distant object, and then turning the telescope half round on its own axis; and both wires may be proved by observing a small object, as a circular chalk mark, &c., to be in the intersection of both wires; and turning the tube round on its axis, it will, if right, appear in the intersection in all positions. The instrument is now prepared for taking levels in the manner explained under LEVELLING; and, if carefully used, need not be re-adjusted for many days.

The level above described, is that which is in the most general use, great numbers having been made by Mr. Ramsden, and since his decease by his numerous pupils. It is certainly an excellent instrument in the hands of those who are ready and expert in the manipulation of the adjustments just described, and who are careful to repeat them when necessary.

The instrument delineated in *fig. 4*. has lately been brought forwards by Mr Edward Troughton. Its construction is so compact, that the parts are little liable to derangement, and therefore do not need so many provisions for adjusting, by which the instrument is simplified and rendered more portable. *A B* is the telescope, and *D E* the level; its brads tube being partly received into the telescope, and soldered fast thereto, so as to be in no danger of altering its position: the telescope is screwed to a strong brads bar *F F*, which screws fast to the top of a conical socket *G*, that turns upon a vertical axis fastened to the plate *H*: this is united to the lower plate *I* by a ball and socket, and the four screws screwing through the upper plate, and resting on the lower, give the means of always setting the axis vertical: the joints *O* for the three legs *L, M, N*, are fixed to the lower side of the plate *H*: the compass-box *P* is supported over the level by four small pillars; by this means it is more readily observed than when beneath, and gives the means of laying the telescope so close to the brads bar *F*, that it is much more firm than the former instrument. The bubble of the level is so long, that its ends appear on both sides of the compass-box, and is shewn to be in the middle by scratches on the glass at *a b*, as usual.

The screws which hold the telescope to the plate *F* are covered by caps of brads, which defend them from accidental alteration, but admit their adjustment when necessary. To make the telescope exactly perpendicular to the vertical axis, the only adjustment the instrument requires besides this is the eye-piece. It has, in lieu of cross-wires, a small micrometer or divided scale, of mother-of-pearl, fixed perpendicularly across the field of view, the divided edge intersecting the line of collimation: the central division of the

## L E V E L.

scale has a small hole through it for distinction. It is this by which the levels of objects are observed, and it therefore crosses the axis of the telescope. It can be adjusted exactly to this by a screw *d* at top, and another *e* beneath the tube.

The manner of adjusting this instrument is as follows: the legs being set on firm ground, the vertical axis is adjusted, in the same manner as every other level is preparatory to making observations, *viz.* by setting the telescope over any opposite two of the four screws in the parallel plates, and turning these screws, one in and the other out, till the bubble comes right; then turn it half round, by applying the finger and thumb to the large milled nut on the top of the socket *G*. If it is level when thus reversed, all is right; if not, it shows the level is not perpendicular to the axis, and one-half the error must be corrected by the screws under the ends of *F*, and the other half by the screws of the parallel plates, the telescope being turned over the other pair of screws; and they are adjusted in the same manner. Now the axis is vertical, as is shown by the bubble standing still while the telescope is turned all round. The plate *F*, being once adjusted in this manner, will not soon be deranged, and when it is will immediately discover itself, and be as easily restored. The line of light, or line of collimation of the telescope, is made parallel to the level, by an actual trial in the field, which indeed is the most accurate method, and is resorted to for very delicate purposes. In the instrument before described, to verify the adjustments after making them, the method of trial is applicable to a level of any kind, and is described under LEVELLING. The micrometer scale in the eye-piece is very useful in levelling; it gives the means of roughly estimating equal distances from the instrument in any direction. A man who attends the observer holds up a staff of six feet, or any other length, perpendicular, and the observer, looking at it through the telescope, notices how many divisions of the micrometer scale the staff appears to subtend; then, if the man recedes from the instrument until the same staff reaches the same number of divisions, he will be at the same distance from the instrument. This property is extremely convenient in many instances which occur in the use of a level.

LEVEL, *American*, is an instrument which is formed of two pieces of thin wood of equal length, joined together at top, and connected below by a cross bar; from the angle at top a lead plummet is suspended by a small cord, which, when the instrument stands level on both legs, strikes upon a mark in the centre of the connecting bar, as represented by *a*, *fig. 4.* in *Plate VI. Surveying.* The manner of using it is simply this: At the place from which the level is to be taken, drive a wooden peg in the ground, close in to the top, upon which one of the legs of the frame may rest; then bringing round the other leg till it touch the ground, then drive in a second peg, turning round the other leg as before; and where it touches the ground again, drive in another peg, and so on along the whole line to be levelled. Thus, with very little trouble, and with as much accuracy as with the finest spirit-level, will the course of the drain be easily ascertained. But as it is necessary the drain should have as much declivity as to allow the water to run freely, it will be requisite, in taking the level, to regulate the direction of the line accordingly. Half an inch fall in the length of the frame will be sufficient, and sometimes even less. For this purpose, it will be expedient to have, besides a number of wooden pegs, one iron pin, with inches and halves marked regularly upon the sides of it from the top downwards. After having drove in the first wooden peg at the point from whence you mean to conduct the drain, and

having rested the one leg of the frame upon it, turn round the other till it be level with the first peg; there put in the iron pin, so that this leg of the frame may rest on the top of it when level; then drive in a wooden peg so far, as that the top of it may be half an inch lower than that of the iron pin. Place the leg of the frame again upon this second peg, turn it round to a level, putting in the iron pin till the top of it be equal with the foot of the frame; then drive in another wooden peg close by the side of it, till the top of the wooden one be half an inch lower than that of the iron pin. Proceed in this manner so far as you mean to carry the drain, which will have the same degree of declivity all the way along. A line thus set off is marked from *c* to *d* in the figure. When made on a smaller scale, it is useful in ascertaining the proper descent along the bottom of a drain, while the workmen are laying it; but when made for this purpose, the cross bar must be fixed to the bottom of the legs, as marked with dotted lines in the plate.

There is a watering level which is much used in some places, which is formed of different pieces of wood, &c.; the usual length given it being five feet and a half, and the height from four feet to four feet and a half, according to the height of the person who is to make use of it.

The *object staff*, *fig. 5, Plate VI. Surveying*, should be made exactly of the same height with the level. The cross piece, *fig. 6*, should be sufficiently large to be seen distinctly at a distance, and must be painted white for the purpose.

This level, in the experience of Mr. Marshall, has been found "preferable to any other level now in use, as being equally accurate in ascertaining the relative heights of distant objects, as in minutely tracing step by step the required line of communication, so as to give every part of it an equal and uniform descent." In its use in setting out a level, so as to fix the fall accurately at one inch, foot, or yard, in a hundred of any of them, on the face of the level, which is found in general to be the most proper; it is directed to measure out one hundred feet on level ground, placing the level at one end, the object-staff at the other, and then adjusting their tops to a dead level, by a dead level line exactly drawn on the face of the implement (*viz.* a line drawn at right angles with the upper edge of the top rail), as shewn at *a*, in the figure, then measuring one foot downward on the staff, and there holding a rule or other straight edge level across the staff; bringing the top of the level, by raising its hinder foot, to range accurately with the upper side of the rule, and while they remain at rest in this position, a mark must be made where the plummet-line rests against the face of the level. After this measure out a hundred yards, and proceed in the same manner, in order to prove or rectify the first mark, on which a permanent line must be sunk on the face of the level *b*, in the figure, which in water-work is better than the plumb-line. Where the ground to which the water is to be conducted can be seen from the place whence it is to be taken, the staff should be set upon the highest part to which it is desirable to raise the water, and the level at the source, and after having correctly adjusted the top of the latter to that of the former mark, where the plummet rests on the face of the level, where it rests between *a* and *b*, it is necessary to consider the case, as, where the extent of land is small, and that of the water unlimbed, little fall may be sufficient; but in the contrary circumstances, it would be improper to let it waste by the way more than is necessary; of course where the plummet rests much within the water-line, the staff must be moved and set lower down on the slope till the requisite fall is gained. But where the plummet is found to rest on the

right-

right-hand side of the water-line, mark the plan and draw a pencil line, (which will be sufficiently durable for a single work, and may afterwards be easily rubbed out on the face of the level,) corresponding to the line of the plummet, as the dotted line *c*, and thus fix the fall in this case, always making due allowance, in tracing and staking out the line with the level thus set, for the crookedness of the course; as from this lengthening the line, the declination of the channel is proportionally lessened.

It is supposed further, that "many ingenious additions" might be made to this level; but that "they would be injurious to its present simplicity;" Any country carpenter may be easily instructed to construct it in its present form, and "any common labourer be easily taught to use it, either in forming roads or water-courses." It is, however, best adapted to the latter use.

Dr. Defaguliers contrived an instrument, by which the difference of level of two places, which could not be taken in less than four or five days with the best telescope levels, may be taken in as few hours. The instrument is as follows:

To the ball C (*Plate VI. Surveying, fig. 7.*) is joined a recurved tube B A, of a very fine bore, with a small bubble at the top A, whose upper part is open. From the construction of this instrument, it is evident, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and the tube, when the instrument is set upright. If the air at C be so expanded by heat, as to drive the liquor to the top of the tube, the cavity A will receive the liquor, which will come down again, and settle at D, or near it, according to the level of the place where the instrument is, as soon as the air at C returns to the same temperament as to heat and cold. For preserving the same degree of heat, when the different observations are made, the machine is fixed in a tin-vessel, E F, filled with water up to *g h*, above the ball, and a very sensible thermometer has also its ball under water, that one may observe the liquor at D, in each experiment, when the liquor in the thermometer stands at the same height as before. The water is poured out when the instrument is carried, which may be done conveniently by means of the wooden frame (*fig. 8.*), which is set upright by three screws, S, S, S, and a line and plummet P P (*fig. 9.*) At the back part of the wooden frame (*fig. 10.*) from the piece at top, K, hangs the plummet P, over the brass point at N. M, m, are brackets for keeping the upright board, K N, at right angles with the horizontal one at N. The machine seen in front is represented *fig. 11.* supposing the fore-part of the tin vessel transparent; and here the brass socket of the recurved tube, into which the ball is screwed, has two wings at I I, fixed to the bottom, that the ball may not break the tube by its endeavour to emerge, when the water is poured in as high as *g h*.

After Dr. Defaguliers had contrived this machine, he considered, that as the tube is of a very small bore, if the liquor should rise into the ball A (*fig. 7.*) in carrying the instrument from one place to another, some of it would adhere to the sides of the ball A, and upon its descent in making the experiment, so much might be left behind, that the liquor would not be high enough at D to shew the difference of the level; therefore, to prevent that inconvenience, he contrived a blank screw, to shut up the hole at A, as soon as one experiment is made, that in carrying the machine, the air in A may balance that in C, so that the liquor shall not run up and down the tube, whatever degree of heat and cold may act upon the instrument, in going

from one place to another. Now because one experiment may be made in the morning, and the water may be so cold, that when a second experiment is made at noon, the water cannot be brought to the same degree of cold it had in the morning; therefore, in making the first experiment, warm water must be mixed with the cold, and when the water has stood some time before it comes to be as cold as it is likely to be at the warmest part of that day, observe and set down the degree of the thermometer at which the spirit stands, and likewise the degree of the water in the barometer at D; then screw on the cap at A, pour out the water, and carry the instrument to the place whose level you would know; then pour in your water, and when the thermometer is come to the same degree as before, open the screw at top, and observe the liquor in the barometer.

The doctor's scale for the barometer is ten inches long, and divided into tenths; so that such an instrument will serve for any heights not exceeding ten feet, each tenth of an inch answering to a foot in height.

The doctor made no allowance for the decrease of density in the air, because he did not propose this machine for measuring mountains (though with a proper allowance for the decreasing density of the air, it will do very well,) but for heights to be known in gardens, plantations, and the conveyance of water; where an experiment that answers to two or three feet in a distance of twenty miles, will render this a very useful instrument. Defaguliers's Exp. Phil. vol. ii. p. 372, &c.

LEVEL is a term used to denote a length or pound of a canal, and also the adit or fough to a mine or engine-pit.

LEVEL-piſs, are small flakes used in levelling out an intended canal; and they are usually placed at the level of the top bank, as at *d*, *Plate I. Canals, fig. 7* and *8*.

LEVELLING, the art or act of finding a line parallel to the horizon, at one or more stations, in order to determine the height of one place with respect to another; for the laying grounds even, regulating descents, draining morasses, conducting waters, for the irrigation of land, &c.

The first process, preparatory to taking any levels, is to prove the correctness of the instrument you employ for that purpose. Some instruments are contrived to prove themselves, as described in LEVEL; but others require an actual trial in the field, which is a general method, and applicable to a level of any kind. If the level is made with plain sights, the proof is very simple: first set it level, and observe some distant object; then turn the level, end for end, and observe the same object through the other sight. If it is the same both ways, all is right; if not, the level must be altered one-half of the error thus discovered, which is doubled by this method of trial. For instance, if the line of sight pointed down the first time, it will point as much upwards when used at the other end. A level with a telescope cannot be used at either end, and therefore this method is inadmissible, and the following may be adopted.

Choose a spot of ground where it is tolerably level for about twenty chains; set up the instrument at the point B, *fig. 1. Plate VII. Surveying,* and, levelling the telescope by the parallel plates, that the bubble will stand while it is turned all round, direct the telescope to a target held up by an assistant, upon a stake driven in the ground at D, at 20 chains distant. Your assistant must, according to your signals, elevate or depress the vane of the target, till it appears in the intersection of the cross wires; now measure and write down the height B *b* of the centre of the telescope above a stake driven into the ground at B, suppose it four feet; and also write down the height D *d* at which the vane of the target

## LEVELLING.

get stands, which suppose six feet; the difference between them, two feet, shews that B is two feet higher than D; but the line *b d*, being a tangent to the earth's surface at the point B, will be the apparent level; and the true level will be found, by deducting the allowance for 20 chains, shewn by the table of the earth's curvature to be .041 of a foot. Making, therefore, the true difference of level between B and D to be 1 959 feet, to prove this, level it the other way, removing the instrument to D, and the target to the stake at B. Observe in the same manner as before, and if it gives the same difference of level as before, after deducting the allowance, the instrument is correct; if, on the other hand, the results by the two methods do not prove the same, take half the difference between the two, and elevate or depress the target that quantity, according as the last observation was greater or less than the first, and adjust the instrument, either by the screw under the level, or the screws of the cross wires, until they appear to cut the vane of the target so corrected, when the bubble is in the middle. The instrument is now corrected, but the trial should be repeated to make it certain.

The following method of adjusting a spirit-level is rather preferable, as it does not require the instrument to be removed; but it is only applicable to those instruments where the telescope lies in wyes, and can be removed. Set up the level, as at A in *fig. 2*, so that you can see both ways for about 100 yards; fix up a staff in each direction at B and C, 100 yards distant, so that the two staves and the telescope are in a line. Now give your assistant two circular pieces of card, about twice the diameter of the telescope where it lies in the wyes, with a hole through the centre of each, large enough to receive the tube of the eye-piece of the telescope; now level the telescope, and your assistant applies one of the cards against one of the staves, B for instance, and moves it up and down, till its centre appears to the observer to intersect the wires. The assistant now fastens it to the staff at *a*, by two pins, but so that the centre hole can be seen clear through by the side of the staff. The telescope is now turned half round, and directed to the other staff C, which is fitted with a card at *b*, the same as the former. This being done without disturbing the instrument, take the telescope out of its wyes, and shut down the clips again; carry the telescope to one of the staves B, and applying its eye-piece to the hole in the centre of the card at *a*, direct the telescope to the wyes of the level, and, looking through them, if the card *b* on the distant staff C appears to sit in the wyes, the level is proved correct; if it does not, mark the place where the card *a* is fixed to the staff B, unpin it, and slide it up or down, till the distant card appears to fit in the wyes. Mark this position of the card, *viz.* at *d*, and pin it on in its first position; repeat this operation at the staff C, and the card *b* will be removed to E. The figure explains the principle of this process: in the first operation the telescope set out the inclined line A *a*, instead of a horizontal line; the next operation was observing the inclined line A *b*; the third operation at the staff B formed a continuation of the inclined line B A to *d*; and the fourth operation continued A A as far as *e*. In this state it is evident, if the spaces *a, d, b, c*, each of which are double the error of the instrument, are divided into two equal parts at the points *f, g*, that the line *f A g* will be truly horizontal, and the instrument may be adjusted by the screws under the level, so as to point to *f* or *g* when the bubble is in the middle.

One place is said to be higher than another, or *out of level* with it, when it is more remote from the centre of the earth; and a line equally distant from the centre of it in

all its points, is called the *line of true level*: whence, because the earth is round, that line must be a curve, and make a part of the earth's circumference, or an arc concentrical with it, as the line B C F G, *Plate VII. Surveying, fig. 3*, all the points whereof are equally distant from the centre of the earth A.

But the line of sight, which the operations of levels give, is a tangent, or a right line perpendicular to the semi-diameter of the earth; one extreme of which tangent being the point of contact, the other will be that of a secant drawn from the centre of the earth; and the point which determines it, will be above the surface of the earth, and of the true level, as much as that secant exceeds the radius, or semi-diameter of the earth.

This extremity of the tangent is said to be in the apparent level, as being that given by the sight; but is easily reduced to the true level, because we know by trigonometry, how much each secant exceeds the radius; and because by measuring, we have discovered the precise length of that radius. Or, since the apparent level between the places B and C is B D, and the true level is the arc B C; it is plain that the former rises above the latter by the line C D. But by a well known property of the circle  $2 AC + CD \times CD = B D^2$ , and the diameter of the earth being so great with respect to the line C D at all distances to which the operation of levelling commonly extends, that  $2 AC$  may be safely taken for  $2 AC + CD$  without any sensible error, we shall have

$2 AC \times CD = B D^2$ , and  $CD = \frac{B D^2}{2 AC}$ ; *i. e.* the difference between the true and apparent level is equal to the square of the distance between the places divided by the diameter of the earth, or the rise of the apparent above the true level is proportional to the square of the distance. It was for want of the knowledge of this, that the ancients were not able to reduce the apparent level to the true one; and accordingly, to prevent falling into an error, never levelled above twenty feet at once, where such reduction was not necessary.

By the table since made, it appears, that at the distance of 100 yards the apparent level is raised above the true one about one-third of a line; so that the ancients, in this respect, were more scrupulous than needful. By means of this reduction, we are now able to level distances of one or two miles at a single operation, which the ancients could not do in less than three hundred.

The following table, for shewing the height of the apparent level above the true, was calculated by Mr. Ferguson, to the extent of a whole degree of a great circle on the earth's surface, and it agrees so nearly with one of the same sort in Dr. Long's Astronomy, as not to differ quite two inches from it at the end of the whole degree, which contains 60 geographical miles, equal to  $69\frac{1}{2}$  English miles. The use of this table is as follows: If the quantity of an arc of a great circle on the earth's surface is given in minutes or seconds of a degree, its measure may be found in feet and inches. Thus, suppose the arc contains ten seconds, which is the sixth part of a geographical mile, its measure is 101 5 feet 8 inches. So an arc of one minute of a degree, which is one geographical mile, contains 6094 feet, or 2031 yards 1 foot; which is 271 yards 1 foot longer than an English mile. To find how far one can see in a true horizon (as at sea) when the eye is raised to any given height above the horizon: suppose the eye of an observer upon a ship at sea to be 23 feet two inches above the surface of the water, he will then see 30,470 feet all around him, or to the distance of 5 geographical miles.

Suppose.

## LEVELLING.

Suppose the top of a mountain in the sea to be seen at the distance of 60 geographical miles, or one degree, by an observer, whose eye is close at the surface of the sea; the height of that mountain is 3191 feet 1 inch, nearly, above the surface of the sea. An English mile is 5280 feet, a geographical mile 6094.

Suppose a spring to be on one side of a hill, and an house on an opposite hill, with a valley between them; and that the spring seen from the house appears, by a levelling instrument, to be on a level with the foundation of the house, and is a mile from it; the apparent level of the spring is 10 $\frac{1}{2}$  inches above the true level of the house: and this difference would be sufficient for the water to be brought in pipes from the spring to the house; the pipes being laid all the way in the ground.

If the distance of the object be greater than 60 minutes, or geographical miles, its height above the true level may be found thus. Suppose an eye at the surface of the sea sees

the top of a mountain, which he knows to be 90 geographical miles, or a degree and a half distant from him: take half that number of miles, and multiply the height of the apparent level above the true, answering to that half distance, by 4; and the product will give the perpendicular height of that mountain. Thus, the half of 90 is 45, against which (in the table) stands 1794 feet 11,703 inches; which being multiplied by 4, gives 7179 feet 11 inches for the perpendicular height of the mountain above the level of the sea.

According to these measures, the earth's circumference is 131,630,400 feet, or 24,930 English miles.

At the distance of 1 second of a degree (or  $\frac{1}{60}$ th of a geographical mile) the height of the apparent level above the true is .0029547 parts of an inch; at two seconds distance it is four times as much; at three seconds, nine times; at four seconds, 16 times as much; and so on, always increasing in proportion to the square of the distance.

A TABLE, shewing the Height of the apparent Level above the true, at any Distance within a Degree of a great Circle on the Earth's Surface; calculated to the 1000th Part of an Inch.

Ferguson's Tables and Tracts, p. 243, &c. See DEPRESSION of the Horizon.

The operation of levelling is as follows: Suppose the height of the point A (*Plate VII. Surveying, fig. 4.*), on the top of a mountain, above that of the point B, and at the foot thereof, required: place the level about the middle distance, between the two points, as in D, and staves in A and B; and let there be persons instructed with signals for raising and lowering, on the said staves, little marks of paste-board, or other matter. The level being placed horizontally by the bubble, &c. look towards the staff A F, and cause the mark to be lowered, till the middle, upper edge, or other most conspicuous part, appear in the visual ray. Then measuring exactly the perpendicular height of the point E. above the point A, which suppose 6 feet 4 inches, set that down in your book: then turn the level horizontally about, that the eye-glass of the telescope may be still next the eye when you look the other way (if you have only plain sights, the instrument need not be turned); and cause the person at the staff B to raise or lower his mark, till some conspicuous part of it fall in the visual ray, as at C; then measure the perpendicular height of C above B, which suppose 16 feet 8 inches; set this also down in the book above the other number of the first observation; subtract the one from the other, the remainder will be 10 feet 4 inches, which is the difference of level between A and B, or the height of the point A above the point B.

Note, If the point D, where the instrument is fixed, be in the middle between the two points A and B, there will be no necessity for reducing the apparent level to the true

level; the visual ray, in that case, being raised equally above the true level.

If it be farther required to know whether there be a sufficient descent for conveying water from the spring A to the point B, *Plate VII. Surveying, fig. 5.*—Here, in regard the distance from A to B is considerable, it is required that several operations be made. Having then chosen a proper place for the first station, as at I, set up a staff in the point A, near the spring, with a proper mark to slide up and down the staff, as L; and measure the distance from A to I, which suppose 2000 yards. Then the level being adjusted in the point I, let the mark L be raised and lowered till such time as you spy some conspicuous part of it through the telescope, or sights of the level, and measure the height A L, which suppose 13 feet 5 inches. But in regard the distance A I is 2000 yards, you must have recourse to your table for a reduction, subtracting 10 inches 3 lines, which will leave the height A L, 12 feet 6 inches 9 lines; and this note down in your book. Now turn the level horizontally about, so as the eye-glass of the telescope may be towards the staff at A; and fixing up another staff at H, cause the mark G to be moved up and down, till you spy some conspicuous part through the telescope, or sights. Measure the height H G, which suppose 6 yards, 4 feet, 2 inches. Measure likewise the distance of the points I, H, which suppose 1300 yards; for which distance, according to the table, 4 inches 3 lines must be subtracted from the height H G, which, consequently, will but leave 6 yards, 3 feet, 9 inches, 9 lines, to be taken down in your book.

This done, remove the level forwards to some other eminence,

# LEVELLING.

nence, as E, whence the staff H may be viewed; as also another staff at D, near the place whither the water is to be conveyed. The level being again adjusted in the point E, look back to the staff H; and managing the mark as before, the visual ray will give the point F. Measure the height HF, which suppose 11 feet 6 inches. Measure, likewise, the distance HE, which suppose 1000 yards; for which distance the table gives 2 inches, 5 lines of abatement; which being taken from the height HF, there will remain 11 feet, 3 inches, 7 lines, which enter in your book. Lastly, turning the level to look at the next staff D, the visual ray will give the point D. Measure the height of D from the ground, which suppose 8 feet 3 inches. Measure also the distance from the station E to B, which suppose 900 yards; for which distance the table gives 2 inches, 1 line of abatement; which being taken from the height BD, there will remain 8 feet 11 lines, which enter as before.

For the manner of entering down observations in your book, observe, that when a proper place or station for the level, between the two points, has been pitched upon, you must write down the two heights observed at that station in two different columns, *viz.* under the first column, those observed in looking through the telescope when the eye was from the spring, or towards the point, which we may call *back-sights*; and under the second column those observed when the eye was next the spring, which we call *fore-sights*, in the manner following:

Back-sights.		Fore-sights.
feet. inch. line.		feet. inch. line.
First height		Second height
corrected	}	21 : 09 : 9
11 : 3 : 7		Fourth height
Third height	}	8 : 00 : 11
12 : 3 : 7		29 : 10 : 8
23 : 10 : 4		_____

Having summed up the heights of each column separately, subtract the lesser from the greater, the remainder will be the difference of level between the points A and B; as in this example;

feet. inch. line.
29 : 10 : 08
23 : 10 : 04
6 : 00 : 04—The difference of height, or level, between the points A and B.

If the distance of the two points be required, add all the distances measured together; and dividing the difference of height by the yards of the distances; for each 200 yards you will have a descent of about 2 inches 9 lines. This problem may be otherwise solved in the following manner: let the line *fg*, Plate VII. *Surveying*, fig. 6. represent the line of sight of the telescope drawn from *f*, the intersection of the cross-hairs, through *g* the centre of the object-glass; and the points *b*, *b*, be the marks on the glass tube, or spirit-level, *abc*. While these parts of the instrument are immutably fixed, with respect to each other, it is manifest, that as often as the air-bubble is exactly reduced to the marks *b*, *b*, the line of sight will be always reduced to the same position, with respect to the horizon, or to a plumb-line. Now is it at all necessary, in the business of levelling, that the line of sight and plumb-line should be exactly at right angles; but only that the angles they make shall be always the same. Let *p* and *q*, fig. 7, be two given points in two

remote places, and let it be required to find which is the lower, and how much. Let *pa* and *qb* represent two straight staffs, or poles, fixed upright by means of a plumb-line. Having placed the telescope by the side of the pole *pa*, and directed the line of sight to the pole *qb*, alter its elevation by the screw adapted to this purpose, till the air-bubble rests exactly at the marks upon the tube. Then let an alfidant mark the point *b*, which appears to be covered by the cross-hairs; and also the point *a* exactly upon a level with the cross-hairs; which is easily done by a common square applied to the side of the pole *pa*. Then remove the telescope to the pole *bq*, and here let the same things be repeated; that is, let *d* be the place upon a level with the cross-hairs, and *e* the point upon the other pole *pa*, that appears to be covered by them while the air-bubble rests at the same mark as before. Bisect the interval *ac* in *g*, and the interval *bd* in *h*, and the points *g*, *h*, will be upon a level; that is, if we suppose *gpgb* to represent a long canal full of stagnating water, the points *g*, *h*, will both be in its surface; and, consequently, taking the lesser depth *pg* from the greater *qh*, their difference *qr* shews how much the point *q* is below the point *p* or *r*.

If the places *p*, *q*, cannot be seen from each other, or if the difference of their heights be greater than the length of any common poles, then one or more intermediate stations must be chosen; and by repeating the same practice between every two successive stations, we shall find the level of the extremes.

When the points *g*, *h*, are once found upon two poles not far asunder, it will be convenient, by moving the cross-hairs, to rectify the line of sight, so as to be nearly coincident with the line *gh*, or with a line parallel to it, for then in future levellings, at greater distances, the marks *b*, *c*, will be less subject to fall above or below the poles.

This reciprocal way of levelling seems to be the most exact of any, especially if it be performed by two instruments made to agree together before-hand; which may be done by placing them together, and by altering the cross-hairs in either of them, till the same mark upon a remote object is covered by both the crosses, while both the bubbles rest at their marks upon the tubes. Then may two observers find the marks upon the opposite poles at the same time; and, consequently, the refractions of the rays in the air, whatever be their quantities, will be equal as near as possible: and then the result of the practice will be as accurate as if there had been no refractions at all. For let the curve *bias*, fig. 8, represent the course of the visual ray from *b* to *a*; and let the lines *ak*, *bl*, touch it at *a* and *b*. Then, because the points *a*, *b*, are very nearly upon a level, the density and constitution of the air and vapours at the same instant will be nearly the same in each place; and by consequence the curve *aib* and its tangents at *a* and *b*, will be equally inclined to the chord *ab*. For the same reasons the curve *emd* will be similar and equal to the curve *aib*, being situated so very near to it. Therefore, the angle *edn*, under the chord *ed* and tangent *dn*, will be equal to the angle *abl* or *bak*; and, consequently, since the angles *qdn*, *pak*, are made equal in the two observations, by taking away the equal angles *edn*, *bak*, caused by the equal refractions, the remaining angles *qdc*, *pab*, will be equal to each other, as if there were no refractions at all.

If the reciprocal observations be made about the middle of the same day, when the air is the purest, there will scarcely be any occasion for two instruments: but if they be made near the morning or evening, even on the same day, an equality of refractions cannot be depended upon, unless they

## LEVELLING.

are made at the same instant. The members of the Royal Academy of Sciences at Paris tell us, in their Account of the Measure of the Earth, they often found that an object, which at break of day appeared in the level, and sometimes a little above it, did afterwards, when the sun was up, appear below it. And, on the contrary, after the setting of the sun, objects far distant appeared to be raised so sensibly, that in less than half an hour their apparent height was augmented more than three minutes. As to the cause of these appearances, they add, that the coolness of the night condenses the vapours, which descend to a lower place, leaving the air in the higher stations more pure than in the day time. And on the contrary, when the heat of the sun has made a part of the vapours to mount to more elevated stations, there must be less difference of the mediums, and consequently a less refraction.

Setting aside the curvity of a ray, which Mr. Picard tells us is scarcely sensible about noon, when the distance of the object does not exceed 1000 toises, the line of sight through the telescope may be set perpendicular to a plumb-line, or parallel to the horizon, in this manner. Having found two points  $g, h$ , *fig. 9*, upon a level as before, let  $gi$  be perpendicular to  $gc$ , and cut  $cb$  in  $i$ , and having computed the line  $bi$  (as follows), and made a mark at  $i$ , place the level at  $g$ , and alter the place of the cross-hairs in the focus, till they appear to cover the point  $i$ , when the air-bubble is at its marks, and the business is done. Now the line  $bi$  is equal to the square of  $gb$  applied to  $2gc$ , and, consequently, may be found by measuring the distance  $gb$ , and dividing its square by the diameter of the earth, which may be supposed equal to  $2gc$ , though it is not exactly so, the earth being not exactly spherical. For bisecting  $gb$  in  $k$ , draw  $ck$  cutting  $gi$  in  $i$ ; and since the triangles  $kgh, kcg$  are similar, we have  $ki : kg :: kg : kc$ , and by doubling them all, we have  $ki : gb :: gb : 2kc$ . Mr. Picard computes that when the distance  $gb$  is 300 toises, or 1800 Paris feet, the line  $bi$  is one inch: and hence any other  $bi$  may be found for any other known distance; it being as the square of the distance  $gb$ .

Hence, when the instrument is thus rectified, the point  $b$  upon the level with  $g$ , may be found by one observation; that is, by marking the point  $i$  covered by the cross-hairs, and by computing  $ib$  by the rule above. As the intervals between the stations must be but small in this method, because of refractions, as was said above, the readiest way is to make them all equal; which may be known exact enough for this purpose, by observing whether the pole be removed to such a distance, that its image (or the image of any given part of it) in the focus of the telescope shall be always of the same length, being measured by the distance between two parallel hairs in the focus: and then the same allowance must always be made for the depth of the point  $b$  below  $i$ .

Lastly, by means of these parallel hairs, it is easy to find when the telescope is placed in the middle between two stations; and then the points upon a level at each pole are presently found, by directing the telescope first to one pole and then to the other, and by marking the points covered by the cross-hairs. And these points will be upon a level, notwithstanding any refractions of the visual rays, because the refraction of each ray will be equal. Smith's Optics, book iii. chap. 14.

Dr. Halley suggests a new method of levelling, which has been put in practice by some of the French academy: this is performed wholly by means of the barometer, in which the mercury is found to be suspended to so much the less height as the place is farther remote from the

centre of the earth. Hence it follows, that the different heights of the mercury, in two places, give the difference of level.

Mr. Derham, from some observations he made at the top and bottom of the Monument, found that the mercury fell one-tenth of an inch at every 82 feet of perpendicular ascent, when the mercury was at 30 inches. Dr. Halley allows of one-tenth of an inch for every 30 yards; which, considering how accurately the barometers are now made, an inch, in some of them, being divided into an hundred, or more parts, all very feasible, he thinks this method sufficiently exact to take the levels for the conveyance of water, and less liable to errors than the common levels.

The same author found a difference of three inches eight-tenths, between the height of the mercury at the top and bottom of Snowdon-hill, in Wales.

Mr. Ferguson has calculated the following table, for shewing how much the mercury would sink in a barometer at given heights above the earth's plane surface; and consequently, how the perpendicular height of any hill may be found thereby.

By this table, and a common barometer tube, the perpendicular height of any hill may be found in the following manner.

The lower end of the tube being immersed in quicksilver in the common way, and the tube fixed to a board, let a scale, eighteen inches in length, be divided into inches, and each inch into a hundred equal parts, by diagonal lines, the divisions to be numbered downward from the top. This scale must be made to slide in a groove on the board, and have a cross index to slide upon it to any division.

Then, at the bottom or foot of the hill, place the scale so as the beginning of the divisions at its top may be just even with the top or surface of the mercury in the tube. This done, carry the machine up to the top of the hill; then set the index to the surface of the mercury, and it will shew how much the mercury has sunk in the tube, at the top of the hill, from the point where it stood when at the bottom; and the number of feet expressed in the table, against the like sinking of the mercury, will be the perpendicular height of the hill.

Thus, supposing the mercury had sunk eight inches and three hundredths part of an inch, the height of the hill must be 8500 feet, or a mile, and somewhat more than a quarter. Proportionable allowance is easily made for intermediate heights in the table, which are only to whole hundredths of feet.

As Mr. Derham found the difference of height of the mercury at the bottom and top of Snowdon-hill, in Wales, to be three inches eight-tenths (the same as three inches eighty hundredths) it shews, that the height of that hill is 3700 feet, or almost three quarters of a mile.

N. B. 660 feet make an eighth part of a mile, 1320 feet a quarter of a mile, 2640 feet half a mile, 3960 feet three quarters of a mile, and 5280 feet make a whole mile. See **BAROMETER and ATMOSPHERE.**

For the common occasion of levelling to be performed, without much apparatus of instruments, time, or trouble,

the following method may serve: set a pole upright in a spring, pond, river, or other place, whence water is to be brought, and mark how many feet and inches are above water. Then set up another pole, of equal length with the other, in the place to which the water is to come. Place the centre of a quadrant on the top of this last pole, the plummet hanging freely; spy through the sights the top of the pole that is in the water, and if the thread cuts any degree of the quadrant, the water may be conveyed by a pipe laid in the earth. If you cannot see from one extreme to the other, the operation may be repeated in the manner already directed.

**LEVELLING Staves**, are instruments used in levelling; serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist each of two long square wooden rulers, made to slide over one another, and divided into feet, inches, &c.

The levelling staff is represented in *Plate VII. Surveying*, fig. 10. It is composed of two pieces which slide on each other, as *aa* and *bb*: they are each of about five feet in length, so as to form, when fully extended; a rod of ten feet. They have a graduated line of feet into hundredth parts. The index, *c*, slides firmly on them; and is moved up or down (by signal) by the attendant who carries the staff, till the observer finds it coincide with the intersecting wires of his telescope. Its height on the staff, of course, marks the difference of the level; and it has two horizontal and parallel black stripes, which, at considerable distances, are of use to direct the eye more readily to the fiducial edge at *x*.

With regard to the manner of directing its application in the business of draining, it has been observed, that after it has been properly adjusted, and the staff about ten feet in length, with the moveable vane or sight, has been affixed to it, the instrument should be set up in a situation between the object from whence the level is to be taken, and that to which it is to be directed, provided the distance from the instrument to each of them is not too great. The situation of it should also be no higher than the length of the staff will answer, and so as it may be seen from it both ways; then the man with the staff should be directed to hold it at the main spring, or place from whence you mean to carry the drain; and after directing the telescope to the staff, and adjusting it to a level, make a sign to him to move the sight up or down, till it be exactly opposite the cross-hair in the telescope. This done, without shifting the instrument from its first position, and cautioning the man to fix the sight to the staff at the point directed, he may proceed forty or fifty yards farther; and after having again adjusted the level, make a sign to him to move to higher or lower ground, till the sight on the staff coincide exactly with the cross-hair or wire on the telescope. He may then leave a peg at the place where he held the staff, and proceed in like manner to other stations, till the whole line is finished; leaving pegs, or making pits, at the places where the staff is held during the operation.

But if the length of the line to be levelled requires the instrument to be shifted from its first position, the level must again be taken from the last station where the staff was held, and the sight on it fixed in the proper place, as before directed; proceeding in the same manner at every forty or fifty yards in length, till the whole is accomplished. After the line is thus levelled, and ascertained by marks left at every station where the staff was fixed, it may again be examined, and other pegs put in between the first, the better to direct the workmen in cutting the drain; giving the line

such turnings, and even small deviations from the course of the level, as may shorten or straighten it, and humour the situation of the ground. And for the sake of accuracy, where the work requires it, especially if the water is to be conveyed to any considerable distance, or wanted to supply a house, or for the purpose of irrigation, the levels may be proved by reversing the former line of direction. The spirit level is also necessary for ascertaining how much fall can be obtained from the drain to the nearest outlet where the water can be discharged; the shorter that distance the better, provided fall enough can be gotten. It is often necessary to level a much longer distance than the length of the drain may require to be cut, in order to come at the true level.

**LEVELLING of Land, in Agriculture,** the method of filling up the holes, hollows, or other depressions and inequalities that are met with in lands, whether they are in the state of fward, or in that of tillage. It should always be performed in such a manner, as the parts thus filled up may at first be somewhat higher than the common surface round them, in order to allow for the settling, which necessarily takes place; and should be done with such materials as can be most conveniently procured, and which are proper for the purpose, being filled in an even and regular manner, and well trodden down at the time. The ridges of such lands as have been long under the plough also sometimes require to be levelled down, the proper methods of doing which, under different circumstances, will be taken notice of under that head. Care is, however, constantly to be taken in the execution of this sort of business. See **RIDGE**.

**LEVELLING Poles,** long wooden rulers, divided into feet and inches, made to slide over each other, serving to carry the marks to be observed in levelling, as well as to measure the heights from the surface of the ground. They are likewise termed staves occasionally. See **LEVELLING Staves**, *supra*.

**LEVEN, in Natural History,** a term used by Boccone for the milky juice contained in the globules placed at the tops of the stalks of red coral. These round buttons are the only part of the coral which are soft while under water, and from these the milky juice is easily expressed by a gentle squeezing between the fingers. The globules are each made up of five or six little cells, not communicating with one another, and each containing its own separate quantity of this white and thick fluid. When the coral is newly taken up out of the sea, this juice is of a sharp, acrimonious, and astringent taste; but when it has been some time exposed to the air, it loses the acrimony, and the astringency of the taste only remains. This change in the taste is made in six or eight hours, in hot weather, and the juice, in the same time, loses its colour and consistence, growing hard and brown. Philof. Transf. N 100.

**LEUENFIORDE, in Geography,** a town of Westphalia, in the principality of Calenberg, on the Weser; 25 miles W.N.W. of Gottingen.

**LEVENHOOKIA, in Botany,** named in memory of the celebrated microscopic philosopher Anthony Van Leeuwenhoek, whose works, as Mr. Brown observes, abound with excellent observations on the structure of vegetables. Brown. Prodr. Nov. Holl. v. 1. 572.—Class and order, *Gynandria Diandria*. Nat. Ord. *Sylidæ*, Brown.

Eff. Ch. Calyx superior, two-lipped, in five deep segments; the fifth (or lip) unlike the rest, vaulted, longer than the column, articulated with the tube, and moveable. Column erect, attached below, like the lip, to the side of the tube. Lobes of the anthers one above the other, divaricated. Stigmas two, capillary. Capsule of one cell.

*L. pusilla*, the only known species, found on the southern coast of New Holland by Mr. Brown. A little smooth herb, with nearly the aspect and stature of *Radiola*. Leaves alternate, stalked; those about the tops of the branches crowded, intermixed with clustered flowers. The moveable joint of the lip is analogous to the irritability in the column of *Styidium*, and answers the same end, which is the preservation of the organs of impregnation; for this lip, which is deflexed in the expanded flower, when affected by any irritating cause, is turned upwards with violence, so as to cover the upright and immoveable column with its concave part. Brown.

**LEVENS, LEVA, or Levenez,** a town of Hungary, near the river Gran, where the Turks were defeated, after a desperate engagement, in the year 1664, with the loss of 12,000 men killed, and 1500 taken prisoners, with their artillery, &c.; 24 miles N.N.E. of Gran.

**LEVENTAN,** a lake of Prussia; 56 miles S.E. of Konigsberg.

**LEVENTI.** See **LAWEND**.

**LEVER, Sir ASHTON, in Biography,** was the son of sir D'Arcy Lever of Alkington, near Manchester. He finished his education at Corpus Christi college, Oxford; and on leaving the university he went to reside with his mother, and afterwards settled at his family-seat, which he rendered famous by the best aviary in the kingdom. He next extended his views to all branches of natural history, and became at length possessed of one of the finest museums in the world, sparing no expence in procuring specimens from the most distant regions. This museum was disposed of by lottery in 1785, but to the great loss of the proprietor. It was, for some years after this, exhibited to the public at a small charge, but is now dispersed, the articles having been sold separately by auction. Sir Ashton died in 1783. Europ. Mag.

**LEVER, or Leaver, in Mechanics,** an inflexible straight bar, supported, in a single point, on a fulcrum, or prop, and used for the raising of weights.

The word is formed of the French *levier*, which signifies the same; formed of the verb *lever*, or Latin *levare*, to raise.

The lever is the first of those called mechanical powers, or simple machines, as being, of all such, the most simple; and is chiefly applied for raising weights to small heights.

In a lever there are three things considered: the weight to be raised, or sustained, as O, *Plate XXX. Mechanics, fig. 4*; the power by which it is to be raised, or sustained, as B; and the fulcrum, or prop, D, on which the lever is sustained, or rather on which it moves round, the fulcrum remaining fixed.

Levers are of three kinds: sometimes the fulcrum, or centre of motion, is placed between the weight and the power, as in *fig. 4*. This we call a *lever of the first kind*, or *velis heterodromus*; to which may be reduced leissars, pinners, snuffers, &c. Sometimes the weight is between the fulcrum and the power, which is called a *lever of the second kind*, as in *fig. 5*. Of this kind are the oars and rudder of a boat, the masts of ships, cutting knives fixed at one end, and doors whose hinges are as the fixed point. And sometimes the power acts between the weight and the fulcrum, which is the *lever of the third kind*. Such is a ladder lifted by the middle to rear it up against a wall: these two are called *velis homodromi*.

In this last, the power must exceed the weight in proportion as its distance from the centre of motion is less than the distance of the centre from the weight. And as the first two kinds of lever serve for producing a slow motion by a swift one, so the last serves for producing a swift motion of the

the weight by a slow motion of the power. It is by this kind of levers that the muscular motions of animals are performed, the muscles being inserted much nearer to the centre of motion than the point where the centre of gravity of the weight to be raised is applied; so that the power of the muscle is many times greater than the weight which it is able to sustain. Though this may appear at first a disadvantage to animals, because it makes their strength less: it is, however, the effect of excellent contrivance; for if the power was, in this case, applied at a greater distance than the weight, the figure of animals would be not only awkward and ugly, but altogether unfit for motion; as Borelli has shewn in his treatise "De Motu Animalium." The power of the lever is founded on the following theorem; *viz.* "That the space, or arc, described by each point of a lever, and consequently the velocity of each point of a lever, is as its distance from the fulcrum, or prop."

From hence it follows, that the action of a power, and the resistance of the weight, increase in proportion to their distance from the fulcrum.

And hence also it follows, that a power will be able to sustain a weight, if the distance of the point in the lever, to which it is applied, be to the distance of the weight, as the weight to the intensity of the power; which, if it be ever so little increased, must raise the weight. See this doctrine demonstrated under the word *Mechanic Powers*; and farther illustrated under the word *BALANCE*; between which and the lever there is a great analogy; a lever of the first kind being a sort of steelyard to raise weights.

The power and action of the lever will be fully illustrated by the following propositions:

1. If the power applied to a lever of any kind sustain a weight, the power is to the weight in a reciprocal ratio of their distances from the fulcrum.

2. The weight of a lever of the first or second kind,  $A, B$ , *fig. 4*, the distance of the centre of gravity from the fulcrum  $C, V$ , and the distances of the weight, and the power  $A, C$  and  $C, B$ , being all given, to find the power that will sustain it. Suppose the lever void of gravity, but in lieu thereof a weight hung at  $V$ ; if then  $A, C$  be made to  $C, V$ , as the gravity of the lever to a fourth number, we shall have the weight which the lever is able to sustain; and this subtracted from the given weight, the remainder will be the weight to be sustained by the power. Let  $C, B$  then be to  $C, A$ , as the remaining weight to a fourth weight, and we shall have the power to be applied in  $B$ , in order to sustain the given weight with the given lever.

3. The gravity of a lever of the first or second kind,  $A, B$ , the distance of the centre of gravity from the fulcrum  $C, V$ , the distances of the power, and the weight  $B, C$  and  $C, A$ , being all given, to find the weight to be sustained. Find the part of the weight sustained by the lever alone, as in the former problem: in the same manner find the other part of the weight, which the power applied in  $B$  is able to sustain; add the two numbers together, and the sum is the weight required.

4. The gravity, and centre of gravity  $F$ , of a lever of the second kind  $C, B$ , *fig. 5*, with the weight  $G$ , its distance from the fulcrum  $C, A$ , and from the power  $C, B$ , being given, to find the power capable of sustaining the weight. Suppose the lever void of gravity, but in lieu thereof a weight equal thereto hung in  $F$ , the power required to sustain the lever alone; then find the power requisite to sustain the given weight  $G$ ; add the powers together, and the sum will be the power required.

5. If a power applied to a lever of any kind lift a weight, the space of the first is to that of the last, as is this last to a

power able to sustain the same weight; whence it follows, that the gain of force is always attended with the loss of time, and *vice versa*.

When the two arms of a lever are not in a right line, but contain any invariable angle at  $C$ , *fig. 6*, the lever is called a bended lever; and is evidently of the first kind, and the law of the equilibrium is the same; *i. e.* if the power  $P$  be applied at  $B$  to the arm  $C, B$ , and the weight  $W$  acts by means of a pulley  $M$ , in the direction  $A, M$ , perpendicular to the arm  $A, C$ , the power and weight will sustain each other, if  $P$  be to  $W$ , as  $C, A$  to  $C, B$ , or  $P \times C, B = W \times C, A$ . If several powers act upon the arm  $C, A$ , find their centre of gravity,  $A$ , on the arm  $C, A$ , and suppose all the powers to be united there; and if the power  $P$  be to their sum as  $C, A$  to  $C, B$ , it will sustain them. The sum of the powers being given, it is manifest that the farther their centre of gravity  $A$  is removed from the centre of motion  $C$ , the greater resistance they will oppose against the power  $P$ , and it will require the greater force in the power to overcome them. Hence Galileo justly concludes, that the bones of animals are the stronger for their being hollow, their weight being given; or if the arm  $C, B, F$  represents their length, the circle  $C, H, D$  a section perpendicular to the length  $P$ , any power applied along their length, tending to break them; then the strength or force of all their longitudinal fibres, by which the adhesion of the parts is preserved, may be conceived to be united in  $A$ , the centre of the circle  $C, H, D$ , which is the common centre of gravity of those forces, whether the section be a circle or annulus. But it is plain that when the area of the section, or the number of such fibres is given, the distance  $C, A$  is greater when the section is an annulus than when it is a circle without any cavity: consequently the power with which the parts adhere, and which resists against  $P$ , that endeavours to separate them, is greater in the same proportion. For the same reason, the stalks of corn, the feathers of fowls, and hollow spears, are less liable to accidents that tend to break them, than if they were of the same weight and length, but solid, without any cavity. In this instance, says Mr. Maclaurin, (View of Sir. I. Newton's Phil. Disc. book ii. chap. 3. § 13.) art only imitates the wisdom of nature. See *MECHANICAL Powers*.

*LEVER, or Vesicis, in Midwifery*, an instrument used to facilitate the birth of the head of the child, when it remains long fixed in the brim of the pelvis of the mother. It is usually called the lever of Roonhuysen, the name of a surgeon of Amsterdam, who has the credit of having invented, or first made use of it. Roonhuysen is said to have been instructed by Dr. Hugh Chamberlen in the method of using the *forceps*, (see that article,) for which he paid him a considerable sum of money: but finding, in many cases, great difficulty in introducing the second blade of the forceps, he confined himself to the use of a single blade; and procuring an instrument to be made upon that principle, he called it his lever. Ruyfch was also said to participate with him in the use of this new contrivance. It was for a long time applied with great caution, and only shewn to such of their pupils as paid them a specific sum for the purpose. At length De Vischer and Van de Poll, two physicians of Amsterdam, purchased the secret of a descendant of Roonhuysen, and published a description of the instrument, and of the manner of using it, in the Dutch language. This account was, many years after, translated into French by M. Preville, and affixed to his translation of Smellie's Treatise of Midwifery, to which he added an engraving of the instrument.

The lever is a flat piece of iron, twelve inches in length,

one inch in breadth, and a quarter of an inch in thickness. It is straight in the middle for four inches, and moderately curved at each end. (See *Plate Surgery*.) In using it, one or two fingers of the right hand (the woman lying on her left side, as in a natural labour) must be introduced under the pubes, and so far, if practicable, as to reach an ear of the child, when the lever is to be slowly and gradually insinuated between the fingers and the head of the child. The fingers are now to be withdrawn, and the handle of the lever to be raised towards the belly of the woman, and gently moved about, until the head of the child is lodged in its curve. The more completely the curve touches and embraces the head of the child, the more speedily and easily the delivery will be effected. During every pain, the handle of the lever must be raised with the right hand, and its middle pressed down with the left hand. This will prevent the soft parts of the woman covering the os pubis from being injured. When by this means the head of the child has been made to descend into the vagina, the left hand must be removed from the middle of the instrument, and applied over the anus and the perineum, to guard those parts, (which will be found to be much distended,) and to prevent their being lacerated; for which purpose, also, the whole of the operation (which will usually be completed within between ten and twenty minutes) must be performed slowly and cautiously, imitating as much as possible a natural labour.

For further information on this subject, see Dr. Bland's Account of the Invention and Use of the Lever, published in the second volume of Medical Communications, 1790.

LEVERANO, in *Geography*, a town of Naples, in the province of Oranto; 7 miles N. of Nardo.

LEVERET, amongst *Sportsmen*, a young hare, in the first year of its age.

LEVERETT, in *Geography*, a township of America, in Hampshire county, Massachusetts, near Connecticut river; 94 miles W. from Boston; incorporated in 1774, and containing 711 inhabitants. A copper-mine has been lately discovered in this township.

LEVERIDGE, RICHARD, in *Biography*, was a singer of Purcell's songs, in the time of Charles II. and in that of William and Mary. During the reign of queen Anne, he performed in 1706 the part of Sir Truitt, in Addison's *Rofamond*; and in the first attempts at opera on the Italian model, he sung his part in English, in Camilla and Thomyris; while Nicolini, Valentini, and the Margarita, performed their parts in Italian.

He had a deep and powerful base voice; was a useful performer on the English stage on many occasions, particularly at Covent Garden, where he attached himself to Rich, and his pantomime entertainments, to the end of his life. He was not, however, without genius for poetry and composition, as far as a ballad went. We remember his singing one written and set by himself, "Ghosts of every Occupation," and several of Purcell's base songs occasionally, which, fifty years ago, seemed antediluvian; but as he generally was the representative of Pluto, Neptune, or some ancient divinity, it corresponded perfectly with his figure and character. As he was not only a celebrated singer of convivial songs, but the writer of many that were in great favour with singers and hearers of a certain class, who more piously performed the rites of Comus and Bacchus than those of Minerva and Apollo, he had always a crowded house at his benefit; nor did he leave this subliminary world, or the stage, till 1758, at 88 years of age.

LEVET, in *Geography*, a town of France, in the de-

partment of the Cher, and chief place of a canton, in the district of Bourges; 6 miles S. of Bourges. The place contains 645, and the canton 5263 inhabitants, on a territory of 2324 kilometres, in 16 communes.

LEVI, BEN-GERSHOM, in *Biography*, a learned rabbi, who flourished in the fourteenth century, was born in Provence about the year 1290. His celebrity is founded chiefly on his philosophical and theological writings. He was a disciple of Aristotle, and philosophizes in the spirit of his master, when discussing subjects of sacred literature. He died in 1370, when he was 80 years of age. He was author of "Commentaries" on all the books of the Old Testament, of which some are inserted in the great bibles of Venice and Basil; and others were separately printed at Pesaro, Venice, and Paris. He was author of a philosophical work, entitled "Millemot Hachem," or "The Battles of the Lord," divided into treatises on the immortality of the soul, the knowledge of future events, prophecy, the interpretation of dreams, the omniscience of God, &c.; and of various other treatises, which were formerly preserved in MS. in the Vatican library, and in that belonging to the congregation of the fathers of the oratory at Paris.

LEVI, *Ile du Fort*, in *Geography*, an island in the river St. Lawrence, Upper Canada, in front of the township of Edwardburg. On this island are the ruins of a French fortification.

LEVIEION, a town of Persia, in the province of Irak; 36 miles S.W. of Isfahan.

LEVIER, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Pontarlier; 10 miles W. of Pontarlier. The place contains 1065, and the canton 7727 inhabitants, on a territory of 310 kilometres, in 15 communes.

LEVIGATION, the reduction of hard and ponderous bodies, as coral, tutty, precious stones, &c. into a fine subtil powder, by grinding them with water upon porphyry, or the like, as painters do their colours.

Levigation is much used in pharmacy and chemistry; but unless the grinding instruments be extremely hard, they will wear away, so as sometimes to double the weight of the medicine thus managed.

LEVIRATE, in the *Jewish Customs*, a term used by authors who have written on the law and customs of the Jews, to denote particularly that law of Moses, which obliges one brother to marry the widow of another, who died without children, to raise up seed to him.

The word is derived from *levir*, which signifies, in Latin, the husband's brother, or the brother-in-law; and the word levirate has been hence formed, to express the law whereof we have been speaking.

This law, which is an exception to that which condemns marriages between brothers and sisters, and between brothers-in-law and sisters-in-law, seems to have been in use among the Hebrews and Canaanites before the time of Moses; since Judah gave his first-born Er, and Onan his second son, successively to Tamar, and obliges himself to give her likewise to Sela his third son. Calm. Dict. Bibl.

LEVISANUS, in *Botany*, a name given by Petiver, who wrote it *Levisianus*, in honour of the Rev. Dr. Lewis, who sent him several plants as well as shells from Madras. The Cape shrub to which this appellation was given, having been referred by Linnæus at one time to *Brunia*, at another to *Protea*, is now *Leucadendron Levisianus*, Brown Tr. of Linn. Soc. v. 10. 55. (See *LEUCADENDRON*.) Schreber in his Gen. Pl. 149, established another *Levisianus* out of  
*Brunia*;

*Bruria*; but this is now *Stavia* of Willdenow, Sp. Pl. v. 1. 1144, a name which we presume will remain.

LEVITA, in *Geography*, an island in the Grecian Archipelago, about eight miles in circumference. N. lat. 37°. E. long. 26° 14'.

LEVITE, an inferior kind of minister in the Jewish tabernacle and temple, who had the care and management of the sacred utensils.

The word comes from the Greek *λειυτης*, the root of which is the name *Levi*; which was given to that patriarch by his mother Leah, from the Hebrew *לוי*, *lavah*, *to be tied*, or *united*; Leah hoping, by the birth of this son, to be more closely linked to her husband Jacob; and, therefore, in a large sense, the Levites were the posterity of this patriarch, and constituted one of the twelve tribes of Israel. In a more restrained and peculiar sense, they were a lower order of ecclesiastical persons, inferior to the priests, and their assistants in the sacred service. The sons of Levi were appointed to this office, in consequence of the extraordinary zeal they discovered against idolatry, in the case of the golden calf. Exod. xxxiii. 26. 28.

When God miraculously destroyed all the first born of the Egyptians (Exod. xii. 29.), he spared the first born of the Israelites; and in order to preserve the remembrance of the miracle, and of that great deliverance from his bondage in Egypt, which that miracle occasioned, he was pleased to appoint that for the future all the first-born males "should be set apart unto himself." (Exod. xiii. 12. 16. Numb. viii. 17.) But afterwards, on the occasion above mentioned, the whole tribe of Levi had the honour assigned them, instead of the first-born of Israel. And that it might appear there was a just substitution of the Levites for the first-born, number for number, he ordered an estimate to be made of both; and when, on casting up the poll, the first-born were found to exceed the Levites by 273, the surplus was redeemed at the price of five shekels a head, which was paid to the priests for the use of the sanctuary. (Numb. iii. 14, ad fin.) We may here observe, as a circumstance worthy of notice, that the posterity of Moses were no more than common Levites, while the descendants of his brother Aaron were advanced, by the appointment of his law, to the dignity of the priesthood. (1 Chron. xxiii. 13, 14.) This is a plain evidence that Moses was not influenced by any worldly or ambitious views, or rather that he was not the contriver and author of the law which he gave to Israel, but received it from God: for if he had framed it, it is natural to suppose that he would have made some better provision than he did for his sons, and for the grandeur of his house, and not have advanced his brother's above his own.

The Levites were originally divided into three classes, or families, from the three sons of Levi, Kohath, Gerson, and Merari; but afterwards by David into twenty-four courses. 1 Chron. xxiii. 6. ch. xxviii. 11—13.

The Levites, in the Jewish church, were an order inferior to the priests; and answered, in some measure, to deacons, in the Christian church. On their first institution, a great part of the service that was assigned them was peculiar to the state of the Israelites at that time; and it was servile and laborious. But when they were settled in the land of Canaan, and the tabernacle was no longer carried about as before, the service of the Levites was, of course, changed, and became much more easy. On which account, in the time of David, they were thought fit to enter on their office at the age of 20 years; whereas, by the original appointment of Moses, they were not admitted till they were 25 or 30 years of age, and were discharged at 50. (Numb.

iv. 3. 13. 43. ch. viii. 24, 25.) It is an opinion among the Jews, that the Levites passed through four different degrees. From one month old to their twentieth year they were instructed in the law of God; from twenty to twenty-five, in the functions of their ministry; from that period to thirty, they served a kind of apprenticeship, beginning to exercise themselves in some of the lower branches of the sacred service; and lastly, when they attained their thirtieth year, they were fully instituted in their office. A similar gradation, probably borrowed from that of the Jewish Levites, has been observed among the vestal virgins; and some have supposed that this gradation is referred to by the apostle, when he tells Timothy, that they who perform the office of a deacon well purchase to themselves a good degree, *καλον βεδμουν*. 1 Tim. iiii. 13.

We have already observed, that the Levites were originally distributed into three families; and in David's time, they were distinguished into three classes, to each of which a different service was assigned; and probably each was divided into twenty-four courses. The first class was appointed to assist the priests in the exercise of their ministry; the second class formed the temple choir; the third class had the charge of the several gates of the courts of the sanctuary assigned them by lot. (1 Chron. xxvi. i. 15. 19. 2 Chron. xxxv. 15. viii. 14.) The Levites exercised the office of magistrates, which office belonged to them, not as Levites, but as persons who generally addicted themselves more to the study of the law, and had more leisure to attend on the duties of the magistracy, than others who were employed in secular business. The magistrates of different ranks, both the "shophetim" and "shoterim," were very generally, though not always, chosen out of the tribe of Levi. Thus the prophetic curse, denounced by Jacob against Levi, (Gen. xlix. 7.) was remarkably accomplished, (though in effect converted into a blessing,) not only in respect to the appointment of their habitation, but likewise of their offices and employments; more of them, than perhaps of all the tribes taken collectively, being officers and judges throughout the whole country; and probably, as the rabbies tell us, some of them were generally directors of their seminaries of learning. Of the consecration of the Levites, and of the ceremonies attending it, we have an account in Numb. viii. 10, 11.

As to the residence and subsistence of the Levites, we may observe that they had no settled lands allotted them for their maintenance, as the other tribes had, but lived chiefly on the offerings made to God. (Deut. xxiii. 1, 2.) They were distributed through all the tribes, each of which gave some of their cities to the Levites, amounting in all to the number of thirty-five, with grounds in their neighbourhood for the subsistence of their flocks. (Numb. xxxv. 4, 5.) In the weeks of their attendance at the sanctuary, they were maintained by the dues arising from the sacrifices; besides these dues, the first fruits, which were brought to the temple, and the money paid for the redemption of the first-born, contributed to their subsistence. But, when they were out of waiting, their maintenance partly arose from the glebes belonging to their cities, and chiefly from the tithes of the produce of the whole country, which the law allotted to the tribe of Levi, (Numb. xviii. 21.) a tenth of which they paid to the priests. See *TITHE*.

According to the numeration made by Solomon, from the age of twenty there were thirty-eight thousand Levites capable of serving; twenty-four thousand of these he appointed for the daily ministry under the priests; six thousand to be inferior judges in the cities, and to decide matters relating

lating to religion, and of no great consequence to the fate; four thousand to be door-keepers, and to take care of the riches of the temple; and the rest to do the office of chantors, or singers.

**LEVITICAL DEGREES**, in *Law*. See **MARRIAGE**.

**LEVITICI**, in *Church History*, a sect of heretics, who sprung from the Gnostics and Nicolaitans.

**LEVITICUS**, a canonical book of the Old Testament, so called from its containing the laws and regulations relating to the priests, Levites, and sacrifice. See **CANON** and **PENTATEUCH**.

**LEVITY**, the privation or want of weight in any body, when compared with another that is heavier.

In which sense, levity stands opposed to gravity.

The schools maintain, that there is such a thing as *positive* and *absolute* levity, and impute to this the rise or emergency of bodies lighter in specie than the bodies wherein they rise.

But we find by experience, that all bodies tend towards the earth, some slower, and some faster, in all fluids, or mediums, whether water, air, &c. Thus, cork is only said to be lighter than gold, because, under equal dimensions, the gold will sink in, and the cork swim upon water.

Archimedes has demonstrated, that a solid body will float any where in a fluid of the same specific gravity; and that a lighter body will keep above a heavier. The reason is, that of bodies falling towards the earth, those which have a like number of equal parts, have equal gravity; since the gravity of the whole is the sum of the gravity of all its parts. Now two bodies have an equal number of equal parts, if under the same dimensions there be no intervals destitute of matter; whence it follows, that as no portion of matter is so small, but that the body wherein it is contained may be wholly divided into parts equally small, there can be no reason for the descent of these, which will not equally hold for the descent of that.

Hence it may be concluded, that those bodies which do not equally gravitate under the same dimensions, do not contain equal portions of matter; and, therefore, when we see, that a cube of gold subsides in water, at the same time that an equal bulk of cork swims upon it, it is evident, that the gold must have a greater number of equal parts of matter, under the same bulk, than the cork; or the cork must have a greater number of vacancies than the gold; and that there is also in the water a greater number of vacancies than in gold. See **FLUIDS**, and *Specific GRAVITY*.

Hence we have a clear idea both of *density* or gravity, and of *levity*; and know, that the latter cannot, in a strict sense, be accounted any thing positive, but only a mere negation or absence of body; which determines that body to be lighter than another which contains more matter.

Dr. Hook, it is true, seems to maintain something like a positive levity; which, if we mistake not, is what he means by the term *levitation*; viz. a property of bodies directly contrary to that of gravitation towards the sun.

This, he thinks, he has discovered in the streams of several comets; which, though they had a descent from the nucleus of the comet towards the sun, yet they quickly returned, and went opposite to the sun, and that to a prodigious extent. In effect, where the power of gravitation ceases, it should seem force such contrary force does begin; whereof we have instances in the phenomena of attraction. This is what sir Isaac Newton calls the *vis repellens*, and appears to be one of the laws of nature; without which it would be hard to account for rarefaction, and some other appearances.

**LEVIZANO**, in *Geography*, a town of Italy, in the department of the Panaro; six miles S.E. of Modena.

**LEUK**, a small town of Switzerland, built upon an eminence about a mile from the Rhine, and the principal place of one of the dixains of the Vallais; containing two churches and a large palace of the bishops of Sion. At the distance of six miles N. are celebrated baths, said to be beneficial in rheumatism, diseases of the skin, &c. and to resemble those of Bath. Here are several springs of different warmth and of different qualities. According to accurate experiments, the mercury in Fahrenheit's thermometer, when plunged into the principal source, stood at 115, and at 120 in the spring which flows near the bridge over the Dola. Leuk is distant 20 miles E. from Sion.

**LEVKOPOL**, a town of Russia, in the province of Tauris; 80 miles S. of Perekop. N. lat. 45° 6'. E. long. 34° 24'.

**LEUNCLAVIUS**, JOHN, in *Biography*, an eminent man of letters in the seventeenth century, son of a gentleman of Westphalia, was brought up to the profession of the law, with which science he was intimately acquainted, as well as with literature in general. He was a great traveller, and resided a considerable time in Turkey. He died at Vienna in 1693, about the 60th year of his age. From his knowledge of the Turkish language he was enabled to collect some valuable materials for the history of that nation, which he published under the title of "Historiæ Mullimanicæ Turcarum," and his "Annales Turcici cum Supplemento et Pandectis Hist. Turcicæ." His intimate knowledge of the Greek language was displayed in several Latin translations of Greek authors, viz. Xenophon, Zozimus, the annals of Constantine Manasses, and of Michael Glycas; the Greek abridgment of the sixty books of Roman law; various works of St. Gregory of Nazianzen, &c. Bayle.

**LEVONOVK**, in *Geography*, a town of Russia, in the government of Irkutsk, on the Lena; 52 miles S.W. of Kirensk.

**LEUPOLD**, JAMES, in *Biography*, a very celebrated mechanician, and noted for his construction of mathematical instruments, and other machines for the elucidation of facts in philosophy, was commissary of mines to the king of Poland, and a member of the Royal Society of Berlin, and other scientific bodies. He died at Leipzig in 1727, after having acquired celebrity by the publication of a work, which is still highly esteemed, entitled "Theatrum Machinarum," in three vols. folio.

**LEVRET**, ANDREW, an eminent French surgeon and accoucheur, was admitted a member of the Royal Academy of Surgery at Paris in February, 1742. He obtained a high and extensive reputation in his department of the art, by the improvements which he made in some of the instruments necessary to be employed in certain difficult cases, (especially the forceps,) and by the prodigious number of pupils whom he instructed. He was employed and honoured with official appointments by all the female branches of the royal family. He published several works, which underwent various editions and translations. "Observations sur les causes et les accidens de plusieurs accouchemens laborieux," Paris, 1747. To the fourth edition, in 1770, were added, "Observations on the lever of Roonhuyfen." "Observations sur la cure radicale de plusieurs polypes de la matrice, de la gorge, et du nez, opérée par de nouveaux moyens," ibid. 1749, &c. "Suite des observations sur les causes et les accidens de plusieurs accouchemens laborieux," ibid. 1751. "Explication de plusieurs figures sur le mécanisme, de la grossesse et de l'accouchement," ibid. 1752. "L'Art des accouchemens démontré par des principes de physique

physique et de mécanique," *ibid.* 1753, &c. "Essai sur l'abus des règles générales, et contre les préjugés qui s'opposent aux progrès de l'art des accouchemens," *ibid.* 1766. Eloy Diët. Hill.

LEVROUX, in *Geography*, a town of France, in the département of the Indre, and chief place of a canton, in the district of Chateauroux; 10 miles N. of Chateauroux. The place contains 2800, and the canton 8904 inhabitants, on a territory of 552½ kilometres, in 15 communes. N. lat. 46° 59'. E. long. 1° 41'.

LEUSDEN, JOHN, in *Biography*, an eminent philologist, was born at Utrecht in 1624. He laid the foundation of a learned education in his native city, and then went to Amsterdam to improve himself in the Hebrew language, and in the knowledge of the Jewish ritual from conversation with the learned rabbis. He obtained, in the year 1649, the professorship of Hebrew and Jewish antiquities at Utrecht, which he held, with great reputation, till his death in 1699. He was a capital critic, and was highly celebrated as a teacher. He gave correct editions of the works of Bochart and Lightfoot, and of Poole's Synopsis. His own writings are numerous and very valuable, of which the principal are "Clavis Hebraica et Philologica Vet. Test." 4to. "Clavis Græca Novi Test. cum Aenot." "Compendium Græcum Novi Test." "Philological Notes upon Jonas, Joel, and Hosea," two vols. 8vo. Moreri.

LEUTENBERG, in *Geography*, a town of Germany, in the county of Schwartzburg-Kudolstadt, on the Sorbitz; near which are mines of silver and copper; eight miles S.E. of Saalfeld. N. lat. 50° 28'. E. long. 11° 35'.

LEU'HEN, a town of Silesia, in the principality of Breslau; 10 miles W. of Breslau.

LEUTKIRCH, a town of Bavaria, near the Eschach, on a heath to which it gives name. This town was free and imperial till the year 1802, when it was conveyed, among other indemnities, to the elector of Bavaria. It has a Lutheran and a Roman Catholic church, together with a nunnery of Franciscans. The magistrates are mostly Lutherans; 28 miles S. of Ulm. N. lat. 47° 53'. E. long. 10°.

LEUTMISCHL, or LITOMYSL, a town of Bohemia, in the circle of Chrudim; 22 miles E. of Chrudim. N. lat. 49° 47'. E. long. 16° 5'.

LEUTO, *Ital.* in *Music*. See LUTE, and THEORO.

LEUTSCH, in *Geography*, a town of the duchy of Carniola; eight miles S.S.E. of Hydria.—Also, a town of Hungary, which has frequently suffered from fire; 14 miles W. of Szeben.

LEUTZBURG, a town of Switzerland, in the canton of Berne; six miles S. of Brugg.

LEVY, LEVARE, in *Law*, signifies to gather or collect; as, to levy money, to levy troops, &c.

LEVY sometimes also denotes to erect, or set up; as, to levy a mill. Levy also signifies to raise or call up; as, to levy a ditch. To levy a fine of lands, is to pass a fine.

LEVYING Money without Consent of Parliament. No subject of England can be constrained to pay any aids or taxes, even for the defence of the realm or the support of government, but such as are imposed by his own consent, or that of his representatives in parliament. See *lats.* 25 Edw. I. c. 5. & 6. 34 Edw. I. *lat.* 4. c. 1. 14 Edw. III. *lat.* 2. cap. 1. the petition of right, 3 Car. I. c. 1. *lat.* 1 W. & M. *lat.* 2. c. 2.

LEVYING War against the King. See TREASON.

LEUZE, in *Geography*, a town of France, in the département of the Jemappe, and chief place of a canton, in the district of Tournay, seated on a brook near the Dender; eight miles E. of Tournay. The place contains 3528, and

the canton 14,448 inhabitants, on a territory of 122½ kilometres, in 15 communes.

LEWALDE, a town of Prussia, in the province of Oberland; 12 miles N.N.W. of Soldau.

LEWARDEN, a city of Holland, and capital of Friesland, situated in a quarter called "Ooltergoog." From being a small town in 1190, when it was surrounded with a wall, it has become large, rich, and populous, fortified with ramparts, and defended by a large ditch, bastions, and other works: the streets are regular and spacious, and separated by canals which intersect each other, facilitate communication with the sea and with the internal parts of the province, and contribute to an extensive trade with Holland, Bremen, Hamburg, and other places. The town house, erected in 1715, is a handsome building. The magistracy consists of three burgo-masters and nine eschevins; 28 miles W. of Groningen. N. lat. 53° 12'. E. long. 5° 43'.

LEWCKOCE, a town of Poland, in Podolia; 44 miles N.N.E. of Kamniec.

LEWDNESS is punishable by our law by fine, imprisonment, and such corporal infamous punishment, as the court may think meet, according to the heinousness of the crime. (1 Hawk. 7.) And Mich. 15 Car. II. a person was indicted for open lewdness, in showing his naked-body in a balcony, and other misdemeanors, and was fined two thousand marks, imprisoned for a week, and bound to his good behaviour for three years. (1 Sid. 168.) In times past, when any man granted a lease of his house, it was usual to insert an express covenant, that the tenant should not entertain any lewd women, &c. See ADULTERY, BASTARD, BAWDY-HOUSE, INCEST, &c.

LEWEHAGEN, in *Geography*, a town of Prussia, in the circle of Natangen; eight miles E.S.E. of Konigsberg.

LEWEN, a town of Bohemia in the circle of Leitmeritz; eight miles N.E. of Leitmeritz.

LEWES, a considerable borough and market town in the hundred of Barcombe, rape of Lewes, and county of Sussex, England, is situated on the eastern extremity of one of those bold and fertile eminences called the South downs, and so justly celebrated in the topography of that county. Lewes, being anciently a demesne of the crown, appears to have appertained to the South-Saxon kings, then to the West-Saxon, and afterwards to the Saxon and Danish monarchs of all England; and, though each of those revolutions by which it changed its royal lord, removed the court still farther from this town, its natural advantages secured it a respectability not inferior to that of the first boroughs in the kingdom. During the Danish ravages from the close of the eighth century to the beginning of the eleventh, Lewes was rendered, both by art and nature, the most eligible place of refuge for the inhabitants of the adjacent country, and a firm barrier against the invaders. In the reign of Athelstan, Lewes was a very considerable place; for it was then the chief town and mart of more than half the shire. And in that king's ordinance for prohibiting the coinage of money, except in towns of especial note, Lewes was allowed two mints, and Chichester but one; a proof of the early respectability of the former. On the death of Edward the Confessor, this town, with the other appanages of the crown, devolved to Harold, and on his defeat was given by the Conqueror to his son-in-law William, lord of Warren, who made it his chief residence, and built here a grand mansion and fortifications; the gate and two towers of his castle still remain. In the time of Edward the Confessor here were 127 burgesses. Lewes continued in the possession of the lords Warren for nearly three centuries, when the male line being extinct, it descended to Richard Fitz-Allen, earl of Arundel, son of Alice, sister of the late earl of Warren.

**ren.** In his heirs the barony of Lewes has continued to the present time. A memorable battle was fought in the vicinity of this town in the year 1264, between Henry III. and the confederate barons under Simon de Montfort. A particular account of this is printed in *Lees History*, &c. of Lewes, 8vo. 1795.

Lewes is a well built town, and one of the largest and most populous in the county. It had formerly twelve parish churches, which are now reduced to six, including St. Thomas at Cisse, so called from its standing under the high chalky cliffs at the out-forts of the town. The other churches are All-Saints, St. John's under the Castle, St. Michael's, St. Peter's and St. Mary's Weilton, now called St. Ann's, and St. John's, Southover. The dissenters, who have been respectable and numerous in this town, have also their places of worship.

Lewes is a borough by prescription, but not incorporated; the civil government is vested in two constables, who are annually chosen by the burgesses. Two members have been returned to parliament ever since the 26th year of Edw. I. The right of election is in the inhabitants paying foot and lot, in number about 310. In the year 1504 an act of parliament was obtained for holding the shire or county-court alternately at Lewes and Chichester. From the town-book, since that time, a few items may be extracted, calculated to display the local and general customs of the ages in which they occurred. In 1542 the duke of Norfolk's officers were treated with "two couple of rabbits," price 6*d.*; a pottle of sack, 6*d.*; a quart of sack and a quart of red-wine, 6*d.* In 1544, the "year's wages" of John Payne, one of the burgesses in parliament for this borough, was 63 shillings. The two burgesses were paid 6*l.* 10*s.* in the year 1555. The following year was distinguished by the burning of four men, in this town, for "heresy." Here are a free grammar-school, a charity-school, and several private charities. On the banks of the river Ouse, which is navigable for barges, are several iron-works, where cannon of small sizes, and several other articles, are cast.

Lewes is 40 miles distant from Chichester, and 49 from London. Four fairs are held annually; and a weekly market on Saturdays. The population, in the year 1801, was stated in the parliamentary return to be 3309, occupying 512 houses. The farmer assizes are alternately held here and at Horsham.

A priory of Cluniac monks, the first and chief house of that order in England, was founded at Lewes, in 1078, by William lord Warren and Gundreda his wife. Here was also a priory of Grey Friars; and two hospitals dedicated to St. James and St. Nicholas.

LEWES, See *LOUISOVNE*.

LEWESTEIN, a town of Prussia; 16 miles N.W. of Ralenburg.

LEWING, a town of Silesia, in the principality of Glatz; 15 miles W. of Glatz. N. lat. 50 14'. E. long. 16° 4'.

LEWING, in *Metallurgy*, the sifting of the ores of metals in water. This is done in fine sieves moved backward and forward under water; and is the method of separating the finer part of the ores which had subsided on the larger lumps, under that part of it separated for use in the various washings. The coarser matter, left in the sieve, is powdered again with the larger masses, and all thus sifted together for the blowing-houe.

LEWIS I., in *Biography*, emperor and king of France, surnamed *L. D. bonnaire*, the son of Charlemagne, by a second wife, was born in 778, and while a child he was crowned king of Aquitaine, to which state he was sent to reside. Here he was carefully educated in the dead lan-

guages, and in the other branches of learning that were cultivated at that period. During his administration in Aquitaine, on account of the suavity of his manners, he obtained the surname already mentioned; and at his father's death in 814, he succeeded to the imperial throne, without opposition. At this period he had three sons, Lothaire, Pepin, and Lewis, among whom he divided his dominions: the first he raised to the dignity of emperor by associating him with himself; the second he created king of Aquitaine; and to the other he gave the title and power of king of Bavaria. A worse system could not have been adopted, which Lewis found to his cost, as each of his sons, feeling themselves independent of the father, violated every tie of filial and fraternal duty. Bernard, king of Italy, natural son of Pepin, the eldest son of Charlemagne, took up arms with the hope of deposing Lewis, but his army, in the critical moment, deserted him, and he was obliged to throw himself at the emperor's feet, to implore that clemency, which his misdeeds were ill calculated to inspire. The emperor referred him to the assembly of the states of Aix-la-Chapelle; by whom his conduct was investigated, and himself and associates were condemned to death. This sentence was commuted for that of depriving the guilty of their eyes; the extreme torture of the operation was the cause of Bernard's death, which happened almost immediately after the cruel deed had been performed. The recollection of the sufferings of his nephew so afflicted the mind of Lewis, that he performed a public penance on account of it, a circumstance that rendered him contemptible in the eyes of his subjects. The fierce nations of the north, scarcely to be controlled by the genius of Charlemagne, disdained the weak arm of his successor, and it was with the utmost difficulty that their rude assaults were repelled, and themselves confined within their proper circle. The most disastrous events of this period were the death of the empress, and the subsequent marriage of Lewis with Judith, daughter of Guelf of Bavaria, whose splendid accomplishments concealed an ambitious mind, the source of equal calamities to her consort and the empire. For a time Lewis was obliged to resign his power, but the jealousy of his three sons against each other caused a change in his favour, and he was again restored to power. The three brothers, in 832, joined in a new league against their father; they were supported by the pope, Gregory IV., and the emperor, deserted by his troops, surrendered himself a prisoner to his undutiful children. He was now solemnly deposed, the imperial dignity was conferred upon Lothaire, and Judith was sent into a nunnery. The misfortunes and distresses of the great ever affect the minds of the multitude, and the compassion of his people soon began to operate in favour of the fallen sovereign. Pepin and Lewis took up arms against their elder brother, who was obliged to throw himself at the feet of his father, and ask his pardon. Lewis was again reconciled to the church, and replaced on the throne by the bishops. He now recalled his empress Judith, whose mind, unbroken by adversity, engaged in new plots against the government, with the hope of advancing her son Charles, to the prejudice of the other branches of the family. She had the address to cause him to be declared king of Neustria, and afterwards, on the death of Pepin, king of Aquitaine, in opposition to the claims of the sons of Pepin. This circumstance induced Lewis of Bavaria to assemble an army, with the intention of seizing for himself as much of the territory bordering on his dominions as he could occupy. He accordingly made himself master of the best part of Germany: the unwelcome news was received by the emperor at a moment when his mind was broken down with age, and with terror occasioned by a total eclipse of the sun: he withdrew from the seat of govern-

ment, to an island in the Rhine, where he refused almost all assistance, excepting the elements administered at the sacrament, and died at the age of sixty-two, in the year 840. He appointed Lothaire his successor in the empire, but his last moments were embittered with the most lively resentment against the king of Bavaria: he was reminded by the bishop of Mentz that it was his duty to forgive; he replied, "I pardon him, but tell him from me, that he must seek pardon of God, for having brought my grey hairs with sorrow to the grave." The placid virtues and the urbanity of temper, which distinguished the character of this emperor, very ill compensated for the miseries which were engendered by his feeble administration; and a prince, to whose name has been added the epithet of gentle, lived without the regard, and expired without the regret of his subjects.

Lewis II, emperor and king of Italy, the eldest son of the emperor Lothaire I, was created by his father king of Italy in 844, and was sent to Rome, where he was crowned by pope Sergius II. In about two years he returned to Germany, and was associated with his father in the empire. An irruption of the Saracens gave him employment; he hastily went into Italy, and defeated them in several engagements. He afterwards called a council, to be held at Telfino, for the reformation of ecclesiastical abuses. In 855, by the death of Lothaire, he succeeded to the title of emperor, in addition to his kingdom of Italy. The repeated incursions of the Saracens called forth his military talents and ardour, and the factions of his own nobility were a source of much uneasiness and great disorders. He lived, in general, on good terms with the holy see, and in 871, was crowned king of Lorraine by pope Adrian II. He died in 875, greatly respected by his subjects, to whom he administered justice with impartiality.

Lewis III, emperor, called also Lewis IV, was son of the emperor Arnulf, whom he succeeded when he was only seven years old, in the year 880. During the course of his reign, Germany was desolated by the Hungarians, and torn asunder by civil discord. He died in 912, and his death is regarded as an era in the Germanic history, as he was the last king or emperor of the race of Charlemagne.

Lewis IV or V, emperor, son of Lewis, duke of Bavaria, and Matilda, daughter of Rodolph I, was born in 1284. By the death of his father, when he was only 12 years of age, his education devolved chiefly on his mother, and he distinguished himself beyond all the princes of his age. In 1314, he was chosen emperor at Frankfort by a part of the electors, while another part of them adhered to Frederic, son of Albert, emperor and duke of Austria. Lewis was crowned at Aix-la-Chapelle by the archbishop of Mentz, while Frederic received a similar honour from the elector of Cologne. A civil war ensued, and in 1316 an indecisive battle was fought between them, at Eßlingen on the Neckar. In Italy, the Ghibelline faction espoused the cause of Lewis, while the Guelphs supported that of Frederic, and the flames of war spread over Lombardy, till at length he gave his rival a signal defeat and took him prisoner. From this period those contests commenced between Lewis and the holy see, which disgraced all the latter part of his reign. The pope, John XXII, issued a bull, assuming the right of deciding between the competitors of the empire, and commanding Lewis to desist from exercising the imperial functions, till he should obtain his express permission. The emperor protested against the bull, and was excommunicated. To conciliate the minds of the German princes, he made a peace with the Austrian family, and set at liberty duke Frederic, whom he had hitherto kept in prison. In 1327, he marched into Italy, and was crowned

king of that country; and in the following year he proceeded to Rome, and was crowned at St. Peter's by the bishops attached to his party. The pope renewing his bulls of excommunication and deposition against him, he retaliated by publicly pronouncing his holiness a heretic, and a defiler of his flock; and he even pronounced upon him sentence of death. By a change of circumstances he was obliged to quit Rome in haste, and from this moment his cause declined in Italy, and he found it necessary to return into Germany. He now sought a reconciliation with the pope, and was treated with contempt. The death of John, in 1336, was of no advantage to the emperor, as the succeeding pope, Benedict XII., persevered in the hostility manifested by his predecessor. About the year 1336, the princes of the empire, as well ecclesiastical as secular, assembling at Spire, declared the empire independent of the see of Rome, and pronounced Lewis the lawful emperor: after this a diet was convoked at Frankfort, in which a constitution was passed into a law, for ever establishing the independence of the empire. These decrees did not put an end to the disputes between Lewis and the holy see: the breach was widened by the secret investigations of Philip of Valois; nevertheless, the emperor retained the allegiance of the greater part of the empire. He died, as he was in the act of hunting, in October 1347, at the age of sixty-three. This prince is said to have surpassed all his contemporaries, both in personal and mental qualities, and accomplishments. His manners were gay and highly polished for the times in which he flourished; and although he was capable of concerting his measures without assistance, he willingly sought the aid of good counsel. He appears to have been famed for piety; for, notwithstanding the papal anathema, he received the appellation of "Most Christian," and the monks of Germany, as fervid, as superstitious, preserved his knives, napkins, &c. with religious veneration. Modern Univer. Hist.

Lewis I. king of France, has already been noticed under the first emperor of that name, having reigned as chief of the Germanic empire, and monarch of France. We therefore proceed to

Lewis II. king of France, surnamed the *Stammerer*, son of Charles the Bald, who was born in 843, created king of Aquitaine in 867, and succeeded his father in the throne of France in 877. This prince exposed his kingdom to the fatal consequences of a weak and divided administration. To obtain the support of the principal people, he profusely lavished the honours and estates of the crown upon those who made the earliest application, so that having exhausted his bounties, those who were the last to present their claims were disappointed in their hopes and expectations. Neglected themselves, they murmured, and denied the right which he had assumed of disposing of these possessions, without the consent of the general assemblies. His party prevailed by the force of numbers; and at his coronation he took a solemn oath to maintain the privileges of the grandees, and to respect the donations which he had conferred on them. The vassals of Lewis soon became his equals, and contended for the superiority. A rebellion caused him to take the field in his own defence, but on his arrival at Autun he was attacked with a dangerous disease, supposed to have been occasioned by poison, which carried him off, after a reign of about eighteen months. At the time of his death the queen was pregnant, and was afterwards delivered of a son, who in due time succeeded to the kingdom, under the title of Charles the Simple. Previously to his death, and sensible of his approaching end, he desired that his sword and crown might be delivered to his son,

Lewis III. king of France, who was at that time about seventeen years of age. The great lords were desirous, in opposition to the wishes of the late sovereign, to establish his other son Carloman on the throne. To prevent, however, the evils of a civil war, they agreed that the crown should be worn by both. The division of territory was made in 88c, when Lewis had for his share France Proper, and Neustria; and to Carloman were assigned Burgundy and Aquitaine. The two brothers lived and reigned together in the most perfect harmony, and they displayed some of the qualities of their ancestor Pepin. They, in some measure, put a stop to the ravages of the northern brigands, fifty thousand of whom had entered by the river Somme, and had taken several strong places, among which was Amiens. Lewis defeated them in an engagement near Courtray, but having neglected to follow up his victory, they rallied, and made incursions into Picardy; here he again encountered, and gave them a most signal defeat, leaving on the field of battle 9000 of the enemy, with their leader Guaramond. This victory had displayed much wisdom and valour; and the demise of Lewis of Germany proclaimed the moderation of the young king of France, who rejected with firmness the crown offered him by the inhabitants of Lorraine, and yielded to the superior pretensions of the emperor, Charles the Fat. The French were, however, permitted to contemplate the rising virtues of their prince only a short time. While he was indulging the hope of erecting fresh trophies over the Normans, a mortal disease compelled him to renounce the enterprise. He returned to St. Denis, where he expired in the twenty-second year of his age. His premature death was marked with the suspicion of poison, a suspicion countenanced by the turbulent temper of the nobles, jealous of his active and glorious reign.

Lewis IV. king of France, surnamed *D'Outre-mer*, beyond the sea, on account of his having been educated in England, was the only son of Charles the Simple, by Egira, daughter of Edward the Elder. He was born in 917, and upon the deposition of his father, was taken by his mother to the court of Athellian, in England. Here he remained till the year 936, when he was invited to return and ascend the throne of his ancestors. He landed at Boulogne, proceeded to Laon, and was crowned in that city by Artaud, archbishop of Rheims. His return was chiefly owing to the influence of the powerful Hugh the Great, duke of France. The first measures of Lewis promised to maintain the internal tranquility of his kingdom. To discharge his obligation to Hugh, and to secure the fidelity of that nobleman, he appointed him minister, and committed the reins of government into his hands. The servant soon raised himself above the master; and the attempts which Lewis made to free himself from this state of dependence, gave rise to a civil war, which for several years threw the kingdom into confusion. By the mediation of Otho, his brother-in-law, emperor of Germany, and that of William, duke of Normandy, a peace was concluded in 942, between Lewis and his rebellious subjects. On the death of the duke of Normandy, Lewis attempted to add that duchy to the kingdom: for this purpose he united with Hugh the Great, in an open invasion of the country. Lewis was entirely defeated and carried prisoner to Rouen, whence he was not released till he had entered into a treaty to secure the independence of Normandy; even after this he was detained in captivity till he had procured for himself a grant of the city and territory of Laon. Lewis seized upon the first opportunity to avow his resentment against his powerful vassal, and the provinces of France were alternately afflicted by the arms of Lewis,

of Otho, and of Hugh. During five years the flames of civil war raged without intermission, and the precarious peace which was concluded in a personal interview, may be considered as a suspension of hostilities rather than a restoration of tranquillity. The latent embers of discord were still kept alive: they broke out with renewed violence, and were finally extinguished by the two sisters, consorts of the king and Hugh. A permanent peace was established, and Lewis prepared to assert his authority over the revolted lords of Aquitaine, when his plans were broken by a sudden and accidental death. As he was pursuing a wolf, roused by chance, with inconsiderate ardour, his horse stumbled and threw him: the injury proved fatal, and in a few days he closed his life at Rheims, after a stormy reign, having been eighteen years on the throne.

Lewis V. was associated with his father Lothaire in the government, whom he succeeded in the year 986, being in the nineteenth year of his age. He manifested a violent and turbulent character: he quarrelled with the queen-dowager; expelled the bishop of Laon from the kingdom; and upon a dispute with the archbishop of Rheims, forcibly entered that city with a considerable slaughter. At the time that he was preparing to march against the Saracens, he was taken off by poison, administered, it was imagined, by his own wife Constance. With him ended the race of kings of the house of Charlemagne, which had swayed the sceptre nearly 240 years.

LEWIS VI., surnamed *Le Gros*, son of Philip I., was born in 1081. He was associated with his father in the government in the year 1100, having already acquired a high reputation for valour, prudence, moderation, and a freedom from those vices incident to his age and rank. By the vigour of his conduct he held in awe the discontented nobles, repressed the rebellious, demolished their castles, and compelled them to restore the estates which they had usurped from the clergy. His mother-in-law, Bertrade, jealous of the reputation of the young prince, and considering him as the only obstacle to the elevation of her own sons, attempted, by every means in her power, to destroy him. He happily escaped her machinations, and Philip, discovering her real character, forced her to make such submissions as disarmed the resentment of his son. In 1108, Lewis, by the death of his father, succeeded to the throne, and in a short time he became engaged in a quarrel with Henry I., which may be regarded as the commencement of the long contests between the kings of France and England. Lewis, in the first instance, wishing to avoid the effusion of blood, sent a challenge to Henry to decide the point at issue in single combat, which Henry declined. A battle ensued, Lewis was victorious, and in a treaty concluded not long after, it was agreed that William, the son of Henry, should do homage to the sovereign of France for the duchy of Normandy, which Henry himself had refused to do. War was again renewed, and in an action at Breneville, an English warrior seized his horse's bridle, crying, "the king is taken;" to which Lewis replied, "at cheis, the king is never taken," and instantly laid his antagonist dead with his sword. Lewis endeavoured to deprive Henry of the dukedom of Normandy, but was unsuccessful. In 1119, at a council at Rheims, in which the emperor Henry V. was excommunicated by pope Calixtus II. Lewis lodged his complaints against the king of England, but was unable to draw down the censures of the church upon him. After this the emperor, excited by Henry I., who was his father-in-law, invaded France, but the common danger induced the French to rally round the standard of their king, and he shortly found himself at the head of 200,000 men. It was at this crisis

eris that the famous oriflamme, or banner of the abbey of St. Denis, was displayed as the king's standard. Lewis next had a dispute with some of his prelates, which brought upon him a sentence of excommunication from the bishops of Paris and Sens, but it was taken off by the pope. He now attempted to put an end to the schism in the popedom between Innocent II. and Anaclet, the former of whom he supported as lawful pontiff. The gross habit of his body, from which he derived his surname, forewarned him of his approaching end, for which he prepared by settling the affairs of his kingdom. He caused his son Lewis to be solemnly crowned, and when he found himself almost in the last stage of existence, he drew the signet from his finger, and fixed it upon that of his son, charging him at the same time to remember, that the sovereign authority, of which this was the symbol, was a public trust, for which a strict account would be required in a future world. He died in 1137, greatly lamented by his people, whom he had never burthened with taxes, and whom, in many respects, he had freed from the oppressions of the great. Lewis VI. was unquestionably one of the most irreproachable monarchs of France. His reign is reckoned the era of the commencement in France of that balance to the power of the feudal lords which arose from the order of citizens. He conferred new privileges on the towns within his domains, by what were entitled charters of community, and formed them into corporations or bodies politic, with the right of administering justice, levying taxes, and embodying a militia within their own districts.

LEWIS VII., son of the preceding, was born in 1120, and succeeded to the throne in 1137, having by his marriage with Eleanor, the heiress of the duke of Guienne and count of Poitou, united to the crown of France an extensive country from the Loire to the Pyrenées. He began his reign by repressing some outrages of his nobles, and a revolt of the commons. The election of an archbishop of Bourges, without his consent, involved him in a quarrel with the clergy, and with pope Innocent II. who supported them. In the course of this dispute, Lewis made an incursion into Champagne, sacked the town of Vitri, and set fire to a church, in which more than 1300 people miserably perished. Struck with remorse for this savage act, he resolved to expiate the foul crime by an expedition to the Holy Land. In 1146, Lewis took the cross, and his example was followed by the queen, and all the principal nobility. In the following year he set out at the head of 80,000 men, on his march by land to Constantinople: from this city the French army marched through Asia Minor, to Antioch, and at length undertook the siege of Damascus. The enterprize entirely failed, and Lewis returned dispirited and disgraced. To public calamity succeeded the pang of domestic misery, and it could not be concealed from the eye of a husband that the fidelity of his queen, who had accompanied him in this expedition, had been sacrificed to her own uncle, Raymond. On his return he determined to divorce himself from the queen, which he carried into effect in 1152. By this event the provinces of Aquitaine were detached from the crown of France, and in six weeks they were transferred to that of England by Eleanor's marriage to Henry Plantagenet, then duke of Normandy, and soon after king of England, under the name of Henry II. The facility with which he parted from these wealthy provinces has for ever annexed to him, by way of reproach, the surname of *Young*. Lewis married for a second wife Constance, daughter of Alphonso, king of Castile, and soon after displayed his piety in a pilgrimage to the shrine of St. James, at Compostella. This queen dying without any male issue, he married Adelaide,

daughter of his old enemy, Thibault, count of Champagne, by whom he had a son, named Philip. While a mere child, the royal youth, engaged in the pleasures of the chase, was lost in the thickneses of a gloomy forest, and the heir of France was condemned to pass a tedious night, oppressed by solitude and despair. His feeble mind was incapable of sustaining the horror of his situation, and when found in the morning, a dangerous fit of illness was the effect of the fright. The superstitious monarch visited the tomb of Becket, to solicit the interposition of a saint, who had experienced his earthly protection. Having been kindly received at Canterbury by Henry, and having presented his offerings at the shrine of Thomas, he embarked again for France, and on his arrival his heart was gladdened with the intelligence of his son's complete recovery. The mind of the king had, however, received a blow, from the effects of which he never recovered, and in 1180, he experienced a paralytic seizure. Sensible of the great danger which hung over him, he determined to hasten the coronation of his son, and having languished about a year under his malady, he expired, after a reign of forty-three years. "If," says the historian, "the prudence and judgment of the king, in restoring the dowry of Eleanor have been arraigned, his humanity has been seldom, and his piety has never been impeached. A tender husband and an affectionate father, the errors of the monarch, were lost in the virtues of the man."

LEWIS VIII., grandson of the preceding, was born in 1187, and displayed, at a very early age, a martial disposition under his father at the war in Flanders, and against king John of England in Poitou. In 1216, he was invited by the barons of England to ascend the throne, of which their own sovereign had proved himself unworthy. He landed in Kent, and marched to London, where he was at first received with respect and gratitude: in a very short time the tide of public favour completely turned, and he was glad to obtain permission to return un molested. He succeeded to the crown of France in 1223, and scarcely had ascended the throne of his ancestor, when he was urged by Henry III. of England, to make restitution of the provinces taken by his father from king John; he refused, and war was declared. Lewis was every where victorious, and the power of the English in France was greatly curtailed, so that nothing was left in their possession but the town of Bourdeaux, and the country beyond the Garonne. To preserve these, Henry conferred on his brother Richard the title of count of Poitou, and furnished him with ample means to support his new dignity. The inhabitants of Poitou crowded to his standard, and the spirit of opposition being revived, the career of Lewis was checked, and he was glad to make a truce for three years. The court of Rome strongly solicited the king of France to resume the cross, and to march against the Albigenses. From Lyons he directed his march along the banks of the Rhone, and invested Avignon with 50,000 men. The inhabitants, animated by despair, defended themselves with the most obstinate valour; and the king, after the loss of the bravest of his troops, was forced to grant that capitulation at last, which he had refused at first. On his return home, he was seized with an illness which put an end to his life, in November, 1226, after a reign of about three years.

LEWIS IX., king of France, named *Saint*, son of the preceding, was born in 1215, and succeeded to the crown in 1226: being only in the twelfth year of his age he was placed under the guardianship of his mother, Blanche of Castile, who was nominated regent of the kingdom. Her first efforts with regard to the young king was to inspire him with a love of religion, and an attachment to the principles

ciples of pure morality. When he attained the age fit for taking upon himself the rule of the kingdom, such was the respect which he bore for his mother, that her authority remained unimpaired, and for several years they may be said to have reigned jointly. Though the piety of this prince obtained for him the title of saint, yet he knew the limits between secular and ecclesiastical jurisdictions, and was jealous of usurpations in the latter. He refused to join in the crusade recommended by pope Gregory IX., though encouraged to the undertaking by the most flattering proposals. Lewis shewed himself a good warrior by his exertions in suppressing a revolt supported by Henry III. of England: he gained two victories in person, and constrained his rival to submit to humiliating conditions of peace. Two regulations proclaim the prudence and policy of this prince. The first, under pretence of preventing strangers from inheriting lands in France to the prejudice of the natives, precluded the nobles from marrying their daughters to foreigners, and restrained them from increasing their influence by connections and alliances with the neighbouring powers. The second compelled the vassals of the crowns of France and England to make a public avowal, as to which sovereign they would do homage; and, finally, abolished the dangerous custom of adhering to either, as their caprice or interest suggested. Yet, even in this edict, the humanity of Lewis was conspicuous, and his justice indemnified those who adhered to him for the land they forfeited, by seceding from the king of England. A dangerous indisposition, which menaced the life of Lewis, was productive of a fatal vow to march in person against the infidels, whose successive victories had overwhelmed the Christians of the East: no remonstrances from his counsellors, his nobles, and even his prelates, could divert him from the resolution of fulfilling his vow. The blind zeal, however, which induced him to descend from his throne to seek the adventures of a spiritual knight-errant, did not prevent him from concerting his measures with the utmost prudence and foresight, as well with respect to the enterprise itself, as the government of the realm during the king's absence. Having entrusted the kingdom to his mother, Blanche, he prepared for his departure. "To furnish," says the historian, "an armament equal to the arduous enterprise, France was exhausted of troops and treasures; the sea was whitened with eighteen hundred sails; and nine thousand five hundred horse, and one hundred and thirty thousand foot, have been computed as the number of the martial pilgrims. The fleet, with favourable winds, reached the coast of Cyprus; the troops were disembarked on the friendly shore, and during the severity of winter, their strength was recruited and their health restored by the plenty of that island." Here it was determined to make war first upon the sultan of Egypt, for the purpose of facilitating the recovery of Palestine. In 1249, he arrived at the mouth of the Nile, and leaping into the sea, sword in hand, gained the beach, and drove away the Saracens drawn up to defend it. Damietta instantly yielded to the aggressor, but it was now found the expedition was ill-timed: the rising of the Nile prevented his farther advance, and the delay introduced disease into his army, and all the disorders naturally attendant upon idleness and the want of subordination. From this period he was no longer successful: every new attempt at conquest ended in disaster, till at length himself, his brothers who had accompanied him in the expedition, and his whole army, were under the necessity of surrendering themselves prisoners. The enemy scarcely knew any bounds to their revenge: they massacred the captives without mercy, and even treated the fallen monarch with a great degree of insolence and ri-

gour, to which it is said he submitted with firmness and dignity. The king was at length liberated, having first agreed to pay a high ransom, and to agree to a truce of ten years between the Christians and Mahometans in Egypt and Syria. This treaty was punctually executed, and so high was the honour of Lewis, that upon discovering a considerable mistake made by the Saracens in the value of the money to their own loss, he caused it to be rectified. He left the country with his queen and brothers, and carried with him about 6000 men, the sole remains of the vast army which he had collected in the outset of the business. He embarked for Palestine; and though it might have been expected, that, after his late misfortunes, he would readily have relinquished the vain hope of eastern laurels, and returned to the government of his own kingdom, yet he seemed unwilling to revisit his dominions without glory, trusting for tranquillity at home, in the vigilance and fidelity of his mother Blanche. His ambition now was to secure Jerusalem from the hollidays of the Saracens; with this view he repaired the fortifications of the places still possessed by the Christians, made pilgrimages of devotion, attempted conversions, and sunk the character of a mighty monarch into that of a superstitious crusader. News was brought him of the death of his mother, who had undergone much disquiet from various circumstances during the absence of her son, and whose grey hairs were brought with overwhelming sorrow to the grave. The king was now obliged to return, and in his passage the vessel which carried him and his family struck upon a rock, and was in the most imminent danger; nevertheless, the fortitude of the monarch was so great, that he refused to avail himself of another ship, determining to share the fate of all who were exposed to similar risks with those that threatened his own life. On his return, he was received by the acclamations of the people; his dress was plain; and his features were impressed with melancholy; the former still bore the sign of the cross, the latter evidently displayed the marks of defeat. The magnificence of the monarch was, however, beheld with admiration in his reception of Henry III. of England, who embraced the opportunity of an expedition into Gascony, to visit Paris. The splendour of his entertainment was enhanced by the courteous manners of Lewis; and the interview between the two kings was followed by a renewal of a former truce for two years longer. He began to apply himself with all diligence to the government of his kingdom, by his strict and impartial administration of justice. In the simplicity of ancient manners, he was accustomed to seat himself under a spreading oak at his castle of Vincennes, and there, in person, to decide the causes that were brought before him. He protected the lower orders from the oppressions of the great, and would not suffer his own brothers to pass over the limits of law and equity. He was extremely severe in every thing that regarded religion; and the edicts which he issued against blasphemous and impious persons, as those were called who doubted the truths of an established faith, might have been worthy of a bigotted inquisitor. So great was his character among foreign nations for equity, that he was often applied to for a settlement of disputes between kings and their nobles. The barons of England and Henry III., in their disputes, agreed to make Lewis the arbiter: his decision was favourable to the royal authority, but with a large reservation of the rights and privileges of the subject, so that, in fact, it determined nothing. He enlarged his own kingdom by the acquisition of various places on the borders of the Low Countries, and he acquiesced in the pope's donation of Naples and Sicily to Charles of Anjou, brother to Lewis. At length the zeal for propagating his religion seized again upon the mind of Lewis;

Lewis; the latent flame of enthusiasm which had been damped by his defeat in Egypt was not extinguished; and an opportunity was only wanting to revive the dormant embers. The wisdom of his regulations had restored the tranquillity of his dominions; his coffers were recruited, his finances augmented, and his hopes of success were expanded, and very sanguine. His silent preparations had been incessantly directed towards the single object of his devout ambition; the loss of Antioch provoked the more immediate execution of his designs. His example was followed by his three sons, by his nephew the count d'Artois, and by a multitude of the most gallant spirits of the court of France. He entrusted the reins of government, during his absence, to the vigilance and superintendance of Matthew, abbot of St. Denys, who derived his noble lineage from the counts of Vendome; and to Simon de Clermont, count of Nefle. A sea-port of Languedoc, near the mouth of the Rhone, was rendered a second time remarkable by the embarkation of Lewis, and the fleet of France steered immediately for the coast of Africa. An obscure king of Tunis had professed an inclination to abjure the tenets of Mahomet for those of Christ; and the vain report of an immense treasure reconciled the more interested pilgrims to the wild and visionary enterprise. But caprice or policy had already united the sly and crafty barbarian to the precepts of the Koran; and instead of a zealous proselyte, Lewis encountered an active and formidable enemy. The walls of Carthage were, indeed, stormed by the impetuous valour of the French; but their strength was exhausted before the gates of Tunis; and the warriors of the west panted beneath the sultry heats, and expired on the burning sands of Africa. The king himself was infected by the pestilential blast, and he breathed his last on the inhospitable shore, in the 44th year of his reign. In his singular character were united the virtues of the saint and the hero: his piety and equity in peace were not more conspicuous than his fortitude and valour in war. The father of his people, his heart sympathized with their miseries, and his hand was ever stretched out to relieve their distress. His excellent understanding was clouded by the fumes of enthusiasm; and the slaughter of his subjects, his own captivity, and at length his death, were the fatal consequences of a blind superstition. Pope Boniface VIII. canonized him in 1297; and his descendant, Lewis XIII., procured the day, dedicated to his honour, to be declared a general feast of the church.

Lewis X., furnished the *Boisterous*, from the rude promise of his infant years, son of Philip, was born in 1291, and succeeded his father in 1314. He, in a short time after his coronation, caused his first wife to be strangled in the prison of Chateau Gailard, where she was confined, and endeavoured to forget the vices of a licentious woman in his nuptials with Clemence, the daughter of the king of Hungary. An empty treasury delayed, for some time, the ceremonies of the coronation, and the king diligently applied himself to conciliate the jealousies and appease the discontents of his new subjects. Lewis, notwithstanding the surname which he had acquired, was of a quiet disposition, and surrendered the chief authority in the state to his uncle, Charles of Valois. The finances of the kingdom having fallen into disorder, the superintendent, Enguerand de Marigni, was made a sacrifice to the revengeful passions of the new minister. Marigni vindicated his character with vehemence; but his eloquence was of no avail, he was confined to an ignominious death on the gibbet, and his fortunes were confiscated to the use of the sovereign, and were applied to defray the expences of the coronation, which was celebrated at Rheims; and as much as they fell short of public expectation, so much

did the deficiency contribute to establish the innocence of the unfortunate superintendent. Far different supplies were necessary for the support of a war with Flanders, which Lewis was desirous of engaging in, and he accordingly proposed to raise the necessary supplies by a general enfranchisement throughout the kingdom. The inhabitants of the towns were already free, but those of the country were not so, and few were found willing to pay for that freedom which was forced upon them. The decree was, however, gone forth, and they were compelled to accept of their liberties upon the terms proposed by the sovereign, who preaced his edict with these words: "Since, according to natural right, every person ought to be free, &c." a maxim not very consistent with the compulsory purchase of liberty. The money being provided, Lewis made a campaign against de Bethune, count of Flanders, who, feeling himself unable to withstand the army brought against him, determined to bend against the storm. By the specious language of submission, he involved the king in a series of fruitless negotiations, till the season of action was passed, and the French army was obliged to retreat, without obtaining any advantage. While the king, indignant at the arts of his adversary, was meditating new projects for revenging himself upon his adversary, his designs were interrupted by death. A sudden disorder, imputed by some to poison, by others to drinking a glass of cold water when he was heated, proved fatal to him in June, 1316, after a reign of about a year and a half.

LEWIS XI. son of Charles VII. was born in 1423, and at an early age displayed considerable talents, united to a turbulent disposition. At the age of seventeen he headed a party of discontented nobles, who engaged in a petty war, which was soon suppressed, and the prince was glad to submit. After this he reinstated himself in the royal favour by his skill and valour in relieving Harfleur, invested by the English. He was soon sent with a body of troops to assist the duke of Austria against the Swiss, and obtained some advantages over them, which were succeeded by a negotiation with the Cantons, in which he concluded the first treaty between them and the crown of France. In 1446, disguised with the ascendancy of Agnes Sorel, his father's mistress, he left the court, and retired into Dauphiné, in which province he exercised the sovereign authority. He established the parliament of Grenoble, made laws, and even coined money. At length his conduct created so much uneasiness in the breast of his father, that he was determined to get possession of his person; but the prince, being made acquainted with his intention, escaped, and took refuge in the court of Philip the Good, duke of Burgundy. Here he was treated in a manner consistent with his rank; but Philip would not encourage any of his seditious projects. In the mean time the king brought back the government of Dauphiné to its ancient form, and kept a watchful eye over his son's motions: so jealous was he of his intentions, that the dread of being poisoned by his contrivance was the cause of his death. In the year 1461, Lewis received the news of his accession to the crown of France; he did not affect to conceal the joy which the intelligence excited in his breast. The competition of his younger brother, the duke of Berri, vanished at his appearance, and his own coronation was celebrated with vast magnificence at Rheims, and honoured with the presence of Philip, his noble host, and that of his son, the count of Charolois. The first emotions of the king's gratitude for the protection he had met with, was displayed in his declaring the count his lieutenant-general in Normandy, with a very munificent salary; but these marks of esteem and confidence soon vanished, and

were succeeded by an enmity between these rival princes, which only expired with life. The new king immediately dismissed the ministers of his father with disgrace, and at the same moment released from imprisonment the duke of Alençon, who had been confined for treasonable practices. With regard to foreign potentates, his conduct seemed to be destitute of every principle of justice, and dictated merely by what appeared to be the interest of the moment. In pope Pius II. he met with a politician more refined than himself, for in the hope that this pontiff would assist in replacing the house of Anjou on the throne of Naples, Lewis cancelled the pragmatic sanction of his father, which established the liberties of the Gallican church: afterwards, finding himself deceived in his expectations, he permitted its execution in certain points. Being constituted mediator in a dispute between the kings of Castile and Arragon, he had an interview with the former, in which he displayed the singularity of his disposition: for while the Spanish monarch with his attendants displayed the greatest magnificence in their apparel, he appeared in a dress of coarse cloth, with an old hat upon his head, upon which was stuck a leaden image of the Virgin. This contrast inspired them with mutual aversion, and the two kings, after a fruitless conference, returned with a thorough contempt of the forbiddens of the one and the incapacity of the other. It was a great object of his policy to reduce the formidable power of the house of Burgundy; and, in the execution of his plans, he was suspected of a plot for the seizure of the persons of the duke and his son. In return, the count of Charolois joined the duke of Brittany in caballing with his discontented nobles, and formed a confederacy, called "the league for the public good," into which the king's brother, the duke of Berri, entered. The revolted took up arms, and the count attempting to surprize Paris, an engagement took place at Monthléry, in which the victory remained undecided. Paris was, however, besieged, and the king, to avert the danger, followed the advice of Sforza, duke of Milan, which was to break the league by liberal promises, and trull to events for eluding the execution of them. He accordingly agreed to a disgraceful treaty in 1465, by which he ceded the duchy of Normandy to his brother, and granted lands out of the royal domains to others of the leaders. Some disputes between the dukes of Brittany and Normandy gave him an opportunity of recovering his power, and of divesting his brother of the dukedom of Normandy, and of that which he before possessed. The accession of the count of Charolois to the dukedom of Burgundy on the death of his father Philip, gave Lewis much uneasiness. The fiery temper of that prince, and his declared enmity to the king, involved them in perpetual hostilities. In the course of these, the king's brother, whom he had been obliged to make duke of Guienne, died, not without suspicion of poison, and the duke of Burgundy, openly accusing Lewis of fratricide, refused his arms. An invasion of France by the duke's ally, Edward IV. of England, threatened great danger; but Lewis, adhering to his favourite principle of diverting rather than confronting a storm, lavished his treasures upon English ministers and generals, and allured Edward himself by a promised pension of 50,000 crowns for life, by which means a treaty between them was concluded in 1475. The duke of Burgundy made a separate peace afterwards. Having thus extricated himself from foreign foes, Lewis indulged his severe disposition in taking vengeance on domestic traitors. The constable St. Pol, who had served under and betrayed both him and the duke of Burgundy, was brought to the scaffold, as was likewise the duke of Nemours. The cruelty of making

the innocent children of the latter nobleman stand under the scaffold, at his execution, that they might literally be sprinkled with their father's blood, inspired universal horror and general detestation of the tyrant who could devise such a deed. In 1476, Lewis was delivered from his most dangerous enemy Charles, who fell before Nanci; and he felt no scruple in making all possible advantage of this event, to the prejudice of the heirs, Charles's only daughter, Mary of Burgundy: but his attempts against her were unsuccessful, and Flanders and Artois declared for the dukes. Another scheme which Lewis meditated, was to oblige Mary to marry the young dauphin, but his hostile procedure had the effect of throwing her into the arms of Maximilian, archduke of Austria, an event which proved the fertile source of war for centuries. A war was the immediate consequence of this alliance, but mutual convenience soon brought about a suspension of arms. Lewis then turned his attention to the neighbouring states, and managed several negotiations with his wonted dexterity. He provided for the security of the family and dominions of his deceased sister, the duchess of Savoy; he supported the house of Medici against pope Sixtus IV., made an alliance with Ferdinand and Isabella, and renewed his treaty with Edward IV. One of the last public events of this reign was the union of Provence to the crown of France, by the bequest of Charles, count of Maine, the last prince of the house of Anjou. Lewis had now attained to a state of great external prosperity, was regarded throughout Europe for his power and dextrous policy, and feared by those who did not esteem him. The decline of his health, and the dread of death, filled him with jealousies and suspicions relative to his temporal authority. The nearer he approached his end, the more he clung to life; and he endeavoured, by superstitious practices, to quiet the upbraidings of a guilty conscience. He had a strong guard round his palace, who kept at a distance all visitors, except a very few, whom he permitted into his presence singly. He changed his domestics every day, sacrificed many to his suspicions, and felt more dread than he inspired. "The walls of the castle," says the historian, "were covered with iron spikes, a guard of cross bow-men watched the gates and ramparts night and day, and the guilty tyrant heard his enemies in every passing wind." Earth was in vain ransacked to revive his jaded appetites; heaven was invoked with prayers and processions to avert his impending doom; all hope was fled, and his favourite, Oliver le Dain, pronounced to him the sentence of certain and approaching dissolution; the king heard him without betraying any emotions of terror: he sent for his son Charles, and employed his last moments in advising him to cherish the princes of the blood; to govern by the counsels of his nobles; to maintain the established laws of the kingdom; and to diminish the extraordinary imposts with which he had burdened his subjects. This last effort exhausted the strength of the fainting monarch, and he died, after a reign of twenty-three years, in August 1483. Dreaded by his subjects, whom he had continually oppressed, and detested by his neighbours, whom he had assiduously deceived, he yet obtained from the obsequious temper of the representative of St. Peter, the title of Christian King, a title that was ever after held by his successors. He instituted the order of St. Michael. He was author of several useful establishments, and the administration of justice was generally pure where he himself was not concerned.

LEWIS XII., son of Charles, duke of Orleans, descended from Charles V., was born in 1462: he married Joan, daughter of Lewis XI., and at the death of that monarch, in 1483, and the accession of Charles VIII. he stood as presumptive heir of the crown, with the title of duke of Orleans.

leans. On the death of Charles, in 1498, he succeeded to the crown without opposition. Among the very earliest efforts of his reign were his attempts to diminish the taxes levied upon the people. He is also celebrated at this period for the well known sentiment with which he quieted the apprehensions of his enemies. "It is," said he, "not for the king of France to revenge the injuries done to the duke of Orleans." Turning his attention to the duties of his new station, he introduced various reforms into the civil administration and military discipline, exhibiting at the same time a steady mind in every thing which he undertook. He was anxious to obtain a divorce from his wife, the daughter of Lewis XI., because, being deformed, she was not likely to bring him any children, and also, because he wished to espouse Anne of Brittany, widow of the late king, who had refused her duchy. The pope, Alexander VI., was ready to favour him on this occasion, in order that, in return, he might obtain an establishment for his natural son, Cæsar Borgia. On the oath of the king of France, that he had never consummated the marriage, the holy pontiff declared the union void and illegal. Jane submitted with decent resignation to a sentence which deprived her of a crown, retiring to a nunnery, in which she took the veil, and closed a life of humble virtue; and, in January 1499, he was married to Anne of Brittany. The queen, though willing to ascend the throne of France, was anxious to secure the independence of her native duchy, and stipulated, that if their union should be productive of two sons, the younger should inherit Brittany, with all the prerogatives of its former princes. This agreement proved ineffected, by her having no son, and by the marriage of her eldest daughter Claude to Francis, count D'Angoulême, who afterwards ascended the throne. The claims of Lewis upon the Milanese, and the kingdom of Naples, now began to excite in his breast the ambition of conquest; he accordingly made an alliance with the Venetians, and, in conjunction with them, invaded the dominions of Ludovico Sforza, duke of Milan. The French generals, in the short space of three weeks, made themselves masters of Milan, Genoa, and all the strong places in the country: Lewis entered Milan in triumph, while Sforza retired with his family and treasures to Inspruck. A sudden revolution caused the expulsion of the French, and the return of the duke, but the troops of Lewis shortly entered the Milanese, and got possession of the person of the duke, who was sent into France, where he died. Lewis now made a treaty with Ferdinand of Arragon, for the partition of the kingdom of Naples between them. In 1501 this plan was successfully executed, and Frederic, king of Naples, expelled from his dominions, put himself into the hands of Lewis, as the most generous of his two enemies. Ferdinand was not content with a part of the conquest, but took every method to secure to himself the whole spoils; and by means of his famous captain, Gonsalvo de Cordova, obtained possession, in 1503, of the whole kingdom of Naples, after defeating the French at Seminara and Cerignole. It was on this occasion that Gonsalvo got possession of the young prince, whom he conveyed to the king of Arragon, and though treated with lenity, he was for fifty years the captive of the court of Spain, till Death, that last friend to captives, extinguished in him the Arragonese line of Neapolitan kings. In the year 1507, a revolt of Genoa called Lewis, in person, into Italy with a powerful army; he entered it as a conqueror, seemingly bent on vengeance, but his natural clemency was displayed in a moderate chastisement which he inflicted upon it. In the following year he joined the famous league of Cambray against the Venetians, formed by the temporary union of powers

mutually jealous of each other, and opposite in interests. Lewis became a party in the league through the influence of cardinal d'Amboise. He even marched at the head of his army, and, in May 1509, gained a complete victory at Aignadel, which reduced the republic of Venice almost to ruin. Its safety arose from that disunion which might be expected in a league formed of such discordant materials. Pope Julius II. who had chiefly contributed to its formation, resolved, after the purposes of his own ambition were answered, to employ all his efforts to expel the foreign powers from Italy. With this view he made peace with the Venetians, and openly declared war against the French. A new league was now formed, of which Julius was the chief mover: he attacked in person the duke of Ferrara, its ally, and excommunicated the council of Pisa, which had been assembled under the auspices of Lewis and the emperor. The military reputation of the French was ably supported by the duke of Nemours, who, in 1512, gained the battle of Ravenna, but fell in a rash pursuit of the enemy. The king, his uncle, was deeply affected by the loss of him, and of many other brave men; and deprecated a victory purchased so dearly. In a short time after this, the Swiss overran the Milanese, and the French were expelled. It was again recovered, and again lost. At this period Henry VIII. of England joined the papal league, invaded Picardy, and routed the French in an action, since denominated the battle of the Spurs. Henry pursued his career of success, which was interrupted by the retreat of the Swiss and the desertion of his allies; he determined, therefore, to repass the seas with the greater part of his army, ill compensated for the expence with which it had been attended. In 1514 the queen died, and he proposed marriage to Mary, sister of Henry VIII.: his offers were accepted, and a league offensive and defensive was formed between the two kings. Lewis, however, was obliged to purchase this alliance with a great sum of money, instead of receiving a portion with his wife. It was agreed that Henry should receive the payment of a million of crowns, being the arrears due by treaty to his father and himself; and that the princess Mary should bring four hundred thousand crowns as her portion, and enjoy as large a jointure as any queen of France. Lewis also agreed that Tournay should remain in the hands of the English; and that Richard de la Pole, an exile in France, who affected to revive the pretensions of the house of York, should be banished.

The new queen, being young and beautiful, was welcomed with universal acclamations by the people; who rejoiced in an alliance that converted a formidable enemy into an important friend. In the midst of festivities given on account of the marriage, formidable preparations were made for renewing the war in Italy; but his designs were broken. He had often repeated the adage, that "love is the king of youth, but the tyrant of old age," and he was now condemned to experience its truth. His constitution, already shaken, was exhausted by his affection for Mary, with whose beauty, grace, and numerous accomplishments he was enchanted. He died within three months of his marriage by a disorder of debility, in the seventeenth year of his reign, and the fifty-fourth of his age. The character of this prince was distinguished by a superior integrity, seldom to be discerned in princes; and though sometimes the dupe of his goodness of heart, and often of the treachery of his neighbours, yet he well deserved the appellation of "the father of his people." In him expired the elder branch of the house of Orleans, and the sceptre of France was transferred to that of Angoulême.

"History," says the biographer, "has taken pleasure in recording, that when, according to the usual custom, the criers announced his death, it was done in these words, 'the good king Lewis, the father of his people, is dead.'" He was naturally inclined to economy: this was once made a topic of ridicule in his presence, to which he replied, "I had rather see my courtiers laugh at my avarice, than my people weep at my extravagance." In his manners and conversation, Lewis was affable, mild, and cheerful, prone to fallies of innocent pleasantry, and fond of literature. He assembled men of learning at his court, and employed them in public affairs. Greek was first taught at the French universities in his reign.

LEWIS XIII., son of Henry IV., by Mary de Medicis, succeeded to the throne in 1610, under the regency of his mother, being only in the thirteenth year of his age. He was declared in his majority in the year 1614, and soon after the states-general were convoked. At the meetings of this assembly many abuses were discussed, and some few were remedied. During the minority of the king, France had been, on account of the mal-administration of the queen, a scene of faction and civil commotions: these troubles continued, and were greatly aggravated by a religious war. Lewis's character, as it opened, displayed that propensity to be governed, which indicates weakness of mind, together with much coldness and indifference. The great duke of Sully, inflexible in his plans, confiding in the integrity of his own heart, and disdainful the arts of courts, found that sincerity, which had been esteemed by Henry, no longer acceptable; he indignantly retired to the estates which he had purchased through the bounty of the late king, and resigned his offices. Every day now revealed the ascendancy of Concini, who endeavoured to remove from the eyes of the people the unpopular circumstance of foreign birth, by assuming the title of marquis d'Ancre. During the administration of this favourite, the annals of France, as they respect the internal affairs of the country, present a dreary prospect of uninteresting anarchy and barren discord. The princes of the blood, insatiate of power, and the nobles turbulent and discontented, repeatedly erected the standard of revolt against the regal authority; as frequently, with contemptible levity, they courted the returning friendship of the crown, whose timid counsels were content to soothe, without presuming to repress, their capricious arrogance. Amidst these hostilities at home the king concluded his marriage, and received at Bourdeaux the hand of Anne, the infanta of Spain. Immediately after the celebration of that ceremony, Lewis marched at the head of his army with the view of reducing the prince of Conde, in order that he might impress his subjects with favourable sentiments of his courage and activity. The approach of winter suspended the operations of the contending parties, who, while they rejected all terms of accommodation, seemed studious, in every enterprize, to avoid the effusion of blood. With the return of spring the royal forces were again assembled, and were again led on by the presence of their sovereign; but much was the surprize of his subjects to learn the intelligence that the king had subscribed a peace, and submitted to the demands of those princes whom he had solately declared traitors to his throne. In 1617, Concini was murdered in the Louvre, at the instigation of Luynes, whom he had introduced to the king, and who now superseded him in the royal favour. The principal events which occurred in this reign during the administration of Luynes, were quarrels with the queen-mother, and a renewed war with the Calvinists, who were headed by the duke de Rohan. During this war Luynes died, and the Calvinists obtained an advantageous peace.

In 1624, cardinal Richelieu, who, while bishop of Luçon, had been gradually rising to political reputation, acquired the chief management of affairs, which he held with untroubled sway so long as he lived. This great minister found a very difficult task before him, owing to the weakness of the king, the selfish ambition of the nobles, and the prevalence of different factions. War broke out again with the Calvinists, who complained that the conditions of a former treaty had not been observed. The sovereign appeared in arms, but the chief honour was due to Richelieu, who, after a long siege, took Rochelle, by means of a vast dyke thrown across the harbour to cut off supplies by sea. This important conquest was the means of reducing the party to civil obedience, and, to the honour of the victor, they were still allowed a good share of religious liberty. In addition to the civil contentions, a war with Spain broke out in 1635, which was at first unsuccessful on the part of France; but at length the Spaniards were reduced to sue for peace. In the mean time the spirit of Richelieu's domestic administration was highly arbitrary, and the king displayed great harshness in his addresses to the parliament. The last of his favourites was Cinqmars, who was recommended to the monarch by his minister, but who was led by his ambition to cabal against his friend and patron. His ruin was the consequence, and Lewis gave him up to execution with the most perfect indifference. (See CINQMARS.) On the morning of the execution of this man, intelligence was brought of the surrender of Perpignan, and the total discomfiture of the enemy, of which facts the minister apprised the king in a single and very short sentence, "Your troops are in Perpignan, and your enemies in their graves." Immediately after these events, Mary de Medicis closed a wretched life, reduced to the utmost indigence, at Cologne. The filial affection which Lewis denied to her while living, was revived on the news of her death; but the attention of France was now completely engrossed by the approaching dissolution of him, whose daring counsels had driven her into banishment. The glories and life of Richelieu drew near their end; after the reduction of Perpignan, exhausted in body, but still vigorous in mind, he had approached the capital by slow and triumphant journeys; his last moments attested his ascendancy over the sovereign. On his death-bed he protested to Lewis, that his counsels had ever been directed to the honour of the crown and the welfare of the kingdom. (See RICHELIEU.) From the death of this minister, Lewis aspired to hold the reins of government for himself: the war was prosecuted with diligence, vigour, and success, and the spirit of Richelieu seemed still to impel the machine which his genius had set in motion. But victory could not check the progress of disease, and Lewis was sensible that the inevitable moment was rapidly approaching when his life and reign must terminate together. A slow fever had already worn him to a skeleton, and he prepared to meet with firmness and composure the last scene of human greatness. "When," says the historian, "his physician, at his earnest desire, numbered the fleeting minutes that remained, and pronounced that his life could not exceed two or three hours; he received the intelligence with resignation, and even satisfaction; and looking fervently up to heaven, added, 'Well! I consent with all my heart.'" The prediction was strictly verified by the event, and he expired in the forty-second year of his age, and in the thirty-third of his reign. In estimating his character; he was devout, but his devotion shewed itself in minute observances and submission to his confessors. He was not greatly addicted to pleasure, and the mistresses on whom he bestowed his favours, were rather the objects of his jealousy than

than of his love. He had a share of judgment and solid sense, and did not want decision. In the administration of justice, he was inclined to rigour, and thence acquired the epithet of "The Just;" though it must be admitted that his administration of justice was frequently impeached by his severity, and sometimes by his cruelty.

LEWIS XIV., son of the preceding, was born in 1638, and succeeded to the crown, under the regency of his mother, Anne of Austria, on the death of his father in 1643. She soon resigned herself to the influence of cardinal Mazarin, who had succeeded Richelieu in the last reign. In the early part of this reign, the kingdom was involved in a bloody and extensive war with the house of Austria. The peace of Munster, in 1648, relieved France from the greater of her foreign foes; but it was soon succeeded by the civil war of the Fronde, during which the royal family was obliged to leave the capital, and wander as fugitives from province to province. The education of the young king was much neglected, and he was left ignorant of the points of knowledge most useful and reputable to a prince. The more valuable part of his reading was the tragedies of Corneille, which improved his taste, and gave him ideas of true grandeur; but the want of solid instruction, moral and literary, marked his character through life. The lesson most strongly impressed on his mind in his very childhood, was the sentiment of his own importance, which, though it led him to adopt a dignified propriety of conduct, nourished in him that pride and vanity, and that impatience of controul, which were the leading features of his reign. Taught by flatterers that he himself was every thing, and that his subjects were nothing in the comparison; he was habituated to think no sacrifice of their's too great for the promotion of his glory and the gratification of his desires. The convulsions of the state had not ceased when Lewis XIV. had attained the age fixed for his assuming the reins of government, and his majority was solemnly declared in parliament; but he was still in leading-strings, influenced wholly by the counsels of his mother, and he seemed to inherit her fond partiality for Mazarin, though he was shortly after, by the instigation of his parliament, obliged to give him up, and suffer him to retire into exile. No sooner was it known that Mazarin had left the city of Paris, than the king was welcomed by the inhabitants with the loudest acclamations, and he found himself freed from the clamorous importunities of a discontented parliament, and firmly fixed on his throne. Scarcely, however, was he expelled by the general voice of the nation, and by the royal declaration, than he was recalled by the king, and, to his own infinite surprize, entered Paris once more in full power, and without the least disturbance. The king received him as a father, and the people as a master; but the cardinal, amidst the satisfaction of this change, could not repress his contempt of the national levity. The minister applied himself with vigour to extinguish the sparks of revolt; and, in 1653, the war of the Fronde was terminated with his complete triumph. Condé, who had joined the Spaniards, continued to maintain a kind of civil war on the frontiers, where he was held in check by his rival in glory, the great marshal Turenne. In 1659, the peace of the Pyrenées advantageously concluded the long quarrel with Spain. One of its conditions was the marriage of the king with the infanta Maria Theresa, which took place in 1660. The king, during the life of Mazarin, interfered very little in public affairs; but after his death, in 1661, Lewis began to govern for himself, and from that moment the post of prime minister became vacant: he had, however, able men about him; among these was Colbert, who had been recommended to him by

Mazarin, as a most able financier. To his genius was owing the revival of commerce and the marine, and all the splendid establishments of arts and manufactures which adorned the early part of this reign. It was he who, though not learned himself, was capable of appreciating the true value of literature, and suggested to the king, his master, that plan of pensioning all the eminent men of letters throughout Europe, which, at a comparatively small expence, secured to him more adulation from persons of real learning, than any prince of modern times. His leading object was personal grandeur. In whatever point any other prince had attained to greatness, he was resolved to emulate him. He employed all the resources of a rich and flourishing country to surpass every competitor, in whatever could conduce to his glory. This spirit led him to attempt many great and useful projects, but for want of limit and moderation, it defeated its own purposes, and exhausted its means before it had attained its end. The age of Lewis XIV. was that in which the reputation of France for arms, arts, literature, and magnificence, stood at its highest pitch; at the same time, it was that which demonstrated its wretchedness and humiliation, and the impartial historian has held up the king rather as the squanderer of his country's prosperity, than as the author of it. Of the wars of this monarch we cannot pretend to give a detailed account; the most that this article will allow will be a sketch of the principal events of the reign, as connected with the personal character of the king. A quarrel concerning the precedence between the French and Spanish ambassadors at London, gave occasion to Lewis to assert in such high terms the superiority of his crown, that the point was never after contested. Shortly after, the insolence of the French ambassador's servants at Rome, having brought upon them an attack from the pope's Corsican guard, in which some were killed, and the French quarters violated, the king seized upon Avignon, and obliged the pope's nephew, a cardinal, to come to Paris and ask pardon; the Corsican guard was broke, and a column was erected in Rome as a memorial of the event. War with Spain was renewed in 1667; the king in person took the field, though the measures of the campaign were probably directed entirely by the great Turenne. The whole of Flanders was reduced in this campaign, and at the close of it Franche Comté was conquered. A triple alliance between England, Holland, and Sweden, checked the progress of the French arms, and produced the peace of Aix-la-Chapelle in 1668. In 1672 Lewis, with a vast army, commanded by the ablest generals, burst upon the provinces of Holland; and Amsterdam, the capital, was rescued from his grasp only by laying the surrounding country under water. At this juncture, William, prince of Orange, raised to the office of stadtholder, revived the drooping spirits of his countrymen; and the principal potentates of Europe, alarmed at the success and ambition of France, leagued against her. Holland was now evacuated as fast as it had been over-run. The French arms were again turned upon Franche Comté; it was conquered a second time, and became inseparably annexed to the crown of France. War with Spain, the empire, and other powers, continued some years longer, but it was terminated, in 1678, by the peace of Nimeguen. Lewis, attended by all the pomp and luxury of a court, formed several sieges in person; he carried with him historiographers to record his exploits, and every art was employed to exalt him in his own estimation, and in the eyes of Europe. He received from his subjects the title of "Le Grand," which for a considerable time seemed durably attached to his name; but he lived to lose it in the estimation of foreigners, and it has, by the events of the last twenty years, finally become obsolete among his own countrymen.

countrymen. The peace of Nimeguen did not terminate the projects of Lewis XIV. ; he attacked, and brought to submission, the piratical states of Algiers, Tripoly, and Tunis ; and next, upon very trifling grounds of offence, made war upon Genoa, and forced the doge to come in person and ask pardon of the king. With pope Innocent XI. he quarrelled respecting the supposed rights of the Roman church, and because he insisted upon retaining the franchises of ambassadors from Rome, which other powers had agreed to renounce, as inconsistent with a safe and regular police. On this occasion Lewis declared to the nuncio, "that he would never take the example of others as the rule of his conduct, but that it was for him to give the example." He was now ambitious of the fame that would attach to the extirpation of heresy from his kingdom. Calvinism, in France, since the victory over it by Richelieu, had become a peaceful separation from the national church, and its sectaries were useful citizens chiefly attached to manufactures and commerce. Lewis, animated by a spirit of intolerance and bigotry, undertook to put an end to it. The privileges of the Protestants were openly violated ; missionaries were sent for their conversion, supported by dragoons ; and severities were exercised, which excited the horror and indignation of all the reformed states of Europe. In 1685 the revocation of the edict of Nantes, first granted by Henry IV. and confirmed by Lewis XIII. deprived the Protestants of all exercise of their religion, and tore from them their children to be educated Catholics. The tyrant at the same time issued his decrees against emigration, and placed guards on his coast ; nevertheless vast numbers escaped from his machinations, and carried their arts and industry to foreign and hostile nations. Lewis, though a pretended votary to religion, and a zealous son of the church, was not free from that licentiousness which is regarded as highly culpable by persons of real and unaffected piety. Several mistresses, in succession, enjoyed his favours ; with one of whom, madame de Montespan, a married woman, he lived a long time, in the most open manner, and indulging her haughty and capricious humour. Her influence declined with her personal charms, and the king's advancing years ; and she was superseded by the widow Scarron, elevated from that low condition to the title of madame de Maintenon, a person who, by the powers of her understanding, and consummate skill in the art of pleasing, obtained a complete ascendancy over the king's mind. On the death of the queen he privately married her, but she was never acknowledged as queen. The league of Aunbourg, formed in 1687, between the emperor and most of the German princes, the king of Spain, the United Provinces, the duke of Savoy, and other Italian potentates, had for its object the reduction of the power of France. The great leader in this league was William, prince of Orange, who, when he ascended the throne of England, contrived to add that kingdom to the confederacy. The forces of France had proved victorious in many quarters ; marshal Luxembourg, and other eminent generals, renewed the successes of the former war, and the king in person took Namur. The defeat at La Hogue was, however, a fatal blow to the French marine ; the finances of the country began to be depressed, a circumstance that led to much domestic distress, and Lewis XIV. was obliged, in the midst of victory, to sign the general peace of Ryfwick in 1697. The declining health of Charles II. king of Spain, who was without heirs, became a subject of universal interest with respect to the disposal of his vast inheritance ; and Lewis, fearing lest it should fall into the hands of the house of Austria, joined England and Holland in a scheme for the partition of the Spanish dominions. At length, however, the dying king

made his will, appointing, as his general heir, Philip, duke of Anjou, second grandson of Lewis. The wary monarch foresaw the danger of accepting the legacy, but was decided by a regard for the glory of his house, and the wish of uniting the interests of two great monarchies, which had generally been at variance. The hopes of the king have been completely disappointed, and every attempt to form an union of interest and affection between two nations radically opposite in character and circumstances, has been baffled. Neither the intrigues nor the power of the present emperor of France have, at present, been able to effect that which was unquestionably an object near the heart of Lewis XIV.

The jealousy excited in England and Holland by this accession to the influence of France, was converted into open hostility by the imprudence of Lewis in declaring the son of James II., king of England, at the decease of his father in 1701. This step, contrary to the unanimous advice of his council, and his own judgment, was taken in consequence of a generous emotion of pity for the family of his royal friend, enforced by the sollicitations of madame de Maintenon ; it was not only impolitic, but, in fact, it amounted to a declaration of war, because an article in the peace of Ryfwick, explicitly acknowledges William's title to the crown of England. A new league was immediately formed between the maritime powers and the emperor of France ; and the death of king William, during the preparations for war, did not prevent its being carried into execution under his successor queen Anne. From this period to the year 1711, the reign of Lewis was one continued series of defeats and calamities ; and he had the mortification of seeing those places taken from him, which, in the former part of his reign, had been acquired at the expence of many thousand lives. The domestic misery of Lewis had kept pace with the public calamities ; the court, the splendour and magnificent entertainments of which had excited the admiration and envy of Europe, had long been impressed with a deep and settled gloom. The art of forgery, in Europe, was yet feeble and crude ; a fitula, with which the king was attacked, spread a general alarm ; and though the operation was successfully performed, yet he never recovered his accustomed spirits, but led a more serious and retired life, and chiefly devoted his hours to the conversation of madame de Maintenon, whose influence increased with his years. To his own private afflictions were added many family losses. The death of the king's only son, which happened in 1712 ; the duke of Burgundy, the duchess his wife, and their eldest son, all swept away within a few months, and laid in the same tomb ; the only surviving child at the point of death ; these private woes, added to those of the public, mark the close of the reign of Lewis, as an era of calamity ; and a wretched people, who conceived that their own happiness was concerned in the glory of the king, awaited in silence to behold the former greatness of their monarch extinguished by the dark cloud of misery which obscured his setting sun. Another mortification remained for the king ; he had enlarged the canal of Mardyke, and formed an harbour there, equal, it was thought, to that of Dunkirk. The ambassador for England remonstrated against this evasion of the treaty of Utrecht, and Lewis was under the necessity of discontinuing the works. At the age of seventy-seven, that vanity and ambition which had agitated the years of manhood were nearly extinguished. He coolly listened to the sollicitations of the unfortunate James, who aspired to ascend the throne of his late sister, queen Anne, already filled by the elector of Hanover, under the title of George I. To the importunities of the prince he granted a small supply of money, and a vessel fitted out in the name of an individual ; but while

that enterprize hung in suspense, Lewis was seized with a mortal disease which soon brought him to the grave. In his last hours he displayed a greatness of mind worthy of his exalted situation. "Why do you weep," said he to one of his domestics, "did you think me immortal?" His fortitude was tempered with humility; he recollected his own weakness, and had sufficient magnanimity to confess them; his advice to the infant that was to succeed him was to avoid that glory which he had hoped to attain by war, and to consider the happiness of the people as the principal object of his government. To madame de Maintenon he left no fixed stipend, but contented himself with recommending her to the care of the duke of Orleans. She retired to St. Cyr, which had been founded, at her persuasion, for the education of young ladies, and demanded but little more than *zooool. per annum* during her life; this was regularly paid till her death, which happened in about four years. Lewis XIV. had the misfortune of outliving his popularity, and an indecent joy was manifested by the people at his funeral. As a monarch he had none of the commanding qualities which create a nation or an era, and would scarcely have been distinguished from common princes under common circumstances. The masculine beauty of his person was embellished with a noble air; the dignity of his behaviour was tempered with the highest affability and politeness; elegant without effeminacy; addicted to pleasure without neglecting business; decent in his vices, and beloved though invested with arbitrary power. Nevertheless his qualities seemed those that rather attract a momentary regard, than command a permanent esteem. The talents, the fire of the statesman, and the hero were still wanting; vanity rather prompted him to insult, than ambition to enslave his neighbours. Though he frequently took the field, and reduced countries and the strongest towns, yet in all his campaigns he never exposed his life to the hazard of a battle. The age of Lewis XIV. will always be a memorable period in his country and of Europe. His own intellectual acquisitions were very limited, but he was the patron of learning and science.

LEWIS XV., son of the duke of Burgundy, (grandson of Lewis XIV.) was born at Versailles in 1710, and succeeded to the crown on the death of his great grandfather, when he was but five years of age. By the last will of Lewis XIV., a council of regency was appointed during the minority of the young king, at the head of which was the duke of Orleans. That nobleman, however, disgusted with an appointment which gave him only a casting vote, appealed to the parliament of Paris, who set aside the will of the late king, and declared the duke sole regent. His first acts were extremely popular, and gave the most favourable ideas of his government and character. He restored to the parliament the right which had been taken from them, of remonstrating against the edicts of the crown; and compelled those, who had enriched themselves during the calamities of the former reign, to restore their wealth. The young king was placed under the tutelage of Fleury, bishop of Frejus, afterwards cardinal, who, by his insinuating and very gentle manners, acquired his affection and esteem. His minority ended in 1722, and he was solemnly crowned; but the regent retained his chief power during another year. He now resigned his high office as prime minister to the duke of Bourbon, who negotiated a marriage between the king and Maria Leczinski, daughter of Stanislaus, king of Poland, which took place in 1725. Shortly after this, Fleury became prime minister; which post, notwithstanding his great age, he held till his death in 1743. The spirit of his government was economical and pacific; and a war with the empire, in 1733, was the principal foreign occurrence.

This terminated in the annexation of Lorraine and Bar to the crown of France. Lewis lived for some years in conjugal affection and fidelity with his queen, by whom he had one son and several daughters. At length, however, he was captivated by the allurements of some ladies of the court, and received, it is said, the favours of three filters at the same period: and from this time he indulged his propensities for the female sex without moderation and delicacy. On the death of the emperor Charles VI. in 1740, a new continental war was excited. France joined with Prussia and Poland, in raising to the empire the elector of Bavaria, in opposition to the interests of the house of Austria, whose cause was maintained by England, Holland, and Sardinia. In 1744 Lewis took the field in person, and was at the reduction of several strong places; but at Metz he was attacked with a dangerous illness, which occasioned a general conflagration through France. His recovery was celebrated with all those transports of joy which could proceed from the awakened sensibility of a nation, then remarkable for an enthusiastic attachment to its sovereigns. The surname of "Well-beloved" was given to the king on this occasion; and, in return for the affection of his people, he displayed the feelings of a good heart, and exclaimed very sincerely, as well as very naturally, "How sweet is it to be thus loved! What have I done to deserve it?" Soon after his recovery, he beheld at a distance the bloody battle of Fontenoy, gained by marshal Saxe. The French were generally successful in Austria and the Dutch Netherlands, but were defeated in Italy; and their marine was totally ruined by the English. The treaty of Aix-la-Chapelle, in 1748, restored peace to Europe: and, as far as the exhausted finances of France would allow, useful plans of domestic improvement were executed; and the most splendid establishment of the reign, the royal military school, was instituted in the year 1751. About this time, some warmly contested disputes between the magistracy and clergy occasioned the interference of the king, who, instead of making a firm decision between the contending parties, upon principles of justice and true policy, acted the part of a despot, by alternately banishing both. It was in consequence of the ferment produced by these quarrels, that a fanatic, named Damien, was induced, in 1757, to attempt the life of the king at Versailles, in the midst of his guard. He received a slight stab between his ribs. Damien was evidently insane: he was instantly seized by the soldiery, and put to the rack, in which he endured the most exquisite tortures that the wit of the most savage hearts could invent. In the midst of these he persisted in an obstinate manner to declare, that he had no intention to take away the life of the king: his only object was to wound him, that Almighty God might by that means affect his heart, and thereby incline him to restore peace to his dominions. These expressions had no weight with his merciless tormentors, who consigned him to the most terrible death which they could devise. This circumstance had probably some effect on the king himself; for he soon after banished the archbishop of Paris, and accommodated matters with his parliament. The war of 1755 had brought the nation to the brink of ruin, when Lewis implored the assistance of Spain; and on this occasion the celebrated "Family Compact" was signed, by which, with the single exception of the American trade; the subjects of France and Spain were naturalized in both countries, and the enemy of one sovereign was to be invariably regarded as the enemy of the other. At that time, the accession of Spain to her cause only added new laurels and acquisitions to Great Britain. Lewis's attachment to a selfish and imperious mistress, madame de Pompadour, who

was allowed to appoint and dismiss ministers and commanders at her pleasure, and sacrificed every thing to her avarice and ambition, was greatly instrumental in producing the disasters which followed one another at this period in rapid succession. The conclusion of the seven years' war, in 1763, gave the nation repose, but not without a considerable diminution of territory; and in the following year, the society of Jesuits, as celebrated for their great learning as famous for their unbounded intrigues, was abolished in France. The death of madame de Pompadour did not free the king from female influence, who by this time had incurred all the habits of a confirmed debauchee. He fell under the dominion of madame de Barré, who, by her dissolute arts, provoked his languishing desires; and his latter years, as might have been anticipated by the conduct of the former part of his life, was disgraced by the grossest sensuality. At the same time, the government became more severe and arbitrary. Though the arms of Lewis had extinguished the flame of freedom in Corsica, in France it was revived by the breath of the parliaments, and cherished with a fond regard that threatened the most important consequences. An edict issued by the king, which transferred some new and extraordinary powers to the grand council, was strenuously opposed by the parliament of Paris. Sixty-four members of that assembly voted for utterly abolishing that council; and the question was lost by a majority of two, though all the princes of the blood attended to support the court; and the duke de Choiseul endeavoured to overawe the independent spirit of the patriotic party, by continuing in the assembly throughout the debate. The minister, finding his exertions in the support of despotism of no avail, attempted to conciliate those whom he had vainly endeavoured to intimidate. Hitherto the sovereign had resisted the solicitation of the people to restore the parliament of Brittany: he now aspired to popularity, by doing of his own accord that which he had been frequently impetioned to grant; and the duke de Duras was sent into that province to re-establish the parliament, and to recall the members from exile. But concession, which a short time before would have been ascribed to the benignity of the monarch, was now attributed to his fears; and the parliament had scarcely assembled before they convinced their countrymen, that oppression had confirmed, and not extinguished their zeal for the public welfare. The province of Brittany had long groaned under the iron rule of the duke d'Aiguillon; who for four years had persecuted with unremitting vengeance M. de Chalotais, the attorney-general to the parliament. That unfortunate gentleman had opposed, with the indignation of a virtuous magistrate, the oppressive measures of the duke; he was therefore driven into exile, and pursued from dungeon to dungeon, till at length a sentence was procured against him that would have involved his life, and which his cruel persecutor was hastening privately to carry into execution. The parliament of Brittany interfered, and prevented the perpetration of so foul a deed. The rescue of M. de Chalotais laid open a scene of the blackest iniquity; and the parliament of the province, possessed of new proofs, commenced a process against the duke d'Aiguillon, whose trial was conducted in the presence of the king, the princes of the blood, the peers, and the parliament of Paris. Before so high a court thus specially assembled, the written proceedings carried on against M. de Chalotais were produced, and disclosed such a complicated system of guilt and cruelty as exceeded every thing that could have been imagined. Amidst these domestic disquietudes, the dauphin, afterwards Lewis XVI., received the hand of Maria Antoniette, sister to the emperor of Germany. The crowd that eagerly pressed forward

to be spectators of the fire-works, displayed on this occasion, was so great, and the confusion that prevailed was so completely overwhelming, that several hundred persons perished, by being literally trampled to death. This loss, however, which was felt in one way or other by almost all the families of Paris, did not divert the public attention from the prosecution of the duke d'Aiguillon. But at the moment that the nation was expecting, with the most earnest solicitude, the decision of this most important cause, Lewis thought proper, by a violent exertion of his power, to put a stop to the whole course of justice, and to all farther inquiries into the conduct of the duke. All the parliaments of the kingdom made a common cause: the ordinary course of justice was suspended; and, in conclusion, the king, in 1771, overthrew the whole system of judicial administration, and established a new one. This was not effected but with force. The language of the parliament of Paris was worthy the indignant feelings of free men: "Your edict, sire," say they, "is destructive of all law: your parliament is sworn to maintain the law; and the law perishing, they should perish with it: these, sire, are the last words of your parliament." Lewis, unaccustomed to such language, prepared to support his authority by the most violent measures. In the dead of the night, the members were roused from their slumbers by parties of the guards sent into each house, who presented to every individual a lettre de cachet, which enjoined them to declare whether they would resume the administration of justice. In the moment of confusion, several of them were surprised into acquiescence; yet they soon retracted, and, in the end, the whole body of parliament was banished the capital. Here then was the foundation of that revolution, which must be touched upon in the next reign, and which has introduced such scenes into the political world which the wildest imagination could not have conceived. The exhausted state of the finances suggested new and burdensome imposts on the great body of the people, which augmented the public discontents. In the midst of these, Lewis found no solace even in the company of his mistress madame de Barré: her beauty proved insufficient to excite desire; and he became discontented with himself, and with all about him. A succession of mistresses became necessary to rouse the languid appetites of the king. One of these, who was infected with the small-pox, communicated the disease to the king, who in a short time died of it, unpitied and unlamented, May 1774, in the sixtieth year of his reign. He had lost his only son in 1765, and his crown devolved upon his grandson.

Such was the fate of Lewis XV., who at length fell a victim to those sensual appetites, in the gratification of which he had sacrificed his own fame, and the welfare of his subjects. The enviable appellation of *well-loved*, which he was conscious, as we have seen, he had not merited, but which had been conferred in the moment of danger by a loyal and affectionate people, was completely obliterated from memory, by 30 years of lascivious excess, profusion, and rapacity: his example had loosened the bands of morality; his prodigality had exhausted the credit and resources of his country; and his wanton pride had trampled upon every form that had been held sacred in the constitution. His affections seemed to have been confined within the narrow limits of his personal pleasures and security. It was by the perpetual suggestions of the countess de Barré, that his safety was at stake, which stimulated him to decisive measures in suppressing the parliaments of France. Though concealed from the public eye, the embers of freedom were still carefully cherished, and, as will be seen in due time, burst forth with accumulated force, and overwhelmed

wheimed the throne of despotism. During this reign the arts and sciences made a rapid progress in France, which was aided by the munificence of the court, as long as other demands did not anticipate the funds for this purpose. The voyages of the French mathematicians to the equatorial and polar regions, in order to measure a degree of the meridian, were equally honourable to the government and the persons employed. The king was deeply read in history and geography. As a gentleman he was polite, affable, and naturally mild and humane; but fondness for sensual indulgence degraded him as a king and a man.

Lewis XVI. grandson of the preceding, and son of the dauphin, Lewis, and of Maria Josepha of Saxony, was born in August, 1754. His father carefully superintended the education of his three sons, and placed them under the direction of preceptors, who were particularly attentive to their morals, and who instilled into their minds sound principles. With respect to the subject of the present article their cares perfectly succeeded; he, whose title at that time was the duke of Berry, was naturally modest, timid, and docile, and repaid, by his virtues, the attention bestowed upon him. In his earliest years, though he did not manifest any brilliancy of parts, he shewed a disposition capable of attaining useful knowledge, and manifested a memory retentive of the minutest facts. He had a sound judgment, great patience and application. He ascended the throne in 1774, being then in the 20th year of his age, and, to secure himself against the dire effects of that disease, which had proved fatal to his predecessor, submitted to inoculation, with several others of the royal family. Their quick and easy recovery contributed much to extend the practice throughout the kingdom. The king, as soon as he had gained his health, applied himself diligently to extinguish the differences which had taken place betwixt his predecessor and the people. He removed those from their employments, who had given cause of complaint by their oppressions; and he conciliated the affections of his subjects, by dismissing the new parliaments and recalling the old ones. Though the prudence of Lewis had suggested these compliances, he was anxious to preserve the royal authority pure and entire: he avowed in one of his earliest speeches, in the great chamber of parliament, that the steps he had taken were designed to ensure the tranquillity and happiness of his subjects; and he hoped, from the zeal and attachment of the present assembly, for an example of submission to the rest of his subjects; he farther said, he was desirous of burying in oblivion all past grievances, and that he should ever behold with extreme disapprobation, whatever might tend to create divisions and disturb the general tranquillity. It was, however, the misfortune of this monarch, as it was that of Charles I., to come to the crown at a period when a great change in public opinion had long been preparing, and was now arrived at a point, which announced a speedy crisis in the political system. The despotism of the last two reigns had exasperated men's minds, and rendered them alive to the evils of arbitrary power, while the weakness and debauchery of Lewis XV. had accustomed the nation to regard the crown with contempt. "The profligacy of the nobles, the rapacity of the courtiers, the disputes and vices of the clergy, had sapped the foundations of social order; and, in the mean time, a set of able and eloquent writers had arisen, who, by the united powers of argument and ridicule, aggravated all the faults of ancient establishments, and endeavoured to subvert public opinion." The finances were in a state of derangement, and though the king himself was extremely moderate in his expences, his economical plans were thwarted by the queen and the princes of the blood.

The final conquest of the Corsicans, who, provoked by the oppressions of their governors, had, once more attempted to regain their former liberty, was the first event of importance which took place after the restoration of public tranquillity; but the kingdom was a prey to disorder from other causes. A scarcity of corn happening to take place just at the time that some new regulations had been made by M. Turgot the new financier, the populace rose in great bodies, and committed such enormous outrages, that a military force became absolutely necessary to quell them. The humanity of Lewis was shewn in an edict, which he caused to be registered in parliament, sentencing the deserters from the army, in future, to work as slaves on the public roads, instead of punishing them, as formerly, with death; and with equal attention to the general welfare of his subjects, he seized the moment of peace to fulfil those promises of economy, which on his accession he had given to the people. Particular attention was paid to the state of the marine; and the appointment of M. de Sartine, in 1776, to that department, did honour to the penetration of the sovereign. Shortly after this, notwithstanding the danger of the example, France took a decided part in the quarrel between England and her American colonies, permitting some of her subjects, men of high rank and station in the country, to cross the Atlantic, and serve in the republican armies. The consequence of these measures was a declaration of war on the part of England. After a variety of fortune, France and her allies succeeded in detaching America from the British crown; yet the expence of such widely extended operations left the French finances in a state of aggravated disorder, while the event could not fail to operate in behalf of antimonarchical principles. In the mean time successive ministries had adopted various and contradictory systems with regard to external and internal policy; and several projects of reform had been proposed and discussed, with no other advantage than that of accustoming the nation to debate with freedom all public topics, and open its eyes to existing abuses. Without pretending to enumerate the events of the present reign as they occurred, the record of which would fill a volume much larger than that of which we can only occupy a very few pages, in the description of an era more important to France and the world than can be found in history; we shall only refer to some of the more prominent events, which led to the fatal, unjust, and cruel termination of the reign and life of Lewis XVI.

Of the ministries employed by Lewis, several were distinguished for enlarged and philosophical views, though, as it afterwards proved, they were very little accommodated to circumstances and the ancient constitution of the country. Among the more remarkable occurrences of the period of which we are speaking, was the appointment of M. Neckar to the administration of the finances of the country. Hitherto France had carefully excluded aliens from the country and established faith from the controul of her revenue; nor was it less hostile to the feelings of the court, that a person without rank should be elevated to so high an office in the state: nevertheless M. Neckar was a Swiss by birth; a Protestant in religion; and a banker by profession. In the year 1780, the king fixed on the anniversary of his birth to render the day memorable in the annals of his country by a new instance of humanity, and abolished for ever the savage custom of "putting the question," as it was denominated, that is, of extorting confession from persons accused, by the instrumentality of the rack and other engines of torture;—a custom which had been so long established by the practice of ages, that it seemed to be an inseparable part of the constitution of the courts of justice in France. At  
the

the same time, he rendered himself worthy of public esteem, by diminishing his own expenditure, and by sacrificing the magnificence of his court to the ease of his subjects. Unfortunately, however, the popular discontents were excited in the following year, by the dismissal of the then popular minister M. Neckar. He had conceived the arduous project of supporting the war by loans without taxes; and the rigid economy which he had introduced into all the departments of the household, and the various resources that presented themselves to his fertile genius, had supported him amidst the difficulties that attended his system. The austerity of his manners, increased probably by the difficulties with which he was surrounded and interrupted, rendered him exceedingly obnoxious to the queen and persons about the court, who took every opportunity of representing the reforms, which he had introduced, as inconsistent with the dignity of the crown: he was therefore dismissed from the high office, which he had held with great reputation. The effect of his dismissal was a vast abatement of public confidence in the permanency of the state; three different persons succeeded one another in rapid succession, as finance ministers; these, however, whatever might be their intentions, served only to increase the jealousy of the people, and the failure of the celebrated "Caisse d'Escompte" completed the universal consternation. The stoppage of this national bank was imputed to a scarcity of specie, but the real cause was probably owing to an immense loan advanced secretly to the government. Some successful expedients revived the credit of the bank, and its stock rose to above double the original subscription; by these means public credit was restored throughout the kingdom. In 1783 M. de Calonne, who had already successfully filled with acknowledged reputation the office of intendant of Metz, and afterwards of the provinces of Flanders and Artois, was nominated to the post of comptroller-general. This gentleman, whose name was accidentally omitted in the alphabetical arrangement of the Cyclopaedia, was born at Douay, in 1734, educated at Paris, and became an advocate of considerable reputation. After some attendance at the bar, he obtained, as we have seen, various important trusts, till he became prime minister. When he succeeded to this office, it was said, he did not find a single crown in the treasury. In this important office he continued about four years, and by some specious operations he restored an apparent prosperity to the affairs of the state, and maintained the public credit by a punctuality, till then almost unknown, in the payments from the royal treasury. He laboured with unwearied assiduity to restore the equipoise between the annual income and expenditure, and to provide a supply for the emergencies of the state, without vastly increasing the burdens of the people, which, even before his administration, they were scarcely able to sustain. For this purpose, he advised the king, to revive the ancient usage of convening national assemblies of the *Notables*, to whom he proposed the bold project of suppressing the pecuniary privileges and exemptions of the nobility, clergy, and magistracy. This measure was too daring even for him to carry; it excited indeed to much ill-will and determined hatred from these powerful bodies, that M. de Calonne found it necessary to retire to England, where he wrote two defences in justification of himself and his measures. At the end of the war he returned to Paris, where he died in 1802. He was author of several other works, on the situation of his country, and on the state of its finances.

The states-general of the kingdom, as a body formidable to monarchical authority, had never been convoked since the year 1614, and it was therefore determined first to have re-

course to an inferior kind of assembly, denominated the *Notables*, because these were to be selected by the king from the different orders of the state, and therefore it was expected they would the more readily submit to the guidance of the court. This assembly had been convened by Henry IV. and again by Lewis XIII. and was now to be summoned by the authority of Lewis XVI. The writs for calling them together were dated the 29th of December 1786; and they were addressed to seven princes of the blood, nine dukes and peers of France, eight field marshals, twenty-two nobles, eight counsellors of state, four masters of requests, eleven archbishops, thirty-seven persons high in the profession of the law, twelve deputies of the *pays d'états*, and twenty-five magistrates of the different towns in the kingdom. The first meeting of this assembly, in the month of February 1787, disclosed an enormous deficit which had hitherto been concealed. Great taxes were proposed to make good the deficiency, which the parliament of Paris refused to register, and thus refusing, that body was immediately banished the capital. The duke of Orleans, a man who disguised the worst principles, and the most criminal ambition under the mask of patriotism, and who probably, from this moment, was perpetually engaged in intrigues to ruin the king and subvert the constitution, having entered a protest in favour of the parliament, partook of its punishment. Various measures, some harsh, some conciliatory, succeeded, all displaying the embarrassment of the government, and the progress of the public discontents. M. de Calonne was now dismissed; Neckar was recalled; and at length, after a third convocation of the notables to no good effect, it was resolved to adopt the alarming expedient of calling together an assembly of the states-general, a circumstance that was looked on with anxious dread by the partisans of the court, and which was anticipated with pleasure and delight by those who were hoping for some radical change in the affairs of the state. On the dismissal of the notables, they were addressed in a moderate and very conciliatory speech from the throne. During the delay, the popular cause had still been gaining ground in the public mind, by meetings held in the capital and provinces, at which the utmost freedom, and no small portion of violence, in discussing political points, were indulged, and men of the inferior classes were habituated to act in concert, and become familiar with their own strength.

The time appointed for the convention of the states-general was now approaching, and the means of assembling them formed a matter of difficult deliberation in the cabinet. The last meeting, in 1614, had been convened by application to the bailiwicks. This mode was liable to strong objections; the bailiwicks had been increased in number and jurisdiction, several provinces having, since that period, been united to France; and the numbers and quality of the members were no less an object of serious attention: it was not, therefore, till the close of the year, that the proposal of M. Neckar was adopted, which fixed the number of deputies at 1000 and upwards, and decreed that the representatives of the third estate or commons should equal in number those of the nobility and clergy united. It remained now, as a matter of vast importance, for the popular party to carry the measure of the votes being taken, not by orders in three distinct houses, but by numbers in one house. As this would infallibly throw the whole power into the hands of the third estate, it was long and vigorously opposed by the royalist and aristocratical parties. At length the commons, thinking themselves sufficiently supported by the voice of the people, declared themselves "The National Assembly," and assumed the whole legislative authority. (For an account of the great operating and immediate

causes of the French revolution, we shall refer to the article *REVOLUTION*, and in the present article confine ourselves to those events which were closely connected with the conduct of the king.) During the violent and momentous contentions which were excited in every part of the kingdom, and particularly at Paris, the king, never steady to his purpose, fluctuated between opposite councils. His chief desire was, evidently, to preserve tranquillity, and prevent the effusion of blood, and he was prepared on his own part to submit to any sacrifices for this purpose that might be required of him. The states had been summoned to meet at Versailles on the 27th of April, and most of the deputies arrived at that time; but the elections for the city of Paris not being concluded, the king deferred the commencement of their sessions till the 4th of May. During this period, the members assembled, having little to do, spent their time in forming an intimacy with each other. Some of them united themselves into a club, into which none were admitted but those who were deemed zealous advocates for the popular cause. This society, originally formed at Versailles, was, hereafter, found sufficiently powerful to give laws to France, under the appellation of the Jacobin club, and to excite an almost universal terror and alarm through Europe. The states-general commenced their business by going in solemn procession, preceded by the clergy, and followed by the king himself, according to ancient custom, to church, to perform an act of devotion. The nobles and superior clergy were splendidly arrayed: the commons appeared in black. The assembly was now opened by a short speech from the throne, in which the king congratulated himself on thus meeting the people assembled; and having alluded to the difficult circumstances in which they were placed, he concluded with the following prayer, "May an happy union reign in this assembly, and may this epocha become ever memorable for the glory and prosperity of the country. It is the wish of my heart; it is the most earnest desire of my prayers; it is the price which I expect from the sincerity of my intentions and my love for my people." Several weeks were spent in discussing mere matters of form; in the mean time the people from without were vexed that no important step was taken to remedy the evils under which they laboured. They imputed this delay to the nobles and clergy, who became exceedingly unpopular. The leaders of the commons, called at that period the *tiers état*, took advantage of the change which was taking place in the minds of their countrymen, and formed the project of seizing the legislative authority of France: they almost instantly declared that the representatives of the nobles and clergy were only the deputies of particular incorporations, whom they would permit to sit and vote among themselves, but who had no title in a collective capacity to act as legislators of France. Some of the clergy had joined them; and they then proceeded to announce themselves, by a solemn decree, the sovereign legislators of their country, under the name of the "National Assembly." M. Bailly, the celebrated astronomer, was the first president: its earliest acts were decisively expressive of its own sovereignty. This was in the middle of June, and by the 19th a majority of the clergy voted for the verification of their powers in common with the national assembly, and they resolved to unite with them on the following day. At this important crisis the nobles perceived, that unless they could make a decisive stand all would be lost: they accordingly addressed the king, intreating him to dissolve the states-general; and on the next day, the 20th, when the president and members were about to enter as usual into their hall, they found it surrounded by a detachment of the guards, who refused them admission, while the heralds at the same time proclaimed "A royal

session." Alarmed and irritated by this unexpected event, they instantly retired to a neighbouring tennis-court, where, in the vehemence of enthusiasm, they took a solemn oath, "never to separate till the constitution of their country should be completed." The royal session was held in the most splendid form, but altogether in the style of the ancient despotism: the superior orders were seated while the commons were kept an hour in the open air, while it rained, before they were admitted. The king now assumed a high tone, delivered his speech, ordered the deputies to retire, and then left the assembly. He was followed by the nobles and part of the clergy, but the commons and those attached to them remained in gloomy silence, which being interrupted by an officer of the crown, who was left to see the intentions of his majesty carried into effect, the count de Mirabeau, starting from his seat, indignantly exclaimed, "The commons of France have determined to debate; you, sir, who have neither seat nor voice, nor a right to open your lips here, are not to remind us of the king's intentions. Go tell your master, that we are here by the power of the people, and that nothing shall expel us but the point of the bayonet." The king gave way, and at first, anxious to spare the blood of his people, recommended the higher orders to join the deputies of the commons; but, in a few days, he saw, or was persuaded by the queen and her party, that the obvious tendency of the popular measures was the entire subversion of all monarchical power; he therefore gave orders for the assembling of troops round the capital, and ventured upon the step of dismissing Neckar, and commanding him instantly to quit the kingdom. Paris burst into a flame upon this unexpected event; commotions took place; the soldiers were commanded to suppress the seditious assemblies; but they without hesitation grounded their arms instead of firing on the people; a vast body of national militia was organized, who supplied themselves with arms from the arsenal of the invalids, and on the memorable 14th of July, 1789, hostilities against the royal authority openly commenced by the storming of the Bastille. Resistance to the popular torrent was now in vain; the king recalled Neckar, who returned amidst the acclamations of the whole nation, and resumed the reins of government. Schemes for a new constitution and new measures of finance were discussed with calmness and composure, till a scarcity of provisions, joining with other causes of public agitation, inspired the populace with uncontrollable fury. In the beginning of October a dreadful insurrection took place, in which an immense armed mob marched to Versailles, broke into the palace, massacred some of the guards, and compelled the king, with the queen and his family, to accompany them to Paris. The triumph of the popular party was followed by the emigration of some of the most zealous friends to royalty, who carried into foreign countries a desire of exciting those hostile interferences on the part of the neighbouring powers in the affairs of France, which in the end proved destructive to the king and his family. On the 19th of October the national assembly, which had followed the king to Paris, opened its first session; and a constitution was speedily formed on the basis of a limited monarchy; a decree was passed, which put an end to all distinction of orders and immunities, so far as privileges were concerned, and the whole of the lands belonging to the church were confiscated for the purpose of supplying the exigencies of the state. This measure was proposed by M. Talleyrand, the bishop of Autun, who afterwards took a lead in the revolution. A provision was, at the same time, made for the national clergy, who were in future to be paid by the state. On the day following that, on which this important measure was adopted, a decree was passed, suspending the parliament of the kingdom.

dom from the exercise of their functions. During the winter the king had been strictly watched by numerous guards placed round his palace, so that he was regarded as in a state of captivity. To obliterate this impression, if possible, he appeared in the assembly, and in the presence of the deputies of the nation made a solemn declaration of his resolution to adhere to and defend the new constitution to the last moment of his life. On the 14th of July it was determined to commemorate the destruction of the Bastille, that fortress of despotism: never was a more splendid spectacle. The national assembly and the court joined in the procession that was made on the occasion, and when every thing was properly arranged to create effect, the king, after a serious invocation to God, approached the altar, and amidst the most solemn and awe-inspiring silence, took the following oath: "I the king of the French do swear to the nation, that I will employ the whole power delegated to me by the constitutional law of the state, to maintain the constitution, and enforce the execution of the law." The national assembly then took oaths of fidelity to the nation: as did La Fayette and others in the name of the national guards. After this a "Te Deum" was sung, the performance of which was sublime beyond the power of description. "Never," says the historian, "was there before such an orchestra, or such an audience; their numbers baffled the eye to reckon, and their shouts in full chorus rent the skies. It is impossible to enumerate all the means which were employed to add splendour to this day. It ended with a general illumination, and no accident occurred to disturb the public tranquillity."

Several new efforts were now making by the disaffected among the nobles and clergy to excite disturbances in various parts of the kingdom. Emigration became more frequent, and comprehended the king's aunts, and most of the princes of the blood, while troops were collected and openly formed into an army on the frontiers. The public suspicions were naturally kept awake by these circumstances, and popular ferments occasionally broke out in the capital and provinces. In April, 1791, the king and his family preparing to go to St. Cloud, to spend the Easter holidays, were forcibly stopped by the populace, who were suspicious that he meant to quit the capital. La Fayette drew out the national guard, but they, with one consent, refused to act against the citizens: "We know," say they, "that we are violating the laws, but the safety of our country is the first law." The king went to the assembly and complained of the insult: he was answered respectfully by the president, and continued his journey. He now endeavoured to convince foreign courts that he was no longer in a state of thralldom, declaring his cordial assent to the new order of things.

About this period, M. de Brouillé, to whom the protection of the frontiers was entrusted, was employing every means in his power to render the country defenceless. The garrisons were left unprovided; disunion was spread among the national troops, who were removed from the frontiers, and their place was occupied by foreigners, wherever it could be done. The emigrants abroad, and their friends at home, were lying in wait for an opportunity of revolt; when suddenly, on the 21st of June, it was announced from the Tuilleries, that the king, the queen, their children, together with the king's eldest brother and his wife, had quitted the palace and the capital. The national assembly took upon themselves the government, and decreed their sittings to be permanent: they sent at the same time messengers in all directions to attempt to lay hold of the fugitives. At Varennes they were stopped, arrested, and brought

back to Paris in triumph. The alleged reason for this departure was the danger and insult to which the king, and more especially the queen, were exposed, from the licentious violence of the Parisian mob; but there is no doubt that it was connected with the plans of the emperor Leopold and the emigrants, who were prepared, by force of arms, to make a grand effort in behalf of a counter-revolution. The king's brother, with his consort, who took a different road, made their escape. The national assembly proceeded with their labours, which they brought to a conclusion on the following September. The constitution, as fixed on at that time, was presented to the king, who solemnly accepted it, and swore to maintain it inviolate. On the 30th of September, the national assembly, which has been known since by the name of the "Constituent Assembly," dissolved itself, and gave place to the succeeding "Legislative National Assembly," which had been elected according to the rules prescribed by the new constitution. It was soon evident that France would have a foreign war to sustain with the powers coalesced for the restoration of the ancient monarchy, and for the further purpose of making conquests upon the French territories. In proportion to the national danger, the suspicions of the people increased, and their lost confidence in the king could never be recalled. New jealousies were excited by the interposition of the royal negative, allowed by the new constitution, against two decrees of the assembly, one levelled at the emigrants, the other at the non-juring priests. War was declared by the assembly against the emperor in April, and armies marched to the frontiers. A decree passed the assembly for forming a camp of 20,000 men near Paris, which Lewis, conceiving it a plan designed to overawe the more moderate party, and strengthen that of the Jacobins, refused to sanction, as he did likewise a severe decree against the refractory clergy. He also dismissed some of the popular ministers who had been forced upon him. The discontent which these measures excited burst out into a furious insurrection on the 20th of June, in which an armed mob made their way into the Tuilleries, and treated the royal family and their attendants with the grossest personal insults. The king displayed on this, as on all other occasions, great fortitude; and in reply to threats against his life, repeated in the lowest and coarsest language, he exclaimed, "Alas! would that my life could secure the happiness of the country, how readily would I offer it as a sacrifice." A calm now succeeded, in which the king and the national assembly appeared to unite in plans for the defence of the country: in the mean time dangers were accumulating, and the approach of the duke of Brunswick, with the Prussian army, preceded by a most menacing manifesto, in which the king's accession to the new constitution was represented as a mere involuntary compliance, stimulated the people almost to madness. The republican party determined to take advantage of this circumstance, with a view of deposing the king, and instituting a republic. At length, Petion, the mayor of Paris, appeared at the head of the sections, at the bar of the national assembly, to demand the deposition of the king. This was on the 9th of August; and at six on the following morning the king was seen reviewing his troops. He was received at first with shouts of *Vive le roi*, which were shortly overwhelmed with those of *Vive la nation*. The king returned to the palace, and the multitude continued to collect. The national guard seemed undetermined what to do as they assembled in divisions near the palace, and had a steady resistance been made from within, it has been thought they would have joined the royal party. The king was advised to seek protection in the hall of the national assembly: he was willing to comply; but

but the queen opposed, with vehemence, the humiliating proposal, till actual danger surrounded her person and children; she then consented, and the king, queen, the princes Elizabeth, the king's sister, with the dauphin and princefs royal, went on foot to the hall of the assembly. "I am come hither," said his majesty, as he entered the doors, "to prevent a great crime. Among you, gentlemen, I believe myself in safety." By an article of the constitution, the assembly could not deliberate in presence of the king. The royal family were, therefore, placed in a box separated from the hall, where they remained 14 hours, without refreshment, obliged to hear discussions in which the royal character and office were treated with every mark of insult. At length the fatal decree was passed that the royal authority should be suspended, and the nation was invited to elect a Convention, to determine on the nature of its future government. On that fatal day a numerous body of insurgents attacked the palace of the Thuilleries, which was defended by Swiss guards: a bloody engagement ensued, which terminated in the massacre of the greatest part of the Swiss, and several other regiments. As soon as the royal authority was suspended, the king and his family were sent to the Temple as a state prison. Massacre succeeded now upon massacre, till at length, on the second and third days of September, the most cruel and savage scenes were exhibited that were ever witnessed in a civilized country. More than a thousand state-prisoners were basely and infamously murdered by the ruffians of the capital, among whom was the beautiful princefs of Lamballe, whose bleeding head was carried on a pike through the streets of the city, and under the windows of the room in which the queen was confined, whose intimate favourite she had been. These acts, to which the royal family could not be strangers, they might well regard but as preludes to their own death: there was no party left in the country to espouse their cause; and no individual durst lift up his voice in their defence. The new convention was assembled on the 20th, and their first decree was the eternal abolition of royalty, which was carried by acclamation: this object being attained the house adjourned, and copies of the decree was sent into every village and commune of France. The most violent measures were adopted; nor could the moderate party in the convention restrain the madness of the Jacobins, who were bent on levelling all distinctions; to bring into contempt every thing in letters and in science that was in the least raised above the comprehension of the lowest of the people. The intention was soon avowed of bringing the king to trial. It was in vain that those, who were anxious to save his life, appealed to the inviolability of his person, declared by the constitution he had accepted: principles, however sacred, were made to yield, and a committee was appointed to give in a report upon his conduct. The result of this was, that various accusations were brought against him, and the convention resolved to take upon themselves the part of accusers and judges. On the 11th of December, the fallen monarch was brought to the bar to answer to the heads of accusation drawn up against him for the crime of tyranny and treason towards the nation. He defended himself with judgment and presence of mind, and received the advice and assistance of three eminent advocates, who generously and nobly undertook his cause, though with great hazard to themselves. The proceedings were carried on till the 26th of December, when M. Defeze, one of his advocates, read a defence of his client, which being finished, the king rose, and holding a paper in his hand, pronounced, in a calm and dignified manner, and with an impressive tone of voice, "Citizens, you have heard my defence; I now speak to you, perhaps

for the last time, and solemnly declare that my counsel have asserted nothing to you but the truth; my conscience reproaches me with nothing." The discussion was finally closed on the 16th of January; and after a sitting of 34 hours, the punishment of death was awarded by a very small majority of the convention. M. Defeze then invoked the assembly, in the name of his colleagues, to consider by what a trifling majority the punishment was pronounced against the dethroned monarch; "Do not afflict France," said he, "by a judgment that will appear terrible to her, when five voices only were presumed sufficient to carry it." He appealed to the eternal justice and sacred humanity, to induce the convention to refer their sentence to the tribunal of the people. "You have either forgotten or destroyed," said M. Tronchet, another of the king's advocates, "the lenity which the law allows to criminals, of requiring at least two-thirds of the voices to constitute a definite judgment." The sentence was ordered to be carried into execution without delay. The king and his family had been kept separate from each other; but he was now permitted to see them. The short interval allowed him he employed in the preparations for death enjoined by his religion, to which he was sincerely attached. The final meeting and separation of the king from his family was affecting in the extreme. On the morning of the 21st of January, at eight in the morning, he was summoned to his fate. He ascended the scaffold with a firm and dignified step; and his behaviour there partook of the calm fortitude which had distinguished him through all his scenes of suffering. Raising his voice, he exclaimed, "Frenchmen, I die innocent; I forgive my enemies." He would have proceeded, but was prevented by the beating of the drums, placed on the spot purposely to drown his voice. The executioners came forward to perform the bloody deed, which being perpetrated, the bleeding head was held up to the view of the surrounding crowd, of whom some few exclaimed "Vive la Republique;" but the great mass of spectators was too deeply absorbed in thought to join in the shout which the leaders attempted to excite. The body of the deceased victim was thrown into a pit filled with quicklime, and a guard placed around it till it should be consumed. The unhappy monarch was in the thirty-ninth year of his age, and the nineteenth of his reign. He left two children, a son and a daughter, of whom the son died very miserably in 1795, and his sister in the following year. The queen was brought to the scaffold in 1793, and his sister in 1794. Such were the misfortunes to which this royal house was subject. Lewis XVI. possessed from nature a good understanding, which, however, was blunted by the early indulgences of a court. He had a strong sense of justice, and his humanity was much superior to what could have been expected from a person in his high station in life. By posterity he will be regarded as one of the best and most virtuous of the French kings. He had acquired a large portion of general knowledge, and on some literary subjects he entered rather deeply. He wrote well, and excelled in clearness of expression and methodical arrangement. In vigour of mind he was unquestionably deficient; but in reviewing the history of the period, we cannot conceive how he could have acted so as to have successfully opposed the voice of the people. It was his misfortune to have fallen on difficult times; he could not stem the torrent of public opinion; and it is probable that few princes, if any, would have been capable of extricating themselves from such difficulties as surrounded Lewis XVI. during a great part of his calamitous reign. For farther particulars relating to Lewis's of France, the reader is referred to the Modern Universal History; to the History of France, London, 1790; and

and to the History of the French Revolution, by Rabaut St. Etienne.

LEWIS, JOHN, a learned English divine, was born at Britton in 1675. He was educated in grammar learning at the free-school of Winbourn, in Dorsetshire, and received his academical education at Exeter college, Oxford, where he took his degrees. Having been ordained, he officiated some time as curate of St. John's, Wapping. In 1699 he obtained the rectory of Acris, in Kent, which he resigned in 1706, when he was presented by archbishop Tension with the rectory of Saltwood in Kent, with the chapelry of Hythe annexed. He was afterwards collated to the vicarage of Minter, in the isle of Thanet, and in 1719 archbishop Wake constituted him master of Eastbridge hospital, in the city of Canterbury. He died at Margate in 1746. He was author of a great number of publications, which reflected credit on his industry and learning; among these were "The Life of Wickliffe;" "Wickliffe's Translation of the New Testament;" "The History and Antiquities of the Isle of Thanet;" "The History of the Abbey and Church of Faversham;" "The Life of William Caxton;" "The History of the Translations of the Holy Bible and New Testament into English."

LEWIS, in *Geography*, is the most northern, and the largest of the Hebrides, or Western Islands, of Scotland. It is connected with the island of Harris by a narrow isthmus, which at low water is left entirely dry, and even at high water is not completely covered; whence the whole may be considered as one island. (See HARRIS.) The isle of Lewis is of very irregular form and boundary; and extends about 50 miles in length from north to south, by about twenty, on an average, in a transverse direction. Towards the centre the land is mountainous and boggy; but near the shore it is rather flat, and is intersected by numerous inlets or bays of the sea. The island is almost destitute of wood; a few birches, hazles, and a little heath, being the only species of shrubs seen here: but it is said that Lewis was formerly covered with plantations; the decay and destruction of which contributed to form the peat-earth, with which the island abounds. Springs, lakes, and rivulets, scattered through the island, furnish in all parts abundance of fresh water. With respect to the climate, the spring is uncommonly cold and backward, the summer warm, the autumn accompanied by profuse rains, the winter without long or severe frosts, or very weighty falls of snow, but with constant winds, and these stormy and sharply cold. Among the wild animals, the isle still produces deer or rocs. Great numbers of wild fowls of many different species frequent the shores, the lakes, and the cliffs of the mountains; among others, is the eider goose, the down of which is held in high estimation. Immense shoals of fish, of an innumerable diversity of kinds, haunt the coasts.

The island is intersected by arms of the sea, called lochs, which run to a considerable distance inland, both from the eastern and western sides. One of the chief is loch-Roag, on the west, which is two leagues in breadth at the entry, and runs up, in a south-eastern direction, about twelve miles into the island. This loch contains several islands, some of which are inhabited; one, called Large Bernera, is eight miles in length. The whole of this curious loch abounds with safe places of anchorage, sufficient to hold the whole British navy, or even that of all Europe. About 140 tons of kelp, of a superior quality, are annually made from loch Roag. On the eastern coast, loch Seaforth runs into the country to a great distance; loch Keose and loch Leurbust advance also far inland from the east; but loch Stornaway is most important, on account of the town which

stands near it, and which is the capital of the island. On the coast, in this parish, is a large cave, into which the sea enters at high tide; this cavern is only accessible from the sea. When it was first noticed, a great number of seals were killed annually in it; and the practice is still continued. The entrance of the cave is very deep and narrow, and does not admit more than the breadth of a six-oared boat. The interior is divided by a large pillar into two arches. Its whole length is about an English furlong.

The island of Lewis is divided into four parishes; named Barvas, Lochs, Stornaway, and Uig. It has various small islets attached to it. In the parish of Barvas is the island of Rona, which is a mile in length, and half a mile in breadth; it is situated in the Northern ocean, and is supposed to be the farthest to the north-west of any land in Europe. The parish of Lochs derives its name from the great number of lakes which are interperfed over its surface. It is about nineteen miles in length and nine in breadth; along the coast it has a bold and rocky appearance; in the interior it is barren and inhospitable. About 50 tons of kelp are manufactured here annually; and the greater number of the inhabitants are employed in the fisheries on the coast. The parish of Stornaway is of very great extent; but the inhabited part is of a triangular form, of which two of the sides are about ten miles, the other seven. The town of Stornaway, from a very small origin, has of late, by the exertions of lord Seaforth, arrived at a considerable extent. The harbour is excellent, and well frequented; the principal source of employment is the prosecution of the white and herring-fisheries in the bays, in which about 35 or 40 small vessels are annually fitted out. It is a port of the custom house, and has a post-office, and a regular weekly packet. The houses of the town are, in general, well built: here are a convenient custom-house, a town-house, a commodious church, an assembly-room, and two school-houses. On an elevated situation, near the town, stands Seaforth lodge, the seat of lord Seaforth, who is the proprietor of the island. The parish of Uig is fifteen miles in length, and thirteen in breadth: the interior is hilly, covered with heath, and interperfed with small lakes; the coasts are mostly level and cultivated. The fisheries and the manufacture of kelp are here also the chief sources of subsistence to the inhabitants. Near the hamlet of Calarnish, at a short distance from loch Roag, is a Druidical temple, formed by a circle of twelve stones or obelisks, each about seven feet high, and six feet distant from each other: in the centre is one of a larger size, thirteen feet from the ground: directly south from the circle are three obelisks, standing in a line; another such to the west, and one to the east; each stone being nearly equal in size, and arranged at equal distances. Towards the north are two straight ranges of obelisks, forming an avenue to an opening between two of the stones which form the circle. Each of these ranges consists of six stones, regularly placed, one opposite to another. All the stones are in a rough natural state, as taken from the shore. At Melita are the remains of a nunnery, still called in the Gaelic *Teagh nan caith-chan dhu*, "the house of the old black women." At Caillaway is a Danish fort, quite circular, with a double wall of stone, thirty feet in height. This is broad at the base, and narrower at the top, like the frustum of a cone. In the year 1794, there was living in this parish a *lusu nature*, of which Mr. Monro, the minister, gives the following account in his statistical report to sir John Sinclair.—"Very near the manse there lives a woman, who has four distinct breasts or *mammae*. She has had several stout, healthy children, and suckled them, and likewise one of the minister's children. She has nipples and milk in each of the four breasts; the

two upper are situated under the arm-pits, and by being diffended with milk, are very troublesome to her for the first two or three months after delivery."

The population of Lewis, in the year 1796, was 8311; which was an increase of 1925 from an enumeration which was made in the year 1755. The inhabitants of the whole island are scattered, for the most part, in single families, or clusters of two or three families, around the coast, or through the interior parts. Some large tracts are without inhabitants; while upon others the population is more closely assembled. There is scarcely any regular road: the moor, which reaches across the island from Stornaway to Uig, is so extensive and soft, that it would require the labour of many ages to form a regular road through it. Martin's Description of the Western Islands of Scotland, 8vo. 1716. Buchanan's Travels in the Western Hebrides, from 1782 to 1790," 8vo. 1793.

LEWIS, a town of America, in Essex county, S.W. of Lemington adjoining, in Vermont; about 8 miles S. of the Canada line.

LEWIS CREEK, a small stream in Vermont, which falls into lake Champlain at Ferrisberg, a little N. of Little Otter creek.

LEWIS and Rehoboth, a town in Suffex county, Delaware, containing 1514 inhabitants.

LEWISBURG. See LOUISBOURG.

LEWISBURG, a county in Orangeburgh district, South Carolina.—Also, a post-town of North Carolina, and capital of Franklin county, which lies on Tar river, and contains between twenty and thirty houses, a court-house, and gaol; 30 miles N. of Raleigh.—Also, a post-town and chief town of Greenbrier county, Virginia, on the north side of Greenbrier river, containing about sixty houses, a court-house, and gaol; 250 miles W. by N. of Richmond. N. lat. 38° 8'.—Also, a post-town of Northumberland county, Pennsylvania, called also "Taritown," on the W. side of the Susquehanna, 7 miles above Northumberland; containing about 60 houses, and well situated for a good trade with the N.W. part of the state; 30 miles E. by N. from Aaronsburg.

LEWISHAM, a populous village, in the upper half-hundred of Blackheath, parish of Sutton at Hone, and county of Kent, England, is situated 5½ miles from London, and extends nearly a mile in length on the road to Bromley. Here was anciently a Benedictine priory, subordinate to the abbey of St. Peter in Ghent, and most probably founded in the Saxon times; this manor having been given to that abbey by Elthruða, niece to king Alred. After the suppression of the alien priories, Henry V. made this a part of the endowment of his newly erected Carthusian priory at Shene. Lewisham is now the property of the earl of Dartmouth, whose seat on Blackheath is within the bounds of this parish. The present church was erected in the year 1774: its form is that of an oblong square, with a semi-circular recess at the east end for the altar. It contains two handsome monuments: one to the memory of Anne, wife of John Petrie, esq., was executed in Italy; it includes a fine bas-relief in marble, representing the deceased on her death-bed, with her husband and children lamenting round her. The other commemorates Margaret, relict of the Rev. Robert Petrie, and was sculptured by Banks; it represents Mrs. Petrie dying in the arms of Religion, supported by Faith and Hope. Many old monuments were thrown carelessly into the vault, when the church was rebuilt. An excellent free grammar school was founded by the Rev. Abraham Colfe, who was rector of this parish from the year 1610 to 1657. His will contains the regulations

of the school, and directs that it shall be for the education of thirty-one boys of the several parishes therein named; one scholar yearly to be sent to either of the universities. He also founded an English school here for thirty-one boys, and an alms-house for five "poor godly householders." The population of Lewisham, as returned under the act of 1800, amounted to 4007; the number of houses to 722. In this enumeration was included the chapelry of Sydenham, noted for its medicinal springs. Brayley's Beauties of England, vol. vii.

LEWISTOWN, a post-town in Lincoln county, Maine, on the east side of Androscoggin river, and bounded south-west by Bowdoin; containing 948 inhabitants; 36 miles N.E. of Portland.—Also, a post-town, called "Lewes," in Suffex county, Delaware, pleasantly situated on Lewes creek, three miles above its mouth in Delaware bay; containing a Presbyterian and Methodist church, and about 80 houses, in a street more than three miles in length, extending along a creek which separates the town from the pitch of the cape. Its situation is high. The court-house and gaol are commodious buildings; the entrance of the bay is crowded with vessels from all parts of the world, but during part of the winter is closed with ice. The circumjacent country is beautifully diversified with hills, woods, streams, and lakes, but much infested with mosquitoes and sand-flies. This town carries on a small trade with Philadelphia in the productions of the country. A manufacture of marine and Glauber salts, and magnesia, has been established here; 113 miles S. of Philadelphia. N. lat. 38° 6'. W. long. 75° 18'.—Also, the chief and post-town of Mifflin county, Pennsylvania, situated on the north side of Juniatta river, on the west side of, and at the mouth of, Cihicoquillis creek; about 23 miles N.E. of Huntingdon; regularly laid out, incorporated in 1795, and containing about 120 dwelling-houses, 523 inhabitants, a court-house, and gaol; 150 miles W.N.W. of Philadelphia. N. lat. 40° 33'. W. long. 77° 23'.

LEWUNAKBANNEK, a town on the Ohio, in which is a settlement of Christian Indians, formed by Moravian missionaries.

LEX, LAW. See LAW.

LEX *Amissa*, or *legem amittere*, in Law, is understood of an infamous, perjured person, who is said to *lose his law*; or, as Bracton has it, *non est ulterius dignus lege*. See INFAMOUS.

LEX *Judicialis*, is properly *purgatio, per judicium ferri*; sometimes called simply *judicium*.

LEX *Sacramentalis*, *purgatio per sacramentum*. See OATH and PURGATION.

LEX *Taliois*. See TALIO.

LEX *Terre*, the law and custom of the land; by which name it is distinguished from the *civil law*. See COMMON LAW.

LEX, *Legem terra amittere*. See AMITTERE.

LEXAWASCEIN, in Geography, a small river of Pennsylvania, which rises by several branches in Northampton county, Pennsylvania, on the east side of mount Ararat, which unite about 10 miles from its mouth in Delaware river. It joins the Delaware, after a south-east and east course, about 174 miles above Philadelphia.

LEXEN, a town of Moravia, in the circle of Olmutz; 18 miles N.W. of Olmutz.

LEXIARCHI, Δεξιαρχου, at Athens, six officers, assisted by thirty inferior ones, whose business it was to lay fines upon such as came not to the public assemblies, and also to make scrutiny among such as were present.

The lexiarchi kept a register of the age, manners, and abilities

abilities of all the citizens, who were always enrolled at the age of twenty.

**LEXICON**, Λεξικόν, the same with dictionary.

The word is chiefly used in speaking of Greek dictionaries: it is derived from the Greek λέξις, *word, diction*; of λέω, *I speak*.

**LEXINGTON**, in *Geography*, a county of America, in Orangeburg district, South Carolina.—Also, a post-town of Virginia, and capital of Rockbridge county; situated on the post-road from Philadelphia to Kentucky, by way of the Wilderess, and about a mile south of the north branch of James's river; containing a court-house, gaol, and about 100 houses. Its situation is agreeable and healthy, and the adjacent country highly cultivated. Near it is "Liberty-hall Academy," now "Washington College," built of stone, and capable of containing forty or fifty students, and has its name endowed by the distinguished personage whose name it bears. The town is 159 miles W. by N. of Richmond.—Also, a post-town of Kentucky, formerly the metropolis of that state; situated on a rich extensive plain, in Fayette county, on the north side of Town fork, a small stream, that falls into the fourth branch of Elkhorn river. The town is built on a regular plan, and contains about 350 houses, five places of public worship, a court-house, and gaol, and also an university, with several manufactories and storehouses. It is an agreeable flourishing town, on the head waters of Elkhorn river; 24 miles E. of Frankfort. The number of inhabitants is 1795. Near the town was found, upon digging five or six feet deep, a large flat stone, covering a well, artificially stoned; and in its vicinity are also the remains of two ancient fortifications, furnished with ditches and bastions, overgrown with large trees.—Also, a post-town in Rowan county, North Carolina, 309 miles from Washington.—Also, a small post-town of Georgia, formerly called the "Great Falls," situated on the south side of Ogeechee river, on a beautiful eminence which overlooks the falls of the river; 2 miles from George town.—Also, a town in Middlesex county, Massachusetts, 11 miles N.W. of Boston, having a neat congregational church, and a number of compact houses. This town has been rendered famous by being the scene of a battle, fought April 19, 1775, which may be considered as the commencement of the American revolution. On the ground where this battle was fought is a stone monument, 10 feet high, with the following inscription: "Sacred to Liberty, and the Rights of Mankind!! The freedom and independence of America sealed and defended with the blood of her sons, &c. &c." Concluding, "The die was cast!!! The blood of these martyrs, in the cause of God and their country, was the cement of the union of these states, then colonies, and gave the spring to the spirits, firmness, and resolution of their fellow-citizens!" Morse.

**LEY**, in *Agriculture*, a term used to signify land in the state of sward or grass.

**LEY**, Sir JAMES, in *Biography*, a learned English judge, who flourished in the seventeenth century, the son of Henry Ley, esq. of Jessont, in Wiltshire, was, on account of his great merit, made lord chief justice, first in Ireland, and afterwards in England. He was likewise created baron Ley, lord high treasurer, and earl of Marlborough. His reports were printed in the year 1659.

**LEY**. See LEXIVIUM.

**LEYBA**, in *Geography*, a town of South America, in New Granada; 50 miles N.N.E. of Santa Fé de Bogota.

**LEYBOURNE**, WILLIAM, in *Biography*, a mathematician, was originally a printer in London. He published a course of mathematics, which was held in considerable esti-

mation. He was author of a treatise on Surveying, a work on Dialling, and another work, entitled "The Trader's Guide." He died about the year 1600.

**LEYDECKER**, MELCHIOR, a Dutch divine, was born at Middleburg in 1652. Having received a good education, he officiated as pastor of a church in his native place; and in 1678 was appointed professor of divinity at Utrecht, and soon after took his degree of doctor in divinity. He died in 1721. He was deeply read in theology, ecclesiastical history, and rabbinical learning; but he had no taste for polite literature, and was exceedingly bigotted to his own notions. Still he was desirous of uniting the Lutherans and Calvinists, and made some ineffectual efforts for the purpose. He was a voluminous writer, and his works are all written in Latin: of these the chief are, "A Treatise on the Republic of the Hebrews," in 2 vols.; "An Analysis of Scripture, with Rules for Preaching;" "A History of Janfenism;" "A Continuation of the Ecclesiastical History of Hornius, with Notes;" and "A History of the Church of Africa."

**LEYDEN**, LUCAS VAN. See JACOBS, LUCAS.

**LEYDEN**, in *Geography*, a city of Holland, the "Lugdunum Batavorum" of Ptolemy, and the "Caput Germanorum" of Antonine's Itinerary, is the capital of a small district, called "Rhyndal," comprehending 49 towns or villages, and, next to Amsterdam, the largest and most populous city of Holland; the number of inhabitants being estimated at about 50,000. It is situated on the ancient bed of the Rhine, which, by means of various streams, divides it into a number of islands, that communicate with one another by bridges, which are reckoned to be not fewer than 100. This city likewise carries on a daily intercourse by boats with Amsterdam, Haerlem, Utrecht, Delft, the Hague, &c. It has eight gates; and its ramparts are formed of earth, partly covered with turf, and partly faced with brick, and consisting of several bastions. The cloth manufactured at Leyden has been much celebrated, and it contains a staple-hall erected for the use of the manufacturers and merchants. The chief street of the town is constructed in the form of a crescent; and the principal public building is the town-house, which has many spires, and is a handsome structure, with a stone front. In the burgomaster's chamber is a very capital painting of the Last Judgment by Lucas of Leyden, for which the emperor Rodolphus is said to have offered as many gold ducats as would cover it; together with several other capital paintings, and a representation of the famous siege of 1574, wrought in tapestry. The great church is one of the handsomest in Holland. The common council of the city, called "Vroedschap," is composed of 40 persons, who are required to be natives of Holland, 28 years of age, and Protestants. Here are likewise four burgomasters, and eight echevins, and a grand bailiff, who administers justice in civil and criminal cases, jointly with the echevins. The fair of Leyden is an ancient establishment, and still much frequented: it occupies by its booths, arranged under trees, and along the borders of canals, about a fourth part of the town. In proof of the antiquity of this city, some allege an ancient round tower, called the "Burcht," about 600 feet in circumference, said to have been erected either by the Romans or Saxons; but Joseph Scaliger contends that it was built five or six centuries ago by the comtes of Holland. This city was considerably enlarged towards the south in the year 1389; but it has suffered much from sieges and the plague. In the year 1574, the Spaniards laid siege to it; but it was obstinately defended by the inhabitants, and even by the women, who lined the ramparts, and performed the duties of soldiers.

During

During this resistance, the misery of the inhabitants was extreme: 6000 persons died of famine, and the distress attending it; so that for 14,000 who survived, there remained no more than 107 muids of wheat. The general of the Spaniards, apprized of their situation, summoned them to surrender; but they replied, that they could not want subsistence, as long as their left arms remained, on which they were determined to feed, whilst with the right they defended the city. The constancy and courage of Adrian de Wers, burgomaster of the city, deserve to be recorded; when he was solicited by some of the inhabitants to surrender, he told them, "My friends, since I must die, it is of little importance whether I fall by you or by the enemy; cut me to pieces, and divide them amongst you; I shall die satisfied, if by my death I can be the least useful." Just as they were preparing to surrender, they received notice by some pigeons, that relief was at hand; and the dykes of the Meuse and the Issel having been opened, Louis Boissot, admiral of Zealand, advanced with a number of troops in flat-bottomed boats to their succour. The Spaniards, terrified by the inundation, abandoned the siege. In memory of this event the inhabitants have been accustomed every seven years to exhibit a spectacle of the siege. William Prince of Orange, just recovering from a dangerous illness, was carried to Leyden, that he might in person thank the citizens for their brave defence; he also liberally rewarded Boissot and Janus Douza, lord of Noortwyck, who commanded in the city, not forgetting the officers and soldiers; and besides granting several privileges to the city, he founded an university, and appointed Janus Douza the first curator. This university, says Mrs. Radcliffe, in her "Journey through Holland, &c." would scarcely be known to exist, if it had no more conspicuous objects than its buildings. The Dutch universities have no endowed foundations; so that the professors, who have their salaries from the states, live in private houses, and the students in lodgings. The library, to which Joseph Scaliger was a benefactor, is open only once in a week, and then for no more than two hours. To this, and other measures of Dutch policy, it is owing that the university has been of late years declining. There are students, however, of many nations and different religious profession, no oaths being imposed, except upon the professors. Physic and botany are cultivated with much success; and there is a garden to which not only individuals, but the East India company, contribute foreign plants. The salaries of the professors, exclusively of fees from the students, are nearly 200*l.* a-year. The government of the university is in the rector, who is chosen out of three persons, returned by the senate to the states; the senate consists of the professors; and, on extraordinary occasions, the senate and rector are directed by curators, who are agents for the states. The land adjoining to Leyden is very fertile and productive, and is much cultivated by gardeners, who supply Amsterdam with vegetables; and the rich meadows and pastures in the environs furnish excellent butter and cheese. Leyden is distant 14 miles N. of Rotterdam, and 19 S.W. of Amsterdam. N. lat. 52° 9'. E. long. 4° 20'.

The plays and players of the theatre of Leyden are not of the most refined sort; farce has not yet quitted tragedy, nor has Punch gained force; however, these exhibitions amuse persons, whose taste has not been formed upon refined models, and perhaps come more home to their business and bosoms, than the tragedies of Sophocles, or comedies of Menander, would do, if they were now to be represented in the original Athenian manner.

As to music, mechanical chimes, every quarter of an hour; *carillons* at noon, two or three times a week; and

huge organs, coarsely played, to more coarse plasmody, constitute all that Apollo and the Nine Muses have given to this place, in the way of harmony and melody, as far as we could discover. Burney.

LEYDEN, a small island in the East Indian ocean, near the coast of Java, within view from Batavia.—Also, a small island in the gulf of Manar, near the W. coast of Ceylon; 12 miles W. of Jaffnapatam.—Also, a small island in a bay of the Pacific ocean, on the N. coast of New Guinea. S. lat. 3° 58'. E. long. 135° 39'.—Also, a town of Prussia, 27 miles S.S.E. of Konigsberg.—Also, a post-town of America, in Oneida county, New York; 330 miles N.E. from Washington.—Also, a township in Hampshire county, Massachusetts, between Colerain and Bernardston; 29 miles from Northampton, incorporated in 1784, and containing 1095 inhabitants.

LEYDEN *Phial*, in *Electricity*, is a glass phial or jar, coated both on the inside and outside with some conducting substance, for the purpose of being charged, and employed in a variety of entertaining and useful experiments. See COATING and CHARGE.

It was thus called because Mr. Cunæus, a native of Leyden, was supposed to have first contrived, about the close of the year 1745, to accumulate the electrical power in glass by this method; and hence the operation of charging and discharging coated glass, in general, has been denominated the *Leyden experiment*; and a vacuum produced in a jar of this kind has been called the *Leyden vacuum*. But Dr. Priestley, the historian of electricity, informs us, that the person who first made this great discovery was Mr. Von Kleift, dean of the cathedral in Camin; who, on the 4th of November, 1745, sent an account of it to Dr. Leiberkuhn at Berlin: however, those, to whom Mr. Kleift's account was communicated, could not succeed in performing his experiments. The views which led to this discovery in Holland are stated by Dr. Priestley in the following manner: professor Muschenbroeck and his friends, observing, that electrified bodies, exposed to the common atmosphere, which is always replete with conducting particles of various kinds, soon lost their electricity, and were capable of retaining but a small quantity of it, imagined, that if the electrified bodies were terminated on all sides by original electrics, they might be capable of receiving a stronger power, and retaining it a longer time. Glass being the most convenient electric for this purpose, and water the most convenient non-electric, they first made these experiments with water in glass bottles; but no considerable discovery was made, till Mr. Cunæus, happening to hold his glass vessel in one hand, containing water, which had a communication with the prime conductor by means of a wire; and with the other hand disengaging it from the conductor, when he imagined the water had received as much electricity as the machine could give it, was surprized by a sudden shock in his arms and breast, which he had not in the least expected from the experiment. This experiment was repeated, and the first account of it published in Holland by Mr. Allamand and Mr. Muschenbroeck; by the able Nollet, and M. Monnier, in France; and by Messrs. Gralath and Rugger, in Germany. Mr. Gralath contrived to increase the strength of the shock, by altering the shape and size of the phial, and also by charging several phials at the same time, so as to form what is now called the *electrical battery*. He likewise made the shock to pass through a number of persons connected in a circuit from the outside to the inside of the phial. He observed that a cracked phial would not admit of being charged; and he discovered what is now called the *residium of a charge*. Dr. Watson, about

## LEYDEN PHIAL.

about this time, observed a circumstance attending the operation of charging the phial, which, pursued, would have led him to the discovery which was afterwards made by Dr. Franklin. He says, that when the phial is well electrified, and you apply your hand to it, you see the fire flash from the outside of the glass, wherever you touch it, and it crackles in your hand. He also observed, that when a single wire only was fastened round a phial, properly filled with warm water, and charged; upon the instant of its explosion, the electrical corrutations were seen to dart from the wire, and to illuminate the water contained in the phial. He likewise found, that the stroke, in the discharge of the phial, was, *ceteris paribus*, as the points of contact of the non-electrics of the outside of the glass, which led to the method of coating glass: in consequence of which he made experiments, that led him to conclude, that the effect of the Leyden bottle was greatly increased, if it was not principally owing to, not so much the quantity of non-electric matter contained in the glass, as the number of points of non-electric contact within the glass, and the density of the matter of which these points consisted; provided the matter was, in its own nature, a ready conductor of electricity. He farther observed, that the explosion was greater from hot water inclosed in glasses, than from cold, and from his coated jars, warmed, than cold. For his manner of explaining the shock of the Leyden phial, see AFFLUX.

Mr. Wilson, in 1746, discovered a method of giving the shock to any particular part of the body, without affecting the rest: he also increased the strength of the shock by plunging the phial in water, thereby giving it a coating of water on the outside as high as it was filled on the inside; he likewise found, that the law of accumulation of the electric matter in the Leyden bottle was always in proportion to the thinness of the glass, the surface of the glass, and that of the non-electrics in contact with the inside and outside thereof. Mr. Wilson made a variety of other experiments with the Leyden phial, which our limits will not allow us to recite.

Mr. Canton found, that if a charged phial was placed upon electrics, the wire and the coating would give a spark or two alternately; and that, by continuing this operation, the phial would be discharged; though he did not observe that these alternate sparks proceeded from the two contrary electricities discovered by Dr. Franklin.

The abbé Nollet made several experiments with this phial. He received a shock from a bottle, out of which the air had been exhausted, and into which the end of his conductor had been inserted. He ascribed the force of the glass in giving a shock, to that property of it, whereby it retained it more strongly than conductors do, and was not so easily divested of it as they are. He also first tried the effect of the electric shock on brute animals, and enlarged the circuit of its conveyance. See CURETIV.

M. Monnier is said to have been the first who discovered that the Leyden phial would retain its electricity for a considerable time after it was charged, and to have found it to do so for thirty-six hours, in time of frost; and it is remarkable that the French as well as the English philosophers made several experiments, which, with a little greater degree of attention, would have led them to the discovery of the different quality of electricity on different sides of the glass. But this was reserved for the ingenious doctor Franklin, who, in explaining the method of charging the Leyden phial, observes, that when one side of the glass is electrified positively, or *plus*, the other side is electrified negatively, or *minus*; so that whatever quantity of fire is thrown upon one side of the glass, the same is thrown out

of the other; and in a phial not charged, none can be thrown into the inside, when none can be got out from the outside; and there is really no more electric fire in the phial after it is charged than before; all that can be done by charging being to take from one side and convey to the other. Dr. Franklin also observed, that glass was imperious to electricity, and that therefore, since the equilibrium could not be restored to the charged phial by an internal communication, it must be done by conductors externally joining the inside and the outside. These capital discoveries he made by observing that, when a phial was charged, a cork-ball, suspended on silk, would be attracted by the outside coating, when it was repelled by a wire communicating with the inside, and *vice versa*. But the truth of this maxim appeared more evident, when he brought the knob of the wire communicating with the outside coating within a few inches of the wire communicating with the inside coating, and suspended a cork-ball between them; for, in that case, the ball was attracted by them alternately, till the phial was discharged.

Dr. Franklin also shewed, that when the phial was charged, one side lost exactly as much as the other gained, in restoring the equilibrium. Hanging a small linen thread near the coating of an electrical phial, he observed that whenever he brought his finger near the wire, the thread was attracted by the coating: for as the fire was taken from the inside, by touching the wire, the outside drew in an equal quantity by the thread. He likewise proved, that the coating on one side of a phial received just as much electricity as was emitted from the discharge of the other, in the following manner: he insulated his rubber, and then, hanging a phial to the conductor, he found it could not be charged, even though his hand was held constantly to it; because, though the electric fire might leave the outside of the phial, there was none collected by the rubber to be conveyed to the inside. He then took away his hand from the phial, and forming a communication by a wire from the outside coating to the insulated rubber, he found that it was charged with ease. In this case it was plain, that the very same fire which left the outside coating, was conveyed by the way of the rubber, the globe and the conductor, and the wire of the fire into the inside. This new theory of charging the Leyden phial led Dr. Franklin to observe a greater variety of facts, relating both to charging and discharging it, than other philosophers had attended to. This maxim, that whatever the phial takes in at one surface it loses at the other, led Dr. Franklin to think of charging several phials together with the same trouble, by connecting the outside of one with the inside of another; whereby the fluid that was driven out of the first would be received by the second, &c. By this means he found, that a great number of bottles might be charged with the same labour as one only; and that they might be charged equally high, were it not that every bottle receives the new fire, and loses its old with some reluctance, or rather gives some small resistance to the charging. On this principle he constructed an electrical battery.

When Dr. Franklin first began his experiments upon the Leyden phial, he imagined that the electric fire was all crowded into the substance of the non-electric, in contact with the glass; but he afterwards found that its power of giving a shock lay in the glass itself, and not in the coating, by the following ingenious analysis of the bottle. In order to find where the strength of the charged bottle lay, he placed it upon glass; then first took out the cork and the wire, and finding the virtue was not in them, he touched the outside coating with one hand, and put the finger of the

other into the mouth of the bottle; when the shock was felt quite as strong as if the cork and wire had been in it. He then charged the phial again, and pouring out the water into an empty bottle, insulated, expected that, if the force resided in the water, it would give the shock, but he found it gave none. He then judged that the electric fire must either have been lost in decanting, or must remain in the bottle; and the latter he found to be true; for, filling the charged bottle with fresh water, he found the shock, and was satisfied that the power of giving it resided in the glass itself. The same experiment was made with panes of glass, laying the coating on lightly, and changing it as the water had been before changed in the bottle, and the result was precisely the same. He proved in other ways that the electric fire resided in the glass. Franklin's Letters and Observations, &c. Priestley's Hist. of Electricity, vol. i. p. 191, &c.

From the above account of Dr. Franklin's method of analysing the Leyden phial, the manner of charging and discharging it, and the reason of the process, are easily understood. Thus, if a coated phial be placed near the prime conductor, so that the knob of its wire may be in contact with it; and the winch of the machine be turned, the index of the electrometer, fixed to the conductor, will gradually rise as far as go nearly, and then rest; which shews that the phial has received its full charge; then if the discharger be held by its glass handle, and one of its knobs be applied to the outside coating of the phial, and the other be brought near the knob of the wire, or near the prime conductor that communicates with it, a report will be heard, and luminous sparks will be discovered between the discharger and the conducting substances communicating with the sides of the phial, and by this operation the phial will be discharged. If, instead of using the discharger, a person touches the outside of the phial with one hand, and brings the other hand near the wire of the phial, the same spark and report will be observed, and a shock will be felt, that affects the wrists and elbows; and, when the shock is strong, the breast likewise; and a shock may be given to any single part of the body, if that part alone be brought into the circuit. If a number of persons join hands, and the first of them touches the outside of the phial, and the last touches the wire communicating with the inside, they will all feel the shock at the same time. If the coated phial be held by the wire, and the outside coating be presented to the prime conductor, it will be charged as readily, only with this difference, that in this case the outside will be positive, and the inside negative; and if the prime conductor, by being connected with the rubber of the machine, be electrified negatively, the phial would be charged in the same manner; but the side that touches the conductor would be electrified negatively, and the opposite side would be electrified positively. But if the phial be insulated, and the same process repeated, the index of the electrometer will soon rise to 90°, yet the phial will remain uncharged; because the outside, having no communication with the earth, &c. cannot part with its own electricity, and, therefore, the inside can acquire no additional quantity; but when a chain, or any other conductor, connects the outside of the phial with the table, the phial may be charged as before. Moreover, if a phial be insulated, and one side of it, instead of being connected with the earth, be connected with the insulated rubber, whilst the other side communicates with the prime conductor, the phial will be expeditiously charged; because, whilst the rubber exhaults one side, the other side is supplied by the prime conductor; and in this way the phial is charged with its own electricity; or the natural

electric matter of one of its sides is thus thrown on its other side. This last experiment may be diversified, by insulating the phial, and placing it, with its wire, at the distance of about half an inch from the prime conductor, and holding the knob of another wire at the same distance from its outside coating; then turning the winch of the machine, and a spark will be observed to proceed from the prime conductor to the wire of the phial, and another spark will pass at the same time from the outside coating to the knob of the wire presented towards it; and thus it is seen, that as a quantity of the electric matter is entering the inside of the phial, an equal quantity of it is leaving the outside. If the wire presented to the outside of the phial be pointed, it will appear illuminated with a *flar*; but if the pointed wire be connected with the coating of the phial, it will appear illuminated with a *brush* of rays. See CHARGE, ELECTRICAL Experiments, &c. ELECTRICITY, ELECTROMETER, &c.

Mr. Cavallo has described the construction of a phial, which, when charged by an electrical kite, in examining the state of the clouds, or in any other way, may be put into the pocket, and which will retain its charge for a considerable time. Besides the coating on the inside and outside, which this phial has like others of the same kind, a glass tube open at both ends is cemented into its neck, and passes, within the phial, having a small wire fastened to its lower extremity, which touches the inside non-electric coating. The wire, with the knob of this phial, is cemented into another glass tube, which is nearly twice as long, and smaller than the tube cemented into the neck of the phial. The wire is cemented in such a manner, that only its knob projects out of one end, and a small length of it out of the other end of the tube. If this piece, with the wire, be held by the middle of the glass tube, it may be put in or out of the tube, which is in the neck of the phial, so as to touch the small wire at the lower extremity of it; and this may be done without discharging the phial, if it be charged. A phial of this kind has been kept in a charged state for six weeks. Cavallo's Elect. p. 340. See CONDUCTOR.

We shall close this article with an account of the method by which Mr. Cavallo repairs coated phials, that have been cracked or perforated, either by a spontaneous discharge, or other accident. He removes the outside coating from the fractured part, and then makes it moderately hot by holding it to the flame of a candle; and whilst it remains hot, he applies burning sealing-wax to the part, so as to cover the fracture entirely; taking care that the thickness of this wax coating may be greater than that of the glass. Lastly, he covers all the sealing-wax, and also part of the surface of the glass beyond it, with a composition made with four parts of bees' wax, one of resin, one of turpentine, and a very little oil of olives. This he spreads upon a piece of oiled silk, which he applies in the manner of a plaster. In this way several phials have been so effectually repaired, that, after being frequently charged, they were at last broken by a spontaneous discharge, but in a different part of the glass. Phil. Trans. vol. lxxviii. part ii. p. 1011.

LEYGAGER is used for wager of law.

LEYMEN, or LEINEN, in Geography, a town of Germany, in the palatinate of the Rhine; eight miles S. of Heidelberg.

LEYPÄ, or LEIPPA, a town of Bohemia, in the circle of Leitmeritz; 20 miles N.E. of Leitmeritz. N. lat. 50° 39'. E. long. 14° 43'.

LEYRE, a town of Spain, in Navarre; eight miles N.E. of Sanguesa.

LEYRIA, a city of Portugal, in the province of Estremadura, the see of a bishop, erected in 1545; containing a glass-house built by Englishmen, and about 3500 inhabitants. Near it, on an eminence, is an ancient castle built by the Moors; 57 miles N.N.E. of Lisbon. N. lat. 39° 59'. E. long. 8° 34'.

LEYSE, a town of Prussia, in Ermeland; 18 miles N.E. of Heilsberg.

LEYSENER, in *Botany*, so denominated by Linnæus, in honour of Frederick William Von Lésyer, author of the *Flora Halensis*, published in 1761, in one volume octavo. This is a synopsis of the plants found about Hall in Saxony, disposed according to the Linnæan system, with scarcely any synonyms. The number of species is only 1122, embracing few novelties or rarities, and bearing a great analogy to the lowland Flora of Britain. Haller, however, in his *Bibl. Bot.* v. 2. 510, terms it "a rich Flora, with original remarks, as well as new plants." The most original part seems, in our opinion, a chronological and local distribution of the plants, inserted by way of appendix. A second edition appeared in 1783.—*Linn. Gen.* 431. *Schreb.* 562. *Willd. Sp. Pl.* v. 3. 2132. *Mart. Mill. Dict.* v. 3. *Ait. Hort. Kew.* v. 3. 229. *Thunb. Prodr.* 160. *Juss.* 179. *Lamarck. Illustr.* t. 688. *Gært. t.* 173. (*Asteropterus*; *Vall. Mem. de l'Acad. des Sc.* 1720. *Gært. 460. t.* 173.) *Class and order, Syngnesia Polygamia-superflua. Nat. Ord. Compositæ Discoideæ, Linn. Corymbifera, Juss.*

*Gen. Ch. Common Calyx* ovate, imbricated; scales obtuse, concave, scarious. *Cor.* compound, radiated; florets of the disk several, perfect, tubular, funnel-shaped, five-cleft, nearly erect; those of the radius several, ligulate, lanceolate, entire. *Stam.* (in the perfect florets) Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* (in the same) Germen small; style thread-shaped; stigma notched. In the female ones the style is shorter, and the stigma more divided. *Peric.* none, except the unchanged calyx. *Seeds*, in both kinds of florets, solitary oblong; down, in those of the disk, long, of five feathery bristles, surrounding a very short chaffy crown; in those of the radius the feathery bristles are wanting. *Recept.* naked in the disk, the florets of the circumference only being separated by narrow chaffy scales.

*Obs.* In *Leysera paleacea* the feathery bristles of the radius are wanting. Gærtner restrains the genus of *Leysera* to such species, keeping Vaillant's name *Asteropterus* for those which have the two kinds of seed-down as above described; but such a distinction appears to us, as it did to Linnæus, merely to separate a very natural genus, and it serves, among many other instances, displayed in this part of Gærtner's admirable work, to prove that technical characters must never be followed, without taking natural ones as a clue.

*Eff. Ch.* Receptacle chaffy in the circumference. Seed-down chaffy; in the florets of the disk mostly feathery also. Calyx scarious.

Linnæus has three species of this genus.

1. *L. gnaphalodes*. *Linn. Sp. Pl.* 1249. *Levf. Hall. ed.* 2; frontispiece, inscribed "unicum præmium, sed immortale." (After æthiopicus, stoechadis foliis, flore aureo; *Herm. Lugd. Bat.* 68. t. 71.)—Leaves linear-awlshaped, downy and glandular. Calyx-scales lanceolate.—Native of the Cape of Good Hope, as are all the known species hitherto discovered. The stem is shrubby, determinately branched, leafy, downy. Leaves copious, spreading every way, feathered, brittle-shaped, hardly an inch long, downy, as well as besprinkled with little prominent glandular bristles. Flowers mostly terminal, solitary, on long slender stalks, with yellow

rays, and a shining membranous calyx. The feathery down of the seeds is very conspicuous among the numerous florets of the disk.

2. *L. Callicornia*. *Linn. Mant.* 286. (*Calicorni gnaphaloides*; *Burm. Prodr.* 24. *Hieraciæ penularis* genus, *cordis folio, æthiopicum, feminum pappi densius radiatis*; *Pluk. Mant.* 103. *Phyt. t.* 350. f. 4.)—Leaves linear-threadshaped, rough. Scales of the calyx acute. Flowers nearly sessile. This differs at first sight from the former in its sessile flowers, solitary at the summit of each branch, and the scales of the calyx are more pointed.

3. *L. paleacea*. *Linn. Syst. Veg. ed.* 13. 641. ed. 14. 771. (*L. ericoides*; *Berg. Cap.* 204. *Relbania paleacea*; *L'Herit. Ser. Angl.* 24. *Thunb. Prodr.* 146. *Willd. Sp. Pl.* v. 3. 2137.)—Leaves linear, channelled, downy. Calyx sessile, turbinate; its inner scales thin and pointed. Feathery down wanting. Marginal scales of the receptacle surmounting the florets.—The leaves of this are not so slender as either of the former, being triangular, furrowed above, very cottony, but not glandular. Flowers sessile at the end of each branch, solitary. Outer scales of the calyx less scarious than in the former. On account of the want of the feathery seed-down, M. P. Heritier referred this species to his genus *Relbania*, which is rather a heterogeneous assemblage. In this, however, he is followed by Thunberg and Willdenow, who also agree in removing the Linnæan *Stabelina gnaphaloides* to *Leysera*, a measure which seems to us rather unnatural.

Thunberg adds seven more species to this genus, the specific characters of which are given in his *Prodr.*, but nothing more is known concerning them. They are named *ciliata, incana, arctostoides, Pilosella, ovata, picia, and polifolia*.

LEYTA, in *Geography*, one of the Philippine islands, about 250 miles in circumference; the soil is so fertile as to yield two hundred fold; the mountains abound in deer, cows, wild hogs, and fowls; cocoas grow spontaneously; the air is pure and healthy, and more temperate than at Luçon. The inhabitants are mild and peaceable in their disposition, and hospitable to strangers. Their number is estimated to be about 9000, who pay tribute in wax, rice, or cloth. N. lat. 10° 50'. E. long. 124° 40'.

LEZAIJSKO, a town of Austrian Poland, in Galicia; 56 miles W.N.W. of Lemberg.

LEZANDRIEUX, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Lannion, four miles E. of Treguier. The place contains 1763, and the canton 12,289 inhabitants, on a territory of 142½ kilometres, in six communes.

LEZERS, an Indian nation, which inhabits between the mouth of the Ohio and Wabash rivers. They can furnish 300 warriors.

LEZIGNAN, a town of France, in the department of the Aude, and chief place of a canton, in the district of Narbonne. The place contains 1505, and the canton 6827 inhabitants, on a territory of 270 kilometres, in 17 communes.

LEZOUX, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the district of Thiers; seven miles W.S.W. of Thiers. The place contains 3307, and the canton 10,581 inhabitants, on a territory of 197½ kilometres, in 12 communes.

LGOV, a town of Russia, in the government of Kurk. N. lat. 48°. E. long. 35° 54'.

LHOTA, a town of Bohemia, in the circle of Konigin-gratz; six miles S.E. of Trautenau.

LHOTKA, a town of Bohemia, in the circle of Konigin-gratz; 14 miles W. of Konigin-gratz.

LIADOVA, a town of Moldavia, on the Dniester; 56 miles E.N.E. of Choczim.

LIASON, *Fr.* in *Musci*, connection, relation, combination. See RELATIVE.

LIASKOI, in *Geography*, a town of Russia, in the province of Uding, on the Vm; 48 miles E. of Yarensk.

LIAM, a town of Lower Siam, on the E. side of the gulf. N. lat. 12° 35'. E. long. 102° 18'.

LIAMONE, a river of Corfica, which runs into the sea; 10 miles N. of Ajaccio. It gives name to one of the two departments into which Corfica is divided; the other being Golo. It is formed by the southern part of the island, in N. lat. 41° 30', containing 149 square leagues, and 63,347 inhabitants. It is divided into three circles, *viz.* Vico, containing 10,049 inhabitants; Ajaccio, 26,918; and Sartone, including 26,350 inhabitants. In the valleys and acclivities of the hills, the soil is fertile, yielding grain, fruits, pastures, and, in some districts, delicious wines.

LIAM-PO. See NING-RO.

LIAMSA, a town of Russia, in the government of Archangel, on the coast of the White sea; 56 miles N.N.W. of Oueg.

LIANCOURT, a town of France, in the department of the Oise, and chief place of a canton, in the district of Clermont; four miles S. of Clermont. The place contains 962, and the canton 10,365 inhabitants, on a territory of 125 kilometres, in 22 communes.

LIANGA, a town on the E. coast of Mindanao. N. lat. 8° 21'. E. long. 126° 10'.

LIANG-CHAN, a town of Corea; 40 miles S.S.E. of Kang-teheou.

LIANGDAL, a river of Sweden, which rises in the province of Harjedalen, and runs into the gulf of Bothnia, near Sundfval.

LIAN-TCHUEN, a town of Corea; 25 miles E.N.E. of Haimen.

LIAR-DSAKE, a lake of Thibet, about 30 miles in circumference. N. lat. 34° 34'. E. long. 90° 44'.

LIATRIS, in *Botany*, a name of whose meaning or origin we are not able to discover any thing satisfactory. *Gært.* t. 167. *Schreb.* 542. *Willd. Sp. Pl.* v. 3. 1634. *Mart. Mill. Dict.* v. 3. (Suprago; *Gært.* v. 2. 402. *Anonymous*, n. 309; *Walt. Carol.* 196. *Cirsium*; *Dill. Eth.* t. 71, 72. See *Serratula*; *Juff.* 174.)—Class and order, *Syngenesia Polygamia-aqualis*. *Nat. Ord. Compositae capitatae*, *Linn. Cinarocephales*, *Juff.*

*Gen. Ch.* Common Calyx oblong, imbricated, of numerous, somewhat ovate, unarmed, coloured scales. *Cor.* compound, uniform, tubular; florets are perfect and equal, monopetalous, funnel-shaped; their tube inflexed; limb in five recurved segments. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen to each floret, oblong; style thread-shaped, very long, divided as far as the top of the stamens, straight; stigmas rather acute. *Peric.* none, except the permanent unaltered calyx. *Seeds* solitary, angular; down sessile, feathery, sometimes coloured. *Recept.* naked, flat.

*Eff. Ch.* Receptacle naked, Calyx oblong, imbricated, unarmed, coloured. Down leathery.

This genus appears to have been originally separated from *Serratula* by *Gærtner*, who altered the name by which he at first distinguished it, *Suprago*, to that it now bears. *Serratula* differs from it in having a fealy or hairy receptacle, as well as in habit. Eight species are defined by *Willdenow*, of which the following are the most characteristic and remarkable.

*L. scariosa*, *Willd.* n. 2. (*Serratula scariosa*; *Linn.*

*Sp. Pl.* 1147. *Eupatorio adinis americana bulbosa, floribus scariosis calycibus contectis*; *Pluk. Phyt.* t. 177. f. 4.)

—Leaves lanceolate, tapering at each end, rough-edged. Flowers on long bracteated stalks. Calyx-scales obovate, spreading.—Native of North America; sometimes seen with us in curious gardens, where it is a hardy perennial. *Root* a bulb-shaped tuber. *Stem* three or four feet high, leafy, finely hairy, racemose at the upper part, each flower supported by a stalk from two to four inches long, bearing a few leafy bractes. The stigmas are long, purplish, as well as the florets. *Calyx-scales* more or less obtuse, leafy, widely spreading.

*L. elegans*, *Willd.* n. 3. (*Stachelina elegans*; *Walt. Carol.* 202. *Serratula speciosa*; *Ait. Hort. Kew.* v. 3. 138.)—Leaves linear, dotted. Spike very long and dense. Calyx-scales lanceolate, acute, hairy; the innermost elongated, coloured, somewhat toothed. Florets few.—Gathered by *Bartram*, in Georgia, in 1765; by *Walter* in Carolina. The upper stem-leaves are widely spreading, or reflexed; lower longer, more distant and upright; all finely dotted on both sides. Spike long, dense, erect, slender, of numerous, nearly sessile, bracteated flowers, whose long, leafy, fine pink, inner scales of the calyx are very beautiful.

*L. pilosa*, *Willd.* n. 4. (*Serratula pilosa*; *Ait. Hort. Kew.* v. 3. 138.)—Leaves linear, hairy, somewhat dotted. Cluster long, loose, hairy. Bractes and calyx-scales obtuse, fringed.—Native of North America, from whence it was introduced, in 1783, into Kew garden, where we gathered it in flower two years after. It is perennial and hardy, blooming in the autumn. As there is no description nor figure extant, the following may be acceptable. The stem is three feet high, slender, leafy, angular, clothed with longish scattered hairs, at least in the upper part. Leaves narrow, reflexed, fringed with similar hairs, and irregularly dotted on both sides; the upper ones dilated at the base, and embracing the stem. Cluster terminal, simple, long, loose, leafy, slightly hairy. Flower stalks about an inch long, axillary, bearing at their upper part two or three short, obtuse, fringed, dotted bractes, resembling the lower scales of the calyx; whose inner-scales are gradually longer, with a membranous, fringed, white or reddish edge. Florets and stigmas pink.

We cannot but lament, that while so many well-known plants are figured over and over again in every publication, such curious and beautiful species as the two last should remain neglected and unknown.

*L. spicata*, *Willd.* n. 6. (*Serratula spicata*; *Linn. Sp. Pl.* 1147. *Cirsium tuberosum, lacteae capitulis spicatis*; *Dill. Eth.* 85. t. 72. f. 83.)—Leaves linear, minutely dotted, fringed at the base. Spike leafy; dense above. Calyx-scales obtuse, smooth.—Native of various parts of North America, from whence it was brought to the English gardens about eighty years ago, and still remains at Kew. The nearly sessile flowers, and smooth-edged calyx, distinguish it from the last, to which it is otherwise nearly allied.

*L. odoratissima*, *Willd.* n. 5. (*Anonymous odoratissimus*; *Walt. Carol.* 198.)—Leaves elliptic-oblong, smooth; the upper ones heart-shaped, clasping the stem. Panicle corymbose, spreading. Calyx-scales obovate, glandular.—Gathered by *Walter* in Carolina, from whence it was brought by the late Mr. *Frazer* in 1787. This species is remarkable for its fine scent when dried, which resembles that of the *Woodruff*, and *Holcus odoratus*. The radical leaves are stalked, three or four inches long, nearly elliptical; those of the stem numerous, much smaller. Flowers small, purple, very numerous, in a smoothish, spreading, bracteated, corymbose panicle. Florets not numerous.

**LIBA**, in *Geography*, a town of Bohemia, in the circle of Saatz; 10 miles E. of Eger.

**LIBAN**, a town of Bohemia, in the circle of Boleslaw; 12 miles E. S. E. of Jung-Buntzel.

**LIBANIUS**, in *Biography*, a celebrated Greek sophist, or rhetorician, was born of an ancient family at Antioch, about the year 314. He devoted himself from his youth to the interests of literature, and pursued his studies at Athens. Having finished his education he collected disciples, and made himself known by various rhetorical compositions. His reputation was so high at Constantinople, that some other professors, jealous of his fame, procured his banishment on the charge of magic. He then went to Nicomedia, where he obtained a great number of disciples, among whom, in a private manner, was Julian, afterwards denominated the Apostate. He finally returned to Antioch, where he spent the remainder of his day. About the year 360, he was preceptor to Basil and Chrysofom, persons afterwards very celebrated in the church, though he was always zealously attached to the ancient religion; and on the accession of Julian, he was one of the first whom that emperor invited to be near his person. He declined the honours intended him, preferring a life of privacy to the bustle of a court. He was, however, warmly attached to a prince who patronized his studies, and supported the same religious cause; and was enabled, by the influence which he had over him, to soften many of the emperor's resentments. Julian admitted him to the equality of a friend, and is thought to have derived some assistance from him in his compositions. He survived to an advanced age, but the time of his death is not known. The writings of Libanius were very numerous, consisting chiefly of orations, declamations, dissertations, and epistles; which are characterized by Gibbon as, "for the most part, the vain and idle compositions of an orator who cultivated the science of words;" yet he admits that he had merit, and that his correspondence was various and elaborate; "he praised the virtues of his own times; he boldly arraigned the abuses of public and private life; and he eloquently pleaded the cause of Antioch against the just resentment of Julian and Theodosius." Some of the works of Libanius, consisting of his orations, declamations, &c., were published in two volumes, folio, in Greek and Latin, in the years 1626 and 1627; but the most complete collection of his epistles is that published at Amsterdam in 1738. A volume, containing seventeen of his harangues, from the library of St. Mark, was printed at Venice in 1755. In reference to the conclusion of this writer's life, Gibbon observes, "it is the common calamity of old age to lose whatever might have rendered it desirable; but Libanius experienced the peculiar misfortune of surviving the religion and the sciences, to which he had consecrated his genius. The friend of Julian was the indignant spectator of the triumph of Christianity; and his bigotry, which darkened the prospect of the visible world, did not inspire Libanius with any lively hopes of celestial glory and happiness." The judicious and excellent Lardner has translated the whole of Libanius's oration to the emperor Theodosius, every part of which, he says, is of importance to Christians. The occasion of this oration was, that in the reign of Theodosius, several heathen temples had been pulled down and destroyed by the monks, with the consent or connivance, as Libanius thought, of the bishops, and without the orders of the emperor to that purpose. Of this Libanius complains and implores the protection of Theodosius, that the temples may be preserved. Dr. Lardner, therefore, gives the oration at length, to shew that the testimony of this heathen writer went directly to

prove the divine origin of Christianity. And he concludes by maintaining, that the greatness and splendour to which the Christian church had attained from small beginnings, by the force of truth against worldly terrors and allurements, was a greater wonder and a work of greater power than the magnificence of Rome and the grandeur of her empire. Libanius has given an interesting detail of the private life of Julian, quoted and referred to by Gibbon; the mention of which affords us an opportunity of making an additional reference to the article JULIAN in our last volume. The works of Dr. Lardner should have been cited as containing a summary of the arguments respecting the extraordinary interpositions that prevented this emperor from rebuilding the Jewish temple. See Lardner's testimonies of Ancient Heathens, vol. iv. or vol. viii. edit. 1788. Gibbon, vol. iv. Moreri.

**LIBANIUS, GEORGE**, who flourished in the sixteenth century, was descended from a respectable family at Lignitz, in Poland, of which place he was a native. He pursued his studies for several years in the most celebrated German universities; and coming to reside at Cracow, he was appointed one of the professors in the principal college of that city. He is said to have been the first person who introduced there the study of the Greek language. He published several works; as "Æconomicorum Aristotelis Libri Græcis et Latinis Annotationibus illustrati;" "Carmina Sibyllæ Erithrææ, &c.;" "Paræclis, id est adhortatio ad Græcarum Literarum studiosius, habita Cracovæ;" "De Musica Laudibus Oratio, &c.;" He also compiled an "Anthology;" or choice Collections from the Works of St. Basil, St. Gregory Nazianzen, and St. Chrysofom. Moreri.

**LIBANOMANTIA**, *Λιβανομαντεία*, in *Antiquity*, a species of divination performed with frankincense; which, if it presently caught fire, and sent forth a grateful odour, was esteemed a happy omen, and *vice versa*.

**LIBANOTIS**, in *Botany*, the ancient appellation of a plant, supposed by some to have been the name of a boy, changed into the plant in question; but the most evident and generally received etymology is from *λίβανος*, *frankincense*, which the root is said to resemble in scent. The *λίβανός* of Dioscorides appears to be our Rosemary, as has been usually supposed; which shrub is by the modern Greeks called *δευδελολίβανος*, or Tree Libanos. *Libanotis* however has at different times, been employed to designate various umbelliferous plants, of an aromatic quality, and generally of mountain origin, which may have been found under the genera of *Ahamanota*, *Cachrys*, *Bupleurum*, &c.

**LIBANUS**, in *Geography*. See **LEBANON**.

**LIBATION, LIBATIO**, a ceremony in the heathen sacrifices, wherein the priest spilt some water, wine, milk, or other liquor, in honour of the deity to whom the sacrifice was offered; after having first tasted it himself.

Alexander is said to have sacrificed a bull to Neptune; and, for an offering to the sea-gods, to have thrown the golden vessels used for the libation into the sea.

Libations were also in use under the law of Moses, being enjoined by God in Exodus xxix. and Numbers xv.

**LIBAU**, in *Geography*, a sea-port of the duchy of Courland, situated on the Baltic, built by the Lettonians, and deriving its name, as it is said, from the word "Leepaja," which, in the Lettonian language, signifies a piece of ground planted with linden-trees, suggested by the circumstance that many of these trees formerly grew here. This etymology is further confirmed by the consideration that the Lettonians even now call the town "Leepaja." Some Germans intermixed with the inhabitants of this town in the

13th century, and about the close of the fifteenth, and commencement of the 16th centuries, many of that nation united together, and in 1625 it obtained the privileges of a city. In 1737, the harbour was cleared by Ernest John, and the future accumulation of mud and sand prevented, so that it is now a commodious port for vessels of light burden; a considerable number of which repair hither and are loaded with hemp, linseed, &c. This town was often taken by the Swedes, but ceded to Courland by the peace of 1660; 66 miles W. of Mittau. N. lat. 55° 28'. E. long. 21° 37'. In this part of the Baltic, as well as in the whole province of Courland belonging to Russia, accounts are kept by merchants, as at Riga, in Alberts dollars of eighty ferdings, or of ninety Alberts groschen; but retail traders mostly reckon two guldens of ninety current groschen, four of which are equal to three Alberts groschen. The coins chiefly circulating here are Dutch ducats, and Alberts dollars; and also pieces coined in the country of the same standard and value with these two coins. The ferding is an old silver coin; but the grosche is imaginary. The Russian coins are also current here. (See RIGA.) The last of wheat, rye, barley or pease, contains 48 loafs; that of oats and malt 60 loafs, which are equal to 106 English bushels; so that a loaf of wheat contains about 10½ English quarters, and a last of oats 13½ English quarters: one hundred lasts of falt are equal to 11,110 English bushels. Libau exchanges with London at four Alberts dollars fifty groschen, more or less, for 1*l.* sterling, at three months date. The old flyle is still used at Libau. Kelly's Un. Cambit, vol. 1.

**LIBAVIUS, ANDRECO,** in *Biography*, a physician and chemist, was born at Hall, in Saxony. He was professor of history and poetry at Jena, in 1588. But he removed to Rothenburg, on the Tauber, in 1591, and to Coburg, in Franconia, in 1605, in consequence of an appointment to the office of principal of the college of Calmir, at that place. He died at Coburg in 1616. Libavius obtained a considerable reputation in his time by his chemical works, having pursued that science upon better principles than most of his contemporaries. He employed many chemical preparations in medicine; nevertheless, he avoided the violence of Paracelsus and his disciples, whose principles he often refuted, and against whom he frequently defends the doctrines of the Galenical school. But, like the chemical philosophers of the age, he did not altogether escape the delusions of alchemy. He left his name long attached, in the laboratories, to a particular preparation of tin with muriatic acid, which was called "the fuming liquor of Libavius." It is unnecessary to enumerate the titles of his many works, which have now become obsolete, and are almost forgotten. His last work, published at Francfort in 1615, under the title of "Examen Philosophiz Novæ, quæ veteri abrogandæ; opponitur;" folio, is remarkable for the first mention of the transfusion of blood from the vessels of one living animal to those of another, of which he speaks with great confidence. The suggestion, however, was not submitted to the test of experiment until the middle of the same century, when the subject made a great noise throughout Europe, and many physicians anticipated from it no less than a remedy against all diseases; nay, some of them felt a confident expectation of rendering life perpetual. But these notions were presently confuted by the numerous fatal terminations of the experiment. See Eloy Dict. Hist. Haller. Bibl. Med.

**LIBAVIUS, Liquor of.** See LIQUOR.

**LIBEL, Famous Libellus,** a writing or report, unlawfully published abroad, containing injurious reproaches, or accusations, against the honour and reputation of any person, par-

ticularly of a superior or governor: or, it is defined to be a malicious defamation of any person, expressed either in printing or writing, signs or pictures, to asperse the reputation of one that is alive, or the memory of one that is dead. According to judge Blackstone, libels, in their most extensive sense, signify any writings, pictures, or the like, of an *immoral* or *illegal* tendency. Considered particularly as offences against the public peace, they are malicious defamations of any person, and especially a magistrate, made public by either printing, writing, signs, or pictures in order to provoke him to wrath, or expose him to public hatred, contempt, or ridicule.

Platina is of opinion, that a writing, how injurious soever it is, cannot be called a libel, if the author's name be to it. Libellers, among the ancient Romans, were punished with death, but in after-times they were only whipped. Augustus ranked *fanctos libellos*, detamatory libels, among the crimes *lese majestatis*, of high treason; and under the emperor Valentinian it was made capital, not only to write, but to publish or even omit destroying them. F. Baldwin has published a comment on the imperial laws against libels. Scandalous pictures are reckoned amongst libels.

A libel, the lawyers say, may be either in *scriptis*, or *sine scriptis*: in *scriptis*, when a writing is composed, or published to another's disgrace; which may be done either *verbis aut cantalensis*; as where this is maliciously repeated, or sung, in the presence of others: or else *traditione*, when the libel, or any copy of it, is delivered out, to scandalize the party. 3 Inst. 174.

A *libel sine scriptis*, may be twofold. 1. *Picturis*, as to paint the party in a shameful or ignominious manner: or, 2. *Signis*, as to fix a gallows, or other ignominious signs, at the door of the party, or elsewhere.

Where a writing inveighs against mankind in general, or against a particular order of men, this is no libel; in order to make it a libel, it must descend to particulars and individuals. (3 Salk. 224.) But a general reflection on the government is a libel, though no particular person is reflected on; and the writing against a known law is held to be criminal. (4 St. Tr. 672. 903.) According to C. J. Holt, scandalous matter is not necessary to make a libel; it is enough if the defendant induces an ill opinion to be had of the plaintiff, &c. And if a man speak scandalous words, unless they are put in writing, he is not guilty of a libel; for the nature of a libel consists in putting the infamous matter into writing. (2 Salk. 437. 3 Salk. 226.) A defamatory writing, expressing only one or two letters of a name, in such a manner, that from what goes before and follows after it may be understood, by the natural construction of the whole, to signify and point at such a particular person, is as properly a libel as if the whole name were expressed at large. (1 Hawk. P. C. c. 73. f. 4.) On application for information against this offence, some friend to the party complaining should in such case state by affidavit his having read the libel, and that he understands and believes it to mean the party. (3 Bac. Abr. 12.) And in the case of actions for libels by signs or pictures, it seems necessary always to shew, by proper innuendoes and averments of the defendant's meaning, the import and application of the scandal, and that some special damage has followed; otherwise it cannot appear that such libel by picture was understood to be levelled at the plaintiff, or that it was attended with any actionable consequences. (Bl. Com. iii. c. 8.) Although a private person or magistrate be dead at the time of making the libel, yet it is punishable, as it tends to a breach of the peace. (Hob. 215. 5 Co. 125. 1 Hawk. P. C. c. 73.) But an indictment for publishing libellous matter

matter reflecting on the memory of a dead person, not alleging that it was done with a design to bring contempt on the family of the deceased, and to stir up the hatred of the king's subjects against them, and to excite his relations to a breach of the peace, cannot be supported; and judgment was in this case accordingly arrested. (4 Term Rep. 126.) No writing is esteemed a libel, unless it reflect upon some particular person. And a writing full of obscene ribaldry is not punishable by any prosecution at common law; but the author may be bound to good behaviour, as a person of evil fame. (1 Hawk. P. C. c. 73.) Printing or writing may be libellous, though the scandal is not directly charged, but obliquely and farcally. Id.

It is certain that he who composes a libel, or procures another to compose it, and also he who publishes or procures another to publish it, is in danger of being punished for it; and it is said not to be material, whether he who disperses a libel know any thing of the contents or effect of it, or not; for nothing would be more easy than to publish the most virulent papers with the greatest security, if concealing the purport of them from an illiterate publisher would make him safe in dispersing them. (1 Hawk. c. 70.) It hath also been said, that if he who hath either read a libel himself, or hath heard it read by another, do afterwards maliciously read or repeat any part of it in the presence of others, or lend or shew it to another, he is guilty of an unlawful publication of it. (Id.) It hath also been holden, that the copying of a libel shall be a conclusive evidence of the publication of it, unless the party can prove that he delivered it to a magistrate to examine it. (Id.) When any one finds a libel, if it be against a private person, he ought to burn it, or deliver it to a magistrate; and where it concerns a magistrate, he should deliver it presently to a magistrate. (5 Rep. 125.) If a libel be found in a house, the master cannot be punished for framing, printing, and publishing it; but it is said he may be indicted for having it, and not delivering it to a magistrate (1 Vent. 31.); or it may, in some cases, be considered as evidence of his being the author or publisher. (2 Salk. 418.) It hath been ruled, that the finding of a libel on a bookfeller's shelf is a publication of it by the bookfeller, and that it is no excuse to say, that the servant took it into the shop without the master's knowledge; for the law presumes the master to be acquainted with what the servant does. (1 Seff. C. 33. R. v. Dodd. 10 G.) The sale of the libel by a servant in a shop is *prima facie* evidence of publication, in a prosecution against the master; and is sufficient for conviction, unless contradicted by contrary evidence, shewing that he was not privy, nor in any way assenting to it. 4 Term Rep. 126. 5 Burr. 2686. 7. 1 Hawk. P. C. c. 73.

It is said to be immaterial, on a criminal prosecution, with respect to the essence of a libel, whether the matter of it be true or false, or whether the party against whom it is made be of good or bad fame; for in a settled state of government, the party grieved ought to complain for any injury done to him, in the ordinary course of law, and not by any means to revenge himself either by the odious course of libelling or otherwise. (5 Co. 125.) But this is to be understood, when the prosecution is by information or indictment; but in an action on the case, which is to repair the party in damages, the defendant may justify the truth of the facts, and shew that the plaintiff hath received no injury. Although it has been held, agreeably to the doctrine maintained by lord chief justice Mansfield, for at least two centuries, that the truth of a libel is no justification in a criminal prosecution, yet in many instances it is considered as an extenuation of the offence; and the court of king's bench

has laid down this general rule, *viz.* that it will not grant an information for a libel, unless the prosecutor who applies for it makes an affidavit, asserting directly and pointedly that he is innocent of the charge imputed to him. This rule, however, may be dispensed with in particular cases; as if the person libelled resides abroad, or if the imputations of a libel are general and indefinite, or if it is a charge against the prosecutor for language which he has held in parliament. Where, on application for an information, the truth of the libel is not denied, the court, except in the instances above mentioned, will leave the injury to be remedied in the ordinary course of justice by action or indictment. (Stra. 493.) But the court will not grant this extraordinary remedy by information, nor should a grand jury find an indictment, unless the offence be of such signal enormity, that it be reasonably construed to have a tendency to disturb the peace and harmony of the community. (1 Hawk. P. C. c. 73.) There are authorities, that truth is not a justification even in an action for a libel; and a very learned writer seems to doubt whether such a plea would now be admitted by the court, if the accusation in the libel did not amount to an indictable offence. (3 Woodd. 182.) It seems, however, that the contrary is the prevalent opinion; and that in every action for a libel, if specific instances can be stated upon the record, so as to support the general charge of the libel, the courts would determine them to be a sufficient justification of the defendant. 1 Term Rep. 748.

The punishment of libellers for either making, repeating, printing, or publishing the libel, is fine, and such corporal punishment (as imprisonment, pillory, &c.) as the court in its discretion shall inflict; regarding the quantity of the offence, and the quality of the offender. (1 Hawk. P. C. c. 73.) If a printer print a libel against a private person, and much more against a magistrate, or against the king and state, he may be indicted and punished for it; nor is it any apology to say, that it was done in the way of trade, or to maintain a family. (1 St. Tr. 982. 986.) Also, if bookfellers, &c. publish or sell libels, though they know not the contents of them, they are punishable. It has been resolved, that where persons write, print, or sell any pamphlets, scandalizing the public, or any private persons, such libellous books may be seized, and the persons punished by law; and all persons exposing books to sale, reflecting on the government, may be punished; also, writers of news (though not scandalous, seditious, or reflecting on the government, if they write false news) are indictable. St. Tr. 477.

With regard to libels in general, there are two remedies; one by indictment and another by action. The former for the public offence; for every libel has a tendency to break the peace, or to provoke others to break it; which offence is the same, in point of law, whether the matter contained be true or false; and, therefore, the defendant on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification. In such prosecutions the only facts to be considered are, first, the making or publishing of the book or writing; and secondly, whether the matter be criminal. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and shew that the plaintiff has received no injury at all. Blackst. Com. vol. iii. and vol. iv.

In information and law proceedings, there are two modes of describing a libel; *viz.* by the sense, and by the words; the first is "*cujus tenor sequitur*," and the second "*quæ sequitur in hæc Anglicana verba, &c.*" in which the description

description is by particular words, and of which every word is a mark, so that if there is any variance, it is fatal; in the other description by the sense, it is not material to be very exact in the words, because the matter is described by the sense of them (2 Salk. 660.) It hath been adjudged, that libels, as having a direct and immediate tendency to a breach of the peace, are indictable before justices of the peace. (1 Hawk. c. 8.) A libel must be proved to be written or published in the county laid in the indictment; all matters of crime being local. An information for a libel need not charge the offence to have been committed "vi et armis," or allege that the libellous matter is false. (7 T. R. 4.) The declaration for a libel must lay it to be "of and concerning the plaintiff;" otherwise there can be no judgment. (2 Strange, 934.) A very important subject of litigation has arisen from prosecutions for libels, and particularly for state libels; and that is, whether juries are, or are not, judges of *law* as well as of *fact*. With regard to libels, it had for a long time been the usage for the judge to direct the jury, that if the fact of the publication of the paper charged to be a libel was proved, and if they believed the innuendoes in the indictment, they must find the defendant guilty; without adverting to any other circumstances, such as whether the paper were, in their opinion, a libel, or published with a malicious, seditious, traitorous, &c. intention. The counsel for the defendants in such prosecutions always maintained, that it was the province of the jury to judge whether the paper was a libel (a question of mere law); and also whether it were published with a malicious, seditious, &c. intention, as charged,—a complicated question of law and fact. Mr. (now lord) Erskine was the most strenuous assertor of this latter doctrine; and by the indefatigable exertions of him and the late Hon. Charles Fox, the following act of parliament was obtained with a view expressly of settling this question by legislative authority; and in consequence of it a great, and, as many have deemed it, a very favourable, alteration has taken place in the trials for libels. The statute is that of 32 Geo. III. c. 67. After reciting that doubts had arisen whether on the trial of an indictment or information for making or publishing a libel, where an issue is joined on the plea of not guilty, it were competent to the jury to give their verdict upon the whole matter in issue, it enacts that on every such trial the jury may give a general verdict of guilty or not guilty upon the whole matter; and shall not be required or directed by the court or judge, before whom such indictment or information shall be tried, to find the defendant guilty merely on the proof of the publication by such defendant of the paper charged to be a libel, and of the sense ascribed to the same in such indictment or information. (f. 1.) Provided always, that on every such trial the court or judge before whom such indictment or information shall be tried, shall, according to their or his discretion, give their or his opinion and directions to the jury on the matter in issue between the king and the defendants, in like manner as in other criminal cases. (f. 2.) Provided also, that nothing herein contained shall extend, to prevent the jury from finding a special verdict, in their discretion, as in other criminal cases. (f. 3.) Provided also, that in case the jury shall find the defendant guilty, it shall and may be lawful for him to move in arrest of judgment on such ground, and in such manner, as by law he might have done before the passing of this act.

When a person is brought before the court to receive judgment for a libel, his conduct, subsequent to his conviction, may be taken into consideration, either by way of aggravation or mitigation of his punishment. (3 Term Rep. 432.)

Judge Blackstone observes, that in all the instances where blasphemous, immoral, treasonable, schismatical, seditious, or scandalous libels are punished by the English law, some with a greater, and others with a less degree of severity, the liberty of the press, properly understood, is by no means infringed or violated. See *Liberty of the Press*.

**LIBEL**, or *libellus*, a little book, in the spiritual court signifies the original declaration of any action in the civil law. (Stat. 2 Edw. VI. c. 53.) The libel used in ecclesiastical proceedings consists of three parts. 1. The major proposition, which shews a just cause of the petition. 2. The narration, or minor proposition. 3. The conclusion, or conclusive petition, which conjoins both propositions. Blackll. Com. vol. iii.

**LIBEL**, in the *Law of Scotland*, is used for a criminal accusation or indictment.

**LIBELLA**, in *Natural History*. See **LIBELLULA**.

**LIBELLA**, among the Romans, was the tenth part of the denarius.

**LIBELLATICI**, an ancient kind of apostates from Christianity, under the persecution of Decius; who, to prevent their being obliged to renounce the faith, and sacrifice to idols in public, made application to the magistrates, and abjured their faith in private; obtaining certificates of them, either by intreaty, or by money; by which they were attested to have complied with the orders of the emperor; and were thereby sheltered from any farther molestation on account of their religion.

These certificates were called *libelli*; whence the people who obtained them came to be denominated *Libellatici*.

Others, particularly the centurions of Magedbourg, are of opinion, that the Libellatici were only such as furnished the magistrates with money, to screen them from prosecution, and from being obliged to renounce Christianity.

M. Tillemont retains something of each opinion; he thinks, the Libellatici, applying themselves to the magistrates, bought off the sacrificing and abjuration; and obtained letters, by which they were declared to have renounced Christ, and sacrificed to idols; though, in effect, they had done neither.

**LIBELLULA**, or *Dragon Fly*, in *Entomology*, a genus of the order Neuroptera; the character of which, according to Gmelin, reduced to the arrangement of the "Systema Naturæ," consists in the mouth armed with jaws, more than two in number; lip trisid; antennæ very thin, filiform, and shorter than the thorax; wings expanded; tail (of the male insect) furnished with a forked process.

In this genus the antennæ are very short, being merely a pair of small hairs, the wings large and spreading, and the body lengthened. The libellulæ, or dragon-flies, exhibit an instance scarcely less striking than the butterfly of that dissimilitude in point of form under which one and the same animal is destined to appear in different periods of its existence. Persons not conversant with natural history, would scarcely believe that these brilliant insects, flying with vast strength and rapidity, and pursuing other insects still smaller, after the manner and with the velocity of a hawk, had been inhabitants of the water, in which they resided a considerable time before they had assumed the flying form. The whole tribe, which is divided into sections, and one of which sections is subdivided, is exceedingly ravenous, and generally seen hovering over stagnant waters: the larvæ are six-footed, active inhabitants of the water, furnished with an articulate forspicated mouth; and prey with the utmost rapaciousness upon aquatic insects and the larvæ of others; the pupa resembles the larva, but, in the former state, it has the rudiments of wings. The libellulæ, or dragon-flies, are some-

## LIBELLULA.

times, though very improperly, called horse-flingers. There are nearly sixty species: before, however, we come to the enumeration of these, we may relate some facts common to the tribe itself. The addressees of the male libellula to his female seem carried on in a rough but very efficacious manner. He hovers about on the wing, till the object of his amours makes her appearance; he then watches an opportunity of seizing her by the head with those pincers with which his tail is armed. In this manner he travels through the air, till the female, yielding either to superior strength or inclination, forms her body into a kind of circle, adapted to the purpose of nature; hence the libellule are frequently seen coupled in the air, exhibiting the form of a ring. The female, at a proper period, retires to some stagnant water, where, by the assistance of a flick or reed, she lowers herself down, by moving backwards, till the tip of the tail is immersed a little in the water; she is then seized with a tremor of the body, during which she deposits the egg in the water. In this way the operation is repeated. The tail is withdrawn from the water, by contracting the annuli; and, by the pressure of these upon each other, the egg is gradually forced from the ovary to the extremity of the tail; whence it is separated by shaking that part in the water. The eggs are of a white colour, resembling those produced by the common blow-fly. The larvæ are disgusting in appearance, but beneath the head is placed an instrument excellently adapted for seizing and holding their prey. It is furnished with a forceps at the end, and can be advanced or drawn back with the agility of the human hand! The larva remains in the same state about a year before it attains its full size: when the period of its transformation has arrived, it repairs to the margin of the pond in quest of a convenient situation during the season of its inaction. It there attaches itself to a plant or piece of dry wood, and the skin, which has gradually become parched and brittle, at length splits opposite the upper part of the thorax. Through this aperture the winged insect quickly pushes its way, and being thus extricated from confinement, begins to expand its wings, to flutter, and finally to launch into the air. The complete insect, in its winged state, continues to pursue food similar to that by which it had been supported before, and remains insectivorous. The lepidopterous insects, the butterflies, and phalænae, are defined for the support of the larger libellula, which are a part of those numerous tribes appointed to confine these prolific genera within due bounds. The life of the libellula, in its winged state, is short in comparison with that which it passed in its aquatic form, the frosts of the early autumn destroying all those that have not been devoured by birds in the preceding months. It is impossible not to be struck with wonder in contemplating the changes of the libellula, which, while living in the water, would perish by a long exposure to the air, while the winged insect, having escaped from the pupa, would be destroyed by submersion under the water, of which, not an hour before, it was the legitimate inhabitant.

The species are divided into the sections A and B. Section A. Wings expanded when at rest. The insects of this division are subdivided into a Dorsal division of the lip very minute; and 2 Divisions of the lip equal; constituting the tribe *Æthna* of Fabricius. B. Wings erect when at rest; eyes distinct; outer divisions of the lip bifid. The tribe *Agriion* of Fabricius.

### Species.

Section A. Wings expanded when at rest: a Dorsal division of the lip very minute.

VOL. XX.

4-MACULATA. Lower wings at the base, and all in the middle on the fore-part with a blackish spot; abdomen depressed, downy. It is an European insect, and described by Reaumur.

DEPRESSA. All the wings blackish at the base; abdomen depressed, yellowish at the sides. This also is an European insect; figures and description are given by Edwards and Donovan. The male is of a bright sky-blue, with the sides of the body yellow; the female of a fine brown, with yellowish sides. The wings in both sexes are transparent, except at the shoulders, where they are each marked by a broad bed of brown with a stripe of yellow; the tips of each wing have also a small oblong-square black spot on the outer margin. The larva is of a greyish-brown.

TRIMACULATA. All the wings hyaline, with a ferruginous spot at the base, and band in the middle. It inhabits Carolina.

BIFASCIATA. Wings hyaline, with a brown spot at the base and two bands. It inhabits America. The thorax is villous-brown, with two yellow lines under the wings; abdomen depressed, brown, the sides yellowish.

4-PUNCTATA. Wings white; lower ones black at the base with a yellow line; all with a black dot; abdomen cylindrical. It inhabits America. Thorax is of a downy green; front vesicular green; abdomen greenish at the base, but towards the tip blackish; all the wings with a black dot in the middle at the rib, and an oblong stigma at the tip.

FLAVEOLA. Wings pale yellow at the base. Inhabits Europe. Its wings are sometimes without the yellow spot.

LINEATA. Wings white with a yellowish base, and black band and tip; abdomen yellow, with a lateral black line. This species is found in India. Its head and thorax are yellow; abdomen compressed.

STIGMATIZANS. This is a yellowish insect; has wings with a brown spot, the tip brown with a snowy stigma. It is found in New Holland. Sir Joseph Banks has a specimen in his museum. The abdomen is marked with black lines; wings hyaline.

OCULATA. Like the last, this is of a yellowish colour; the upper wings are hyaline at the tip, lower ones at the margin, with a snowy stigma. It inhabits New Holland.

INDICA. This species has wings varied with yellow and brown, and white at the tip; the lower ones have a blue spot at the base. It is found, as its name imports, in India. The body is brown; tip of the wings hyaline.

MUNCIA. Bronzed; wings are of a whitish colour spotted with brown; the lower ones yellow at the base. Inhabits India.

VESICULA. Wings white; takes its name from an elevated vesicular front, and thorax yellow immaculate. Is found in America, and is a large insect; the abdomen is cylindrical, the segments pale at the base and black at the tip; tail with cylindrical scales.

RUBICUNDA. Lower wings only blackish at the base; body square. An inhabitant of Europe. In one sex the back is spotted with red, in the other with yellow.

VULGATISSIMA. Thorax yellow, with eight black streaks. It inhabits Europe.

OBSCURA. All its wings are ferruginous; the body of a dusky hue; an American insect; the abdomen is cylindrical; wings with an oblong brown marginal dot.

VULGATA. Wings hyaline immaculate; abdomen cylindrical and reddish. Inhabits Europe.

SIBERICA. Wings hyaline, with a transverse broad ferruginous

## LIBELLULA.

ruginous band towards the tip; body reddish. Inhabits Siberia.

**SINATA.** The wings of this insect are flat, longitudinally sinuate, and black on the thicker margin, with a white stigma. The body is bluish. There is a specimen in the British Museum.

**CANOPULATA.** Wings immaculate at the base; back and fides of the abdomen interrupted by yellow. It inhabits Europe.

**PEDEMONTANUS.** Found among the mountainous parts of Italy; wings flat, cinereous, with a brown band at the tip. It is small, and the body of an obscure yellowish.

**FASCIATA.** Wings flat, brown, with a white streak. It inhabits India.

**UMBRATA.** Found in America. Wings flat, with a brown band.

**SERVA.** Wings flat, white, with an oblong black spot at the base and band in the middle. It inhabits China. The body is cylindrical.

**NOTATA.** The wings of this are flat, with white spots and tip. It inhabits Africa. A specimen is in the museum of Sir Joseph Banks.

**DIMIDIALA.** Wings flat and black from the base to the middle. It is found in America.

**EQUESTRIS.** Wings half black, with a snowy band in the middle. It inhabits Africa. A specimen in the museum of Sir Joseph Banks. The head is brown, with a yellow dorsal line; all the wings are black from the base to the middle, then a snowy band; the tip hyaline with a common brown spot.

**FLUCTUANS.** Wings black tip with white. It inhabits India, is small, and brown; the front is vesicular yellowish.

**NEBULOSA.** Wings white tip with black. It inhabits India; the body is black; mouth yellow; fides of the thorax and abdomen spotted with yellow; tail with yellow appendages.

**CHINENSIS.** The upper wings faint testaceous; lower ones green tip with brown. It inhabits China.

**VERSICOLOR.** Wings flat, white with three black and three cinereous spots. It inhabits America. A specimen is in the museum of Dr. Hunter. The head is brown, spotted with yellow; thorax brown, with two yellow lines each side under the wings; the abdomen is brown.

**VIBRANS.** Wings flat, white with a black spot in the middle, the tips ferruginous.

**AMERICANA.** Notwithstanding the name, this species is found in India. Wings purplish, with a white band; upper pair tipped with white, lower ones with a white line at the base.

**MARGINATA.** Wings black; upper pair with a white spot at the tip; lower ones edged with white. It inhabits Africa; may be seen in Sir J. Banks's museum. The front is blue; eyes brown, dotted with yellow; thorax black; abdomen brown, whitish at the base.

**FERRUGINEA.** Wings white, yellow at the base; body red. It inhabits China.

**TOMENTOSA.** The wings of the insects of this species are also white; but the body is downy variegated with brown and green. It is found in America. The front is blue; abdomen cylindrical black, the segments with a greenish dot on each side.

**ÆNEA.** Wings hyaline; thorax green bronzed. It inhabits Europe.

**CYANEA.** Wings white, with a snowy spot terminated by a brown one. The body is blue. It inhabits America.

**6-MACULATA.** Wings with three black costal spots, the last with a snowy stigma; lower ones with yellowish bands. It inhabits China. The head is yellowish; thorax yellowish with black lines; abdomen flat and yellowish with black lines.

**CONTAMINATA.** Yellowish; wings whitish, with a yellowish shade in the middle. It inhabits India. The head, thorax, and abdomen yellowish.

**EPONINA.** Wings yellowish, with about three black bands. Is found in Carolina. Head and thorax yellowish; abdomen cylindrical, with a yellowish dorsal and lateral line; all the wings have a white costal spot near the tip.

**VARIA,** or great variegated libellula, the most remarkable English species, makes its appearance towards the decline of summer, and is an animal of singular beauty; it is three inches long, and the wings, when expanded, measure about four inches from tip to tip. Wings varied with yellow and brown, the tip with a white spot terminated by a black one. The head is very large, and affixed to the thorax by an extremely slender neck; the eyes occupy by far the greatest part of the head, and are of a pearly blue-grey cast, with a varying lustre; the front is greenish-yellow; the body is long, slender, and black, with rich variegations of bright blue, and deep grass-green. The wings are perfectly transparent, strengthened by numerous black reticular fibres, and exhibit a strongly iridescent appearance, according to the different inflections of light. This insect, in its motions, is extremely rapid, flying about in pursuit of its prey during the middle of the day, and is at this time taken with extreme difficulty, darting off on the slightest alarm from the spot on which it settled, and in the space of a second or two flying to a great distance. During the early hours of the morning, and the late ones in the evening, it is easily taken; at such times it is offered to fit with its wings expanded, but in so inert a state, that it will suffer itself to be readily seized by one of its wings, without attempting to move from its place.

**JUNCEA.** Wings with a blackish accessory membrane; thorax with six yellow lines; abdomen tapering towards the base. Inhabits Europe.

**CAROLINA.** Wings whitish; lower ones indented ferruginous at the base; thorax brown. An inhabitant of America.

**CAPENSIS.** In this species the whitish wings are every where spotted and dotted with brown; it is found, as its name imports, at the Cape of Good Hope.

**TRICOLORA.** Wings variegated with brown, bluish, and yellow, the tip hyaline. An inhabitant of India.

**RUBRA.** Is so named from its reddish colour; the wings with a ferruginous base and marginal lines. It inhabits Europe.

### ♁ Divisions of the Lip equal.

**FORCIPATA.** This insect, like the *varia*, is very large, and expands full four inches and a half. Nose yellow, with a black line on the prominent part; thorax black, with several broad yellow stripes, two on the front, and two behind the ligaments of each pair of wings; abdomen black, with two streaks resembling a erecton on each segment; wings transparent and white, with a tinge of amber; tail with three incurved claws.

**GRANDIS** is the largest of this genus found in Britain, and is, perhaps, not inferior in bulk to any insect which this country produces; the fore-part of the head is yellow; the eyes brown, and so large, that they meet at the top of the head. The thorax is of a dun colour, with four oblique bands on each side of a lemon colour. The abdomen

is reddish, often spotted with white and black upon the top and bottom of each segment; the small appendices which terminate the abdomen are very long; the wings have more or less of a yellow complexion, and are distinguished by a brown spot on the exterior edges. The colours of the insect vanish when dead.

**VARIIGATA.** Thorax with two yellow lines on each side; wings with a white spot at the base. It inhabits Terra del Fuego. A specimen is in the museum of sir Joseph Banks. The body is brown; mouth yellowish, with a black dot at the base; the abdomen is round and ferruginous, the segments are edged with black, and in each a white spot divided by a black line.

**CLAVATA,** has a clavate abdomen, which is gibbous at the base, variegated with brown and green. It inhabits China. The head is vesicular green; thorax green with black lines; abdomen green with black streaks, the middle thinner and black with lateral yellow spots, the tip thickened black with a white tail.

**MINUTA.** Abdomen yellow, with two black lines; lower wings yellow with two black spots. It is an inhabitant of China. The head is yellow, eyes brown; thorax with yellow lines beneath; abdomen with two black lines above and beneath; upper wings black at the base with a yellow spot.

*B. Wings erect when at rest; eyes distinct; outer divisions of the tip bifid.*

**VIRO.** This is one of the most elegant of the European insects, but is smaller than the *varia* or *grandis*, and is distinguished by its slender, long, cylindrical body, which, as well as the head and thorax, is usually either of a bright but deep golden-green, or else of a deep gilded blue; the wings are transparent at the base and tips, but are each marked in the middle by a very large oval patch of dark violet blue, accompanied with iridescent hues, according to the direction of the light; sometimes the wings are entirely violet-black, without the least appearance of transparency either at the base or the tips, and sometimes they are altogether transparent, without any appearance of the violet-black patch which distinguished most of the individuals: lastly, the insect sometimes appears with transparent wings, but shaded with a strong cast of gilded greenish-brown, each being marked by a small white speck at the exterior edge near the tips. The genus is divided into varieties, *viz.*

*a.* Body shining green-blue; wings blueish in the middle, the base and tip whitish, the margin immaculate. Donovan. *b.* Body silky; wings blueish-green, the tip brown, the margin immaculate. Reaumur. *c.* Body silky-green; wings brownish with a white marginal dot. *d.* Body silky; wings brown-gilt with a black spot. It inhabits Europe, and is common about waters.

**PUELLA.** Wings hyaline, not coloured. This is a much smaller species than the *virgo*. It varies in colour, but is generally of a bright and beautiful sky-blue, variegated with black bars on the joints, and with the thorax marked by longitudinal stripes; the wings are transparent, and each marked near the tip with a small, oblong, square, black, marginal spot: the head in this species is broader and narrower in proportion than that of the *L. varia*, and the eyes are round, protuberant, and placed on each side at a distance from one another. From the brilliancy and richness of its colours, it has been called the king's-fisher; it frequents little rivulets of water overhaded with bushes. There are several varieties of this species, taken from the difference of spots and colours: as *a.* Body red with yellow and black lines at each segment; thorax green with yellow lines; wings with marginal spots. This is given by Mr. Donovan.

*b.* Body flesh colour; wings with a brown marginal dot. *c.* Body alternately blue and cinereous; wings with a black dot. *d.* Body beneath blue-green, above brown; thorax with alternate brown and blueish bands; wings with a black marginal dot. *e.* Body green with a flesh-colour bluish; thorax with three black lines; wings with a brown marginal dot. It inhabits Europe, in almost endless varieties.

**CILIATA.** Green-bronzed; abdomen brown; legs fringed black. Inhabits Coromandel. A specimen is in sir Joseph Banks's museum. Head and thorax bronzed; abdomen cylindrical.

**NOBILITATA.** Upper wings dusky; lower ones silky green tipped with black. Is found in South America. Body glossy green; lower wings beneath black.

**LINEARIS.** Wings with a yellowish or black stigma; abdomen extremely strong. Is found in India, and is figured by Drury; who, according to Dr. Shaw, has given a beautiful figure of a species not mentioned by Gmelin, *viz.* the

**LUCRETIA,** which is a native of the Cape of Good Hope, and is distinguished by the length of its slender body, which is about five and a half inches long, though scarcely the tenth of an inch in diameter. The wings of this species are transparent, slender, and narrow; they measure from tip to tip five and a half inches. The colour of the head and thorax is brown, with a yellowish stripe on each side, and the body is of a deep mazarine blue.

Having described the several species of the libellula, we shall close our account of this interesting genus of insects with some account of the eyes, as described in Adams' Essays. These are finely adapted for microscopical examination; and by the assistance of a good instrument, it will be seen that the eye is divided into a number of hexagonal cells, each of which forms a complete eye. The external parts of these eyes are so perfectly smooth, and so well polished, that when viewed as opaque objects they will, like so many mirrors, reflect the images of all surrounding objects. The figure of a candle may be seen on their surface multiplied almost indefinitely, shifting its beam to each eye according to the motion given to it by the hands of the observer. Læwenhoeck says, there are twelve thousand five hundred and forty-four lenses on each eye of the libellula. If one of the protuberant substances be nicely taken from the head of the insect, washed clean, and placed before the microscope, its structure is elegantly seen, and it becomes an object worthy of the highest admiration. Each of the eyes is a hexagon, and has the same effect as a convex lens in forming the image of an object placed before it, as may be seen by turning the mirror of the microscope so as to bring the picture of some well-defined object under the eye. If turned to a single house, in the eye of the insect the house is diminished very much, but it is multiplied into a city; if turned to a soldier, there will be seen an army of pigmies performing every motion at the same instant of time; if turned towards a candle, there will be a beautiful and resplendent blaze from multitudes of regular flames. See Adams' Essays, 4to. p. 195-6.

**LIBEN,** in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 11 miles N. of Leitmeritz.

**LIBER,** in *Vegetable Anatomy*, an ancient Latin word for the thin inner bark or rind of a tree, which being used to write upon before the invention of parchment or paper, is supposed to have given its name to a book. For the nature and functions of the *liber*, see BANK and CORTEX.

**LIBER Niger,** *domus Regis*, is the title of a book in which there is an account of the household establishment of king Edward IV., and of the several musicians retained in his

service, as well for his private amusement, as for the service of his chapel. See KING'S BAND, HOUSEHOLD, and CHAFEL *Establishment*. See also, N 203 of the Harl. MSS. Brit. Mus. and N° 1147, 2, 3, 11, of the Ashmol. Collect. Oxf. for "ordinances touching the king's household," made in the time of Edward II. as well as in that of Edward IV. And in the Liber Niger published by Batman, with additions.

LIBERA, in *Mythology*, the name of a goddess, which Cicero, in his book of the Gods, represents as the daughter of Jupiter and Ceres. Ovid in his *Fasts* says, that the name was given by Bacchus to Ariadne.

LIBERA is exhibited on medals, as a kind of female Bacchus, crowned with vine-leaves.

LIBERA, in *Law*, a livery or delivery of so much corn or grafs to a customary tenant who cut down or prepared the said grafs or corn, and received some part or small portion of it as a reward or gratuity. Cowell.

LIBERA *Chafsa habenda*, a judicial writ granted to a person for a free chafe belonging to his manor, after proof made by inquiry of a jury, that the same of right belongs to him. Reg. Orig. 36.

LIBERA *Piscaria*, a free fishery, which being granted to a person, gives him a property in the fish, &c. (2 Salk. 637.) See FISHERY.

LIBERAL ARTS, are such as depend more on the labour of the mind than on that of the hand; or, that consist more in speculation than operation; and have a greater regard to amusement and curiosity than to necessity.

The word comes from the Latin *liberatus*; which, among the Romans, signified a person who was not a slave; and whose will, of consequence, was not checked by the command of any master. See ARTS.

LIBERALE VERONESE, in *Biography*. By this name Vafari speaks of an historical painter, born at Verona in 1451. He was at first a disciple of Vincenzo di Stefano; but afterwards he imitated the style and manner of Bellini of Venice, whom, while a youth, he saw painting in the chapel of St. Nicolo at Verona.

He began to paint very early in life, and filled the churches and convents of his native city with highly wrought pictures, which were very much esteemed; and of which the author above-mentioned speaks with high encomiums.

His style appears by his account to be of the early dry manner in art. Compositions consisting of a number of figures, all finished with great minuteness; and frequently of small proportions.

LIBERALIA, feasts celebrated by the ancient Romans, in honour of Liber, or Bacchus, the same with those which the Greeks called *Dionysia*, and *Dionysiacs*.

They took their name from *liber*, i. e. *free*, a title conferred on Bacchus, in memory of the liberty or freedom which he granted to the people of Bœotia; or, perhaps, because wine, whereof he was the reputed deity, delivers men from care, and sets their minds at ease and freedom. Varro derives the name of this feast from *liber*, considered as a noun adjective, and signifying *free*; because the priests were free from their function, and eased of all care, during the time of the liberalia, as the old women officiated in the ceremonies and sacrifices of these feasts.

LIBERAM LEGEM. See LEX.

LIBERAN, in *Geography*, a small island of the East Indian sea, near the N.E. coast of the island of Bornoe, on which are many deer. N. lat. 6° 2'. E. long. 116° 8'.

LIBERANDIS TERRIS. See TERRIS.

LIBERATE, in *Law*, a writ that lies for the payment of a yearly pension, or sum of money, granted under the

great seal, and directed to the treasurer, chamberlains, and barons of the exchequer, &c. for that purpose.

In another sense it is writ to the sheriff of a county, for the delivery of possession of lands, and goods extended, or taken upon the forfeiture of a recuzance.

Liberate is also used for a writ issuing out of the chancery, directed to a gaoler for delivery of a prisoner, who hath put in bail for his appearance. F. N. B. 132 6 Inst. 116.

LIBERATI, ANTIMO, in *Biography*, a singer in the pontifical chapel at Rome in the 17th century. When a youth, he was a choirster in the chapel of the emperor Ferdinand III., and his brother Leopold, previous to his admission into the pope's chapel: where, besides his vocal abilities, he distinguished himself as a composer. He was, likewise, organist della santissima Trinità di Pellegrini, and maestro di cappella, and organist of the church di Santa Maria dell' anima della nazione Teutonica at Rome. In this quality he wrote a letter, which is often quoted, particularly by Adami, in his *Osservazioni per ben reg. il cocomo de i Cantoci della Cap. Pont.* This letter is addressed to Ovidio Persapegi, in answer to some queries he had sent to him, concerning the state of music in the pontifical chapel; and the character of some musicians in its service, who were candidates for the place of maestro di cappella of the Metropolitan church at Milan.

This letter, printed at Rome 1685, contains characters of the great Roman maisters, and descriptions of styles, more resembling sound criticism than any musical work of the last century; but it is, unluckily, written in such a vein of general panegyric, as is more likely to generate scepticism in the minds of modern readers, than conviction. Liberati was a disciple of Benevoli, and his voice a soprano.

LIBERATUS, a deacon of the church of Carthage, flourished about the middle of the sixth century. In the year 534, he was sent to Rome by a council of African bishops held at Carthage for the purpose of consulting with pope John about some dubious points; and he was frequently employed respecting affairs of importance. He drew up an historical memorial of the contents which arose about the opinions of Nestorius and Eutyches, entitled "Breviarium de Causa Nestorii et Eutychetis, &c." The materials made use of on this occasion were collected from the relations of various credible persons, the history of the church, translated out of Greek into Latin, authentic acts of councils, and the letters of different bishops. An appendix to this Breviarium is given by father Crabe, in the second volume of his edition of the Councils. Moreti.

LIBERGA, in *Geography*, a town of Prussia, in the palatinate of Culm: 26 miles E. of Culm.

LIBERHOF, a town of Prussia, in the province of Pomerania; 18 miles S.S.E. of Dantzic.

LIBERI *Tauri Libertas*. See TAURI.

LIBERIA, a feast held among the Romans, on the day whereon their children laid aside their juvenile habits, and assumed the robe called *toga liberia*.

The liberia were kept on the 16th of the kalends of April; that is, on the 17th of March.

LIBERIUS, pope, in *Biography*, a native of Rome, who, having discharged the duties of different ecclesiastical offices with reputation, was chosen bishop in 352. Immediately after his election he wrote to Athanasius, summoning him to appear at Rome, and clear himself from the accusations preferred against him by the eastern bishops. It should seem he had afterwards a much better opinion of Athanasius, and undertook his defence with great zeal. With this view he sent legates to a council which the emperor Constantine had summoned to meet at Arles, but had

the mortification to hear they had betrayed the cause entrusted to them. When Liberius was told of the conduct of his deputies, he was filled with resentment and sorrow, and disavowed it in the strongest terms, as well in his declarations, as in his correspondence. He requested the emperor to assemble a new council, for the purpose of examining the matters in dispute between Athanasius and his opponents, and of restoring peace and tranquillity to the Catholic church. A council was accordingly held at Milan in 355, at which there were 300 western bishops, and a few from the east. So far from calm discussion into the merits of the question, the emperor insisted upon it, as a preliminary measure, that they should give their signatures to the condemnation of Athanasius, and also to an edict containing the chief tenets of Arius, which had been published in his name. Those who had resolution to oppose the will of the emperor were threatened with instant execution, and were actually banished. Such were the means used by Constantius in obtaining the signatures of the by far the greater part of the western bishops to the condemnation of Athanasius; but Liberius still declared in his favour, and exerted himself, by all the means in his power, to gain others to his party. At length, the emperor having failed, by threats and proffered bribes, to gain the suffrages of the pope, he determined to apprehend him, and gave his order accordingly. This was executed in the dead of night, to prevent any commotion among the people, who were much attached to their bishop; he was carried first to Milan, and thence to Berræa in Thrace. The hardships which Liberius experienced in exile, disposed him to yield to conditions which at one time he would have rejected with the utmost indignation. He not only subscribed to the condemnation of Athanasius, but received, as Catholic, the Arian confession, and made other concessions still more disgraceful to his reputation as bishop of the holy Roman see. Before he could reach Rome, the emperor had embraced the doctrine of the Semi-Arians, and obliged Liberius to do the same; so that this pontiff, who, of course, was always the infallible head of the church, avowed himself an Athanasian, an Arian, and a Semi-Arian. On account of his obedience, he was permitted to return to Rome, on condition that he should govern the church jointly with FELIX II. (See the article.) Liberius arrived at Rome in August, 358, and entered the city in a kind of triumph, being met on the road, and received by the people at large with loud acclamations of joy. He died in September, 366, after he had presided over the Roman see fourteen years; and notwithstanding his repeated change of religious opinions, he is honoured both by the Latin and Greek churches as a saint. "A Dialogue with the Emperor Constantius" is ascribed to Liberius; so, likewise, are twelve "Letters," inserted in the second volume of the *Collect. Concil.* Bower. Moreri.

**LIBERO**, *Ital.*, free, unconfined, in *Musick*, the same as *fiolito*; opposed to *Legato*, restrained by particular laws. Thus, a *free fugue*, is distinguished from a canon; *fuga fiolita*, or *Libera*, from *Fuga perpetua*. See *CIOLTA*, and *LEGATO*.

**LIBERTAS ECCLESIASTICA**, *Church Liberty*, a frequent phrase in old writers, who treat of ecclesiastical immunities. The right of investiture, extorted from our kings by the papal power, was at first the only thing challenged by the clergy, as their *libertas ecclesiastica*, but by degrees under the title of *church liberty*, they contended for a freedom of their persons and possessions, from all secular power and jurisdiction; as appears by the canons and decrees of the councils held by Boniface, archbishop of Canterbury, at Merton, A. D. 1258, and at London, A. D. 1260, &c.

See Lord Littleton's *Hill.* of Hen. II., and Robertson's *Hill.* of Ch. V.

**LIBERTATE PROBANDA**, in *Law*, an ancient writ that lay for such as being demanded for villains, offered to prove themselves free; directed to the sheriff, that he should take security of them for the proving of their freedom before the justices of assize, and that in the mean time they should be unmolested. F. N. B. 77.

**LIBERTATIBUS ALLOCANDIS**, a writ lying for a citizen or burgher, impleaded contrary to his liberty, to have his privilege allowed. Reg. Orig. 262.

If any claim a special liberty to be impleaded within a city or borough, and not elsewhere, there may be a special writ *de libertatibus allocandis*, to permit the burghesses to use their liberties, &c. These writs are of several forms, and may be sued by a corporation, or by any single person, as the case shall happen. (New Nat. Br. 509, 510.) The barons of the Cinque Ports, &c. may sue forth such writs, if they are delayed in having their liberties allowed them.

**LIBERTATIBUS Exigendis in Iinere**, an ancient writ by which the king commands the justices in eyre to admit of an attorney for the defence of another man's liberty. Reg. Orig. 19.

**LIBERTATIS Angliæ Custodes**. See *CUSTODES*.

**LIBERTE' de la Musique**, is the title of one of the late M. D'Alembert's Essays in his "Melange de Litterature," published in 1767. After being the champion of Rameau's system, and his *basse fondamentale*, he became his opponent, and a convert to Italian music. He enters into all the reasoning of Rousseau against the French style of composition, but in a more guarded manner. Indeed, he appears never to have heard good Italian music well performed. The *Suva Paderna* of Pergolesi, executed by a troop of Italian burlesque singers, not of the first class, was his standard of perfection. He tries hard to persuade the French that their music is bad, without knowing very well in what the Italian was superior. Rousseau had resided at Venice a considerable time, and seems forcibly to have felt all the lyric beauties of Metastasio's poetry, as well as the merit of the great composers and enchanting powers of the great singers of his time. This, D'Alembert only knows by tradition. It was easy for a man of his abilities to ridicule the old French music, and praise the Italian; but he was too little acquainted with its real beauties to know why Italian dramatic vocal music was superior to all other music, and the French inferior. But it may, perhaps, be roundly asserted that the French vocal music *was, is, and probably ever will be* inferior to the Italian from bad singing, as well as from the nasal nature of their language, and the national expression founded upon it, by which the vocal organ is vitiated from infancy to age, and its tones in their expression rendered unpleasing to all ears but those of the natives.

The French, since the time of Rameau, have often had fine compositions performed in their theatres, and a well disciplined band to execute them *instrumentally*; yet, for want of good singers, the vocal part, which is the best and most interesting in an Italian opera, is the worst in the musical dramas of France. And for this there are two causes which affect the composition as well as the performance of French opera songs: the composer, be he a Gluck, a Piccini, or a Sacchini, having no great vocal talents to display, dares not give way to fancy, or aim at new passages, but, of necessity, *underwrites* the vocal part so much, that the productions of these great masters for the French stage are never in favour elsewhere with their greatest admirers. And even the simple

Simple and common passages given to the voice, are so ill sung, that they give pleasure to no ears but those which are accustomed to nothing better.

In 1707, when D'Alembert wrote in favour of *toleration* in the musical religion of France, the accompaniments to what were called songs at the opera were so busy and so loud, that he compares the effect to twenty people reading different books at the same time.

Though D'Alembert and Rousseau quarrelled about the expediency of allowing plays to be acted within the walls of Geneva; yet the mathematician in his discourse on the Liberty of Music, is but a commentator on the citizen of Geneva's "Letter concerning French Music."

On the subject of adapting Italian melody to French words, the great geometrician has not taken into his calculation all the objections to its success. In Italian poetry each verse is terminated by a double rhyme; and in the French poetry, the masculine and feminine rhymes are alternate. This must affect the melody. The mute syllables in French poetry (which are dogrel in English), can alone receive Italian melody: the masculine rhymes admit of no imitation.

M. D'Alembert, however, modestly says, that all his reflections are not worth, a single fine air in music; and adds (after Rousseau), that "inventing what succeeds is infinitely preferable to philosophical reasoning: a composer never thinks of giving precepts who is able to furnish models: Raphael produced pictures, not dissertations. In music, we (the French) write reveries; and the Italians compose and execute music." The two nations, in this respect, resemble the two architects who were candidates at Athens for the erection of a monument which the republic wished to raise to a deceased hero; one of them spoke a long while with great eloquence on his art; the other, after listening with great attention, only uttered these words: "What he says, I have done."

**LIBERTINES.** See **FRANCHISE.**

**LIBERTINES**, in *Scripture History*, the denomination of a class of Jews, or Jewish proselytes, who had a synagogue at Jerusalem, which is mentioned in the book of Acts, ch. vi. 9. Libertinus, or Libertine, denoted a person who had been a slave, but who had obtained his freedom; or one who was the son of a person that had been a slave, and was afterwards made free. Several learned men have supposed, that the libertines above-mentioned were Jews, or proselytes of the Jewish religion, who had been slaves to Roman masters, and had been made free, or the children of such. In proof of this, the learned Lardner alleges, that there was a great number of Jews at Rome; and, according to Philo, they occupied a large quarter of the city; and they were chiefly such as had been taken captive at several times, and had been carried into Italy, and were made free by their Roman masters. That these Jews were called Libertines, appears plainly from passages, which Lardner has cited from Tacitus, Josephus, and Suetonius, in which they speak of the banishment of the Jews from Rome in the reign of Tiberius. Josephus and Suetonius expressly call those Jews, whom Tacitus calls men of the Libertine race; and as there were many of them at Rome, it is not at all unlikely that they had a synagogue at Jerusalem. Such are the sentiments of Grotius and Vitringa, adopted by Lardner's Works, vol. i. p. 114.

**LIBERTINES**, *Libertini*, in *Eccl. scissal History*, a religious sect, which arose in the year 1525, whose principal tenets were, that the Deity was the sole operating cause in the mind of man, and the immediate author of all human actions: that,

consequently, the distinctions of good and evil, which had been established with regard to those actions, were false and groundless, and that men could not, properly speaking, commit sin; that religion consisted in the union of the spirit, or rational soul, with the Supreme Being; that all those who had attained this happy union, by sublime contemplation and elevation of mind, were then allowed to indulge, without exception or restraint, their appetites or passions; that all their actions and pursuits were then perfectly innocent; and that, after the death of the body, they were to be united to the Deity.

They likewise said that Jesus Christ was nothing but a mere *je ne sçai quoi*, composed of the spirit of God, and of the opinion of men.

Their maxims occasioned their being called Libertines: and the word has been used in an ill sense ever since.

The Libertini spread principally in Holland and Brabant. Their leaders were one Quintin, a Picard, Poekelius, Ruffus, and another called Chopin, who joined with Quintin, and became his disciple.

This sect obtained a certain footing in France through the favour and protection of Margaret, queen of Navarre, and sister of Francis I., and found patrons in several of the reformed churches. This sect was probably a remnant of the more ancient *Beghards*, or *Brethren of the Free Spirit*. Mosheim's *Eccl. Hist.* vol. iv.

**LIBERTINES of Geneva**, were a cabal of rakes rather than of fanatics: for they made no pretences to any religious system, but pleaded only for the liberty of leading voluptuous and immoral lives. This cabal was composed of a certain number of licentious citizens, who could not bear the severe discipline of Calvin, who punished with rigour not only dissolute manners, but also whatever bore the aspect of irreligion and impiety. In this turbulent cabal there were several persons who were not only notorious for their dissolute and scandalous manner of living, but also for their atheistical impiety and contempt of all religion. To this odious class belonged one Gruet, who denied the divinity of the Christian religion, the immortality of the soul, the difference between moral good and evil, and rejected with disdain the doctrines that are held most sacred among Christians; for which impieties he was at last brought before the civil tribunal, in the year 1550, and condemned to death. The Genevan spirit of reformation, improperly directed by the violence and zeal of Calvin, did at this time operate to a degree, which has marked the character of this great reformer with reproach. For, in 1544, Sebastian Castalia, master of the public school at Geneva, who was a man of probity, and distinguished by his learning and taste, was, nevertheless, deposed from his office and banished the city, because he disapproved some of the measures that were pursued, and some of the opinions entertained by Calvin and his colleagues, and particularly that of absolute and unconditional predestination. Jerome Bolsee, also, a man of genius and learning, who became a convert to the Protestant religion, and fled to Geneva for protection, was cast into prison, and, soon after, sent into banishment, because, in 1551, he imprudently and indecently declaimed, in full congregation, and at the close of public worship, against the doctrine of absolute decrees. Mosheim's *Eccl. Hist.* vol. iv.

**LIBERTUS**, or **LIBERTINUS**, among the Romans, a freedman, or a person set free from a legal servitude.

These still retained some mark of their ancient state; he who made a slave free having a right of patronage over the libertus; so that if the latter failed of shewing due respect to his patron, he was restored to his servitude; and if the liber-

tus died without children, his patron was his heir. See SLAVE.

In the beginning of the republic, *libertinus* denoted the son of a *libertus*, or freed-man; but afterwards, before the time of Cicero, and under the emperors, the terms *libertas* and *libertinus*, as Suetonius has remarked, were used as synonymous.

**LIBERTY**, in *Geography*, a post-town of America, in Virginia; 15 miles from New London. This is the chief town of Bedford county; it has a handsome court-house, and contains 50 or 60 houses.—Also, a county of Georgia, bounded N. by Brian, S. by Mackintosh, W. by Alamaha, and N. E. by the ocean. It is 40 miles long, and 22 broad. The productions are cotton and rice. An acre of land yields 25 or 30 bushels of corn. It derives its name from the circumstance, that its inhabitants were the first in the state who declared for liberty, and sent a delegate to the congress at Philadelphia. It is divided into five towns, and contains 5313 inhabitants, of whom 3940 are slaves.—Also, a post-town of Maryland, in Frederick county; 12 miles N. E. of Fredericktown, and about 44 miles N. N. W. of the Federal city.

**LIBERTY**, *Libertas*, is usually understood of that state wherein a man acts freely; or that power by which he determines himself voluntarily either to good or evil, to this thing or that.

This is what some have denominated a liberty of *indifference*, *natural* liberty, *philosophical* liberty, or liberty of choice; defining it to be a power of doing an action or its contrary, all the previous circumstances remaining the same. In this sense it stands opposed to *necessity*, and is distinguished from *external* liberty, or liberty of *action*, which is defined to be the power of doing what we please or will; or, in other words, the power of carrying our volitions or purposes into effect. This *external* liberty is opposed to *compulsion* from external force, as *philosophical* liberty is to *necessity*, or the definite influence of motives, in definite circumstances. Accordingly it is said, that liberty of *action* may exist independently of liberty of *choice*; that is, the mind may be wholly untrammelled in the execution of its volitions, though in the same circumstances it could not have made a different choice. Liberty of *choice* likewise, if it exists at all, is perfectly independent of liberty of *action*.

Most of the schoolmen confound liberty and the will together, and make one definition serve for both. Whereas Mr. Locke observes, that liberty does not belong to the will, but to the man or agent; and therefore, that the question, in the usual manner of stating it, whether man's will be free or not, is absurd and unintelligible. Liberty, which is but a power, belongs only to agents, and cannot be an attribute or modification of the will, which is also but a power. They distinguish liberty into a great many kinds; as liberty of *contrariety*, and liberty of *contradiction*. (See FREEDOM.) Also, *next* liberty, *proxima*, which is a full absolute freedom of doing any thing: *remote* liberty, which is a liberty that comprehends a natural power, though embarrassed with obstacles, which it is in our power to remove, and to attain to a next liberty. Some writers have divided liberty into

**LIBERTY**, *Physical*, or *Philosophical*, or liberty of *choice*, which is that principle of spontaneity or self-determination, that constitutes us agents; or that gives us a command over our actions, rendering them properly our's and not effects of the operation of any foreign cause. Without this liberty, or being under a necessity of always following some will different from his own, man would be a machine acted upon by mechanical springs, having no principle of motion in himself

or command over events: and, therefore, incapable of all merit and demerit.

Whether man is endued with this kind of liberty or self-determining power has been a subject of much controversy: it was agitated at the beginning of the last century, between Leibnitz, Collins, &c. on one side, and Clarke, Jackson, &c. on the other; and has been more lately revived by Dr. Priestley.

Cicero defines liberty the power of living after a man's own wish, without any cause or impediment to oblige him to do one thing rather than another.

F. Malebranche gives us a still more philosophical definition: the will he defines to be that impression, or natural motion, which inclines towards good in the general; and by liberty, he understands, that power which the mind has of determining this general impression towards such objects as please us; and so of directing our general inclinations to some particular things.

When it is easy to perceive, that though all natural inclinations be voluntary, yet they are not all free; not, we mean, with a liberty of indifference, which includes a power of willing, or not willing, or of willing quite the contrary to that which our natural inclinations lead us to. For though it is voluntarily and freely that we love good in general, it is absurd to suppose we should love any thing without the will, or that the will can ever be constrained; yet we do not love it freely (in the sense just laid down) because it is not in the power of the will not to desire to be happy.

It must be observed, however, that the mind, considered as determined towards good in general, cannot divert its motion to any particular good, unless the same mind, considered as capable of ideas, have some knowledge of that particular good: that is, in plainer terms, the will is a blind power, that cannot direct itself to any thing but what the understanding represents to it; so that the power which the will has to determine its impression towards general good, or its natural inclinations, variously, consists in the power it has to command the understanding to represent some particular good.

Thus, a person, for instance, represents some dignity to himself, as a good to be wished for, immediately the will desires this good; that is, the impression which the mind continually receives towards good in general, determines it to this dignity. But as that dignity is not the universal good, nor is perceived clearly and distinctly as such by the mind (for the mind cannot conceive a thing clearly which is not), the impression we have towards good in general, is not entirely exhausted by that particular good; the mind has an inclination to go farther; it does not love that dignity necessarily or invincibly, and in this respect is free.

Now its liberty consists in this, that, not being fully convinced that this good contains in it all the good it is capable of enjoying, it may suspend its judgment and its desire.

The case is nearly the same with regard to the knowledge of truth: we love this, as we do the enjoyment of good, by a natural impression; which impression is not invincible in the latter, excepting evidence be full, and our knowledge of the object complete. We have the same liberty in our false judgments, that we have in our irregular appetites. See JUDGMENT and WILL.

Mr. Locke defines liberty to be the power which a man has to do or forbear doing any particular action, according as its doing or forbearance has the actual preference in the mind, which is the same thing as to say, according as he himself wills it: and he observes, that so far as a man has power to think or not to think, to move or not to move, according

## LIBERTY.

ording to the preference or direction of his own mind, so far as a man free. The will, he acknowledges, is always determined by some, and for the most part, by the most pressing uneasiness or desire of happiness. The liberty for which he contends, and for the existence of which he appeals to experience, is a liberty of suspending our determination. The mind, he says, having in most cases, as is evident in experience, power to suspend the execution and satisfaction of any of its desires, and so all, one after another, is at liberty to consider the objects of them, examine them on all sides, and weigh them with others. In this lies the liberty a man has. He has a power to suspend the prosecution of this or that desire, as every one daily may experience in himself. This seems to be the source of all liberty. In this seems to consist, as he thinks, that which is improperly called free-will. And he adds farther, that perfect indifference in the mind, not determinable by its last judgment of the good or evil, that is thought to attend its choice, would be so far from being an advantage and excellency of an intellectual nature, that it would be as great an imperfection as the want of indifference to act or not to act; till determined by the will, would be an imperfection on the other side. *Ess. vol. i. chap. 21.*

From these concessions the advocates for necessity have pleaded the authority of Mr. Locke, though he does not seem to have been apprized of the consequences of his principles. Mr. Hobbes, who seems to have been the first who understood and maintained the proper doctrine of philosophical necessity, defines liberty to be the absence of all impediments to action, that are not contained in the nature and intrinsic quality of the agent. And Mr. Collins, the principal writer on the side of necessity, defines liberty to be a power in man to do as he wills, or pleases; though he denies, that we are at liberty to will, or not to will; or to will one or the other of two or more objects, between which, all things considered, we perceive a difference; or that we are free in our choice among things different or alike.

Dr. Clarke has remarked, that, in the above definition, there is an ambiguity in the words, "wills or pleases;" because they may either denote the last perception or judgment of the understanding, which is entirely passive; or the first exertion of the self-moving power, which is essentially active. Now, though the self-moving power is an adequate cause of action, yet understanding, or judgment, or assent, or approbation, or liking, or whatever name it is called by, can no more possibly be the efficient cause of action, than rest can be the cause of motion. Nothing can possibly be the cause of an effect more considerable than itself. Nothing that is passive can possibly be the cause of any thing that is active: an occasion indeed, it may be; and action may be consequent upon perception or judgment; it may easily be supposed to be always consequent upon it, and yet at the same time there may be no manner of physical or necessary connection between them. Besides, the word "do," in this definition of Mr. Collins, has no signification. For his meaning is not, that the man "acts" or "does" any thing; but the liberty or power in man to do as he wills or pleases, is with him exactly and only the same as the liberty or power in a balance would be to move as it wills or pleases; supposing the balance endued with such sensation or intelligence, as enabled it to perceive which way the weights turned it, and to approve the motion, so as to fancy that it moved itself, when indeed it was only moved by the weights. Mr. Collins makes the difference between a man and a clock, to consist only in sensation and intelligence, not in any power of acting: whereas the whole essence of liberty consists in the

power of acting: so that action and liberty are identical terms.

The liberty of a moral agent, according to Dr. Reid, is a power over the determinations of his own will. If, in any action, he had power to will what he did, or not to will it, in that action he is free. But if, in every voluntary action, the determination of his will be the necessary consequence of something involuntary in the state of his mind, or of something in his external circumstances, he is not free; he has not the liberty of a moral agent, but is subject to necessity. This liberty supposes the agent to have understanding and will; for the determinations of the will are the sole object about which this power is employed; and there can be no will without such a degree of understanding at least, as gives the conception of that which we will. The liberty of a moral agent implies, not only a conception of what he wills, but some degree of practical judgment or reason. For if he has not the judgment to discern one determination to be preferable to another, either in itself or for some purpose which he intends, what can be the use of a power to determine? His determinations must be made perfectly in the dark, without reason, motive, or end. They can neither be right nor wrong, wise nor foolish. Whatever the consequences may be, they cannot be imputed to the agent, who had not the capacity of foreseeing them, or of perceiving any reason for acting otherwise than he did. The author now cited restricts his attention to the liberty of moral agents, who are capable of acting well or ill, wisely or foolishly; and this liberty he calls, by way of distinction, "moral liberty." By necessity he understands the want of this moral liberty. This moral liberty a man may have, though it do not extend to all his actions, or even to all his voluntary actions. He does many things by instinct, many things by the force of habit, without any thought at all, and consequently without will. But in general this power over the determinations of his own will extends to every action for which he is accountable. This power may be impaired or lost, by disorder of body or mind, as in melancholy, or in madness; it may be impaired or lost by vicious habits; and, in particular cases, it may be restrained by divine interposition. In fact, man is a free agent in the same way as he is a reasonable agent. His reason is liable to be impaired or lost by his own fault, or by other means. It is also the case with respect to his freedom of action. The liberty above stated and explained has been represented by some philosophers as inconceivable, and as involving an absurdity. "Liberty," say Hobbes and others who have adopted his reasoning, "consists only in a power to act as we will; and it is impossible to conceive in any being a greater liberty than this. Hence it follows, that liberty does not extend to the determinations of the will, but only to the actions consequent to its determination, and depending upon the will. To say we have power to will such an action, is to say, that we may will it, if we will. This supposes the will to be determined by a prior will; and for the same reason, that will must be determined by a will prior to it, and so on in an infinite series of wills, which is absurd. To act freely, therefore, can mean nothing more than to act voluntarily; and this is all the liberty that can be conceived in man or in any being." The advocates of necessity maintain, that this is the only liberty that is possible, that is conceivable, and that does not involve an absurdity. Dr. Reid, however, mentions three other kinds of liberty, to which the term is very commonly applied: such are liberty, as opposed to external force or confinement of the body; liberty as opposed to obligation by law, or

## LIBERTY.

by lawful authority; and liberty as opposed to necessity, in which latter sense it extends to the determinations of the will only, and not to what is consequent to the will. It has been a question among philosophers, whether, in every instance, the determination of the will, which is the first part of the action in every voluntary action, and upon which alone the moral estimation of it depends, be the necessary consequence of the constitution of the person, and the circumstances in which he is placed; or whether he has not power, in many cases, to determine this way or that? This has, by some, been called the "philosophical" notion of liberty and necessity; but it is by no means peculiar to philosophers. The lowest of the vulgar have, in all ages, had recourse to this necessity for exculpating themselves or their friends when they do wrong, though, in the general tenour of their conduct, they act upon the contrary principle. Whether the notion of moral liberty, above stated, be conceivable or not, every man must judge for himself. "To me," says Dr. Reid, "there appears no difficulty in conceiving it. I consider the determination of the will as an effect. This effect must have a cause which had power to produce it; and the cause must be either the person himself, whose will it is, or some other being. The first is as easily conceived as the last. If the person was the cause of that determination of his own will, he was free in that action, and it is justly imputed to him, whether it be good or bad. But if another being was the cause of that determination, either by producing it immediately, or by means and instruments under his direction, then the determination is the act and deed of that being, and is solely imputable to him." Should it be said, that nothing is in our power but what depends upon the will; and therefore the will itself cannot be in our power; it may be replied, that this is a fallacy arising from taking a common saying in a sense which it was never intended to convey, and in a sense contrary to what it necessarily implies. To say that what depends upon the will is in a man's power, but the will is not in his power, is to say that the end is in his power, but the means necessary to that end are not in his power, which is a contradiction.

The principal arguments in favour of liberty, as it is popularly understood, and as it is defined in the beginning of this article, are the following: this principle is necessary to constitute man an *agent* (see *AGENT*); for, as far as it is true of a being that he acts, so far he must himself be the cause of the action, and, therefore, not necessarily determined to act: but if he has no absolute power over his own actions, *i. e.* if he be not a free agent, the actions which he performs cannot properly be said to be his own, but must be ascribed to some other power, by which he is led on to perform them; as a good clock or watch performs the motions assigned to it by the artist. This argument is excellently illustrated by Dr. Clarke: man, says he, either has within himself a principle of action properly speaking, *i. e.* a self-moving faculty, a principle or power of beginning motion; or he has not. If he has within himself such a principle, then he is a free, and not a necessary agent: for every necessary agent is moved necessarily by something else; and then that which moves it, not the thing itself which is moved, is the true and only cause of the action. That any other thing operating upon an agent, should efficiently and necessarily produce self-motion in that agent, is a direct contradiction in terms. If man has not within himself a principle or power of self-motion, then every motion and action of man is chiefly and properly produced by the efficiency of some extrinsic cause; which cause must be either what we usually call the motive or reason upon which a man

acts; or else it must be some insensible subtle matter, or some other being or substance making an impression upon him. If the reasons or motives upon which a man acts be the immediate and efficient cause of the action, then either abstract notions, such as all reasons and motives are, have a real subsistence, that is, are themselves substances; or else that which has itself no real subsistence can put a body into motion; either of which is manifestly absurd. If insensible subtle matter, or any other being or substance, continually making impression upon a man, be the immediate and efficient cause of his acting; then the motion of that subtle matter or substance must be caused by some other substance, and the motion of that by some other, till at last we arrive at a free agent; and then liberty is a possible thing, and man possibly may have liberty: and if he may possibly have it, then experience will prove that he probably, nay, that he certainly, has it. If we never arrive at any free cause, then there is either *in infinitum* a progression of motions without any mover, of effects without any cause, of things acting without any agent; which is a manifest contradiction: or else motion exists necessarily of itself. If motion exists necessarily of itself, it must be either with a determination every way, or one certain way; if with a determination every way, this is no motion at all; if with a determination one certain way, then that determination is either necessary, and consequently all other determinations impossible, which is contrary to experience; or else there must be a particular reason of that determination, and so backwards *in infinitum*, which comes to the forementioned absurdity, of effects existing without any cause.

Farther, liberty is the dictate of our own consciousness: we have, really, the same constant and necessary consciousness of liberty that we have, that we think, choose, will, or even exist; and whatever men may say to the contrary, it is impossible for them, in earnest, to think they have no active self-moving powers, and are not the causes of their own volitions, or not to ascribe to themselves what they must be conscious they think and do. Mr. Hume, though he denies the reality of liberty, grants that we have a feeling of it; that the divine plan required that we should be so made, as to seem to ourselves free; that the whole constitution of things is as if we were free; and that being under a necessity of approving and disapproving actions and characters, we are so far under a necessity of believing ourselves and others free. After these concessions, it can hardly be imagined that the constitution of nature should be altogether imposition and deceit.

"We have by our constitution," says Dr. Reid, "a natural conviction or belief that we act freely; a conviction so early and so universal, that it must be the result of our constitution, and the work of him that made us." And he adds, "the genuine dictate of our natural faculties is the voice of God no less than what he reveals from heaven; and to say that it is fallacious, is to impute a lie to the God of truth." Moreover, in favour of free-will an appeal has been made to "common sense," that is, to the irresistible conviction and universal consent of mankind. To this purpose it has been said, that very few have denied the existence of liberty of choice even in theory; but "this," says a necessarian writer, "is only saying that there have been very few philosophers," as if the denial of liberty of choice were a test of true philosophy. All men, it has been alleged, without excepting professed necessarians themselves, are under the necessity of acting upon the principles of liberty, whatever their hypothetical speculations may be.

All men agree in applauding some actions and condemning others,

others, which would be absurd upon the supposition that men were destitute of free will; all men make a distinction between harm and injury, e. g. between a blow given by design and another occasioned by accident; and the laws of all nations agree to punish an action performed by a man in possession of reason, when they excuse a lunatic; the former being free, and the latter not.

Besides, if man be not, in the strictest sense of the word, a free agent, he can be no moral agent: It is hard to say, what virtue and vice, commendation and blame, mean, if they do not suppose agency, voluntary motion, free choice, and an absolute dominion over our resolutions. Can we applaud or reproach ourselves for what we were no more the causes of than of our own beings, and what it was no more possible for us to prevent than the returns of the seasons, or the revolutions of the planets? On the system of necessity, conscience is an inexplicable principle: its censures or applause are equally futile and groundless: the approbation of mankind is an insult with regard to those on whom it is bestowed, because they can have no merit; and the reproach of men unjust and cruel, because there can be no demerit and ground of blame. Whatever difficulties, therefore, may attend the nature of that influence which we ascribe to motives, (see MOTIVE,) they cannot be the efficient necessitating cause of human actions: since, on this supposition, there could be but one agent in the universe; who must equally be the author of all the good and evil in the world, and on whom must ultimately be charged the sin and misery, as well as the virtue and happiness of his creatures.

Moreover, it has been urged by the advocates of liberty, that if men's determinations and actions flow necessarily from the previous state of their minds and the motives or influences resulting from a nature or condition, imposed upon them without their own consent or choice, the idea of responsibility or accountability must vanish, and there can be no propriety or use of rewards or punishments. God cannot reward without virtue, and there can be no virtue without a self-determining power: he cannot punish without guilt, and there can be no guilt when men do what they cannot avoid doing, and when their actions arise from circumstances in which their Creator placed them.

It is also equally unjust and useless to threaten punishment or inflict it on men to prevent crimes, when they are necessarily determined in all their actions. And if men are necessary agents, though we cannot well admit this verbal contradiction, it can be of no use to reason with them, to admonish or treat them; and God must be insincere in his addresses and invitations, and cruel in his requirements and commands. But such is the whole tenour of revelation, and, therefore, the conclusion is necessary, that man is a free agent, capable of good or evil, and of determining his pursuit of either, from the sole power of his own judgment or will.

"If we adopt the system of necessity," says Dr. Reid, "the terms *moral obligation* and *accountableness*, *praise* and *blame*, *merit* and *demerit*, *justice* and *injustice*, *reward* and *punishment*, *wisdom* and *folly*, *virtue* and *vice*, ought to be disused, or to have new meanings given to them when they are used in religion, in morals, or in civil government; for upon that system, there can be no such things as they have been always used to signify." Another argument for proving that man has power over his own actions and volitions has been deduced from the consideration that he is capable of carrying on wisely and prudently, a system of conduct, which he has before conceived in his mind, and resolved to prosecute. If all the particular determinations, which concurred

in the execution of the plan which such a person had formed, were produced, not by himself, but by some cause acting necessarily upon him, then there is no evidence left that he contrived this plan, or that he ever spent a thought about it. The cause that directed all these determinations so wisely, must be wise and intelligent. If it be said, that this whole course of determinations was produced by motives, motives surely have not understanding to conceive a plan, and intend its execution. We must therefore revert to some intelligent being, who had the power of arranging these motives, and applying them, in their proper order and season, so as to bring about the end. If man, then, had no concern in the execution, we have no evidence left, that he had any concern in the contrivance, or even that he is a thinking being. Man, with all his boasted faculties, is reduced to the state of a mere automaton or machine. Whereas, if wise conduct in a man demonstrates that he has some degree of wisdom, it demonstrates, with equal force and evidence, that he has some degree of power over his own determinations. We shall close this article with observing, that Mr. Abraham Tucker, the acute author of a work entitled "The Light of Nature pursued," by Edward Search, esq. after having argued strenuously against the existence of a liberty of indifference, contends for the existence of free-will, the exercise of which he conceives "to be only a particular species of action, performed in raising up ideas, or fixing them on the mind, which shall determine us to such volitions as we want." He expressly disavows the doctrine of necessity. See on this subject Collins's Enquiry concerning Human Liberty, first printed in 1717. Clarke's Remarks, 1717, and Collection of Papers which passed between Mr. Leibnitz and Dr. Clarke, in 1715 and 1716. Jackson's Vindication and Defence of Human Liberty, 1730. For the objections against liberty, and the arguments in support of necessity, see NECESSITY.

**LIBERTY of conscience**, a right or power of making profession of any religion, or of serving God in any manner that a man sees fit.

This seems to be a natural right; it is vigorously opposed by the generality of the Romanists, and even by many of the reformed, though it seems as if the reformation could scarcely subsist without it. See TOLERATION and PERSECUTION.

**LIBERTY, Moral**, is the power of following, in all circumstances, our sense of right and wrong; or of acting in conformity to our reflecting and moral principles, without being controlled by any contrary principles or habits. See LIBERTY, *supra*.

**LIBERTY, Religious**, is the same with liberty of conscience, and signifies the power of exercising, without molestation, that mode of religion which we think best; or of making the decisions of our own consciences, respecting religious truths, the rule of our conduct, and not any of the decisions of others.

**LIBERTY, Civil**, is the power of a civil society or state, to govern itself by its own discretion: or by laws of its own making, without being subject to any foreign discretion, or to the impositions of any extraneous will or power. Civil liberty, says judge Blackstone, adopting the definition of the Institutes, consists in the power of doing whatever the laws permit; or it is natural liberty, or a power of acting as one thinks fit, without any restraint or controul, unless by the

## LIBERTY.

Law of nature, so far restrained by human laws, and no farther, as is necessary and expedient for the general advantage of the public. Others have defined civil liberty, in contradistinction from political liberty, to be that power over their own actions, which the members of the state reserve to themselves, and which their officers must not infringe. This extends no farther than to a man's own conduct, and signifies the right he has to be exempt from the controul of the society or its agents, that is, the power he has of providing for his own advantage and happiness. It is a man's civil liberty, which is originally in its full force, and part of which he sacrifices when he enters into a state of society.

*Civil liberty*, according to the definition of archdeacon Paley, "is the not being restrained by any law, but what conduces in a greater degree to the public welfare." To do what we will, he says, is natural liberty; to do what we will, consistently with the interest of the community to which we belong, is civil liberty; that is, the only liberty to be desired in a state of civil society. The definition above laid down imports that the laws of a free people impose no restraints upon the private will of the subject, which do not conduce in a greater degree to the public happiness; by which it is intimated, 1st, that restraint itself is an evil; 2dly, that this evil ought to be overbalanced by some public advantage; 3dly, that the proof of this advantage lies upon the legislature; 4thly, that a law, being found to produce no sensible good effects, is a sufficient reason for repealing it, as adverse and injurious to the rights of a free citizen, without demanding specific evidence of its bad effects. This maxim, our author adds, might be remembered with advantage in a revision of many laws of this country; especially of the game laws; of the poor laws, so far as they lay restrictions upon the poor themselves; of the laws against papists and dissenters; and amongst a people enamoured to excess, and jealous of their liberty, it seems a matter of surprize that this principle has been so imperfectly attended to. The degree of actual liberty always bearing, according to this account of it, a reversed proportion to the number and severity of the restrictions, which are either useless, or the utility of which does not outweigh the evil of the restraint, it follows, among other conclusions of a more general nature, that we may hence be enabled to apprehend the distinction between *personal* and *civil* liberty. A citizen of the free republic in the world may be imprisoned for his crimes; and though his personal freedom be restrained by bolts and fetters, so long as his confinement is the effect of a beneficial public law, his civil liberty is not invaded. Another idea of civil liberty places it in security; making it to consist not merely in an actual exemption from the constraint of useless and noxious laws and acts of dominion, but in being free from the danger of having any such hereafter imposed or exercised. The definitions which have been framed of civil liberty are most of them adapted to this idea. Thus one political writer makes the very essence of the subject's liberty to consist in his being governed by no laws but those to which he hath actually consented; another is satisfied with an indirect and virtual consent; another again places civil liberty in the separation of the legislative and executive offices of government; another in the being governed by law, that is, by known, preconstituted, inflexible rules of action and adjudication; a fifth in the exclusive right of the people to tax themselves by their own representatives; a sixth in the freedom and purity of elections of representatives; a seventh in the controul which the democratic part of the constitution possesses over the military establishment. Of these and similar accounts of liberty, it may be observed, that they all labour under one inaccuracy, *viz.* that they describe not fo

much liberty itself, as the safeguards and preservatives of liberty; e. g. a man's being governed by no laws but those to which he has given his consent, were it practicable, is no otherwise necessary to the enjoyment of civil liberty, than as it affords a probable security against the dictation of laws, imposing superfluous restrictions upon his private will. The same remark is applicable to the rest. We may farther observe, that in most of these definitions civil liberty and political liberty are confounded. Upon the whole we may remark, that whatever definitions of either kind of liberty we adopt, that people, government, and constitution is the *freest*, which makes the best provision for the enacting of expedient and salutary laws.

*LIBERTY, Political*, sometimes used, but improperly, as synonymous with civil liberty, in a distinct sense, consists in the share which the members of the state possess in the direction of its affairs, and the power which they reserve to themselves of arriving at the public offices, or, at least, of having votes in the nomination of those who fill them: and this is that which a man may or may not acquire in the compensation he receives for it. In a state of civil liberty, a man retains the most important of his natural rights: in a state of political liberty, he moreover acquires a controul over the conduct of others. It is, therefore, for his advantage to lose as little of the former, and to gain as much of the latter as he can. In countries where every member of the society enjoys an equal power of arriving at the supreme offices, and consequently of directing the strength and the sentiments of the whole community, there is a state of the most perfect political liberty. On the other hand, in countries where a man is, by his birth or fortune, excluded from these offices, or from a power of voting for proper persons to fill them; that man, whatever be the form of the government, or whatever civil liberty or power over his own actions he may have, has no power over those of another; he has no share in the government, and therefore has no political liberty at all. Nay, his own conduct, as far as the society does interfere, is, in all cases, directed by others.

Political liberty is the only safe-guard of civil liberty; and it is chiefly valuable on that account. Civil liberty stands first in the order of things, and political liberty the second. The former is the end, and the latter the means of preserving it. Every man has an absolute and unalienable right to civil liberty; and for the security of it, political liberty should be extended as widely as possible. No man should be excluded from the exercise of it, excepting from circumstances of unavoidable necessity. It may appear, at first sight, to be of little consequence whether persons in the common ranks of life enjoy any share of political liberty or not. But without this, there cannot be that persuasion of security and independence, which alone can encourage a man to make great exertions. A man who is sensible that he is at the disposal of others, over whose conduct he has no sort of controul, has always some unknown evil to dread. He will be afraid of attracting the notice of his superiors, and must feel himself a mean and degraded being. But a sense of liberty, and a knowledge of the laws by which his conduct must be governed, with some degree of controul over those who make and administer the laws, give him a constant feeling of his own importance, and lead him to indulge a free and manly turn of thinking, which will make him greatly superior to what he would have been under an arbitrary form of government. The distinction here made between *civil* and *political* liberty was, we believe, first laid down by Dr. Priestley in his "Treatise on Government."

Mr. Christian, in his edition of Blackstone's Commentary; has

has suggested the difference between civil and political liberty, unnoticed by the learned judge and by other eminent writers. He defines *political liberty* to be the security with which, from the constitution, form, and nature of the established government, the subjects enjoy *civil liberty*.

The importance of liberty, civil and political, as well as religious, to the honour and prosperity of a nation, is sufficiently evinced by both ancient and modern history. It has been observed by the ancients, that all the arts and sciences arose among free nations; and that the Persians and Egyptians, notwithstanding their ease, opulence, and luxury, made but faint efforts towards a relish in those finer pleasures, which were carried towards such perfection by the Greeks, amidst continual wars, attended with poverty, and the greatest simplicity of life and manners. Greece, says Mr. Hume, was a cluster of little principalities, which soon became republics; and being united both by their vicinity, and by the ties of the same language and interest, they entered into the closest intercourse of commerce and learning. There concurred a happy climate, a soil not infertile, and a most harmonious and comprehensive language; so that every circumstance among these people seemed to favour the rise of the arts and sciences. Each city produced its several artists and philosophers, who refused to yield the preference to those of the neighbouring republics. Their contention and debates sharpened the wits of men: a variety of objects was presented to the judgment, while each challenged the preference to the rest; and the sciences, not being dwarfed by the restraint of authority, were enabled to make such considerable shoots, as are, even at this time, the objects of our admiration. Hence, and from other circumstances detailed by Mr. Hume, he concludes, that it is impossible for the arts and sciences to arise, at first, among any people, unless these people enjoy the blessing of a free government. It has been further observed, that when the Greeks lost their liberty, though they increased mightily in riches, by means of the conquests of Alexander; yet the arts, from that moment, declined among them, and have never since been able to raise their head in that climate. Learning was transplanted to Rome, the only free nation at that time in the universe; and having met with so favourable a soil, it made prodigious shoots for above a century; till the decay of liberty produced also the decay of letters, and spread a total barbarism over the world. From these two experiments, of which each was double in its kind, and shewed the fall of learning in absolute governments, as well as its rise in popular ones, Longinus thought himself sufficiently justified in asserting, that the arts and sciences could never flourish, but in a free government; and in this opinion he has been followed by several eminent writers in our own country, particularly Mr. Addison and lord Shaftesbury, who either confined their views merely to ancient facts, or entertained, says Mr. Hume, too great a partiality in favour of that form of government established among us. This writer has alleged, as instances which serve to restrain the extent of the opinion maintained by the celebrated authors above cited, those of modern Rome and of Florence. The former carried to perfection all the finer arts of sculpture, painting, and music, as well as poetry, though it groaned under tyranny, and under the tyranny of priests: while the latter made its chief progress in the arts and sciences, after it began to lose its liberty by the usurpation of the family of Medici. Ariosto, Tasso, Galileo, any more than Raphael and Michael Angelo, were not born in republics. And though the Lombard school was famous, as well as the Roman, yet the Venetians have had the smallest share in its honours, and seem rather inferior to the other Italians in

their genius for the arts and sciences. Rubens established his school at Antwerp, not at Amsterdam. Dresden, not Hamburg, is the centre of potencies in Germany. France has, at a former period, to say nothing now of its present condition, furnished an eminent instance of the flourishing of learning in absolute governments. Although it had scarcely ever enjoyed any established liberty, it has nevertheless carried the arts and sciences as near perfection as any other nation. The English are perhaps greater philosophers, the Italians better painters and musicians, the Romans were greater orators; but the French, says Mr. Hume, are the only people, except the Greeks, who have been at once philosophers, poets, orators, historians, painters, architects, sculptors, and musicians. With regard to the stage, they have excelled the Greeks, who far excelled the English. And in common life, continues the same author, they have, in a great measure, perfected that art, the most useful and agreeable of any, "l'art de vivre," the art of society and conversation. He adds, if we consider the state of the sciences and polite arts in our own country, Horace's observation, with regard to the Romans, may, in a great measure, be applied to the British.

"—— Sed in longum tamen ævum  
Manferunt, hodieque manent vestigia ruris."

It has become an established opinion, that commerce can never flourish but in a free government; and this opinion seems to be founded on a longer and larger experience than the foregoing, with regard to the arts and sciences. If we trace commerce in its progress through Tyre, Athens, Syracuse, Carthage, Venice, Florence, Genoa, Antwerp, Holland, England, &c., we shall always find it to have fixed its seat in free governments. The three greatest trading towns in Europe now, says Mr. Hume at the time when he wrote, are London, Amsterdam, and Hamburg; all free cities, and protestant cities; that is, enjoying a double liberty. Hume's Essays, vol. i. Ess. xiii. and xiv. See *LIBERAL ARTS* and *COMMERCE*.

*LIBERTY, Personal*, consists in the power of locomotion, or of changing situation, or removing one's person to whatsoever place one's own inclination may direct, without imprisonment or restraint, unless by due course of law. See *HABEAS CORPUS*, *IMPRISONMENT*, and *FALSE IMPRISONMENT*.

*LIBERTY of the Press*. See *LIBERTY of the Press*.

*LIBERTY of the Tongue*, in the *Manège*, is a void space left in the middle of a bit, to give place to the tongue of a horse, made by the bit's arching in the middle, and rising towards the roof of the mouth. The bit, according to the various forms of the liberty, acquires different names; hence we say a *snatch-mouth*, a *Pignatelli*, i. e. with the liberty after Pignatelli's fashion, and a *canon-mouth*, with the liberty like a pigeon's neck.

In forging the bit, care must be taken not to make the liberty too high, lest it hurt, or at least tickle the palate, and make the horse carry low. See *BITS*.

*LIBERTY*, in *Mythology*, was a goddess both among the Greeks and Romans. Among the former she was invoked under the title *Eleutheria*; and by the latter she was called *Libertas*, and held in singular veneration; temples, altars, and statues, were erected in honour of this deity. A very magnificent temple was consecrated to her on mount Aventine, by Tiberius Gracchus, before which was a spacious court, called *atrium libertatis*. The Romans also erected a new temple in honour of Liberty, when Julius Cæsar established his empire over them, as if their liberty had been secured by an event which proved fatal to it. In a medal of Brutus, Liberty is exhibited under the figure of a woman, holding in

one had a cap, the symbol of liberty, and two poniards in the other, with the inscription *IDIVS MARTIS*.

**LIBETEN**, in *Geography*, a town of Hungary; 54 miles E.N.E. of Leopoldstadt. N. lat. 48° 47'. E. long. 19° 37'.

**LIBETHRA**, in *Ancient Geography*, a town of Greece, placed by Pausanias on mount Olympus, on the side of Macedonia. M. d'Anville places it upon the river Sus, at a small distance from Hecraclum, which lay to the east, upon the sea-coast. This is said to have been the town where Orpheus was born, and whence his monument was transferred to Dion by the Macedonians, when Libethra was destroyed by an inundation of the river Sus.

**LIBETHRIDES**, in *Mythology*, a surname given to certain nymphs which were supposed to inhabit near mount Libethra in Bœotia, which was distant about 40 stadia from Coronea; and the Libethridian fountain, in Theffaly, led the poets to call the Muses by this name. Virgil, *Ecolg* vii. v. 21.

**LIBICI**, in *Ancient Geography*, a people of Italy, who were planted eastward of the Salassi, in a district now called the lordship of Verceelli. Verceelle, or Vercelli, the capital, stood on the right bank of the Seslino, near Sefia, between Turin and Milan. Istimulum, above Vercelez, was situated at the foot of the Alps, near some gold mines. In that retired corner, there was a grove containing a temple sacred to Apollo.

**LIBILITZ**, in *Geography*, a town of Sweden, in the government of Kuopio; 55 miles E.S.E. of Kuopio.

**LIBISCHAU**, a town of Bohemia, in the circle of Chrudim; 13 miles N. of Chrudim.

**LIBITINA**, in the *Roman Mythology*, a goddess which presided over funerals. This goddess was the same with the Venus infera or Epithymbia of the Greeks. She had a temple at Rome, where was lodged a certain piece of money for every person who died, whose name was recorded in a register called *Libitinæ ratio*. This practice was established by Servius Tullius, in order to obtain an account of the number of annual deaths in the city of Rome, and consequently the rate of increase or decrease of its inhabitants.

**LIBITUM**, in *Music*. Sometimes, in the course of a composition, the Latin words *ad libitum* occur, which signify, at the pleasure of the principal performer, who is at liberty to do what he pleases, in order to manifest his fancy, taste, and execution; and to return to the text of the composer whenever he pleases: as to the rest of the band who accompany him, they are to remain inactive, and await his return to the written melody. The difference between *cadenzas*, and *ad libitum* is, that a *cadence*, or *close*, is terminated by a shake, whereas an *ad libitum* may be allowed to the performer by the composer, at any part of the piece he pleases. These Latin words are likewise joined to some instrument of accompaniment, in the title page of a work; as at the beginning of a piece, to say that such an instrument is *non obligato*, or not absolutely necessary; as in a symphony, when the *corni*, or French horns, may be dispensed with; and in a composition for a pianoforte, when the violin has no solo parts or passages, that will be missed, notice is then given by the words *corni ad libitum*, or "with a violin accompaniment *ad libitum*."

**LIBLE**, in *Geography*, a town of Bohemia, in the circle of Koniggratz; 13 miles E.S.E. of Koniggratz.

**LIBOBO**, a small island in the East Indian sea; on the S.E. coast of Gilolo. S. lat. 10° 43'. E. long. 123° 25'.

**LIBOCH**, a town of Bohemia, in the circle of Leitmeritz; 14 miles S.E. of Leitmeritz.

**LIBONA**, in *Ancient Geography*, a town of Spain, in Celiiberia. Ptolemy.

**LIBONATI**, in *Geography*, a town of Naples, in Principato Citra; four miles E.N.E. of Policeastro.

**LIBONGO**, a town of Africa, in the kingdom of Lo-cango, on the Lusana, near the sea; 50 miles S.S.W. of Bombi.

**LIBONOTUS**, in *Physiology*, one of the twelve winds of the ancients. See *WIND*.

**LIBORA**, in *Ancient Geography*, a town of Spain, in the Tarragonensis, in the country of the Carpetanians; situated on the Tagus, N.E. of Angutobriga, and almost bordering on Lusitania.

**LIBOURNE**, in *Geography*, a town of France, in the department of the Gironde, and principal place of a district. The place contains 8076, and the canton 17,376 inhabitants, on a territory of 117½ kilometres, in nine communes. N. lat. 44° 55'. W. long. 0° 9'.

**LIBRA**, BALANCE, one of the mechanical powers. See *BALANCE*.

**LIBRA** is one of the twelve signs of the zodiac; exactly opposite to Aries; so called because when the sun is in this sign, at the autumnal equinox, the days and nights are equal, as if weighed in a balance.

The stars in this constellation, according to Ptolemy, are seventeen; Tycho ten; Hevelius twenty; and Flamsteed fifty-one. See *CONSTELLATION*.

**LIBRA** also denotes the ancient Roman pound, borrowed, as some have said, from the Sicilians, who called it *libra*, λιβρα.

Mr. Pinkerton (*Essay on Medals*, vol. i. § 7.), though he allows that the Greek pound in Sicily was called λιβρα, as it was in Greece, and divided into 12 ογραμια, or ounces, and that the Roman word libra is derived from the Greek λιβρα, will not admit the as or libra, a coin, to have been deduced from a Sicilian medal. The Sicilians had a coin called λιβρα, but it was of silver, and equal to the obolus of the Egeian standard, ten of which constituted the Sicilian τετραλιβρον. The Syracusans, it is well known, were the chief people of Sicily, and they were a colony from Corinth. Gronovius takes pains to prove, that the standard of Egina was used at Corinth, and of course in Syracuse; but all the Corinthian coins now remaining are upon the Attic model, which circumstance at once confutes all his arguments; and it appears from Aristotle, as quoted by Pollux, that the Sicilians had a money talent, or standard, of their own. The λιβρα, or Sicilian silver obolus, contained also, like the Roman primitive as, 12 ογραμια, or chalcis, so called at first because they weighed an ounce, but afterwards because twelve of them went to the silver λιβρα, as twelve ounces to the pound. It is of the Sicilian λιβρα, or libella, says Mr. Pinkerton, that Varro speaks, when he says it was of silver; and not of the Roman libella, or as, which we may safely suppose was never struck in that metal. For after the Punic wars, of which Sicily was the grand scene, the Sicilian coins must have been frequent at Rome, and the Roman in Sicily. But the Greeks, or Phœnicians, of which nations the chief towns of Sicily were colonies, never knew such coins as the as libralis, or any of its parts; and it is well known that the ancient colonies commonly followed the plan of their parent countries. And though it must be granted, that the Sicilians had their own standard, it yet bore a resemblance of the Greek; their λιβρα being equal to the Egeian obolus, and their τετραλιβρα the drachma of Egina; and it is not to be supposed that when the Greek of brass coinage was always of the most minute form, they should coin pieces of that metal weighing

weighing a pound. Mr. Pinkerton cannot agree in opinion with those, who strenuously maintain, that the Roman silver denarius owes its origin to the Sicilian *Δεκαλίτρον*. The *Δεκαλίτρον*, containing 10 *λίτρα*, or Eginia oboli, would weigh about 180 grains, whereas the Roman denarii do not amount to above 60, or a third part. There seems, therefore, to be no connection between the two. Upon the whole Mr. Pinkerton is convinced, that the Romans did not derive one idea of their coinage from Sicily; but that the Sicilians had their *λίτρα*, divided into 12 *ουγκια*, from the Etruscans; though, according to the more elegant Greek plan, they made the first a small coin in silver, and never struck any brass coin larger than the *ουγκια*, or piece of an ounce weight; if, indeed, the Sicilians had not this idea of 12 *ουγκια* to the *λίτρα* from the Romans themselves, which is much more probable, than that the Romans had it from Sicily. It is a further and stronger argument against the opinion of the Roman coinage being copied from the Sicilian, that, though we have innumerable Sicilian coins in every cabinet, yet not one of them resembles the Roman *As libralis*, or its early divisions, in the very smallest degree. This argument Mr. Pinkerton deems to be conclusive. Besides, in most cabinets there are Etruscan coins upon the exact scale of the *As libralis*, and of its several parts; whence it follows of course, that these, and these alone, must have afforded a pattern to the primitive Roman coinage. The Etruscans, to whom the most ancient brass coins found in Italy are known to belong, are more a colony from Lydia, a country to which Herodotus ascribes the first invention of coinage. See COINAGE.

The libra was divided into twelve uncies, or ounces, and the ounce into twenty-four scruples.

The divisions of the libra were the *uncia*, one-twelfth; the *sextans*, one-sixth; the *quadrans*, one-fourth; the *triens*, one-third; the *quincunx*, five ounces; the *semis*, six; the *septunx*, seven; the *bes*, eight; the *addrans*, nine; the *destans*, ten; *deunx*, eleven; lastly, the *as* weighed twelve ounces, or one libra.

Learned writers are not agreed as to the true weight of the Roman pound. Villalpandus and Greaves, relying on the coins of Vespasian for its standard weight, have from hence attempted to determine this intricate question. This Roman congius contained ten pounds weight of wine; Villalpandus found by filling it to the narrow part of the neck, with spring water, that it contained just ten modern Roman pounds, which are equal to 52560 Troy grains. Azout filled it to the same height, and, having weighed its contents twice, found a result very nearly agreeing with Greaves's measure, stated by Millet, in Phil Trans. vol. li. p. 790. His greater weight was 63024 Paris grains, equal to 51699½ Troy; his lesser, 62760 Paris grains, equal to 51482½ Troy. The mean between both is 51501½ Troy grains, which, divided by 10, give 5159½ such grains for the weight of the ancient Roman pound. Several objections have been made to this pound derived from the congius, which Mr. Raper, *ubi infra*, has collected into one view; from which he infers, that it is more probable, that this standard should give too great a Roman pound, than too small a one. But as the result from hence must be uncertain, he has recourse to the coins. Having weighed nine gold pieces in the Pembroke collection, containing 34½ Roman scruples, he found their weight to amount to 608 Troy grains, which divided by 34½, give 17½ for the scruple, whence the Roman pound should weigh 5075½ grains. From some other coins of the same kind, a scruple appears to be 17½ grains. Instead of this scrupular standard, an-

other was introduced by Sylla; and from the heaviest of four pieces of this standard, allowing thirty of them to have been coined out of the Roman pound, its weight is found to be 5040 grains. The standard of forty in the pound, mentioned by Pliny, succeeded this of Sylla, and continued to the establishment of the monarchy under Augustus; and from ten different coins of this standard, he deduces a mean aureus of 126  $\frac{1}{7}$  grains; and supposing the aureus of forty in the pound to weigh 126 Troy grains, the Roman pound must weigh 5040. In Pliny's time forty-five aurei were struck out of the pound; and the mean aureus from Nero to Titus, in whose reign Pliny died, was under 112 grains; and if the standard weight of the imperial aureus of forty-five in the pound did not exceed 112 grains, the Roman pound will weigh 5040 grains, as it is found from the consular aureus. Soon after the reign of Alexander Severus, in whose time the aureus came to be called solidus, the coinage became very irregular, till Constantine entirely modelled it anew, by coining seventy-two solidi of four scruples out of the pound of gold. From twenty-nine of these solidi in the interval from Constantine to Heraclius, it appears that the mean weight is 69 grains, which, multiplied by 72, gives but 4968 grains for the Roman pound. But if the standard weight of this coin amounted to 70 grains, the pound will weigh 5040, as before. If we take 5040 Troy grains for the weight of the Roman pound, the scruple will weigh 17½ grains; the consular aureus 126; the imperial aureus 112, and the solidus 70; and the consular denarius of 84 in the pound will weigh just 60 Troy grains. (Phil. Trans. vol. lxi. part ii. p. 462, &c.) The common Roman pound, still used at Rome, consisted of 12 ounces, of 458 grains each, equal to one ounce avoirdupois; but the money ounce seems to have had only 420 Troy grains in the pound 5040. See farther on this subject the articles DENARIUS and MILLARENIS.

The Roman libra was used in France for the proportions of their coin till the time of Charlemagne, or perhaps till that of Philip I. in 1093, their sols being so proportioned, as that twenty of them are equal to the libra.

By degrees, it became a term of account; and every thing of the value of twenty sols, was called a *livre*.

*LIBRA Pensit*, in our *Law Books*, denotes a pound of money in weight.

It was usual, in former days, not only to tell the money, but to weigh it; because many cities, lords, and bishops, having their mints, coined money, and often very bad too; for which reason, though the pound consisted of twenty shillings, they always weighed it.

*LIBRARI*, among the ancients, were a sort of copyists, who transcribed in beautiful, or at least legible, characters, what had been written by the notarii in notes and abbreviations.

*LIBRARY*, an edifice or apartment destined for the placing of books; or the collection of books themselves lodged therein. See Book.

Some authors refer the origin of libraries to the Hebrews; and observe, that the care these took for the preservation of their sacred books, and the memory of what concerned the actions of their ancestors, became an example to other nations, particularly to the Egyptians. Osmandus, king of Egypt, is said to have taken the hint first; who, according to Diodorus, had a library built in his palace, with this inscription over the door, ΨΥΧΗ ΙΑΤΡΕΙΟΝ. Nor were the Ptolemies, who reigned in the same country, less curious and magnificent in books.

The scripture also speaks of a library of the kings of Persia, Ezra, v. 17. vi. 1. which some imagine to have consisted of the historians of that nation, and of memoirs of the affairs of state; but in effect it appears rather to have been a depository of laws, charters, and ordinances, of the kings. The Hebrew text calls it the *house of treasures*, and afterwards the *house of the rolls*, where the treasures were laid up. We may, with more justice, call that a library, mentioned in the second of Eldras to have been built by Nehemiah, and in which were preserved the books of the prophets and of David, and the letters of their kings.

The first who erected a library at Athens, was the tyrant Pisistratus; and yet Strabo refers the honour of it to Aristotle. That of Pisistratus was transported by Xerxes into Persia, and was afterwards brought back by Seleucus Nicator to Athens. Long after, it was plundered by Sylla, and re-established by Hadrian. Plutarch says, that under Eumenes there was a library at Pergamus, containing two hundred thousand books. Tyrannion, a celebrated grammarian, contemporary with Pompey, had a library of three thousand volumes. That of Ptolemy Philadelphus, according to A. Gellius, contained seven hundred thousand, all in rolls, burnt by Cæsar's soldiers. See ALEXANDRIAN.

Constantine, and his successors, erected a magnificent one at Constantinople; which, in the eighth century, contained three hundred thousand volumes, all burnt by order of Leo Isaurus: and, among the rest, one in which the Iliad and Odyssey were written in letters of gold, on the guts of a serpent.

The most celebrated libraries of ancient Rome, were the Ulpian, and the Palatine. They also boast much of the libraries of Paulus Æmilius, who conquered Perseus; of Lucilius Lucullus, of Æmilius Pollio, Atticus, Julius Severus, Domitius, Serenus, Pamphilus Martyr, and the emperors Gordian and Trajan.

Anciently, every large church had its library; as appears by the writings of St. Jerom, Anastasius, and others. Pope Nicholas laid the first foundation of that of the Vatican, in 1450. It was destroyed by the confiable Bourbon in the sacking of Rome, and restored by pope Sixtus V. and has been considerably enriched with the ruins of that of Heidelberg, plundered by count Tilly in 1622. One of the most complete libraries in Europe, was said to be that erected at Florence by Cosmo de Medicis; over the gate whereof is written, *LABOR ÆSQUE LAORE*: though it has been since exceeded by that of the late French king; begun by Francis I., augmented by cardinal Richelieu, and completed by M. Colbert.

The emperor's library at Vienna, according to Lambecius, consists of eighty thousand volumes, and fifteen thousand nine hundred and forty curious medals.

The Bodleian library at Oxford, built on the foundation of that of duke Humphry, exceeds that of any university in Europe, and even those of all the sovereigns of Europe, except the emperor's, and late French king's, which are each of them older by a hundred years. It was first opened in 1602, and has since found a great number of benefactors; particularly Sir Robert Cotton, Sir H. Savil, archbishop Laud, Sir Kenelm Digby, Mr. Allen, Dr. Pococke, Mr. Selden, and others. The Vatican, the Medicean, that of Bessarion at Venice, and those just mentioned, exceed the Bodleian in Greek manuscripts; which yet outdoes them all in Oriental manuscripts.

As to printed books, the Ambrosian at Milan, and that of Wolfenbuttle, are two of the most famous, and yet both inferior to the Bodleian.

LIBRARY, *King's*, at St. James's, was founded by Henry, eldest son of James I. and made up partly of books, and partly of manuscripts, with many other curiosities, for the advancement of learning. It has received many additions from the libraries of Isaac Casaubon, and others.

LIBRARY, *Cottonian*. originally consisted of nine hundred and fifty-eight volumes of original charters, grants, instruments, letters of sovereign princes, transactions between this and other kingdoms and states, genealogies, histories, registers of monasteries, remains of Saxon laws, the book of Genesis, thought to be the most ancient Greek copy extant, and said to have been written by Origen in the second century, and the curious Alexandrian copy or manuscript, in Greek capitals. (See ALEXANDRIAN.) This library is kept in the British Museum, with the large and valuable library of Sir Hans Sloane, amounting to upwards of forty-two thousand volumes, &c. There are many public libraries belonging to the several colleges at Oxford and Cambridge, and the universities in North Britain. The principal public libraries in London, beside that of the Museum, are those of the College of Heralds, of the College of Physicians, of Doctor's Commons, to which every bishop, at the time of his consecration, gives at least 20*l.* sometimes 50*l.* for the purchase of books; those of the Gray's Inn, Lincoln's Inn, Inner Temple, and Middle Temple; that of Lambeth, founded by archbishop Bancroft in 1610, for the use of succeeding archbishops of Canterbury, and increased by the benefactions of archbishops Abbot, Sheldon, Tenison, and Secker, and said to consist of, at least, fifteen thousand printed books, and six hundred and seventeen volumes in manuscript; that of Red-Cross Street, founded by Dr. Daniel Williams, a presbyterian divine, and since enriched by many private benefactions, and by an annual fund appropriated to its increase; that of the Royal Society, called the Arundelian or Norfolk library, because the principal part of the collection formerly belonged to the family of Arundel, and was given to the society by Henry Howard, afterwards duke of Norfolk; in 1666, which library has been increased by the valuable collection of Francis Aiton, esq. in 1715, and is continually increasing by the numerous benefactions of the works of its learned members, and others; that of St. Paul's, of Stion College, the queen's library, erected by queen Caroline, in 1737; and the surgeon's library, kept in their hall in Lincoln's Inn Fields; the Westminster library, the library of the Royal Institution, incorporated in 1800; the library of the London Institution, established in 1805; those of the Surry Institution and Ruffell Institution, &c. &c.

Where a library is erected in any parish, it shall be preserved for the uses directed by the founder; and incumbents and ministers of parishes, &c. are to give security for it, and make catalogues of the books, &c. None of the books shall be alienable, without consent of the bishop, and then only when there is a duplicate of such books. If any book shall be taken away and detained, a justice's warrant may be issued to search for, and restore the same: also, action of trover may be brought in the name of the proper ordinary, &c. And bishops have power to make rules and orders concerning libraries, appoint persons to view their condition, and enquire of the state of them in their visitations. (Stat. 7 Anne, cap. 14.) Bray's Institution for parochial libraries is under the direction and management of a number of associates, a treasurer and secretary. See the biographical article THOMAS BRAY.

LIBRARY, *Musical*. Dr. Burney complains, in the second vol. of his General History of Music, p. 444, that in his

his travels through France, Italy, Germany, Holland, and the Netherlands, in search of materials for his work, he was able to find no complete musical library. "Something like a chain or series of musical theorists (he says) may perhaps be found at Vienna, where the emperor Leopold I. began to form a musical library; and the elector of Bavaria another at Munich in the seventeenth century. But both have been long neglected, and are now in a very confused and imperfect state. Nor is a complete series of musical compositions by the best masters, from the earliest period of counterpoint to the present time, to be found in any public or private library in Europe, to which I have ever had access. Indeed the collectors of books for royal, collegiate, or public libraries, seem never to have had an idea of forming any regular plan for making such a collection; and though many individuals have been possessed of a rage for accumulating musical curiosities, it has seldom happened that they have extended their ideas to musical productions in general; so that no more than one class or species of composition has been completed by them, and even this, at the death of the proprietor, is usually dispersed.

"In a library, formed upon so large a scale as that of the king of France at Paris, the Bodleian, and Museum in England, it seems as if music should be put on a level with other arts and sciences, in which every book of character is procured. In a royal or ample collection of pictures, specimens at least of every great painter are purchased, and no private library is thought complete while the writings of a single poet of eminence are wanting."

As the author, in a note upon this passage has given a sketch of such a musical library as he thinks wanting, and which has been inserted in the *Ecyelopédie Methodique*, we shall give it a place here, in his own words.

In forming such a musical library as would assist the student, gratify the curious, inform the historian, and afford a comparative view of the state of the art at every period of its existence, it were to be wished that the books, when collected, were classed in a way somewhat like the following:

Masses	} to Latin words,	} From the infancy of counterpoint to the year 1500.
Motets		
Madrigals	} In modern lan- guages,	
Songs in parts, and single songs		

The same continued to the year 1600; to which should be added:

Services and full anthems	} To English words, as well as those of other modern languages.
Verse and solo anthems	
Psalms, in two or more parts	

The same classes completed to the year 1700, with the addition of masques, intermezzi, serenatas,

- Operas, serious and comic.
- Otorios.
- Cantatas.
- Fantasia and Recercari, for various instruments.

All the above continued to the present time, with an addition of full

- Concertos, symphonies, and overtures.
- Concertos, with solo parts for particular instruments.
- Quintets.
- Quatuors.

Sonatas, or trios, duets, and Solos for every instrument for which music has been composed, including voluntaries for the organ, and lessons for every species of keyed instrument.

The music published in single parts should be scored, and that published in partition transcribed, in single parts; to be alike ready for the eye or the ear, for the theorist to examine, or the practical musician to perform.

And in order that science and criticism may keep pace with the mechanism and practice of the art, all the treatises, tracts, and essays, both in the dead and living languages, should be collected, arranged chronologically, and assigned a particular portion of the library.

The Bodleian library, the Museum, and Royal Society, with some other libraries, have copies of new books sent to them, by the Stationers' company, and by individuals either by law or by courtesy; and when once such a foundation of old music is laid as we have here sketched out, it would soon become a custom, or might be made one by the legislature, for copies of all music that is published in England, as well as books on the subject, to be presented by the authors or editors to the public library. And the same means should be used for procuring all foreign musical publications as are employed in accumulating books from all parts of the globe, where the press is at work.

The librarian, *custode*, or keeper of these books, should be a good practical musician, as well as theorist and scholar, in order to know the worth of the productions he has in charge, and to be enabled to give instructions at least how to draw single parts from a score, and score single parts; to explain difficulties to the ignorant, and display curiosities to the learned; to know the rank each composer should hold in every class, and perhaps record the degree of respect that has been paid to him by his contemporaries, and which is due to him from posterity.

**LIBRATA TERRE**, a portion of ground, containing four oxgangs, and every oxgang thirteen acres.

It was anciently so much land as was yearly worth 20s. and in Henry III.'s time, he that had *quindecim libratas terre*, was to receive the order of knighthood.

Some say, that as money is divided into pounds, shillings, pence, and farthings, the same degrees are to be observed in the division of lands; and, therefore, as *quadrans* signifies a farthing, so *quadrantata* is the fourth part of an acre; *obolata*, an half; *denariata*, a whole acre; *solidata*, 12 acres; and *librata*, 20 times 12 acres; i. e. 240 acres.

This is the same with what in Scotland is called *pound-land* of old extent.

**LIBRATION** of the Moon, in *Astronomy*. Few persons are unacquainted with the remarkable circumstance, that the moon always presents nearly the same face to the earth. Sometimes, however, we see rather more of the eastern, and sometimes rather more of the western hemisphere than at other times. The same occasional variation is likewise observable in the north and south hemispheres. This sensible oscillation, partly real and partly apparent, is called the libration of the moon.

Galileo was the first astronomer who observed and attempted to explain the libration of the moon; his explanation was, however, very imperfect, not being aware that the most considerable part of the libration arises from the unequal motion of the moon in its orbit, as was first discovered by Hevelius in 1654. Laplace gives the following popular explanation of the astronomical appearances connected with the libration. For the physical explanation the reader is referred

ferred to a memoir of Lagrange (Memoires de l'Academie) which obtained the prize in 1764, and likewise to the Berlin Memoirs, 1760, in which the same author has investigated this subject at great length.

To form a just idea of the principal causes of this phenomenon, we should consider the disk of the moon, when seen from the centre of the earth, as terminated by a great circle of the lunar globe, perpendicular to its radius vector (a line joining the centres of the earth and moon); on the plane of this great circle, that hemisphere of the moon which is presented to the earth is projected, and the various appearances of this hemisphere are connected with the rotatory motion of the moon on its axis. If this motion did not exist, its radius vector would trace a great circle on its surface, every part of which would be successively turned towards us, during every lunar revolution. But at the same time that the radius vector would describe this circumference, the moon, by its revolution, brings very nearly the same point of its surface to the radius, and consequently turns the same hemisphere towards the earth. The inequalities in the moon's motion produce some slight variation in the appearance of this hemisphere; for as the motion of rotation does not partake perceptibly of these inequalities, it is variable with respect to the radius vector, which thus intersects its surface at different points. The lunar globe, therefore, makes, with respect to this radius, oscillations corresponding to the inequalities of its motion, which cause some part of its surface to be alternately concealed, and exposed to our observation.

This libration, referred to the ecliptic, is called the *libration in longitude*. But the moon has another *libration in latitude* perpendicular to this, and by which the parts near the poles of the axis of rotation of this globe alternately appear and disappear. To comprehend this phenomenon, let us suppose the axis of rotation to be perpendicular to the ecliptic. When the moon is in its ascending node, these two poles will be at the northern and southern extremity of the visible hemisphere. In proportion as the moon is raised above the ecliptic, the northern pole and the parts surrounding it will disappear, while the regions near the south pole will become more and more visible, till the moon, having arrived at its greatest northern latitude, will return again towards the ecliptic. These phenomena will then be reproduced in the reverse order; and when the moon, having reached its descending node, passes below the ecliptic, the north pole will present the same phenomena as the southern one had offered.

The axis of rotation of the moon is not always perpendicular to the ecliptic, and its inclination produces appearances which may be understood by supposing the moon to move upon the plane of the ecliptic, so that its axis should always remain parallel to itself; it is obvious that then each pole will be visible during half a revolution of the moon round the earth, and invisible during the other half, so that the regions which surround them will be alternately visible and invisible.

And lastly, the observer is not at the centre of the earth but at the surface. It is the visual ray drawn from his eye to the visible hemisphere, which determines the middle of the visible hemisphere, and it is clear that from the effect of the lunar parallax, this radius cuts the surface of the moon at different points, according to its height above the horizon.

All these causes produce only an apparent libration of the lunar globe; they are mere optical illusions, and do not affect its real motion of rotation; it is nevertheless true, that this rotation may be subject to some small irregularities, but they have not yet been detected by observation.

It is not the same with the inequalities of the lunar equator. In endeavouring to determine its position by observations of spots on the moon, Dominique Cassini was led to this remarkable result, which contains all the astronomical theory of the real libration of the moon. If we conceive a plane to pass through the centre of the moon, perpendicular to its axis of rotation, which plane will coincide with that of the equator; if, moreover, we imagine a second plane parallel to that of the ecliptic, and a third plane, which is the mean plane of the lunar orbit, these three planes will always have a common intersection. The second plane, situated between the two others, forms with the first an angle of about  $1^{\circ} 30' 10''$ , and with the second, an angle of  $5^{\circ} 8' 49''$ . Thus the intersections of the lunar orbit with the ecliptic or its nodes, always coincide with the mean nodes of the lunar orbit, and, like them, have a retrograde motion, whose period is  $18^{\circ} 22' 7'' 13' 17''$ . In this interval the two poles of the equator and of the lunar orbit describe small circles parallel to the ecliptic, in such a manner, that these three poles are constantly situated on a great circle of the heavenly sphere.

*LIBRATION of the Earth*, is a term applied by some astronomers to that motion, whereby the earth is so retained in its orbit, as that its axis continues constantly parallel to the axis of the world. See PARALLELISM.

This Copernicus calls the *motion of libration*; and may be illustrated thus: Suppose a globe, with its axis parallel to that of the earth, painted on the flag of a mast, moveable on its axis, and constantly driven by an east wind, while it falls round an island; it is evident, the painted globe will be so librated, as that its axis will be parallel to that of the world, in every situation of the ship.

**LIBSHAUSEN**, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 15 miles S.W. of Leitmeritz.

**LIBUN**, a town of Bohemia, in the circle of Boleslaw; 16 miles N.E. of Jung-Buntzel.

**LIBURNIA**, in *Ancient Geography*, a province of Illyria, along the Adriatic sea, over-against Italy, between Dalmatia on the south, and Istria on the north. This peninsula runs into the sea between the rivers Tedanus and Titius, now the Zermagne and Kerka, the latter of which was in the Roman times the boundary between Liburnia and Dalmatia. Zara, anciently Jadera, and afterwards Diadora, was once the capital of Liburnia. The ruins of Burnum, the Liburnia of Strabo, are to be seen on the right hand of the Titius, or Kerka, in the desert of Bukoviza.

**LIBURNII**, or **LIBURNIANS**, the denomination of one of the three nations which sprang from the Illyrians, having left the country which bore their name in Illyria. They were probably the first people who penetrated into Italy by its northern part, about the sixteenth century before the Christian era, and in process of time settled along the sea-coast. In Italy they were divided into three branches, viz. the Apuli, the Pædiculi, or Padieli, and the Calabri. The country which they inhabited was called Apulia by the Romans, or Japygia by the Greeks.

**LIBYA**, the name anciently given to that part of the world called *Africa* (which see), comprehending in its whole extent Egypt, Marmarica, Cyrenaica, the Syrtic region, Libya proper, Numidia, Mauritania, Libya or Africa interior, Ethiopia, &c.; and bounded on the N. by the Mediterranean, on the E. by the isthmus of Suez, the Red sea or the Arabian gulf, and the Eastern ocean; on the S. by the Ethiopian sea; and on the W. by the Atlantic sea. In a more restricted sense, the name has been applied to that division of Libya or Africa called. "Li-

bya Interior," which lay westwards with regard to the other division of Ptolemy denominated Ethiopia sub Ægypto. The line of division between these two parts, marked by this geographer, passes through Darnis, a city on the confines of Cyrenaica. In this western part, called Libya interior, the inhabitants consisted chiefly of the Gattuli, Garamantes, Nigritæ, and Hesperian Ethiopians, besides many other people, less considerable and less known. See **ÆTULIA**, **GARAMANTES**, and **ETHIOPIA**.

**LIBYA**, a town of Hispania interior. Anton. Itin.

**LIBYA Palus**, a lake of Africa, properly so called. Ptolemy.

**LIBYARCHÆ**, a people of Africa, in Libya, and more particularly in Marmarica, of which they occupied the northern part. Ptolemy.

**LIBYECUM MARE**, or sea of Libya, a name given by the ancients to part of the Mediterranean sea, which adjoined the coast of the Mærotide Libya; bounded on the W. by the sea of Africa, and on the E. by the sea of Egypt.

**LIBYCUS MONS**, a mountain of Egypt, near the city of Thebes. The Nile ran between this mountain and the Sacred mountain.

**LIBYPHÆNICES**, a name given by some authors to the Phœnician colonies established in Africa, in contradistinction to the Syro-phœnicians, or the Phœnicians of Asia.

**LIBYSSA**, a maritime town of Asia, in Bithynia, situated between Chalcedonia and Numidia. It was the place of Hannibal's retreat for avoiding the hatred of the Romans.

**LICANIA**, in *Botany*, Aublet. Guian. 119. t. 45. See **HEDYCREA**.

**LICAVO**, in *Geography*, a town of the island of Corsica; 20 miles E. of Ajazzo.

**LICE**. See **LOUSE**.

**LICE of trees**. See **APHIS**.

**LICEA**, in *Botany*, a genus of *Fungi*, Schrad. Nov. Gen. 16. Pers. Syn. 195, the species of which have been, some of them, referred to *Trichia*, *Sphaerocarpus*, (not the true *Sphaerocarpus* of Micheli, which belongs to the order of *Asce*), and *Didymium*. Its character is thus given by Perfoon.

*Peridium*, (or *case*), naked, roundish, or somewhat indeterminate in shape, brittle. Internal membrane wanting. Seminal powder destitute of fibres.

The species he enumerates are five, all very minute productions, scarcely bigger than pins' heads, found chiefly on rotten wood of the fir kind.

1. *L. bicolor*, the first species, (*Didymium parietinum*; Schrad. Nov. Gen. 24. t. 6. f. 1.) is singular for being found on white-washed mud walls. Its outer case is dark olive, enclosing a quantity of bright yellow powder, which, according to Schrader's generic character of *Didymium*, should be intermixed with fibres. Within is another, much smaller, brown, likewise globular, rather hard and rough case, full of a coarser brown powder.

2. *L. circumscissis*, (*Sphaerocarpus fœcilis*; Bulliard t. 417. f. 5.) is brown and clustered, opening by a circular division. Found in autumn or winter, between the bark and wood of the Aspen-tree.

3. *L. pusilla*, Schrad. Nov. Gen. 19. t. 6. f. 4. is hemispherical, polished, chestnut-coloured, with a blackish powder.

4. *L. variabilis*, *ibid.* 18. t. 6. f. 5, 6, is various in figure and colour, reddish-brown; the powder dirty yellow.

5. *L. flexuosa*, is described by Perfoon as creeping or

oblong, shining red brown, somewhat wavy, with saw-like incisions. These three last are found on fir wood.

Some of Schrader's species are removed by Perfoon to other genera. Albertini and Schweiniz, in their *Conspicetus Fungorum*, have described two new species.

*L. strabulina*, n. 303. t. 6. f. 3, found on the inner sides of the scales of cones of *Pinus Picea*, growing regularly in clusters, brown, with a dull yellow powder.

*L. incarnata*, n. 304. t. 10. f. 6, observed once only, on rotten fir wood in a moist forest, the beginning of October. It is crowded, flesh-coloured with a steely gloss; the powder at first white, then flesh-coloured, finally deep rose-coloured.

**LICENCE**, **LICENTIA**, in *Law*, a power or authority given to another to do some lawful act.

A licence is a personal power, and cannot be transferred to another; though a licence may be granted to a man and his assigns. (12 Hen. VII. 25.) There may be a parol licence, as well as by deed in writing; but if it be not for a certain time, it passes no interest. (2 Nelf. Abr. 1123.) By licence a man may practise physic and surgery in London: licences are also necessary for carrying on various trades and professions, on which a duty is laid, for the purpose of raising a revenue to government. If a lessor license his lessee (who is restrained by covenant from aliening without licence) to alien; and such lessor dies before he aliens, this is no countermand of the licence: so it is if the lessor grants over his estate. (Cro. Jac. 133.) But where a lord of a manor for life granteth a copyhold tenant to alien, and dieth, the licence is destroyed, and the power of alienation ceaseth. (1 Inst. 52.) Copyhold tenants leasing their copyhold for a longer time than one year, are to have a licence for it; or they incur a forfeiture of their estates. (1 Inst. 63.) If any licence is given to a person, and he abuses it, he shall be adjudged a trespasser *ab initio*. 8 Rep. 146.

**LICENCE to alien in mortmain**. Alienations in mortmain to ecclesiastical persons, &c. are restrained by several statutes; but the king may grant licence to any person or bodies politic, &c. to alien or hold lands in mortmain. 27 Ed. I. 7 & 8 W. III. cap. 37.

**LICENCE** is also used, in the *Civil Law*, for a permission or leave granted by a superior.

Justinian appointed four years to be spent in the study of the law; after which, those who had discharged this obligation, were said to have licence or permission to retire from study.

**LICENCE** is also applied to the letters, or certificates, taken out in universities, whether in law, physic, or divinity.

Licence in the Sorbonne, denotes a period of two years, which the bachelors are obliged to pass in assisting at acts, and disputing in them, to qualify themselves for being admitted doctors. See **DEGREE**.

**LICENCE, letter of**. See **LETTER**.

**LICENCE to arise**, in *Law*, *Licentia surgendi*, is a liberty, or space of time given by the court to a tenant, who is essoined de malo leñi in a real action, to rise out of his bed, and go about his business.

**LICENCE for election of bishops**. See **CONGE d'Elire**.

**LICENCE of marriage**. Bishops have power to grant licences for this purpose; and persons marrying any person without publishing the bans of matrimony, or without licence, incur a forfeiture of 100l. &c. by 7 & 8 W. III. cap. 35. See also stat. 26 Geo. II. c. 33. See **MARRIAGE**.

**LICENCE**, in *Painting*, are the liberties which the painter takes

takes in dispensing with the rules of perspective, and the other laws of this art.

**LICENCE, poetical**, is the liberty which poets claim of dispensing with the ordinary rules of grammar.

Anciently poets had much greater licences than are now allowed. The Greeks, by having recourse to the several dialects of their tongue, could lengthen out a word, if it were too short, or retrench something from it, if it were too long. The old poets did what they pleased with their language, and subjected it not only to all their necessities, but their caprices too:

“Et data Romanis venia est indigna poetis.”

But these became ridiculous in course of time; and the poets are now despoiled of most of their ancient privileges.

**LICENCE, in Music**, a seeming breach of rule.

There are licences in harmony as well as in melody. As the laws of counterpoint were at first arbitrary, and formed of narrow and contracted principles, they became subject to change at the caprice or taste of the composer, and at all times, the breach of an old rule by a great master became the establishment of a new one for a composer of inferior fame. At present, except the two fundamental prohibitions of *two 5ths* and *two 8ths* in regular progression, there is no rule that has not been happily infringed, at one time or other, by some man of genius; so that it may be said, perhaps, that whatever does not offend a cultivated ear in harmony or melody, is allowable in music. Of the disallowances of former times, there was none that seemed so inviolable as false relation, such as naturals against sharps, or sharps against naturals: in the perfect concords, as a redundant 5th, a diminished 4th, or a false octave. Yet these licences, of late years, have been so frequently practised, as almost to establish them into rules. The good or bad effect determines the expediency.

If the effect be good, it is a *licence*, if bad, a *fault*. Emanuel Bach, we believe, was the first who ventured to hazard a false 8th, or a sharp against a natural in melody. But Haydn and Mozart having since frequently violated the rule with effect, it almost ceases to be a licence, and every sonata in composition assumes the same privilege. These licences, however, can only be defended on the principle of *apocriphaturas*, as they are certainly inharmonical.

**LICENSED CURATE**. See **CRURATE**.

**LICENSING of Books**. See **LIBERTY of the PRESS**, and **PRINTING**.

**LICENTIA CONCORDANDI**, in *Law*, is that licence for which the king's silver is paid in passing a fine, mentioned in 12 Car. II. cap. 12.

**LICENTIA loquendi**. See **EMPARLANCE**.

**LICENTIA trans fretandi**, a writ or warrant directed to the keeper of the port of Dover, or other sea-port, commanding them to let such persons pass over sea, who have obtained the king's licence for the purpose. Reg. Orig. 193.

**LICENTIATE**, or **LICENCIATE**, he who has obtained the degree of a licence.

Most of the officers of judicature in Spain are known by no other name than that of licentiates. To pass licentiate in the common law, civil law, or physic, they must have studied seven years; in divinity, ten.

**LICENTIA**, among us, is usually understood of a physician, who has a licence to practise, granted him by the College of Physicians, or by the bishop of the diocese.

A person practising physic without such licence, in case

his patient dies under his hands, is guilty of felony in the eye of the law.

**LICETO**, **FORTUNIO**, in *Biography*, a celebrated physician and philosopher, was born at Rapallo, in the state of Genoa, on the 3d of October, 1577, where his father, Joseph Liceto, was also a physician. His education was conducted with great care, and he afterwards spent four years in study at Bologna, which he quitted in 1599. He then settled at Pisa, where he soon obtained the professorship of philosophy, which he filled with so much reputation, that he was invited to the same chair in the university of Padua in 1609, which he occupied until 1636. He removed at that time to Bologna, in consequence of failing to obtain the professorship of medicine, which became vacant by the death of Cremonini. But the Venetian states very soon perceived, and acknowledged the loss which the university of Padua had sustained by the retirement of Liceto; and when a vacancy occurred in the first chair of the theory of physic in 1645, he was induced, by the pressing invitations which were made to him, to return to Padua, where he held the professorship, at an advanced salary, till his death in 1657. He was a very copious writer, having published upwards of fifty treatises upon medical, moral, philosophical, antiquarian, and historical subjects; but they are no longer sufficiently interesting to require a detail of their titles. He was a man of considerable erudition, and an ardent admirer of the doctrines of Aristotle; but displayed little acuteness in research or originality of conception. He wrote a treatise “De Lucernis Antiquorum reconditis,” in which he maintains the opinion, that the ancients were possessed of a secret process for making incombustible lamps, by some mode of condensing the vapour into oil, which returned to the reservoir, and was extremely credulous in respect to the pretended discoveries of sepulchral lamps of this sort. But his opinions were positively refuted by professor Ferrari of Padua, in a treatise, “De veterum lucernis sepulchralibus.” Among his medical writings, his treatise, “De Morborum Causis, Natura, et Differentiis,” is best known; but it is replete with instances of credulity, and with the fables and superstitutions of his predecessors, and contains a classification of the monsters, which had been previously described, without any correction from his own observations. The best edition is that of Gerard Blasius, in 1668. Eloy Dict. Hist. Gen. Biog.

**LICETO**, in *Ornithology*. See **CENOTZQUI**.

**LICH**, in *Geography*, a town of Germany, in the principality of Hohen-Solms, on the Wetter; 12 miles E.S.E. of Wetzlar. N. lat. 50° 31'. E. long. 8° 49'.

**LICHAN**, a town of Corea; 17 miles E.S.E. of Het-sin.

**LICHANOS**, in the *Ancient Music*, is the name of the 3d found of the two lowest tetrachords in the system of the Greeks; as this sound was produced by the index or fore-finger, which was called *lichanos*. The 3d found of the lowest tetrachord ascending, was that of the *hypate*, and called *lichanos-hypaton*, sometimes *hypaton-diatonos*, enharmonic, or chromatic, according to the genus. That of the 2d, or mean tetrachord, was called *lichanos-meson*, or *Meson diatonos*.

**LICHEN**, in *Botany*, *λίχην*, a name borrowed by the Romans from the Greeks for the disease called a tetter, or ringworm, and applied by both to some plant of a mossy nature, growing on stones, which was thought a cure for such complaints. What the *Lichen* of the ancients may have been is very obscure, and the enquiry is given up by

Dillenius himself in despair. He has applied this name to the *Marchantia* of other writers, under which he comprehends the very distinct genera of *Targionia*, *Riccia* and *Sphaerocarpus*; see his t. 78. Linnæus much more happily adopts the *Lichen* of Tournefort and Micheli, whose erulaceous and scurfy nature, in many instances, is associated with the original idea of the word. This Dillenius terms *Lichenoides*, from which he distinguishes *Coralloides* and *Usnea*, but all three are comprehended in the Linnæan *Lichen*.—Linn. Gen. 566. Schreb. 67. Mart. Mill. Dict. v. 3. Hudf. 523. Juss. 7. Tourn. t. 325. Mich. Gen. t. 36—53. Hedw. Theor. 120. t. 30, 31. Lamarck. Illustr. t. 878. (*Lichenoides*; Dill. Mufc. 124. t. 18—30. *Coralloides*; *ibid.* 75. t. 14—17. *Usnea*; *ibid.* 56. t. 11—13.)—Class and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*, Linn. Juss.

Eff. Ch. Male, scattered powdery warts?—Female, shields or tubercles, in whose disk the seeds are lodged.

Obf. Linnæus takes for male what are now known to be the female flowers, and, *vice versa*, takes for the female those powdery heads, warts or sifures in the frond, which are by some thought buds, by others the male blossoms. We have therefore ventured to reverse his character of this val genus, which properly embraces an entire natural order. (See LICHENES.) It is necessary however here to give a compendious view of *Lichen*, as understood by Linnæus. The species defined in the 14th edition of his *Syftema Vegetabilium* amount to 130; but the insufficiency of this catalogue, to comprize all the Lichens in the world, will be strikingly evident, when we consider that about 345 British species have already appeared in English Botany, and that several more remain to be published there. We shall on this occasion prefer illustrating the nine sections, into which Linnæus has divided his genus, by species of his own, rather than by new ones. Most of these exist in his herbarium, few or none of them being adopted from Dillenius or other cryptogamists, which cannot so generally be said of the Linnæan proper *Mufci*.

SECT. 1. *Leprosi tuberculati*. Twenty-one species.

These consist of a leprous perennial crust, of more or less density, hardness and smoothness, its surface often granulated, sometimes powdery, of various colours, (white, grey, greenish, or yellowish), in different species; the internal substance however is generally very white, often with a green stratum immediately below the actual surface. This crust spreads circularly, with more or less regularity, over stones, rocks, earth, the bark of trees, or even dead wood, to which it frequently adheres so strongly, that, being moreover in some cases very thin, it cannot be separated entire. Fibrous roots, of the cartilaginous or chalky substance of the crust, may be detected in species that grow upon uneven bodies, or on the ground. The circumference or border of the crust is always thin; often marked with a dark-coloured line; occasionally beautifully fibrous and branched. The central part first decays, and finally crumbles away, young plants, of the same or a different species, soon afterwards springing up there from seed; while the marginal boundary of the original crust, if its situation be convenient for the purpose, is sometimes extended to ten times its usual limits.

The crust of the thicker or tartareous species, more especially, is liable to assume a red or purplish hue, from the access of volatile alkali; which is seen when certain animal substances fall upon these plants in their native situations. The observation of this has led to the use of some of them in dyeing; but several of the next and following sections are preferable for this purpose.—The female fructi-

fication, or rather the fruit itself, of this first section, is, or ought to be, convex, without any border; except in a young state, when there is usually a thin margin of its own substance. The disk is most frequently black, in some brown, pale grey, or reddish; and in its solid internal substance are innumerable, vertical, closed cells, each containing about eight minute seeds. It may be observed that the increasing convexity of this disk seems well calculated to allow room for the swelling of the seeds; and finally, by separating or expanding the cells, to promote the escape of their contents. The subjacent crust, under each tubercle, is elevated into its core or centre, so as to form a nucleus there.—Discoveries subsequent to the time of Linnæus have found this section to be rather heterogeneous, as to the affinities of the several kinds, as will be explained hereafter. (See LICHENES.) Our purpose is now merely to indicate the most remarkable species, for the elucidation of our author.

*L. scriptus*. Syst. Veg. ed. 14. n. 1. Linn. Sp. Pl. 1606. (*Lichenoides* *suilla* tenuissima, *pregnaris* velut *litis* inscripta; Dill. Mufc. 128. t. 18. f. 1. *Opegrapha scripta*; Engl. Bot. t. 1813.)—Leprous, whitish, bearing small, black, branched, letter-like lines.—Common on the smooth bark of young trees. The *crust* is a fine, inseparable, whitish film. The *fructification* conveys an idea of Hebrew or Chinese writing, in a very striking manner. This plant however, as understood by Linnæus, Dillenius, and most of their followers till lately, embraces at least 30 known species, together constituting a most natural and distinct genus, of which we shall speak hereafter more than once, under the name of *Opegrapha*.

*L. geographicus*. n. 2. Sp. Pl. 1607. Engl. Bot. t. 245. (*Lichenoides* nigro-flavum, *tubule* geographicæ *in*itar pictum; Dill. Mufc. 126. t. 18. f. 5.)—Leprous, yellowish, with black lines resembling a map.—Frequent on the hard rocks of mountainous countries, and almost as hard itself, at least to the touch, forming broad inseparable patches, of a vivid greenish-yellow, or lemon-colour, curiously streaked and dotted with black marks, composed of the *tubercles*, which are flat, not elevated above the *crust*, frequently confluent or crowded.

Of this species, *atrovirens*, n. 3, is thought to be a variety, or rather an early stage of its growth.

*L. sanguinarius*. n. 9. Sp. Pl. 1607. Engl. Bot. t. 155. (*Verucaria* *sanguinaria*; Hoffm. Pl. Lich. t. 41. f. 1.)—Crust tartareous, white, polished, uneven. Tubercles black, without a border; bright red within.—Found on granite rocks; copiously upon Cromford Moor, Derbyshire; very rarely on the rugged barks of trees. This is extremely remarkable for the internal stains of bright red, perceived when the *tubercles*, and even some parts of the *crust*, are broken; which resembling blood, gave occasion to the very apt name. Several species, destitute of that property, and which otherwise but imperfectly resemble this, are confounded with it by Linnæus, Hudson, Lightfoot, and others.

*L. ventosus*. n. 17. Sp. Pl. 1607. Engl. Bot. t. 906. (*L. cruentus*; Web. Goett. 184. t. 1. *L. flavescens*; Jacq. Mufc. v. 2. 79. t. 9. f. 1. *L. gelidus*; Hudf. 528. *Lichenoides* *tartareum* lividum, *scutellis* rufis, *marginibus* exill; Dill. Mufc. 133. t. 18. f. 14.)—Crust tartareous, rugged, pale sulphur-coloured. Shields irregular, a little swelling, blood-red, with a narrow pale border.—Found on large exposed granite or sand-stones, in mountainous places, forming patches as broad as the hand, easily pared from the rock when moist. The crust is of an elegant pale lemon or sulphur-colour, turning white the second year, but in either case it is strikingly contrasted with the crimson *shield*. These having a permanent border, of a different substance and colour

## L I C H E N.

colour from their disk, are *shields*, not *tubercles*, so that the plant belongs properly to the second section of its genus, of which we shall next give a few examples, and to which it is referred by Murray in Syft. Veg. ed. 14, under Jacquin's name of *flavifens*, so that it occurs twice in that edition.

SECT. 2. *Leprosi scutellati*. Twelve species.

The crust of these is almost universally tartareous, sometimes very thick, less hard than in several of the former, and more easily separable from the stones or bricks on which it may happen to grow. The essential difference resides in the fructification, which consists of flatish shields, or, as Diljenius terms them, saucers, whose elevated permanent margin is of the substance and colour of the crust, not of the disk.

*L. tartareus*. n. 25. Sp. Pl. 1608. Engl. Bot. t. 156. (Lichenoides crustaceum et leprosum, acetabulis majoribus luteis, limbis argenteis; Dill. Musc. 132. t. 18. f. 13.)—Crust tartareous, rugged, granulated, whitish. Shields tawny buff-coloured, with a white margin.—The largest of the crustaceous Lichens; very frequent upon rocks in the north, and important as an article of commerce. The diameter of the *crust* is six, eight or ten inches, and its thickness a quarter or half an inch. The *shields* are frequently half an inch wide, conspicuous for their full buff colour, and white, smooth, wavy border. This species is much used in dyeing, being scraped from the rocks when fully grown, which is about the fifth year of its age, and mixed with volatile alkali and alum. It is sold to the dyers in the form of a purple powder, called *Cudbear*, which being boiled with woollen yarn, communicates any shade of its own colour that may be desired, but does not dye vegetable substances. This colour is by no means permanent, being far inferior, in that respect, to what is given by the Orchard of the Levant, *Lichen Rocella*.

*L. frigidus*. n. 24. Swartz Meth. Musc. 36. t. 2. f. 4. Engl. Bot. t. 1879, found on the Scottish mountains, is pretty generally believed to be a mere variety of *tartareus*, with a thinner *crust*; but it seems to differ in throwing out slender branched brittle processes, not found in the former.

*L. Perellus*. n. 32. Linn. Mant. 132. Engl. Bot. t. 727, is like *tartareus* on a smaller scale, with *shields* of the same white colour as the *crust*, and is used likewise for dyeing purplish colours, chiefly in the fourth of France.

*L. upsaliensis*. n. 33. Sp. Pl. 1609. Engl. Bot. t. 1634, differs from *Perellus* as *frigidus* does from *tartareus*, in having slender awl-shaped bristles protruded from the crust.

*L. subfulvus*. n. 30. Sp. Pl. 1609. Engl. Bot. t. 2109. (Lichenoides crustaceum et leprosum, scutellis subfulvis; Dill. Musc. 134. t. 18. f. 16.)—Crust thin, continued, smoothish, brownish-white. Shields sessile, slightly convex, reddish-brown, with a tumid, whitish, entire border.—This is one of the thinnest, and usually least tartareous, of the present section, and is very common every where on the smooth barks of trees, being distinguished by its copious, bay or chefnut *shields*, whose white smooth border renders them conspicuous. Their disk is sometimes curiously proliferous, which happens also in *tartareus*. Sometimes it is parti-coloured, or mixed with a pale waxy hue, as if withered or abortive there. Numerous species greatly resemble this, but have been distinguished from it and from each other, generally very successfully, by the acuteness of the learned professor Acharius and others.

In this same section Linnaeus places his *candelarius*, see Engl. Bot. t. 1704, but improperly; doublets from his having, at one time or other, confounded with it, as others

have done; the *vitellinus* of authors, Engl. Bot. t. 1792, and *citrinus*, t. 1793. These are all yellow in their *crust* or *frond*, as well as the *shields* of their margins; and serve to give a golden colour to candles, used on festival days in the Swedish churches, by being mixed with the melted wax or tallow.

Some of this section have a lobed, though not easily separable, *crust*, as *knigerus*, n. 29. Engl. Bot. t. 871; and *gelidus*, t. 699. The true *shields* of the latter, whose disk is of a fine pink colour, were not known to Linnaeus, who mistook for the fructification of this rare species certain brown warts, or proliferous excrescences of the crust, which he termed *pelæ*; see his *Mantissa*, 133. Having nevertheless true shields, it properly belongs to this second section. *L. muscorum*, n. 31. Engl. Bot. t. 626, on the contrary, having only a black and evanescent border to its black convex tubercles, should have been placed in the first.

SECT. 3. *Imbricati*. Thirteen species.

The plants of this section do not consist of an adherent *crust*, but approach more or less to a leafy structure, being either of a membranous, cartilaginous or gelatinous texture. The segments spread from a centre, lying over one another like tiles, the central ones being most divided and elevated, the marginal part more depressed, rather plaited than deeply cut, and most dilated outwards. The two sides differ remarkably; the upper being usually either pitted, wrinkled, warty, or besprinkled with mealy cracks, but destitute of hairs, and frequently polished, variously coloured; the under opaque, sometimes pale or white, sometimes quite black, always beset with innumerable fibrous perpendicular radicles, by which it is firmly attached to the bark, wood, earth or stones on which the plants grow. The shields are horizontal, feathered over the upper surface, to which they are attached chiefly by their central part. Their border is of the substance and colour of the frond; the disk somewhat deeper in hue, and much inclined to a chefnut or tawny cast. The mealy warts or cracks in the upper side of the frond are presumed to be the male blossoms, because no other are known. This is a miscellaneous and unnatural combination of species, as will be explained under the next section.

*L. centrifugus*. n. 34. Sp. Pl. 1609. Fl. Lapp. ed. 2. 357. n. 448. t. 11. f. 2.—Imbricated, membranous; greenish-white and smooth above; white, with brownish fibres, beneath; segments linear, divaricated, bluntish. Shields feathered towards the circumference, reddish-brown, with an inflexed, almost entire, border.—This is, according to Linnaeus, extremely common on large stones throughout Lapland, where Lichens that grow on stones are more rare than in other places. It is of all others most remarkable for its centrifugal mode of growth, forming circles a foot or two in diameter, and indeed sometimes, as we are told, eight or ten feet, consisting of a whitish band two or three inches broad, while the central part is quite decayed and obliterated. Linnaeus errs in citing under this a synonym of Diljenius, t. 24. f. 75, which is the *conspersus* of Acharius and Engl. Bot. t. 2097, a species found in various parts of Europe, of a more compact manner of growth and greener colour, with broader lobes and larger, concave, dark chefnut shields.

*L. saxatilis*. n. 35. Engl. Bot. t. 603; and *omphalodes*, n. 36. Engl. Bot. t. 604; are of a more lax and leafy habit than the last, as well as different in colour. The former of them is very common; the latter confined to mountainous rocky heaths or moors. Both are used to dye browns or dull reds in the ruder states of human society, or amongst the inhabitants of the Alps.

*L. parietinus*. n. 43. Sp. Pl. 1610. Engl. Bot. t. 1944. (Lichenoides

(*Lichenoides vulgare sinuofum*, foliis et scutellis luteis; Dill. Musc. 180. t. 24. f. 76.) Imbricated, membranous, stellated, roundly lobed and crisped, orange-coloured; pale and fibrous beneath. Shields of the same colour, with a thin entire border.—One of the most common of its genus, very conspicuous on old walls, as well as on rocks, wooden buildings, trees and bushes. Its rich golden colour is most vivid in exposed situations; assuming an olive, greenish, or greyish cast in the shade and damp. Several species however are perhaps confounded under this by Linnæus and his followers.

*L. stellaris*. n. 45. Sp. Pl. 1611. Engl. Bot. t. 1697, coloured too green.—“Imbricated; leaflets oblong, lacinated, narrow, ash-coloured. Shields brown.” Linn.—Very common on trees. Under this a great number of species are undoubtedly confounded by Linnæus, though Acharius may possibly have gone too far in dividing them. Some are green when wet; others continue grey, whether moist or dry. The shields in all of them are of a greyish-black, not verging towards red, and are usually plentifully produced.

SECT. 4. *Foliacei*. Twenty-six species.

What Linnæus refers to this section are all naturally allied to one or other species of the last, so that the two sections ought to form but one, those of the present being only more leafy, less imbricated, and in some cases quite erect. Nothing however can be more miscellaneous than this division of the genus.

*L. Burgessii*. n. 48. Lightf. Scot. 827. t. 26. Engl. Bot. t. 300.—Gelatinous, membranous, crisped and fringed, of a dark glaucous green. Shields depressed, dark brown, with a leafy, crisped, elevated border.—Found on the trunks of old trees in Scotland and Wales. One of the most elegant of its tribe, consisting of dark-green patches as broad as the hand, of delicate pellucid curled and wavy leaves, bearing numerous shields, very remarkable on account of their leafy, complicated, wreath-like borders. *L. ornatus*, n. 71, is the very same species. When dry the whole frond becomes more opaque, verging towards a lead colour. This belongs to a tribe called gelatinous Lichens, which constitute a very natural genus, now named *Collema*. All agree in their peculiar dark-green colour, semi-pellucid pulpy texture, and reddish or tawny-olive, generally small, shields. Some of them are placed by Linnæus in the former section, others in this.

*L. cilicaris*. n. 49. Sp. Pl. 1611. Engl. Bot. t. 1352; is of the same natural family as *stellaris* of the last order; only larger, more lax, and remarkably fringed.

*L. caperatus*. n. 65. Sp. Pl. 1614. Engl. Bot. t. 654; is in like manner allied to *saxatilis*, &c. and is properly an imbricated species.

*L. islandicus*. n. 50. Sp. Pl. 1611. Engl. Bot. t. 1330. Fl. Dan. t. 155. Hoffm. Pl. Lich. t. 9. f. 1; is celebrated as a restorative medicine in consumptive complaints. This with the three following of this section, *nivalis*, n. 51. Engl. Bot. t. 1994; *juniperinus*, n. 64. Hoffm. Pl. Lich. t. 7. f. 2; and *glauca*, n. 67. Engl. Bot. t. 1606, all elegant species, form a natural assemblage, which Acharius has separated, with some others, under the generic name *Cetraria*. See LICHENES.

*L. ampullaceus*. n. 54. Sp. Pl. 1613. (*Lichenoides tinctorium glabrum vesiculosum*; Dill. Musc. 188. t. 24. f. 82.) see Hoffm. Pl. Lich. t. 13. f. 2. is only a morbid variety of the last, *glauca*, caused apparently by the wound of some insect, which produces a sort of gall. The original specimen of this, having been stolen by a foreigner, more curious than honest, from the Dillenian herbarium about thirty or

thirty-five years ago, was detected by the late professor Sibthorp when abroad, in this person's collection, and recovered. It is not however restored to its original place, where the figure only is now found. But this is of the less consequence, as Mr. Menzies has gathered the plant in the very same state, which has been dissected in our presence, and its importance as a species thus falls to the ground. By the manner in which the history of this Lichen is related by our friend Mr. Turner, Tr. of Linn. Soc. v. 7. 112, it might seem that the excellent professor Von Jacquin was the thief, from which we think it essential to exculpate him, nor did Mr. Turner mean to imply any such thing.

To the section in question belong several species of a very distinct tribe, named *Physcia* by Acharius (but since sunk in his *Parmelia*, the above *Cetraria* being separated from it), of which the following are examples.

*L. farinaceus*. n. 56. Sp. Pl. 1613. Engl. Bot. t. 889. (*Lichenoides segmētis argutioribus*, ad margines verrucosis et pulverulentis; Dill. Musc. 172. t. 23. f. 63.)—Leafy, much-branched, upright, leathery, glaucous-ash-coloured, smooth, pitted; the branches tapering, studded with lateral, convex, pale, mealy warts. Shields scattered, stalked, flat, pale-buff.—Common on trees, but the shields are extremely rare, whence *L. fastigiatus*, Ach. Prod. 175. Engl. Bot. t. 890, came to be taken for the same thing. Its very abundant shields are nearly of the greenish-white hue of the frond, and the mealy warts are wanting.

*L. fraxineus*. n. 61. Sp. Pl. 1614. Engl. Bot. t. 1781, is so common on trees, conspicuous for its large size, and lanceolate figure, that nothing need be said of it.

*L. fuciformis*. n. 61. Sp. Pl. 1614. Engl. Bot. 728. (*Lichenoides fuciforme tinctorium*, corniculis longioribus et acutioribus; Dill. Musc. 168. t. 22. 23. f. 61.)—Leafy, divided, pointed, flat, nearly upright, tapering at each end, greyish-white, obscurely downy, with white mealy warts. Shields convex, blackish.—This is found on granite rocks upon the Cornish coast, but more plentifully in the Mediterranean, the Canary islands, and the East Indies, in which last climate it grows to the length of a foot. It is extremely important as an article of commerce, being used indiscriminately with, and according to some preferred to, the famous *L. Rocella*, for dyeing. See section 8.

SECT. 5. *Coriacei*. Thirteen species.

This is in itself a very natural section, but Linnæus has referred to it one or two species totally foreign to the nature of the rest; as *perlatus*, n. 82. Engl. Bot. t. 341. (*Lichenoides glaucum perlatum*, subtus nigrum et cirrosum; Dill. Musc. 147. t. 20. f. 39.)—This is in habit, texture, and natural affinity, closely allied to *saxatilis*, in sect. 3.—*L. aquaticus*, n. 73. Sp. Pl. 1615; for which a synonym of Dillenius, t. 20. f. 44, is quoted with doubt, has always been involved in much obscurity. The plant of Dillenius is *perforatus* of Jacquin and others, well figured in Hoffm. Pl. Lich. t. 13. f. 1. That of Linnæus, preserved in his herbarium, is said in the Flora Succica to have been found in mossy boggy places at Norrby, near Upsal, his own country residence; but no one has ever discovered what was meant. On a careful examination of the specimen, it proves to be

*L. corrugatus*. Sm. Tr. of Linn. Soc. v. 1. 83. Engl. Bot. t. 1652. Ach. Prodr. 122. (*Lichenoides acetabulis cutaneis et rugosis*; Dill. Musc. 185. t. 24. f. 79.) a plant found on trees throughout Europe, though long neglected by Linnæan botanists, some of the most distinguished of whom have mistaken it for *olivaceus*.

The real coriaceous Lichens, which constitute this fifth section, are, as their denomination implies, of a tough leathery

they texture; smoothish above; strongly veined and bearing numerous coarse radicles beneath. Their fields, called *petle*, or targets, are peculiar, perfectly sessile, and as it were glued to the frond towards its margin, sometimes at its under side! They are oblong or kidney-shaped, often slightly convex; their border merely a thin film which, in a tender state, covers their disk, and finally recedes to the edge as it withers. The plants of this section molly grow on the ground, either at the roots of trees, or on shady mossy banks.

*L. resupinatus*. n. 74. Sp. Pl. 1615. Engl. Bot. t. 305. (Lichenoides fuscum, peltis pollicis ferruginis; Dill. Musc. 206. t. 28. f. 105.)—Coriaceous, creeping, lobed, brownish-grey. Targets oblong, at the under side of each small ascending lobe.—Native of moist shady rocks, or of the mossy roots of trees in mountainous countries. The fronds are imbricated, smooth, of a dull brownish lead-colour, composing broad depressed patches; the targets reddish-brown, concave, plentifully produced, but each solitary at the concave extremity of its own small lobe.

*L. arcticus*. n. 77, and *antarcticus*. n. 78, both one species, are united by Acharius under the name of *Peltidea polaris*, being found in very high northern or southern latitudes only. They are remarkable for the great size of their targets, which grow at the back of the greenish-white frond, and are as big as the thumb-nail, orbicular, of a dark livid flesh-colour.

*L. caninus*. n. 79. Sp. Pl. 1616. Engl. Bot. t. 2299. (Lichenoides digitatum cinereum, lacune foliis sinuosis; Dill. Musc. 200. t. 27. f. 102.)—Coriaceous, dilated, ascending, furrowed, grey; white, with brown veins and fibres beneath; lobes very broad, with marginal fruit-bearing processes. Targets in front, vertical, revolute, roundish, red-brown, with a pale border. The largest, most common, and most famous of its tribe, being the celebrated "Ash-coloured Ground Liverwort," extolled by Dr. Mead as a cure for the bite of a mad dog, whence the above specific name. It was given with black pepper in milk, the patient being first bled, and afterwards bathed in cold water; but whatever accidental circumstances might confirm that famed physician in his opinion, the medicine has long been entirely laid aside.

*L. faccatus*. n. 83. Sp. Pl. 1616. Engl. Bot. t. 288. (Lichenoides lichenis facie, peltis acetabulis immerfis; Dill. Musc. 221. t. 30. f. 121.)—Slightly coriaceous, roundish, creeping; green above; white beneath. Targets scattered, blackish, sunk in pits. Found on the ground among rocks in mountainous countries.

*L. croceus*. n. 84. Sp. Pl. 1616. Fl. Lapp. t. 11. f. 3. Engl. Bot. t. 498. (Lichenoides fubris croceus, peltis appressis; Dill. Musc. 221. t. 30. f. 120.)—Coriaceous, creeping, rounded at the extremities; green above; orange and veiny beneath. Targets scattered, brown, flat.—Found only in the moist alpine situations, near the limits of perpetual snow, growing on the ground.—These two last, elegant and rare productions, are not exactly of the habit of the rest. Acharius, in Schrader's New Journal, v. 1. fasc. 3. 20, 21, has referred them to his new genus *Arthonia* (see LICHENES); from the true species of which they differ in their leafy, not crustaceous, habit, nor is it easy to say to what family they properly belong.

SECT. 6. *Umbilicati*. Eleven species.

A most distinct and natural tribe, constituting the genus *Gyrophora* of Acharius, of which we have spoken in its proper place. (See GYROPHORA.) Linnæus defines these plants as umbilicated, or attached by their centre, and dirty as it were with foot. The latter perhaps may be their male

warts. The fruit exhibits the most essential character in the concentric folds observable in its disk. The first species however, *miniatus*, n. 86. Engl. Bot. t. 593, though it agrees with the rest in its umbilicated habit, differs from them in fructification, in which latter respect it accords with *Endocarpon*; see that article. True *Gyrophora* are

*L. velleus*. n. 87. Sp. Pl. 1617. (Lichenoides coriaceum, latifimo folio umbilicato et verrucoso; Dill. Musc. 545. t. 82. f. 5.)—Umbilicated, stalked, dilated, wavy; brownish-grey and smooth above; covered beneath with black, branched, crowded fibres. Tubercles clustered, flat.—Native of rocks in Lapland and North America. Often as broad as both the hands, tough and leathery, remarkable for its dense, black, hairy clothing beneath. In this last respect indeed it accords with the much smaller, green or olive-coloured, British *pellitus*, Engl. Bot. t. 931, which Hudson mistook for *velleus*.

*L. pululatus*. n. 88. Sp. Pl. 1617. We need not repeat what is laid of this under the article GYROPHORA.

*L. viridis*. n. 96. Linn. Suppl. 451, gathered at the Cape of Good Hope by Thunberg, is *Endocarpon Thunbergii*, Ach. Meth. 129, has nothing of the character of a *Gyrophora*.

SECT. 7. *Scyphiferi*. Nine species.

The natural family of cup-bearing Lichens, or *psycidati*, being one of the most distinct and strongly characterized, has been separated as a genus of itself by most who have considered the subject. (See LICHENES.) The species are extremely confused and difficult to define, being variable in themselves and much resembling each other. Their frond or basis consists of small, rounded, more or less dispersed, horizontal scales, or leaflets; smooth and green or greyish above; pure white beneath, as well as at the edges and within side. In some few instances they are dilated, and lobed or pinnatifid. From these arise upright stalks, terminating in a cup-shaped figure, of a large proportion compared with the leaflets, of a greenish-grey colour, and mealy or scaly surface; the edges of the cup producing the fructification, which consists of small globular tubercles, either brown, or of a most beautiful scarlet, sessile, or variously stalked. Sometimes the cup is proliferous from its edges or centre; sometimes obsolete, or, as it were, starved.—These plants come under the *Coralloides* of Dillenius, t. 14. 15.—Examples are

*L. cociferus*. n. 97. Sp. Pl. 1618. Engl. Bot. t. 2051. (Coralloides scyphiforme, tuberculis coccineis; Dill. Musc. 82. t. 4. f. 7.)—Cup-shaped, leathery, pale greenish-grey, mealy. Cups dilated, somewhat toothed. Tubercles fungous, scarlet. Leaves minute, lobed and crenate.—A beautiful species, not uncommon in woods, or on heaths among ling, or in various dry sandy places. The large scarlet tubercles render it very conspicuous. Several other species indeed have the same coloured fructification, but smaller, and they differ in other respects. The *cupæ* in this are shorter, broader, and more perfect than in any other with scarlet tubercles.

*L. psycidatus*. n. 99. Sp. Pl. 1619. Engl. Bot. t. 1393. (Coralloides scyphiforme, tuberculis fuscis; Dill. Musc. 79. t. 14. f. 6.)—Cup-shaped, leathery, greyish-green, scaly, often proliferous. Cups dilated, nearly entire. Tubercles brown. Leaves minute, imbricated, crenate.—The most common of this tribe, occurring every where, in broad patches, on heaths, sandy banks, and under hedges. Its cup-like shape is usually pretty regular, at least before the tubercles appear; but the edges of the cup, or its centre, occasionally throw up others, even to four or five ranks or stages,

ages, one upon another, in beautiful luxuriance. More frequently the first cup bears unequal and imperfect cups, or tubular stalks, crowned with the brown *tubercles*. The *stalks* of all are frequently leafy or scaly, especially their lower part.

*L. gracilis*. n. 101. Sp. Pl. 1619. Engl. Bot. t. 1284. (Coralloides scyphiforme ferratum elatius, caulibus gracilibus glabris; Dill. Musc. 88. t. 14. f. 13.)—Cup-shaped, long, slender, smooth, cartilaginous, greenish-brown; at length somewhat branched. Cups conical, sharply toothed. Tubercles brown. Leaves minute.—In healthy dry mountainous places, or in woods, in the north, not unfrequent. The character of this is widely different from the two preceding, displayed in its brown hue, tall slender form, and sharp teeth or terminal branches. The *tubercles* are dark brown. *Leaves* very minute, and frequently obliterated.

*L. flammeus*. n. 105. Linn. Suppl. 451. Hoffm. Pl. Lich. t. 3. f. 1; is very improperly referred to this section by Murray, merely, as it seems, on account of its tubular stem and branches. It ought, according to the Linnæan arrangement, to stand in section 3, after *parietinus*, n. 43, and before *physodes*, n. 44, agreeing with the former in colour, with the latter somewhat in structure. We mean not, however, to say there is any considerable real affinity between these three species.

SECT. 8. *Fruticulosi*. Ten species.

A vague section, comprising, though small, several discordant things, of which no general definition can be given, except that they are of an upright bushy habit.

*L. rangiferinus*. n. 106. Sp. Pl. 1620. Engl. Bot. t. 173. (Coralloides montanum, fruticulosi speciei, ubique candicans; Dill. Musc. 107. t. 16. f. 29; et corniculis rufescentibus; t. 16. f. 30.)—Bulky, tubular, very much branched, white and hoary; the little branches divaricated and drooping. Tubercles terminal, globose, mostly clustered, dark brown.—This is the Reinder Lichen, so celebrated by Linnæus, in his Flora Lapponica and Lapland Tour, as the food of that animal. In the wide heathy tracts and forests of those northern regions, it covers the ground like snow, rising to the height of a foot or more; with us it is much humbler and more dispersed; always choosing the most sterile heathy soil, and not very generally producing fruit. Its texture is thin and brittle, soft to the grasp of the hand, and excellent for package, the only use for which it can serve in this climate. The *branches* are occasionally, not always, perforated at their divarications. The surface is hoary, or rough with minute warts. *Tubercles* very small, terminal, abundant when they occur at all.

*L. uncialis*. n. 107. Sp. Pl. 1621. Engl. Bot. t. 174.

*L. vermicularis*. n. 108. Swartz Meth. Musc. 37. Engl. Bot. t. 2029.

*L. subulatus*. n. 109. Sp. Pl. 1621. (Coralloides corniculis longioribus et rarioribus; Dill. Musc. 102. t. 16. f. 26.)

These three are naturally akin to *rangiferinus*. The following are very different.

*L. globiferus*. n. 110. Mant. 133. Engl. Bot. t. 115. (Coralloides cupressiforme, capitulis globosis; Dill. Musc. 117. t. 17. f. 35.)—Shrubby, solid, much branched, cylindrical, brownish and polished; branches with minute divaricated terminations. Fruit globular, smoothish, enclosing a ball of black powder.—This very pretty coral-like production occurs on mountainous rocky heights, or in dry stony woods. Its *stems* compose loose entangled tufts, of a tawny light polished brown, and are white and solid within; the ultimate branches are innumerable, short, slender, tufted, and divaricated. The *fructification* is altogether different

from every thing we have hitherto described, consisting of terminal solitary balls, the size of a vetch seed, smooth, of the substance of the stem, opening by a wide irregular perforation at the top, and containing a globular mass of black condensed powder, presumed to be the seeds. This plant therefore, by its fructification and habit, has every right to constitute a distinct genus, and is now, with the two following, admitted as such by the name of *Spherophoron*. See LICHENES.

*L. fragilis*. n. 113. Fl. Suec. ed. 2. 425. Fl. Lapp. n. 44. t. 11. f. 4. (Coralloides fragile; Hoffm. Pl. Lich. 34. t. 33. f. 3. Spherophoron fragile; Ach. Meth. 135. t. 3. f. 5.)—Shrubby, solid, brittle, ashy brown; branches level-topped, cylindrical, crowded, naked. Fruit globular, rugose, enclosing a ball of black powder.—Found in similar places with the last, with which most botanists, in Britain and elsewhere, have confounded it, taking the following for the true *fragilis*.

*L. compressus*. (*L. fragilis*; Ach. Prodr. 211. Hudf. 558. Engl. Bot. t. 114. *L. melanocarpus*; Swartz Prodr. 147. Spherophoron compressum; Ach. Meth. 135. Coralloides alpinum, coralline minoris facie; Dill. Musc. 116. t. 17. f. 34.)—Shrubby, solid, cartilaginous, white, branched, compressed; branches clustered, somewhat palmate. Fruit depressed, containing a cake of black powder.—The most elegant of this new genus, remarkable for its white coral-like appearance, having the splendour of porcelain when fresh. The above characters mark it sufficiently. The fruit is rare, produced in moist shady situations only. This species seems to prefer limestone rather than granite rocks.

To a very different family belongs

*L. paschalis*. n. 111. Sp. Pl. 1621. Engl. Bot. t. 282. (Coralloides crispum et betryforme alpinum; Dill. Musc. 114. t. 17. f. 33.)—Shrubby, solid, clothed with minute crustaceous leaves. Tubercles terminal, prominent, brown.—This Lichen, found on a calcareous alpine rocks, is destined to perform an important office in the economy of nature, being the first vegetable that takes root upon lava, whose porous surface will admit no crustaceous species. Thus it composes a decaying a portion of vegetable mould, fit for the reception of the seeds of other plants. Its *roots* and *stem* are very tough and strong, and the assidue lapse of minute greyish-brown *leaves*, that cover the whole, gives it a peculiar and distinct aspect. The tubercles are solid, white within, convex, without any border.

Three species only remain, having little or no affinity to any of the above, or to each other.

*L. trifidus*. n. 112. Web. Goett. t. 5. Swartz. Meth. Musc. 37. Engl. Bot. t. 720. This alpine Lichen has real shields. It occurs among the imbricated species, by Jacquin's name of *rigidus*, n. 42; and it is curious that Murray, the editor, has quoted in both places the same synonym of Haller, n. 1966 t. 47. f. 1.

*L. verrucosus*. n. 114. Suppl. 451. (Stereocaulon tabulare; Ach. Meth. 316. t. 7. f. 2.)—Found at the Cape of Good Hope; It consists of dense, broad, white tufts of low branched *stalks*, tumid and globose at their summits, and agrees altogether in genus, very nearly in species, with Mr. Dickson's *oculatus*, Engl. Bot. t. 1833. Yet professor Acharius considers the fructification of *verrucosus* as unknown, and refers the plant to his genus *Stereocaulon*, of which *paschalis*, n. 111, above-mentioned, is a genuine example.

*L. Roccella*. n. 115. Sp. Pl. 1622. Engl. Bot. t. 211. (Coralloides corniculatum fuciculare tinctorium, fuci teretis facie; Dill. Musc. 120. t. 17. f. 39.)—This we have mentioned in speaking of *tartareus*, n. 25; and *fuciformis*, n. 61.

It agrees very much with the latter, except in being cylindrical, and less soft or flexible, and their shields are exactly alike.—A Cape variety, as it is thought to be, of *Rocella*, is partly cylindrical, partly flat, and much dilated.

Seçt. 9. *Filamentosi*. Fifteen species.

A very curious, striking, and, for the most part, very natural assemblage. Many of them hang in long, black, grey, or white clusters, from the branches of aged pines, oaks, or chestnuts, in alpine forests, to which they give a singular and romantic aspect. Their fronds are filamentous, often a foot or more in length, repeatedly branched, either solid, or apparently jointed, in a beard-like manner, with a central tough fibre; sometimes they are compressed, sometimes pitted; in one nondescript species exquisitely reticulated like lace. The fructification is various and uncertain; in some perfect shields with a true disk, and a border like the frond; in others a spurious kind of shield, *orbillus*, is found, along with coloured seed-bearing tubercles; in others, again, powdery warts only are discoverable.

A few examples will suffice.

*L. plicatus*. n. 116. Sp. Pl. 1622. Engl. Bot. t. 257. (*Ufnea vulgaris*, *loris longis* implexis; Dill. Musc. 56. t. 11. f. 1.)—Filamentous, cylindrical, pendulous, whitish; branches entangled. Shields (spurious) whitish-green, radiated. Tubercles yellowish.—Found in ancient woods. The fronds are excessively and finely branched, a foot or two long, pendent in dense clusters from the trees. Their surface is minutely warty. The proper tubercles, described by Acharius, we have never seen. The spurious shields, his *orbilli*, are rare. The latter are improperly made reddish in English Botany.

*L. divaricatus*. n. 119. Syst. Nat. ed. 12. v. 2. 713. (*Ufnea mollis*, *ramis longis compressis*; Dill. Musc. 62. t. 12. f. 5. *U. flaccida*; Hoffm. Pl. Lich. t. 67.)—Filamentous, pendulous, angular, jointed, pale sulphur-coloured; branches divaricated. Shields sessile, chestnut-coloured, with a narrow border of the substance of the frond.—Native of fir woods on the alps of Savoy, Switzerland, &c. Often a foot and a half long, soft and flexible, conspicuous for its yellowish hue. The shields are those of an Acharian *Parmelia*. See LICHENES.

*L. aurantiaco-ater*. n. 128. Jacq. Misc. 369. t. 11. f. 2, (very badly drawn,) seems to us also a true *Parmelia*, though retained in *Ufnea* by Acharius; see his *Methodus*, 307.

*L. capensis*. n. 130. Suppl. 451. (*Ufnea capensis*; Hoffm. Pl. Lich. t. 10. f. 1.) is properly referred by Acharius to his *Parmelia*.

*L. floridus*. n. 129. Sp. Pl. 1624. Engl. Bot. t. 872. Ehrh. Crypt. 148. *Ufnea vulgatissima tenuior et brevior, cum orbiculis*; Dill. Musc. 69. t. 13. f. 13.)—Filamentous, with a central thread, bushy, erect, greenish-grey; branches round, fibrous, warty, with radiated spurious shields. Tubercles on the branches, lateral, flesh-coloured, rugged.—Not uncommon on dead branches of oaks in old woods, but the *orbilli* seldom occur except on the higher trees, and the real tubercles are extremely rare. The latter were supposed to have been published for the first time in Engl. Bot. vol. xiii. in 1801, but the celebrated Schrader appears to have described though not figured them two years earlier. They are conformable to what have long been known in other genuine species of this tribe. We cannot but think *L. hirtus*, n. 125, Engl. Bot. t. 1354, specifically distinct from *floridus*, of which professor Acharius makes it a variety. The tubercles of *hirtus* grow chiefly on the stem or large branches, which are continued straight beyond them, not strongly bent backwards, as in *floridus*. These species

boiled with wool, without alum, dye it of a rich tawny yellow.

The most minute species of this great genus, or natural order, hold a much more important place in the economy of nature than is apparent to superficial observers. They are the first beginning of vegetation on stones of all kinds exposed to the air, whose decomposing surfaces are the receptacle of their imperceptible seeds, and soon afford nourishment to the sprouting plants, whose minute fibrous roots still further insinuate themselves. The larger species take possession of every cavity and fissure, both of stones and the decaying external bark of trees. In time they all decay, and furnish a portion of vegetable mould, capable of nourishing mosses, or still larger plants. The residuum of these, being still more considerable, is washed by rains into larger cavities, where even forest trees can scatter their seeds, by the penetrating power of whose roots, great masses are dislodged from the most lofty rocks. Thus the vegetable kingdom exercises dominion over the tributary fossil world, and, in its turn, affords the same no less necessary aid to animal existence. Nothing in nature is allowed to remain stationary, idle, or useless, and the most inconsiderable agents frequently appear, in the hands of Divine Providence, to be the most irrefragable. S.

LICHEN, in the *Materia Medica*. The *Lichen islandicus* is a native of Britain, particularly on the mountains of Wales and Scotland. In Iceland this is used as food. For this purpose, a dish of it is prepared by chopping it small, boiling it in three or four successive portions of water to take off its natural bitterness, and then for an hour or two in milk. When cold this preparation has the form of a jelly, which is eaten with milk or cream, and makes a very palatable dish. The medicinal qualities of this lichen have of late been so well established at Vienna, that the plant is admitted into the *Materia Medica* of the Edinburgh Pharmacopoeia, and into the London Pharmacopoeia of the year 1809. It is extremely mucilaginous, and to the taste somewhat bitter and astringent; but its bitterness, as well as the purgative quality which it manifests in its recent state, are in a great measure dissipated by drying, or, as we have already observed, may be extracted by infusion in water. An ounce of this lichen boiled a quarter of an hour in a pint of water, yielded seven ounces of a mucilage as thick as that procured by the solution of one part of gum arabic in three pints of water. Lord Dundonald (*Phil. Mag.* vol. x.) has given the following directions for preparing the mucilage from the lichen. The lichen has an outer skin, covering a green resinous substance; and the remainder of the plant consists chiefly of gum and of silicious matter, on which water does not act. In order to separate the outer skin from the resinous matter, the plant must be scalded two or three times with boiling water, which causes the skin to crack, swell, and peel off. It is then put into a boiler with about three quarts of water for every pound of the plant, and about half an ounce of potash or soda, and the boiling should be continued till the liquor acquires a considerable degree of gummy consistence. The liquor is then to be taken out and strained from the plant, and fresh water added to the same material, for the purpose of further exhausting the gum. The several liquors, after standing some hours to settle, and then removing the dregs, are to be boiled down in a regulated heat to the consistence which is required for use, but not further, lest it should burn and become coloured. Two or three boilings will be necessary for entirely exhausting the lichen of its mucilage.

The medicinal virtues of this lichen were probably first

learned from the Icelanders, who employ it in its fresh state as a laxative; but deprived of this quality and properly prepared, it is said to be an efficacious remedy in consumptions, coughs, dysenteries, and diarrhoeas. Dr. Crichton informs us (Med. Journ. vol. x.), that during a residence of seven months at Vienna, he had frequent opportunities of seeing the lichen islandicus tried in phtisis pulmonalis at the General Hospital, and he confesses, "that it by no means answered the expectation he had formed of it." He adds, however, "from what I have seen, I am fully convinced in my own mind, that there are only two species of this disease, when this sort of lichen promises a cure. The two species I hint at, are the *phtisis hæmoptæica*, and the *phtisis pituitosa*, or *mucosa*. In several cases of these I have seen the patients so far get better of their complaints, as to be dismissed the hospital cured; but whether they remained long for or not, I cannot take upon me to say." That this lichen strengthens the digestive powers, and proves extremely nutritious, there can be no doubt; but the great medicinal efficacy attributed to it at Vienna will not readily, says Dr. Woodville, be credited at London. It is commonly given in the form of a decoction, an ounce and a half of the lichen being boiled in a quart of milk. Of this a tea-cup full is directed to be drank frequently in the course of the day. If milk disagree with the stomach, a simple decoction of the lichen in water is to be used. Care should be taken to boil it over a slow fire, and not longer than a quarter of an hour. In the London Pharmacopœia the decoction is directed to be prepared by boiling down an ounce of the lichen in a pint and a half of water to a pint, and then straining it.

The *lichen caninus*, or *cineræus terrestris*, which grows on heaths, dry pastures, and woods, has a weak faint smell, and a sharpish taste. It was for a long time extolled as a medicine of singular virtue in preventing and curing that dreadful disorder which is produced by the bite of rabid animals. The "pulvis antilyssus," a powder composed of equal parts of this lichen and black pepper, was first recommended as a preservative against the rabies canina by Mr. Dampier, brother of the celebrated circumnavigator, and by the authority of sir Hans Sloane, it was published in the Philosophical Transactions, (vol. xx. p. 49.) The quantity of pepper having been found to render the medicine too hot, the powder was afterwards prepared of two parts of the lichen and one of pepper. This powder was afterwards adopted in the London Pharmacopœia in 1721, at the desire of Dr. Mead, who seems to have had repeated experience of its good effects, and who declares that he had never known it to fail, where it had been used, with the assistance of cold-bathing, before the hydrophobia came on. He directs the patient to be blooded to the extent of nine or ten ounces; afterwards a dram and a half of the powder is to be taken in the morning fasting, in half a pint of cow's milk warm, for four mornings successively. After these four doses are taken, the patient is directed to go into the cold-bath every morning for a month, and then three times a week for a fortnight longer. On the character of Mead, the pulvis antilyssus was long retained in the London Pharmacopœia; but on the revision of that book in 1788, it was deservedly expunged. Woodv. Med. Bot. See *ANTILYSSUS Pulvis*.

**LICHEN**, in *Medicine*, a cutaneous eruption, consisting of *papule* (pimples), affecting adults, connected with internal disorder, and usually terminating in scurf. It is not contagious.

Such is the character of an eruption, to which Dr. Willan has appropriated the term *lichen*, in his valuable treatise

on cutaneous disorders. (Order i. Genus ii.) In the writings of Hippocrates, he remarks, the term lichen, or lichenes, (*λιχηνες*) is employed to express an eruption of papule, and he did not include under that appellation any pustular disease. There is, however, an extreme confusion, as in the case of almost every other denomination of cutaneous affections, among the subsequent writers, in the acceptance of the word. The later Greek authors extend the application of it, so as to comprehend a pustular affection of the face, sometimes called *sycofis*, and likewise the *menagra*, a contagious disease, together with the simple and rank lichen (*λιχην αγριος*). Pliny in one passage (Nat. Hist. l. xx. cap. 1.) seems to use the term lichen as synonymous with the *impetigo* of the Latins: he is, however, inconsistent with himself in other places. The only author to whom we can refer for a definition of *impetigo* is Celsus; and his account of it does not, in any respect, correspond to that which the Greeks have given of the lichenes. Under the denomination of *papula*, Celsus has comprised, and accurately described, two varieties of lichen, the *L. agrius*, and *L. circumscriptus*; and he has correctly stated the real relation between the lichen and impetigo, when he says, that "the papula agria, through neglect or improper treatment, is often changed into impetigo." (De Med. lib. v. cap. 28.) Nevertheless, all the translators of the Greek medical writers have used *impetigo* as synonymous with the original term lichen; and their example has been followed by many respectable authors on the subject of cutaneous disorders.

By more modern writers, again, the lichen has been arranged under other genera of disease, with which it has still less affinity than with impetigo. Thus Sauvages describes it under the title of herpes farinosus; and Lorry confounds both lichen and impetigo with herpes: while Plater, Hafensser, and others, arrange lichen under the genus scabies. By adopting the character of the lichen, stated by Dr. Willan, we may avoid this extreme degree of confusion.

An eruption, thus characterized, occurs under five or six varieties of form, to which Dr. Willan has appropriated the following titles: 1. *Lichen simplex* is preceded by symptoms of feverishness, or rather by a state of irritation not amounting to fever, which is relieved after five or six days, on the appearance of the eruption. This consists of distinct red papule, with but little inflammation round their base, first appearing on the face or neck, and spreading thence over the body and limbs. In about a week, the colour of the eruption fades, and the cuticle separates in scurf. The duration of the complaint, however, is seldom in two cases alike; from fourteen to twenty, or thirty days, sometimes intervene between the eruption and the renovation of the cuticle. It occurs, as well as some other of the species, annually about the beginning of summer, or in autumn, in persons of a very weak and irritable constitution. 2. *Lichen pilaris* is merely a modification of the foregoing species, the papule appearing only at the roots of the hairs of the skin. 3. In the lichen *circumscriptus*, or papulated ring-worm, the papule are arranged in clusters, or patches, which are of an irregular form, but with a well-defined margin, and appear in succession on the limbs or trunk of the body, sometimes by repeated eruptions, lasting for six or eight weeks. It is excited both by internal and external causes of irritation, and is at first attended with slight febrile symptoms for a day or two. 4. *Lichen agrius* is preceded by nausea, pain in the stomach and limbs, with shivering and depression of strength for several days, which sometimes diminish when the eruption appears. The papule are distributed in great numbers in various parts of the body, face, and limbs, having a high red

red colour, and being attended with itching, heat, and painful tingling. The redness is augmented, and a sensation of burning and smarting is excited by the warmth of bed, by washing, especially with soap, by violent exercise, or wine. Its duration is uncertain. Women are more liable to it than men; and it affects those especially who have undergone long continued fatigue, watching, and anxiety. In men it is often produced by the intemperate use of spirituous liquors.

*Cure*.—Every thing heating or stimulating should be avoided, whether great exercise, or stimulant food and liquors; gentle laxatives should be used; and the skin should be washed with warm-water, or thin gruel, by which the irritation and itching are alleviated. All frong applications are improper, and aggravate the complaint, producing intolerable smarting. Mild cooling ointments, as the rose-potatum, relieve the uneasy sensations of heat and itching.

Two other varieties of lichen are noticed by Dr. Willan, one of which he terms lichen *lividus*, and the other *L. trospicus*. The former of these is characterised by papulæ of a dark or livid hue, is more permanent than the species before described, and principally affects persons of weak constitutions, who live on a poor diet, and labour hard, or reside in close situations. The lichen is sometimes intermixed with *petechiæ* in the latter cases, or larger purple patches, which point out its affinity with the *purpura*, or land-scurvy. It is cured also by the same means as are successful in the latter disorder; namely, by nourishing food, moderate exercise in the open air, with the use of cinchona and sulphuric acid, or the tincture of muriate of iron. The lichen tropicus signifies the eruption which is well known in hot climates by the appellation of *prickly heat*, of which we have already given some account. See HEAT, *Prickly*.

LICHENASTRUM, in Botany, so called by Dillenius, from its affinity to *Marchantia*, his *Lichen*. See JUNGERMANNIA.

LICHENES, a Natural Order of vegetables of the Cryptogamic class, (*Aspidospora* of Wiggers's *Hollat*. 85.) allied on one hand to the *Algae*, in which it was included by Linnæus, and on the other to the *Fungi*, with many of which it nearly agrees in habit, and with some of them very strikingly in the character and situation of its seeds. This family has risen gradually to the consequence it now holds among botanists, first by the labours of Dillenius and Micheli, and next by those of Linnæus and his pupils; but the celebrated Dr. Acharius, professor at Vadstena in Sweden, has finally elucidated it fully, with respect to characters and synonyms, in several separate works; not merely as a genus, but as a natural order, comprising many genera. Professor Hoffmann indeed, and other German botanists, had already considered it in the same light; but none has so completely treated the whole subject as this learned Swede. For a general view of the nature of this family, with the leading sections to which its species have been reduced, see LICHEN. We shall now proceed to explain what has been done towards its generic sub-division, the first attempt at which, by the fruit, was made in Wiggers's *Primitiæ Fl. Holsaticæ*, a work of which Weber, in a copy before us, claims being the author.

It would be tedious and difficult to trace minutely every step in the progress of those who have at any time adverted to the generic distribution of Lichens. Weber's is but a rude attempt. The labours of Hoffmann, having led the way to Acharius, require some previous explanation.

That writer, in his *Flora Germanica*, v. 2, published in 1795, established an order of *Cryptogamia Scutellata*, as distinct from *Alge*, which is intended to embrace all the certain

*Lichenes*, though it does not, in fact, admit all that are reckoned such by Acharius. It is thus defined.

*Scutellata*. Female fructifications in orbicular, flat or convex fields, radiated or naked, bordered or without a border, or spirally twilled, fixed to the frond either by their centre or their margin; and this frond is either gelatinous, coriaceous, umbilicated, caulescent, strap-like, filamentous, leafy, tartarous, or leprous; its duration perennial, throwing out various buds or offsets. Each field contains seeds within its fibrous or spongy substance.—This order contains nine genera.

1. *Collema*. Frond pellucid, gelatinous. Shields bordered.—This comprehends the gelatinous Lichens of other authors, of which 26 species are here described as natives of Germany. (See LICHEN; sect. 4. n. 48.) *Collema* is recently admitted as a genus in *Engl. Bot. v. 32. t. 2284*, where the essential character is “*Shields orbicular, horizontal, nearly sessile, superficial, with a gelatinous accessory border*.” There can be no doubt of its constituting one of the most natural genera to be found in any order.

2. *Peltigera*. Frond coriaceous. Shields (or targets) compressed, attached by their margin.—The true coriaceous Lichens, sect. 5, as *resupinatus*, *caninus*, &c.; nine species in Germany.

3. *Umbilicaria*. Frond leafy, peltate. Shields contorted.—Ten species. The umbilicated Lichens, sect. 6; *Gyrophora* of Acharius.

4. *Cladonia*. Frond caulescent, cylindrical, hollow. Shields tubercular.—Thirty-seven species.—This genus embraces not only those of the Linnæan *fruticulosa*, sect. 8, to which *rangiferinus* belongs, but likewise all the *scyphoseri* (or *pyxidati*) sect. 7.—Thirty-seven species are described.

5. *Stereocaulon*. Frond caulescent, cylindrical, solid. Shields tubercular, globose.—This is, perhaps, the most exceptional genus, confounding *L. paschalis*, (see LICHEN, sect. 8. n. 111.) along with the powdery-fruited kinds, *globiferus*, *fragilis*, and *compressus*; and with these the coral-crusted tribe, which make the Acharian genus *Idium* hereafter mentioned. Even *L. niger* of Hudson and Linnæus, *Engl. Bot. t. 1161*, perhaps more akin to *Collema*, though its shields have no border, is joined with them. The whole however make but nine species.

6. *Ufnea*. Frond strap-like, or filamentous. Shields radiated or naked.—Equivalent to the *filamentosa*, sect. 9, of Linnæus. Sixteen German species.

7. *Lobaria*. Frond lobed, lacinated, much divided, erect, or depressed. Shields bordered.—This large and rather multifarious genus, comprehending 62 German species, is divided into four sections, which perhaps run so much into each other as to justify the whole assemblage. They are

\* *Platysma*. Frond (mostly) pitted.  
To this belong many of Linnæus's sect. 4, *foliacei*, as the *farinaceus*, *frazineus*, and their allies. To these the *rigidus*, which is *trifidus*, n. 112, of the Linnæan arrangement, is sub-joined. Then follow *islandicus*, &c.; then *furfuraceus*, Linn. n. 53. *Engl. Bot. t. 984*, and *ciliaris*. All these are characterised as having a pitted or cellular frond, which is more or less erect. They are however a very various tribe.—Five species have a pitted depressed frond, as *saxatilis*, and *pulmonarius*, Linn. n. 52. *Engl. Bot. t. 572*.—Twelve are defined as having a dilated frond, in which *saccatus* is included, with *caperatus*, *perlatus*, *parietinus*, and others, which are by no means naturally allied, nor is the character expressive, if it means absolutely that the frond is never pitted, or that it is more dilated than in the preceding ones.

\*\* *Phycia*. Frond inflated, as in *L. physodes*, Linn. n. 44. *Engl. Bot. t. 126*.

## LICHENES.

\*\*\* *Squamaria*. Frond narrowly divided, as in *stellaris*, and its numerous allies.

\*\*\*\* *Placidium*. Frond crustaceous, obscurely imbricated. In the beginning of this section, several species occur which are not really crustaceous, and which are closely akin to *stellaris*, though more depressed. True examples of *Placidium* are *L. javicola*, Engl. Bot. t. 1695; as well as *candicans*, t. 1778; and *gelidus*, Linn. n. 23.

8. *Pfora*. Crust figured. Shields bordered, convex.—Twenty-six German species are enumerated under this genus, many of which are among the imbricated Lichens of Linnæus, others amongst his leprous or crustaceous ones. In all of them the crust is either formed into leaflets, or granulations of a determinate shape, seated on a homogeneous white chalky basis, the outer surface being variously coloured.

9. *Verrucaria*. Crust leaflets, leprous, tartareous. Shields with or without a border.—This genus comprehends most of the leprous Lichens of Linnæus. See LICHEN, sect. 1 and 2. Seventy-one German species are defined, disposed according to the colours of their shields.

Such is the method of Hoffmann, who in his sumptuous and truly excellent work, entitled *Plantæ Lichenosæ*, consisting of three thin folio volumes, with seventy-two fine coloured plates, has described and figured a great number of species from all parts of the world. This book however does not exactly agree in generic distribution with his *Flora Germanica*, but they are easily compared together. The same writer has left unfinished an *Enumeratio Lichenum*, in quarto, begun in 1784, of which we have 102 pages, and 22 uncoloured plates, very finely drawn by the author. In this book *Lichen* stands as one genus, divided into several sections; improperly termed orders.

Professor Acharius, above-mentioned, having previously in several papers, with plates drawn by himself, in the Stockholm Transactions, elucidated various species or tribes of Lichens, published in 1798 his *Lichenographiæ Suevicæ Prodrômus*, in one volume octavo, with coloured figures of five species only. This work marks an era in cryptogamic botany. Though it professes to treat of Swedish Lichens only, it in fact indicates all of which the learned writer could discover any tidings, with their specific characters, synonyms, and places of growth, besides innumerable valuable observations. The whole are ranged under the name of *Lichen*, as one genus, but divided into twenty-eight tribes, or sections, of which the genera of Hoffmann form the basis. These tribes compose three families, under whose subdivisions we shall indicate them all. The peculiar terms which occur will be explained hereafter.

### Family 1. CRUSTACEOUS LICHENS.

Having a crustaceous, more or less expanded, base.

A. Crust irregular, powdery, or in fibrous flakes.

1. *Lepraria*. Receptacles scarcely known.—(Most of these come under the genus *Byssus* in Linnæus.)

B. Crust solid, flattish, uniform, nearly orbicular.

2. *Verrucaria*. Receptacles (*thalami*) hidden in the crust, roundish, concave, opening by a perforation at the top.

3. *Opegrapha*. Clefts (*lirellæ*) closely attached to the crust, and opening longitudinally.

4. *Variolaria*. Powdery little masses (*glomeruli*) attached to the surface of the crust.

5. *Ureolaria*. Shields hollowed, sunk in portions or warts of the surface of the crust.

6. *Patellaria*. Shields attached to the surface of the crust, either concave or flat, with a border, or convex and hemispherical, with scarcely any.

7. *Bæomyces*. Tubercles smooth and even, nearly globose, fungus-like, terminating elevated stalks.

8. *Calicium*. Tubercles stalked, lenticular, opening by a torn border, discovering a powdery elevated disk.

C. Crust unequal, composed of coral-like, crowded little branches.

9. *Isidium*. Tubercles terminal.

D. Crust rather leafy.

10. *Pfœroma*. Crust irregular, covered with minute somewhat imbricated scales. Shields lateral, as well as marginal.

11. *Placidium*. Crust globe-puffed, flat, orbicular, with a lobed permanent margin. Shields lateral.

### Family 2. LEAFY LICHENS.

Without a stem, and consisting of a simple or multiplied, sessile, divided, somewhat membranous leaf.

E. Receptacles scattered, sessile on the leaf.

12. *Imbricaria*. Shields and powdery masses (*glomeruli*) lateral. Leaves membranous, depressed, imbricated, spreading circularly, minutely fibrous underneath.

13. *Collema*. Shields lateral and marginal. Leaves gelatinous.

14. *Endocarpon*. Receptacles (*thalami*) hollow, immersed in the leaf, opening by a prominent mouth. See EXOCARPON.

15. *Umbilicaria*. Receptacles (*trixæ*) convoluted, raised. See GYROPHORA.

16. *Lobaria*. Shields and powdery masses lateral. Leaves somewhat coriaceous, widely spreading, ascending, villous underneath.

17. *Sticta*. Shields scattered; or Targets marginal. Leaves somewhat coriaceous, stamped beneath with little bald pits, amongst down.

18. *Peltidea*. Targets lateral and somewhat marginal, on the front or back of the leaf. Leaves coriaceous, mostly veiny, as well as downy, beneath.

19. *Platyma*. Shields target-like, scattered. Leaves membranous, ascending, crisp, naked on both sides.

20. *Physcia*. Shields scattered. Leaves rather cartilaginous, smooth, tufted, linear and jagged.

F. Receptacles elevated far above the leaves, on the tops of stalks.

21. *Scyphophorus*. Tubercles on hollow stalks, dilated upwards, and closed.

22. *Helopodium*. Tubercles fungous, on nearly solid, simply sub-divided stalks, scarcely dilated upwards.

23. *Cladonia*. Tubercles nearly globose, on taper-pointed, elongated, tubular, branched and shrubby stalks.

### Family 3. CAULESCENT LICHENS.

Stems either solid, branched, round and shrubby, or elongated and thread or strap-like.

G. Shrubby, with solid rigid stems.

24. *Stereocaulon*. Shields globose, solid, scattered.

25. *Sphaerophorus*. Cellules terminal, finally bursting.

26. *Cornicularia*. Shields radiated, at length rather convex, terminal.

H. Filamentous, elongated.

27. *Selaria*. Shields and powdery masses lateral. Branches naked, smooth and contiguous.

28. *Ufnea*. Shields flat and radiated, or convex and slightly bordered, scattered; as well as powdery masses. Branches with a crustaceous, somewhat jointed, coat.

It will easily be seen, by comparison, how far these sections answer to Hoffmann's genera. The first five have nothing corresponding with them. *Patellaria* is equivalent to his

## LICHENES.

*Verrucaria*, at least in idea. *Beomyces*, *Scyphophorus*, *Helopodium*, and *Cladonia*, are included in his *Cladonia*. *Pforoma* and *Placodium* are his *Pfora*. *Collema*, *Peltidea*, (his *Peltigera*), *Umbilicaria*, and *Usnea*, agree with his. *Calcium*, *Isidium*, *Endocarpon*, *Sticta*, *Sphaerophorus*, and *Cornicularia*, are not found in his system, except that *Sphaerophorus* is, in his *Pl. Lieb.*, called *Coralloids*. *Imbricaria*, *Lobaria*, *Platisma*, and *Physcia* are nearly comprehended under his *Lobaria*.

It is to be remarked that, in his generic characters, Hoffmann takes the habit into consideration. To this perhaps Acharius, as a philosophical Linnæan, had objections, which induced him to consider these different assemblages of species rather as sections of one great natural genus, the fructification being still much in the dark. In 1803 however he published his *Methodus*, in 8vo. with eight coloured plates, and, soon after, a supplement. In this new work, still keeping the Linnæan principle in view, he aimed at distinguishing the *Lichenes*, as a natural order, into several genera, by the fructification alone. Before we detail these, it is necessary to take a view of the physiology of the order, as explained in his able preface, as well as of his technical terms. Both these subjects are treated also in the preface to his *Prodromus*; but it is best to consider here his latter view of them only, and they are so united together, that an explanation of the terms will sufficiently elucidate the physiological ideas of the author.

*Thallus* is used by Acharius for the whole plant, or herbage, of a *Lichen*, the *frons* of Linnæus (see *FROND*); distinct from every thing belonging to the fructification. It is root, stem, stalk, and leaf, all in one, its substance seeming to assume the nature of either, according to circumstances; but this is, in some measure, the case with every vegetable body, and by no means peculiar to a *Thallus* or *Fronde*. Acharius is unwilling to use the latter word for a mere shapeless crust or mass of powder; but we confess ourselves unable to discover any use, or indeed any distinct meaning, in the new term, unless it were restricted to such crust or powder. Its meaning moreover, *θαλάσσιος*, a *green bough*, is precisely equivalent to *frons*; but this objection is not material.—Of the different forms and textures of this part, we have sufficiently spoken under the article *LICHEN*. It is an essential part, though sometimes nearly or quite destroyed by age, though the fructification may still, for a while, remain.

*Apothecium* (*αποθήκη*, a *receptacle*), is the *receptaculum* of Linnæus, the part where the seeds are formed and brought to maturity. Acharius defines it as “bearing, encompassing, or containing the organs subservient to the propagation of Lichens; distinct in figure, generally in colour and nature, from the *thallus*, or frond, on which it is situated, and which sometimes furnishes it with an exterior covering.” The fecundation having taken place, in some manner unknown to us, within the frond, these receptacles, (as we must still beg leave to call them,) gradually increase, and finally expose their internal part, which is either occupied by a fibrous texture, more or less dense, or is, when moist, in some measure gelatinous, rarely appearing hollow. Their shape is most frequently roundish, but otherwise very various, as has been already explained. (See *LICHEN*, sect. 1.) When ripe they discharge their seeds, either naked, or contained in cases. Sometimes, though rarely, their under-side produces naked seeds. To the various situations of these receptacles, the generic characters already explained have sufficiently alluded; their various kinds have also been mentioned, but will now be more fully described. Hedwig and Gärtner differ about the seeds of Lichens; the latter supposing them (for it is entirely supposition) to be rather of the

nature of buds or offsets, which he terms *propagines*, and not actual seeds produced by sexual impregnation. The reason for this opinion seems to be, that the mode of such impregnation has not been discovered, any more than in ferns or sea-weeds.

Acharius defines thirteen sorts of receptacle, or *apothecium*.

1. *Scutella*, shields. These are open, orbicular, compared by Dillenius to a saucer; their border, and under-side, of the substance, and usually of the colour of the crust, or leaf. Their disk, (*stratum proliferum* of Acharius) almost always differing in colour, and totally distinct in substance from the margin, contains the seeds in the vertical parallel cells of its internal substance. Their border is termed an *accessory*, not a *proper*, one. The shields are either thick, tumid, entirely sessile, or even funk, as in many crustaceous Lichens; or membranous, often elevated, somewhat stalked; very rarely they become perforated in the centre.

2. *Patellula*. Spangles. (See Dillenius, p. 133.) Open and orbicular, like shields, but sessile, and by no means formed of any part of the crust, from which they differ in colour, being most usually black. The seeds are lodged beneath the membrane that covers their disk, as in the former; and the disk is surrounded by a *proper* border, that is, of its own substance and colour. Their seeds are observed to be naked in the cellular substance of the disk, not inclosed in cases. The figure of the *patellula* is not liable to much variation, except that the disk is sometimes concave, sometimes flat, but more frequently convex, and in an advanced state often globose, so that the border disappears. This kind of receptacle is properly that of the *leprosus tuberculatus* Lichens of Linnæus, and belongs to the genus *Lecidea* of Acharius.

3. *Cypbella*. Pits. Open cup-like little naked, white or yellow spots, on the under, generally downy, side of the leaf, in the Acharian genus *Sticta*; see Engl. Bot. t. 2298, 2359. They are at first minute dots, globose, and immersed in the substance of the leaf; at length they burst, with an irregular margin, and discharge a powder, which Acharius, who has first defined and named them, supposed to be of “a spermatic nature;” by which we presume he means of the nature of pollen.

4. *Lirella*. Clefs. Open, elongated, sessile, black receptacles, with a somewhat spongy, very narrow, or quite linear disk, and a proper border, parallel to it on each side. Sometimes there is an accessory border from the crust besides. This is the peculiar fructification of the genus *Opegrapha* of Perfoon; see Engl. Bot. v. 25 and 26 especially. The *lirella* are either simple and solitary, or aggregate, confluent, and branched. These differences often occur in the same species. *L. scriptus* of Linnæus is a specimen of the genus.

5. *Pilidia*. (*πιδίον*, a little cap or hat.) Puffs.—Little round bordered knobs, whose disk, at first covered with a membrane, and often clothed with fine grey hoariness, finally turns to powder. They are elongated below into a stalk, fixed to the crust, but totally different from it. *Calcium* of Perfoon has this sort of fructification.

6. *Orbilla*. Orbs. Flat, orbicular and dilated, of the substance of the frond, terminal, peltate, without a border, but often surrounded with radiating shoots. The membrane, or disk, under which the seeds are lodged, is smooth, mostly of the colour of the frond. These are seen in the filamentous Lichens, or *Usnea*. Spurious *orbilla*, bordered like shields or spangles when young, are found in some *Cornicularia* of Acharius.

If *orbilla* produce real seeds, the filamentous Lichens have two kinds of fruit, for they bear also proper tubercles, or rather

rather *cephalodia*; see n. 12. But we cannot easily assent to this; see *Ufnea* hereafter.

7. *Pelva*. Targets. Flat, closely pressed, and attached by their whole under-side, as if glued, to the frond, sometimes at its back. They are broad, kidney-shaped or oblong, rarely irregular, covered with a thin coloured disk, with no border, except occasionally a very minute accessory one, which seems to circumscribe them. In an early stage they are concave, and concealed by a thin gelatinous fugacious membrane, or veil. (See LICHEN, sect. 5.)—The genus *Cetraria* is thought by Acharius to have spurious *pelva*, with a more evident border, entire, crenate or lobed, which is unconnected with the frond beneath, though the greater part of the receptacle is closely attached thereto, and sometimes sunk into its substance.

8. *Trica*. Buttons; (*Dill.*)—Roundish, sessile, unexpanding receptacles, of a peculiar, compact, black, solid substance, continued along their whole surface. Their upper side is distinguished by concentric or plaited and twisted folds, covered by one common membrane through all their convolutions, and lodging in their inside naked seeds, destitute of cases, or cells. See *Gyrophora*, to which these buttons are peculiar.—Sometimes the presence of but one marginal fold gives this kind of receptacle the appearance of a *patellula*, see n. 2; but others will usually be found with more, on the same plant, even in *Gyrophora pusillata*, Engl. Bot. t. 1283.

9. *Thalamia*. Hollows.—Spherical, nearly closed receptacles, lodged in the substance of the frond, lined with a proper coat, under which, in their spongy texture, are cells, each containing from two to four seeds. Each hollow finally opens by an orifice in the surface of the frond above, which sometimes supplies it with a spurious border. These are the proper receptacles of *Endocarpon*; see that article.

10. *Tubercula*. Tubercles.—Spherical, or slightly conical, nearly closed, crustaceous, black, more or less immersed in the surface of the crustaceous frond, or *thallus*, which they elevate; or sometimes they are exposed, being merely sessile. Each contains a ball or mass of connected seeds, destitute of cells, but enveloped in one common membrane, and the whole are finally discharged together by an orifice at the top of the tubercle. Such is the fruit of *Verrucaria*, and if this account be correct, that genus is certainly as distinct in fructification as in habit from *Endocarpon*. The nature of these minute parts is very hard to determine, especially as the tubercles of *Verrucaria* often come under our inspection after they are emptied of their contents.

It must be remembered that Acharius here uses the term tubercle in a restricted sense, and not with that latitude habitual to Linnæus and his followers, amongst whom it commonly, when applied to Lichens, means almost any thing that is not a *field*.

11. *Cistule*. Cellules.—Globose terminal receptacles, formed out of the substance of the frond, filled with uncoated seeds intermixed with fibres, and at length bursting irregularly; as in *Sphaerophoron*. See LICHEN, sect. 8.

12. *Cephalodia*. Knobs.—Convex, or more or less globular, covered externally with a coloured seed-bearing crust, and placed generally at the extremities of stalks originating from the frond (being rarely sessile and scattered as in *Stereocaulon*), permanent. Such are seen in *Baomyces*, or the Cup-bearing Lichens. (See LICHEN, sect. 7.) In some of the filamentous tribe, *Ufnea*, they are at first like *patellula*, and sessile, becoming afterwards convex and irregular. See *orbille*, n. 6.—*Cephalodia* are sometimes simple, sometimes compound or conglomerated.

13. *Globuli*. Globules.—Globose, solid and crustaceous, formed of the substance of the frond, and terminating its points or branches, from whence they fall off entire, leaving a pit or cavity. They are supposed to be covered all over with a coloured seed-bearing membrane, and are taken for one of the modes of fructification in the *Isidium* of Acharius; see hereafter.

Acharius explains as follows certain terms used in his descriptions of Lichens.

*Theca* are the cases or cells containing the seeds, in the disk of most receptacles, at least in *scutelle*.

*Spore* are the seeds, of whose nature very little is known. This author declines calling them *femina*, because they are presumed to have no cotyledons; but that is no sufficient reason. The question is, whether they are produced by sexual impregnation; if not, they are *gemma* (buds or offshoots). We need not here repeat what is said under the article *GEMMA*.

*Propagula* are those little roundish deciduous bodies, commonly termed *powder* in speaking of these plants, but which may be called the *efflorescence*. These bodies are either dispersed or clustered on the surface of the frond, and each of them is asserted by Schreber to be a hollow vesicle, and by Hoffmann to discharge, through an orifice, a quantity of fine dust. They are also not unfrequently powdery at their outside; sometimes interwoven with very short and slender threads, and finally pass into what is supposed by Acharius to be an assemblage of minute buds, *gemma*.

Acharius observes, that "some have taken these bodies for pollen, or male flowers; but that this conjecture is utterly contrary to the observations of Micheli and Schmidt, who saw them germinate, and produce offspring." Schmidt's remarks we have not seen, but Micheli certainly asserts, in his *Nova Plantarum Genera*, 74, t. 41, Q, R, that he saw this powdery matter germinate, and produce plants, in the cup-bearing tribe of Lichens. He therefore takes the shields and their contents, which he has delineated in his t. 52, for male blossoms, and this opinion was adopted by Linnæus. Hedwig nevertheless, in his *Theoria*, p. 120, strongly combats this doctrine, asserting that Micheli might easily be mistaken, as the real seeds, visible only with a very high magnifier, would escape observation, when fallen among the powder, and vegetating there, would cause the young plants to seem the offspring of the latter. Gærtner thinks the powder is of the nature of buds; but his opinion is equally theoretical with that of Adanson, who takes the contents of the shields for seeds. Acharius adopts both these opinions, and offers an ingenious conjecture of his own, which is, that the powdery buds may be destined to produce individual plants that propagate themselves subsequently by the same mode; while the seeds of the shields or tubercles may produce complete fructifying plants, which go on to increase by seed. Hence, his genus *Lepraria*, as he presumes, propagates itself by the former means, without any other. We confess this genus is very puzzling; but when so conspicuous a plant as *Lemna* has so long flowered and fruited without observation, and supposed *Lepraria* are from time to time detected with fields, we are disposed to attribute much to our ignorance. We certainly cannot agree with Dr. Acharius when he goes so far as to suggest that the seeds, which originate from the shields, may sometimes produce shields alone without any frond! The latter is well known to be now and then fugacious, and so is invariably the root of *Cuscuta*, though absolutely essential to the young plant. It is very desirable that some person should see the germination of the seeds of Lichens, taken from the fields; though there seems little reason to doubt

their being such, whatever the powdery masses or warts may be. We are chiefly led by the observation of Hoffmann, above-mentioned, to persist in the opinion of Hedwig. If the powdery granules in question be really vascular, and emit a dust, it is so analogous to the anthers of all other known plants, and so unlike the nature of *gemmae*, that, if the contents of the shields can be proved to be seeds, of which indeed we have no doubt, there would be little reason to hesitate respecting the others. We do not mean that every granular appearance about the fronds of Lichens must be anthers. Much of it, doubtless, is gemmaceous, but anthers may accompany it; and the latter may in *Lepraria* impregnate minute or solitary seeds, that also accompany the granules, and that have hitherto escaped detection.

*Soredia* are assemblages of the above powdery bodies, collected on a sort of receptacle. This Acharius exemplifies by *Variolaria*, as will be mentioned in speaking of that genus. Some *soredia* originate from cracks in the frond.

*Pulvinuli* are excrescences found occasionally on the surface of the frond, often clustered or branched, whose use and nature are unknown. They occur in *Gyrophora pustulata*; but are most remarkable in *Lichen glomuliferus* of Lightfoot. See Engl. Bot. t. 293.

*Verrucae* are variously-shaped protuberances, solid, and usually smooth, originating from the crust, and sometimes, though rarely, bearing or lodging the fructification, as in *Lichen pertusus* of Linnæus. See Engl. Bot. t. 677; also t. 2317. 2336.

*Podetia* are stalks elevating the fruit, as in the Cup Lichens, and are either solid or hollow.

*Lorulae* are the long thread-like branches of the *Ufnea* tribe.

We are now to take a compendious view of the genera of the Lichenes, as defined in the *Methodus* of Acharius, upon principles dependent on the parts of fructification, or, at least, propagation. These genera are 23, disposed in three sections.

SECT. I. STEREOTHALAMI; (from *στερω*, to deprive, and *θαλαμος*, a bed.)

Receptacle none. Organs of propagation naked, scattered or aggregate.

1. *Pulveraria*. Efflorescence powdery, collected into tufts by fine, slender, interwoven threads. (Frond none.)

This genus is now reduced by its author to the following. See *Lepraria chlorina*, Engl. Bot. t. 2038, a most beautiful production, which covers rocks with a coat many inches, or some feet, broad, resembling bright lemon-coloured cloth or velvet.

2. *Lepraria*. Efflorescence somewhat globular, scattered loose over a crustaceous base, which it often entirely covers superficially. (Frond crustaceous, indeterminate.)

This, like *Pulveraria*, comes under the *Elysius* of Linnæus, who has described some species of it. The most common is *L. botryoides*, Ach. n. 7. Engl. Bot. t. 2148, seen every where on the trunks of trees, and on posts, to which it gives a green colour in winter. Another very common species, *incana*, n. 2, has been found with *patellulae*, which make it a *Lecidea* of Acharius. See Engl. Bot. t. 1683; as has his *lephæma*, n. 3, which is his *Lecidea* (or rather *Parmelia*) *Stonæ*; Meth. 65; *Lichen Hæmatomma*; Engl. Bot. t. 486. *Lepraria rubens*, n. 6, is *Conferva lichænicola*; Engl. Bot. t. 1609; and probably Michel's *Lichen crustaceus, arboribus adnascens, tenuissimus, pulverulentus, ruber*; Nov. Gen. 100. n. 73.

Wiggers, or rather Weber (see the beginning of this article), places this genus (under the name *Lepra*, by which

Haller had previously distinguished it), in his order of *Asperma*, defined as "defluite of fructification." But many of the plants, which he refers to that order, are now known to have seeds, and his genera are liable otherwise to much exception.

3. *Spiloma*. Efflorescence? in shapeless, superficial masses, woolly and powdery, rigid. (Frond crustaceous, indeterminate, thin, uniform.)—Of this genus several species may be seen in Engl. Bot. v. 29 and 30. Notwithstanding the above character, the crust may be seen to be determinate, or limited, in Engl. Bot. t. 2150, where it has a very distinct and curious border.

4. *Variolaria*. Efflorescence globose, collected in distinct assemblages (*soredia*). (Frond crustaceous, mostly determinate.)—Great light has been thrown upon this genus since the publication of the *Methodus* of Acharius. See Turner Tr. of Linn. Soc. v. 9. 137—140, and Engl. Bot. v. 28. t. 2008; v. 29. t. 2061; so that it is now removed by Acharius himself to the second section of his *Lichenes*, as having true receptacles. It seems indeed, in our opinion, to give no small support to the theory of the powdery efflorescence (*propagula*), above-described, being the male part of the fructification. *Variolaria* has true receptacles, seated on a thick tartareous crust, which supplies them with an accessory border, of more or less thickness or regularity. Their disk, or space within the border, is occupied with an assemblage of the powdery substance in question, of which so much has already been said, and under which has been observed, in several species, a coloured fleshy or waxy disk, lodging seeds (as we all presume them to be) in vertical cells; like a true shield. Here then the two sexes seem united in one receptacle. In some cases the male is most abundant and predominant, and the waxy disk is scarcely discernible; at least at that period of growth when such specimens have happened to come under examination, which is when the powdery substance renders them most obvious; but it is most likely, from analogy of other plants, that the disk may subsequently increase. In other instances, as in *Lichen multipunctus*, Engl. Bot. t. 2061, the powder is in less proportion, sooner almost disappears, and the disk is very evident beneath it. Some traces of a disk may be found, in what we would term the flowering state of the original *Variolaria faginea*. See Engl. Bot. t. 1713.—The Hedwigian theory of the impregnation of Lichenes appears to us greatly confirmed by these observations, and we cannot but think that the opinion of the germination of their powdery efflorescence has been too hastily admitted by recent naturalists.

SECT. 2. IDIOTHALAMI; (from *ιδιος*, proper, and *θαλαμος*.)

Receptacle composed of a peculiar compact hardish substance, not in any manner formed out of the frond, from which it differs in colour (being mostly black).

The seeds are naked, not enclosed in proper cells, except in *Endocarpon*; upon which we shall offer some remarks hereafter.

\* *Receptacles open.*

5. *Opegrapha*. Clefts black, sessile, oblong or linear, simple, confluent, or branched, straight or zigzag, bordered; their disk flat or slightly concave, naked or powdery, narrow, linear, rarely dilated; their border (of their own substance) often very narrow and scarcely perceptible, sometimes tumid, elevated, and somewhat inflexed. Sometimes there is a spurious accessory border, or mere swelling of the crust. (Frond crustaceous, uniform, thin, generally indeterminate; occasionally leprous.)

*Lichen scriptus* of Linnæus, with about thirty known species

cies besides, compose this genus. See Engl. Bot. v. 25, 26. 32, &c.

5\*. *Acharia*. Achar. in Schrad. N. Journ. v. 1. fasc. 3. t. 5. 3. Receptacles flattish, shapeless, smooth, without a border, sessile.

We introduce this, as described by the author since the publication of his *Methodus*. A genuine example of it is *A. Swartziana*, see as above, p. 13. t. 4. f. 1. Engl. Bot. t. 2079. We conceive several plants are improperly referred to this genus by Acharius, as *Spilona vesiculosor*, Engl. Bot. t. 2076, and *Opegrapha asporoides*, Ach. Meth. 25. Engl. Bot. t. 1847; to lay nothing of *Lichen croc.* t. 498, and *saccatus*, t. 288; whose shields or targets have no irregularity of shape, and whose fronds are of so totally different nature from the crust of *A. Swartziana*. In short, we can scarcely find another certain species to associate with this; except possibly *A. gyrosa*, Ach. as above, p. 14. t. 4. f. 3.

6. *Lecidea*. Spangles sessile, with a flattish or convex disk. (FronD various; crustaceous, whether uniform and limited, or scattered and indeterminate; or even leafy, somewhat membranous, or flattened. Acharius adds "rarely umbilicated;" from an idea now proved erroneous, that *Gyrophora pustulata* was a *Lecidea*.) See GYROPHORA.

This is an extensive genus, excellent as far as only crustaceous species are admitted, such being the genuine *Lichenes leprosi tuberculati* of Linnæus. See LICHEN, section the 1st; and the term *patellula* in the present article.—These constitute the first section named *cailliraria*, comprising 80 species, 45 of which have black or bluish receptacles, the rest red, yellow, or brownish.—The second section, *lepidoma*, has a figured or lobed crust, often imbricated, and embraces 14 species, among which are *Lichen niger*, Engl. Bot. t. 1161, and *deciptens*, t. 870.—The third is a small section, with a leafy crust, *sapbenaria*, into which should be admitted *Lichen dedaleus*, Engl. Bot. t. 2129.—The fourth, *omphalaria*, contains only *Gyrophora pustulata*, with its near relation *penlywanica*, and ought to be abolished.

7. *Calcium*. Puffs (*psilidia*) turbinate, lenticular, or nearly globose. They are generally elevated on a rigid simple stalk, of a totally different substance from the crust. (FronD crustaceous, either leprous, or tartareous, uniform or scattered, powdery and granulated, or solid and chequered, or somewhat leafy and imbricated; see *Lichen phaeocephalus*, Turn. Tr. of Linn. Soc. v. 8. 260. t. 6.) Acharius describes 18 species, to which several have since been added by discoveries in Lapland and England. They are minute productions, long confounded with *fungi*, from which they were first distinguished by Perfoon on account of their crust. It must be acknowledged that they bear the same analogy to several genera of *fungi*, that other Lichens, with proper shields, do to others, the *Oëospore* of Hedwig. Examples of *Calcium* are seen in Engl. Bot. t. 1465; 1539; 1540. 1832. &c.

\* Receptacles closed, at length opening.

8. *Gyrophora*. Buttons (*trica*) superficial, flattish. (FronD leafy, peltate, between membranous and leathery.) See GYROPHORA, in its proper place.

9. *Bathelium*. Receptacles sessile, somewhat globose, opening by a deciduous lid, hollow, of one to three cells, lined with seeds. (FronD crustaceous, indeterminate, uniform.) This genus consists of only *B. majloideum*, Ach. Meth. 111. t. 8. f. 3, found on the bark of trees at Sierra Leone by Dr. Azelius.

10. *Verrucaria*. Tubercles elevated, discharging their concatenated seeds by a terminal pore, or else falling out entire. (FronD thin crustaceous, uniform.)

A minute tribe, of which about 40 species are known. See *Lichen Schraderi*, Engl. Bot. t. 1711; and *analeptus*, t. 1848.

11. *Endocarpon*. Hollows (*thalamia*) hidden in the substance of the frond, each opening by a little mouth. Seeds enclosed in cells. (FronD membranous, somewhat crustaceous, of a determinate figure.) See ENDOCARPON in its proper place.

As the seeds are certainly enclosed in cells, like the genera of the next section, it seems desirable to range this genus with them. We are moreover now well aware that it differs sufficiently from *Verrucaria* in having parallel cells, lodged in a disk lining the cavity of the receptacle; whereas, in that, the concatenated naked seeds, clustered into a ball, fill the cavity. Their habits indeed are also totally unlike.

The receptacles of *Endocarpon* are, moreover, so united to the substance of the frond, that they may perhaps be considered as belonging to it, though somewhat different in colour; see Hedw. Crypt. v. 2. t. 20, A.

SECT. 3. CENOTIALAMI; (from *κενος*, common or general, and *θηλαμος*.)

Receptacle formed of the frond itself, with which it agrees in substance and colour. Seeds enclosed in proper cells, except in *Sphaeroboron*.

\* Receptacles compound, either pierced or gaping.

12. *Thelotrema*. Receptacle compound; the outer one wart-like, elevated, of the substance of the crust; inner somewhat globular, with a concave disk. (FronD a firm, continued, indeterminate crust.)—Examples are *Lichen pertusus*, Linn. Mant. 131. Engl. Bot. t. 677; and *L. inclusus*, t. 678. Acharius seems to have had the former in view when he defined the receptacles as "compound and opening by several little mouths." They are, in that species, generally aggregate or confluent, but each is internally distinct; and in others they are usually as distinct and separate as the shields of any other Lichen.

\* Receptacles nearly globular, closed, at length bursting.

13. *Sphaeroboron*. Cellules nearly globose, each enclosing a roundish ball of naked compact seeds, which turns to black powder, and is discharged by the torn orifice, leaving the cellule hollow and empty. (FronD shrubby, branched, solid, rigid; tartareous or minutely fibrous within; with a smooth cartilaginous coat.)—This elegant genus is exemplified by *Lichen globiferus*, Engl. Bot. t. 115; and *frogillus*, t. 114; which, with the real *fragilis* of Linnæus, make up the list of known species; see LICHEN, sect. 8 *fruticulosi*.

14. *Isidium*. Receptacle of the seeds terminal, somewhat discoid, solid, various in thickness, covered with, and shining through, the crust of the *papille* of the frond, which at length bursts, and each receptacle appears coloured, and partly exposed. *Globules* also either terminate each of the *papille*, or are nearly sessile on the crust itself. These are coloured, and finally fall out, each leaving a little pit at the summit of the *papilla* or branch. The globule is internally solid, and both sides are covered with a seed-bearing coat. (FronD crustaceous, leprous and tartareous, cracked, rather indeterminate, either papillary only, or throwing up solid branches.)

Such is, as precisely as we can give it, the character of *Isidium*, a genus founded by Acharius. He allows in a note that this genus is doubtful and ambiguous, nearest to *Sphaeroboron*, but differing in having a properly crustaceous frond, or basis, and especially in the nature of its *stratum proligerum*, (disk, or receptacle of the seeds,) which does not turn to dust; as well as in the presence of terminal *globules* (see the explanation of this term, n. 13, among the kinds of receptacles,) even when the other receptacles are wanting.

## LICHENES.

wanting. He adds that this double sort of fruit in *Isidium* demands further enquiry, for he is firmly persuaded that these globules belong to the organs of fructification.—We presume that *Lichen oculatus*, Engl. Bot. t. 1833, (see *Stereocaulon* hereafter) exhibits the former kind of receptacle, and *L. Weylingii*, t. 2204, the latter; but of this we have no certain knowledge.—*Isidium gonatodes* of Acharius appears by his *Supplementum* to be a mere variety of the crust of *L. tartareus* of Linnæus.

\*\*\* Receptacles orbicular, open; their border of the colour of the frond, surrounding a variously-coloured disk.

15. *Urecolaria*. Shields or spangles cup-shaped, variously coloured, sunk into the substance of the crust, or of its fragments or warts. Disk concave, rarely becoming flattish by age, but never elevated above the crust. Proper border often scarcely manifest, of the colour of the disk; the accessory one sometimes formed of the crust, which is elevated like a ring, surrounding the disk of each shield; but it is generally spurious, not united to the shield throughout. (Frond crustaceous, tartareous, uniform, determinate, checked or cracked, rarely figured or lobate.)—Examples of this genus are the common *Lichen scruposus*, Engl. Bot. t. 266; the rare *exanthematicus*, t. 1184. Tr. of Linn. Soc. v. 1. t. 4. f. 1; and *Urecolaria calcarea*, Ach. Meth. 142, very common on grey marble tombstones, in exposed country churchyards, where it forms inseparable hard white patches, two or three feet broad. This last is *Zatellaria multipunctata*, Hoffm. Pl. Lieb. t. 63. f. 1—3; *Lichen cinereus*, Engl. Bot. t. 820, but not that of Linnæus. It is erroneously made a *Parmelia* in Ach. Meth. 158.

16. *Parmelia*. Shields superficial, or elevated, thick or somewhat membranous, flattish, convex, or concave, crowned with a free accessory border. (FronD various, crustaceous, leafy, branched or lacinated, cartilaginous, membranous or gelatinous.) This vast and various genus swallows up the greater part of the natural order; *Lecidea*, n. 6, being far inferior to it in number of species, though greatly superior as a natural and consistent genus. 204 *Parmelia* are defined in the *Methodus*, besides several in the *Supplementum* of Acharius. This author is often in doubt to which genus some species belong, for want of knowing them in every state of growth. The true *Parmelia* have an accessory border of the colour and substance of their crust, but no proper border formed of the substance of the disk. The sections of this genus are eleven, distinguished by the nature of their frond, the first three being crustaceous, as in *Lichen tartareus* (see LICHEN, sect. 2.); the two next are leafy, more or less depressed. The sixth section consists of Hoffmann's *Collema*, (see the early part of the present article,) and has been lately restored to the rank of a genus in Engl. Bot. t. 2284, with this character. "Shields orbicular, horizontal, nearly sessile, superficial, with a gelatinous accessory border." The five remaining sections are the most miscellaneous possible, nearly as much so as the original genus *Lichen* in Linnæus.

\*\*\*\* Receptacles flattened, nearly destitute of a border; their upper side entirely covered with a thin seed-bearing disk, of considerable solidity at the surface.

17. *Stictia*. Shields on the upper side of the frond, sessile, close-pressed, orbicular, membranaceous; their disk flat, rarely somewhat convex; their border accessory, thin, entire, free, slightly tumid, rarely fringed, of the colour of the frond. Pits amongst the down of the under side, scattered, sessile, minute, coloured; their disk roundish, powdery; border elevated, a little inflexed, entire or jagged, sometimes obliterated. (FronD leafy, membranous or in

some measure coriaceous, lobed or jagged, downy or shaggy beneath.)

A beautiful and natural genus, of which the pits (*cyphellæ*) at the back of the frond form the most essential character. Acharius seems to have admitted them as a part of the fructification. If so, they should seem to be the male blossoms. The species of this genus, however, often abound with powdery efflorescence. See *Lichen limbatas*, Engl. Bot. t. 1104; also *Sylvaticus*, t. 2298; *erocatus*, t. 2110; and *curvatus*, t. 2359. Acharius has fourteen species in all, several of them extra-european.

18. *Pelidea*. Targets closely attached to the frond, about the margin, on the upper or under side, rarely lateral, or towards the middle, each entirely consisting of a flattish, very rarely concave, coloured disk; border accessory, very thin and scarcely discernible, united with the frond, and of the same colour. (FronD leafy, rather leathery; with downy veins and fibres beneath, rarely naked; the circumference lobed, its barren lobes depressed, fertile ones elongated, ascending, naked at the back.)

One of the most natural genera, the *Peligeria* of Hoffmann; most allied to *Stictia* in habit, but wanting the *cyphellæ*, instead of which the prominent veins or ribs underneath are remarkable.—See *Lichen caninus*, Engl. Bot. t. 2299; *rufifens*, t. 2300; and the more rare *venosus*, t. 887; *aphthosus*, t. 1110; and *colinus*, t. 1834; which last Dr. Acharius now admits as distinct from *rufifens*, and the same plant with his *P. lidia* *scutata*. He also informs us that his *P. chlorophylla*, n. 7, is no other than his *Cetraria spinicula* &c. For mention of other species, see LICHEN, sect. 5.—*Lichen crceus*, Engl. Bot. t. 498; and *saccatus*, t. 288, seem to us much better placed in this genus, as in Ach. Meth. 290, than in *Arthonia* above-mentioned.

19. *Cetraria*. Targets shield-like, thickish, flat, close-pressed, sessile, near the margin; their circumference loose, rounded, deformed or wavy; disk coloured, slightly convex; border accessory, very narrow, entire or crenate, of the colour of the frond. (FronD leafy, membranous or somewhat cartilaginous, rigid, smooth and naked on both sides; sometimes cellular or pitted; lobed and jagged, often crisped at the edges.)

The receptacles of this genus are, as it were, of an intermediate kind between shields and targets, rather most akin to the latter. The nature of the frond however, its smoothness, polish, and membranous, somewhat rigid, texture, render *Cetraria* very distinct, on the score of habit, from the last. But eight or nine species are described; among which are *Lichen islandicus*, Linn. n. 50. Engl. Bot. t. 1330; *oculatus*, Sm. Tr. of Linn. Soc. v. 1. 84. t. 4. f. 7; *glucosus*, Linn. n. 67. Engl. Bot. t. 1606. See LICHEN, sect. 4.

20. *Cornicularia*. Orbs shield-like, terminal, peltate, thickish, cartilaginous, orbicular, flat; at length rather convex, uneven, and irregular; disk generally of the colour of the frond; border scarcely any, except in a young state, a slight accessory one, entire, naked, or radiated, at length reflexed. (FronD cartilaginous, rigid, smooth, rather solid, spongy within, of a shrubby, tufted, branched habit, the branches acute.)—This genus is about as numerous in species as the last. It is conceived by Acharius to be intermediate betwixt *Parmelia* and *Uynea*, approaching the former most in the frond, the latter in the fruit, except that the occasionally deeper colour of the disk, and the presence of an early border, betray more affinity to the latter.—Examples of *Cornicularia* are, *Lichen trifidus*

Weber, Linn. n. 112, described in Engl. Bot. t. 720; and *lupuloides*, t. 452; which last is *C. spadicosa* of Acharius; also *L. bicolor*, Engl. Bot. t. 1853, which has lately been shown by the Rev. H. Davies to be the *Ufnea lana nigra infula saxis adhaerens*; Dill. Musc. 66. t. 13. f. 8, a long-disputed and uncertain plant; t. 13. f. 9. being *L. lanatus*, Engl. Bot. t. 846.

21. *Ufnea*. Orbs somewhat coriaceous, flattened, pel-tate, naked and smooth on both sides, mollly very much dilated; disk first concave, then flat, even; subsequently rather convex and cracked, or warty, scarcely convex; border either none at all, or an accessory one, which is entire or toothed in the circumference, very often radiated. Knobs (*cephalodia*) on the same, or a different plant, sessile, lateral, scattered; at first shield-like, and sometimes, in a manner, bordered; finally convex and warty, coloured.

This apparently double mode of fructification in the *Ufnea*, or proper filamentous Lichens, see LICHEN, sect. the last, involves as great a mystery as the *propagula* and seeds. Experiments are requisite to determine whether the *orbilla* produce seeds, as well as the *cephalodia*. Till this is proved, we cannot but feel persuaded that the former are more probably the male blossoms; or possibly they may be abortive or imperfect female ones. Being much the most frequent and conspicuous of the two, and greatly resembling shields, they have been of course taken for the fruit, the *cephalodia* having nearly escaped observation, till lately; see Sm. Tour on the Continent, ed. 2. v. 1. 335, and Engl. Bot. t. 872.—(The frond of *Ufnea* is branched, with elongated, cylindrical, three-angled shoots, either nearly erect, prostrate or pendulous, beset with small fibres, and tapering towards the extremities; their coat crustaceous, more or less distinctly jointed like a necklace, and roughish, having a central or medullary thread, which is semipellucid and elastic.)

There can be little doubt of the natural distinctness of the present genus, though some *Parmelias*, (as *L. divaricatus* of Linnaeus), greatly resemble it in general aspect. The jointed frond is very curious, and we believe essential. See examples of *Ufnea* in *Lichen floridus*, Engl. Bot. t. 872; *hirtus*, t. 1354; *plicatus*, t. 257; and *articulatus*, t. 258. Many species referred by Hoffmann and others to the same genus, as *L. divaricatus*; and *subulatus*, Engl. Bot. t. 1880; make a section in the *Parmelia* of Acharius, called *tricharia*.—If the knobs be the true female fructification, *Ufnea* rather belongs to the following section.

\*\*\*\* Receptacles convex, more or less globose, clothed with a seed-bearing layer, or disk, sessile either on the branches, papillary processes, or petiolar stalks, of the frond, terminal and permanent.

22. *Stereocaulon*. Knobs somewhat turbinate; at first furnished with a proper border; then globose, without stalks, simple or clustered, coloured, permanent; disk at first flat and small, but gradually occupying the whole; border of the same uninterrupted substance and colour, entire, at length obliterated. (Frond solid, almost woody, caulescent, erect, branched, mostly clothed with scales, rough and fibrous.)

This genus is more restricted than the *Stereocaulon* of Hoffmann, yet not much more certain or definite. Its proper type is *Lichen paschalis*, Engl. Bot. t. 252. Many others are doubtful. We can scarcely distinguish *S. tabulare*, Ach. Meth. 316. t. 7. f. 3, from *Lichen oculatus* of Dickson, Engl. Bot. t. 1833, *Isidium* & *oculatus* of Acharius.

23. *Beomyces*. Knobs capitate, nearly globose, with reflexed, scarcely bordered, edges, terminating their own proper fruit-stalks, simple or clustered, coloured, permanent;

disk properly none, the whole globose surface being covered with the thin, solid, seed-bearing coat; border none. (Frond either somewhat crustaceous, foetish, granulated, indeterminate, rarely figured; or consisting of a cartilaginous, leamy and lobed crust: fruit-stalks elongated out of the very substance of the frond, simple or branched, tubular or nearly solid, either dilated or tapering upwards, sometimes barren.)

A great genus, very difficult for the determination of its species, of which about 50 are described. Acharius divides it into six sections; in the first are *Lichen byssoides*, Engl. Bot. t. 373, and the beautiful *L. Beomyces*, t. 374; in the second *L. Papillaria*, t. 907; in the third *L. rubiformis*, t. 2112, and *caespitosus*, t. 1796; and in the fourth *L. delicatesus*, t. 2052, and *microphyllus*, t. 1782. These four sections comprise in all but 14 or 15 species.—The fifth is by far more considerable, consisting of the true cup-bearing Lichens, *Scyphisiferi* or *Psixidati* of authors, which terms express the cup-like dilatation of their fruit-stalks upwards. We have already spoken of this tribe; see LICHEN, sect. 7. Acharius defines 24 species, with numerous varieties. They seem to have engaged much of his attention. Beautiful specimens of them are his *Beomyces bacillaris*, (*Lichen filiformis*, Engl. Bot. t. 2028; *L. coccoiferus*, t. 2051; *bellidiflorus*, t. 1894; and *albicornis*, t. 1392.—The sixth section, consisting of 11 species, embraces the shrubby and awl-shaped kinds of Hoffmann's *Cladonia*. Such are *L. uncialis*, Linn. n. 107. Engl. Bot. t. 174; *rangiferinus*, n. 106. t. 173; and *vermicularis*, n. 108, t. 2029.

By the above detail, this arrangement of the Lichens by their fructification will be sufficiently intelligible to any who will bend their attention to the subject; and the more it is studied, the more honour will it be found to confer on its author. Whatever occasional laxity, or want of precision, may be observable in his use and adaptation of terms, will be found inevitable in so intricate a study, in which he was himself learning, as well as teaching, at every step. We have unfortunately not yet been able to procure a sight of his more recent publication, entitled *Lichenographia Universalis*; but from a manuscript scheme of the whole, and some information given by an intelligent friend, we learn that the great object of this work is the establishment of a new distribution of Lichenes, in which the genera are vastly multiplied. Most of the new ones seem formed out of the sections, or subdivisions, of those of his *Methodus*; so that he has here given into the plan of taking *habit* into the generic character, to a great extent. How far this may be eligible, we dare not, without seeing his reasons, decide. The few plates of the book in question are, as we understand, entirely subservient to this object, and the synonymy, as well as every thing relating to specific illustration, are but compendiously touched. Such subjects will receive a full and sufficiently diffuse exposition, in a new work, the first sheets of which we have lately been allowed to peruse, the *Lichenographia Britannica* of Mr. Dawson Turner, and Mr. William Borrer. This, when completed, will exhibit a finished history of the British species, the knowledge of which is nearly equivalent to an acquaintance with the characters of the whole order. An almost complete series of their figures is already before the public in the *English Botany*, to which we have so often referred. No other work, in any country, contains so many. The discrimination of the species, in this and the other tribes of British plants, has all along been a primary object of that publication: the new genera of Lichenes having been very cautiously adopted; indeed scarcely at all till lately, they having been considered by the author as in too

fluctuating a state, an idea which the above account will abundantly justify. The same reason, in addition to some inevitable impediments, has hitherto kept back the fourth volume of the *Flora Britannica*, where the Lichens will make a principal figure.

A very interesting work, on the dyeing properties of Swedish Lichens, is published at Stockholm, in 8vo. numbers, from the pen of Dr. Welsing. Seven numbers have reached us, in which 21 species of this natural order are illustrated by admirable coloured plates, with dissections, drawn by the hand of Professor Acharius himself, and accompanied by specimens of all the colours yielded by each species, the manner of procuring which is the chief subject of the Swedish letter-press. We regret that it is not given to the public in a language more generally understood. The variety of beautiful colours afforded by *Pulveraria* (or *Lepraria*) *chlorina*, t. 1, are very striking, and amount to 14, in which blue, green, and yellow are conspicuous. *Isidium Welsingii*, t. 4, yields beautiful shades of red, which colour, with different browns, is derived from most of the tartarous-crusted tribe. The leafy membranous ones seem to excel in browns, as *L. saxatilis*, t. 2; *omphalodes*, t. 7; and *encrasmus*, t. 19, Sm. Tr. of Linn. Soc. v. 1. 83. t. 4. f. 6. The cup-bearing kind appears also by the common *L. pyxidatus*, t. 17, to promise much in dyeing. When the high price of Orchard, *Lichen Rocella*, is considered, the investigation of different species under the guidance of improved chemistry, can hardly be thought an idle speculation, even by those who have no other motive for the study of nature.

We cannot conclude this article, without adverting to a subject, the consideration of which we have been disposed to put off as long as we could, because it is painful to differ decidedly from those who have made any subject their frequent and patient study, and to whom, moreover, natural science is so much indebted in other respects. We allude to the supposed transformation, for we can call it nothing less, of one species of this family into another. We can readily explain why *Lichen niger*, Engl. Bot. t. 1161, may seem to be turned into *plumbicus*, t. 353, from the seeds of the latter falling into the decayed crust of the former, and finding there a most excellent situation for their germination; as an acorn might vegetate in a bed of rotten moss. But the transformation of a tuft of moss into a forest of oaks would scarcely be a less miracle than that suggested above, or than the change of *Lichen tricolor*, or *cornuus*, into a *Sphæra*. It is but justice, indeed, to the excellent botanist who has asserted these changes, to declare, that we have no less extraordinary reports of the same kind from another quarter, respecting the progress from one species to another; in all which cases, doubtless, the intricacies of nature have deceived a most acute observer. We should scarcely venture to speak on this subject, however clear to our reason, from the botany of the closet only. A slight degree of practical observation will serve to convince any one, that the dissemination of many far more obvious plants than these, is hardly to be explained, and that the shifting scenes of nature, in the animal as well as vegetable theatre, are almost a metamorphosis. But we assert, with the confidence of experience, that the species of Lichens themselves, although undoubtedly liable to varieties like other plants, of which we have traced some curious instances amongst the alpine *Cyrophora* in particular, are as constant as those of any other plants, and even better defined than many of the most splendid. They differ indeed much in duration, somewhat in season, and above all perhaps in luxuriance, according to favourable or unfavourable circumstances; for they are

amongst the most hardy children of Flora, destined to thrive where others would perish, and to prepare the way for such as are less able to provide for themselves. To understand them well requires laborious research, and perpetual observation; but the curiosity and beauty of their structure will repay our toil, whilst, if we mistake not, the certainty of their characters and distinctions will afford satisfaction, as well as instruction to the scientific mind. 8.

LICHENOIDEÆ, Dill. Musc. 124. See LICHEN.

LICHFIELD, or LITCHFIELD, in *Geography*, an ancient city situated in the hundred of Oflow, and county of Stafford, England. According to the parliamentary returns of 1800, it then contained 873 houses, and 4712 inhabitants, of whom 1666 were found to be engaged in various trades and manufactures. The more ancient name of this city was Lichenfield, which, according to some antiquaries, signifies the "field of dead bodies," from a massacre of the Christians, said to have taken place here during their contests with the Pagans in the reign of the emperor Dioclesian. Mr. Shaw, however, in his "History of Staffordshire," expresses his decided opinion against the truth of this tradition, and with greater probability considers it as deriving its name from its marshy or watery situation; the word *Leccian*, from which *lic* comes, signifying, in Saxon, land covered with water. Lichfield is supposed to have arisen on the ruins of a Roman station called *Etactum*, which lies about a mile from the present city. Whether this idea be correct it is not easy to determine; but it seems to be clear that Lichfield was totally unknown, or, more properly speaking, had no existence either in the time of the Britons, or Romans. The origin of it, according to the best authorities, is attributed to the Saxons; and Mr. Shaw says, it was the first established seat of that people in England. In the year 669, when St. Chad was bishop of Lichfield, it was little more than a trifling village. Even after the Norman conquest, it was considered by the synod, then held at London, as too mean a place for the residence of a bishop, for till this time the bishops lived in an obscure manner; and seem to have done little towards adorning, or extending the town. However, trifling as it was, it received great honours and privileges from several of the Saxon kings. Borrocaphill, in the neighbourhood of this city, was in all probability one of the camps, or chief residences, of some Saxon princes; for, though no traces of building remain, the situation is too fine and commanding to have escaped the notice of that warlike people. In the reign of Henry I. Lichfield was encompassed with a ditch, and the castle was fortified by bishop Clinton. No part of the fortifications of the latter are now visible; but the field in which it stood is still denominated Cattlefield, and the ditch around the city may be easily traced by an attentive observer. The right of coivage was granted to the bishops of this diocese by king Stephen; but they did not enjoy this privilege for any considerable period. Bishop Langton, who flourished in the time of Edward I. was a great benefactor to this city, having built, among other things, an excellent bridge over the pool which separates the town from the clove. In the twenty-third year of the reign of the last-mentioned prince, (1305,) Lichfield first sent members to parliament, which it ever after continued to do. Edward VI. constituted it a city by charter in the year 1549. This charter gave the corporation power to appoint bailiffs and other chief officers, who should be entitled to hold all pleas within the precincts of the city. Queen Mary, with the authority of parliament, confirmed these privileges in the year 1553, and added several others of importance. The city, which before that time formed a member or parcel

parcel of Staffordshire, was then declared to be a county of itself for ever, from and after the ensuing fealt of St. Thomas. All actions of whatever denomination arising within the city, were ordained to be held by the bailiffs and citizens, if they could determine them, and if not by the justices next coming into the city, and not on any account by any authority out of the city. These great privileges were conferred in consequence of the faithful services of the citizens in the time of rebellion. Both these charters were ratified by queen Elizabeth, and afterwards confirmed by her successor James I. who granted still further immunities to this city. Charles II. confirmed all the privileges of this city, by a charter dated the 5th of November 1664. The government at present is vested in two bailiffs, elected from the common council, one of whom is named by the bishop, and the other by the council themselves, a recorder, a sheriff, a steward, and other inferior officers. The burgesses are twenty-four in number. Lichfield sends two members to parliament, the right of election being in the bailiffs, magistrates, freeholders of 40s. a-year, the holders of burghage tenements, and such freemen as are enrolled and pay foot and lot. The number of voters is estimated at 620.

This city has been the seat of a bishop's see from a very early period. The famous St. Coada was consecrated in the year 669. The great Offa, king of Mercia, of which Staffordshire formed a part, insisted upon his kingdom being governed by an archiepiscopal power, and that the bishop of Lichfield should be appointed to that dignity. Accordingly Adulphus, the successor of Sigebert, was created archbishop of Lichfield by pope Adrian, and the pall sent to him from Rome, about the year 785. Lichfield, however, did not long enjoy the pre-eminence it had thus acquired, for upon the death of Offa it was again reduced to a bishopric, at the earnest request of the archbishop of Canterbury, who presented pope Leo, the then possessor of the papal chair, with a large sum of money, in order to give weight to his entreaties. For a considerable period the bishoprics of Coventry and Lichfield were united, but at the reformation they were again disjoined. In the tower, built by bishop Clinton, king Richard II. is said to have kept his sumptuous Christmas festival, in the year 1397, when he consumed two hundred tuns of wine and two thousand oxen. This fortress was likewise the place of his confinement when on his way to the Tower of London as a prisoner, about two years afterward. Here he attempted to effect his escape, by slipping from the window of the high tower into the garden, but being discovered was carried back to his confinement. Lichfield has ever been celebrated for the attachment of its citizens to the cause of royalty. When the civil war commenced between king Charles and the parliament, his majesty having sent an order to the inhabitants of his loyal city to bring in their arms, his order was not only willingly complied with, but many of the inhabitants voluntarily subscribed considerable sums of money for his use, and enrolled themselves as soldiers under the command of captain Richard Dyott, for the protection of their own city against the parliamentary forces. This officer being joined by many gentlemen and gentlemen of the country under the earl of Chellerfield, the cathedral and clove were fixed upon as a proper place of defence from the height of its situation, and the strength of the fortifications around it. In a short time after the garrison was attacked by the republican troops. During this siege they maintained their post with great resolution, but the town as well as the cathedral suffered very material damage. In one assault, lord Brock, a most furious fanatic, who commanded the parliamentary army, lost his life in a manner somewhat

singular. Having drawn up his army about half a mile from Lichfield, and prayed most devoutly for the destruction of the cathedral, he ordered an immediate attack, and placed himself in a small house near the south gate, with the view of directing the operations of the gunners, whom he had stationed against this gate, in order, if possible, to open a breach. Upon some sudden accident which occasioned the soldiers to give a shout, lord Brock came to the door, and being perceived by a gentleman of the name of Dyott, who stood on the top of the tower, he levelled his piece at him, when the ball penetrated directly into the socket of the eye and lodged in the brain, causing instant death. As this happened on the festival of St. Chad, the patron of the church, the ball was supposed to have been guided by the influence of that saint. The loss of their commander, however, did not dismay the besieging army, who continued to carry on the siege with great vigour, and at last succeeded in compelling the garrison to submit. The troops of the parliament left to secure this fortress were in their turn attacked by prince Rupert, about the year 1643. Colonel Rowwell then commanded the garrison, who evinced the utmost bravery in the defence of his post. The commanding situations chosen by prince Rupert, however, for erecting his batteries, and the explosion of a mine, soon effected an extensive breach, and the garrison was compelled to surrender. The prince conferred the government on colonel Hervey Bagot, who maintained it for the king till the utter destruction of his majesty's affairs, when he very properly surrendered upon honourable terms.

Lichfield stands in a very pleasant and healthful valley, almost in the centre of England, at the distance of 120 miles from the metropolis. It is surrounded by hills of a moderate size, easy of ascent, and of very agreeable appearance. It is chiefly inhabited by gentry, being of little importance in a mercantile point of view. The buildings of this city have generally assumed the air and taste of modern times, and the spirit of improvement, so conspicuous in the present age, is plainly manifested in many alterations which have taken place within these few years. This city was formerly divided into two portions, by three lakes or pools of water, one of which is now dried up. It contains three parishes, but part of the lands of St. Chad's and St. Michael's lie without the boundaries of the city. Lichfield is adorned with a number of buildings well worthy of notice, both on account of their antiquity and the splendid style of their architecture. Of these the most conspicuous in every respect is the cathedral, which stands in the clove, and is said to have been fortified by bishop Clinton; though Dr. Shaw thinks he only repaired the fortifications which had existed there from the time of the Saxons. Some are of opinion, that the cathedral was first founded by king Oswy, in the year 655; but others attribute it to Peada, his son-in-law. Who was the first bishop is somewhat uncertain, but St. Chad is generally allowed that honour. The buildings of this cathedral, which was then called the Mercian church, were probably at first only constructed of wood. The whole of them were pulled down, in the year 1148, by bishop Clinton, and another of enlarged dimensions, and more elegant design, commenced in the place of the Saxon structure. To this prelate the cathedral is indebted for that noble stone vault, which is at this day the admiration of architects, and is undoubtedly one of the finest works of its kind extant in England. The next benefactor to this cathedral was Walter de Langton, who laid the foundation of the choir. He expended the sum of two thousand pounds on a shrine for the reliques of St. Chad, and obtained many privileges for the vicars and canons, one

of which was the right of hanging upon the next gallows, without trial, divers persons who withheld their lands from the church. This beautiful shrine continued in its full glory till the dissolution, when the cathedral was despoiled of this and many other valuable relics to satiate the avarice of the tyrannical Henry.

During the sieges which it sustained, as already mentioned, in the time of the civil wars, this noble building suffered much, being the first cathedral that fell into the hands of the parliament. The roof was stripped of its lead; and many of the curious statues, monuments, and other carved works, were demolished with axes and hammers. The costly and beautiful painted windows were battered to pieces. In short, little of this splendid structure escaped ruin, except the noble vaulted roof already mentioned. What did remain was ultimately destroyed in 1651, when colonel Danvers, by authority of the Rump Parliament, employed workmen in order to effect this purpose. At this time, the remarkable bell, called "Jesus bell," was knocked to pieces by a pewterer named Nicklin. During this perfection of the established church, Dr. John Hacket rendered himself remarkable by his courage and resolution. When a serjeant with a trooper were sent to stop the performance of the daily service, and, putting a pistol to his head, threatened to shoot him instantly if he did not desist, this noble prelate calmly, but resolutely, replied, "Soldier, I am doing my duty; do you your's?" a sentence which may justly be reckoned among the remarkable instances of the sublime, and which so impressed the minds of the soldiers, that they left him to the free exercise of the duty he thus evinced himself so worthy to perform. No sooner was he nominated to the bishopric of Lichfield, than he vigorously set himself to restore the ancient splendour of the cathedral. By his large contributions, the benefactions of the dean and chapter, and the money arising from his assiduity in soliciting aid from the gentlemen of his diocese, he succeeded in restoring this building to the admiration of the country. The whole underwent a thorough repair in the bishopric of Dr. James Cornwallis, when it received its last finish by the addition of a painted window at the east end of the choir, the execution of which reflects the highest honour on the artist Mr. Eginton. This cathedral is 411 feet in length, and 153 in breadth. From the centre rises a spire 256 feet high, of most elegant proportions. At the west front are two towers, terminated by spires, 66 feet in height. The portico can hardly be equalled by any thing of the kind in England. The chancel is paved with alabaster and channel stone, in imitation of black and white marble. The north door is particularly rich in sculpture. On the western front are a number of images, beautifully executed and arranged; the subjects of which are taken from the sacred writings. The statue of king Charles II. stands between the two western spires, where a figure of Adam, or of Christ, was also formerly placed, beneath which the other statues are ranged. These figures were originally all richly gilt and painted; but the embellishments have suffered much injury from the action of the elements. With regard to the interior ornaments of this church, they are by far too numerous to admit of particular notice in a work of this kind. Every part of it is filled with statues and tombs, both ancient and modern. The nave, 60 feet in height, is supported by pillars formed from a number of slender columns, with neat foliated capitals. Along the walls of the aisles are rows of arcades, with seats underneath. The upper windows in the nave are of uncommon appearance, being triangular, and including three circles in each; and over the western door is a very beautiful one, raised by the duke of York in the

reign of Charles II., and afterwards beautifully painted by a gift of the benevolent dean Akenbrooke. Behind the choir was the chapel of St. Mary, which contained a stone screen of the most elegant and splendid workmanship that can be imagined, embattled at the top, and adorned with several rows of niches most exquisitely finished. Each of these formerly contained a small statue. The stone screen was taken down during the late alteration, and the materials employed to fix the organ upon, and form pillars for the entrance into the choir. This chapel now forms part of the body of the choir. It is neatly paved, and contains, besides, forty-eight stalls, which are richly carved, and appropriated for the use of the members of the church. The altar is of free stone very neatly sculptured. The government of the cathedral is vested in a dean and four residentiary canons. The diocese of Lichfield, joined to Coventry, contains all the county of Stafford, (with the exception of Bromes and Clent,) all Derbyshire, and nearly one-half of Shropshire. The archdeacons are those of Coventry, Stafford, Derby, and Salop. The bishop's palace is situated at the north-east side of the clofe. The original building is said to have been founded by bishop Clinton, but it was probably of earlier date. This palace was quite destroyed in the civil wars, when bishop Hacket, having expended 1000*l.* on the prebendal house, fixed upon it as his residence. Whether the present palace is the same, or another wholly erected by his successor bishop Wood, is uncertain. It is now inhabited by different families; the bishop's residence having been for many years at Ecclell hall.

The next building worthy of notice is the church of St. Chad, now called Stowe church, and is generally considered as the oldest foundation in or near the city. By some writers it is even supposed to have been erected by the Romans, towards the end of the second century. St. Ceadda or Chadda, the saint to whom the church is dedicated, had his cell here in the year 653. The interior of this fabric has been lately repaired and beautified. It contains a number of neat monuments. The church of St. Mary's stands in the market-place, near the Guild-hall. Leland says, "St. Maries is a right beautiful piece of work, in the very market-place." The body of the present building is very neat, and is adorned with a handsome altar-piece, and a few ancient monuments to the memory of the family of the Dyotts. St. Michael's church is situated at the south-east extremity of the city, on the summit of Greenhill, and is remarkable for the extent of its burial-ground, which is scarcely to be paralleled in England. It contains within its limits not less than six or seven acres of excellent pasture land. This hill is remarkable for a court held here annually on Whitmonday, in a temporary stand of wood erected for the purpose. This court was anciently called the *Court of Array*, or view of men and arms. The high constables having assembled all the inhabitants, they perambulate the whole city; and the whole concludes with a procession through the principal streets to the market-place, where the town-clerk, in the name of the bailiffs and citizens, delivers an oration or charge to the high constables, thanking them for their attendance, and urging them to the due execution of their office. The origin of this remarkable custom is uncertain. On the top of the same hill, a small edifice has been erected by subscription, with seats; from this spot there is a very beautiful and extensive view of the circumjacent country, and of the many interesting objects it affords. South of Greenhill is Folly-hall, which also commands a very fine prospect. Not far from hence is the hospital and chapel of St. John, which was originally a monastery. When it was first founded is unknown. The front of the present building

building is remarkable for the number and antique form of its chimnies. According to an inscription over the door it was erected by bishop Smith, who was also the founder of Brazen-nose College, Oxford. The free grammar school, built at the same time with the hospital, stands nearly opposite to it.

This city can boast of having been the place at which some of the brightest ornaments of the two last centuries were educated. Among others were the unrivalled Garrick and his friend Dr. Samuel Johnson, whom Mrs. Barbauld designates as the Hercules of literature. The latter was born in a stuccoed house situated at the corner of Market-street, where his father kept a bookfeller's shop. The Guildhall, the theatre, and the free English school, are situated in Broad-street. The latter is an ancient building, erected and endowed by Thomas Minors about the year 1670. At the back of the Guildhall is a goal for the confinement of debtors and felons apprehended within the boundaries of the city. To the west of Bird-crest is a very pleasant seat called the Friary, having been formerly a monastery of Franciscan or Grey friars, founded about the year 1329. On the east side there still remains an antique monument in honour of a merchant named Richard. It is inscribed with a very singular epitaph, which the limits of this article, however, will not admit of being inserted. The residence of the late celebrated Dr. Darwin is situated in a street called Beacon-street, which was nearly burnt to the ground during the civil wars. Opposite to the shrobbery which surrounds Dr. Darwin's house is an hospital, built by Dr. Milley in the year 1704, for the support of fifteen poor women. Contiguous to this spot there formerly stood a very stately edifice, once the residuary house of the archdeacon of Chester. Lichfield contains, besides these, many objects which deserve the attention of the inquisitive and curious. The museum and the botanic garden of Dr. Darwin are particularly interesting to all who have the slightest taste for the subjects of natural history. Lichfield was long the residence of Miss Seward.

The markets are held here on Tuesday and Friday; the fairs on the three first Thursdays after Twelfth day, Ash Wednesday, May 1st, and the Friday before St. Simon and St. Jude. By means of canals this city communicates with a variety of rivers, some of which discharge themselves into the German ocean, and others into the Irish sea and St. George's channel. Harwood's History and Antiquities of Lichfield, 4to. 1806. Jackson's History of the City and Cathedral of Lichfield, 8vo. 1805. Shaw's History, &c. of Staffordshire, vol. i. folio.

**LICHTENBERG**, a town of France, in the department of the Lower Rhine; 22 miles N.N.W. of Straßburg.

**LICHTENAU**, a town of Austria; 12 miles W. of Crems.—Also, a town of Austria; 6 miles S.E. of Aigen.—Also, a town of Westphalia, in the bishopric of Paderborn; 9 miles S.E. of Paderborn. N. lat. 51° 32'. E. long. 8° 58'.—Also, a town of Hesse-Cassel; 13 miles S.E. of Cassel. N. lat. 51° 12'. E. long. 9° 24'.—Also, a town of Germany, in the principality of Hanau-Lichtenberg; 12 miles N.E. of Straßburg.—Also, a town of Germany, in the territory of Nuremberg, with a fortress on the Retzart, insulated in the margravate of Ansbach; 23 miles S.W. of Nuremberg. N. lat. 49° 17'. E. long. 10° 12'.—Also, a town of Prussia, in the province of Ermeland; 12 miles N.W. of Heilberg.—Also, an island near the W. coast of East Greenland. N. lat. 60° 30'. W. long. 45° 19'.—Also, a Moravian settlement in America, on the E. side of Muskingum river, 3 miles below Gochsachguenck; afterwards removed to Salem, 5 miles below Guadenhuett.

**LICHTENBERG**, a town of Prussian Pomerelia; 57 miles S.W. of Dantzic.—Also, a town of Germany, in the county of Henneberg; 8 miles S.E. of Meiningen.—Also, a town of France, in the department of Mont-Tournerre; 9 miles W.S.W. of Lautereck.—Also, a town of Silesia, in the principality of Neisse; 3 miles N.N.W. of Grotkau.—Also, a town of Germany, in the principality of Culmbach, on the Selnitz; having in its vicinity quarries of marble, and mines of copper and iron; 22 miles N. of Bayreuth. N. lat. 50° 22'. E. long. 11° 48'.—Also, a town of Saxony, in the circle of Erzgebirg; 5 miles S.S.E. of Freyberg.

**LICHTENECK**, a town of Carniola; 10 miles E.S.E. of Stein.

**LICHTENFELS**, a town of Austria, on the river Kamp; 7 miles E. of Zweth.—Also, a town of Bavaria, situated on the Maie; 20 miles N.N.E. of Bamberg. N. lat. 50° 10'. E. long. 11° 8'.

**LICHTENFELT**, a town of Prussia, in Pomerelia; 12 miles E.S.E. of Marienburg.

**LICHTENHAGEN**, a town of Prussia, in the circle of Natangen; 8 miles S.S.W. of Königsberg.

**LICHTENSTEIG**, a town of Switzerland, and capital of the county of Tockenburg, seated on the Thur, and the residence of a bailiff. It has places of worship for Roman Catholics and Protestants; 27 miles E. of Zurich. N. lat. 41° 17'. E. long. 9° 6'.

**LICHTENSTEIN**, a principality of Germany, on the E. side of the lake of Constance, situated on the Rhine, betwixt the lordships of Pludenz and Feldkirch.—Also, a town of Saxony, and chief place of a lordship, belonging to the counts of Schonburg; 5 miles N.E. of Zwickau. N. lat. 50° 44'. E. long. 12° 31'.

**LICHTENTANEN**, a town of Germany, in the principality of Culmbach; 7 miles N.W. of Bayreuth.

**LICHTENWALD**, a town of the duchy of Stiria; 12 miles S.E. of Cilly.

**LICHTENWALD**, a town of Prussia, in Ermeland; 23 miles N.W. of Heilberg.

**LICHVIN**, a town of Russia, in the government of Kaluga, on the Oka; 28 miles S. of Kaluga. N. lat. 54°. E. long. 35° 44'.

**LICHWE**, a town of Bohemia, in the circle of Königgratz; 6 miles W. of Czersberg.

**LICINIO, GIOVANNI ANTONIO**, in *Biography*. See **PORDENONE**.

**LICINIUM**, a word used by many chyrurgical writers to express a tent.

**LICINIUS**, in *Biography*, a Roman emperor, a native of Dacia, of an obscure origin, and accustomed from his infancy to the toils and hardships of rural life, became a Roman soldier, and rose through all the gradations of the service. He was raised to the rank of Augustus in the year 307. When the civil war broke out between Constantine and Maxentius, the former secured the friendship of Licinius by promising him in marriage his sister Constantia, which alliance took place in 313, when the two emperors had an interview at Milan, and joined in an edict in favour of the Christians. In the same year Maximin invaded the territories of Licinius, and took Byzantium and Heraclea; his success was very short lived, for Licinius advanced to meet him, and by his military skill obtained a complete victory. Maximin died soon after, and Licinius succeeded to his authority over the provinces of the East. The conqueror, who was harsh, ignorant, and brutal, knew not how to use his success with generosity or even with humanity; he put to death a great number of persons, and among others Val-

leria, the widow of Galerius, who had been a great benefactor to Licinius. This lady had taken refuge at his court, but terrified with his savage conduct, she took flight, and with her aged mother wandered long in disguise through the provinces; but being at length discovered, they were both beheaded, and their bodies thrown into the sea. After the display of these barbarities the two emperors did not live long in peace. A civil war broke out between them, in which the first battle was fought in 315; Licinius was vanquished, and after another attempt or two to maintain his ground against his rival, he was obliged to sue for peace, which he obtained on the condition of putting to death Valens, whom he had lately created Cæsar, and of resigning all his European provinces. In 317 he created his own son Cæsar, and peace was maintained during the eight following years. About this period, Licinius, growing suspicious of his Christian subjects, who seemed to be attached to his rival, began to banish them from about his person and palace, and to prohibit bishops from visiting each other, and from holding councils and assemblies. By degrees the restrictions that were laid upon them were exchanged for direct and cruel persecution, which produced another civil war in 323. The rivals met near Adrianople, and after some time spent in skirmishes, a general engagement was brought on, in which the superior skill of Constantine, and valour of his European soldiers, gained a very decisive victory over the much more numerous but less warlike host of Licinius. The vanquished emperor shut himself up within the walls of Byzantium, while his fleet was destroyed in the Hellespont by Crispus, the son of Constantine. Licinius escaped to Chalcedon, and collecting a new army made one more effort to oppose his foe, but being again defeated, he seems to have abandoned all ideas of farther resistance. He retired to Nicomedia, rather with a view of gaining some time for negotiation than with the hopes of effectual opposition. His wife Constantia, the sister of Constantine, interceded with her brother in favour of her husband, and obtained from his policy, rather than from his compassion, a solemn promise, confirmed by an oath, that after the resignation of the purple, Licinius should be permitted to pass the remainder of his days in peace and affluence. Licinius solicited and accepted the pardon of his offences, laid himself and the insignia of his office at the feet of the conqueror; he was raised from the earth with insulting pity, was admitted the same day to the imperial banquet, and soon afterwards was sent to Thessalonica, which had been chosen as the place of his confinement. His imprisonment was soon terminated by death, but whether this was occasioned by a tumult of the soldiers, or by a decree of the senate, is uncertain. He was accused of forming a conspiracy, and of holding a treasonable correspondence with the barbarians; but as he was never convicted, either by his own conduct or by legal evidence, his innocence, in this respect, has been presumed by many writers. The memory of Licinius was branded with infamy, his statues were thrown down, and by a rash edict, all his laws, and the judicial proceedings of his reign, were at once abolished. By this victory of Constantine, the Roman world was again united under the authority of one emperor. See CONSTANTINE. Gibbon.

LICINIUS CAIUS, a Roman tribune, of a plebeian family, rose to that rank by his own aspiring temper: he was the first plebeian who was raised to the dignity of master of horse to the dictator. He was surnamed *Stolo*, or *useless sprout*, on account of the law which he caused to be enacted during his tribuneship. By this law no person was permitted to hold more than 500 acres of land, it being alleged, that when more was held by one proprietor, he would not have

leisure to pull up the useless shoots (*Stolones*) which grew from the roots of trees. He afterwards carried a law which permitted the plebeians to share the consular dignity with the patricians, and was himself one of the first plebeian consuls, in the year 364 B.C.

LICINIUS, TEGULA, a comic Latin poet, flourished about 200 years before the Christian era. His fragments have been published by H. Stephens, and in the *Corpus Poetarum*, Maittaire. There was an orator and poet of this name, who lived at the same time with Cicero, and who has been compared with Catullus. His orations are highly commended by Quintilian: he is supposed to have written annals quoted by Dionysius Halicarnassus. He died in the 30th year of his age.

LICIO, in *Geography*, one of the smaller Lipari islands. N. lat. 38° 54'. E. long. 15° 20'.

LICK, a town of Prussia, with a castle; 80 miles S.E. of Königsberg. N. lat. 53° 39'. E. long. 22° 38'.

LICK, a name given to the salt-springs in the western parts of the United States.

LICKING, a navigable river of America, in Kentucky, which rises on the western confines of Virginia, interlocks with the head-waters of Kentucky river, runs in a north-west direction upwards of 180 miles, and by a mouth 150 yards wide through the south bank of Ohio river, opposite to Fort Washington. On this river are iron-works and numerous salt-springs. Its chief branch is navigable nearly 70 miles. From Limestone to this river the country is very rich, and covered with corn, rye-grass, and natural clover. Morfe.

LICKING *Creek*, a river of Maryland, which runs into the Potomack, N. lat. 39° 38'. W. long. 78° 5'.

LICKING *Hole Creek*, a river of Virginia, which runs into James river, N. lat. 37° 42'. W. long. 78° 5'.

LICKNENA, a town of Spain, in Arragon; 18 miles S.S.W. of Huesca.

LICKY, the name of a small river in the county of Waterford, Ireland, which falls into the river Blackwater, a little above Youghal.

LICNON, Λικνον, in the Dionysian solemnities, the mystical van of Bacchus; a thing so essential to all the solemnities of this god, that they could not be duly celebrated without it. See DIONYSIA.

LICNOPHORI, Λικνοφοροι, in the Dionysian solemnity, those who carried the licnon.

LICODIA, in *Geography*, a town of Sicily, in the valley of Neto; 18 miles S.W. of Lentini.

LICONDA, a town of Africa, in the country of Tripoli, situated on the sea-coast. N. lat. 30° 36'. E. long. 18° 10'.

LICOSTAMO, a town of European Turkey, in Thessaly, the see of a bishop, suffragan of Larissa; 16 miles E.S.E. of Larifa.

LICQUES, a town of France, in the department of the straits of Calais; 10 miles S. of Calais.

LICTORS, among the Romans, were officers established by Romulus, who always attended the chief magistrates when they appeared in public.

The duty of their office consisted in the three following particulars: 1. *Submotio*, or clearing the way for the magistrate they attended: this they did by word of mouth; or, if there was occasion, by using the rods they always carried along with them. 2. *Animadversio*, or causing the people to pay the usual respect to the magistrate, as to a knight, if on horseback, or in a chariot; to rise up, uncover, make way, and the like. 3. *Prætio*, or walking before the magistrates: this they did not confusedly, or all together, nor

by two or three abreast, but singly following one another in a straight line. They also preceded the triumphal car in public triumphs; and it was also part of their office to arrest criminals, and to be public executioners in beheading, &c. The ensigns were the *scales* and *securis*.

As to the number of *licitors* allowed to each magistrate, a dictator had twenty-four, a master of the horse six, a consul twelve, a prætor six; and each Vestal virgin, when she appeared abroad, had one.

**LICUALA**, in *Botany*, is the vernacular appellation of this palm among the natives of the Molucca islands. The name was adopted by Rumphius, and has been retained by all succeeding botanists. Linnæus and Willdenow properly refer it to the sixth class, ranking it there amongst others of the natural order of *Palme*, Schreber having classed it in his *Appendix Palmæ*. Schreb. 774. Linn. Syst. Veg. ed. 14. 313. Willd. Sp. Pl. v. 2. 201. Mart. Mill. Dict. v. 3. Thunb. Nov. Gen. 70. Juss. 39. Gært. t. 139.—Class and order, *Hecvandia Monogymia*. Nat. Ord. *Palme*, Juss.

Gen. Ch. Cal. Perianth inferior, three-cleft, permanent, outwardly hairy. Cor. of one petal, cleft almost to the base into three equal, ovate, acute, concave segments; Nectary annular, truncated, twice as short as the corolla. Stam. Filaments six, inserted into the nectary, erect, very short; anthers oblong, in pairs. Pist. Germen superior, convex, three-cleft, furrowed, smooth; style simple; stigmas two. Peric. Drupa globose, the size of a large pea. Seed a hard nut.

Efl. Ch. Calyx three-cleft. Corolla three-cleft. Nectary annular, truncated. Drupa single-seeded.

1. *L. spinosa*, Linn. and Willd., is the only species known; a native of the Moluccas, and figured by Rumphius in his *Herb. Amboin*. v. 1. 44. t. 9, under the name of *L. arbor*. The trunk of this palm is from three to four feet in height, and about the thickness of a man's arm, jointed, dividing in the upper part into five or six *footstalks*, scarcely so thick as a finger, triangular, their lower part serrated at the angles with thick rows of teeth or spines. Each of the stalks bears a *leaf* which is fan-shaped, and divided down to the base into about fourteen lateral, ribbed rays. *Flower-stalk* rising from the trunk, in the midst of the leaves, of the same length with them, and involved from the bottom in sheaths, dividing at the top into about five smaller ones, which bear green heads, in three rows, expanding into flowers. *Fruit* green for a long time, then brown or blackish. *Nut* oblong, very hard, longitudinally striated.

The natives of Macassar make use of the smaller leaves for tobacco pipes, after they are dried, rolled, and properly prepared. The larger leaves are used for packages, but the wood is not sufficiently durable to be considered useful.

**LICZ**, in *Geography*, a town of Austrian Poland, in Galicia; 30 miles W. of Przemyl.

**LID**, or **LYD**, a river of England, which runs into the Tamar, 4 miles N.N.W. of Tavistock.

**LIDA**, a river of Sweden, which runs into the Wenner lake, at Lidkioping.

**LIDA**, a town and castle of Lithuania, in the palatinate of Wilna, in which is held a provincial diet; 48 miles S. of Wilna. N. lat. 53° 52'. E. long. 25° 35'.

**LIDBECKIA**, in *Botany*, named by Bergius, in honour of Professor Eric Gustaf Lidbeck, of Lund, Knight of the order of Wasa, author of several botanical and economical treatises in the Stockholm Transactions. Berg. Cap. 306. Willd. Sp. Pl. v. 3. 2163. Juss. 183. (Lancitia; La-

marck. Illustr. t. 701. Gært. v. 2. 422.)—Class and order, *Syngenesia Polyantha-superflua*. Nat. Ord. *Compositæ Discoidæ*, Linn. *Corymbifera*, Juss. See **LANCISTIA**, and **COTULA**, section 2.

**LIDDEL**, **DUNCAN**, in *Biography*, a physician of the sixteenth century, was a native of Aberdeen; but he was elected professor of astronomy in the university of Helmstadt in 1587. He afterwards taught geometry, and ultimately medicine, of which he was appointed professor in 1596. He was likewise made first physician to the duke of Brunswick. But he quitted these advantages, and returned to his native country in 1607. He left the following works: "De Facultate vegetante ejusque Functionibus," Helmstadt, 1592; "Universe Medicinæ Compendium," *ibid.* 1605, 1620; "Ars medica succinctè et perspicuè explicata," Hamburg, 1607, several times reprinted; "De Febribus Libri tres," *ibid.* 1610; "Operum Iatro-Calculatorum, ex intimis Artis medicæ adytis et pentalibus erutorum," a posthumous work, Leyden, 1624. Eloy Dict. Hist.

**LIDDEL**, in *Geography*, a river of Scotland, which rises in Roxburghshire, and joins the Elk, three miles south of Longholm, in the county of Dumfries; giving to the valley in which it flows the name of Liddefdale, or Lithdale.

**LIDEN**, a town of Sweden, in Angermanland; 60 miles N.N.W. of Hernofand.

**LIDENS**, a town of Sweden, in the province of Medelpadia; 24 miles N.N.W. of Sundfval.

**LIDFORD**, a village of England, in the county of Devon, near the forest of Dartmoor, situated in a parish said to be the largest in England, including almost the whole of Dartmoor. It was formerly a fortified town, surrounded with walls and a moat, and having three gates, of which no trace now remains. It is supposed to have been destroyed by the Danes in the year 997. In this village is an ancient castle, in which courts are held for the duchy of Cornwall; and offenders against the stannary laws were here confined in a dreary and dismal dungeon, which gave rise to a proverb, "Lydford laws punish a criminal first, and try him afterwards." This village contains only about 15 houses, and its situation is bleak and dreary; 28 miles W. of Exeter. Cf. *Swetwall*.

**LIDHULT**, a town of Sweden, in the province of Smaland; 60 miles S. of Jonkoping. N. lat. 56° 50'. E. long. 15° 14'.

**LIDKIOPING**, a small, neat, trading town of Sweden, situated in the midst of a plain near lake Wetter or Wenner, at the influx of the Lide, and containing the episcopal palace, the cathedral, and the palace in which resides the governor of East Gothland; 42 miles E.N.E. of Uddevalla. N. lat. 58° 33'. E. long. 12° 54'.

**LIDL**, in *Biography*, a native of Germany, who arrived in England about the year 1785, and was a remarkable fine performer on the viol da gamba. His taste and expression on this ungrateful instrument were exquisite; though he had embarrassed himself with the additional difficulties of base strings at the back of the neck of his instrument, with which he accompanied himself, thrumming them in pizzicato with his left thumb; an admirable expedient in a desert, or even in a house, where there is but one musician; but to be at the trouble of accompanying yourself in a great concert, surrounded by idle performers who could take the trouble off your hands, and leave you more at liberty to execute, express, and embellish the principal melody, seemed at best a work of supererogation. The tone of the instrument will do nothing for itself, and it seems with music as with agriculture, the more barren and ungrateful the soil, the more art is necessary in its cultivation.

tion. And the tones of the viol da gamba are radically fo crude and nasal, that nothing but the greatest skill and refinement can make them bearable. A human voice of the same quality would be intolerable.

This excellent musician died of a consumption in London, at about 30 years of age, in 1788; as was the case, about the same time, with two other admirable German professors, and worthy men, Pfifer and Eichner. See their articles, and that of Lamotte, who had likewise been in England, and died young of a consumption.

LIDMEE, or *Indian Antelope*, *Antilope Cervicapra*, in *Zoology*, a species of antelope, having long, round, prominently annulated, tapering, and spirally twisted horns, which are smooth and sharp at the points. The body is of a brown colour above, and white on the under parts. This is the common and brown antelope of Pennant; the gazella africana S. antelope of Charleton, Ray, and Grew; the capra cervicapra of the Syst. Nat.; the capra bezoartica of Aldrov.; Olear.; the tragus strepticeros of Klein; the hircus gazella of Brisson; the Lidmee Arabium of Shaw's Travels.

It inhabits Barbary and India; it is somewhat smaller than a fallow-deer, brown clouded with reddish and dusky; the belly, breast, and inside of the thighs are white; the circumference of the orbits is white; the horns are erect, about sixteen inches long, of a black colour, and almost entirely covered with prominent rings, the points only being small, and are about twelve inches distant. The female has no horns, and after going nine months with young, brings generally twins. Pennant distinguishes between the Lidmee of Barbary and that found in India; though the only difference seems to consist in the greater size of the former, the latter being rather smaller than a roe. He likewise mentions horns frequently sent from India, which have been used as daggers, that seem to belong to this species, but with all their rings polished off.

LIDO di Malamocco, in *Geography*, a small island in the Adriatic, defended by a fort; 12 miles from Venice.

LIDO di Padesirina, a long island in the Adriatic, with a fort to defend the city of Venice.

LIDO di Sottomarino, a town in the island of Chioggia, forming as it were the suburbs of that city.

LIDS, a small island in the Baltic, near the south coast of Laaland. N. lat. 54° 41'. E. long. 11° 20'.

LIE, a town of Arabia, in Yemen; 20 miles S. of Abuarifch.

LIE, or *Lye under the Sea*. See LYING, &c.

LIEBAU, in *Geography*, a town of Silesia, in the principality of Schweidnitz, on the river Schwartbach; 22 miles S. of Schweidnitz.

LIEBAU, *Liebe*, or *Libona*, a town of Moravia, in the circle of Prerau; 13 miles N. of Prerau. N. lat. 49° 38'. E. long. 17° 28'.

LIEBENAU, a town of Silesia, in the principality of Glogau; 8 miles W.N.W. of Glogau. N. lat. 52° 25'. E. long. 15° 56'.—Also, a town of the principality of Hesse, on the Dimel; 20 miles N.W. of Cassel. N. lat. 51° 30'. E. long. 9° 22'.

LIEBENGRUND, a town of Saxony, in the circle of Neustadt; 14 miles S. of Neustadt. N. lat. 50° 30'. E. long. 17° 41'.

LIEBENTHAL, a town of the duchy of Stiria; 12 miles S.E. of Gratz.—Also, a town of Bohemia, in the circle of Chrudim; 13 miles E. of Hohenmaut.—Also, a town of Silesia, in the principality of Jauer; 30 miles W. of Jauer. N. lat. 50° 57'. E. long. 15° 37'.—Also, a town

of Saxony, in the margravate of Meissen; 7 miles S.W. of Stolpen.

LIEBENWALD, a town of Brandenburg, in the Middle Mark, on the Havel; 24 miles N. of Berlin. N. lat. 52° 51'. E. long. 13° 30'.

LIEBENWARDA, a town of Saxony; 22 miles N. of Meissen. N. lat. 51° 28'. E. long. 13° 26'.

LIEBENZELL, or ZELL, a town of Wirtemberg, on the Nagold; having two warm baths in its vicinity; 35 miles E.N.E. of Straßburg. N. lat. 48° 51'. E. long. 8° 43'.

LIEBEROSE, a town of Lusatia; 17 miles W. of Guben. N. lat. 52°. E. long. 14° 16'.

LIEBETEN, a town of Hungary; 65 miles N.N.E. of Gran.

LIEBMUHL, a town of Prussia, in the province of Oberland, with a castle; 66 miles S.S.W. of Königsberg. N. lat. 53° 42'. E. long. 19° 45'.

LIEBO SEE, a lake of Brandenburg, in the Ucker Mark; situated to the S. of Dolgen See.

LIEBSTADT, a town of Saxony, in Meissen; 14 miles S.S.W. of Dresden.—Also, a town of Prussia, in Oberland, with a castle; 48 miles S.S.W. of Königsberg. N. lat. 53° 57'. E. long. 25° 2'.

LIECHEN, a town of Brandenburg, in the Ucker Mark; 40 miles N. of Berlin. N. lat. 53° 12'. E. long. 13° 24'.

LIECHSTAL, or LIESTAL, a tolerably fruitful district of Switzerland, containing a small, regularly built, populous town of the same name, consisting of three parallel streets, in the canton of Basle; 2½ leagues S.E. of the capital, on the river Ergetz, which forms a cascade below it. In this district are the remains of a large Roman aqueduct.

LIEES, *Fr.*, a musical term, equivalent to tied, bound, sustained. It likewise implies blurred, in music, for bowed instruments, when two or more notes are played with one stroke of the bow, or with one touch of the tongue on the flute or hautbois. What musicians call a *sur* is a semicircle, (—). The same character is used over or under two or any number of notes, in vocal music, that are sung to one syllable.

LIEFDE BAY, in *Geography*, a bay on the north coast of Spitzbergen. N. lat. 70° 32'. E. long. 12° 30'.

LIEGE, a bishopric and electorate of Germany, before the French revolution; bounded on the north by Brabant; on the east by Limburg, Juliers, and Luxemburg; on the south by Luxemburg and the French department of the Ardennes; and on the west by Brabant, Namur, and Hainaut; about 80 miles in length from north to south, and of an irregular breadth. The soil is fertile, yielding corn and pastures, and also wine that resembles the midding wines of Burgundy and Champagne. In this district are also considerable forests, and mine-works of copper, lead, iron, and coal, stone quarries, and some of marble. Its chief mineral waters are those of Spa and Chaudfontaine. Its principal rivers are the Meuse and Sambre. This bishopric is now united to France, and forms the department of the *Ourte*; which fee. Its chief exports are beer, arms, nails, serge, leather, and coal. It formerly contained 26 towns, divided into Walloon and Flenish.

LIEGE, a city of France, and capital of the department of the Ourte, and a bishop's see. It is large, populous, and rich, divided into four parts, each consisting of 12,500 inhabitants, and four cantons; the 1st containing 16,664 inhabitants, on a territory of 12½ kilometres, in four communes; the 2d canton, including 13,966 inhabitants, on a territory of 20 kilometres, in two communes; the 3d comprehending

17,408 inhabitants, on a territory of 15 kilometres, in two communes; and the 4th containing 17,237 inhabitants, on a territory of 25 kilometres, in one commune. This city is situated on the Meuse, in a pleasant valley between hills, watered by the rivers Loofe, Ourte, and Ambleve, which discharge themselves into the Meuse, as it enters this city. It is proverbially called the hell of women, the purgatory of men, and the paradise of priests. Liege has ten grand faubourgs, and two smaller, 16 gates, 17 bridges, and 154 streets, and also two quays planted with rows of trees. Before the revolution, it had within the city and faubourgs, besides the cathedral, seven collegiate and 50 parish churches, and 46 religious houses. The cathedral of St. Lambert is a large building, erected by St. Hubert in the year 712, on the spot where his predecessor St. Lambert, bishop of Maestricht, had suffered martyrdom. On the 22d of November 1792, Dumourier, at the head of the French troops, took possession of Liege; but in the following March they were driven out of Liege and Brabant. In 1794 the French troops again entered Liege, and it was annexed to the dominions of France. N. lat. 50° 40'. E. long. 5° 37'. Accounts are kept in this city in florins or gulden current; each florin being divided into 20 fous or fivers, and each fiver into 16 pfenings. The fiver is sometimes divided into four oertjes or liards. The patacon of account is four florins, eight efcalus or schillings, or 80 fivers. The gold coins of Liege are the ducat of 8½ current florins or 17 efcalins, the florin d'or or gold gulden of 5 current florins or 10 efcalins. The silver coins are the patacon of 4½ current florins or 8½ efcalins, the efcalin of 10 fivers, and the blamafe of five fivers. The fiver is a copper coin. Since the year 1792 there has been no coinage at Liege; the city and its territory having been soon after united to France, and the new French momes and coins introduced here. The commercial weight of Liege is four per cent. less than that of Amfterdam; 21lbs. of Liege being = 22lbs. avoirdupois nearly. A laft of corn contains 96 fetiers, the fetier being 1827 English cubic inches, fo that 20 fetiers are = 17 English bushels. The foot is 11½ English inches, the ell is 21½ English inches; fo that 18 feet of Liege = 17 English feet, and 63 ells of Liege = 38 English yards. Since its union with France, Liege has adopted the new French denominations of money in the business of exchanges. Kelly's Univ. Cambist. vol. i.

Citizen Gretry, the eminent composer of French comic operas, a native of that city, in his Memoirs, vol. i. p. 125, gives an account of the college established at Rome for the reception of students in all the arts from the city of Liege. There was a time, before Rome was bereaved of its models of perfection, that we should have devoutly wished for an English college of arts, similar to that of France and Liege, where our young artists of promising talents, pining to visit Italy, but unable to bear the expence, might have an asylum in which they could be received and supported during a certain number of years, while they were pursuing their studies. Such an establishment would reflect honour on an opulent and learned nation, always disposed to patronize, and collect specimens in all the fine arts, particularly in painting, music, sculpture, and architecture.

LIEGE, *Ligiur*, properly signifies a *vassal*, who holds a kind of fee that binds him in a closer obligation to his lord than other people.

The term seems to be derived from the French *lier*, to bind; on account of a ceremony used in rendering faith or homage; which was by locking the vassal's thumb, or his hand, in that of the lord, to shew that he was fast bound by his oath

of fidelity. Cujas, Vigenere, and Bignon, choose rather to derive the word from the same source with *leudis*, or *leodi*, *loyal*, *faithful*. But Du-Casse falls in with the opinion of those who derive it from *liti*, a kind of vassals, so firmly attached to their lord, on account of lands or fees held of him, that they were obliged to do him all manner of service, as if they were his domestics. He adds, this was formerly called *ligium servitium*, and the person *lige*. In this sense, the word is used, Leg. Edw. cap. 29. "Judex sub tutela regis ligea debent esse;" that is, wholly under his protection.

By *lige* homage, the vassal was obliged to serve his lord towards all, and against all, excepting his father. In which sense, the word was used in opposition to *simple* homage; which last only obliged the vassal to pay the rights and accustomed dues to his lord; and not to bear arms against the emperor, prince, or other superior lord; so that a *lige man* was a person wholly devoted to his lord, and entirely under his command.

"Omibus, &c. Reginaldus, rex Insularum, salutem. Sciatis quod deveni homo ligeus domini regis Anglie Johannis, contra omnes mortales, quamdiu vixerio; et inde ei fidelitatem et sacramentum prelati, &c." MS. penes W. Dugdale.

But it must be observed, there were formerly two kinds of liege homage: the one, by which the vassal was obliged to serve his lord against all, without exception even of his sovereign; the other, by which he was to serve him against all, except such other lords as he formerly owed liege homage to. See HOMAGE.

In our old statutes, lieges, and liege people, are terms peculiarly appropriated to the king's subjects; as being *ligei*, *ligi*, or *ligati*, obliged to pay allegiance to him; 8 Hen VI. 14 Hen. VIII. &c. though private persons had their lieges too.

"Reinaldus, Dei gratia, abbas Ramefæ, præposito et hominibus de Brancefere, et omnibus vicinis Francis et Anglis, salutem. Sciatis me dedisse terram Ulfe, in depedene (hodie depedale) huic Boselino, et uxori ejus Alfnæ—ea conditione quod effecti sint homines." Lib. Ramef. See ALLEGIANCE and FEALTY.

LIEGE *vassalage*. See VASSALAGE.

LIEGNITZ, or LIGNITZ, in *Geography*, a town of Silesia, one of the best as well as most ancient in the country, and capital of a principality of the same name; situated on the Katszbach. The palace, within the town, is surrounded with a moat and high wall. Here, in a very stately stone edifice, the states of the provinces assemble. The Lutherans have two churches in this town; and the Roman Catholics are in possession of the collegiate church, a magnificent college, and other religious foundations. The emperor Joseph founded here a spacious academy for the instruction of young gentlemen of both religions in military exercises. The trade of Lignitz in cloth and madder is considerable; 32 miles W. of Breslaw. N. lat. 51° 11'. E. long. 16° 10'.

LIEN, *Fr.*, a word used in the law, of two significations: *personal* lien, such as bond, covenant, or contract; and *real* lien, a judgment, statute, recognizance, which oblige and affect the land. Term de Ley.

Lien signifies an obligation, tie, or *claim* annexed to, or attaching upon any property; without satisfying which such property cannot be demanded by its owner. Thus, the costs of an attorney are a *lien* upon deeds and papers in his hands; a factor has a lien on goods in his hands for balance due from his principal. &c.

LIEN-CHAN-POU, in *Geography*, a town of Chinese Tartary; 12 miles N.N.E. of Ning-yaen.

LIENIS.

LIENIS INPARCTUS. See SPLEEN.

LIEN-TCHEOU, in *Geography*, a city of China, of the first rank, in the province of Quang-tong, seated on the river Lien-kiang, which forms a very convenient harbour for Chinese barks. The territory of this city borders on the kingdom of Tong-king, from which it is separated by inaccessible mountains. It has under its jurisdiction one city of the second class, and two of the third. N. lat. 21° 40'. E. long. 108° 30'.

LIENTERY, in *Medicine*, signifies that variety of diarrhœa, in which the alimentary matters pass off by stool, in an undigested or almost unchanged state. The term is derived from *LIENS*, smooth, or polished, and *VIÆRIS*, intestines, the ancients having been of opinion, that this affection was owing to the too great smoothness and lubricity of the internal membrane of the intestines, which allowed the food to slip off in an undigested state.

Some writers have treated of the lientery as a disease altogether distinct from diarrhœa; but Dr. Cullen properly considered it as only a variety of that complaint. The principal cause of the lenteric diarrhœa appears to consist in a morbid state of irritability of the stomach and bowels; whence the former organ is excited to an excessive motion of its muscular coat, by the stimulus of whatever aliment is introduced into it, and consequently expels it into the bowels in an undigested state; and the latter, being likewise morbidly sensible to the same stimulus, hurries on the undigested matter speedily through the whole canal. The motions are at the same time loose or liquid, because, on the one hand, the undigested matter is not taken up by the lacteals, and, on the other, the irritation of this matter, thus rapidly passing, excites the exhalent vessels, and the excretories of the mucous glands to pour out a more abundant quantity of their fluids. This affection is generally accompanied with a great weakness of the digestive power, as well as a morbid irritability of the stomach.

From this view of the subject, two indications present themselves with a view to the method of cure in lientery; namely, first, to lessen the irritability of the whole alimentary canal; and secondly, to strengthen the digestive power of the stomach. For it must be observed, that, although food, when converted into a proper bland chyle by the process of digestion, passes through the bowels without producing any irritating effect: yet the same food, when it is transmitted into them from the stomach in a crude and unaltered condition, operates as an extraneous and foreign matter on the irritable villous lining of the bowels, and excites them to an extraordinary peristaltic action.

The first indication, of allaying the irritability of the stomach and intestines, is to be fulfilled by the administration of opiates, or other narcotic medicines, and of astringents. Opium itself is the most effectual soother of morbid irritability that we possess; and in cases, like that under consideration, its operation is improved by the union of some aromatic substance; hence the form of the opiate confection, according to the formula of the London pharmacopœia, is a grateful and efficacious medicine for this purpose. But the irritability is still more effectually allayed, when astringents and absorbents are employed at the same time with the opiates; the best of these are the catechu, kino, and the terebinthaceous powders, or chalk. The confection catechu of the Edinburgh pharmacopœia, which combines the opiate, astringent, and aromatic in one substance, is a valuable medicine for the fulfilment of this indication. These substances may be administered in a little distilled water of some aromatic vegetable, as of mint, cinnamon, pimento, &c.

Or, with a view to the second indication, of strengthening the digestive power of the stomach, the same medicines may be combined or alternated with the tonic bitter medicines; such as the infusion of calcarilla, gentian, or orange-peel, or the decoction or infusion of the cinchona. At the same time moderate exercise, especially on horseback, will aid in re-establishing the functions of the stomach; and all cold and debilitating articles of diet, or substances of difficult solubility, should be studiously avoided. Of the former are ice, fallads, water-cresses, cucumbers, or other raw vegetables, vegetable acids, &c. We once witnessed a severe instance of lientery, which was brought on by eating a little ice-cream, at a time when a considerable degree of indigestion already prevailed; it appeared at once to sink the feeble digestive powers of the stomach, and the food was discharged almost unchanged. Of the latter, or food of difficult solubility, we may mention cheese, hard or salted meats, fatty substances, &c. which require all the energy of the healthy stomach to subdue them into chyle. When the alimentary canal is in the irritable condition above-mentioned, it is advisable for the invalid to avoid active exercise immediately after his meals, which is liable to hurry on the food into the intestines before the digestion is completed, and thus to occasion a lenteric attack. We have known persons, subject to habitual indigestion, or at least great feebleness of stomach, who at those times certainly brought on a diarrhœa of the lenteric kind, unless they remained quiet for some time after every meal. See DIARRHŒA.

LIEOU-KIEOU, in *Geography*, islands situated between Corea, Formosa, and Japan, which are 36 in number. The principal and largest is called *Lieou-kiou*, and the rest have each a particular name. The large island extends from N. to S. almost 440 lys (200 lys making 60 geographical miles), and 120 or 130 from E. to W.; but on the S. side, the extent from E. to W. is not 100 lys. The S.E. part of the island, where the king resides, is called "Cheouli," and it is in this part (according to Grotius, but in the S.W. part according to d'Anville and others), that "Kint-ching," the capital city, is situated. (See KIN-TCHIN.) These isles form a powerful and extensive empire, the inhabitants of which are civilized, and ought not to be confounded with other savage nations dispersed throughout the islands of Asia. If we believe the islanders themselves, the origin of their empire is lost in the remotest antiquity. They reckon 25 successive dynasties, the duration of which forms a period of more than 18,000 years; but it is needless to expose the absurdity of these pretensions. It is certain, however, that the existence of the country called Lieou-kiou was not known in China before the year 605 of the Christian era. In the course of this year one of the emperors of the dynasty of Soui deputed some messengers to enquire into their situation. Some information having been obtained concerning them, the emperor Yang-ti sent skillful persons, accompanied by interpreters, to summon the prince to do homage to the emperor of China, and to pay him tribute. The king of Lieou-kiou took offence, and returned an answer to the demand, that he acknowledged no prince to be his superior. An armament was fitted out by the emperor, and a fleet, in which was embarked 10,000 men, was equipped for the expedition. This fleet arrived in safety at the port of Napakiang, and, in spite of the natives, the army landed on the island. The king fell in battle, upon which the Chinese pillaged, sacked, and burnt the royal city, made more than 5000 slaves, and returned to China. In 1291 Ching-tson, emperor of the dynasty of Yuen, thought of reviving the pretensions of his predecessors; and fitted out a fleet to subdue

these islands; but this fleet proceeded no further than the isles of Pong-hou, and the western coast of Formosa, from whence, under various pretensions, they returned to Fo-kien. It was not till the year 1373, under the reign of Hong-vou, founder of the dynasty of Ming, that these islands voluntarily submitted to the Chinese government. T'fay-tou, the prince, was solemnly declared a vassal of the empire; and when Hong-vou had received his first tribute, consisting of valuable horses, aromatic wood, sulphur, tin, &c. he sent to this prince a golden seal, and confirmed the choice he had made of one of his sons for a successor. The emperor afterwards sent 36 families, almost all from the province of Fo-kien, to Lieou-chieou. These families were hospitably received, and had lands assigned them near the port of Napa-kiang, and certain revenues were appointed for their use. These families first introduced into Lieou-kiou the learned language of the Chinese, the use of their characters, and the ceremonies practised in China in honour of Confucius. On the other hand, the sons of several of the grandees of the court of T'fay-tou were sent to Nan-king to study Chinese in the imperial college, where they were treated with distinction and maintained at the emperor's expence. As these isles had neither iron nor porcelain, they were supplied by Hong-vou. Commerce, navigation, and the arts soon began to flourish. These islanders learned to cast bells for their temples, to manufacture paper and the finest stuffs, and to make porcelain, with which they had before been supplied from Japan. The subsequent revolution, which placed the Tartars on the imperial throne of China, produced no change in the conduct of the kings of Lieou-tcheou. The emperor Kang-hi (about A.D. 1720) paid a more marked attention to these isles than any of his predecessors. He caused a superb palace to be erected in honour of Confucius, and a college, where he maintained masters to teach the sciences and the Chinese characters. He also instituted examinations for the different degrees of the literati. He ordained that the king of Lieou-kiou should never send in tribute rose-wood, cloves, or any other production which was not of the growth of the country; but that he should find a fixed quantity of sulphur, copper, tin, shells, and mother-of-pearl, which is very beautiful in these islands. He permitted, that, besides the usual tribute, he might present him with horse furniture, pistol-cases, and other things of the same kind, which these islanders are said to manufacture with great taste and neatness.

It is more than 900 years, says Grosier, since the bonzes of China introduced at Lieou-kiou the worship of Fo, and the principal books belonging to their sect. This worship is at present the established religion both of the grandees and of the people. In the royal city there is still to be seen a magnificent temple, erected in honour of another idol borrowed from the Chinese, named *Tien-fey*, which signifies "celestial queen, or lady." These islanders do not swear or make promises before their idols. For this purpose they burn perfumes, present fruits, and stand reverently before some stone, which they call to witness the solemnity of their engagements. Of these stones many are to be seen in the courts of their temples, in most public places, and upon the mountains; and they are appropriated to this use. They have also among them women consecrated for the worship of spirits, who are supposed to have great influence over these beings. They visit the sick, distribute medicines, and write prayers for their recovery. They respect the dead as much as the Chinese, but their funerals are less pompous. They burn the flesh of the deceased, and preserve only the bones. They place round them lamps, and burn perfumes, and different families are distinguished by surnames, as in China;

but a man and woman of the same surname are not allowed to marry. The king is not at liberty to marry except in the three grand families, among which the highest offices are distributed. A plurality of wives is allowed in these isles. The women are very reserved; they neither use paint, nor wear pendants in their ears; they collect their hair on the top of their heads, in the form of a curl, and fix it in that manner by long pins made of gold or silver. Besides the vast domains which the king possesses, he receives the produce of all the sulphur, copper, and tin-mines, and of the salt-pits, together with what arises from the taxes; and from these revenues he pays the salaries of the mandarins and officers of his court. Of the mandarins there are, as in China, nine orders, distinguished by the colour of their caps, or by their girdles and cushions. In the royal city tribunals are established for managing the revenue and affairs of the principal island, and of all the others dependent upon it. There are also particular tribunals for civil and criminal matters, for the affairs of religion, for manufactures, commerce, navigation, &c. The vessels built in this country are highly valued by the people of China and Japan. In these the natives sail not only from one island to another, but also to China, Tonquin, Cochinchina, Corea, &c. Besides those articles of commerce, which their manufactories of silk, cotton, paper, arms, copper utensils, &c. furnish them, they also export mother-of-pearl, tortoise and other shells, coral and whetstones, which are held in high estimation both in China and Japan. Three languages are spoken in the isles of Lieou-kiou, different from those of China and Japan. The language of the large island is the same as that of the neighbouring isles; but it differs from those of the isles which lie to the S.W. and N.E. Letters, accounts, and all the king's orders are written in Japanese characters, not in the language of the country; books of morality, history, medicine, astronomy, and astrology, are written in Chinese characters. The distribution of time, and the division of the year, are the same in Lieou-kiou as in China. The edifices, temples, and palace of their kings are built after the Japanese manner; but the houses of the Chinese, the hotel of the ambassador, the imperial college, and the temple of the goddesses "*Tien-fey*," are built after the fashion of China. The natives of Lieou-kiou are, in general, mild, affable, and temperate; they are active and laborious, enemies to slavery, and detest falsehood and dishonesty. Excepting the grandees, bonzes, and Chinese established in Lieou-kiou, few of the inhabitants of these islands can either write or read. The people are fond of games and diversions. They celebrate with great pomp and splendour, those festivals that are instituted in honour of their idols, and those which are appointed for the termination and commencement of the year. Great harmony prevails among families and individuals, which they take care to preserve by frequent repasts, to which they invite one another. Suicide is unknown among these islanders; and they are free from those crimes that are common in the isles situated to the N.E. of them, which being nearer to Japan, have adopted the vices of its inhabitants, as well as their manners and customs. Grosier's China, vol. i. The capital is in N. lat. 26 2'. E. long. 128 40'.

LIEOU-TCHEOU, a town of Corea; 37 miles S.E. of King ki-tao.—Also, a city of China, of the first rank, in the province of Quang-fu, situated on the river Leng. N. lat. 24 12'. E. long. 108 47'.

LIEPE, a town of Prussia, in the palatinate of Culm; 14 miles E.S.E. of Culm.

LIEPPE, a town of Prussia, in Oberland; eight miles from Osterrod.

**LIERGANES**, a town of Spain, in the province of Biscay; 10 miles S.E. of Santander.

**LIERN**, a town of the republic of Lucca; 7 miles N.W. of Lucca.

**LIERNAIS**, a town of France, in the department of the Côte-d'Or, and chief place of a canton, in the district of Beaune; 10 miles N.W. of Arnay-le-Duc. The place contains 705, and the canton 8602 inhabitants, on a territory of 260 kilometres, in 15 communes.

**LIERNES**, a town of France, in the department of the Two Nethe, and chief place of a canton, in the district of Malines, seated on the Nethe; 10 miles S.E. of Antwerp. The place contains 9581, and the canton 13,159 inhabitants, on a territory of 105 kilometres, in four communes.

**LIETZAN**, a town of the Middle Mark of Brandenburg; 15 miles S.W. of Custrin. N. lat. 52° 28'. E. long. 14 30'.

**LIEURE**, a town of France, in the department of the Straits of Calais; 11 miles S. of Calais.

**LIEUREY**, a town of France, in the department of the Eure; 7 miles S. of Pont-Audemer.

**LIEUTAUD, JAMES**, in *Biography*, a French mathematician, who flourished in the former part of the eighteenth century, was the son of a gun-smith at Arles, and died at Paris in the year 1733. He particularly attached himself to the study of astronomy, and from the great proficiency which he made in this branch of knowledge, he obtained a seat in the French Academy of Sciences. He published twenty-seven volumes of the "Connoissance des Temps," from the year 1703 to 1739.

**LIEUTAUD, JOSEPH**, a celebrated physician and anatomist, was born at Aix, in Provence, on the 21st of June, 1703. His family had been established from time immemorial at Aix, and had produced a great number of distinguished officers, ecclesiastics, lawyers, and useful citizens. He was at first intended by his parents for the church; but the reputation of his maternal uncle, Garidel, the professor of medicine in his native place, gave him a bias to the study of medicine. Botany was the first object of his pursuits. He travelled into the countries which Tournefort had surveyed before him, and brought back many plants which had escaped the observation of that distinguished botanist. This success gained him great applause in the universities of Aix and Montpellier, and he soon obtained in the former the reversion of the chairs of botany and anatomy, which his uncle had long filled. Being appointed physician to the hospital at Aix, the necessity of pursuing his anatomical studies presented itself to his mind, together with the greater facilities which this appointment afforded, and he thenceforth nearly abandoned the subject of botany. His audience soon became numerous, comprising many persons not engaged in the study of medicine, and among others the marquis d'Argens, the intimate friend of the king. M. Lieutaud published, in 1742, a syllabus of anatomy for the use of his pupils, entitled "Essais anatomiques, contenant l'Histoire exacte de toutes les Parties qui composent le Corps humain;" it was several times reprinted, with improvements, and in 1777 was edited by M. Portal, in two volumes. He communicated also several papers on morbid anatomy, to use a common phrase, and on physiology, to the Academy of Sciences, of which he was elected a corresponding member. In 1749, however, he quitted his post at Aix, and went to Versailles, at the instance of the celebrated Senac, who then held the highest appointment at court, and who obtained for Lieutaud the appointment of physician to the Royal Infirmary. This act of friendship is

faid to have originated from the private communication of some errors, which Lieutaud had detected in a work of M. Senac, and which he did not deem it proper to publish. At Versailles he continued his anatomical investigations with unabated zeal, and was soon after his arrival elected assistant-anatomist to the Royal Academy, to which he continued to present many valuable memoirs. He also printed a volume, entitled "Elementa Physiologia, &c." Paris, 1749, which had been composed for the use of his class at Aix. In 1755, he was nominated physician to the royal family, and, twenty years afterwards, he obtained the place of first physician to the king, Louis XVI. In 1759, he published a system of the practice of medicine, under the title of "Precis de la Médecine pratique," which underwent several editions, with great augmentations, the best of which is that of Paris, 1770, in two volumes, 4to. In 1766, he published a "Precis de la Matière médicale," in 8vo. afterwards reprinted in two volumes. But his most important work, which still ranks high in the estimation of physicians, is that which treats of the seats and causes of diseases, ascertained by his innumerable dissections. It was entitled "Historia Anatomico-médica, siliens numerosissima cadaverum humanorum extirpata," Paris, 1767, in two volumes, 4to. M. Lieutaud died on the 6th of September, 1780, after an illness of five days. Eloy Dict. Hist. Hist. de l'Acad. Roy. des Sciences, for 1780, p. 48.

**LIEUTENANT, LOCUMTENENS**, a deputy, or officer, who holds the place of a superior, and discharges in his absence the duties of the office which he ought to exercise in person. The term is originally derived from *legatus* (which see), and more immediately from the French *lieutenant*, supplying or holding the place of another.

Of these, some are civil; as lords lieutenants of kingdoms; who are the king's viceroys, and govern in his stead, such as the lord lieutenant of Ireland; and lords lieutenants of counties. See **LORDS Lieutenants**.

But the term is most frequent among military men, among whom there is a variety of lieutenants.

**LIEUTENANT** is the second commissioned officer in every company of both foot and horse, and next to the captain, who takes the command upon the death or absence of the captain. Fusilier corps, grenadiers, and light infantry, have second lieutenants and no ensigns. See **CAPTAIN**.

**LIEUTENANT of Artillery**, is an officer of the artillery in each company, of which there are one first and three second lieutenants. The first lieutenant has the same detail of duty with the captain, because, in his absence, he commands the company. The second lieutenant is the same as the ensign in an infantry regiment, being the youngest commissioned officer in the company, and it is his duty to assist the first lieutenant.

**LIEUTENANT-General of Artillery**. See **Lieutenant-GENERAL of Artillery**.

**LIEUTENANT-Captain**. See **CAPTAIN**.

**LIEUTENANT of Engineers**. See **ENGINEER**.

**LIEUTENANT-General**. See **GENERAL, Lieutenant**.

In France they have also lieutenant-generals of their naval forces, who command immediately under the admirals.

In Holland they have a lieutenant-admiral, which is the same with what we call a vice-admiral.

**LIEUTENANT-General of the Ordnance**, is he who has the charge of the artillery, batteries, &c. under the master-general, or in his absence. This officer was first established in 1597. See **ORDNANCE**.

**LIEUTENANT-Colonel of Foot**. See **Lieutenant-COLONEL**.

The dragoons have also a lieutenant-colonel; but the horse have not, properly, any; the first captain of the regiment supplies the office.

**LIEUTENANT-Colonel of Horse**, is only the first captain of the regiment, who commands in the absence of the colonel, taking place of all other captains.

**LIEUTENANT of a Ship of War**, is the officer next in rank and power to the captain, in whose absence he is charged with the command of the ship, and also the execution of any orders which he may have received from the commanders relating to the king's service. The lieutenant, who commands the watch at sea, keeps a list of all the officers and men belonging to it, in order to muster it, and report to the captain the names of those who are absent from their duty. During the night-watch he occasionally visits the lower deck, or sends thither a proper officer to see that order is observed. He is always to be upon deck in his watch, to give orders for trimming the sails and superintending the navigation, and for preserving order; but he is never to change the ship's course without the captain's direction, unless it be to avoid an immediate danger. In time of battle he is to see that all the men are present at their quarters, to order and exhort them to perform their duty, and to inform the captain of any misbehaviour. The youngest lieutenant of the ship, who is also called lieutenant at arms, is, besides his common duty, to train the seamen to the use of small arms, and in time of battle to attend and direct them for this purpose.

**LIEUTENANT de Roy**, the deputy governor of all strong towns in France before the revolution, who is a check upon the governor, and commands in his absence.

**LIEUTENANT Reformed**, is he whose company or troop is broke or disbanded, but continued in whole or half-pay, and still preserves his right of seniority and rank in the army.

**LIFE**, in *Physiology*, is the peculiar condition or mode of existence of living beings. Surrounding matter we observe to be divided into two great classes, living and dead: the latter is subject to physical laws, which the former also obeys in a great degree: it exhibits also physical properties, which we find equally in the latter. But living bodies are endowed moreover with a set of properties altogether different from these, and contrasting with them in a very remarkable way; these are the vital properties, powers, faculties, or forces. They animate living matter so long as it continues alive, and are the source of the various phenomena which constitute the functions of the living animal body, and which distinguish its history from that of dead matter. The study of life, then, which is the object of the science of physiology, as organization is of anatomy, includes an inquiry into the properties that characterize living matter, and an investigation of the functions which the various organs, by virtue of these properties, are enabled to execute.

As the animals, which belong to the different classes of natural history, differ greatly in the number of functions, which they can execute, as we have every gradation from that of the greatest simplicity, to as great a complication in structure and functions; life includes very different notions in the different instances. Our view would be very imperfect if we observed it only in one example; we shall, therefore, extend our survey in a very general manner, through all the orders of animals. For this purpose we shall avail ourselves of the very excellent introductory lecture to the *Leçons d'Anatomie comparée* of Cuvier, which exhibits a luminous and philosophical view of life in general, and of its principal modifications in the different classes of animals. We shall subjoin a general account of

Bichat's division of the animal functions, and of the vital properties by which they are executed, from his *Recherches sur la Vie et la Mort*.

The idea of *life* is one of those general and obscure ideas produced in us by observing a certain series of phenomena possessing mutual relations, and succeeding each other in a constant order. We know not indeed the nature of the link that unites these phenomena, but we are sensible that a connection must exist; and this conviction is sufficient to induce us to give it a name, which the vulgar are apt to regard as the sign of a particular principle, though in fact that name can only indicate the totality of the phenomena which have occasioned its formation.

Thus, as the human body, and the bodies of several other animals resembling it, appear to resist, during a certain time, the laws which govern inanimate bodies, and even to act on all around them in a manner entirely contrary to those laws, we employ the terms *life* and *vital force* to designate what are at least apparent exceptions to general laws. It is therefore by determining exactly in what the exceptions consist, that we shall fix the meaning of those terms. For this purpose, let us consider living bodies in their active and passive relations with the rest of nature.

For example, let us contemplate a female in the prime of youth and health. That elegant voluptuous form, that graceful flexibility of motion, that gentle warmth, those cheeks crimsoned with the roses of delight, those brilliant eyes, darting rays of love, or sparkling with the fire of genius, that countenance, enlivened by sallies of wit, or animated by the glow of passion, seem all united to form a most fascinating being. A moment is sufficient to destroy this illusion. Motion and sense often cease without any apparent cause. The body loses its heat; the muscles become flaccid, and the angular prominences of the bones appear; the lustre of the eye is gone; the cheeks and lips are livid. These, however, are but preludes of changes still more horrible. The flesh becomes successively blue, green, and black: it attracts humidity, and while one portion evaporates in infectious emanations, another dissolves into a putrid fæces, which is also speedily dissipated. In a word, after a few short days there remains only a small number of earthy and saline principles. The other elements are dispersed in air, and in water, to enter again into new combinations.

It is evident that this separation is the natural effect of the action of the air, humidity, and heat,—in a word, of external matter upon the dead body; and that it has its cause in the elective attraction of those different agents for the elements of which the body is composed. That body, however, was equally surrounded by those agents while living, their affinities with its molecules were the same, and the latter would have yielded in the same manner during life, had not their cohesion been preserved by a power superior to that of those affinities, and which never ceased to act until the moment of death.

Of all the phenomena, the particular ideas of which enter into the general idea of life, this is what at first sight appears to constitute its essence, since we can form no conception of life without it, and since it evidently exists without interruption until the instant of dissolution.

But a further study of any living body convinces us, that the power which preserves the union of the molecule, notwithstanding the external forces which tend to separate them, does not confine its activity to this tranquil operation, and that the sphere of its action extends beyond the bounds of the living body itself. At least it does not appear that this power differs from that which attracts new molecule

molecule to deposit them between those that already exist : and this action of the living body, in attracting the surrounding molecule, is not less constant than that which it exercises in retaining its own ; for, besides that the absorption of the alimentary matter, its conversion into nutritive fluid, and its subsequent transmission to all the parts of the body, experience no interruption, and continue from one repast to another ; another absorption constantly takes place at the external surface, and a third by the effect of respiration. The two latter are those only which exist in all living bodies which do not digest, that is to say, in all plants.

Living bodies, however, do not increase indefinitely. Nature has assigned to each limits which it cannot exceed. It follows, therefore, that they must lose, in one way, a great part of what they gain in another ; and indeed an attentive observation has convinced us, that transpiration, and a number of other causes, tend continually to diminish their substance.

This consideration must modify the notion which we at first formed from the principal phenomenon of life. Instead of a constant union in the molecule, we cannot avoid observing, that there is a continual circulation from the exterior to the interior, and from the interior to the exterior of bodies ; a circulation which, though uniformly preserved, is notwithstanding fixed within certain limits. Thus living bodies may be considered as a kind of receptacles, into which inert substances are successively thrown, in order to combine among themselves in various manners, maintain a certain place, and perform an action determined by the nature of the combinations they have formed ; and from which they escape in order to become again subject to the laws of inanimate nature.

It must be observed, however, that there is a difference, depending on age and health, in the proportion of the parts which enter into this kind of circulation, and those which abandon it ; and that the velocity of the motion usually varies according to the different conditions of each living body.

It appears, at the same time, that life is terminated by causes similar to those which interrupt all other known motions, and that the hardening of the fibres, and the obstruction of the vessels, render death the necessary consequence of life, as repose is of motion, even though the crisis were not accelerated by innumerable causes which are foreign to the living body.

This general and common motion of all the parts forms so peculiarly the essence of life, that the parts which are separated from a living body soon die, because they possess no motion of their own, and only participate in the general motion produced by their union. Thus, according to the expression of Kant, the reason of the mode of existence of each part of inanimate bodies belongs to itself, but in living bodies it resides in the whole.

The nature of life, as above described, being once well ascertained by the observation of the most constant of its effects, a wish would naturally arise to investigate its origin, and to inquire how it is communicated to the bodies it animates. Living bodies have, therefore, been traced to their infancy ; and it has been endeavoured to carry this examination as near as possible to the moment of their formation. But they have never been observed otherwise than completely formed, and already enjoying that vital force, and producing that circulatory motion, the first cause of which we are desirous of knowing. In fact, however feeble and minute the parts of an embryo, or of the seed of a plant, may be at the moment we are first capable of perceiving them, they

then enjoy a real life, and possess the germ of all the phenomena which that life may afterwards develop. These observations, extended to all the classes of living bodies, lead to this general fact, that there are none of *those bodies* which have not heretofore formed parts of bodies similar to themselves, from which they have been detached. All have participated in the existence of other living bodies, before they exercised the functions of life by themselves ; and it was even by means of the vital force of the bodies to which they formerly belonged, that they were enabled to develop themselves so completely as to become capable of enjoying separate vitality ; for though the particular action of copulation is necessary for the production of a number of species, many are produced without it ; copulation, therefore, is only a circumstance belonging to certain cases, and does not change the essential nature of generation. It appears then that the motion proper to living bodies has really its origin in that of their parents. It is from them they have received the vital impulse ; and hence it is evident, that, in the actual state of things, life proceeds only from life, and that there exists no other except that which has been transmitted from one living body to another by an uninterrupted succession.

Unable to ascend to the origin of living bodies, there remains then within our reach no source of information respecting the real nature of the powers which animate them, except the examination of the composition of those bodies, that is to say, of their texture, and the union of their elements : for, though it may be truly said, that this texture, and this union are in some manner the result of the action of the vital impulse which has given them being, and which maintains them ; it is also evident, that in themselves this impulse can have its source and foundation : and if the first union of the chemical and mechanical elements of any living body has been effected by the vital force of the body from which it descended, we ought to find in it a similar power, and also the causes of that power, since it has to exercise a like action in favour of the bodies which are to descend from it.

But this composition of living bodies is too imperfectly known to enable us to deduce clearly from it the effects they exhibit. We observe, in general, that they are composed of fibres or laminae, forming altogether a series of reticulated substances more or less compact, which form the bases of all their solids, as well of those that are maffy, as of those that present the appearance of laminae and filaments. We are acquainted with the form, the confidence, and the position of the larger of those solids ; the ramifications of the most considerable of their vessels, and the course of the fluids they contain : but their more minute branches, and their more secret texture, cannot be traced by our instruments. We likewise know the chemical characters of the most apparent of the different fluids and concrete substances : we can even decompose them to a certain point. This investigation, however, is not only imperfect, since we cannot recombine them, but the phenomena indicate, that there must exist several other fluids which we have not yet been able to discover.

The efforts hitherto made by naturalists to prove a connection between the phenomena of living bodies and the general laws of nature, have doubtless been unsuccessful. It would, however, be wrong, on that account, to conclude that those phenomena are absolutely of a different kind ; but, on the other hand, there would be much temerity in refusing this talk, while our knowledge of the bodies in which the phenomena appear is so limited. We should be able to give only an empirical exposition, instead of a  
rational

rational system. All our labours on organic economy must therefore be confined to its history.

If, however, our knowledge of the composition of living bodies be not sufficient for the explanation of the phenomena they exhibit, we may at least employ it in recognizing those bodies when out of a state of action, and in distinguishing their remains long after death; for we find in no inert body that fibrous or cellular texture, nor that multiplicity of volatile elements which form the characters of organization and organized bodies, whether in those that are alive, or in those that have lived.

We know that inert solids are composed only of polyatomic molecules, which attract each other by their sides, and never move except to separate—that they are resolvable into a very small number of elementary substances—that they are formed of the combination of those substances, and the accumulation of those molecules—that they grow only by the juxtaposition of new molecules, the strata of which envelope the preceding mass—and that they are destroyed only by some mechanical agent separating their parts, or some chemical agent altering their combinations; but organized bodies, which are tissues of fibres and laminae, and have their interstices filled with fluids, resolve almost entirely into volatile substances, are produced by bodies similar to themselves, from which they do not separate until they are sufficiently developed to act by their own force; constantly assimilate foreign substances, and deposit them between their particles; grow by an internal power, and finally perish by that internal principle, or by the effect of life itself.

Origin by *generation*, growth by *nutrition*, termination by *death*, are the general and common characteristics of all organized bodies: if, however, there are bodies which perform only these functions, and those which are subsidiary to them, and possess only the organs necessary for such operations, there is a great number of others which perform particular functions, that not only require appropriate organs, but necessarily modify the manner in which the general functions are performed, and the organs proper to those functions.

Among the less general faculties which indicate organization, but which are not the necessary consequences of it, the faculty of sensation, and that of voluntary motion, in whole or in part, are the most remarkable, and those which have the greatest influence on the other functions.

We are conscious that these faculties exist in ourselves, and we attribute them, by analogy, and from their apparent existence, to a number of other beings, whom we therefore name *animated beings*, or, using a single word, *animals*.

It appears that these two faculties are necessarily connected, the idea of *sensation* is even included in that of *voluntary motion*; for we cannot conceive volition without desire, and unaccompanied by the sentiment of pleasure or pain. There may indeed exist inanimate bodies, that manifest external motion produced by an internal principle; but their movements are not of the same nature as those which constitute the functions essential to life, and do not merit the name of voluntary.

On the other hand, the bounty which nature displays in all her productions, does not permit us to believe that she has deprived beings susceptible of sensation, that is to say, of pleasure and pain—of the power, in a certain degree, of avoiding the one and pursuing the other. Among the misfortunes which afflict our species, one of the most painful is the situation of a man of courage withheld by a superior power from resisting oppression; and the poetic fictions best calculated to excite compassion, are those which represent sentient beings inclosed within immovable bodies. The

sighs of Clorinda issuing, with her blood, from the trunk of a cypress, would arrest the fury of the most savage of mortals. *La Gerusalemme Liberata*, canto xiii.

But, independently of the chain which connects the two faculties, and the double system of organs they require, they are accompanied by several modifications in those faculties which are common to all organized bodies: these modifications, joined to the two first mentioned faculties, are what more particularly constitute the nature of animals.

With respect to nutrition, for example, vegetables, which are attached to the soil, absorb immediately, by their roots, all the nutritive parts of the fluids which they imbibe. These roots are subdivided to extreme minuteness; they penetrate into the smallest interstices, and proceed, if it may be so said, to seek at a distance food for the plant to which they belong. Their action is tranquil and uniform, and never is interrupted except when deprived by drought of the juices which they require.

Animals, on the contrary, which are not fixed, and which frequently change their place, can transport with themselves a portion of the substances necessary for their nutrition: they have therefore received an internal cavity, into which they deposit the matters destined for their aliment; and the inward surfaces of this cavity are furnished with innumerable absorbing pores or vessels, which, according to the energetic expression of Boerhaave, are real *internal roots*: the magnitude of this cavity, in a number of animals, permits them to introduce solid substances into it. It was necessary, then, that they should have instruments for dividing those substances, and liquors for dissolving them. In a word, with such animals nutrition does not immediately commence upon the absorption of the substances which the soil or the atmosphere furnish them. It is necessarily preceded by a vast number of preparatory operations, the whole of which constitute *digestion*. See DIGESTION.

Thus, it appears, that digestion is a function of a secondary order, proper to animals, the existence of which, as well as of the alimentary canal in which it is performed, is rendered necessary by the faculty they possess of voluntary motion; but this is not the only consequence of that faculty.

The faculties of vegetables being very few, their organization is very simple; almost all their parts are composed of fibres, which are either parallel, or diverge very little. Further, their fixed position admits, that the general motion of their nutritive fluid may be preserved by simple external agents. It appears that it proceeds upwards, by the effect of the suction of their spongy or capillary texture, and the evaporation which takes place at their top, and that its motion in that direction is the more rapid in proportion as the evaporation is great. It appears also that the motion of this fluid may even become retrograde, when it ceases to flow in its usual course, or changes into absorption by the coolness and humidity of the air.

It is not only necessary that animals destined continually to change their place of existence, and to live in all kinds of situations and temperatures, should possess within themselves an active principle of motion for their nutritive fluid; but their more numerous and more developed faculties requiring a much greater complication of organs, their various parts being differently formed, often at a distance from each other, and even capable of changing their respective positions and directions, means more powerful, and otherwise disposed than in vegetables, are necessary for transmitting this fluid through such a multiplicity of intricate windings.

In the greater part of animals, therefore, this fluid is contained in innumerable canals, which are the ramifications of two trunks communicating with each other, in such a man-

ner, that the one receives in its roots the fluid which the other has pushed into its branches, and carries it back to the centre, to be again driven forward from that point.

Where the two great trunks communicate, the heart is placed: it is merely an organ, the contractions of which drive this fluid forward with great force into all the ramifications of the arterial trunk. It has two orifices, the valves of which are so disposed that the fluid contained in the whole vascular system can proceed in no other manner than in that we have pointed out; that is to say, from the heart towards the other parts of the body by the *arteries*, and from those parts back to the heart by the *veins*. See CIRCULATION and HEART.

In this movement, by rotation, consists the circulation of the blood, which is another function of a secondary order, proper to animals, and of which the heart is the principal agent and the regulator; but this function is not so necessarily connected with the faculties of sensation and motion as the function of digestion is; for two numerous classes of animals are completely deprived of circulation, and are nourished like vegetables, by simply imbibing a fluid which is prepared in the intestinal canal.

In the animals that have a circulation, the blood appears to be merely a vehicle which is continually receiving from the alimentary canal, from the external surface of the body, and from the lungs, different substances, which are intimately incorporated with it, and continually furnishing substances to all the different parts of the body, for their preservation and growth. In its passage through the extremities of the arteries the blood effects the real nutrition of the parts; at the same time it changes its nature and its colour: and it is only by the accession of the different substances, which have just been pointed out, that the venous blood is rendered proper for nutrition, or, in one word, becomes *arterial* blood.

It is by particular vessels, called *lymphatics*, that the venous blood receives the substances with which the skin and the alimentary canal supply it. By them, also, it receives even the residuum of nutrition, and the particles which are detached from different parts, to be carried out of the body by various excretions. See ABSORBENTS and ABSORPTION.

With respect to the lungs, the air that penetrates into them produces, with the venous blood, a kind of combustion, which appears to be necessary to the existence of all organized bodies: for it takes place in them all, though in very different ways. See RESPIRATION.

Vegetables, and animals which have no circulation, respire throughout the whole of their surface, or by vessels which introduce the air at different points into the interior of their bodies. No animals respire by a particular organ, except those that have a real circulation, because, in them, the blood coming from one common source, the heart, to which it constantly returns, the vessels that contain it are so disposed, that it cannot arrive at the other parts until it has passed through the lungs. This, however, cannot take place in vegetables, or in those animals in which this fluid is every where diffused in an uniform manner, without being contained in vessels.

Hence it appears that pulmonary or bronchial respiration is a function of a third order, the existence of which depends on that of circulation, and that it is a remote consequence of those faculties that characterize animals.

Even the mode of generation in animals, at least as far as the fecundation of the ova is concerned, depends on their particular faculties; for the faculties they possess of moving and advancing towards each other, of desiring and enjoying,

has fitted them for tasting all the delights of love: while, with respect to the purely mechanical part, their spermatic fluid has no occasion for any envelope, and is capable of being transmitted directly to the ova; but in vegetables, which do not possess within themselves the power of directing this fluid, it was necessary that it should be enclosed in little capsules, which are susceptible of being transported by the winds, and which form what is called the *pollen* of the *stamina*. Thus, while animals, for the performance of most of their other functions, have, in consequence of faculties peculiar to themselves, received more complicated organs, they are enabled, by those characteristic faculties, to exercise the function of generation in a manner more simple than vegetables.

These examples show how much influence the faculties of sensation and motion, which animals possess in addition to those of vegetables, have over the organs of all the other faculties which are common to both these kinds of beings. The comparison which we shall hereafter make of the different orders of animals, will, in the same manner, demonstrate that the modifications of their principal functions exercise a similar influence on all the others:—such is the union and harmony which prevails in all the parts of living bodies.

We have thus described the principal functions which compose the animal economy. It is obvious that they may be divided into three distinct orders. There are some which, in constituting animals what they are, fit them for fulfilling the part that nature has assigned to them in the general arrangement of the universe,—in a word, which would be sufficient for their existence, if that existence were only momentary. These are the faculties of sensation and motion: the latter enables them to execute certain actions, and the former determines their choice of the particular actions they are capable of performing. Each animal may be considered as a partial machine, co-operating with all the other machines, the whole of which form the universe: the organs of motion are the wheels and levers, in short, all the passive parts; but the active principle, the spring which gives the impulse to every part, resides only in the sensitive faculty, without which the animal, plunged in a continual slumber, would be reduced to a state purely vegetative;—plants themselves, as Buffon has observed, may be called animals which sleep. These two functions form the first order, and are termed *animal functions*. But animal machines, unlike those we construct, possess an internal principle of preservation and reparation. This principle consists in the union of the different functions which serve to nourish the body, that is to say, *digestion, absorption, circulation, respiration, transpiration, and the excretions*. These form the second order, and are denominated *vital functions*.

Finally, the duration of each animal's life being determined according to its kind, *generation* is a function of a third order, by which the individuals that perish are replaced by others, and the existence of each species maintained. See FUNCTION.

Having considered these functions with respect to themselves, and to their reciprocal relations, we shall next examine the organs by which they are performed.

*General idea of the organs of which the animal body is composed.*—No part of the animal body is composed entirely of solid particles; they all yield fluids by expression, or lose them by excretion; and they all exhibit the appearance of an areolated or reticular texture.

The mechanical division of the solids conducts us, in the last result, to lamellæ, or filaments, which seem to be the elementary molecule. When the lamellæ are separate, and

interrupted by sensible vacancies, they form what is called cellulosity. This cellulosity not only envelopes and pervades the most dense parts, but it appears to form almost always their basis; for membranes consist only of a more compact cellulosity, the lamellæ of which are more closely approximated, and placed more exactly above each other, and are resolved into an ordinary cellulosity by maceration. (See *CELLULAR substance*, and *MEMBRANE, cellular*.) The vessels are merely membranes rounded into cylinders. All the soft parts of the body, the fibres excepted, seem to be an assemblage of vessels, differing from each other only according to the nature of the fluids they contain, by their number, their direction, and the structure of their coats.

The chemical analysis of these substances, solids as well as fluids, exhibits only a few principles, almost all of which are to be found in each of them, though in very different proportions. Some earths, some salts, phosphorus, carbon, azote, hydrogen, oxygen, a little sulphur, and a little iron, combined in a great variety of ways, produce different compositions, viz. gelatine, albumen, and fibrous matter, &c. which, uniting in their turn, form animal solids and fluids, such as we know them. But, distant as we are from a complete analysis, we see enough to convince us, not only that we alter these compositions by our experiments, but also that several of their principles entirely escape our instruments. For a more particular account of the elementary tissues, into which the body can be resolved, see the article *FIBRE*.

The general organ, by which we exercise the faculty of sensation, is the medullary substance. In all the animals in which we can distinguish it, that substance is divided into filaments, which arising from certain centres, distribute themselves over most parts of the body, where they appear to serve other purposes besides that of procuring sensations. The centres from which those nervous cords proceed, communicate with each other in a manner more or less intimate, and several of the filaments seem of no other use than to establish those communications.

A nerve, when touched by a foreign body, causes the sensation of pain, though its contact with the parts of the body which are naturally contiguous to it, produces no sensible effect in a state of health. The nerves, by which we discern external objects, are provided, at their extremities, with organs, each of which is disposed in a particular manner, and always possesses an admirable relation to the nature of the objects, a knowledge of which each of these senses is destined to convey to us. See *NERVE* and *BRAIN*.

The general organ of motion is the fleshy or muscular fibre. This fibre contracts itself by volition; but the will only exercises this power through the medium of the nerves. Every fleshy fibre receives a nervous filament; and the obedience of the fibre ceases, when the communication of that filament with the rest of the system is interrupted. Certain external agents, applied immediately to the fibre, likewise cause contraction; and they preserve their action upon it, even after the section of its nerve, or its total separation from the body, during a period which is longer or shorter in different species of animals. This faculty of the fibre is called its irritability. Does it in the latter case depend upon the portion of the nerve remaining in the fibre after its section, which always forms an essential part of it? Or is the influence of the will itself only a particular circumstance, and the effect of an irritating action of the nerve on a faculty inherent in the muscular fibre? Haller and his followers have adopted the latter opinion; but

every day seems to add to the probability of the opposite theory. See *MUSCLE*.

Be this as it may, all the internal parts of the body destined to produce a compression on the substances they contain, have their parietes furnished with fleshy fibres, and receive nervous filaments; such is the case with the bladder, the intestines, the heart, &c. But the principal use of these fibres is the formation of *muscle*. This is the name given to the bundles of fleshy fibres, the extremities of which are attached to the moveable parts of the animal body. When the fibres which compose the muscle shorten, the two points to which it is attached are brought towards each other: this is the sole means by which all the external motions of the body and the members, even those which are necessary for removing the body entirely from one place to another, are produced.

Animals that can only crawl have their muscles attached to different parts of their skin, on which they alternately produce dilatations and contractions, which are the only motions of which they are susceptible: but those which are capable of moving themselves by leaps or otherwise, either wholly or partially, have their muscles attached to hard parts placed externally or internally. Those parts perform the office of levers, and have points of support on each other, which are called their *articulations*.

All the hard parts taken together form the skeleton. When they are covered by the muscles, they receive the name of bone; when they cover muscles, they are denominated shell, crust, or scale, according to their degree of consistency. In both cases they always enclose viscera, and determine the exterior form of the body, and the proportions of its different parts.

The articulations are provided with as many muscles as are necessary for the different movements of which they are susceptible; each muscle moving the bone to which it is attached, in its proper direction. They may be regarded as the moving powers. Their force, the point of their insertion, and the length and weight of the parts attached to the lever they have to move, determine the velocity and the duration of the motion they are capable of producing. On these different circumstances depend the force of leaping, the extent of flight, the rapidity of running, and the prehensile power possessed by different species of animals; but, as we have already observed, all this organization would remain immovable, were it not animated by the nervous system.

The soft white substance which forms the essence of this system, is divided into filaments that approach each other, and unite in bundles, which contain more filaments in proportion as they are traced nearer to the common fasciculus of all the nerves, called the spinal marrow, the anterior extremity of which is joined to the brain, that is to say, to a medullary mass of more or less magnitude, and differently formed according to the various kinds of animals.

From the action of external bodies on our own, we perceive that the nerves affected by that action communicate with the common fasciculus, and that it communicates with the brain. A ligature or a rupture intercepts the physical communication, and destroys sensation.

The only sense which belongs generally to all animals, and which pervades almost the whole surface of the bodies of each of them, is that of feeling. It resides in the extremities of the nerves which are distributed to the skin, and makes us sensible of the resistance of bodies, and their temperature.

The other senses seem to be only modifications of this one,

one, but more exalted, and capable of receiving more delicate impressions. Every one knows that the other senses are seeing, which resides in the eye; hearing, which belongs to the ear; smelling, which is attached to the membranes within the nose; and tasting, the seat of which is in the surface of the tongue. These senses are almost always situated in the same extremity of the body which contains the brain, and which we call the head.

Light, the vibrations of the air, the volatile emanations which float in the atmosphere, and saline particles soluble in water, or saliva, are the substances which act on these four senses; and the organs, which transmit the action to the nerves, are appropriate to the nature of each. The eye presents transparent lenses to the light, which refract its rays. The ear offers membranes and fluids to the air, which receive its concussions. The nose inhales the air which is to go to the lungs, and seizes, in their passage, the odorous vapours it contains. Finally, the tongue is covered with spongy papillæ, which imbibe the savory liquids that are taken into the mouth.

By these means we obtain a knowledge of what passes around us: but the nervous system likewise makes us acquainted with a great deal of what passes within us. Independently of those internal pains which indicate some disorder in our organization, and the disagreeable state in which we are placed by hunger, thirst, and fatigue, it is in consequence of the operation of this system that we experience the agonies of fear, the emotions of pity, the delirium of love. Sensations of this last kind seem, however, to be rather the effects of the re-action of the nervous system, than immediate impressions; though, at the sight of any imminent danger, we hasten to avoid it before it appears that the mind has had time to act; and the same observation applies to the transports we feel on the presence of a beloved object, or to the tears we shed over the spectacle of suffering virtue. These effects of the nervous system are produced by numerous communications which particular nerves, called *sympathetics*, establish between different branches of the general trunk, by means of which the impressions are transmitted more rapidly than by the brain. The knots called *ganglia*, when they are considerable, are each a kind of secondary brain; and it is observable, that they are larger and more numerous in proportion as the principal brain is less.

The faculty of sensation, and that of contraction, the first of which, in most animals, is exclusively appropriated to the nervous substance, and the second to the fleshy part, appear to be equally diffused in all the parts of certain gelatinous animals, in which we cannot perceive either fibres or nerves.

It is by the means of these two faculties that animals feel, desire, and are enabled to provide for their wants. The most irresistible feeling of all is that of hunger, which constantly reminds the animal of the necessity of procuring new materials for its nutrition. This third function commences in the mouth, into which the aliments are taken, and, when they are solid, masticated and moistened with dissolving liquors; thence they traverse the alimentary canal, which is longer or shorter, and more or less convoluted and dilated in different animals, and the parietes of which are composed of several continued tunics, analogous to those which form the external teguments of the body.

The coats act in a mechanical manner, on the substances which they contain, by slight contractions of their fibres; and in a chemical manner, by the liquors which are poured out within them.

The first dilatation of the alimentary canal is called the *stomach*. There are sometimes several stomachs, or several

divisions of that organ; its parietes yield a liquid which reduces the aliments to a homogeneous pulp, during the time they remain in it. The remainder of the canal is more particularly called bowels or intestines. Independently of the juices, which the different coats of the bowels produce, there are some which are separated from the mass of the blood by glands, and which penetrate the intestinal canal by particular conduits. The most remarkable and the most general of these glands are the liver and the pancreas. The first, which secretes the bile, is always of a considerable size; and besides the effect of its liquid on the intestines, produces another very remarkable effect on the blood itself, from which it removes several principles. See *STOMACH, INTESTINES, LIVER, and PANCREAS*.

It is in the intestines that the aliments undergo that change which fits them for nutrition. The nutritive part is absorbed, during the act of digestion, either by the pores of the canal itself, in animals that have no circulation, or, in those that have, by very small vessels which conduct it into the general system of nutritive vessels. These small vessels are called *lymphatics*. They are very distinct from the veins, in animals whose structure most resembles that of man: in the more inferior animals they become gradually more like the veins, and cannot be distinguished from them in those which have white blood. The membranes which compose the lymphatic vessels and veins are thin, and without apparent fibres. Internally they are furnished with valves, all opening in the direction in which the fluid they convey has to flow, that is to say, towards the heart. The arteries, on the contrary, are strong and muscular, but have no valves; the vigorous impulse of the heart is sufficient to impels a constant direction on the blood they contain.

But the chyle, or the liquor produced by digestion, is not sufficient for renewing the venous blood, and rendering it fit for the nutrition of the different parts of the body. It is necessary that it should experience the contact of the air before it enters into the arterial system. This is effected by respiration. The organs of respiration, in animals which have blood-vessels, consist in a ramification of those vessels, which increases their surface to such a degree, that almost all parts of the fluid are separated from the surrounding element only by a very thin pellicle, which cannot obstruct its action. This ramification takes place on the surface of certain folds or lamellæ in aquatic animals, and on that of certain cells in aerial animals. In the first case the organ is denominated *branchie*, in the second *lungs*. In animals which have no vessels, the air reaches all parts of the body, and acts on the nutritive fluid at the same moment in which that fluid combines with the parts of the body which it is destined to nourish. This is the case with insects that have *tracheæ*. It will be easily conceived that there must be muscular organs, appropriated to each of those species of respiration, destined to attract or impel the ambient fluid towards the place where it has to act upon the blood. This office is performed by the ribs, the diaphragm, the muscles of the abdomen, the flaps of the gills, and several other parts, according to the nature of the animal. See *LUNG*.

The air cannot be employed in the formation of the voice, except in the animals that respire by cellular lungs, because it is in them only that it enters by a single and lengthened tube. At one or two parts of this tube there are membranes susceptible of tension, which vibrate when the air acts upon them, and thereby produce the various sounds which we call the *voice*. The animals which have no voice, properly so called, are not, however, deprived of the power of producing certain sounds, but they are produced in them by other means. See *LARYNX*.

The blood, on its passage into the organ of respiration, experiences a kind of combustion, which removes a part of its carbon, carrying it off under the form of carbonic acid, and which thereby augments the proportion of its other elements. The effect of this process on the respired air, is to deprive it of its oxygen, which is the only aeriform fluid that can be serviceable to respiration. Its effect on the blood is less known: we know that it heightens the colour of the blood in red-blooded animals, and gives it the power of exciting the heart to contraction. There is even reason to believe that it is this action of the air on the blood which gives, indirectly, to the fleshy fibres their contractile power. It is still necessary that the blood should lose several other principles: some are carried off by the kidneys, which secrete the urine, and which are found in all animals that have red blood. The matter which transpires through the pores of the skin, and the substances which pass through the intestinal canal, a great part of which are carried away with the excrements, relieve the blood of other principles. These three kinds of excretions, to a certain degree, supply the place of each other, and appear, therefore, to tend towards one common object. See INTEGUMENTS, KIDNEY, and RESPIRATION.

These are all the organs which constitute the animal; considered individually, and which are sufficient for its separate existence, while the object is not the multiplication of the species: such are the whole of the organs in the higher orders of animals. We shall see that, in proportion as we descend in the scale of being, they successively disappear, and that at last we shall find, in the lowest classes, only what is necessarily connected with the idea of an animal; that is, a sac, sensible, moveable, and capable of digesting.

Upon a close observation of the action of all these organs, it will appear, that all the operations which take place in the animal body, depend on the combination and decomposition of the fluids contained within it. To the animal process, by which one fluid is separated from another, or is formed from a part of the elements of one, mixed with a part of those of another, we give the name of *secretion*: this term, however, is usually confined to the changes which take place in different kinds of glands, that is to say, in bodies more or less thick, in which the blood-vessels, being infinitely subdivided, permit the liquid which the gland separates from the blood to transude from their extremities. (See GLAND.) But the animal economy exhibits a number of other transformations, or separations of humours, which equally merit this name. It cannot be supposed that the nerves act on the muscular fibres without producing a chemical change on the fluid that may be contained in the one, by the accession of that which the others may transmit, nor that external objects act upon the nerves otherwise than by producing a change of the same kind. The fluid contained in the nervous system must have been separated from the blood in the brain, and, in general, in all the medullary organs. The blood itself does not attain its state of perfection until a multitude of substances have been detached from it by the lungs, the kidneys, the liver, &c. and until after it has received a number of others which have been separated from the alimentary mass by the lacteal vessels: on the other hand, this mass is not capable of yielding chyle until it has in its turn received different liquors which have been secreted from blood by several organs; and the blood only nourishes the parts to which it is distributed, by the particles that are detached from its mass, while other particles are separated from these parts to return into the mass of the blood through the medium of the lymphatic vessels.

In a word, all the animal functions appear to reduce them-

selves to the transformation of fluids. In the manner in which these transformations are produced, the real secret of the admirable economy of animals consists, as health depends upon their perfection and regularity.

If we do not perceive this process in a manner sufficiently clear when the embryos of new individuals begin to develop themselves within or without the bodies of their mothers, we can at least discover it in the preparation of the male liquor, which, by its presence, excites or occasions that development in all the species in which copulation is necessary. This development takes place in the same manner as the ordinary growth. It, therefore, comes under the general rule.

The organs of generation, which alone remain to be noticed, are those which prepare the prolific liquor, and convey it to the ova, and those which are destined to contain and protect the embryo during its development. The first constitute the male, the second the female sex.

The testicles are the glands which secrete the seminal fluid; several other glands prepare liquors which mingle with it. The penis contains the seminal canal; it swells by the accumulation of blood when the nerves are excited by desire: by that means, it is rendered capable of penetrating the vagina, which leads to the matrix, or to the *oviductus*, and of conveying thither the fluid destined to vivify the ova. The oviduct or tube receives the ovum at the moment in which it is detached from the ovary; and conducts it without the animal if it be of the oviparous kind, or into the matrix if it be viviparous. The little embryo develops itself, and draws its nourishment, either from the body of its mother, by the absorption of a large tissue of vessels connected with those of its own body, or from an organized mass attached to it in the same manner, and which forms the yolk of the egg, or the *vitellus*. When the embryo attains a certain state, the matrix expels it; or it breaks the shell of the egg in which it is contained, and escapes from its prison. See GENERATION.

*View of the principal differences which animals exhibit in their several organs.*—It appears from the preceding account, that what is common to each kind of organs, considered in all animals, resolves itself into a very small compass, and that frequently they only resemble one another in the effects they produce. This is particularly obvious with respect to respiration, which is performed in the different classes of animals by organs so various, that their structure presents no common point of comparison. Those differences in the organs of the same kind are precisely the object of comparative anatomy; and the short exposition we are about to make, of the principal of these differences, may be regarded as a general view of this subject. We shall, therefore, return to each of the functions of which we have treated, and examine the different degrees of energy it possesses, and the particular means by which it is carried on in different animals.

The organs of motion present us at first sight with two important distinctions with respect to their situation. Sometimes the bones form an internal skeleton, articulated and covered by the muscles; sometimes there are no internal bones, but merely scales or shells which cover the skin, within which are the muscles: in other cases there is no hard part that can serve as a lever or point of support for the motions of the animal's body.

Animals of the first kind have the whole body supported by a strong pillar, formed of several bony pieces, placed one above the other, and called the spine of the back, or the vertebral column. They are, therefore, denominated *vertebral animals*. These are the mammalia, birds, reptiles, and fishes.

The animals without vertebrae are either entirely soft, or have

have their bodies and members enveloped in scales articulated on one another, or, finally, are enclosed in shells. These are the soft worms, insects, and the testacea.

It is by the greater or less perfection of certain parts that the animals of these different classes become susceptible of various kinds of motion.

The organs of sensation present considerable varieties;—some have a relation to the internal part of the nervous system, others to the external senses. The first give rise to three classes:—that of animals which have no apparent nervous system, and in which we discover neither vessels nor nerves; such are the zoophytes or the polypes:—that of animals in which there is only the brain above the alimentary canal, and which have all the remainder of the common bundle of nerves situated underneath, and contained in the same cavity with the other viscera; these are the mollusca, the crustacea, insects, and a part of the articulated worms: lastly, that of animals in which the common fasciculus of the nerves is situated entirely in the back above the alimentary tube, and enclosed in a canal which passes through the vertebral column; these are all the vertebral animals. Their ganglia are placed on the sides of their medullary cord, or dispersed in the large cavities. Among the invertebral animals there are some that have ganglia only in the large cavities, as the mollusca, and others, which have them all on the medullary cord itself, of which they appear to be swellings; these are the insects, and some articulated worms.

The differences in the external senses consist in their number, and in the degree of energy that belongs to each.

All vertebral animals possess the same senses as man.

Sight is wanting in the zoophytes, in several kinds of articulated worms, in several larvae of insects, and in the acephalous mollusca. Hearing does not exist, at least we have not yet discovered its organ, in some mollusca and insects. The other three senses, but particularly those of taste and touch, appear never to be wanting.

But each of these senses may vary considerably in the degree of its susceptibility, and the complication of its structure. The perfection of the sense of touch, for example, depends upon the delicacy of the external teguments, and on the division of the extremities that more particularly enjoy that sense; their formation rendering them capable of being applied more or less exactly to the bodies of which the animal wishes to acquire a knowledge. Above all, it is in the number and flexibility of the fingers and toes, and the smallness of the claws or nails, that the anatomist discovers important characters.

The eyes may be more or less moveable, more or less covered, and more or less numerous. The ears may be sunk within the cranium, or exposed outwardly; or they may be provided with an external trumpet, which collects the rays of sound. The membranes in which the sense of smelling resides, may be more or less extensive: those which are the seat of taste, may be more or less delicate and humid; but it is only by particularly considering each of these senses, that we can take a comprehensive view of the differences that exist in the various classes of animals.

The organs of digestion exhibit two important differences in their general dispositions. In certain animals, (in the greater part of zoophytes,) the intestines form a sac with only one aperture, which serves at once for the entrance of the aliments, and the issue of the excrements: all other animals have two distinct apertures, for those purposes, at the two extremities of the same canal; but the convolutions of this canal may be such as to remove these openings

to a greater or less distance from each other. Another difference which has much influence on the nature of the aliments appropriated to each species, is, that in certain animals the mouth is armed with teeth, or hard parts proper for grinding solid substances, while in others they do not exist. In the latter case, the animal can only swallow whole bodies if its mouth be large, or merely suck in fluids if its mouth be in the form of a tube. The structure of those teeth has itself much influence on the substances the animal can submit to mastication. The remainder of the alimentary canal varies also considerably in its structure, according to the different substances which the mouth conveys to it. On this likewise depend the length of the canal, and the number of stomachs, cæca, &c.

The chyle produced by the action of the digestive organs on the alimentary substances is transmitted to the various parts of the body in two different ways. It either simply transudes through the parietes of the intestinal canal, to bathe all the interior of the body, or it is absorbed by particular vessels which convey it into the mass of the blood. The first is the mode in which this operation is performed in zoophytes, and, probably, also in common insects, which appear to have no kind of vessels proper for circulation. As to the other animals, *viz.* the mollusca, and the vertebral animals, that have absorbent vessels, they exhibit two new differences. The latter have red blood, and the lymph and chyle white. Almost all the others have these two fluids of the same colour.

Vertebral animals differ among themselves, with regard to the colour of the chyle, which is white and opaque in the mammalia, and transparent, like the other lymph, in birds, reptiles, and fishes. The three last classes, therefore, have no conglobate glands in their chyloferous vessels, while they are very numerous in the first.

The circulation of the blood is accompanied with very important differences in its organs. In the first place, there are animals which have no circulation whatever, *viz.* insects and zoophytes: others have a double, and others a single circulation. We call that a double circulation in which no part of the venous blood can enter the arterial trunk, until it has passed through the organ of respiration, which is generally formed of the ramifications of two vessels; the one arterial, the other venous; each nearly as large, but not so long, as the two principal vessels of the body. Such is the circulation of man, of all mammalia, of birds, fishes, and a number of mollusca.

In the single circulation a great part of the venous blood re-enters the arteries without passing through the lung; because only one branch of the arterial trunk is expanded upon that organ; such is the circulation of the amphibia.

There are, besides, other differences in the hearts, or muscular organs, destined to give impulse to the blood. In the single circulation there is only one heart; but when the circulation is double, there is sometimes an organ at the base of the aorta, and also at that of the pulmonary artery. At other times it is at one of the two only.

In the one case, the two hearts, or rather the two ventricles, may be united, as in man, mammalia, and birds; or they may be separate, as in the cuttle fish.

Where there is only one ventricle, it may be placed at the base of the artery of the body, as in snails, and other mollusca; or at the base of the pulmonary artery, as in fishes.

The organs of respiration are likewise distinguished by a number of remarkable differences. When the element that acts on the blood is the atmospheric air, it penetrates even

into the interior of the respiratory organ; but when that element is water, it simply glides over a surface more or less multiplied.

The lamellæ which compose the organ, in the latter case, are called *branchiæ*. They are found in fishes, and in a number of mollusca: instead of lamellæ, we sometimes find fringes or tufts.

The air either enters the body by a single aperture, or by several. In the first case, which is that of all animals that have what is properly called lungs, the canal which receives the air divides into a number of branches, terminating in as many small cells, that are usually united into two masses, which the animal has the power of compressing or dilating at pleasure.

When there are several apertures, which is the case only with insects, the vessels that receive the air are ramified *ad infinitum*, and convey it to all parts of the body without exception. This we call respiration by tracheæ.

Lately, the zoophytes, if we except the echinodermata, have no apparent organ of respiration.

The organs of the voice present only two differences, which may be regarded as general. They depend on the position of the glottis, in which the sound is formed. In birds, it is at the lower part of the *trachea* or tube, which conducts the air, where it divides into its two branches to pass into the lungs. In quadrupeds and reptiles it is situated in the beginning of the trachea, at the root of the tongue.

Only these three classes have a glottis; but the other animals produce sounds by different means. Sometimes they employ the friction of certain elastic parts; sometimes they beat the air with other parts, or produce a rapid motion in certain portions of air, which they somewhere retain in their bodies.

Generation gives rise to varieties of two kinds. The one relates to the actions which occasion it, the other to the result.

In a small number of animals, belonging almost entirely to the class of zoophyta, generation is performed without copulation, and the young animal grows on the body of the parent, like a shoot on a tree: others only produce in consequence of copulation, and are therefore provided with two sexes; but these two sexes may be separate in different individuals, or united in the same. It is only in the mollusca and zoophyta that this last case occurs: all animals with vertebræ, and insects, have the sexes separate.

Hermaphrodite animals, such as the bivalve shell-fish, generate singly; in others, a reciprocal copulation takes place, each of the two individuals performing the functions of male and female: this is the case with the snails and other mollusca that crawl on the belly.

The produce of generation is either a bud which develops itself into an animal, remaining some time on the body from which it proceeds, and of which it forms as it were a branch; or it is a fetus, which unfolds itself in the uterus of its mother, to which it is connected by a plexus of vessels, and from which it comes forth alive; or, finally, it is a fetus included in a shell, with a substance adhering to it by vessels which it must absorb before it is discharged. These are the gemiparous, viviparous, and oviparous modes of generation.

The first occurs in some zoophytes, and in some articulated worms; the second in man and other mammalia only; the third is common to all other animals; and when their young come forth alive from the body of the mother, as is

the case with the viper, it is because the eggs are hatched in the oviduct.

Lately, if we consider the states through which the young animal is obliged to pass before it becomes, in its turn, capable of perpetuating its species, we again discover two principal differences. Some have at their birth the form which they will always preserve, with the exception of a few inconsiderable parts which have yet to disclose themselves, and to change their proportions: the others, on the contrary, have a form altogether different from their perfect state, and not only have to produce and unfold new parts, but must lose their old ones: these are the animals which undergo a metamorphosis. Hitherto this change has only been observed to take place among insects, and among the reptiles without scales, that is say, frogs and salamanders.

Such are the chief varieties which the organs belonging to the several functions of animals exhibit.

We have, however, yet to notice one very important variety which extends to several of these functions; it relates to the organs of secretion. In the four classes of vertebral animals, and in some mollusca, these organs are glands, or at least expansions of blood-vessels; the name of gland being particularly applied to them when they form masses of some thickness.

It is not so in insects, which, instead of secretory organs, have only tubes more or less long, which attract into the spongy texture of their parietes, that portion they have to separate from the mass of the nutritive fluid.

We are as yet little acquainted with the organs of secretion in zoophytes, if indeed they can be said to have any particular organ for that purpose.

*Division of life into the animal and organic.*—The preceding sketch has exhibited to us a general view of life; when we come to examine it more in detail, it offers to us two remarkable modifications. One is common to vegetables and animals, the other peculiar to the latter. Compare together two individuals, one taken from each of these kingdoms: one exists only within itself, has no other relations to surrounding objects than those of nutrition, is born, grows, and perishes, attached to the soil, which received its germ; the other joins to this internal life, which it possesses in a still higher degree, an external life, which it establishes numerous relations between it and the neighbouring objects, unites its existence to that of other beings, and draws it near to or removes it from them according to its wants or fears. We might say that the vegetable is the skeleton of the animal, and that, in order to form the latter, it was only necessary to clothe the skeleton with an apparatus of external organs, calculated to establish the necessary relations. Hence it follows that the functions of the animal form two very distinct classes. One of these consists of an habitual succession of assimilation and excretion; by which it is constantly transforming into its own substance the particles of other bodies, and then rejecting them, when they have become useless. By the other he perceives surrounding objects, reflects on his sensations, performs voluntary motions under their influence, and generally can communicate, by the voice, his pleasures or pains, his desires or fears. By the one he lives only within himself; by the other he carries his existence out of the sphere of his own body.

I call, says Bichat, the functions of the former class, taken altogether, the organic life, because all organized beings, whether vegetable or animal, enjoy it in a more or less marked degree, and because organic structure is the only condition

## L I F E.

condition necessary for its exercise. The assembled functions of the second class form the animal life, so named because it is the exclusive attribute of the animal kingdom.

Generation does not enter into the series of phenomena of these two lives, which relate entirely to the individual; while that function regards the species, and is consequently connected only in an indirect manner to most of the other functions. Its exercise does not begin until the others have been for a long time in action; and it is extinguished long before they cease. In most animals its periods of activity are separated by long intervals of entire inaction: and in man, where the remissions are less durable, its relations to the other functions are not more numerous.

Each of the lives is composed of two orders of functions, succeeding each other, and mutually connected. In the animal life, the first order takes place from the exterior of the body to the brain; and the second, from the latter organ to those of locomotion and the voice. Objects affect successively the senses, the nerves, and the brain. The first receive, the second transmit, and the last perceives that impression which constitutes a sensation. The animal is nearly passive in this first order of functions; he becomes active in the second, which results from the successive operations of the brain, where volition arises in consequence of sensation, of the nerves, which transmit this volition, and of the locomotive and vocal organs, which are the agents of its execution. A double movement of composition and decomposition exists also in the organic life. Hence the animal is not the same at one time as at another: his organization is unchanged, but the component elements are constantly varying. The order of functions, which assimilate to the animal nutritive substances, consists of digestion, circulation, respiration, and nutrition. All foreign matters undergo the influence of these four functions, before they belong to the elements of the body. After a certain time absorption removes them, and conveys them into the circulation, from which they are separated by the cutaneous or pulmonary exhalation, or by the various secretions. Thus absorption, circulation, exhalation, and secretion, form the second order of functions in the organic life; or the order opposed to assimilation. The circulating system is the common centre in the organic, as the brain is in the animal life. The blood consists of two parts; one, furnished principally by the food, affords the materials of nutrition; while the other, constituting the wreck or residue of all the organs, supplies with materials the secretions and external exhalations. Yet the latter functions sometimes convey out of the body the products of digestion where they have never been employed in nourishing the organs. This is exemplified in the urinary and cutaneous discharges consequent on copious drinking.

The most essential difference that appears to exist between the organs of the animal and those of the organic life, is the symmetry of the one and the irregularity of the other. This observation, indeed, does not apply to all animals; nor is it invariably true in man; but it holds good generally in the latter, and forms a striking general feature. Two globes exactly alike receive the impression of light. Sounds and odours have each their double organ. The median line is clearly marked on the tongue, and its two halves exactly resemble each other. This line is not very manifest in the skin. The nerves, which transmit impressions from the sensitive organs, are arranged in symmetrical pairs. And the brain, in which the impression is received, has a regular form; its double parts resemble each other on the opposite sides; and its single organs are all symmetrically divided by the median line into two exactly corresponding halves. The

nerves, which transmit our volitions from the brain to the agents of locomotion and the voice; and the locomotive organs, composed of a great part of the muscular system, of the bony system and its dependencies; and the larynx and its accessory organs; the double agents for the execution of volitions, have a symmetrical structure throughout.

The muscles and nerves, when they do not belong to the animal life, no longer exhibit this regularity of form. The heart, and the muscular coverings of the digestive viscera, prove this with respect to the muscles; and the great sympathetic nerve, every where employed in the internal life, clearly shews the irregularity in the nerves.

On surveying the parts concerned in the organic life, we shall find that an exactly opposite character is applicable to them. The stomach, the intestines, the spleen, liver, &c. are all irregularly formed in the digestive system. In the circulating apparatus, the heart, and the large vessels, such as the vena cava, the azygos, the vena portarum, &c. exhibit no trace of symmetry. Continual varieties are observed in the blood-vessels of the extremities, and the disposition of one side is often by no means the same with that of the other.

The respiratory apparatus, at the first glance, appears regular; but we find the two branches of the trachea dissimilar in size, length, and direction; the two lungs differing in size and in the number of their lobes, &c. The organs of exhalation and absorption, the serous membranes, the thoracic duct, and the right lymphatic trunk, as well as the other absorbing vessels, have every where an irregular distribution.

Among the glands we see the mucous follicles every where scattered irregularly. The pancreas and liver are out of all symmetry: the kidneys differ in position, size, &c.

It is apparent, from these considerations, that the organs of the animal life in man are essentially characterized by symmetry; while those of the internal life have the constant character of irregularity in their external forms.

It follows from this view, that the animal life is in a manner double; that its phenomena, executed at the same time on the two sides, form an independent system on each side, of which one may go on while the other ceases. This happens in those cases of paralysis called hemiplegia, where the animal life is annihilated on one side of the body, so that the individual has no relation to surrounding objects; while the preservation of sensation and motion on the other side give him all the usual powers. The median line in these cases accurately distinguishes the sound from the affected side.

In the organic life, on the contrary, all the parts conspire to form one system, so that the functions of one side cannot be interrupted without those of the other being affected. The liver on the left influences the state of the stomach on the right; if the colon cease to act on one side, that of the other cannot go on; the same cause that should arrest the circulation in the large venous trunks and the right side of the heart, would stop it also in the left side, and in the arteries, &c. Hence, if all the organs of the internal life on one side should have their functions stopped, those of the opposite side would necessarily remain inactive, and death must follow. This assertion, however, is general, and applies to the organic functions collectively; some of the organs are in fact double, and may supply each other's places, as the kidney and lung.

Bichat proceeds to point out the differences by which the animal and organic lives are distinguished when in a state of action. He observes that harmony is to the functions of the organs, what symmetry is to their conformation; it supposes

supposes a perfect equality of force and action, as symmetry indicates an exact analogy between the external form and the internal structure. It is a consequence of the law of symmetry; for two parts, essentially alike in their structure, cannot act differently. This reasoning would lead to the general position, that harmony is the character of the external functions, and discordance the attribute of the internal ones. He then enters at considerable length into a detailed consideration of this subject; but does not succeed in proving the point to the extent asserted.

A more important distinctive character of the two lives is drawn from the periodical intermissions of the external functions, and the uninterrupted continuity of the internal ones. Whatever suspends respiration and circulation, suspends and even annihilates life if it be continued. All the secretions go on uninterruptedly; if some periods of remission are observed, as in the bile and saliva, when digestion and mastication are not going on, these affect only the degree of activity and not the entire exercise of the function. Exhalation and absorption succeed each other without ceasing; nutrition is never inactive; the double motion, of composition and decomposition, from which it results, ends only with life.

In this concatenation of the organic phenomena, each function depends immediately on those which precede it. The circulation is the centre of the whole, and immediately connected with their exercise; if that is disturbed, the others languish; they cease if the blood no longer moves. Thus, the numerous wheels of a clock stop as soon as the pendulum, which sets them all in motion, is at rest. Not only is the general action of the organic life connected to the particular action of the heart, but each function is also separately connected to all the others. Without secretion there would be no digestion; without exhalation, no absorption; without digestion, no nutrition. We may, therefore, lay down as a general character of the organic functions, their continuity of action and mutual dependence on each other.

On the contrary, consider each organ of the animal life in the exercise of its functions; you will see constantly alternations of activity and repose, complete intermissions, and not remissions like what may be seen in some of the organic phenomena. Each sense, fatigued by a long continuance of sensations, becomes momentarily unfit for the reception of new ones. The ear is not excited by sounds, and the eye is closed against the light, merely because the respective functions have been exerted for some time. Fatigued by a long exercise of the perception, the imagination, memory, &c., the brain requires a suspension of action proportioned to the duration of the preceding activity, in order to recruit the powers, without which it could not again become active.

When a muscle has been contracted strongly, and for a considerable time, it cannot perform new contraction until after a certain interval of relaxation. Hence there are intermissions in the exertions of the locomotive and vocal powers.

This intermission in the animal life may be either partial or general. The former is seen when a particular organ has been a long time in exercise, the others remaining inactive; this organ then relaxes; it sleeps while the others are awake. Each animal function, therefore, is not in an immediate dependence on the others, as is the case with the organic functions. When the senses are closed against external objects, the action of the brain may still continue; memory, imagination, and reflection, are then often exercised. Locomotion and the voice may still remain; when the latter are interrupted, the func-

tions of the senses still go on. The animal can fatigue any part separately. Each, therefore, should have the power of resting in order to recruit its forces separately; this is the partial sleep of the organs. General sleep is the assemblage of these particular acts, and arises from the law which we have just illustrated.

*Differences of the organic and animal lives in respect to the vital properties.*—Physicians and physiologists, in their writings on the vital powers, have generally begun by searching for the principle on which they depend: they have wished to descend from the study of its nature to that of the phenomena, instead of ascending from the result of observation to the conclusions which theory may suggest. The soul of Stahl, the archæus of Van Helmont, the vital principle of Barthez, the *materia vitalis* of Hunter, with a long train of et ceteras, have been regarded in their turns as the single centres of all those actions which bear the character of vitality, and have successively afforded the bases on which all physiological explanations rest in the last resort. Each of these has been successively destroyed, and nothing has been preserved from their wrecks, except the facts afforded by experiment on the powers of sensation and motion. So narrow are the limits of the human understanding, that the knowledge of first causes seem placed for ever beyond our reach. The thick veil which covers them, envelops in its innumerable folds whoever attempts to break through it. In the study of nature, principles are certain general results of first causes, from which innumerable secondary results proceed; the art of discovering the connection between these primary and secondary results is the object of every judicious mind. To seek the connection between first causes and their general effects, is like walking blindfold through a road from which we may stray by a thousand paths.

Moreover, how are we interested in knowing these causes? is it necessary that we should understand the nature of light, oxygen, caloric, &c., in order to study the phenomena? Let us imitate, in the science of physiology, the examples of modern metaphysicians in their investigations of the intellectual phenomena; let us suppose the causes, and fix our attention entirely on the grand results.

We may observe in nature two classes of beings, two classes of properties, and two classes of sciences. Beings are either organic or inorganic, properties vital or not vital, and sciences physiological or physical. Animals and vegetables are organic; minerals, inorganic. Sensibility and contractility are vital properties; gravity, affinity, elasticity, are non-vital properties. Animal and vegetable physiology, and medicine, compose the physiological sciences; astronomy, chemistry, &c. &c. are physical sciences. These two classes of sciences relate merely to phenomena. Two others, relating to external and internal forms, consequently descriptive, correspond to them; these are botany, anatomy, zoology, for organic; mineralogy, &c. for inorganic bodies.

From these properties are derived all the phenomena in each class of sciences. Whatever we see in astronomy, hydraulics, dynamics, &c. must be ultimately referred through the concatenation of causes, to gravity, elasticity, &c. In the same way the vital properties are the mainspring at which we arrive, whatever phenomena we may be contemplating in respiration, digestion, secretion, inflammation, &c.

Each body possesses a certain number of properties, which especially characterize it, and by virtue of which it concurs in its own manner in the production of the phenomena, which are successively developed in the universe.

Observe

Observe surrounding objects; carry your view towards the most distant; use the telescope on the celestial bodies moving in space, or penetrate with the microscope into the world of those concealed from our view by their minuteness; you will constantly see inert bodies gravitating towards each other, living bodies also gravitating, but more-over feeling and performing a motion, which they owe only to themselves. These properties are so inherent in both, that we cannot conceive the bodies without them; to enjoy them and to exist mean the same thing. Suppose that they should be suddenly annihilated, all the phenomena of nature would instantly cease.

*Differences between the vital properties and the physical powers.*—The extent of this difference cannot fail to strike us on the first glance. The vital properties, constantly variable in their intensity, often pass with the greatest rapidity from the lowest to the highest degree of energy, are successively exalted and weakened in the different organs, and assume, under the influence of the slightest causes, a thousand different modifications. Sleep, exercising, rest, digestion, hunger, the passions, the effect of surrounding agents, &c. expose them at every instant to numerous revolutions. The others, on the contrary, constantly the same at all times, give rise to a series of phenomena always uniform. Compare sensibility to attraction; the latter is always in proportion to the mass of the body, in which it is observed, while the former is constantly changing in the same organ, in the same mass of matter.

The invariable nature of the laws which preside over the physical phenomena, enables us to submit to calculation all the sciences of which they are the objects; but the application of the mathematics to vital action can only lead to very general formulæ. The resistance experienced by a fluid in passing through a dead tube, the velocity of a projectile, &c. may be easily reduced to a fixed law; but to calculate with Borelli the power of a muscle, the velocity of the blood with Keil, the quantity of air entering the lungs with Irwine and Lavoisier, is like building on a moving-land an edifice which is solid in itself, but which quickly falls from the insecurity of its foundation.

From the circumstances just explained, the vital and physical phenomena derive respectively the characters of irregularity and uniformity. Inert fluids are known, when they have once been accurately analysed; but one, or even many examinations do not inform us of the nature of the living fluids. Chemical analyses give us, says Bichat, the anatomy (*Anatomic cadaverique*) of them; but their physiology consists in a knowledge of the innumerable variations which they exhibit according to the condition of the respective organs. The urine differs as it is voided after a meal or after sleep; in winter and in summer: the mere passage from a warm to a cold temperature alters its composition: it is not the same in the child, the adult, and the old man; in the male and in the female; in a quiet state of the mind and in the agitation of passion. Add to these differences the innumerable alterations produced by disease. These facts prove that the organs must undergo continual changes in their mode of action, to produce correspondent variations in the substances separated from the blood.

The science of organized bodies should be treated in a manner entirely different from those, which have inorganic matter for their object. We should employ a different language; since words transported from the physical sciences to the animal or vegetable economy constantly recal to us ideas not at all connected with the phenomena of that science. If, says Bichat, men had cultivated physiology before natural philosophy, instead of after it, we cannot doubt that

they would have discovered numerous applications of the former to the latter; that they would have described rivers flowing by the tonic action of their banks; crystals formed by an excitement of the reciprocal sensibilities of the particles; planets moving by their mutual irritation at great distances, &c. All this would appear to us very unreasonable, as we see gravity only at the bottom of these phenomena: it is more rational to have recourse to gravity, chemical affinity, and a language entirely founded on these fundamental data, in a science where their influence is most obscure? Natural philosophy, chemistry, &c. are connected, because the same laws regulate their phenomena: but a vast interval separates them from the science of organized bodies, because a wide difference exists between their laws and those of life. To call physiology the natural philosophy of animals can only lead to inaccurate notions: as well might we denominate astronomy the physiology of the stars.

*Difference between the vital properties and those which arise from organization.*—The properties of any living organ are of two kinds: the one immediately connected with life, beginning and ending with it, or rather forming its principle and essence; the other connected to it only indirectly, and appearing rather to depend on the organization, on the texture of the part.

Sensibility, and the power of contracting, are vital properties. Extensibility (the capability of being stretched), and the power of recovery, when the extension has ceased, are properties resulting from organization. The latter derive an increased energy from life; but they still remain in the organs when life has ceased, and decomposition is the only termination of their existence. We shall consider first the vital properties.

*Of the animal and organic sensibilities.*—The vital properties are reduced to those of perceiving or feeling (sensibility), and moving (contractility): each of these has a different character in the animal and organic lives. In the latter, sensibility is only the capability of receiving an impression: in the former, it is the capability of receiving an impression, with the additional power of referring it to a common centre, or consciousness. The stomach is sensible to the presence of food, the heart to that of the blood, and an excretory tube to the contact of its proper fluid: but this power ends in the organ itself. The organs of sense, the mucous surfaces at their origins, the nerves, &c. are sensible to the impressions of bodies which touch them, and moreover transmit these impressions to the brain, which is the general centre of the sensibilities of these various organs.

Thus we have an organic and an animal sensibility. On the former depend all the phenomena of digestion, circulation, secretion, exhalation, nutrition, &c. it is common to plants and animals; the zoophyte enjoys it as well as the most perfectly organized quadruped. From the latter flow the sensations, perception, and pleasure and pain, which modify them. The perfection of an animal is in proportion to the degree in which he enjoys this sensibility. It is not an attribute of vegetables.

The difference in these two modifications of sentient power is well marked in the mode of their termination in sudden deaths. The animal sensibility is immediately extinguished. There is no trace of this faculty left in the instant which succeeds a powerful concussion of the brain, a great hemorrhage, or an apoplexy: but the organic sensibility still subsists for a longer or shorter time. The lymphatics still absorb: the muscle quivers when pricked; the nails and hairs even seem to grow. All traces of this sensibility are not destroyed until after an interval, occasionally of considerable length.

Yet the essential nature of these two powers is probably the same. In many parts they are connected together and succeed each other in an insensible manner; as we may observe in the origins of the mucous membranes. We are sensible of the passage of the food through the mouth and the pharynx: this sensation becomes weaker in the beginning of the œsophagus, almost ceases in the middle of that tube, and disappears at its lower extremity and in the stomach, where the organic sensibility alone remains. The urinary and generative organs exhibit exactly the same phenomenon; there is animal sensibility near the skin; it gradually diminishes, and becomes at last organic in the interior of the organs.

Different stimuli, applied to the same organ, excite in it one or the other of these sensibilities. When ligaments are cut, or irritated by acids or alkalies, they do not transmit to the brain the strong impressions which they receive. But, if they are twisted, distended, or torn, acute pain is the consequence. The blood circulates in the arteries without our feeling it, but inject an extraneous fluid, and the cries of the animal shew that he is sensible to the impression.

We daily observe inflammation, by increasing the organic sensibility of a part, transform it into animal sensibility. Cartilages, serous membranes, &c. which, in their ordinary state, have only the obscure sensibility necessary for their nutrition, become endued, when inflamed, with animal sensibility, often more acute than that of the organs, in which it resides habitually. Inflammation accumulates the vital properties in a part, and thereby changes the organic into animal sensibility, which differs from it only in degree.

The distinction now explained does not arise from the nature of the faculty, which is every where the same; but is founded on the different modifications of which it is susceptible. The power is common to all organs, and forms their true vital character; but it is distributed in different proportions, and bestows a different mode of existence on each. In these varieties there is a certain measure, below which the excited organ alone receives and perceives the sensation; and above which it is transmitted to the brain.

Although each organ exhibits continual varieties in its sensibility, yet it seems to possess originally a certain proportion, to which it always returns after these alternations of augmentation and diminution. This proportion constitutes the proper life (*vita propria*) of each part, and fixes the nature of its relations to those bodies, which are foreign to it, but which often come in contact with it. The salivary, pancreatic, and biliary ducts, having a proportion of sensibility exactly analogous to the nature of the fluids which pass through them, admit those readily, but reject all others. The larynx refuses admission to every thing except the air. The excretory tubes are in contact, on the mucous surfaces, with various fluids that pass over these surfaces, but they never allow them admission. In the same way the lacteals, which open on the surface of the intestinal canal, absorb chyle only, and not the fluids which may be mixed with it. These relations do not exist only between the different proportions of sensibility in the organs, and the various animal fluids; they may also take place between external matter and the parts of the animal frame. The particular sensibility of the bladder and kidneys, and of the salivary glands, establishes the relations between these organs and cantharides, mercury, &c.

It may be enquired, why nature, in the distribution of the different proportions of sensibility, has bestowed this property only in inferior degrees on the internal organs, or those of the interior life, while she has so abundantly pro-

vided with it the external organs? why, consequently, each organ concerned in digestion, circulation, respiration, nutrition, absorption, does not transmit to the brain the impressions which it receives, while all the acts of the animal life suppose this transmission? The reason seems to be, that all the phenomena, which establish our relations to surrounding beings, must be, and are in effect, under the influence of the will, while those, which are subservient to the purposes of assimilation, ought to be exempt from that influence. To make a phenomenon dependent on the will, we must be conscious of it: to exempt it from the influence of that power, this consciousness must not exist.

*Of the animal and organic contractilities.*—Contraction is the most common form of motion in the animal organs. Some indeed move by dilatation, as the iris, corpus cavernosum, &c.; but we know as yet so little of this kind of motion, that we shall confine our remarks entirely to the former.

Spontaneous motion, a faculty inherent in living bodies, presents, like sensibility, two great modifications distinct from each other, as we observe it in the phenomena of the two lives: these are the animal and the organic contractility. The former, subject to the will, has its origin in the brain, ceases to exist when the organs no longer communicate with the brain, and participates in all the affections of that part. It resides exclusively in the voluntary muscles, and predisposes over the function of locomotion and the other movements, and the voice. The latter, not dependent on any common centre, has its origin in the part, is not connected with any voluntary acts, and produces the phenomena of digestion, circulation, secretion, &c. Like the corresponding sensibilities, they are essentially distinguished in violent deaths, which suddenly annihilate the animal contractility, allowing the organic still to exert itself for a longer or shorter time. The same difference is observed in apoplexy, which so much resembles death: the animal contractility is entirely suspended, the organic still continuing active. In paralysis also, voluntary motion is destroyed, while the organic movements still go on.

These two kinds of contractility are connected to their corresponding species of sensibility. The sensations produced by external objects bring the animal contractility into exercise: and before the organic contraction of the heart takes place, its sensibility has been excited by the contact of blood.

Yet the connection is not the same in the two cases. The animal sensibility may be excited, without the analogous contractility being necessarily brought into action: but the two other powers are never separately exercised. The excretory tubes immediately re-act when the secreted fluids are brought into contact with them: the arrival of blood in the heart is necessarily followed by its contraction. This conjunction is so constant, that authors have included both powers in one name. Irritability designates both the sensation excited by the contact of any body, and the contraction of the organ when it re-acts.

There is a very simple reason for this difference. In the organic life nothing intervenes between the two faculties in their exercise; the same organ is the point at which the sensation terminates and the contraction begins. In the animal life, on the contrary, the two acts are separated by middle functions, those of the nerves and brain, which, if they are not exerted, interrupt the communication. In the same way we explain this further difference; *viz.* that there is always a strict proportion between the sensation and the contraction in the organic life, while they may be separately exalted or diminished in the animal.

*Two varieties of the organic contractility.*—The animal contractility

tractility is always nearly the same, in whatever part it may exist; but the organic displays two essential modifications, which might seem to indicate a difference of nature, although there is only a diversity of external appearance. Sometimes it may be observed very distinctly, while, on other occasions, although it really exists, inspection alone cannot appreciate it.

Sensible organic contractility may be seen in the heart, stomach, intestines, bladder, &c.: its action is exerted on the animal fluids in considerable masses.

It is by virtue of the insensible organic contractility, that the excretory tubes act on their respective fluids, the secretory organs on the blood which they receive, all parts that are nourished on their nutritive juices, the lymphatics on the substances applied to these orifices, &c. Whenever the fluids exit in small masses, where they are minutely divided, this second kind of contractility is developed.

We may illustrate the difference between them, by comparing one to the attraction, which is exerted between large masses of matter, and the other to the chemical affinities, which take place between the component particles of an aggregate. Barthez compares them to the motions of the hands of a watch: that, which marks seconds, moves round the circumference in a very obvious manner; the hour hand moves also, although we cannot perceive its motion.

The sensible organic contractility corresponds nearly to what has been called irritability; the other to the tonic power, or tonicity. These two words are objectionable, because they indicate a diversity of nature in the two properties. The common term which we employ, designates their general character, that of belonging to the internal life, and of being independent of the will; while the additional epithet expresses the peculiar attribute of each. This view of the matter is confirmed by the fact, that the two properties are connected by insensible gradations. Between the obscure, but real contractility necessary for the nutrition of the hair, nails, &c. and that which we see exerted in the motions of the intestines, stomach, &c., there are many shades which form the transition; such as the motions of the dartos, of the arteries, of some parts of the skin.

The circulation will serve to give us an idea of the gradual transition from one to the other kind of organic contractility. In the heart and large vessels, this function is regulated by the sensible kind; it becomes less and less apparent, in proportion as the diameter of the vessels diminishes; and it is lastly insensible in the capillaries where tonicity alone is observable.

To consider, with most authors, irritability as a property exclusively belonging to muscles, and constituting a character by which they are distinguished from other organs, and to express this property by a name indicating this exclusive feat, is taking a confined and erroneous view of the matter. The muscles undoubtedly occupy the first rank in this respect; they possess the greatest share of organic contractility. But every living organ re-acts, like them, though in a less apparent manner, on stimuli artificially applied, or on the fluids which it receives, and which bring to it the materials of secretion, nutrition, exhalation, or absorption.

Hence nothing can be more uncertain than the rule commonly adopted for deciding whether a part be or not of a muscular nature; a rule which consists in examining whether it contracts under the action of natural or artificial stimuli. From this mode of judging, a muscular coat has been assigned to the arteries, although their organization is throughout unlike that of the muscles; the uterus has been pronounced to be muscular, although there are great dif-

ferences between it and any muscles; and a muscular texture has been admitted in the dartos, iris, &c.

This faculty of contraction, like sensibility, is unequally distributed in the organs; and these differences, like those of sensibility, appear to be only differences in degree.

If we were to designate any kind of contraction in the muscles by a particular term, it would be their animal, rather than organic contractility; since they alone, of all parts in the body, move under the influence of the brain. This property is foreign to their tissue, and is derived entirely from the latter organ.

The two kinds of contractility cannot be changed, like the two species of sensibility. The organic is never transformed into animal; however its intensity may be increased, it is still of the same nature. The stomach and intestines are often so susceptible, that the slightest cause will produce violent motions; but these are never influenced by the brain.

*The extensibility and contractility arising from organization.*—These properties depend entirely on the organic arrangement of the parts of the frame. They succeed and are connected to each other, and are in a state of mutual dependence, like the vital phenomena of sensibility and contractility.

The extensibility of tissue, or the power of elongation beyond the ordinary state, from a foreign impulse, belongs in a very sensible manner to a great number of organs. The extensor muscles are remarkably lengthened where the limbs are bent to the greatest degree; the skin gives way and is stretched to envelop tumours; aponeuroses are distended by fluids accumulated under them, as in ascites and pregnancy. The mucous and serous membranes present analogous phenomena. The fibrous membranes and even the bones are susceptible of this distention; as, for instance, the dura mater, cranium and pericranium in hydrocephalus, the extremities and middle of the long bones in the various affections of those organs; the kidneys, brain, and liver, in abscesses of their interior, the spleen and lung when distended with blood, the ligaments in hydrops articuli; in a word, all organs, under a thousand circumstances, offer to us innumerable proofs of this property, which is inherent in their tissue, but not dependent on life. It subsists, as long as the organic structure remains, even for a long time after life has become extinct. Putrefaction, decomposition, and whatever affects the organic tissue, are the only causes that destroy the exercise of this property, in which the organs are always passive, and experience a mechanical influence from the various bodies which act on them.

We may draw out a scale of extensibility for the different organs. At the top are placed those which have the most softness in the arrangement of their fibres, as the muscles, skin, cellular tissue, &c.: at the bottom those characterized by considerable density, as the bones, cartilages, tendons, nails, &c.

A particular mode of contractility corresponds to this extensibility; it may be called the contractility of tissue, or contractility through the cessation of extension. For its exertion in any organ, it is only necessary that the extension should cease. Ordinarily, most of our organs are maintained in a certain state of tension by particular causes; the locomotive muscles by their antagonists; the hollow muscles, by the various substances which they enclose; the vessels by the fluids which circulate in them; the skin of one part, by that of the neighbouring organs; the alveoli of the jaws by the teeth, &c. Now, if any of these causes cease to act, contraction immediately takes place; divide a muscle, and its

antagonist will be shortened; empty a hollow muscular organ, and it will contract; prevent an artery from receiving blood, and it will be converted into a ligament; cut the skin, and the edges of the incision will be drawn asunder; remove a tooth, and the socket will be obliterated.

In all these cases contraction follows the cessation of a natural extension; in other instances it is the consequence of the cessation of an unnatural extension. Thus the abdomen is reduced after parturition or paracentesis; the cellular tissue after the opening of an abscess; the tunica vaginalis after the operation for hydrocele; the skin of the scrotum after the removal of a large diseased testicle; and aneurismal sacs after the evacuation of the contained fluid.

This kind of contractility is perfectly independent of life; like the extensibility, it is connected only to the tissue or organic arrangement of parts; but the vital powers bestow on it increased energy; thus a divided muscle retracts much less in the dead than in the living state. It terminates only by the disorganization of the parts from decomposition, &c., and not by the annihilation of their vital properties.

Most authors, as Haller, Blumenbach, Barthez, &c., have confounded the phenomena of this contractility with those of the organic insensible kind, or tonicity; they refer the reduction of the abdomen after its distention, the retraction of the divided skin, and the corrugation of the scrotum by cold, and the crispation of parts by certain poisons, slyptics, &c. to the same principle. The two former phenomena belong to the contractility of tissue, which never supposes the application of irritants; the latter to tonicity, which is never exerted without their influence.

In order to render the distinctions, which we have made on this subject, more clear, let us select for observation an organ in which all the kinds of contractility are united; a voluntary muscle for example. This muscle acts, first, through the influence of the nerves, which it derives from the brain; this is the animal contractility; 2dly, by the application of a chemical or physical stimulus, which produces in it a general movement analogous to those which naturally belong to the heart and other involuntary muscles; this is the organic sensible contractility or irritability; 3dly, by the arrival of fluids, which convey the materials of nutrition to all its parts, and which excite motion in every fibre and particle,—a motion indispensable to the function of nutrition, as it is in the glands to secretion, in the lymphatics to ab-

sorption, &c.; this is the insensible organic contractility or tonicity; 4thly, by the transverse section of its substance, producing retraction of the divided ends towards their points of insertion; this is the contractility of tissue. Each of these properties may be separately destroyed in a muscle; divide its nerves and the animal contractility ceases, although the two organic kinds still subsist. Apply opium to it, and stimuli will no longer excite it to motion, although the tonic movements determined by the contact of the blood still remain. Kill the animal, or intercept all the vessels which go to the limb, and the tonic powers will be destroyed, leaving only the contractility of tissue, which does not cease until gangrene or putrefaction, the consequences of destroyed vital action, appear.

This example will enable us to appreciate the different kinds of contractility in organs, where they exist in smaller number than in the voluntary muscles, as in the heart or intestines, which have all the kinds except the animal; in the white organs, as the tendons, aponeuroses, bones, &c., where the insensible organic contractility and that of tissue only are found. In general, the two latter belong to all organs, the former belonging exclusively to some particular ones. We may therefore select tonicity, or insensible organic contractility, as the general character of all living parts; and the contractility of tissue as the common attribute of all parts, whether living or dead, which are organically composed. The latter property, like the extensibility of tissue, to which it corresponds, has its different degrees; the muscles, skin, cellular substance, &c. on one part, and the tendons, aponeuroses, and bones, on the other, form the two extremes of the scale.

It will be easily seen, from what we have just said, that in the contractility of any organ two things are to be considered; viz. the power and the cause which brings that power into exercise. The power or the contractility is always the same, connected to, and inherent in the organ; but the cause which determines its exercise varies greatly, and hence the various kinds of contraction. Consequently, the distinctive epithets should be applied rather to the contraction, which expresses the effect produced, than to the contractility which indicates the principle or cause.

The general result of the preceding remarks on the vital properties, is exhibited in the following table, which presents all these properties in one point of view.

	<i>Classes.</i>	<i>Genera.</i>	<i>Species.</i>	<i>Varieties.</i>
Properties	I. Vital	1. Sensibility	1. Animal.	1. Sensible.
			2. Contractility	
II. Of tissue	1. Extensibility.	2. Organic	2. Insensible.	
		2. Contractility.		

The peculiar motions of the iris, corpora cavernosa, &c. and the dilatation of the heart, are not included in this view, because our ideas on the relations which connect these to the other kinds of motion, and the differences which distinguish them, are not yet sufficiently clear.

From the properties which have just been explained, all the functions, all the phenomena of the animal economy, may be deduced; we may refer them all, in ultimate analysis, to one or the other, as we constantly arrive, in the consideration of physical phenomena, at the same principles, viz. attraction, elasticity, &c.

Wherever the vital properties are in activity, a disengagement of caloric takes place, peculiar to the animal, and composing for it a temperature independent of that of the medium in which it lives. The word calorificity, or calorification, is improper to express this phenomenon, which is a general effect of the two great vital powers in exercise, and does not flow from any particular faculty. We do not say digestibility, respirability, &c. because respiration, digestion, and other processes, are the results of functions deduced from the common laws: the production of heat is in the same case. The digestive force of Crimaud is an expression

preſion equally objectionable. The aſſimilation of heterogeneous ſubſtances to our organs is one of the grand reſults of ſenſibility and contractility, and not a peculiar property. The ſame obſervation will apply to the formative power of Blumenbach, that of fixed ſituation of Barthez, and to the various principles admitted by numerous authors who have attributed to functions, or reſults, names that indicate laws, or vital properties.

In the article *EMBRYO* we have given a ſketch of the fate of the two lives in the fetus: we ſhall add here a ſhort view of the changes which occur after birth.

A new mode of exiſtence commences as ſoon as the child has quitted the uterus: various functions are added to the organic life, and the animal, which has not yet begun, comes into exerciſe, eſtabliſhing relations, hitherto unknown, between the individual and ſurrounding objects. While the organs of the internal life act at once in a perfect manner, thoſe of the external require a kind of education, and arrive only by degrees at that perfection which they exhibit in the ſequel. The ſenſations are at firſt confuſed, and offer only general images: habit gradually deadens theſe firſt impreſſions, and then the particular ſenſations come to be diſtinguiſhed, after long and repeated exerciſe. Thus a man, introduced for the firſt time to the magic ſpectacle of an opera, perceives only a whole which pleases him; and he gradually ſeparates the ſources of pleaſure ariſing from the dancing, the muſic, the decorations, &c. The education of the brain in this reſpect reſembles that of the ſenſes: all the mental faculties dependent on its action acquire very gradually the degree of preciſion to which they are deſtined. Perception, memory, and imagination, which are always preceded and determined by ſenſation, are enlarged in proportion to their employment. The judgment, of which they are the triple baſis, at firſt aſſociates irregularly notions which are themſelves irregular: its exertions are ſoon diſtinguiſhed by greater clearneſs; and they become at laſt rigorous and preciſe.

The voice and locomotion preſent the ſame phenomena: the cries of young animals conſiſt, at firſt, of one uniform ſound, without any diſtinct character. Age gradually modifies them; and, after repeated exerciſe, they acquire the characters peculiar to each ſpecies. It is unneceſſary to mention ſpeech, as that is ſo evidently the reſult of education.

The muſcles of the newly born animal are in continual action; but progreſſion, or even ſtanding, cannot be effected. Habit muſt teach the art of connecting together particular contractions for the production of certain effects. Until this period has arrived, there is a vacillation in all the motions, particularly the general ones, which almoſt deprives the child of the power of locomotion.

It is obvious, then, that we are obliged to learn the art of extending our exiſtence beyond ourſelves; that the exterior life acquires freſh development every day, and demands a kind of apprenticeship, which is not obſerved in the organic life.

Society exerciſes a remarkable influence on this kind of education which the external organs undergo: it enlarges the ſphere of action in ſome, contracts it in others, and modifies it in all. The occupation in which an individual is habitually employed, almoſt always exerciſes one particular organ more than the others. The ear of the muſician, the palate of the cook, the brain of the philoſopher, the muſcles of the dancer, the larynx of the ſinger, &c. have, beſides the general education of the external life, a particular education, which frequent exerciſe carries to a high degree of perfection. Hence, the muſician and painter become able to diſtinguiſh in a harmony, or a picture, what eſcapes vulgar obſervation. In ſome inſtances, this perfection of

action in an exerciſed organ is accompanied by an exceſs of nutrition, as in the occupations where particular members are exerciſed greatly and habitually.

It is no leſs true, that when one organ is conſtantly occupied, the others are inactive, and appear to loſe in capability what the other gains. The philoſopher who ſpends his life in his ſtudy, and devotes himſelf to abſtract meditations, condemns his locomotive organs to inactivity, and hence loſes the facility of exerciſing them: the dancer is in the oppoſite ſtate. The obſervation of man in ſociety will lead us every moment to ſimilar remarks: perfection of action in the locomotive organs ſcarcely ever coincides with that of the brain or ſenſes; and *vice verſa*. This obſervation naturally leads to a fundamental principle of ſocial education; *viz.* that we ſhould never direct the attention to ſeveral ſtudies at once, if we wiſh to ſucceed in each; that it is vain for any individual to cultivate various departments of human knowledge and exertion with an expectation of ſhining in each; and that in general the ſecret of excelling in any one, is, to be inferior in all the reſt. For a more detailed account of theſe views, which are not, perhaps, ſtrictly phyſiological, ſee Bichat, *ſur la Vie et la Mort*, p. 121—130.

When the child quits the womb of the mother, its organic life undergoes a remarkable development: ſeveral functions, which did not exiſt before, are now brought into exerciſe; and thoſe which had begun become more enlarged. But the organs, in either caſe, require no education: they exhibit at once a degree of perfection, which thoſe of the animal life arrive at only after frequent exerciſe. Diſtention, reſpiration, a great part of the exhalations, and abſorptions, begin at birth: after the firſt acts in the reſpective organs, they proceed with as great facility as they will ever after poſſeſs. The glands, which had been hitherto inactive, or at leaſt had produced a very ſmall quantity of fluid, are excited by various applications to their excretory ducts. The paſſage of food over the openings of the ſalivary ducts, of the chyme over the pancreatic and biliary tubes, &c. ſtimulates the reſpective glands. The excretions now alſo begin: all theſe phenomena are at once executed with preciſion, and no education is required in the organs which exhibit them.

As all the organs of the internal life act perfectly at once, none can acquire in the ſequel a ſuperiority over the others, as in the animal life. Yet it is common, even here, for one ſyſtem to predominate over the reſt: ſometimes the blood-veſſels, ſometimes the pulmonary ſyſtem, ſometimes the gaſtric organs, and particularly the liver, are exerciſed beyond their due proportion, and give a peculiar character to the temperament. But the foundation of theſe differences ſeems to be laid in original difference of ſtructure: and the ſame is the caſe where one ſyſtem is remarkably weak.

“Such, then, concludes Bichat, is the leading difference of the two lives, in reſpect to the degree of perfection of the various ſyſtems of functions of which each conſiſts: in the animal, predomance or inferiority of one ſyſtem ariſes from the greater activity or indolence of that ſyſtem; in the organic, the original conformation is the cauſe. Hence, the physical temperament and the moral character cannot be changed by education, which has ſo vaſt an effect in modifying the animal life. The character, if I may uſe the expreſſion, is the phyſiognomy of the paſſions; the temperament is that of the internal functions: as both are conſtantly the ſame, and not influenced by habit and exerciſe, they cannot be affected by education. That may, indeed, beſtow ſuch perfection on the judgment and reflection, as to make them more powerful than the paſſions: it may fortify the animal life, and make it ſuperior to the impuſes of the organic

organic. But to attempt altering the character, softening or exalting the passions, of which it is the habitual expression, or enlarging or contracting their sphere, would be an enterprise analogous to that of permanently raising or diminishing the extraordinary force of the heart, or accelerating or retarding the motions of the arteries in the state of health. We should inform any person who entertained the latter project, that circulation and respiration are not under the influence of the will, and cannot, therefore, be modified by the individual, without the occurrence of disease. The same observation will apply to those who think they can change the character, and consequently the passions; since the latter are the produce of the actions of all the internal organs, or, at least, are especially seated in them."

For the mode in which the functions cease, the connections of the animal and organic life to each other, and the reciprocal influences of the heart, brain, and lungs, see DEATH. Cuvier, *Leçons d'Anatomie comparée*, tom. i. Bichat, *Recherches Physiologiques sur la Vie et la Mort*; and his *Anatomie Generale*, in the *Considerations Generales*.

*LIFE of Mind, vita mentis*, as contra-distinguished from life of body, *vita corporis*, is held, by the Cartesianists, to consist in a perpetual cogitation, or uninterrupted course of thinking; which seems likewise to have been Aristotle's meaning, when he calls the soul *ἐνδεχόμενον*, which his interpreters call *actus*; thinking being the only proper act of the mind. But Mr. Locke endeavours to refute this principle. See THINKING and SOUL.

*LIFE of Man, vita hominis*, consists of a continued communication of body and mind; or in operations, to which both the motions of the body and ideas of the mind contribute.

Thus, *e. gr.* the mind now thinking of something, on occasion of that thought there arises a certain motion in the body: and now, again, the body moves first, which motion is followed by some thought of the mind.

In such alternate or reciprocal operation does the life of man consist; considered, as he is a compound of body and mind. See SENSATION and MOTION.

*LIFE* is more particularly used for the duration of an animal's being; or the space of time that passeth between its birth and death.

*LIFE*, considered as an object of Law. See RIGHTS. See also HOMICIDE.

*LIFE-Annuities*, are annuities, the payments of which depend on the continuance of any given life or lives; and they may be distinguished into annuities to commence *immediately*, and annuities to commence at some future period, or *reversionary* life-annuities.

The value of a life-annuity is properly the sum that will be sufficient to enable a *seller* (allowing for the chances of mortality) to pay the annuity without loss; and, supposing money to bear no interest, it is always equal to the *expectation* of the life.

For example:—Observations shew, that according to the *mean* probabilities of the duration of human life, the *expectation* of a life aged ten is nearly forty years; or, in other words, that a set of lives at this age will, one with another, enjoy forty years each of existence, some of them enjoying a duration as much longer as others enjoy a shorter. It is obvious, therefore, that supposing money to bear no interest, 40*l.* in hand for each life, would be sufficient to enable a seller to pay to any number of such lives 1*l.* *per ann.* for their whole duration; or, in other words, that 40*l.* is, on this supposition, the value of a life aged ten.

But if any improvement is made of money by putting it out to interest this will be *more* than the value; because it will be more than sufficient to pay the annuity; and as much more than sufficient as the improvement or the interest is

greater. If, for instance, any sum now in hand may be improved, by being put out to interest, at 4 *per cent.* as to double itself in eighteen years; the seller of such an annuity will (in consequence of putting out *half* the purchase-money to interest) find himself, at the end of eighteen years, in possession of 42*l.* or of 20*l.* more than is sufficient to pay the remainder of the annuities, though he should make no farther improvement of the purchase-money. If he puts out the money to higher interest he will be a greater gainer; if to less, he will be a less gainer; but at any rate of interest he must be a gainer. The truth is, that supposing the interest to be that just mentioned, or 4 *per cent.* and all the improvement possible made of the money at this interest, he will find 17*l.* 10*s.* 6*d.* for each annuity (instead of 40*l.*) to be sufficient to enable him to make all his payments. (See the tables at the end of this article.) But that if he improves the money at 5 *per cent.* he will find 15*l.* to be sufficient.

It may seem to follow from hence, that we have nothing to do to find the value of a life-annuity, but to find the expectation of the life, and then to take out of the common tables the value of an annuity *certain* for a term of years equal to the expectation; and it may appear strange that this should not give the true value.

The truth is, that it will give the value *greater* than it is; or that a less sum than that found in this way will be sufficient to pay the annuity. Supposing the interest 4 *per cent.* the value of an annuity certain for forty years is 19*l.* 16*s.* (see Tab. III. ANNUITIES); but the value of a life aged ten, at this rate of interest, is, as hath been just said, no more than 17*l.* 10*s.* 6*d.* The principal reason of this is the difference between the value of forty payments of an annuity to be made *every* year regularly one after another, till in forty years they are all made; and the value of the same number of payments to be made at greater distances of time from one another, and not to be all made till the end of seventy or eighty years. In this last case there is more time given for the improvement of the purchase-money, and therefore a less sum will be sufficient to enable a seller to make his payments. All that is learned from knowing the expectation of a number of lives, is the *mean* number of payments that will be made to each of them, and not the time in which they will be made. For example:—The expectation of a life at ten being forty years, it follows that to a hundred lives at this age, forty payments for each life, or four thousand in all, will be made. But, as all the lives will not be extinct in less than seventy or eighty years, many of the payments will not be made till after the expiration of forty years; and, therefore, a part of the purchase-money will be improved for a longer time than forty years. In general, it may be observed that *one-half* nearly of the payments of a set of life-annuities will be made after the expiration of a term of years equal to the expectations of the lives; and that this half having a longer time for accumulation than the expectations of the lives, the value of the lives must be less than the value of annuities to be paid regularly every year for a time equal to the expectations. Thus 19*l.* will, in consequence of being improved at 4 *per cent.* pay a hundred annuities of 1*l.* for forty years. But a less sum (or 17*l.* 10*s.*) will pay a hundred such annuities to a set of lives whose common expectation is forty years; because *one-half* nearly of the payments will not be made till after the end of forty years, and some not till after the end of seventy or eighty years; and consequently *one-half* nearly of the purchase-money will be improved for more than forty years, and some of it for more than seventy or eighty years.

These observations demonstrate, that it is a mistake to reckon the value of a life-annuity the same either with the value of an annuity certain for a term of years equal to the

## LIFE-ANNUITIES.

expectation of the life; or with the value of an annuity for a term certain, equal to that which a life has an even chance of exiting. This is an error into which some have fallen, but it only proves their utter ignorance of the subject.

The true method of computing the values of life-annuities may be explained in the following manner. Let us suppose that the duration of the annuity is to be only *one* year. That is, that *1l.* is to be paid a year hence, provided a life now of a given age should be then in being. Were it certain that this life would not fail in the year, the value of the annuity would be the same with the value of it payable a year hence, or with the sum which, now put out to interest, would increase to *1l.* in a year; and this sum, supposing interest at *4 per cent.* is *19s. 3d.* See Tab. II. ANNUITIES.

But the payment not being to be made, should the life happen to fail in the year, this sum ought to be diminished in proportion to the degree of the uncertainty of the life's continuing to exist through the year; and it is easy to see that this *uncertainty* or *chance* is in the proportion of the number of persons at that age living at the end of the year, to the number living at the beginning of it, as shewn by observations. For example:—if it has been found in any situation that but half the number of persons of the given age living at the beginning of the year, are living at the end of it, the uncertainty will be as half; and the value just mentioned ought to be lessened one-half. If it appears that two-thirds, or nine-tenths, or ninety-nine hundredths, are living at the end of the year, the same value must be diminished only one-third, one-tenth, or one-hundredth. That is, it will be ne-

cessary to multiply it by  $\frac{1}{3}$ ,  $\frac{9}{10}$ , or  $\frac{99}{100}$ . Universally

then, the present value of any sum to be paid a year hence, provided a given life should be then existing, is that sum multiplied by the value of *1l.* payable at the end of the year (taken out of Tab. II. under the article ANNUITIES), and also by the fraction formed by making the number of the living at the age of the given life (taken out of the Table of Observations) the denominator, and the number of the living at the next succeeding age (or at the end of the year) the numerator. For example:—let the value be sought of *1l.* payable a year hence, if a child aged ten should be then living, reckoning interest at *4 per cent.* The value of *1l.* reckoning this interest, and payable a year hence, is (as has been just said) *19s. 3d.* or (in decimal parts of a pound,) *.9615*. (See Tab. II. under the article ANNUITIES.) The number of the living at the age of ten (in Tab. III. at the end of this article) is *5675*; and at the next succeeding age (or eleven) is *5623*. It follows, therefore, that according to this table, out of *5675* living at the age of ten, only *5623* are living at the end of the year: or, in other words, that the chance or probability of a life aged ten existing through the year is as  $\frac{5623}{5675}$ , which fraction, therefore, multiplied by *.9615*, gives the value sought, or *.9526* equal to *19s. 0½d.*

Again, let us suppose that the duration of a life-annuity of *1l.* is to be two years, or that one payment of *1l.* is to be made a year hence, provided a given life should exist a year, and a second payment of the same sum at the end of two years, provided the same life should be in existence at the end of two years. The method of finding the value of the first payment has been already explained; and by the very same reasoning it may be easily discovered, that the value of the second payment must be the value of *1l.* payable at the end of two years, diminished in proportion to the uncertainty that the given life will exist two years; or (which is the same) multiplied by the fraction formed by making the num-

ber of the living at the given age the denominator, and the number of the living at the next succeeding age but one, or at the end of two years, the numerator.

Thus. Let the value be required of *1l.* payable yearly for two years, provided a child aged ten should live two years, reckoning interest at *4 per cent.*

The value of the payment at the end of the first year has been just found to be *.9526* in decimal parts of a pound, or *19s. 0½d.*

The value of the payment at the end of the second year is the value of *1l.* payable two years hence, lessened by the uncertainty that a life aged ten will live two years; or in the proportion of the number of the living in the Table of Observations at the age of twelve to the number of the living at the age of ten. That is, it is *.9245* (the said value of *1l.* payable at the end of two years, taken out of Table II. under

the article ANNUITIES) multiplied by the fraction  $\frac{5573}{5675}$ , or

*.9078*, equal to *18s. 2d.* (See Table III. at the end of this article.) To this, add the former value, or *.9526l.* and the total, or *1.8604l.* will be the value of both payments, or of an annuity of *1l.* on a life aged ten for two years.

By proceeding in this way it will appear that the value of

the same annuity for three years is  $.8889 \times \frac{5523}{5675} + 1.8604$

$= 2.725l.$  and for eighty-six years (or the whole duration of life, according to the Table of Observations) *17.5238l.*

It is evident, that in the same method the value of an annuity of *1l.* on a life at any other age is to be found; and that supposing the annuity any other sum than *1l.* its value will be this sum multiplied by the value of an annuity of *1l.*

The calculations of the values of life-annuities may be otherwise explained in the following manner. Suppose a life-annuity of *1l.* payable yearly to every one of *5675* persons, all now aged ten, the first payment of which is to be made a year hence. It appears from the Northampton Table of Observations (or Table III. under the article EXPECTATION), that only *5623* of these persons will be living at the end of the year; and consequently, that the money then to be paid will be only *5623l.* The present value, therefore, of the first payment of the annuities will be the sum which being now put out to interest will increase in a year to *5623l.* That is, it is *5623l.* discounted for a year, or *5406l. 14s. 7od.* for this sum added to its interest for a year (reckoned at *4 per cent.*) will just make up *5623l.* From the same Table of Observations, it appears farther, that of *5675* persons living at ten years of age, only *5573* will be living at the end of two years. The present value, therefore, of the second payment of the annuities will be the sum, which being now put out to compound interest at *4 per cent.* will increase to *5573l.* in two years. The sum is *51526l. 5s.* In like manner *5523, 5473, 5423, &c.* being the number living at the end of three, four, five, &c. years, the value of the third, fourth, fifth, &c. payments of the annuities will be *5523l. 5473l. 5423l. &c.* discounted for three, four, five, &c. years respectively, and continued to the year in which all the lives become extinct. The total of all these values is *99443l.* which, therefore, is the sum that would be sufficient, if improved at *4 per cent.*, to make good the payment of an annuity of *1l.* for life to every one of *5675* persons aged ten, according to the Northampton Table of Observations. The value, therefore, of such an annuity payable to only one of this number, must be the *5675th* part of *99443l.* or *17l. 10s. 6d.*

# LIFE-ANNUITIES.

In the Table of Observations, from which the examples here given have been taken, and also in the table framed by Dr. Halley, from the bills of mortality at Breslaw in Silesia, it may be observed, that the numbers dying every year out of a given number born, continue in the middle stages of life nearly the same for many years together. It was this circumstance that led M. De Moivre to form his hypothesis of an equal decrement of life through all its stages after ten. In this hypothesis, the limit or utmost probable extent of life is fixed to the age of eighty-six; and out of any number living at a given age an equal number is reckoned to die every year, till at eighty-six all the lives become extinct. Thus, for instance, if there are seventy-six persons living at ten, one of them by this hypothesis will die annually during the term of seventy-six years, at the end of which time the last surviving life will have failed. Or, in other words, seventy-five will be living at the end of the first year, seventy-four at the end of the second year, seventy-three at the end of the third year, and so on for seventy-six years; from whence it follows that the probability of one person's living

to the end of the first, second, or third year will be  $\frac{75}{76}$ ,  $\frac{74}{76}$ ,  $\frac{73}{76}$ , &c. respectively, where it appears that the fractions,

and consequently the probabilities they express, decrease arithmetically. The number of years which a life wants of the age of eighty-six is in this hypothesis called the *complement* of the life, and half this complement is always the *expectation* of the life. That is, according to what has been already said, it is the number of years which one with another a set of lives at that age will exit; or, as the writers on this subject sometimes speak, it is the *share* of life due to each of them.

It is extremely easy to calculate the values of life-annuities on this hypothesis. For by what has been just said, the value of an annuity on a life aged ten, is the sum of the series

$$\frac{75}{76} \times .9615 + \frac{74}{76} \times .9245 + \frac{73}{76} \times .8889, \text{ \&c. continued}$$

$$\text{to } \frac{1}{76} \times .05271 - .96151 - .92451 - .88891 \text{ \&c. and}$$

.05271 being the values (reckoning interest at 4 per cent.) of 1*l.* payable at the end of 1, 2, 3, &c. to 76 years; or, calling 1*l.* with its interest for a year, *r*, and 76, *n*, the value of the

$$\text{life is } \frac{n-1}{nr} + \frac{n-2}{nr^2} + \frac{n-3}{nr^3} +, \text{ \&c.} = \frac{1}{r} + \frac{1}{r^2} + \frac{1}{r^3} + \dots + (n) - \frac{1}{nr} - \frac{1}{nr^2} - \frac{3}{nr^3} - \dots - (n) =$$

$$\frac{1}{r-1} - \frac{r}{n \cdot r-1} \times \frac{1}{r-1} - \frac{1}{r^n \cdot r-1}. \text{ But } \frac{1}{r-1} \text{ is}$$

equal to the perpetuity, and  $\frac{1}{r-1} - \frac{1}{r^n \cdot r-1}$  is equal to

an annuity certain for *n* years, therefore we have the following rule:

“Find in Table III. under ANNUITIES, the value of an annuity of 1*l.* certain for a number of years equal to the complement. Multiply this value by the perpetuity increased by unity, and divide the product by the complement. The quotient subtracted from the perpetuity will be the value.”

The complement in the present case being 76, the value of an annuity for 76 years being (see Tab. III. ANNUITIES) 23.7311, and the perpetuity 25, the value of a life aged 10,

will come out 16.881. In the same manner may the value of a life at any other age be computed according to this hypothesis: and these values are the same with those in M. De Moivre's table of the values of lives.

But it is a necessary observation, that in the first and last stages of life, this hypothesis differs too much from fact; which may be easily seen, by comparing it with the following tables of the probabilities of human life. It had better therefore be entirely rejected from the doctrine of annuities, especially as we are now furnished with correct tables, deduced from real observations, of the values both of *single* and *joint* lives. The labour and difficulty of forming such tables are also greatly lessened by means of an easy theorem given by Mr. Simpson in his book on the Doctrine of Annuities; and since by Dr. Price in his Treatise on Reverendary Payments. We shall here give the explanation and proof of this theorem from Mr. Morgan's Treatise on Annuities and Assurances, chap. ii. § 2. p. 56.

“Were it certain that a person of a given age would live to the end of a year, the value of an annuity of 1*l.* on such a life would be the present sum which would increase in a year to the value of a life one year older, together with the value of the single payment of 1*l.* to be made at the end of a year; that is, it would be 1*l.* together with the value of a life aged one year older than the given life, multiplied by the value of 1*l.* payable at the end of a year. Call the value of a life one year older than the given life *N*, and the value of

1*l.* payable at the end of a year  $\frac{1}{r}$ ; then will the value of an annuity on the given life, on the supposition of a certainty that it will exist a year, be  $\frac{1}{r} + \frac{1}{r} \times N$ . But the fact is, that it is *uncertain* whether the given life will exist to the end of the year. This last value, therefore, must be diminished in the proportion of this uncertainty; that is, it must be multiplied by the probability that the given life will survive one year, which supposing  $\frac{b}{a}$  to express this proba-

bility, will make it  $\frac{b}{ar} \times \frac{1}{1+N}$ .”

The great utility of this theorem will appear from the following examples. Suppose the probabilities of life as they are given in the third of the following tables, or the tables of observations for Northampton, and the rate of interest 4 per cent., or *r* = 1.04. By reasoning in the manner already explained, the value of a life aged 95 will be expressed by the single fraction  $\frac{1}{4} \times .9615 = .2403$ . The value of a life one year younger, will, by this theorem, be

$$\frac{4}{9 \times 1.04} \times \frac{1}{1 + .2403} = .5300. \text{ The value of a life}$$

two years younger, by the same theorem, will be  $\frac{9}{16 \times 1.04}$

$$\times \frac{1}{1 + .5300} = .82701. \text{ The value of a life three years}$$

younger, or at the age of 92, will be  $\frac{16}{24 \times 1.04} \times$

$\frac{1}{1 + .8270} = 1.1711$ . If we proceed in this manner, the value of every younger life will be deduced from that next preceding; nor will the number of multiplications necessary to determine the values (agreeably to any table of observations) of all lives, at all ages, much exceed the number of those which must otherwise have been used for finding the single value of the youngest life. See Table VI.

Mr. Morgan, after having given this account of the foregoing

# LIFE-ANNUITIES.

going theorem, and explained the method of verifying all the operations in proceeding by it from one life to another, applies the theorem to the calculation of the values of joint lives, and gives a familiar method of verifying all those operations.

But instead of following him in this, we shall resume our account of the general principles on which the values of life-annuities are calculated. We have already explained these, as far as annuities on single lives are concerned. From the same principles the method of finding the value of annuities on the joint continuance of any two lives, may be understood. Suppose the ages of two persons to be 50 and 60. It appears in Table III. that of 2857 persons living at 50, only 2776 will live to be 51; or, in other words, that the probability that a person at this age will live a year, is

$\frac{2776}{2857}$ . Also, it appears from the same table, that the probability that a person aged 60 will live to 61, is  $\frac{1956}{2038}$ .

The probability, therefore, that they will both live a year, (or the former to be 51, and the latter 61,) is the product of these two probabilities, or  $\frac{2776}{2857} \times \frac{1956}{2038} = \frac{5429856}{5822566}$

For it is well known, that the probability that any two independent events will both happen, is always the product arising from multiplying the probability of one event by the probability of the other.

In like manner, the probability that the former of these lives will live to be 52, 53, 54, &c. and the latter to be 62, 63, 64, &c. or that they will both live two, three, four, &c. years, is by the same table  $\frac{2694}{2857} \times \frac{1874}{2038}$ ,

$\frac{2612}{2857} \times \frac{1793}{2038}$ ,  $\frac{2530}{2857} \times \frac{1712}{2038}$ , &c. And according to the reasoning already used, these probabilities multiplied by the values (in Table II. ANNUITIES) of  $1l.$  payable at the end of one, two, three, four, &c. years, will give the present value of the first, second, third, fourth, &c. payments of an annuity dependent, on the joint continuance of the two lives; and the sum of these products for one, two, three, four, &c. years, will be the value of an annuity of  $1l.$  on the joint continuance of the two lives for one, two, three, four, &c. years; and if the products are continued to the extremity of the oldest life, their sum will be the value of an annuity on the whole duration of the joint lives.

The values of annuities on the joint continuance of three, or any other number of lives, are found in a similar manner. The several fractions expressing the respective probabilities of their continuing one, two, three, four, &c. years, being multiplied into one another, and also into  $1l.$  discounted as before; and the sum of the products arising from these multiplications continued to one, two, three, four, &c. years, or to the extremity of the oldest of the lives, will be the values of the annuity for one, two, three, four, &c. years, or for the whole duration of the joint lives.

With respect to annuities on the *longest* of any number of lives, the reasoning is not so simple. The following explanation, however, of the method of determining their values, when only *two* lives are concerned, will be easily understood. Suppose the ages of the two persons to be 50 and 60; and for the sake of more perspicuity, let  $a, b, c, d, e$ , &c. be the number of persons living in the table at the age of the younger life, at the beginning of the first, second, third, &c. years; and, in like manner, let  $m, n, o, p, q$ , &c. be the number of persons living in the table at the age of

the older life. From what has been already observed, the chances of the younger life's surviving the first, second, third, &c. year, will be  $\frac{b}{a}, \frac{c}{a}, \frac{d}{a}$ , &c.; and the chances

of the older life's surviving those years respectively will be  $\frac{n}{m}, \frac{o}{m}, \frac{p}{m}$ , &c.; and the chances that they will *not*

survive the first, second, third, &c. years, will be  $1 - \frac{b}{a}$ ,

$1 - \frac{c}{a}, 1 - \frac{d}{a}$ , &c. and  $1 - \frac{n}{m}, 1 - \frac{o}{m}, 1 - \frac{p}{m}$ , &c.

The chance, therefore, that both will die in the first year

will be  $1 - \frac{b}{a} \times 1 - \frac{n}{m} = 1 - \frac{b}{a} - \frac{n}{m} + \frac{bn}{am}$ ,

that both will die in the second year  $1 - \frac{c}{a} \times 1 - \frac{o}{m}$ ,

$= 1 - \frac{c}{a} - \frac{o}{m} + \frac{co}{am}$ , and so on for the other years. If

each of these expressions be subtracted from unity, we shall have  $\frac{b}{a} + \frac{n}{m} - \frac{bn}{am}$  for the chance that they will *not* both

die, that is, that one or other of them will live to the end

of the first year,  $\frac{c}{a} + \frac{o}{m} - \frac{co}{am}$  for the chance that they

will *not* both die in two years, &c. By continuing these expressions for as many years as are equal to the difference between the age of the younger life and of the oldest life in the table, and multiplying them respectively into  $1l.$  discounted for one, two, three, &c. years, we shall have the whole value of an annuity on the longest of the two lives. Let

$\frac{1}{r}, \frac{1}{r^2}, \frac{1}{r^3}$ , be  $1l.$  discounted for one, two, three, &c.

years, and the series expressing the annuity will be  $\frac{b}{ar} +$

$\frac{c}{ar^2} + \frac{d}{ar^3} + \&c. \dots + \frac{n}{mr} + \frac{o}{mr^2} + \frac{p}{mr^3} +$

$\&c. - \frac{bn}{amr} - \frac{co}{amr^2} - \frac{dp}{amr^3} - \&c.$  But the first

of these series is the value of an annuity of  $1l.$  on the younger life, the second the value of the like annuity on the older life, and the third the value of the same on the two joint lives: whence it follows, that if "from the sum of the values of the two single lives we subtract the value of the two joint lives, the remainder will be the value of an annuity on the longest of the two lives."

*Example.*—Let the ages of the two lives be 20 and 30, and let interest be reckoned at  $4l.$  per cent. The value by Table VI. of a life of 20 is 16.233, and of a life of 30 is 14.781. The sum of these two values is 30.814. The value of the joint lives by Table IX. is 11.873; and this value subtracted from 30.814, leaves 18.941 for the value of an annuity on the longest of the two lives.

This account leads to an easy explanation of the method of finding the value of reversionary life-annuities mentioned at the beginning of this article, that is, of life-annuities which are to commence on the survivorship of one or more lives beyond others. See REVERSIONS and SURVIVORSHIPS.

*Problem I.*—To approximate to the value of a given life according to any given table of observations.

*Solution.*—Take the difference between twice the expectation

# LIFE-ANNUITIES.

tion of the given life by the given table, and 86; and the value deduced from M. De Moivre's Table of the values of lives corresponding to that difference, provided it is not less than ten, will be the value of the life.

*Example*—The expectation of a life aged 15 is, by the Northampton Table of Observations, (or Table IV. under the article EXPECTATION,) 36½. The difference between twice this number and 86 is 13. And the value corresponding to the age of 13 in M. De Moivre's Table of the values of lives (or Table IV.) is 16.604, reckoning interest at 4 per cent.; and this is nearly the value of a life aged 15, by the Northampton Table.

*Scholium*.—It must be remembered that this rule is only an approximation, and should not be used except when recourse cannot be had to tables giving the values of lives agreeable to given observations. The method of calculating such tables has been before particularly explained.

*Problem II.*—To determine the value of any two joint lives by M. De Moivre's hypothesis, or on the supposition of an equal decrement of life, through all its stages.

*Solution.*—This value is expressed by the series  $\frac{n-1, m-1}{nmr} + \frac{n-2, m-2}{nmr^2} + \frac{n-3, m-3}{nmr^3} + \dots (m)$  supposing  $n$  to be the complement of the younger, and  $m$  the complement of the older life, which Mr. Simpson has given in his Treatise on Annuities, and Mr. Morgan in his edition of Dr. Price's Treatise on Reverfionary Payments, note L, appendix, has demonstrated to be  $= V - \frac{V+1}{n} \times$

$$\frac{P}{n-m-2V-1} \times \frac{P}{m} + 2V, \text{ V being the perpetuity,}$$

and P the value of an annuity certain for  $m$  years. From this theorem may be deduced the following rule. Reserve the difference between the complement of the *youngest* life and the complement of the *oldest* life increased by unity and by twice the perpetuity. Multiply this difference by the value of an annuity certain for a time equal to the complement of the oldest life; and by this complement divide the product, reserving the quotient. From twice the perpetuity subtract the reserved quotient, and multiply the remainder by the perpetuity increased by unity. This last product divided by the complement of the youngest life, and then subtracted from the perpetuity, will be the required value.

*Example.*—Let the joint lives be 10 and 15. Their complements by M. De Moivre's hypothesis are 76 and 71. The complement of the oldest life, increased by unity and twice the perpetuity, (or twice 25, reckoning interest at 4 per cent.) is 122; which lessened by 76, the complement of the youngest life, leaves 46 for the reserved difference. This difference multiplied by 23.456, (the value of an annuity certain for 71 years, by Table III. ANNUITIES,) and the product divided by 71, (the complement of the oldest life,) gives 15.196, the quotient to be reserved; which subtracted from double the perpetuity (or from 50), and the remainder (or 34.803) multiplied by the perpetuity increased by unity (or by 26), gives 904.878; which divided by 76 (the complement of the youngest life), and the quotient subtracted from the perpetuity, we have 13.093 for the value of two joint lives aged 10 to 15, by M. De Moivre's hypothesis.

By this rule, Table V. in the following collection of tables, was computed by Dr. Price. (See his Treatise on Reverfionary Payments.) To this he was induced by the consideration, that there was no table extant at that time of

the values of *joint* lives, except Mr. Simpson's for London, (Table III. in this collection,) which being founded on the state of human mortality in one of the worst of all situations, or among the inhabitants of London taken in the gross, was by no means fitted for general use. The truth also is, as hath been before observed, that neither do the tables formed from M. De Moivre's hypothesis give the values of single and joint lives with the exactness necessary to adapt them properly to general use; nor can it indeed be ever necessary to have recourse to them, as we are now possessed of those tables, deduced from real observations, which are inserted at the end of this collection.

*Problem III.*—To determine the value of an annuity on a given life for any number of years.

*Solution.*—Find the value of a life as many years older than the given life as are equal to the term for which the annuity is proposed. Multiply this value by 1*l.* payable at the end of this term, and also by the probability that the life will continue so long. Subtract the product from the present value of the life; and the remainder multiplied by the annuity will be the answer.

*Example.*—Let the annuity be 10*l.*, the rate of interest 4*l.* per cent., the age of the given life 30 years, and the term proposed 15 years. The value of a life aged 45 (or 15 years older than the given life) appears by Table VI. to be 12.283. The value of 1*l.* payable at the end of 15 years (by Table II. under ANNUITIES) is .5553, and the probability that the life will exist so long is (by

Table III. under the article EXPECTATION)  $\frac{3243}{4385}$ . These

three quantities multiplied into each other are equal to 5.051, which being subtracted from 14.781, (the present value of the given life by Table VI.) we have 9.730; and this remainder multiplied into 10 (the annuity) gives 97.30*l.* for the value required.

*Problem IV.*—To approximate to the value of an annuity for three joint lives, A, B, and C.

*Solution.*—Let A be the youngest, and C the oldest of the three proposed lives. Take the value of the two joint lives B and C, and find the age of a single life D of the same value. Then find the value of the joint lives A and D, which will be the answer.

*Example.*—Let the three given ages be 20, 30, and 60. The value, reckoning interest at 4 per cent., of the two oldest joint lives B and C (by Table XIII.) is 7.802, answering nearly to a single life D of 65 years (by Table VI.); and the value of the joint lives A and D (by Table XVI.) is 6.986, which will be the value required.

This rule was first given by Mr. Simpson in his Select Exercises; and the following comparison, taken from Dr. Price's Treatise on Reverfionary Payments, will shew its correctness.

Ages.	Value by rule at 4 per cent.	Correct Value.	Ages.	Value by rule at 4 per cent.	Correct Value.
10 20 30	10.563	10.433	10 10 10	12.244	12.200
15 25 35	9.840	9.738	20 20 20	10.504	10.342

			75 75 75	2.110	2.119

# LIFE-ANNUITIES.

**Problem V.**—To find the value of an annuity on the longest of three lives, A, B, and C.

**Solution.**—Let  $a, b, c, d, \&c.$  be the number of persons living in the table at the age of A, at the beginning of the first, second, third, &c. years;  $m, n, o, p, \&c.$  the same numbers at the age of B; and  $s, t, u, v, \&c.$  the like numbers at the age of C, the older of the three lives. By reasoning as in the case of the longest of two lives, the probability that A, B, and C, will die in one, two, three, &c.

years, will be  $1 - \frac{b}{a} \times 1 - \frac{n}{m} \times 1 - \frac{t}{s} \dots 1 - \frac{c}{a}$

$\times 1 - \frac{o}{m} \times 1 - \frac{u}{s} \dots 1 - \frac{d}{a} \times 1 - \frac{p}{m} \times 1 - \frac{v}{s}$

$\&c. = 1 - \frac{b}{a} - \frac{n}{m} - \frac{t}{s} + \frac{bn}{am} + \frac{bt}{as} + \frac{nt}{ms} - \frac{bnt}{ams}$

$\dots 1 - \frac{c}{a} - \frac{o}{m} - \frac{u}{s} + \frac{co}{am} + \frac{cu}{as} + \frac{ou}{ms} + \frac{cou}{ams}$

$\dots \&c.$  which being severally subtracted from unity, the

respective remainders, or  $\frac{b}{a} + \frac{n}{m} + \frac{t}{s} - \frac{bn}{am} - \frac{bt}{as} -$

$\frac{nt}{ms} + \frac{bnt}{ams} \dots \frac{c}{a} + \frac{o}{m} + \frac{u}{s} - \frac{co}{am} - \frac{cu}{as} - \frac{ou}{ms} +$

$\frac{cou}{ams} \dots \&c.$  will express the probability that one or

other of them will live to the end of one, two, three, &c.

years. These fractions being multiplied into  $\frac{1}{r}, \frac{1}{r^2}, \&c.$

we have  $\frac{b}{ar} + \frac{c}{ar^2} + \frac{d}{ar^3}, \&c. + \frac{n}{mr} + \frac{a}{mr^2} + \frac{p}{mr^3} +$

$\&c. \dots + \frac{t}{sr} + \frac{n}{sr^2} + \frac{uv}{sr^3}, \&c. \dots - \frac{bn}{amr} -$

$\frac{co}{amr^2} - \frac{dp}{amr^3}, \&c. - \frac{bt}{asr} - \frac{cu}{asr^2} - \frac{dv}{asr^3}, \&c. - \frac{nt}{msr}$

$- \frac{ou}{msr^2} - \frac{pv}{msr^3}, \&c. + \frac{bnt}{amsr} + \frac{cou}{amsr^2} + \frac{dpv}{amsr^3}, \&c.$

for the value required. Therefore the value of an annuity on the longest of the three lives, A, B, and C, is equal to the "sum of each pair of the two joint lives, subtracted from the sum of the three single lives, added to the value of the three joint lives."

**Example.**—Let the ages of A, B, and C, be 20, 30, and 60, respectively, and interest of money 4l. per cent. By Table IX. the value of the two joint lives A and B is 11.873, of B and C 7.802, and by Table XIII. of A and C 7.995; The sum of these three values is 27.67. By Table VI. the value of the single life of A is 16.033, of B 14.781, of C 9.039. By Problem V. the value of the three joint lives is 6.986. These four values added together are equal to 46.839; from which deducting 27.67, the value of each pair of joint lives found above, we have 19.169 for the value sought.

**Problem VI.**—To find the value of an annuity granted upon three lives, A, B, and C, on condition of its ceasing as soon as any two of them become extinct.

**Solution.**—This annuity must be paid during the three joint lives, which may be expressed by  $A \overline{B} \overline{C}$ ; also,

during the two joint lives of A and B, after C; during the two joint lives of A and C, after B; and during the two joint lives of B and C, after A. These last three values are respectively equal to  $A \overline{B} - A \overline{B} \overline{C}, A \overline{C} - A \overline{B} \overline{C},$  and  $B \overline{C} - A \overline{B} \overline{C}.$  (See article REVERSIONS.) Consequently the whole value will be  $A \overline{B} + A \overline{C} + B \overline{C} - 2 A \overline{B} \overline{C}$ ; therefore find the value of each pair of joint lives, viz. of A and B, of A and C, and of B and C. Then from the sum of these three values let twice the value of the three joint lives, A, B, and C, be deducted, and the remainder will be the answer.

**Example.**—Let the ages of A, B, and C, respectively be 20, 30, and 60. By Tables IX. and XIII. the value of the joint lives,

$\left. \begin{matrix} A, B \\ A, C \\ B, C \end{matrix} \right\} \text{ will be } \left\{ \begin{matrix} 11.873 \\ 7.995 \\ 7.802 \end{matrix} \right.$

the sum of which three numbers is 27.670. Moreover, the value of the three joint lives, A, B, and C, by problem V is 6.986; therefore 13.698 is the value required.

See on this subject Simpson's Doctrine of Life Annuities, Dr. Price's Treatise on Reversionary Payments, Mr. Baron Mafers on Life Annuities, and Mr. Morgan on the Doctrine of Life Annuities and Assurances.

This Table is the same with M. De Moivre's Table of the values of single lives, published in his Treatise on Life Annuities, and carried as far as the age of 79 to three places of decimals, by Mr. Dodson, in his Mathematical Repository, vol. ii. p. 169.

TABLE V.

Shewing the value of an annuity on the joint continuance of two lives, according to M. De Moivre's hypothesis.

Age of the younger.	Age of the eldest.	Value at 3 per cent.	Value at 4 per cent.	Value at 5 per cent.
10	10	15.206	13.342	11.855
	15	14.878	13.093	11.661
	20	14.503	12.808	11.430
	25	14.074	12.480	11.182
	30	13.585	12.102	10.884
	35	13.025	11.665	10.537
	40	12.381	11.156	10.128
	45	11.644	10.564	9.646
	50	10.796	9.871	9.074
	55	9.822	9.059	8.391
60	8.704	8.105	7.572	
65	7.417	6.980	6.585	
70	5.936	5.652	5.391	
15	15	14.574	12.860	11.478
	20	14.225	12.593	11.266
	25	13.822	12.281	11.022
	30	13.359	11.921	10.736
	35	12.824	11.501	10.402
	40	12.207	11.013	10.008
	45	11.496	10.440	9.541

TABLE VIII.

Shewing the value of an annuity on the joint continuance of two lives, according to the Northampton Table of Observations.

Difference of age *five* years.

Ages.	Value at 3 per cent.	Value at 4 per cent.	Value at 5 per cent.	Value at 6 per cent.
1—6	12.347	10.741	9.479	8.467
2—7	14.461	12.581	11.100	9.911
3—8	15.300	13.319	11.755	10.498
4—9	15.809	13.775	12.165	10.869
5—10	15.974	13.933	12.315	11.010
6—11	16.110	14.068	12.447	11.136
7—12	16.137	14.111	12.498	11.192
8—13	16.089	14.089	12.492	11.197
9—14	15.957	13.992	12.421	11.144
10—15	15.762	13.841	12.302	11.048

*Life-Annuities, payable half-yearly.* These are more valuable than life-annuities payable yearly, on the two following accounts. First, the annuitant in this case receives one-half of every payment half a year sooner; and, secondly, he has the chance of receiving one half-year's payment more than if he had been paid yearly. Mr. Simpson, in his *Select Exercises*, p. 283, observes, that the value of these two advantages put together (let the rate of interest and the number of lives on which the annuity depends be what they will) will always amount to  $\frac{1}{2}$  of a year's purchase; and that if the payments are to be made *quarterly*, these advantages will be always worth  $\frac{3}{4}$  of a year's purchase. But Dr. Price, in an essay in the *Philosophical Transactions*, vol. lxxi. part 1. p. 109, has stated the differences of value between life-annuities, as they are made payable yearly, half-yearly, or quarterly, with more precision; and from his investigations it appears, that a *fifth* of a year's purchase is generally an addition more than sufficient to the yearly value of an annuity, in order to obtain its value, payable half-yearly; and *three-tenths* of a year's purchase, in order to obtain its value, payable quarterly.

Dr. Price has given the following short and easy theorems for finding in all cases these differences of value.

Let  $r$  be (not  $1l$ . with its interest, but merely) the interest of  $1l$ . for a year,  $n$  the complement of a given life;  $y$ ,  $h$ ,  $q$ ,  $m$ , the values respectively of an annuity *certain* for  $n$  years, payable yearly, half-yearly, quarterly, or momentarily (see the article ANNUITIES);  $P$  the perpetuity;  $Y$  the present value of an annuity on a life, whose complement is  $n$ , payable yearly;  $H$  the value of the same annuity payable half-yearly;  $Q$  the value of the same annuity payable quarterly; and  $M$  its value payable momentarily.

$$\text{Then, } Y = P - \frac{1+r}{rn} \times y$$

$$H = P - \frac{r}{nr} \times h$$

$$Q = P - \frac{r}{nr} \times q$$

$$M = P - \frac{m}{nr}$$

*Example.*—Let the life supposed be of the age of 36. The complement of such a life is (by what has been already said) 50, according to M. De Moivre's hypothesis; therefore,  $n$  will be 50. Let the rate of interest be *4 per cent.*, or  $r = 0.04$ ,  $P = 25$ ,  $Y = 21.482$  (see Table III. ANNUITIES),  $h = 21.549$  (by the theorems given under ANNUITIES),  $q = 21.582$ , (by the same theorems, and  $m = 21.616$ . Therefore,

$$Y = 25 - \frac{1.04}{50 \times 0.04} \times 21.482 = 13.829$$

$$H = 25 - \frac{1.02}{50 \times 0.04} \times 21.949 = 14.010$$

$$Q = 25 - \frac{1.01}{50 \times 0.04} \times 21.582 = 14.101$$

$$M = 25 - \frac{21.616}{50 \times .04} = 14.191$$

These theorems, though founded on the hypothesis of an equal decrement of life, give the differences between the yearly,

yearly, half-yearly, and quarterly values, almost exactly the same, whether those values be deduced from real observations or from this hypothesis.

For determining the differences between the values of annuities on two joint lives, when payable half-yearly, quarterly, or momentarily, Mr. Morgan, in the 6th edition of Dr. Price's Treatise on Reverfionary Payments, (note L, appendix,) has given the following theorems. Let  $b$ ,  $q$ ,  $m$ , denote the same quantities as above for  $t$  years. Let  $n$  be the complement of the younger, and  $t$  the complement of the older life. Let  $r$  also be the interest of 1*l.* for a year, and  $V$  the perpetuity: then will the value of the annuity be

$$V - \frac{V + \frac{1}{2}}{n} \times n - t - \frac{1}{2} - 2V \times \frac{b}{t} + 2V, \text{ or } V - \frac{V + \frac{1}{4}}{n} \times n - t - \frac{1}{4} - 2V \times \frac{q}{t} + 2V, \text{ or } V - \frac{V}{n} \times n - t - 2V \times \frac{m}{t} + 2V, \text{ according as it is payable}$$

half-yearly, quarterly, or momentarily.

Thus, if the ages of the two lives be 20 and 36 years, the value of the annuity at 4*l. per cent.*, when payable yearly, may be found by the theorem in the preceding article to be equal to 11.227; and its value, when payable either half-yearly, quarterly, or momentarily, may be found by these theorems to be either 11.427, 11.565, or 11.629. If the ages of both lives be 36, these values respectively will be 10.394, 10.600, 10.703, and 10.808. It may be observed, that the differences between the values of two joint lives are always greater than the differences between the values of the single lives, when payable at shorter intervals than a year; and therefore, that the addition, in this case, to be made to the value of an annuity on the longest of two lives will be less than the addition to be made either to the joint or single lives.

*LIFE-Annuities secured by land*, differ from other life-annuities only in the single circumstance, that the annuitant, whenever he dies, is entitled to a payment for the time which has lapsed between the payment last due, and the moment of his death; whereas other annuities suppose nothing due for this time. In order to obtain the value of such an annuity,

$\frac{y}{2n}$  must be added to the expression in the first theorem, if it is payable yearly;  $\frac{b}{4n}$  must be added to the expression in the

second theorem, if it is payable half-yearly; and  $\frac{q}{8n}$  must be added to the expression in the third theorem, if the annuity is payable quarterly. For since  $\frac{1}{n}$  is the probability

that a life, whose complement is  $n$ , fails in any year of its duration, and it is an equal chance whether more or less than half the yearly, half-yearly, or quarterly payment is due at the death of the annuitant, it follows that the additional

value of the annuity will be either  $\frac{1}{n} \times \frac{y}{2}$ , or  $\frac{1}{n} \times \frac{1}{2} \times \frac{b}{2}$ , or  $\frac{1}{n} \times \frac{1}{2} \times \frac{q}{4}$ , according as the same is payable either yearly, half-yearly, or quarterly. See Dr. Price's Essay, before quoted.

The value, therefore, in the last example, of an annuity payable yearly on a life aged 36, being 13.829; its value, Vol. XX.

if secured by land, or to be enjoyed to the last moment of life, will be  $13.829 + \frac{21.482}{100} = 14.043$ ; if secured by land, and payable half-yearly, its value will be  $14.010 + \frac{21.549}{200} = 14.117$ ; if secured by land, and payable quarterly, its value will be  $14.101 + \frac{21.582}{400} = 14.155$ .

*LIFE-Annuities*, in the contemplation of *Law*, are in some cases sold and purchased in an improvident manner, and with great privacy; and therefore, in order to throw some check on transactions of this kind, the statute 17 Geo. III. c. 26. has directed, that upon the sale of any life-annuity of more than the value of 10*l. per annum*, (unless on a sufficient pledge of lands in fee-simple, or stock in the public funds,) the true consideration, which shall be in money only, shall be set forth and described in the security itself; and a memorial of the date of the security, of the names of the parties, *cestui que trusts*, *cestui que vies*, and witnesses, and of the consideration money, shall, within 21 days after its execution, be inrolled in the court of chancery, else the security shall be null and void; and, in case of collusive practices respecting the consideration, the court, in which any action is brought, or judgment obtained upon such collusive security, may order the same to be annulled; and the judgment, if any, to be vacated; and also all contracts for the purchase of annuities from infants shall remain utterly void, and be incapable of confirmation after such infants arrive to the age of maturity. By 29 Geo. III. c. 41. § 27, and other acts that respect life-annuities, oath of an annuitant's life may be made before a justice of the peace, who shall give a certificate thereof, without fee or stamp-duty, in order to entitle such person to receive his annuity.

*LIFE-Boat*. See BOAT.

*LIFE*, Complement of. See COMPLEMENT.

*LIFE Estates*, in *Law*, are such estates of freehold as are only for life. (See ESTATE.) Of these some are *conventional*, and others merely *legal*. Estates for life of the first kind, expressly created by deed or grant, are where a lease is made of lands or tenements to a man to hold for the term of his own life, or that of any other person, or for more lives than one; in any of which cases he is styled tenant for life; only when he holds the estate by the life of another, he is usually called tenant *pur autre vie*. These estates for life are like inheritances, of a feudal nature; and for some time were the highest estate that any man could have in a feud, which was not in its original hereditary. They are given or conferred by the same feudal rights and solemnities, the same investiture or livery of seisin, as fees themselves are; and they are held by fealty, if demanded, and such conventional rents and services, as the lord or lessor, and his tenant or lessee, have agreed on. Estates for life may be created, not only by express words, but also by a general grant, without defining or limiting any specific estate. As if we grant to A.B. the manor of Dale, this makes him tenant for life. (Co. Litt. 41.) Such estates for life will, generally speaking, endure as long as the life for which they are granted; but there are some estates for life, which may determine upon future contingencies, before the life for which they are created expires; as an estate granted to a woman during her widow-hood, or to a man till he be promoted to a benefice. These, while they subsist, are reckoned estates for life; because the time for which they will endure being uncertain, they may by possibility last for life, if the contingencies upon which they determine do not sooner happen.

The incidents to an estate for life are principally the following; and they are applicable not only to that species of tenants for life which are expressly created by deed, but also to those which are created by act or operation of law.

1. Every tenant for life, unless restrained by covenant or agreement, may of common right take upon the land demised to him reasonable cisterns, or botes. (Co. Litt. 43.) But he is not permitted to cut down timber or do other waste upon the premises. (Id. 53.) 2. Tenant for life, or his representatives, shall not be prejudiced by any sudden determination of his estate, because such a determination is contingent and uncertain. (Ibid. 55.) The advantages also of emblements are particularly extended to the parochial clergy by stat. 28 Hen. VIII. c. 11. 3. Another incident to estates for life relates to the under-tenants, or lessees. For they have the same, may greater indulgences than their lessors, the original tenants for life.

The second estate for life is of the *legal* kind, as contradistinguished from *conventional*; viz. that of tenant "in tail after possibility of issue extinct." This happens where one is tenant in special tail, and a person, from whose body the issue was to spring, dies without issue; or, having left issue, that issue becomes extinct; in either of these cases, the surviving tenant in special tail becomes tenant in tail after possibility of issue extinct. This estate must be created by the act of God: that is, by the death of that person out of whose body the issue was to spring; for no limitation, conveyance, or other human act can make it. A possibility of issue is always supposed to exist in law, unless extinguished by the death of the parties; even though the donees be each of them 100 years old. (Litt. § 34. Co. Litt. 28.) This estate is of an amphibious nature, partaking partly of an estate-tail, and partly of an estate for life. In truth, the tenant is only tenant for life, but with many of the privileges of a tenant in tail, as, not to be punishable for waste, &c. (Co. Litt. 27.); or, he is tenant in tail, with many of the restrictions of a tenant for life; as, to forfeit his estate if he alienates it in fee-simple (Ibid. 28.); whereas such alienation by tenant in tail, though voidable by the issue, is no forfeiture of the estate to the reversioner; who is not concerned in interest, till all possibility of issue be extinct. But, in general, the law looks upon this estate as equivalent to an estate for life only; and, as such, will permit this tenant to exchange his estate with a tenant for life: which exchange can only be made of estates that are equal in their nature. (Blackst. Com. b. ii.) See LEASE and TENANT.

LIFE, *Expectation of*. See EXPECTATION.

LIVES, *Insurance or Assurance on*. See ASSURANCES on Lives.

LIFE-*everlasting*, a name by which the *ilicbrysum*, or *gnaphalium* of botanical writers, is sometimes called. See CUDWEED.

LIFE *Guards*. See GUARDS.

LIFE *Preserver*, against drowning. Many different articles under this denomination have been made, particularly within these few years, by Collins, Spencer, Daniels, and others. But we believe they have all been copied, in a greater or less degree, from an apparatus constructed by John Bentley, esq. about the year 1797. It is however remarkable, that although he exhibited it in public several times, some very important parts of it seem to have escaped their notice, or at least their application of them to their own purposes. The following is his account of it.

The human body in most instances is of the same specific gravity as water; therefore, any substance which is lighter than water, being attached to the body, must cause it to float. The situation best adapted for fixing it is round the

body, immediately under the arms; and as it is desirable to be able to keep the head, neck, shoulders, and arms above water without any exertion, the article used must displace a bulk of water equal in weight to those parts. The next thing to be attended to, is to enable a person who cannot swim to make progress through the water. The hands and feet are too narrow to accomplish this without a knowledge of the art of swimming, therefore the fingers and feet must be artificially webbed. Thus the whole apparatus, which he calls a *nautilus*, consists of three distinct parts, and are to be thus constructed.

The *buoyant* is made of copper, in the form of a tube, to fit the round of the body, about six inches diameter, the seam brazed with hard solder. It should be made in three lengths, the ends quite flat, to fit each other exactly, so that, when put together, they form a ring or belt. This is in case of accident happening to one part by leaking, that it may not extend to the other two, which will be sufficient to prevent sinking. Each of these parts is sewed up in baize, with three strong tapes near the end of each piece, by which all of them are securely tied together. A flexible pipe, of the thickness of a quill, is inserted in each piece, from the upper side to the bottom, so that if any leakage happens, the water is readily drawn out by the mouth and discharged. The buoyant, thus prepared, must be securely tied with strong tapes, crossed round and over the shoulders, to prevent it getting down. It cannot get over the arms. When it is thus fixed, the body will, by its own gravity, be creft in the water, with the feet downwards, and will always retain this position unless force is applied to alter it, and which it will again recover when the force ceases to act. The second part, which is for the hands, is a pair of oiled silk gloves, which, after being made in the usual way, the fingers are opened to their full extent breadthways, and a piece of the same material sewed over them on the under side. Tapes are sewed at the top to tie them round the wrist.

The third part, being for the feet, is made thus: take a piece of half-inch waincot or mahogany, 11 inches long, and 10 inches wide. Cut it longitudinally into three pieces, two of them  $3\frac{1}{2}$  inches broad, and the other  $2\frac{1}{2}$  inches. Fasten them well together with two pair of brass hinges, and rule joints to fall and rise like a two-leaved table, the narrow piece being in the middle. On the under-side of the middle-piece, in the centre, a wooden turn buckle must be screwed, to prevent the side-pieces from falling down, when walking to or from the water. Two wooden flops are so fixed upon this piece as to prevent the sides, when down, coming to a right angle with the middle-piece, that the rising and falling may be duly performed with the action of the feet. To the upper side of the middle-piece, a common leather shoe, (to fit the person) must be fastened on with two screws through the sole, and near each end of this middle-piece two small holes are made with a centre-bit, through which good tapes are passed, to tie round the instep and over the foot. A pair of these must of course be provided, and a person thus equipped, being perfectly buoyant in water, and web-footed and web-fingered, will be able to outswim any other person, and may exist in the water as long as cold and hunger will permit.

By increasing the dimension of the buoyant, a proportionate quantity of provisions, or any other article, may be carried. The inventor has wrote a letter, and otherwise amused himself on the sea, with this apparatus, and believes he could cross from Dover to Calais in perfect safety. It is very convenient for crossing deep rivers, where there are neither boats nor bridges. It is procured at little expence, very portable,

portable, and put on in one minute. Persons provided with it, and being shipwrecked near the coast, would seldom be lost.

**LIFE-Rent**, in *Law*, a rent which a man receives for a term of life, or for sustentation of it. Skene.

**LIFFAMATULA**, in *Geography*, an island in the East Indian sea, 25 miles long and six broad. S. lat. 2°. E. long. 126° 18'.

**LIFFEY**, a river of Ireland, which rises in the north-western mountains of the county of Wicklow, and winding through the county of Kildare, it passes through the city of Dublin, and flows into Dublin bay. It derives its chief importance from the greatness of the city situated on its banks.

**LIFFORD**, the county-town of the county of Donegal, Ireland, a very small place, and at one extremity of that large county, but fixed upon to accommodate the judges and gentlemen of the bar: one mile W. from Strabane, and 101 N.W. by N. from Dublin.

**LIFRE**, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Rennes; 9 miles N.E. of Rennes. The place contains 2096, and the canton 8372 inhabitants, on a territory of 205 kilometres, in 7 communes.

**LIFTING-PIECES**, in a clock, are those parts which lift up and unlock the detents in the clock part.

**LIFTS**, in a *Ship*, ropes belonging to the yard-arms of all yards. Their use is to stop the yard-arms, *i. e.* to make the end of the yards hang higher or lower, as occasion serves. The top-sail lifts serve as sheets for the top-gallant yards, as well as for lifts to the top-fall yards. The hauling of these ropes is called *topping the lifts*: thus they say, *top a star-board*, or *top a port*, *i. e.* hale upon the starboard or larboard lift.

The lifts for the sprit-fall-yard are called *standing lifts*.

**LIGAMENT**, in its general sense, denotes any thing that ties or binds one part to another.

In which sense the ancients applied the word to membranes, skin, flesh, veins, and arteries; as being common ligaments. **LIGAMENT**, in its more proper signification, denotes a white, tough, solid, inflexible part, serving to inclose, and keep together the junctures of the body.

It has no conspicuous cavity, nor has it any sense, lest it should suffer on the moving of the bones. It is found very different, according to the different parts where it is used. It is harder than a membrane, yet softer than a cartilage: its principal use is to gird and strengthen the junctures, to prevent the dislocation of the bones, and even to fasten them together, when they have no articulation. It also serves as a covering to the tendons to separate them from the muscles, and to hold up the suspended entrails, lest their weight should throw them down. Such are the ligaments of the liver, the bladder, and matrix.

Ligaments are of different substances; some hard, others soft, membranous, nervous, and cartilaginous; as also of different figures and situations: some arise from bones, others from cartilages, and others from membranes.

**LIGAMENTUM**, in *Anatomy*, a ligament or part connecting organs together, and limiting their respective motions. In its most proper sense it denotes the fibrous bodies by which the bones are united at their articulations (see **JOINT**); but it is often applied to parts of an entirely different kind, as to the membranous folds which attach various organs in the chest and abdomen.

**LIGAMENTUM Annulare**, is a name given to different fibrous organs about the wrist and foot, which confine the tendons of the extensor and flexor muscles in their situation. For an account of the annular ligament of the carpus, see **EXTRE-**

**MITIES**. The annular ligament of the fore-arm, which confines the extensor tendons, is described in the articles **EXTENSOR communis digitorum**, and **FASCIA**. The description of the annular ligaments of the cord will be found under **FASCIA**.

**LIGAMENTUM Arteriosum**, is the fibrous cord connecting together the trunks of the pulmonary artery and the aorta, consisting of the remains of the canalis arteriosus of the fœtus. See **EMBRYO**.

**LIGAMENTUM Ciliare**, in the eye, is the white union of the sclerotica and choroid coats. See **EYE**.

**LIGAMENTA Coli**. See **INTESTINE**.

**LIGAMENTUM Denticulatum**, in the spinal marrow. See **BRAIN**.

**LIGAMENTUM Nucha**. See **HEAD**.

**LIGAMENTUM Fallopij**, or *Poupart's Ligament*. See **OBLIQUUS externus abdominis**.

**LIGAMENTUM Latum**, or *Suspensorium Hepatis*, lig. coronarium hepatis, et ligamenta lateralia hepatis. See **LIVER**.

**LIGAMENTUM Latum Uteri**, et lig. rotundum uteri. See the description of the uterus in the article **GENERATION**.

**LIGAMENTUM Teres** of the hip-joint. See **EXTREMITIES**.

**LIGAN**, in *Law*, denotes a wreck consisting of goods sunk in the sea, but tied to a cork or buoy, in order to be found again. Over these, as well as stotam and jetlam, the high-admiral hath jurisdiction, as they are in and upon the sea. 5 Rep. 106.

**LIGANI**, in *Geography*, a town of Turkish Armenia; 30 miles E. of Ipsira.

**LIGARDES**, a town of France, in the department of the Gers; 7 miles N.E. of Condom.

**LIGATURE**, among *Mystic Divines*, signifies a total suspension of the superior faculties, or intellectual powers of the soul. They pretend, that when the soul is arrived at a perfect contemplation, she remains deprived of all her operations, and ceases to act in order to be more ready and prepared to receive the impulse and communications of divine grace. This passive state of these contemplative people they call their *ligature*.

**LIGATURE** is also used for a state of impotency, in respect to venery, pretended to be caused by some charm, or witchcraft.

Kæmpfer tells of an uncommon kind of ligature, or knotting, in use among the people of Massacar, Java, Malaya, Siam, &c. By this charm, or spell, a man binds up a woman, and a woman a man, so as to put it out of their power to have to do with any other person; the man being thereby rendered impotent to any other woman, and all other men impotent with respect to the woman.

Some of their philosophers pretend that this ligature may be effected by the shutting of a lock, the drawing of a knot, or the sticking of a knife in the wall, at the point of time wherein the priest is joining a couple together; and that a ligature, thus effected, may be dissolved, by the spouse's urining through a ring. This piece of superstition is said to obtain also among the Christians of the East.

The same author tells us, that during the ceremony of marriage in Russia, he observed an old fellow lurking behind the church-door, and mumbling over a string of words; and, at the same time, cutting a long rod, which he held under his arm, into pieces; which, it seems, is a common practice at the marriages of great persons, and done with design to elude and counter-work any other person, that might possibly be inducing the ligature.

The secret of inducing a ligature is delivered by the same author, as he was taught it on the spot by one of their adepts; which, being a curiosity, we shall not scruple to add in his

own words; not daring to make it speak English. "Puella amafium, vel conjux maritum ligaturus, abiterget a concubitus actus, priapum, indusio—ut feminis quantum potest excipiet. Hoc probe convolutum sub limine domus sue in terram sepeliat. Ibi quamdiu sepulchrum reliquerit, tandiu ejus hasta in nullius preterquam sui (ascinantis) servitium obediet, et prius ab hoc nexu non liberabitur quam ex clauetro hiniis liberetur ipsum lineum: vice versa, vir lecti sociam ligaturus, menstruatam ab eo lineum comburit; ex cineribus cum propria urina subactis, efformato figuram priapi, vel, si cineres incunucle fingende non sufficiant, eodem subigito cum parte terræ, quam recens permixerit. Formatam iconem caute exsiccat, siccamque asservato loco siccò, ne humorem contrahat. Quamdiu sic servaveris, omnes artus, dum ad scopam sociæ colliverint, momento contabescunt: idè vero dominus. Abrunum hunc prius humectato, quamdiu sic manebit, tandiu suspensio nexu priapi ipsi parebit, quin & alios quotquot sciamina properantes admittit."

M. Marshall mentions another ridiculous form of ligature, which he received from a Bramin at Hindoostan: "If," says he, "the little worm in the wood lukerara kara be cut into two, and the one part stirs, and the other not, if the stirring part be bruised, and given with half a beetle to a man, and the other half to a woman, the charm will keep each from ever having to do with any other person." Phil. Trans. No. 268.

LIGATURE, *Ligatura*, in the *Italian Music*, signifies a tying or binding together of notes.

Hence syncopes are often called ligatures, because they are made by the ligature of many notes. There is another sort of ligatures for breves, when there are many of these on different lines, or in different spaces, to be sung to one syllable.

To understand this, it must be observed, that only breves are capable of this species of ligature, because their figure admits of their being placed so close together, as to seem one character only, though placed on different degrees, unless there be occasion to place a femicircle either above or below them, to shew that they are tied. This kind of ligature regards common time only. Breves again must be considered as simple, as having a tail, and as being of different colours. First, if they be simple  $\square$  and ascend, they contain their natural quantity, *i. e.* each two semi-breves, as in example A. But if they descend, then each is equivalent to four semi-breves, if only two follow one another, as in B. If there are three or four following ones, the first and last contain each four semi-breves, and those in the middle but two, as in C.

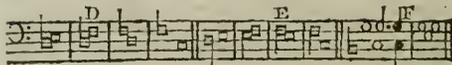

2 2 A 2 2 2 B

C

Secondly, if they have tails  $\square$ , and the tail be turned upwards, the breves contain only one measure, as well ascending as descending. See Ex D. But if it be marked downwards, the breve then contains its natural quantity. See Ex E. This species of ligature was invented only because the minim, being round, could not be used in this manner. And the femicircle was not at that time in use.

It may be here remarked, that ordinarily the first breve alone of every ligature has a tail, and that usually placed on the left side. Lastly, if they be of different colours, *i. e.* if the first be white, or open in the middle, and the second black,

the first contains a semi-breve, and the second a pointed minim. Example F.

I I I I I 2 2 2 2 2

These are the principal ligatures, besides which there are many others, for which see CHARACTER. See also LEGATURA.

LIGATURES, among *Printers*, are types consisting of two letters or characters joined together, as *B, S, ff, fl, fi*. The old editions of Greek authors are extremely full of ligatures; the ligatures of Stephens are, by much, the most beautiful.

Some editions have been lately printed without any ligatures at all; and there was a design to explode them quite out of printing. Had this succeeded, the finest ancient editions would, in time, have grown useless; and the reading of old manuscripts would have been rendered almost impracticable to the learned themselves.

LIGATURE, in *Surgery*, is the only means to be depended upon for putting a permanent stop to all bleedings from arteries of considerable size. In ordinary cases, the mouth of the bleeding vessel being exposed, is taken hold of with the tenaculum, or forceps, and tied. In some instances, the artery being only punctured, and not cut through, nor brought into view, the surgeon has first to cut down to the wounded portion of the vessel, and then pass a double ligature under it by means of an aneurism-needle, or an eye-probe. The latter instrument, having fulfilled its office, is to be removed by dividing the double ligature with a pair of scissors. One part of the ligature is then to be applied round the artery in a firm knot above the opening from which the blood issues, and the other below it. In cases of aneurism, the ligature is introduced under the artery in a very similar way.

Whoever is acquainted with the history of surgery, must be fully sensible of the immense advantage which the moderns have over the ancients in the familiar employment of ligatures for the stoppage of hemorrhage. But, although many years have elapsed since this important improvement in practice began, it was not till very lately that several most interesting circumstances, relative to the use of the ligature, were brought to light. For this elucidation of a difficult, though highly momentous, subject to the practical surgeon, we are indebted to the judgment, accuracy, and talents of Dr. J. F. D. Jones, whose Treatise on Hemorrhage demands the earnest attention of every enlightened practitioner. Before this work appeared, scarcely any surgeon had a just conception of the manner in which ligatures effected the suppression of hemorrhage; nor were the principles on which they ought to be made and applied properly understood. One of the first and most material effects of a ligature applied to an artery, is to produce a division of the middle and internal coats of the vessel. This fact was communicated to Dr. Jones by Mr. Thomson of Edinburgh, and is alleged to have been known to the celebrated M. Default of Paris. The inner coats of the artery, thus cut through by the pressure of the ligature, are in the stiffest state for inflaming and effusing coagulable lymph, and, in short, for undergoing that process, by which the permanent closure of the vessel is to be accompanied. Hence, ligatures should not be thick, irregular, and clumsy; but small,

ish, firm, and round; and they should be applied with tightness, as it is of consequence that they divide the inner coats of the artery, and the fear of their cutting the vessel quite through is destitute of foundation. These, however, and numerous other particulars, having been explained in a previous part of this Cyclopædia, we must avoid unnecessary repetition, by referring the reader to the article HEMORRHIAGE.

**LIGEANCE, LIGENTIA**, in *Law*, is the true and faithful obedience of a subject to his sovereign; and is also applied to the dominion or territory of the liege lord: thus children are said to be born in or out of the ligeance of the king, &c. Stat. 25 Edw. III. See ALLEGIANCE and LEIGE.

**LIGHT**, that sensation occasioned in the mind by the view of luminous bodies; or that property in bodies, whereby they are fitted to excite those sensations in us.

**LIGHT** is also used to denote a certain action of the luminous body, on a medium between it and the eye; by means of which, some suppose the one to act on the other. Thus they call *secondary*, or *derivative* light: to distinguish it from that of luminous bodies, which is called *primary*, or *innate*.

Aristotle explains the nature of light, by supposing some bodies to be transparent, as air, water, ice, &c.; but since, in the night-time, we do not see any thing through those bodies, he says, they are only transparent potentially; whereas, in the day, they become really and actually transparent: and since it is light alone that can reduce that power into act, he defines light to be the act of a transparent body, considered as such. He adds, that light is not fire, nor is it any thing bodily radiating from the luminous body, and transmitted through the transparent one; but the mere presence of fire, or some other luminous body, at the transparent one.

This is Aristotle's doctrine of light, which his followers mistaking, have charged on him another, very different; making light and colours to be qualities of the luminous and coloured bodies themselves, and in all respects like those sensations which they occasion in us: adding, that things lucid, or coloured, could not produce any sensation in us, unless they had something similar in themselves, since  *nihil dat quod in se non habet*.

But the sophism is apparent; for we find, that a needle, in pricking the flesh, gives us pain, which nobody ever imagined to exist in the needle. But that it is not necessary there should be any similitude between the quality of the object, and the sensation it produces, appears still more evident from a glass prism, which is found to exhibit blue, yellow, red, and other colours extremely vivid; and yet no body will say there is any thing in the glass prisms like to those sensations.

The Cartesians have refined considerably on this notion; and own that light, as it exists in the luminous body, is nothing but a power or faculty of exciting in us a very clear and vivid sensation; adding, that what is required to the perception of light, is, that we be so formed, as to be capable of such sensations; that in the hidden pores of transparent bodies, there be a certain subtle matter, which, by reason of its exceeding smallness, may penetrate even glass, and yet be strong enough to shake certain capillaments at the bottom of the eye; and lastly, that this matter be impelled by the luminous body, so as to move the organ of sight.

Primary light, therefore, they say, consists in a certain motion of the particles of the luminous body, whereby they are enabled to propel, every way, the materia subtilis,

lodged in the pores of transparent bodies; and secondary or derivative light, in a conatus to motion, or an inclination of that matter to recede from the centre of the luminous body in right lines.

Father Malebranche explains the nature of light, from a supposed analogy between it and sound.

Thus he supposes all the parts of a luminous body are in a rapid motion, which, by very quick pulses, is continually compressing the subtle matter between the luminous body and the eye, and excites vibrations of pressure. As these vibrations are greater, the body appears more luminous; and as they are more quick, or more slow, the body is of this or that colour.

This hypothesis, how ingenious soever, is now deservedly discarded, since the great discoveries made by sir Isaac Newton on the nature of light. The primary light they talk of, we now know, consists wholly in a certain motion of the particles of the lucid body, whereby they do not propel any fictitious matter, supposed to be lodged in the hidden pores of transparent bodies; but throw off from the luminous body certain very small particles, which are emitted every way with great force; and the secondary or derivative light consists not in a conatus, but a real motion of these particles, receding every way from the luminous body, in right lines, and that with an incredible velocity.

The most distinguishing property of light is that by which it renders objects visible by some power, which transfers their exterior figure to the retina of the eye.

We obtain light from three distinct sources, which will divide our subject into three heads; namely, solar light, light of combustion, and phosphorescent light.

Very little was known of the nature and properties of light before the experimental researches of Newton; and it is remarkable that at this time so little should have been added to the labours of that acute philosopher. It is strange, that after the evidence of his experiments there could have been two opinions respecting the nature of light. Huygens supposed the phenomena of light to be caused by an undulatory motion, excited in a supposed subtle and elastic medium, pervading all space: that these waves or pulses are propagated, first at the luminous body, such as the sun or a candle, and transmitted in all directions. The impression made by these waves upon the eye is the cause of vision. This doctrine has since been taken up by Euler, who, with much zeal and mathematical labour, supported it to his death. Newton, however, had given an hypothesis, supported by clear and striking experiments; and at the same time had pointed out insurmountable objections to the undulatory hypothesis, so that the labour and great talents of Euler were exhausted to little purpose.

Sir Isaac Newton argued, with great propriety, that the undulatory motion was inconsistent with the phenomena of Light. The passage of light would not be confined to straight lines, but might, like sound, be conveyed through crooked tubes, which is contrary to the fact.

Besides, if light consisted in a mere pressure, or pulse, it would be propagated to all distances in the same instant of time; the contrary of which appears from the phenomena of the eclipses of Jupiter's satellites, which we shall presently mention.

We shall therefore, with Newton, consider light as a material agent, moving with an immense velocity from the point where it is liberated. If its motion be in free space, it moves in straight lines in the form of radii, and would continue for ever in the same direction, if not changed in its course by the attraction of other matter. Light, therefore, like electricity and caloric, appears in a high degree to be repellant

repellent of itself, although it possesses attraction for ponderable matter. Indeed, it is to this great repulsion of the particles of light that we are to attribute its progressive velocity, which, therefore, is as the force by which its particles are separated.

The small extent of the limits of vision upon the surface of our globe does not enable us to appreciate the velocity with which light moves.

Roemer, a Danish philosopher, at length found the means of determining this point by the difference of time in the eclipses of Jupiter's satellites, when the earth was on the same, or on the contrary side of the sun, with that planet. The immersions of these satellites, as the earth approaches towards Jupiter, are found to anticipate somewhat on the true time, and to commence sooner; and again, as the earth retires from Jupiter, their immersions, which alone in that case can be observed, happen later and later, or lose time; deviating thus, very considerably on either side, from the true time marked by the tables.

This was first observed by M Roemer, and since by other astronomers; the reason of which is not owing to any eccentricity; but apparently follows from this circumstance, that the light of the sun, reflected from the satellites, has farther to travel, before it reaches the eye, in the one case than in the other, by a space equal to the diameter of the earth's annual orbit.

The observations, whence this conclusion was deduced, were made at the observatory belonging to the Royal Academy of Sciences at Paris, from 1670 to 1675; the principal fact was, that the first satellite sometimes emerged exactly at the times calculated by the tables, and sometimes not, inasmuch that the greatest variation was about fourteen minutes. The particular observation that was the most striking, was the emergence of this satellite observed at Paris, Nov. 9, 1676, ten minutes later than it had been observed in the month of August, when the earth was much nearer to Jupiter. Hence Cassini and Roemer both concluded, that this circumstance depended on the distance of Jupiter with respect to the earth; and that in order to account for it, they must suppose that the light was about fourteen minutes in crossing the earth's orbit.

But the conclusion was afterwards abandoned and attacked by Monsieur Cassini. M. Roemer's opinion found an able advocate in Dr. Halley; who removed Cassini's difficulty, and left M. Roemer's conclusion in its full force. In a memoir presented to the academy in 1707, Monsieur Maraldi endeavoured to give a new force to Cassini's arguments; but Monsieur Roemer's doctrine found a new defender in Mr. Pound. See Phil. Trans. N<sup>o</sup> 136. Phil. Trans. Abr. by Louth, vol. i. p. 409, 422. S'Grav. Phys. Elem. N<sup>o</sup> 2636, seq.

It has been since found, that when the earth is between the sun and Jupiter, his satellites are eclipsed about eight minutes sooner than they could be according to the tables, and that when the earth is nearly in the opposite point of its orbit, these eclipses happen about eight minutes later than the tables predict them. Hence it is undeniably certain, that the motion of light is not instantaneous, since it takes about  $16\frac{1}{2}$  (or  $16\ 10^{\frac{1}{2}}$ ) minutes, of time to go through a space equal to the diameter of the earth's orbit, which is at least 190 millions of miles in length; and consequently the particles of light fly about 191919 or 200000 miles every second of time, which is near a million of miles swifter than the motion of a cannon-ball. And as light is  $16\frac{1}{2}$  minutes in travelling across the earth's orbit, it must be  $8\frac{1}{4}$  (or  $8\ 5^{\frac{1}{2}}$ ) minutes in coming from the sun to us; therefore, if the sun were annihilated, we should see him for  $8\frac{1}{4}$  minutes after;

and if he were again created, he would be  $8\frac{1}{4}$  (or  $8\ 5^{\frac{1}{2}}$ ) minutes old before we could see him. In order to explain this progressive motion of light, let A and B, *Plate IX. Optics, fig. 1*, be the earth in two different parts of its orbit, whose distance from each other is 95 millions of miles, equal to the earth's distance from the sun S.

It is plain, that if the motion of light were instantaneous, the satellite I would appear to enter into Jupiter's shadow FF, at the same moment of time to a spectator in A, as to another in B. But it is now well known that the immersion of the satellite into the shadow is seen  $8\frac{1}{4}$  (or  $8\ 5^{\frac{1}{2}}$ ) minutes sooner when the earth is at B, than when it is at A. As the earth moves from D to C, through the side A B of its orbit, it is constantly meeting the light of Jupiter's satellites sooner, which occasions an apparent acceleration of their eclipses; and as it moves through the other half H of its orbit, from C to D, it is receding from their light, which occasions an apparent retardation of their eclipses, because their light is then longer before it overtakes the earth. That these accelerations and retardations are not occasioned by any inequality arising from the motions of the satellites in eccentric orbits is plain, because it affects them all alike, in whatever parts of their orbits they are eclipsed. Besides, they go often round their orbits every year, and their motions are no way commensurate to the earth's. Therefore a phenomenon not to be accounted for from the real motions of the satellites, but so easily deducible from the motion of the earth, and so unferable to it, must be allowed to result from it. And this affords one very good proof of the earth's annual motion. See the sequel of this article.

We shall here observe, that the first person, who conceived the thought of measuring the velocity of light was Galileo, who has given a particular description of his contrivance for this purpose, in his Treatise on Mechanics, p. 39. He had two men with lights, one of whom was to observe when the other uncovered his light, and to exhibit his own the moment that he perceived it: the experiment was tried, as may naturally be imagined, without success, at the distance of one mile; but the members of the academy Del Cimento resumed the experiment, and placed the observers, to as little purpose, at the distance of two miles. However, the method used by M. Roemer, already mentioned, was the only one adequate to the discovery of the velocity of light.

Our excellent astronomer, Dr. Bradley, has found nearly the same velocity of light, from his accurate observations, and most ingenious theory, to account for some apparent motions in the fixed stars. Phil. Trans. N<sup>o</sup> 406, or Abridg. vol. vi. p. 150. And for a summary account of these observations, &c. see EARTH and STAR.

To understand this, it must be premised, that the fixed stars are luminous bodies, and at rest, with respect to our planetary system, from which they are vastly remote. In this system also the earth is considered as one of the planets, and moving about the sun.

Suppose the sun represented in S, (*Plate IX. Optics, fig. 2*) and that the circle A B C D represents the path of the earth, or the ecliptic. At the centre S suppose a perpendicular SP raised to the plane of the ecliptic, and that this perpendicular passes through any fixed star. If a spectator were placed in S, he would see the star in the same perpendicular; but if the spectator passes over the circle A B C D, the diameter of which is supposed to bear a sensible though small proportion to the distance of the star, it will be perceived to change its situation in the heavens. For a spectator in A would see the star in the line A P a; in C he would see the same star in the line C P c; and

and so in any other point of his progress; whence it follows, that the star would seem to describe a circle in the heavens represented by  $abcd$ . If the distance of the star was fo very great, that in respect of it the diameter of the earth's orbit  $AC$  might be esteemed a point; in this case, the fore-  
said circle would be entirely insensible; and all the lines drawn from the points of the orbit to the star might pass for perpendiculars to the plane of the ecliptic, and in appearance would correspond to the same point in the heavens with the perpendicular in  $S$ , in which point the star would always appear, if its light could reach us in an instant. But if in this case, where the star is fo remote, the light is supposed to be propagated from the star with a certain velocity, at the same time that the earth proceeds in its orbit, the star will be seen in an oblique direction to the plane of the orbit; because of the motion compounded of the motion of light, and that of the spectator.

Suppose the light to move in the line  $EG$  (*fig. 3.*) making an angle with the line  $FG$ , in which the spectator is carried along; whom we shall conceive placed in  $F$ . Let the velocity of the spectator be to the velocity of the light, as  $FG$  to  $EG$ . While the spectator moves along  $FG$ , the light does the same along  $EG$ ; and the particle of light, which is in  $E$  when the spectator is in  $F$ , enters the eye only when he arrives at  $G$ . Now the direction of the light, with respect to the eye, makes with the line  $FG$  the angle  $EGF$ . For if we conceive the line  $FE$  drawn, and to be carried with a parallel motion along with the eye, so that in respect thereof it be at rest, while this continues moving, the light will reach the eye in the direction of the said line; for when the eye shall be in  $f$ , the middle point between  $F$  and  $G$ , the transferred line, will cut  $EG$  in its middle point  $g$ , to which the particle of light has reached, and which is likewise the middle point of the transferred line  $fe$ ; wherefore the particle of light, which was in  $E$ , in the extremity of the line  $E F$ , arrives at, and will enter the eye in the direction  $eg$ .

Let the angle  $E G F$  (*fig. 4.*) be a right one, and  $EG$  to  $FG$  as the velocity of the light to the velocity of the earth in its orbit; then  $EFG$  will be the angle, which the ray of light entering the eye, makes with the plane in which the earth moves round the sun.

If the earth be in  $B$  (*fig. 5.*) it moves in the direction of the tangent to its orbit in this point; that is, if we suppose the spectator in the sun, the direction of the earth's motion is parallel to  $SC$ ; and making the angle  $aSC$  equal to the angle  $EGF$  in the former figure, the line  $Sa$  will represent the line in which the spectator would see the star.

In the same manner when the earth is in  $D$ , the spectator in the sun will see the star in  $S_c$ , the angles  $PS_c$  and  $PS_a$  being equal; and the line  $Sa$  or  $S_c$ , by its revolution about  $PS$ , would describe a cone, whose base in the heavens would be a circle representing the apparent path of the star through a whole year. Let us suppose this circle to be  $abcd$ , as in *fig. 5.*

When the star is not in the perpendicular to the plane of the ecliptic, but the line  $PS$  (*fig. 6.*) is inclined to that plane, the lines which determine the apparent motion of the star in the heavens will form cones, as in the cases already explained; only they would be oblique, and in both cases the apparent path of the star in the heavens would be determined as above: but in this last case it would be an ellipsis, the greater diameter of which would be equal to the diameter of the circle  $abcd$  of the former figures; so that knowing this ellipsis, the circle might easily be found which

the star would describe, if placed in the perpendicular to the plane of the ecliptic.

The only way to determine, whether the stars describe such ellipsis, is by observations; in making which there are great difficulties, which, however, Dr. Bradley has with incomparable industry surmounted.

Nothing can immediately be determined concerning the fore-  
said elliptic motion. The distance of the star from the pole of the world must be measured at different times of the year, and from the different distances the elliptic motion is to be determined by calculation, allowing for the motion of the pole itself during the space of time between the observations; for the pole moves in a lesser circle, one degree of which it passes over in feventy-two years.

Dr. Bradley, making all necessary allowances, observed several stars at different times of the year, whereby he immediately discovered, that their distances from the pole of the world varied; and was convinced that this variation could not be attributed to the nutation of the pole; for he examined two stars at equal distances from the pole, but fo opposite, that the one ought to have receded from the pole as much as the other acceded to it, if the motion was in the pole itself. But this did not fall out fo; for the change of the one star was double of that of the other; a proper allowance being always made for the pole's motion arising from the above revolution. However, this indefatigable observer inferred from his observations, that the stars in certain times receded from, and acceded to, the pole of the world with a motion entirely analogous to that which is performed in an ellipsis; and also that they move in such curves, for each of which the motion in the same little circle, as  $abcd$  (*fig. 6.*) answers, when the stars are referred to the perpendicular in  $S$  to the plane of the ecliptic; and the diameter of this minute circle for them all is  $40\frac{1}{2}$ .

It is plain from observations, to which of the above mentioned causes we are to ascribe the motion of the star. For if the first takes place, the star would be carried from  $a$  to  $c$ , while the earth passed over the part  $ABC$  of its orbit; but this, being contrary to observation, cannot be the true cause. But this change in the situation of the star takes place according to the observations, while the earth describes the part  $BCD$  of its orbit, which is just what the second cause requires.

If both the causes took place at the same time, the arc described by the earth would differ from that indicated by either of them; besides, this concurrence of the causes is contrary to the observations; unless, perhaps, it may be thought reasonable to attribute a little influence to the first cause; but fo very small a portion, as not to be sensibly perceived in the observations.

Dr. Bradley himself considered this matter in the following manner: he imagined  $CA$  (*Plate IX. Optics, fig. 7.*) to be a ray of light falling perpendicularly upon the line  $BD$ ; that, if the eye is at rest at  $A$ , the object must appear in the direction  $AC$ , whether light be propagated in time or in an instant. But if the eye is moving from  $B$  towards  $A$ , and light is propagated in time, with a velocity that is to the velocity of the eye as  $CA$  to  $BA$ , then light, moving from  $C$  to  $A$ , whilst the eye moves from  $B$  to  $A$ , that particle of it by which the object will be discerned when the eye comes to  $A$ , is at  $C$ , when the eye is at  $B$ . Joining the points  $B, C$ , he supposed the line  $CB$  to be a tube, inclined to the line  $BD$  in the angle  $DBC$ , of such a diameter as to admit but one particle of light. Then it was easy to conceive, that the particle of light at  $C$ , by which the object must be seen, when the eye, as it moves along, arrives at  $A$ , would pass through the tube  $BC$ , if

it is inclined to BD in the angle DBC, and accompanies the eye in its motion from B to A; and that it could not come to the eye placed behind such a tube, if it had any other inclination to the line BD. If, instead of supposing CB so small a tube, we imagine it to be the axis of a larger; then, for the same reason, the particle of light at C would not pass through that axis, unless it is inclined to BD in the angle CBD. In like manner, if the eye move the contrary way, from D towards A, with the same velocity, then the tube must be inclined in the angle BDC. Although, therefore, the true or real place of an object is perpendicular to the line in which the eye is moving, yet the visible place will not be so, since that, no doubt, must be in the direction of the tube; but the difference between the true and apparent place will be, *ceteris paribus*, greater or less, according to the different proportion between the velocity of light and that of the eye. So that if we could suppose that light was propagated in an instant, then there would be no difference between the real and visible place of an object, although the eye were in motion; for in that case, AC being infinite with respect to AB, the angle ACB, the difference between the real and visible place, vanishes. But if light be propagated in time, it is evident, from the foregoing considerations, that there will be always a difference between the true and visible place of an object, unless the eye is moving either directly towards or from the object. And in all cases the sine of the difference between the real and visible place of the object will be to the sine of the visible inclination of the object to the line in which the eye is moving, as the velocity of the eye is to the velocity of light.

He then shews that if the earth revolve round the sun annually, and the velocity of light be to the velocity of the earth's motion in its orbit, as one thousand to one, that a star really placed in the very pole of the ecliptic, would, to an eye carried along with the earth, seem to change its place continually; and neglecting the small difference on the account of the earth's diurnal revolution on its axis, would seem to describe a circle round that pole every way distant from it  $3\frac{1}{2}$ ; so that its longitude would be varied through all the points of the ecliptic every year, but its latitude would always remain the same. Its right ascension would also change, and its declination, according to the different situation of the sun with respect to the equinoctial points, and its apparent distance from the north pole of the equator, would be  $7'$  less at the autumnal than at the vernal equinox.

The greatest alteration of the place of a star in the pole of the ecliptic, or which, in effect, amounts to the same thing, the proportion between the velocity of the light and the earth's motion in its orbit being known, it will not be difficult, he observes, to find what would be the difference, upon this account, between the true and apparent place of any other star at any time; and, on the contrary, the difference between the true and apparent place being given, the proportion between the velocity of light and the earth's motion in its orbit may be found.

From all which the following conclusions may be deduced: 1. That the second cause above-mentioned alone takes place in this case, *viz.* that the distance of the stars is so great, that the diameter of the earth's orbit has no sensible proportion to it. 2. That the angle FEG (*fig. 3.*) in the above mentioned triangle, is  $20\frac{1}{4}$ ; or, since the apparent declination of the star  $\gamma$  Draconis, observed by Dr. Bradley, on account of the successive propagation of light, would be to the diameter of the little circle which a star would seem to describe about the pole of the ecliptic as  $39''$  to  $40''$ .4; the

half of this is the angle ACB (*fig. 7.*) which is equal to  $20''$ .2; and consequently the ratio of EG to FG (*fig. 3.*) or of AC to AB (*fig. 7.*) or the velocity of the light to the velocity of the earth in its orbit, as 10210 to 1; whence it follows, that the light comes from the sun to the earth in  $8'12''$ . This, Dr. Bradley observes, is very probably the truth, because it is a medium between 7 and 11, which were the times which it had before been supposed to take up, according to different observations of the eclipses of Jupiter's satellites. Comparing his observations on other stars, he afterwards concluded, that light is propagated from the sun to the earth in  $8'13''$ ; and the near agreement of his observations induced him to think, that this supposition could not differ so much as a second of a degree from the truth; so that the time which light spends in passing from the sun to us may be determined by these observations within  $5''$  or  $10''$ , which is such a degree of exactness as we can never hope to attain from the eclipses of Jupiter's satellites. 3. That the light proceeds with the same velocity from all the stars; for all have the same angle FEG. Whence (if we suppose that all the stars are not equally distant from us, as many arguments prove) it will follow, that the motion of light, all the way it passes through the immense space above our atmosphere, is equal or uniform. And since the different methods of determining the velocity of light thus agree in the result, it is reasonable to conclude, not only that the phenomena above recited are owing to the causes to which they are ascribed, but also that, in the same medium, light is propagated with the same velocity after it has been reflected, as before. 4. Lastly, it must be considered, that very small differences cannot be perceived; and nobody will deny, but that in measuring a small angle, an error of a second may be committed, whatever care is used to prevent it; and therefore, although we have said, that the first cause is to be rejected, we do not deny that the stars may possibly by its influence describe a minute circle, whose diameter is  $1''$ , or even a little more. S'Gravandane's *Phys. Elem. Math. lib. ii. cap. 1. p. 708, seq.*

Hence it appears, that the successive propagation of light will cause an aberration in the appearances of the stars, planets, and comets. (See *ABERRATION.*) After Dr. Bradley had discovered this cause of error in the apparent places of the fixed stars, M. Clairaut and others investigated several rules for the computation of this aberration. M. Euler also has given us a paper on this subject. *Mem. Acad. Scienc. 1756.* Mr. Simpson, in his *Essays. Mem. de l'Acad. de Berlin, tom. ii. p. 141, seq.*

See remarks on the effect of the aberration of light on the time of the transit of Venus over the sun, by Dr. Price, in *Phil. Trans. vol. lx. art. 47. p. 536.*

For an account of Mr. Melville's hypothesis of the different velocities of differently coloured rays, see *REFRACTIBILITY.*

Whether the light emitted by candles and other luminous bodies acquires the same velocity it is difficult to determine. So far as our knowledge extends on that head, it does not appear inferior to solar light.

But to return to the hypothesis of pressure, by which some have accounted for the propagation of light, it might be observed farther, if light were not a body, but consisted in a mere pressure, or pulsion, it would never be propagated in right lines, but would be continually inflected ad umbra. Thus sir Isaac Newton: "A pressure on a fluid medium, *i. e.* a motion propagated by such a medium, beyond any obstacles, which impedes any part of its motion, cannot be propagated in right lines, but will be always inflecting and diffusing

diffusing itself every way, to the quiescent medium beyond that obstacle. The power of gravity tends downwards; but the pressure of water arising from it tends every way with an equable force, and is propagated with equal ease, and equal strength, in curves, as in straight lines. Waves, on the surface of the water, gliding by the extremes of any very large obstacle, inſect and dilate themselves, ſtill diffuſing, gradually, into the quiescent water beyond that obstacle. The waves, pulses, or vibrations of the air, wherein ſound conſiſts, are manifeſtly inſected, though not ſo conſiderably as the waves of water; and ſounds are propagated with equal eaſe, through crooked tubes, and through ſtraight lines: but light was never known to move in any curve, nor to inſect itſelf ad umbram." The rays of light, therefore, are ſmall corpuscles, emitted with exceeding celerity from the luminous body. As to the force wherewith theſe corpuscles are emitted, ſo as to enable them to move at the inconceivable rate of 200,000 miles a ſecond; the ſame great author obſerves; "Among bodies of the ſame kind and virtue, by how much any one is ſmaller, by ſo much is its attractive power greater in proportion to its bulk. This power we find ſtronger in ſmall magnets, than in large ones, regard being had to the difference of their weights: and the reaſon is, that the particles of ſmall magnets being nearer each other, more eaſily unite their forces intimately together, and act conjointly. For the ſame reaſon the rays of light, being of all other bodies the moſt minute, it may be expected that their attractive powers ſhould be, of all others, the ſtrongest; and how ſtrong in effect they are, may be gathered from the following rules: the attraction of a ray of light, according to the quantity of its matter, is to the gravity which any projected body has, according, likewise, to the quantity of its matter, in a ratio compounded of the velocity of the ray of light, to the velocity of that projected body, and of the bending or curvature of the line which the ray deſcribes in the place of refraction, to the bending of the curvature deſcribed by that projected body; provided, however, the inclination of the ray to the refracting ſurface be the ſame with that of the projected body to the horizon. From which proportion I gather, that the attraction of the rays of light is above 1,000,000,000,000,000 times greater than the gravity of bodies on the ſurface of the earth, in proportion to the quantity of matter in each, if the light paſs from the ſun to the earth in the ſpace of ſeven minutes. But now, as in algebra, where affirmative quantities ceaſe, there negative ones begin; ſo in mechanics, where attraction ceaſes, there the repelling power muſt ſucceed: therefore a ray of light, as ſoon as it is caſt off from the luminous body, by the vibrating motion of its parts, and is got out of the ſphere of its attraction, is propelled with an immenſe velocity."

The wonderful diviſibility of the parts of matter is nowhere more apparent than in the minuteness of the particles of light. Dr. Nieuwentyſ has computed, that an inch of candle, when converted to light, becomes divided into 269,617,040 parts, with 40 ciphers annexed; at which rate there muſt iſſue out of it, when burning, 418,660, with 39 ciphers more, particles in the ſecond of a minute; vaſtly more than a thouſand times a thouſand million times the number of ſands the whole earth can contain; reckoning ten inches to one foot, and that 100 ſands are equal to one inch. See Reliq. Philoſ. vol. iii. p. 865.

It muſt be acknowledged, that many difficulties and objections have been urged againſt the materiality of light, or the hypotheſis of light's conſiſting of ſmall particles emitted from luminous bodies; and that many eminent philoſophers, both foreigners and Engliſh, have recurred to the opinion, that

light conſiſts of vibrations propagated from the luminous body through a ſubtile ethereal medium.

The ingenious Dr. Franklin, in a letter dated April 23d, 1752, expreſſes his diſſatisfaction with the doctrine, that ſuppoſes particles of matter, called light, continually driven off from the ſun's ſurface, with a ſwiftness fo prodigious. "Muſt not," ſays he, "the ſmalleſt portion conceivable have, with ſuch a motion, a force exceeding that of a twenty-four pounder diſcharged from a cannon? Muſt not the ſun diminiſh exceedingly by ſuch a waſte of matter; and the planets, inſtead of drawing nearer to him, as ſome have feared, recede to greater diſtances through the leſened attraction? Yet theſe particles, with this amazing motion, will not drive before them, or remove, the leaſt and lighteſt duſt they meet with; and the ſun appears to continue of his ancient dimenſions, and his attendants more in their ancient orbits." Accordingly, he conjectures, that all the phenomena of light may be more conveniently ſolved, by ſuppoſing univerſal ſpace filled with a ſubtile elaſtic fluid; which, when at reſt, is not viſible, but whoſe vibrations affect that fine ſenſe in the eye, as thoſe of air do the groſſer organs of the ear: and that different degrees of the vibration of this medium may occasion the appearances of different colours. The elaſtic fluid, he ſays, is always the ſame, and yet weaker and ſtronger ſparks diſfer in apparent colour, ſome white, blue, purple, red; the ſtrongeſt, white; the weak ones, red. Franklin's Exp. and Obſ. &c. p. 264, &c. ed. 1769.

The celebrated Mr. Euler (as we have already obſerved), has alſo ſtrenuouſly maintained the ſame hypotheſis, in his Theoria Lucis & Colorum. In the ſummary of his arguments againſt the common opinion, recited in Acad. Berl. 1752. p. 271, beſides the objections above-mentioned, he diſputes the poſſibility, that particles of matter, allowed to move with the amazing velocity of light, ſhould penetrate tranſparent ſubſtances with ſo much eaſe. In whatever manner they are tranſmitted, thoſe bodies muſt have pores, diſpoſed in right lines, and in all poſſible directions, in order to form canals for the paſſage of the rays: but ſuch a ſtructure muſt take away all ſolid matter from thoſe bodies, and all coherence among their parts, if they do contain any ſolid matter.

Dr. Horſley has taken conſiderable pains to obviate the difficulties ſuggeſted by Dr. Franklin; and ſuppoſing that the diameter of each particle of light does not exceed one millionth of one millionth of an inch, and that the density of each particle is three times that of iron, that the light of the ſun travels the ſemi-diameter of the orbis magnus in 7', and that this ſemi-diameter is 22919 ſemi-diameters of the earth, he calculates, that the momentum or force of motion in each particle of light coming from the ſun, is leſs than that in an iron ball of 4th of an inch diameter, moving at the rate of leſs than an inch in twelve thouſand millions of millions of Egyptian years. Hence, he concludes, that a particle of matter, which is probably larger than any particle of light, moving with the velocity of light, has a force of motion, which, inſtead of exceeding the force of a twenty-four pounder diſcharged from a cannon, is infinitely leſs than that of the ſmalleſt ſhot diſcharged from a pocket-piſtol, or leſs than any that art can create. Moreover, he thinks it poſſible, that light may be produced by a continual emission of matter from the ſun, without any ſuch waſte of his ſubſtance as ſhould ſenſibly contract his dimenſions, or alter the motions of the planets, within any moderate length of time. In proof of this, he obſerves, that it is not neceſſary to the production of any of the phenomena of light, that the emanation from the ſun ſhould be continual in a ſtrict mathematical ſenſe, or without any interval; and likewise that

part of the light which issues from the sun is continually returning to him by reflection from the planets, and other light is continually coming to him from the suns of other systems. He proceeds by calculation to shew, that in 385,130,000 Egyptian years, the sun would lose  $\frac{1}{1723}$  of his matter, and, therefore, that the gravitation towards the sun, at any given distance, would diminish in the same proportion. But this alteration is much too small to discover itself in the motion of the earth, or of any of the planets. He also computes, that the greatest stroke which the retina of a common eye sustains, when the eye, in a bright day, is turned up directly to the sun, does not exceed that which an iron shot,  $\frac{1}{4}$ th of an inch diameter, would give, moving only at the rate of 16.16 inches in a year; but the ordinary stroke is less than the  $\frac{1}{1723}$ th part of this. (Phil. Transf. vol. lx. art. 35. vol. lxi. part ii. art. 50.) One of the principal difficulties attending the hypothesis of the materiality of light, is the non-interference of its particles with each other. There is, probably, says Mr. Melville, Edinb. Ess. vol. ii. p. 17, &c. no physical point in the visible horizon, that does not send rays to every other point, unless where opaque bodies interpose. Light, in its passage from one system to another, often passes through torrents of light issuing from other suns and systems, without ever interfering, or being diverted from its course either by it, or by the particles of that elastic medium, which some have supposed to be diffused through all the mundane space. In accounting for this fact, he supposes that the particles of light must be incomparably rare, even when they are the most dense; that is, that the semidiameters of two of the nearest particles, in the same, or in different beams, soon after their emission, are incomparably less than their distance from one another. This consideration obviates the objection urged by Euler and others against the materiality of light, from its influence in disturbing the freedom and perpetuity of the celestial motions. Boscovich and others solve the difficulty concerning the non-interference of the particles of light, by supposing that each particle is endued with an insuperable impulsive force; but in this case, their spheres of impulsion would be more liable to interfere, and they would, on that account, be more likely to disturb one another. This difficulty, attending the supposition, that particles of light move through other light, in all imaginable directions, without perpetual collisions among the particles, and continual deflections from a rectilinear course, is, in a great degree, obviated, by an easy computation of Mr. Canton. He observes, that it is necessary to allow only a very small portion of time between the emission of every particle, and the next that follows in the same direction. Suppose, for instance, that one lucid point of the sun's surface emits 150 particles in one second, which are more than sufficient to give continual light to the eye, without the least appearance of intermission; yet still the particles of which it consists will, on account of their great velocity, be more than a thousand miles behind one another, and thereby leave room enough for others to pass in all directions. Phil. Transf. vol. lviii. art. 45. p. 344.

If we adopt the conclusions drawn from the chevalier d'Arcy's experiments on the duration of the sensations excited by light, who states it at the seventh part of a second (Hist. Acad. Scienc. 1765, Mem. 2.) we may admit an interval of more than 20,000 miles between each particle. Some, in order to answer the chief objections of this kind against the materiality of light, have adopted the hypothesis of M. Boscovich; who advances, in his Theoria Philosophicæ Naturalis, that matter is not impenetrable, but that it consists of physical points only, endued with

powers of attraction and repulsion, taking place at different distances; that is, surrounded with various spheres of attraction and repulsion, in the same manner as solid matter is generally supposed to be; provided, therefore, that any body move with a sufficient degree of velocity, or have sufficient momentum, to overcome any powers of repulsion it may meet with, it will find no difficulty in making its way through any body whatever; for nothing will interfere or penetrate one another, but powers, such as we know, do, in fact, exist in the same place, and counterbalance or overrule one another. Priestley's Hist. &c. of Light, &c. p. 391. That light is a real substance, notwithstanding the objections that have been urged against this hypothesis, seems to be established by the phenomena of the Bolognian stone, and of other substances, which possess the remarkable property of imbibing light, of retaining it for some time, and afterwards of emitting it. See PHOSPHORUS, and the sequel of this article.

The doctrine of the materiality of light is farther confirmed by those experiments, which demonstrate, that the colour and inward texture of some bodies are changed, in consequence of their being exposed to the light.

The first observation of this kind appears to have been made by M. Duhamel, who found that the juice of a certain shell-fish in Provence contracted a fine purple colour when it was exposed to the light of the sun, and that the stronger was the light, the more splendid was the colour. Pieces of cloth dipped in this liquor, and exposed to the sun, became red, though they were inclosed in glass; but they acquired none of this colour in the same exposure, if they were covered with the thinnest plates of metal. It was afterwards observed by Beccarius, Com. Bonon. vol. iv. p. 75, that a quantity of luna cornea, exposed to the rays of the sun, became of a violet colour, whilst part of the same composition, covered with black paper, remained white. This effect was found by M. H. Schulze to depend on the silver that happened to be in it. (Ac. Cæsar. vol. i. p. 528, &c.) G. Bonzius was thus led to some subsequent experiments, which seem to prove that various colours are considerably affected by light, exclusive of heat or any thing else. By exposing ribbons of different colours to the rays of the sun for several days in the open air, he found that all, except the yellow and light green, lost part of their lustre, and were considerably faded; but when the same ribbons were exposed to a much greater degree of heat in a dark room, none of the colours were affected, except that a small part of their lustre was lost; nor was any sensible change made in them after remaining for a considerable time in a room that faced the north. By inclosing them in an exhausted receiver, he found that the change was not occasioned by the air; but no change could be produced in them by the light of torches. Beccarius also found by experiments on paper, and a great variety of substances, mineral, vegetable, and animal, that the light of the sun produced many changes in the internal structure of bodies, and that those substances which imbibed light were much injured. The stronger the light, and the longer they were exposed to it, the more injury they received; and the injury thus sustained was found to be lasting. Com. Bon. vol. vi. p. 77, &c. See Priestley's History, p. 378, &c.

Some writers have attempted to prove the materiality of light, by determining the momentum of their component particles, or by shewing that they had a force, so as, by their impulse, to give motion to light bodies. M. Homberg, Ac. Par. 1708. H. p. 25, imagined, that he could not only disperse pieces of amianthus, and other light substances, by the impulse of the solar rays, but also that by throwing them

them upon the end of a kind of lever, connected with the spring of a watch, he could make it move sensibly quicker; whence, and from other experiments, was inferred the weight of the particles of light. But M. Du Fay, and M. Mairan, made other experiments of a more accurate kind, which exhibited no such effects as M. Hombert imagined. However, Dr. Priestley informs us, that Mr. Mitchell endeavoured to ascertain the momentum of light with still greater accuracy, and that his endeavours were not altogether unsuccessful. Having found that the instrument which he used acquired, from the impulse of the rays of light, a velocity of one inch in a second, he inferred, that the quantity of matter contained in the rays falling upon the instrument at that time, amounted to no more than one twelve hundred millionth part of a grain. In the experiment, the light was collected from a surface of about three square feet; and as this surface reflected only about half what falls upon it, the quantity of matter contained in the rays of the sun, incident upon a square foot and half of surface in one second of time, ought to be no more than the twelve hundred millionth part of a grain, or upon one square foot only, the eighteen hundred millionth part of a grain. But the density of the rays of light at the surface of the sun is greater than at the earth, in the proportion of 45000 to 1; there ought, therefore, to issue from one square foot of the sun's surface in one second of time, in order to supply the waste by light, one forty thousandth part of a grain of matter; that is, a little more than two grains a day, or about four millions seven hundred and fifty-two thousand grains, which is about six hundred and seventy pounds, *avoirdupois*, in six thousand years; a quantity which would have shortened the sun's semi-diameter no more than about ten feet, if it was formed of matter of the density of water only. Priestley, *ubi supra*, p. 389.

The nature of light has not been satisfactorily ascertained by any of the experiments and investigations of philosophers. Some incline to the Newtonian hypothesis, which ascribed it to the emission of very minute particles from luminous substances, as we have already stated; and others to the excitation of an undulatory motion, analogous to that which constitutes sound, in a very rare and elastic medium, which pervades the universe. There are also some circumstances which induce those who entertain the first hypothesis, either to believe, with Newton, that the emanation of the particles of light is always attended by the undulations of an ethereal medium, accompanying it in its passage, or to suppose, with Boscovich, that the minute particles of light themselves receive, at the time of their emission, certain rotatory and vibratory motions, which they retain as long as their projectile motion continues. These additional suppositions, however necessary they may have been thought for explaining some particular phenomena, have never been very generally understood or admitted, although no attempt has been made to accommodate the theory in any other manner in these phenomena. Dr. Young, in his "Course of Lectures on Natural Philosophy, &c." has examined in detail the manner in which the two principal hypotheses respecting light may be applied to its various affections and properties; for which we refer to vol. i. p. 453, &c. to the sequel of this article, and to other appropriate terms that occur in the Cyclopaedia.

The expansion or extension of any portion of light is inconceivable. Dr. Hook shows it is as unlimited as the universe; proving it from the immense distance of some of the fixed stars, the light whereof becomes sensible to the eye by means of a telescope: nor, adds he, are they only the great bodies of the sun or stars that are thus

liable to disperse their light through the vast expanse of the universe, but the smallest spark of a lucid body must do the same, even the smallest globule struck from a steel by a flint.

The method of measuring the intensity of different lights, or of the same light in different circumstances, affords a curious subject of investigation. M. Bouguer pursued it with particular attention, and described an apparatus which he has contrived for this purpose, in his *Traité de Optique*, published in Paris, 1760. Dr. Priestley (*ubi infra*) has given an abridged account of the two methods used for this purpose by M. Bouguer. The first of these two methods has been used by others since, and probably before that time, and particularly by count Rumford. See PHOTOMETER.

It is well known that the action of a strong light upon the eye, and also the impression which it leaves upon the eye, makes it insensible to the effect of a weaker light. M. Bouguer found, that when one light is sixty-four times less than another, its presence or absence will not be perceived; and, allowing for different effects on different eyes, he supposes that the boundaries, with respect to different persons, may lie between sixty and eighty. Being unable to determine the variation of the light of the sun, because it is too strong, and that of the stars, because it is too weak, at different altitudes, he made his observations on the moon, the diminution of the light being in the same proportion in this case and in the others, and found that its light at  $19^{\circ} 16'$  is to its light at  $66^{\circ} 11'$ , as 1681 to 2500; or the one is nearly two-thirds of the other. When one limb of the moon touched the horizon of the sea, its light was two thousand times less than at the altitude of  $66^{\circ} 11'$ . But this proportion, he says, is liable to variations, the atmosphere near the surface of the earth varying so much in its density. Hence he concludes, that, at a medium, light is diminished in the proportion of about 2500 to 1681, in traversing 7469 toises of dense air. He also found, that the centre of the sun is considerably more luminous than the extremities of it; whereas, both the primary and secondary planets are more luminous at their edges than near their centres. In a comparison of the light of the sun and moon, he compared each of them to that of a candle in a dark room, one in the day time, and the other in the night following, when the moon was at her mean distance from the earth, and, after many trials, he concluded, that the light of the sun is about three hundred thousand times greater than that of the moon; and, therefore, it is no wonder that philosophers have had so little success in their attempts to collect the light of the moon with burning-glasses; for the largest of them will not increase the light a thousand times, which will still leave the light of the moon, in the focus of the mirror, three hundred times less than the intensity of the common light of the sun. Dr. Smith, in his *Optics*, vol. i. p. 29, thought that he had proved, from two different considerations, that the light of the full moon would be to our day-light as 1 to about 90000, if no rays were lost at the moon. His method of calculation follows, as far as it is just, says Mr. Robins, *Math. Tracts*, vol. ii. p. 225, directly from the proposition for the same purpose of that excellent geometer, James Gregory, in his *Geom. Par. Univers.* p. 144; and the general proposition there mentioned for diluting the proportion between the degrees of light received from any planet, and from the sun, as repeated in David Gregory's *Astronomy*, lib. iii. prop. 58. Mr. Robins remarks, that though his estimate is founded on the supposition, that the moon reflects all the light it receives from the sun; yet his argument is drawn from compar-

paring the light of the moon seen in the day with the light of the clouds; that is, is deduced from the quantity of light actually reflected by the moon. In the first place he supposes that the moon, enlightened by the sun, is as luminous as the clouds are at a medium. He, therefore, supposed the light of the sun to be equal to that of a whole hemisphere of clouds, or as many moons as would cover the surface of the heavens. But upon this it may be observed, that the light of the sun shining perpendicularly upon any surface, would be equal to the light reflected from the whole hemisphere, if every part of it reflected all the light that fell upon it; but the light that would, in fact, be received from the whole hemisphere (part of it being received obliquely) would be only one-half as much as would be received from the whole hemisphere. if every part of it shone directly upon the surface to be illuminated. In his Remarks, &c. p. 17, he draws the same conclusion from a different method of induction; but in this case also he made a mistake of one-half, supposing all the enlightened hemisphere of the moon to receive the direct rays of the sun; whereas, in fact, no more can be received than would fall perpendicularly on the superficial section of one great circle, which is just one-half of the surface of the hemisphere. Priestley, ubi supra, p. 540, &c.

Mr. Mitchell made this computation in a more easy and accurate manner. Considering the distance of the moon from the sun, and that the density of the light must decrease in the proportion of the square of that distance, he calculated the density of the sun's light at that distance, in proportion to its density at the surface of the sun: and in this manner he found that, if the moon reflected all the light it receives from the sun, it would be only the 45000th part of the light we receive from that greater luminary. Admitting, therefore, with M. Bouguer, that the moon reflects only a 300.000th part of it, Mr. Mitchell concludes, that it reflects no more than between the sixth and seventh part of the light that falls upon it. Phil. Trans. vol. lvii. art. 27, P. 234, &c.

Dr. Pemberton, in his Course of Chemistry, lect. 2. states the greatest light which we can receive from the moon, when at the full, and nearest to the earth, to exceed the light of the sun more than 87,000 times, supposing that the moon reflected all the light of the sun which falls upon it; but if it reflects only half the light that falls upon its surface, which is the most that can be supposed, then the light of the moon will be exceeded by the sun's light more than 170,000 times: and in the mean distance of the moon from the earth, her light will be exceeded by the sun more than 190,000 times.

The mutual action between light and other matter is productive of numerous phenomena. These of late have constituted two distinct branches of science. The one has for its object the investigation of the physical properties of light, for which we are principally indebted to Newton, and which forms the basis of the science of optics. The other is confined to the chemical agency of light, resting upon facts discovered since the time of that great genius, and which has hitherto occupied the attention of the chemical philosopher.

When a ray of light falls upon the surface of a body, it is either reflected, absorbed, and extinguished, or transmitted. And under some circumstances all these effects take place.

The reflection of the ray depends, first, upon the nature of the body; secondly, upon the state and colour of the surface; and, thirdly, upon the quantity of the angle of incidence. Under all these circumstances, however, the angle

at which the ray is reflected is equal to the angle of incidence. The same laws, therefore, which govern the collision between perfectly elastic bodies and absolutely hard surfaces, may be applied to the reflection of light. Of the different bodies which reflect light, metals possess this power in the greatest degree, and perhaps in proportion to their density and hardness. Smooth or polished surfaces reflect more light than rough ones.

Of coloured surfaces the lightest colours reflect the most; hence the whitest metals make the best reflectors. The order will therefore, in all probability, be as follows, beginning with the best reflectors, white, yellow, red, blue, black. The two extremes are very striking, in the well-known experiment of two pieces of cloth, one white and the other black, laid on the surface of snow in the sun. The black piece very soon sinks into the snow, from absorbing a greater quantity of light, which causes the heat. The white piece reflects a greater portion, and is longer in becoming heated. With regard to the quantity of reflection, as affected by the angle of the incidence; it is found that opaque bodies are more heated as the rays strike their surfaces more perpendicularly, and the quantity of light which enters transparent bodies is as the same. In both instances, therefore, more light enters the bodies, and less is reflected. In the first instance, the light which is not reflected becomes extinguished, producing heat; in the second it is transmitted, still retaining the property of light. Hence, therefore, we ought to conclude that the reflection will be inversely as the angle of incidence, supposing the angle to be formed by the ray and the surface of the medium.

M. Bouguer has informed us, that the light reflected from a surface of mercury, when the angle of incidence was  $11\frac{1}{2}^\circ$ , was only equal to  $\frac{1}{4}$ th of the whole; and he thinks it probable that no substance reflects more. It is certain, however, that polished silver reflects much more. The same philosopher observes, that metallic reflectors change less in their power of reflection with the angle of incidence. He made the following experiment with polished black marble. At an angle of  $3^\circ 35'$  with the reflecting surface, .6 were reflected, the whole being unity; at  $15^\circ$  of incidence, .156 were reflected; at  $30^\circ$ , .051; and at  $80^\circ$ , .023. The rest of course became extinguished, and would heat the marble.

A similar diminution of the reflective power, with the angle of incidence, is observed in transparent bodies, by the same author. The following Table gives the results with water and plate-glass.

Angle of Incidence.	The Quantity of Light reflected, the whole being 1000.	
	From Water.	From Plate-Glass.
$\frac{1}{2}^\circ$	721	
1	692	
$1\frac{1}{2}$	669	
2	639	
$2\frac{1}{2}$	614	584
5	501	543

## L I G H T.

Angle of Incidence.	The Quantity of Light reflected, the whole being 1000.	
	From Water.	From Plate-Glass.
$7^{\circ}\frac{1}{2}$	409	474
10	333	412
$12^{\circ}\frac{1}{2}$	271	356
15	211	299
$17^{\circ}\frac{1}{2}$	178	
20	145	222
25	97	157

50	22	34
60	19	27
70	18	25
80	18	25
90	18	25

The reflections in this instance are partly made from the upper, and the rest from the under surface. The remainder of the thousand parts are transmitted, with the exception of a few, which are in all probability extinguished.

That, under certain circumstances, the rays of light are extinguished, even in transparent bodies, is rendered highly probable by the above inquirer.

Light becomes so far extinct, by passing through 679 feet of sea-water, as to render it opaque; and a length of seven feet of water has been found to intercept one-half of the light which enters it.

M. Bouguer tells us, that if our atmosphere were 518,385 toises in height, we should have no light from the sun, even in his meridian splendour. It has been estimated, that of the horizontal sun-beams passing through about 200 miles of air, one two-thousandth part only reaches us.

In all the instances in which light is extinguished, it will doubtless be so found that a certain quantity of heat will be generated. Sir Isaac Newton seems perfectly aware of this fact. In his time, however, heat was supposed to arise from motion, and hence he concluded that the light, when it was neither reflected nor transmitted, so acted upon the body it entered, as to put its particles into a vibratory motion, in which he believed the heat to consist.

Dr. s'Gravesande asserts, a lucid body to be, that which emits, or gives fire a motion in right lines; and makes the difference between light and heat to consist in this, that to produce the former, the fiery particles must enter the eye in a rectilinear motion, which is not required in the latter; on the contrary, an irregular motion seems more proper for it, as appears from the rays coming directly from the sun to

the tops of mountains, which have not near that effect with those in the valley, agitated with an irregular motion, by several reflections.

Whether or not there be always light, where there is fire, has been disputed among authors; as also, whether or not there be any luminous body without heat; heat being considered by them as a motion that may be infinitely diminished, and light a matter that may be infinitely rare; to which we may add, that no heat is sensible to us, unless it be more intense than that of our organs of sense. M. De Luc, in his *Lettres Physiques et Morales*, &c. 1780, observes, that the rays of the sun, though not warm in themselves, occasion heat, by giving activity to a substance, which resides in all bodies, and constitutes a part of their mass, and which in certain circumstances is capable of producing heat: and that in consequence of this influence, this substance becomes an elastic or igneous fluid. (See HEAT.) Caloric, however, is now considered material, and a distinct fluid from that of light.

Solar heat is at present accounted for in a different way to that of considering the heat as extinguished light. Dr. Herschel has, from a series of experiments, of which we shall soon give an account, concluded, that the rays of caloric, or rays solely producing heat, are emitted from the sun, as well as from terrestrial bodies, affording light and heat: while the rays of light, or such as are essential to vision and colour, have not the property of producing heat. How far this conclusion is warranted, we shall have occasion hereafter to consider.

Besides the properties of light to be reflected and transmitted, and that of being absorbed and extinguished, we are presented with curious phenomena, arising from the attraction between this substance and other matter, which is the cause of the refraction and inflection of light. When a ray of light enters any transparent medium, in a direction perpendicular to the surface of the same, the ray will maintain its course in the same direction; but if the ray of light make any angle less than a right angle with the surface of the medium, it will not continue in the same direction, but will be drawn towards a straight line, perpendicular to the same surface, and passing through the medium at the point where the oblique ray enters. This line, in optical language, is called the perpendicular. The angle which the incident ray makes with the perpendicular is called the angle of incidence; and the angle which the ray makes with the same perpendicular, after it enters the medium, is called the angle of refraction. In all the degrees of obliquity at which a ray enters any medium, the sine of the angle of incidence has the same ratio to the sine of the angle of refraction.

The refracting power of different transparent bodies is not dependent upon one property alone; it appears, however, to be directly as their density, all other things being equal.

Inflammable bodies are found to refract light much more than bodies not inflammable. Sir Isaac Newton divided diaphanous bodies into two classes, each of which refract light as their density. The first consisted of the inflammable, in which it was much more than according to the ratio of their density.

The other class, which were not inflammable, appeared to obey the same law as to density, with the exception of the diamond and water. The former of these refracted in the compound ratio of inflammability and density; and although it was then not known to be inflammable, Newton strongly suspected it to be entirely an inflammable body; and that water which appeared to have an intermediate power between the two classes, he supposed, was partly inflammable.

these

These prophetic observations have been verified in the discovery of the diamond being pure carbon, and in the decomposition of water.

The late discoveries of Mr. Davy render it very probable that all compound bodies are composed of inflammable matter and oxygen. Hence it would seem, that the refractive power of bodies is less in proportion to the oxygen they contain. Sir Isaac Newton suspected that refraction was caused by inflammable matter alone, from which it would follow, that all diaphanous bodies contained inflammable matter. This, in all probability, is the case with the exception of oxygen. It has, however, been proved by M. Biot, that the refractive power of oxygen, although less than any substance in proportion to its density, is nevertheless appreciable. The same philosopher also ascertained that hydrogen refracts light in a ratio, independent of its density, higher than any other substance.

From the above facts we may, with some certainty, conclude, that the refractive power of bodies, or, in other words, their attraction for light, is in the compound ratio of their inflammability and density.

Light is not only attracted in passing through different media, constituting refraction, but it is attracted towards the sides of bodies by which it passes, and is then said to be inflected. When a beam of light is let through a small hole into a dark room, the rays are found to be drawn towards the sides of the hole, by which means they acquire a certain degree of divergence. In consequence of this change in the direction of the rays, the shadows of hairs, and other slender substances held in the beam of light coming through the aperture, are found to become enlarged in proportion to the distance of the place on which the shadow is cast. See INFLECTION.

From this circumstance Sir Isaac Newton concluded, that the rays of light must have passed as they are represented in *Plate IX. Optics, fig. 8.* in which X represents a section of the hair, and A D, B E, &c. rays of light passing by at different distances, and then falling upon the wall Q O. Since, when the paper which receives the rays is at a great distance from the hair, the shadow is broad, it must follow, as he observes, that the hair acts upon the rays of light at some considerable distance from it; the action being strongest on those rays which are at the least distance, and growing weaker and weaker on those which are farther off, as is represented in the figure; and from hence it comes to pass, that the shadow of the hair is much broader in proportion to the distance of the paper from the hair, when it is nearer than when it is at a great distance. It is of no moment, whether the hair be surrounded with air, or with any other pellucid substance. The shadows of scratches made in polished plates of glass, and the veins in the glass, cast the like broad shadows; so that the breadth of shadow must proceed from some other cause than the refraction of the air.

The shadows of all bodies, metals, stones, glass, wood, horn, &c. in this light, were bordered with three parallel fringes, or bands of coloured light, whereof that which was contiguous to the shadow was the broadest and most luminous, while that which was the most remote was the narrowest, and so faint, as not easily to be visible. The first or innermost fringe was violet, and deep blue next the shadow, light blue, green, and yellow in the middle, and red without. The second fringe was almost contiguous to the first, and the third to the second; and both were blue within, and yellow and red without; but their colours were very faint, especially those of the third. The colours, therefore, proceeded in the following order from the shadow: velvet, indigo, pale blue, green, yellow, red; blue, yellow,

red; pale blue, pale yellow, and red. The shadows made by scratches and bubbles in polished plates of glass, were bordered with the like fringes of coloured light. He also observes, that by looking on the sun through a feather, or black ribbon, held close to the eye, several rainbows will appear, the shadows which the fibres or threads cast on the retina being bordered with the like fringes of colours.

From comparing other experiments, in which a ray of light was made to pass through a hole into a darkened chamber, and then through a hole in a paste-board, first by the edge of a single knife, and then by the edges of two knives placed parallel to one another, Sir Isaac Newton concluded, that the light of the first fringe passed by the edge of the knife at a distance greater than the eight hundredth part of an inch, that the light of the second fringe passed by the edge of the knife at a greater distance than the light of the first fringe, and that of the third at a greater distance than that of the second; and that the light, of which the streams, observed in these experiments, consisted, passed by the edges of the knives at less distances than that of any of the fringes.

In another experiment, he placed at the hole a prism to refract the light, and to form, on the opposite wall, the coloured image of the sun; and he found that the shadows of all bodies, held in the coloured light between the prism and the wall, were bordered with fringes, of the colour of that light in which they were held; and comparing the fringes made in the several coloured lights, he found, that those made in the red light were the largest, those made in the violet the least, and those made in the green were of a middle size. Whence he inferred, that the rays which made the fringes in the red light, passed by the hair at a greater distance than those which made the like fringes in the violet; so that the hair, in causing these fringes, acted alike upon the red light, or least refrangible rays, at a greater distance, and upon the violet or most refrangible rays at a less distance, and thereby occasioned fringes of different sizes, without any change in the colour of any sort of light. It may, therefore, be concluded, that when the hair in the first observation was held in the white beams of the sun's light, and cast a shadow, which was bordered with three fringes of coloured light, those colours arose not from any new modifications impressed upon the rays of light by the hair, but only from the various inflections, whereby the several sorts of rays were separated from one another, which, before separation, by the mixture of all their colours, composed the white beam of the sun's light; but when separated composed lights of the several colours which they are originally disposed to exhibit. But for a fuller account of the author's curious experiments, and the conclusions drawn from them with regard to the inflection of light, we must refer to his well known treatise on Optics, p. 293. &c.

This action of bodies on light is found to exert itself at a sensible distance, though it always increases as the distance is diminished; as appears very sensibly in the passage of a ray between the edges of two thin planes at different apertures; in which there is something very peculiar; the attraction of one edge being increased as the other is brought nearer it. The rays of light, in their passage out of glass into vacuum, are not only inflected towards the glass, but, if they fall too obliquely, they will revert back again to the glass, and be totally reflected.

The cause of which reflection cannot be attributed to any resistance of the vacuum, but must be entirely owing to some force or power in the glass, which attracts or draws back the rays as they are passing into the vacuum. And this

this appears farther from hence, that if you wet the posterior surface of the glass with water, oil, honey, or a solution of quicksilver, then the rays which would otherwise have been reflected, will pass into and through that liquor; which shews that the rays are not reflected till they come to the posterior surface of the glass, nor even till they begin to go out of it; for if at their going out, they fall into any of the foresaid mediums, they will not then be reflected, but perfit in their former course, the attraction of the glass being in this case counterbalanced by that of the liquor.

Experiments, similar to those of sir Isaac Newton on inflected light, were prosecuted by M. Maraldi, whose observations chiefly respect the inflection of light towards other bodies, whereby their shadows are partially illuminated. *Ac. Paris. 1723. M. p. 159.* For an abstract, see Priestley's History, &c. of Light, &c. p. 521, &c. M. Mairan, without attempting the discovery of new facts, endeavoured to explain the old ones, by the hypothesis of an atmosphere surrounding all bodies; and consequently making two reflections and refractions of light that impinges upon them, one at the surface of the atmosphere, and the other at that of the body itself. This atmosphere he supposed to be of a variable density, and refractive power, like the air. M. du Tour succeeded Mairan, and imagined, that he could account for all the phenomena by the help of an atmosphere of a uniform density, and of a less refractive power than the air, surrounding all bodies. Du Tour varied the Newtonian experiments, and discovered in the colours produced by the inflection of light more than three fringes, which he exhibited distinctly in the following manner. He took a circular board, A B E D (*Plate IX. Optics, fig. 9.*) thirteen inches in diameter, the surface of which was black, except at the edge, where there was a ring of white paper, about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A slip of parchment three inches broad, and disposed in the form of a hoop, was fastened round the board, and pierced at the point E with a square hole, each side being four or five lines, in order to introduce a ray of the sun's light. Lastly, in the centre of the board C, and perpendicular to it, he fixed a pin, about one-third of a line in diameter.

This hoop being so disposed, that a ray of light entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and passing parallel to the plane of the board, projected the image of the sun and shadow of the pin at A.

In these circumstances he observed, first, that quite round the concave surface of this hoop, there was a multitude of coloured streaks; but that the space *m A n*, of about eighteen degrees, the middle of which was occupied by the image of the sun, was covered with a faint light only.

2. The order of the colours in these streaks was generally such, that the most refrangible rays were the nearest to the incident ray E C A; so that, beginning from the point A, the violet was the first, and the red the last colour in each of the streaks. In some of them, however, the colours were disposed in a contrary order.

3. The image of the sun, projected on each side of the point A, was divided by the shadow of the pin, which was bordered by two luminous streaks.

4. The coloured streaks were narrower in some parts of

the hoop than others, and generally decreased in breadth in receding from the point A.

5. Among these coloured streaks, there were sometimes others which were white, a line, or a line and a half in breadth, which were always bordered on both sides by a streak of orange colour, at least when the light of the sun was intense, and the chamber sufficiently dark.

From this experiment he thought it was evident, that the rays which passed beyond the pin were not the only ones that were decomposed; for that those which are reflected back from the pin were decomposed also: from which he concluded that they must have undergone some refraction. He also thought that those which went beyond the pin suffered a reflection, so that they were all affected in a similar manner.

In order to account for these facts, our author describes the progress of a ray of light through an uniform atmosphere which he supposes to surround the pin, and shews that the differently refrangible rays will be separated at their emergence from it; but he refers to some experiments and observations in a future memoir, to demonstrate that all the coloured streaks are produced by rays that are both reflected and refracted. *Memoires Présentés, vol. v. p. 636. 641.*

From other observations, M. Du Tour concludes, that the refracting atmospheres, surrounding all kinds of bodies, are of the same size; for when he placed a great variety of substances, and of different sizes also, he always found the coloured streaks of the same dimensions. He also observes, that this hypothesis contradicts an observation of sir Isaac Newton, *viz.* that those rays which pass the nearest to any body are most inflected. *Mem. de Mathem. and de Phys. vol. v. p. 650, &c.* or Priestley, *ubi supra, p. 531, &c.*

M. Le Cat found that, in some cases, objects appear magnified by means of the inflection of light. Looking at a distant steeple, when a wire of less diameter than the pupil of his eye was held pretty near to it, and drawing it several times betwixt his eye and that object, he was surprised to find that, every time the wire passed before his pupil, the steeple seemed to change its place, and some hills beyond the steeple seemed to have the same motion, just as if a lens had been drawn betwixt his eye and them. This discovery led him to several others depending upon the inflection of the rays of light. Thus, he magnified small objects, as the head of a pin, by looking at them through a small hole in a card; so that the rays which formed the image, must necessarily pass so near the circumference of the hole, as to be attracted by it: he also exhibited other appearances of a similar nature. *Traité des Sens, p. 299, &c.* Priestley, *ubi supra, p. 537, &c.*

Several coincident facts induced sir Isaac Newton to believe that reflection, refraction, and inflection resulted from the same cause, namely, attraction: Of the two latter of these properties resulting from this cause there can be little doubt; but the laws by which the first is governed appears to depend rather upon the repulsion than the attraction of the medium. The greatest mystery attending reflection, is in the circumstance of the under surface reflecting light equally with the upper surface. This part certainly goes far to prove, that the reflection of light is not to be explained by considering the reflecting surface as a hard substance, from which the elastic particles of light are repelled, particularly since the reflection from the under surface of any medium is in the inverse ratio of the density of the medium, beyond the reflecting surface, and is greatest when the surface is bounded by a vacuum.

Although

Although sir Isaac Newton does not attempt to explain the reflection from the upper surface by the attraction of the medium, he seems to be of opinion, that the light reflected from the under surface is attracted by the same medium in a contrary direction.

Hence he concludes, that this reflection is less as the density of the under medium is greater, the attraction of the first medium being counteracted by that of the second.

This explanation does not appear satisfactory. If the reflection of the rays from the under surface depended upon the attraction of the same medium, it would not produce the same phenomena which result from the reflection at the upper surface, and which is clearly caused by something like repulsion.

When a ray of light falls upon any reflecting surface, we cannot for a moment suppose that any attraction of the medium could cause it to be reflected, since the effect produced can arise only from a repellent force, exerted in a direction perpendicularly from the surface of the body. And that the elastic force existing between the body and the light is so perfect, as to make the angle of reflection equal to the angle of incidence. Newton very properly argued, that the reflection could not take place from the particles of light striking the hard parts of bodies, on account of the numerous interstices existing between their molecules; on the contrary, he supposed the light which struck the solid parts became extinguished.

It may here be observed, that it is equally difficult to explain the action of one solid body upon another, as it may easily be proved that they do not come into absolute contact in any instance.

When we attempt to unite the surfaces of fractured bodies, we cannot, in most instances, bring the parts within the sphere of attraction; and even where this can be effected, as in two bright surfaces of lead, it may be proved that the parts do not touch.

It seems difficult to conceive how an atmosphere of hydrogen should by its pressure support a column of mercury, by the mere action of the solid parts of the two surfaces, since every particle of hydrogen would be required to act upon 2700 particles of mercury.

We may, without much gratuity, consider all solid bodies as compounded of two species of matter; the one possessing so great an attraction as to bring the particles into absolute contact, and the other so completely repellent of itself, as to be infinitely dissipated, if it were not for its attraction for matter with which it combined. The former of these properties is peculiar to all ponderable matter, the latter to the repellent matter denominated light and caloric, and perhaps electricity and magnetism. Daily experience shews, that the constitution of solid and liquid bodies is dependent upon a certain quantity of caloric, opposed to the opposite and contending force of the attraction of the particles of the solid body, by which also their volumes and relative gravities are governed. Hence we may expect, that when the attraction of the body for caloric is greater than the repellent force of the caloric, the body will possess what is called a greater capacity for heat, and the reverse of this will take place from a contrary change.

Conceiving the above to be the case, it will be easy to infer, that the surfaces of bodies must be surrounded by atmospheres of caloric, and it doubtless is by these atmospheres that we are to account for the difficulty of bringing two surfaces together, and by which we may also explain the action of the hydrogenous atmosphere upon the mercury. May not we, therefore, draw this general con-

clusion, that the particles of all solid matter can never be brought into contact, either in their internal arrangement or on the surfaces; and that the repulsion existing between the particles of bodies, whether in the same or in two different bodies, is solely to be attributed to the repulsion between the particles of caloric? And may we not further conclude, that the particles of bodies, in all situations, and under all circumstances, are constantly exerting an attractive force tending to their ultimate contact? If it should be admitted that caloric is the cause of repulsion, elasticity must be therefore dependent upon its presence, acting in a contrary direction to the attractive force. Hence it would be very absurd to say that caloric itself should be elastic, because this property depends upon two forces. When caloric, therefore, is reflected from the surface of a body, we are to attribute its return to the repulsion between itself and the caloric of the body, the solid matter having nothing to do with the reflection. The rays of caloric, passing from one body to another, may, from what has been observed, be caused by the joint action of two forces. The one arising from the repulsion of the particles of caloric for each other at the heated body, and the other from the soliciting force of the attraction between the caloric and the receiving body. When, however, the repulsion between the radiant caloric and the caloric of the receiving body increases in a greater ratio than their attraction, the radiant caloric will be reflected. A contrary effect would cause them to be absorbed.

When the direction of the radiant caloric is perpendicular to the receiving surface, its projectile force conspires in the greatest degree with the attraction of the body, and less of course in proportion to its obliquity. Does not this agree with the established fact, that the reflection of both light and heat is inversely as the angle of obliquity the ray makes with the surface.

Light and caloric, so far as their reflection is concerned, are so similar, that we may with great propriety apply the same reasoning to the reflection of light, and the same absurdity would arise in considering light as consisting of elastic particles, because this would imply the existence of attractive matter in its composition. When, therefore, light is reflected, we are to consider with sir Isaac Newton, that no action takes place between the particles of light and the solid matter to produce the effect; but, agreeably to our hypothesis, we must conclude that the reflection is caused by the repulsion between the particles of light and the caloric of the body.

If the reflection is caused by the caloric atmosphere on the surface of the body, we may perceive an easy way of explaining why the reflection of light is confined to the surface of bodies, and why the under surface should reflect as much as the upper one.

This hypothesis does not disagree with the fact, of the reflection being, like the refraction, as the density of the medium, because the increase of density will be attended with increase of attraction between the particles, and it will be evident, that the density of the caloric atmosphere will be in the same proportion, therefore reflection will be as the density.

What we observed respecting the obliquity of the rays of caloric, will hold good with respect to light. When the obliquity of rays of light, which fall upon transparent bodies is such, that the repulsion between the light and the caloric of the body is greater than the projectile force of the ray added to the attraction, the medium of the angle of obliquity is called the angle of total reflection. When the reflection is from the under surface, the attraction of the

medium conspires with the repulsion between the light and the caloric atmosphere to cause total reflection, and the angle of total reflection ought to be rather greater at the under than the upper surface, which has been said to be the case; at least it has been observed by Bouguer, that more light is reflected from the internal than the external surface. The additional force given by the attraction of the medium to cause the internal reflection, will be counteracted by any other medium beyond this surface, and this accounts for the transmissibility under such circumstances. Agreeably to the established notion, therefore, we hold, that refraction and inflection are caused by the attraction existing between the light and the body. But it is more consistent with our views, to consider reflection and transmissibility as being caused by the repulsion existing between the particles of light, and between light and the caloric atmosphere of the body, modified and altered under certain circumstances, by the attraction between light and the medium.

Were we only acquainted with the fact, that light was attracted by ponderable matter, we should, from our knowledge of gravity, conclude that the refraction would be as the density of the medium; and we are not so much surprised at the circumstance of light being more attracted by inflammable than other bodies, when we recollect the great quantity of light and heat furnished by those bodies, when they combine with oxygen; and at the same time remember that the attraction of one body for another is as the quantity with which it can combine.

Some very curious facts relative to the properties of light have lately been discovered by M. Malus. (See Memoires de la Société d'Arcueil, vol. ii. p. 143.) It appears from the researches of this philosopher, that light is changed in its properties by particular reflection. If, says he, we take two plates of glass, and let two of their surfaces make an angle of 70° 50'; then imagine a line which shall bisect this angle. Any ray of light falling upon one of these surfaces, in a direction parallel to the above bisecting line, will be reflected to the other. The light, however, is so changed in its properties by the first reflection, as to be completely unreflectible of being reflected from the second surface; but the whole of it will be transmitted. This new property of light has been applied, with some success, to explain the mysterious phenomenon of double images formed by the Iceland crystal, calcareous spar, &c. If it be asked, how it happens, since we ascribe the reflection of the rays to the action of the whole surface of the body without contact, that all the rays are not reflected from every surface; but while some are reflected, others pass through, and are refracted? The answer given by Sir Isaac Newton is as follows:—Every ray of light, in its passage through any refracting surface, is put into a certain transient constitution or state, which in the progress of the ray returns at equal intervals, and disposes the ray at every return to be easily transmitted through the next refracting surface, and between the returns to be easily reflected by it; which alternation of reflection and transmissibility appears to be propagated from every surface and to all distances. What kind of action or disposition this is, and whether it consists in a circulating or vibrating motion of the ray, or the medium, or somewhat else, he does not inquire; but allows those who are fond of hypotheses to suppose, that the rays of light, by impinging on any reflecting or refracting surface, excite vibrations in the reflecting or refracting medium, and by that means agitate the solid parts of the body. These vibrations, thus propagated in the medium, move faster than the rays, so as to overtake them; and when any ray is in that part of the vibration which conspires with its motion, its velocity is in-

creased, so that it easily breaks through a refracting surface; but when it is in a contrary part of the vibration, which impedes its motion, it is easily reflected; and consequently, that every ray is successively disposed to be easily reflected, or transmitted by every vibration which overtakes it. The returns of which disposition of any ray to be reflected, he calls *sits of easy reflection*; and those of its disposition to be transmitted, he calls *sits of easy transmissibility*; and the space between the returns, *the intervals of the sits*. The reason, then, why the surfaces of all thick transparent bodies reflect part of the light incident on them, and refract the rest, is that some rays in their incidence are in *sits of easy reflection*, and others of easy transmissibility. See REFLECTION, REFRACTION, and OPTICS.

Having given some idea of the nature of light in general, we shall next point out the different sources of light; and under each of these heads, detail its more particular properties as a chemical agent, and its connection with the matter of heat.

*Solar Light.*—We have already stated the immense velocity with which light is emitted from the sun's body; and it will be easy to conceive that it cannot suffer any change in velocity or direction, till it meets with some ponderable matter. In approaching any planetary body, such as our earth, we have reason to believe that they are mutually attracted. Rays falling perpendicularly upon the atmosphere are equally attracted on every side, and come in a straight line to the earth; while those rays which fall obliquely are bent out of their original direction; and since the atmosphere is not of uniform density, such oblique rays will come to the earth in curved lines. If our atmosphere were of uniform density, the refraction would not be altered; but the oblique rays falling upon its surface, would be reflected in a very great degree; a circumstance which would deprive us of much of the sun's light. No doubt a great quantity of light becomes extinguished in its passage through the aerial medium, as we may justly learn from the difference of intensity in the light, at different altitudes of the sun; but how much must this loss of light appear, when we recur to the statement already made, namely, that the whole effect of the sun's light would be lost by passing through 679 feet of seawater, and that the same effect would take place by its passage through 3,110,310 feet of air.

The following is a table from M. Bouguer, shewing the intensity of the sun's light, at different altitudes, and the thickness of air it has to penetrate at each angle.

Sun's Altitude.	Thickness of Air in Toises.	Intensity of Light, the whole being 10,000.

The property of light to be refracted had been known long before the time of Newton; but this philosopher was the first who discovered that the light of a sun-beam was not refracted uniformly. If light were uniformly refracted, the rays which enter any plane surface would retain their relative inclination to each other, while they pass through the diaphanous medium; and the same after their emergence, if the surface were a plain. Sir Isaac Newton, however, has proved, by a series of elegant experiments, strengthened by

able reasoning, that the different parts of a solar beam are not refracted in the same degree. He caused a beam of light to pass through a small hole in the window-shutter of a dark room, making the pencil of rays to fall upon one side of a triangular prism. These rays were so refracted as to come out at another side of the prism. These emergent rays, however, were not parallel as they entered the other side; but each made a certain angle with the other, in consequence of some being more bent or refracted than the other. The image, or spectrum, formed by these rays upon a sheet of white paper, instead of being round, which would have resulted from uniform refraction, was of an oblong shape. Those rays which had been the least refracted occupied one end of the spectrum; and those most refracted, the other. The former tinged the paper of a red colour, the latter a violet colour; the intermediate rays exhibiting different colours, which were in the following order: red, orange, yellow, green, blue, indigo, and violet.

In order to shew that each of these rays had specific properties, not depending upon the medium they passed through, he caused them to pass through a second prism, sometimes together, and sometimes separately; but he always found them to retain their original properties.

By means of two contiguous spectrums, he caused a ray of one colour in the one to unite with a different colour in the other, and produced different compound colours. The yellow of one with the red of the other produced orange, which had the appearance of the primitive orange ray, and differed from it only in being decomposable into its original elements.

He ascertained by direct experiment, that those rays which were most refrangible were also most reflexible. In consequence of this property, he could reflect the different coloured rays separately. He caused the light to fall upon a prism, so laid upon a similar prism as to constitute a parallelepiped, so that the rays were parallel at their emergence; but upon turning the two prisms round their common centre, the light became reflected from the upper contiguous surface, and all the rays in their turns arrived at the angle of total reflection. But he observed that those which had been most refracted were first reflected; the least refrangible being the last.

These valuable facts were used by this able philosopher to explain the colours of natural bodies. He has shewn that colour is not a specific property of bodies, but is caused by the different rays of light being reflected from the surface of the body; the rest of the rays passing into, or through the body. Since the time of this philosopher, it has been objected, that the seven colours above mentioned are not primitive. It seems very obvious that there can be only three primitive colours, namely, red, yellow, and blue; since all the colours can be made by means of these. It has lately been advanced by Prieur, that the primitive colours are violet, green, and red: that the yellow is formed with red and green, the latter being in excess; and that when the red is in excess, they form orange; the green and violet form blue.

The colours excited by the different refrangible rays do not appear to determine what are the primitive colours, since we find that different rays are capable of producing the same colour, as a mixture of the yellow with the red, produces orange. And it must be admitted, that the violet, rays excite, in some degree, the idea of red along with the blue; as in the green, the yellow and blue may be discerned, but none of the red.

When the different coloured rays are mixed together, either by recomposition, or by getting each colour from a separate

## L I G H T.

ferre spectrum, the result will be white light. Hence Sir Isaac Newton concluded, that when the rays are promiscuously reflected from any surface it will appear white. It was found by Sir Isaac Newton, and has since been confirmed by the experiments of Dr. Herschel, that the different coloured rays have not by any means the same illuminating power. The violet rays appear to have the least luminous effect, the indigo more, the blue a little more, the green very great, between the green and the yellow the greatest of all, the yellow the same as the green, and the red less than the yellow. When the solar rays are passed through a convex lens, or reflected from a concave, a very intense heat is produced by the concentration of the rays. Count Rumford has shewn, that when the rays of the sun are made to pass through a certain aperture, and fall upon any substance to be heated, while the same area of light is made to pass through a lens, in the focus of which the same quantity of matter is to be heated, they become heated in the same time to the same degree. Nothing is better known, in short, than that the rays of the sun are capable of exciting sensible heat. Newton, and the philosophers of his age, accounted for heat by the motion excited in the parts of the body by the agitating power of the absorbed light. Melville supposed that the heat was expelled from the terrestrial matter by the light. At present, it is generally admitted, on the strength of some valuable experiments made by Dr. Herschel, that the rays of light and caloric are separately emitted from the sun, the luminous rays producing light, and the calorific, heat.

This philosopher introduced a beam of light into a dark room, which was decomposed by a prism, and then exposed a very sensible thermometer to all the rays in succession, and observed the heights to which it rose in a given time. He thus determined, that the heating power of the red is to that of the green rays as  $2\frac{1}{2}$  to 1, and  $3\frac{1}{2}$  to 1 in red to violet.

On repeating these experiments, he found that the greatest quantity of calorific rays were, even beyond the coloured spectrum at about  $\frac{1}{2}$  an inch, from the commencement of the red rays. At a greater distance from this point it began to diminish, but was very perceptible even at the distance of  $1\frac{1}{2}$  inch.

It will appear from what has been stated, that these calorific rays are less refrangible than the rays of light; hence the calorific focus will fall beyond that of the luminous. Dr. Herschel made an experiment to verify this inference, but did not come at any thing very conclusive. He afterwards made experiments to collect these invisible calorific rays, and caused them to act independently of the light, by which he concludes, that they are sufficient to account for all the effects produced by the solar rays in exciting heat; that they are capable of passing through glass, and of being refracted and reflected, after they have been finally detached from the solar beam.

If we are to consider these invisible rays as being truly the same with artificial heat, emanated from terrestrial bodies, under the temperature of  $800^{\circ}$  of Fahrenheit, some of the experiments of Dr. Herschel are strongly at variance with some of the experiments of Mr. Lesley, detailed in his work, entitled "An Enquiry into the Nature of Heat," especially so far as relates to the transmission of heat through transparent bodies. It appears from the facts given by Mr. Lesley, that the heat of  $212^{\circ}$  of Fahrenheit is not transmitted by glass in the radiant form, but is first absorbed by the glass, and radiated afresh from its opposite surface. He was led to this conclusion by the fact, that more heat passed through white paper than the glass. And what still more confirms this idea, he found equally as much heat passed through two plates of tin, one side of

each being blacked, and the other polished. When the bright sides were placed together, and the black outwards, it transmitted as much as the glass; but when the black sides were together, and the bright sides outward, there was no perceptible quantity passed through.

That culinary heat does not pass directly through glass, may be tried by holding a pane of glass before a heated body, and alternately holding the hand on each side the glass. After some time, however, the glass gives heat to the hand, proving that the heat has been transmitted; but this will be found to result from a second radiation, and would have been more abundant, if a plate of metal, painted black, had been in the place of the glass.

The heat from the sun's rays is not so affected. It requires no perceptible time to pass through several thick prisms of glass, and when we hold a convex lens in the sun's beams, we have instantaneous heat produced upon any opaque body in its focus.

We have not yet sufficient ground to establish the identity of light and heat; but if Dr. Herschel's experiments be correct, we must either conclude that the solar calorific rays are of a different nature from the invisible rays, or that solar light is converted into caloric from heated bodies. The same philosopher, however, has made the same experiments with invisible culinary heat, and with similar results. How shall we reconcile the seeming contradictions? Dr. Herschel used two thermometers, one of which was his standard. Mr. Lesley used the differential thermometer, an elegant instrument, invented by himself. Dr. Herschel began his experiments with a red-hot cylinder, and continued them till it became invisibly cold. Mr. Lesley used a cannister filled with boiling water. A more particular set of experiments is still wanting to clear up this mysterious subject.

Dr. Herschel has also given us some useful experimental facts on the relative quantities of light and heat transmitted by different substances. The following Table shews the quantity of light and heat, stopped by colourless and transparent solid substances.

TABLE I.

Substances.	Stops of 1000 Paris	
	Heat.	Light.
Blueish white glass - -	250	80
White flint ditto - -	91	34
Green crown ditto - -	259	203
Coach ditto - -	214	168
Iceland crystal - -	244	150
Talc - -	139	90
Calcinable talc - -	184	288

TABLE II.

Shewing the quantity of light and heat stopped by coloured substances.

Substances.	Stops out of 1000.	
	Heat.	Light.
Very dark red glass - -	800	$999\frac{1}{3}$
Dark red - -	666	$999\frac{1}{3}$
Orange - -	614	779
Yellow - -	333	819
Pale green - -	633	535
Dark ditto - -	849	949

Substances.	Steps out of 1000.	
	Heat.	Light.
Blueish ditto	768	769
Pale blue	812	684
Dark ditto	362	801
Indigo	633	999 <sup>1</sup> / <sub>5</sub>
Pale indigo	532	778
Purple	583	993
Violet	489	955

TABLE III.

Shewing the stopping property of what Dr. Herschel calls scattering substances.

Substances.	Steps out of 1000.	
	Heat.	Light.
Rough crown glafs	464	854
Rough coach ditto	571	879
Doubly rough	667	932
Second doubly rough	735	946
The two first together	698	969
The two next together	800	979
The four first together	854	995
Olive colour burnt in	839	984
Calced talc	867	996
White paper	850	994
White linen	910	952
White Persian	700	916
Black mufsin	714	937

TABLE IV.

Shewing the stoppage out of 1000 of the prismatic red rays, and the invifible rays.

Substances.	Rays.	
	Red.	Invifible.
Blueish white glafs	375	000
Flint glafs	143	71
Crown glafs	294	000
Coach glafs	200	182
Iceland cryftal	250	143
Calced talc	433	—
Dark red glafs	602	250
Orange	500	000
Yellow	417	273
Pale green	588	200
Dark green	786	375
Blueish green	462	500
Pale blue	700	800
Dark blue	71	750
Indigo	367	107
Pale indigo	313	222
Purple	444	250
Violet	400	273
Crown glafs, one fide rough	389	250
Coach glafs, ditto	500	600
Crown glafs, both fides rough	471	500
Coach glafs, ditto	833	600
Calced talc	737	714

TABLE V.

Shewing the stoppage of rays of flame, fire, and invifible rays from a flove.

Substances.	Rays.		
	Flame.	Fire.	Invifible.
Blueish white glafs	625	750	700
Flint glafs	595	750	533
Crown glafs	636	722	783

Black mufsin	565	706	—

The experiments in the first, second, and third tables, were made by letting the sun's rays act directly upon one thermometer, while the same light acted upon another after passing the different substances. The numbers in the tables are the ratios of the differences of the degrees of each, after being acted upon for a given time. Table IV. was made in the same way, the red rays and the invifible rays being each separated by the prism, making two sets of experiments. In each of these, the red, or the invifible, acted on one thermometer, and on the other through each of the substances.

Table V. is formed from three sets of experiments, made at different times, by causing, in the first, the rays of the flame of a candle to act upon one thermometer directly, and upon the other through the substances. In the second set the rays of a common fire were used; and in the third, the invifible rays of an iron flove. See Phil. Transf. for 1800.

An abundance of useful knowledge is to be derived from these researches, which may be of the utmost importance to society, as well as in giving aid to different branches of science.

In delicate experiments of this kind, the thermometer seems to be the most important of the apparatus. The smallness of the scale, and the want of sensibility in those used by our ingenious experimenter, were certainly very objectionable, when compared with the differential thermometer of Lesley. A repetition of these experiments, under

such an advantage, is highly to be recommended. We have already pointed out some contradictions between these and Lefley's experiments.

By comparing the effect of the substances upon the solar invisible rays in Table IV, and upon the invisible rays from the iron stove in Table V., we are led to some very singular conclusions. It appears, for instance, that flint-glass stops none of the invisible rays of the spectrum, although the same substance stops 143 out of 1000 of the red rays, 91 of 1000 of direct solar heat, 34 of the direct light. Hence it would seem that calorific rays mixed with the luminous, must constitute the 91 of 1000, since all the invisible rays pass through. We must from these data conclude, that either the light of the solar spectrum produces heat, or that the calorific part in the coloured rays is of a different nature from the invisible calorific rays. If the latter be admitted, we have as much reason to consider the solar beam as consisting of different kinds of heat, as well as of light.

These anomalies are still increased, when we turn to Table V., where we find that the same flint-glass stops out of 1000 rays 730 invisible rays from a stove, which would seem to establish that this calorific matter is still different from both the visible and invisible calorific of the sun; and in the experiments of Mr. Lefley, calorific appears to possess still very different properties.

We here see so much mystery and contradiction, that we must wait for more particular research. It is unlike the simplicity of nature; the fault must, therefore, rest with the philosophers.

Sir Isaac Newton, on finding so many different species of light, was unwilling to make so many fluids, but supposed they differed in the size of their particles; the largest being the least refrangible, and the smallest the most. The same thing would take place from the same particles moving with different velocities; the most refrangible moving with the least, and the least refrangible with the greatest velocity.

We have already stated a fact discovered recently by Malus, that light acquires new properties by a peculiar reflection. Does it then appear impossible that it should not be changed in passing through diaphanous media? May not that which moves with the greatest velocity have a greater portion converted into heat; or, in other words, may not this conversion be as the velocity? This idea is strengthened, from the circumstance of calorific rays being found throughout the spectrum. The greatest objections raised to this idea of light and heat being excited by the same rays moving with different velocities, are founded on the facts of combined light in phosphorescent bodies, and in the chemical effects which were thought to be peculiar to light. In our next subject, however, we shall shew that all the chemical effects producible by light can be produced by heat.

Besides the properties of the solar beams to produce heat and light, we find it to have other properties equally important to the animated world. This is most conspicuous in the economy of vegetables. It has been many times proved, that vegetables, growing without light, would not, in the first place, have more tendency to grow upwards than in any other direction. This arises from an evident attraction existing between light and living vegetables. This fact is familiar to those who have placed trees in windows. It is observable, that they always lean towards the light. The same effect would doubtless take place, if one side of a vegetable were shaded in the open air. The attraction of light is probably not the same for different vegetables; by which we may account for the different forms of trees. This is rendered plausible, when we contrast the spreading

branches of the oak with the towering branches of the poplar.

Experience has long ago established, that vegetables become delitute of smell and colour, and lose much of their combustibility, by growing in the dark. We find in Dr. Black's lectures, an account given by the celebrated Dr. Robinson of Edinburgh. In the drain of a coal-work under ground, he accidentally laid his hand upon a very luxuriant plant, with large indented foliage, and perfectly white. He had not seen any thing like it, nor could any one inform him what it was. He had the plant with a sod brought into the open air in the light. In a little time the leaves withered, and soon after new leaves began to spring up, of a green colour, and of a different shape from that of the old ones. On rubbing one of the leaves between his fingers, he found that it had the smell of common tanfy, and ultimately proved to be that plant, which had been so changed by growing in the dark. Indeed it was recollected that some soil had been taken into the drain from a neighbouring garden, some time before it was found so altered.

This effect of light is not less conspicuous in the growth of celery. By covering it with earth, the light is shut out, which would very soon turn it green, and make its flavour so strong as to render it unfit to be eaten, at the same time that it would render it more fibrous and tenacious.

From the circumstance of light giving odour and inflammability to vegetables, and since these properties are most common to bodies containing hydrogen, it would appear that light was essential to the production of hydrogen, perhaps by expelling oxygen; and hence it would also appear that hydrogen is necessary to the colour of vegetables. It has been asserted by Humboldt, that he found vegetables growing in the dark mine, having their natural colour, but these plants were enveloped by hydrogen.

Light is found to produce various chemical changes upon bodies. When the oxyd of silver is precipitated from nitric acid by muriatic acid, the insoluble muriat is at first white, and if kept in the dark at the common temperature, would doubtless remain so for an indefinite length of time. If, however, it be exposed to the light for a little time, it begins to assume a purple colour, and ultimately becomes black. This effect takes place more rapidly according to the intensity of the light. Hence it has been proposed to measure the intensity of light by the time of its changing. An instrument has been invented for this purpose by Mr. Lefley. See PHOTOMETER.

The general effect of light, as a chemical agent, appears to consist in disengaging the oxygen, or an acid from bodies which it effects, no doubt, by lessening the affinity of the base for oxygen, or the saline base for the acid. Hence, we find light is capable of decomposing those oxyds and salts, in which the oxygen or acid is held by a weak affinity. It therefore detaches oxygen from the oxyds of gold, platinum, silver, and the peroxyd of lead; also from nitric and liquid oxymuriatic acid. Dr. Herschel, in his experiments upon light, finding that the solar spectrum had different illuminating powers in different parts, conjectured that the power of the sun's light to effect chemical changes, might principally belong to some particular part of the spectrum, and it appears that this ingenious has been confirmed by experiments made by Dr. Woollaston, and also by Ritter. It appears that the invisible rays have no action upon the muriat of silver, the red rays a little more, and so on, increasing to the utmost boundary of the violet ray; but the maximum of effect was found at some distance beyond the violet. It appears, therefore, from this curious fact,

fact, that the solar beam consists of rays which have three distinct effects, one producing light, another heat, and a third producing neither, but which effect the greatest chemical changes in the least time.

Some experiments lately made by Guy Lussac and Thénard, and detailed in their work entitled "Recherches Physiques-Chimiques," vol. ii. p. 186, go far to prove that the chemical changes produced by the solar rays are not dependent upon any specific property of light, as they have produced similar effects by heat alone. Dry oxy muriatic acid gas was not decomposed by light nor heat. Liquid oxy muriatic acid was decomposed by a light not strong, and by a heat equal to obscure red. Nitric acid by the same heat. Oxy muriatic acid gas mixed with hydrogen by light, and by heat equal to 125 to 160° centigrade. The fame was decomposed slowly by diffuse light, but scarcely any at less than 120° centigrade. The first oxyd of mercury was converted into the second oxyd, and running mercury by diffuse light; and the same by heat. The peroxyd of lead was changed into the red oxyd, oxygen gas being disengaged by a vivid light; and the same was produced by a gentle heat. The oxyds of silver and platina were decomposed by light and by a gentle heat.

They next exposed vegetable colours to the action of light as well as heat.

A vegetable rose-colour from saffron became white in a short time by light; and the same by exposure for an hour to 160° cent.

Log-wood dye was changed to dark red by light, and by exposure 1½ hour to 180° cent.

Brazil-wood dye became white by light, and by 180° of heat, for two hours.

The orange colour of Indian saffron became a dull red by light. The fame was produced by 200° of heat, for an hour and a half.

Yellow colour, from woad, was changed to ochre colour by light, and by 210° of heat applied for two hours and a half.

In all the effects of light we have hitherto enumerated, although we have shewn that a mutual attraction exists between light and other matter, we have not adverted to its remaining in bodies from which it may be eliminated without change. Several bodies appear, however, to possess the property in a remarkable degree. Indeed, according to experiments of father Becaria, almost any substance exposed to the light of the sun for a certain time, appeared luminous when brought into a dark room. This he found to be the case, when he made his own hand the subject of experiment. This property is soon gone in moist bodies; but is restored by fresh exposure to light. The substance most remarkable for retaining this quality is Canton's phosphorus, which consists of sulphur and lime. It is prepared by stratifying oyster-shells with sulphur in a crucible, and exposing them to the heat of a brisk common fire. The lime of the shells becomes impregnated with the sulphur, and they are then broken to pieces, and kept for use in a stoppered phial. This substance has the property of shining in the dark, after exposure to the sun's light, for a short time. Its brightness is such, as to point out the hour of the night. If it be kept in the dark, however, for a certain length of time, it becomes less bright, and ultimately loses its shining property; which it re-acquires by exposure to the light. This light is not dependent upon any combination, since it possesses this property without oxygen, and is not increased by its presence. Heat causes it to shine brighter; but it gives out its light sooner, which is only restored by new light.

Canton, the ingenious discoverer of this substance, introduced equal quantities of it into two glass globes, and exposed them to the sun equally, to give them their greatest luminous power. They were then taken into a dark room, when they were equally luminous. One of them was now placed in boiling water, by which means it became much brighter, but it ceased to be luminous in ten minutes; while the other continued to shine for two hours after. After the latter, however, had ceased to shine, it became luminous by the application of heat. It appears, by the account of this author, when it had ceased to shine at one temperature, it always gave out light in a greater, even to the point of ignition; but never after at the same, or a lower temperature, till it had been exposed anew to the sun's light.

These curious facts, on a first view, seem to prove that the light of this substance is derived from the sun's rays, which enters into combination with it, and is eliminated in the dark. This supposition, however, is rendered improbable by other facts. When it has ceased to shine, its property is restored by any of the coloured rays of the solar spectrum. It ought, therefore, to emit that particular light only to which it has been exposed, but contrary to this, under all circumstances, it gives out the same coloured light, which is generally white.

It seems more agreeable to the phenomena to suppose, that the influence of the light upon this substance consists in exciting some chemical action in the body, which cannot be produced by heat, or, perhaps, the phenomena may be electrical, since we find that the electric spark, as well as light, is capable of giving it its luminous property.

A great variety of substances have the property of giving out light by different treatment, some by heat, others by rubbing, and by percussion. Most of the earthy salts have the property of shining in the dark, by being laid upon an iron plate, heated a little short of ignition. Fluat of lime is by far the most brilliant by this treatment. The fame is visible, though in a less degree, in all the carbonats of lime, and in carbonats and sulphat of barytes, and also carbonat of strontian.

Several of the gems have the property of shining by rubbing. Quartz pebbles, rubbed briskly together, in the dark, give brilliant flashes, accompanied by a peculiar odour not unlike that produced by the wheels of a carriage grinding upon stones. The tourmalin also gives out light by rubbing. The shining property of this class of bodies is the same in vacuo, and any of the gases. The cause of these appearances is not even guessed at; they do not acquire these properties from the sun's light, like the phosphorus of Canton.

We are in possession of a number of curious facts relative to phosphorence of animal and vegetable substances. Canton has furnished a number of interesting experiments upon fish and the flesh of animals: and the subject has since been investigated and extended by Dr. Hulme. The flesh of animals, particularly veal, at a certain period after death, begins to be luminous, and continues so for some time. The light is extinguished when the meat has arrived at a certain state of putrefaction. This property, however, is more conspicuous in fish, and sea-fish more than that of fresh-water. A series of experiments is given by Dr. Hulme in the Philosophical Transactions for 1800, page 161.

He generally took about four drachms of the substance of different kinds of fish. This he put into a three-ounce phial, to which he introduced two drachms of sulphat of magnesia, dissolved in two ounces of cold spring-water, but occasionally he used other salts.

Two drachms of the flesh of the herring were put into the solution of sulphat of magnesia. On the second evening he perceived a ring of light round the top of the liquid, but it was dark below. On shaking the phial, the whole became beautifully luminous, and remained in that state. On the third night the light had again risen to the top; but the ring was not so bright as on the preceding night, nor was it so bright after shaking as on the first occasion. In another experiment, the light disappeared entirely on the third night. The same experiment was made with sea-water. On the second night the liquid was dark; on the third lucid; on the fourth very luminous; on the fifth it began to decline; on the sixth it became less; and on the seventh quite gone. At this period, neither the fish nor the liquid had any smell of putrefescence. The same took place in a second experiment. In another experiment, he used four drachms of the roe of the herring, two drachms of sulphat of magnesia, and two ounces of water, as before. On the second night, on shaking the phial, the liquid was luminous; it remained so on the third and fourth; and on the fifth was extinct. In the same experiment, with sulphat of soda, the effect was less, but it was greater with sea-water. Similar appearances took place by a similar treatment of the mackarel.

He next suspended in a room the herring and the mackarel. On the second night the skinny side became luminous; on the third night both fish of the whole were exceedingly luminous. Dr. Hulme observes, that he lost roe of both these fish afforded the most light. At the time these fish became very luminous, Dr. Hulme scraped off some of the luminous matter, which he named herring's light, or mackarel light. This substance he introduced to different solutions of salts.

The solutions used were sulphats of magnesia and soda; muriat and phosphat of soda; nitrat of potash; Rochelle salt; tartar of soda; and sea-water. He also used solutions of honey and sugar: the quantity of water in each was two ounces; the quantity of each substance dissolved in the same was two drachms, with the exception of the nitre, and muriat of soda, the former being half a drachm, and the latter a drachm.

The herring or mackarel light being introduced to the solution of sulphat of magnesia, rendered the whole mass of liquid very luminous, and continued for 24 hours. All the above solutions became luminous by adding the same lucid matter. The phosphat and muriat of soda appear to have been better than the rest. The light with sea-water was more permanent, being luminous for several days. After the above luminous matter had ceased to shine, the light was in some degree revived by motion. What is very remarkable in these experiments, is the circumstance, that when the solutions were made stronger to a certain extent, the light became suddenly extinguished, but was always restored by dilution with water.

The light is also extinguished by water, lime-water, water impregnated with carbonic acid, or with sulphuretted hydrogen, alcohol, alkalies, and acids.

In all the above experiments the light is not attended with the least elevation of temperature.

By exposing this luminous matter to a certain degree of cold the light is extinguished; but is restored with the return of temperature. A moderate heat causes it to be more bright; but the heat of boiling water entirely extinguishes it, and destroys the property. According to another set of experiments by Dr. Hulme, in the Phil. Trans. for 1801, page 483, it appears, that these substances do not shine brighter in oxygen than atmospheric air. In nitrogen gas

they do not begin to shine; although, after the shining has commenced, they continue to shine in this gas for a limited time: the presence of oxygen appears to be essential in first producing this property. Dr. Hulme found, that when two herrings were exposed, with their sides touching, the unexposed parts remained dark: he found the effect produced by covering any part with strong brown paper.

In hydrogen gas the fresh fish begins to shine; and, if begun, it is very soon extinguished: it recovers its property, however, by re-exposure to the air of the atmosphere. By repeated and alternate exposure to these gases, the light is lost and regained a number of times. This light is also extinguished by nitrous, carbonic acid, and sulphuretted hydrogen gases. This phosphorescence is extinguished in vacuo; but is restored by letting in the air. The glow-worm and rotten wood were found to possess similar properties: they were similarly acted upon by the different gases, by cold, and by moderate heat. The light of the shining matter from the fish was extinguished by a heat from 96 to 100 of Fahrenheit: the temperature of 110° impaired, but did not extinguish the rotten wood: the temperature of 114° increased the brilliancy of the glow-worm; but the temperature of 212° extinguished both.

It appears that rotten wood, like the fish, does not give out light till it has been exposed for some time to the air: it retains its luminous property immersed in spring-water, or distilled-water, and also in linseed oil; it is, however, extinguished by acids, by alcohol, and, perhaps, by alkalies. The luminous matter of the glow-worm is a liquid secreted and retained in the lower part of the abdomen. If the fluid be squeezed out, it still retains its shining property, and may be spread upon the palm of the hand; but it soon in this state disappears.

This property is observed in some other insects, particularly the lantern-fly of the West Indies.

The light of a great number of these artificial and natural pyrophori does not appear to depend in the least upon the presence of oxygen. Of this kind are phosphorus of Canton, the different earthy salts which shine by the application of heat, and some other minerals which shine by friction and attrition. Those of which we have last treated require the presence of oxygen, at least to acquire the property of shining. This circumstance renders the supposition of Dr. Hulme rather improbable, namely, that the light is a component part of the body from which it is illuminated. The only thing which the facts above given can be allowed to have established, is that, during a certain state of the animal substance, between death and actual putrefaction, some process is carried on in the presence of oxygen, by which light is evolved; and that during the time the substance is in vacuo, or in some gas which is destitute of oxygen, this process is suspended, and by the presence of other substances totally stopped. The fact of its continuing to shine in nitrogen, might arise from the presence of a small portion of oxygen. It appears, from the circumstance of its shining in atmospheric air, as much as in oxygen, that very little oxygen is necessary. Forster asserts that the glow-worm shines brighter in oxygen, but the oxygen does not appear perceptibly impaired. This shews, that although oxygen is necessary, the quantity required is very small.

It has been too common for chemists to draw the following conclusion, that when light, or light and heat together, are evolved, that it must either have arisen from combustion, or that the light is a component part of the body from which it is disengaged. As, for instance, because Canton's phosphorus shines without the presence of oxygen, the

the light is called light of combination; and Dr. Hulme has, with less foundation, drawn the same conclusion. Instead of saying that light and heat are products of combination, from the union of oxygen with inflammable matter, we should say that it is the result of rapid chemical combination, when the bodies have great affinity for each other.

We have several facts which confirm this idea. When strong mineral acids combine with pure potash, lime, or magnesia, much heat and some light are emitted. The same thing is also observed in slacking of lime. In an experiment, made by a society of chemists, it appears, that when a mixture of sulphur and copper filings is exposed to a red heat, in a glass tube, the oxygen being excluded, the two substances suddenly combine, attended with the disengagement of light. In those chemical changes where heat and light are disengaged, the following law will obtain. The change of temperature will be as the difference between the specific heat of the compound body, and half the sum of the specific heat of the bodies before combination; while the intensity of the light and heat will be inversely as the time in which this change has been taking place.

We shall here leave the subject of phosphorescent light, to give some account of that produced by combustion; in treating which, we shall find our progress much facilitated, by considering combustion as dependent on the above law, rather than upon the laws of combustion, as laid down by Lavoisier, who was of opinion, that the light and heat furnished by combustion were entirely derived from the oxygen. If, as we have supposed, the quantity of heat be greater, as the specific heat of the resulting compound is less than the mean of the bodies before combination, we ought to have heat evolved whenever such change can be proved; and by ascertaining, before hand, the specific heat of the compound, and of the elements, the quantity of heat may be known. Experience has already given great strength to this notion. The intensity of the light and heat, however, during these changes, will not depend upon the absolute quantity evolved, but upon the rapidity of the evolution; and, if we are not greatly deceived, the quantity of light will always be as the rapidity of combustion. In the slow combustion of hydrogen gas, the light is not great, but the whole heat is greater than that afforded by any other combustible body. On the other hand, the absolute quantity of heat afforded by the combustion of phosphorus, is much less than that evolved by burning an equal weight of hydrogen; but the quantity of light given by the former, much exceeds that of the latter. The intensity of light, however, will also be inversely as the space which it occupies, and hence it will be as the specific gravity of the combustible body. We may therefore conclude, that the quantity of light afforded by combustion will be as the rapidity of combustion, which will be as the affinity of the body for oxygen, as the density of the burning body, and inversely as the cohesion of the body. The difference of cohesion between charcoal and the diamond accounts for the relative combustibility of these two bodies. For this reason, soft iron wire ought to afford more vivid combustion in oxygen than steel wire.

In order to obtain a relative idea of the value of different combustible bodies, used for procuring artificial light, we shall detail some ingenious experiments made by Dr. Henry, and published in Nicholson's Journal, vol. xi. p. 65.

Dr. Henry, with a view to ascertain the relative value of the combustible gases, made some trials with hydrogen, carburetted hydrogen, and carbonic oxyd. These he found

did not afford a very inferior light, compared with the splendid light given by the gas afforded by the destructive distillation of pit-coal, which is equal to the light given by the finest spermaceti oil. The following table points out the result of his experiments, and clearly shews the cause of the superior property of coal gas to produce light.

Kind of Gas.	Measures of oxygen gas required to saturate one hundred measures of each.	Measures of carbonic acid produced.
Pure hydrogen	50 to 54	None
Gas from moist coal	60	35
Do. Wood (oak)	54	33
Do. dried peat	68	43
Do. from cannel coal	170	100
Do. Lamp oil	190	124
Do. Wax	220	137
Pure olefant gas	284	179

The first column contains the different gases, 100 measures of each being used in each experiment. The second, the measures of oxygen which were consumed, while each of the 100 measures were burning. The third, the quantity in measures of carbonic acid, which resulted from the combustion. It is a fact, already ascertained, that every measure of carbonic acid gas has resulted from a measure of oxygen; consequently, the quantity of oxygen consumed in its formation is equal in measure to the numbers in the third column; the excess of oxygen, therefore, appearing in the second. By subtracting the number in the third from that in the second, it will give the quantity of oxygen which has combined with the hydrogen in each of the gases. This excess of oxygen, in the second column, will combine with two measures of hydrogen, to form water. In order to form some idea of the relative value of these combustible gases, we will compare the first, which is pure hydrogen, and the last, or the pure olefant gas, which has the greatest efficacy in producing light. The 50 measures of oxygen in the first combine with 100 of hydrogen, and since no carbonic acid is produced, this is the whole effect. In the last experiment, 179 of carbonic acid is formed at the expence of 179 measures of oxygen, and about 3ths its weight of carbon, which would alone have furnished considerable light. Since, however, 284 measures of oxygen are expended, we have  $284 - 179 = 105$  measures of oxygen, which would require 200 measures of hydrogen. If, therefore, hydrogen and carbon were equally efficacious as combustible bodies in producing light, the quantity of light in one, to that in the other, would be as  $210 + \frac{1}{3} \times 179 : 100$ , or as 25 to 1 nearly. The ratio of the specific gravities of these gases is as 90 to 8 nearly; therefore, multiplying these ratios, we get 270 to 8, or 34 to 1 nearly, for the relative intensity of the light of each.

These different gases are here supposed by Dr. Henry to be mixtures of several gases, the composition of which is known, and all consisting of different proportions of hydrogen and carbon, with the exception of the carbonic oxyd,

which

which contains oxygen. Now, setting aside the latter gas, which being partly saturated, the rest will be in their effect to produce light, as the quantity of carbon they contain; not that carbon is more effective than hydrogen, but because the specific gravity of the gas is increased by the carbon. Since, therefore, the olefant gas contains the most, and is of the greatest specific gravity in consequence, those gases which contain the greatest quantity of olefant gas, must be the best for producing light by combustion. Now, it may be seen in the table, that the gases obtained from lamp oil and wax are the next to the olefant gas in their effect of giving light; and hence we may conclude that those gases contain a large proportion of olefant gas, and of course seem well fitted for producing artificial light. If we may judge by analogy, we may expect that the spermaceti fat will stand as high as the oil, and the best tallow may, perhaps, be the next in order. During the burning of these substances, the vapour which, when kindled, constitutes the flame, may consist of a great proportion of the olefant gas. In the burning of all fatty substances, however, there is a great redundancy of carbon, which flies off with the gaseous products in the form of smoke, and which is burnt in the Argand lamp. The above facts will furnish an elegant and simple method of appreciating the relative value of the different combustible bodies to produce light. See GAS-LIGHTS, LAMP, and COMBUSTION.

The light which is furnished by combustion, and commonly called artificial light, is considered by most philosophers as being a component part of the bodies employed in the combustion. Even in the simple process of heating a body red-hot, it is said that the body at that temperature begins to give out light. It is rather curious, that all bodies should give out light at the same temperature, which is said to be about 800° Fah. It would appear, from a fact given by the late Mr. Wedgwood, that the emanating medium is heat or light, according to the density of the body from which it is emanated. The heated air is so hot, as to make a thin slip of gold appear red-hot, although the aerial medium did not become luminous. Terrestrial light, as it appears to possess most of the properties of solar light, like it, can be transmitted and refracted by transparent bodies, and it strictly resembles it in being reflected by the same bodies. It is said, however, to contain a different proportion of the coloured rays from that of solar light, being defective in the blue, and redundant in the red rays.

Doct<sup>r</sup> Herschel has made a number of experiments upon terrestrial light, in order to compare it with the heat furnished by the sun; but he seems to have taken it for granted, that the solar light and the artificial do not differ, although his experiments prove, that terrestrial heat and solar heat differ essentially. Artificial heat does not pass through glass, while the solar calorific rays pass easily through the substance of a prism, and afterwards through a convex lens.

It has been found that artificial light has some chemical properties. The Abbé Tessier found that the green colour of vegetables is produced by the light of a lamp. This fact has been confirmed by Decaudolle.

LIGHT *from Diamonds and other Bodies*. See LIGHT, *supra*, DIAMOND, ELECTRICITY, and PHOSPHORUS.

LIGHT, *Exhibition of, by living Animals*. This singular property belongs only to creatures of a simple structure. It appears to reside only in certain species of the four last classes as established by modern naturalists, *viz.* mollusca, insects, worms, and zoophytes.

The mollusca and worms contain each but a single species, which has been ascertained to shew light; for the account of certain species of *lepas*, *murex*, and *chama* yielding light, does not seem to rest upon any good authority, and the stories told by Bruguiere and by Plaugergues of earth-worms being luminous, are improbable in themselves, even if they were not contrary to common observation. See Journal d'Histoire Naturelle, tom. ii., and Journal de Physique, tom. xvi.

The examples of luminous species are more numerous amongst insects than in any other class. They are to be found in the following genera; *elater*, *lampyrus*, *fulgora*, *pausanus*, *scelopendra*, *cancer*, *lyncus*, and *limulus*.

There are also many luminous zoophytes, particularly in the genus *Medusa*, and in the new genus *Beroe*.

Some writers have attributed the property of shining while alive to certain fishes; but, as it would appear, upon very questionable grounds. In a voyage from France to Cayenne, Mr. Bajon saw in the sea a number of luminous points which shone when struck, and another appearance of pale flames, about three feet below the surface of the water. He likewise observed in the migration of the *dorado* and other fishes, that their bodies were studded with similar luminous points. Upon examination he discovered those to be minute spheres which adhered to the surface of the fish. These were most probably the small species of luminous *medusa*. We shall hereafter notice that Bajon's observations therefore shewed no property of shining in the fish themselves.

Godehen de Riville states in a paper he sent to the Academy of Sciences, that he found in the *Scomber pelamis*, on opening it alive, an oil which was extremely luminous. It should be observed, that Riville was prepossessed with the opinion of all the luminous appearances of the sea being occasioned by a peculiar oily fluid; other parts of his Memoir shew inaccuracy of information; and it may be added, that if the oil of fishes were usually luminous, as supposed by Riville, it would be a fact very generally known.

We shall now proceed to consider the luminous property in those animals which have been ascertained to possess it. Afterwards we shall describe the peculiar organs from which the light is known in certain species to emanate; and lastly, we shall examine the opinions that have been entertained respecting the nature and origin of animal light.

The species of *Pholas*, described by Pliny under the name of *Dactylus*, has long been known to possess remarkable powers of evolving light. It is recorded by Pliny, that every part of this animal's substance is charged with a fluid, which, like liquid phosphorus, renders any object luminous with which it comes into contact.

Reaumur has confirmed the observations of Pliny; he found also that the water contained in the shell of the *dactylus*, and other fluids in which the animal might be immersed, acquired the property of shining, and after touching the creature, the hands communicated to common water a milky or pale phosphoric appearance. Reaumur observed that the light was most vivid when the *dactylus* was fresh; it afterwards gradually declined until it became extinct. He dried the entire animal, which deprived it of all power of shining, but this was restored in a weaker degree even after four or five days, by moistening it either with fresh or salt water. So far from the process of dissolution being at

all necessary to the luminous appearance of the *daæylus*, Reaumur found that it was destroyed by putting putrid individuals amongst those which had been recently taken. Mem. de l'Acad. des Sc. de Paris, 1712.

There are three luminous species of *elater*; the *noctilucus*, *phosphoreus*, and *ignitus*. The first of these shines so brilliantly, that before the arrival of the Spaniards in South America, it is said many tribes of Indians used no other light for transacting their ordinary business; and at present the women wear the insect at night as an ornament in their head-dresses. Dr. Patrick Brown, in his History of Jamaica, says, the *elater noctilucus* is seldom met with during the day, it being then torpid; it flies by night, at which time it emits an unsteady light, having alternate moments of darkness. He observed, also, that the extinction of the light depended upon the will of the animal.

It is well known, that in the *elaters* the light proceeds from the smooth yellow spots situated upon the corcelet; but Dr. Brown seems to think that all the internal substance is equally luminous, and that the yellow spots appear so in a greater degree than the other parts, in consequence of the transparency of the shell at these places favouring the transmission of the light. He says, in forcing the rings that cover the different parts of the body a little asunder, you may observe the same light to issue from all the entrails indiscriminately. The internal parts of insects are so transparent, and would permit so much light to pass through them from the proper organs, that Brown might readily have taken up the above opinion without its being well founded. Thus we have observed, on opening the *glow-worm* at the back in the dark, that the light shone through all the intestinal parts.

There is some obscurity in the accounts of naturalists with respect to the *elater phosphoreus*. Deeger distinguishes it from the *noctilucus*, on account of the yellow spots being visible on both the upper and lower sides of the corcelet; but we have found that this is to be observed in the latter species also. The principal, and perhaps the only real distinction of the *phosphoreus*, is its smaller size than the *noctilucus*.

The *elater ignitus* of Fabricius is considerably smaller than the preceding species, and is sufficiently characterised by having the margins of the corcelet yellow, in place of the two yellow spots.

The genus *Lampyris* contains many species which emit light; of these we may mention the *L. noctiluca*, or common *glow-worm*; *L. splendulida*, which Deeger considers the *noctiluca* as a variety; the *L. ignita*, *L. phosphorea*, *L. nitidula*, *L. lucida*, *L. italica*, *L. japonica*, and *L. pennsylvanica*, which last appears to be the *Pyralis minor* of Brown. Probably other species of *lampyris* might be enumerated amongst those that have the property of shining; but as the light of all the *lampyrides* appears to be produced nearly in the same manner, it is not so necessary to our purpose, to fix with precision the number of the luminous species.

The *lampyrides*, like the *elaters*, have the power of regulating at pleasure the degree of their light, or of suspending it altogether. The colour of the light depends upon its strength; when very weak it is of a faint emerald colour, and in its most vivid state it is a bright yellow or orange colour.

The *glow-worms* of this country are only luminous in the season for procreation, which lasts during the summer months; when the females are impregnated, and have deposited their eggs, they shine no longer. This circumstance has authorised the common opinion, that the exhibition of light is made for the purpose of guiding or inviting the male insect.

The *glow-worms* most frequently assemble in numbers upon dry banks, or under hedges on the sides of unfrequented roads; they are rarely seen on public roads or in fields. They do not display their light upon all nights alike; scarcely one of them will be seen for several nights together, and then, as it were by common consent, they appear with great splendour for a few nights, after which they again retire. Their disappearance probably depends upon their meeting with the male insect, for we have not observed that the state of the weather has any influence upon them. They commonly begin to shine before it is quite dark, and extinguish their light some time before the approach of day. It is remarkable with what regularity their instinct guides them in this particular; we have kept them the whole day in darkness, without their shewing any desire to move or expose their light, yet in the evening, although purposely placed near burning candles, they crawled about and shone with brilliancy.

The light of the glow-worm is always most vivid when the creature is in motion; it may also be excited or increased by turning the insect on its back, or otherwise teasing it. But the luminous appearance is interrupted at all times by short and irregular periods of either diminished light or total darkness; usually, however, there are two small spots on the last ring of the abdomen, which retain their light whilst the other luminous rings cease to shine.

The *lampyris italica* has been observed, like the *noctiluca*, to have the power of modifying its light; it is, however, rendered more brilliant at each motion of its wings. Mem. de l'Acad. des Sc. 1766.

The *pyralis minor* of Brown exhibits a vacillating light; sometimes stronger, sometimes weaker, and at times dying wholly away. The light is always renewed in a few seconds, the obscure intervals being of shorter continuance than the moments of illumination, which the creature seems able to command at pleasure. Every part of the abdomen appears to yield light in this insect, which is stronger and more constant than what is emitted by the *elater noctilucus*. Brown's History of Jamaica.

It has been asserted, that the larva and chrysalis of the *lampyrides* are luminous. Deeger mentions, that the larva of the *lampyris italica* has been mistaken by Linnæus for the perfect female insect.

M. Gueneau de Montbiellard not only states the larva and chrysalis of the glow-worm to be phosphorescent, but that the eggs also for two, three, five, or more days after they are expelled from the female, emit light without intermission or decrease, and that for an equal time their light declines until it becomes extinct. He observes, that it is not necessary for the eggs to be fecundated, but that those which shone longest produced the larvæ. In one instance he did not find the eggs to be luminous; on another occasion, some eggs, which were laid on the 12th of June, showed a degree of light, even on the 28th of July. Memoire sur la Lampyre. Acad. de Dijon.

We have very frequently had great numbers of the eggs of the glow-worm in our possession, but we never saw them in a luminous state, except upon one occasion, when they shone unremittingly for several days together, as described by Montbiellard; the fact is, therefore, the more remarkable, on account of the rarity of its occurrence.

Besides the species of *fulgora*, in which the luminous faculty has been noticed, there are probably several others, if we may judge by analogy of structure, that also possess it. The individuals most distinguished for this property, are the *lanternaria*, *candelaria*, and *pyrorhynchus*.

The *fulgora lanternaria* displays a very brilliant sparkling light,

light, which is only seen during the night when the insect is in motion. Madam Merian having once collected a number of this species, she enclosed them in a box, without being aware of their luminous property. Being one night attracted by the noise that proceeded from the box, she opened it, and to her great surprize, found every insect in motion, and yielding a strong light. Merian Surin.

Cuvier seems to entertain some doubts of the luminous property of the *lanternaria*. He says, in his Tableau Elémentaire de l'Histoire Naturelle, some voyageurs have asserted, that the projection from the head of the insect emits a vivid light, but it appears, at least, that this does not exist at all times.

The *fulgora candelaria* has been observed to throw out flashes of light, which are succeeded by moments of obscurity.

The *fulgora pyrrhynchus* has been reported to shed a radiant light.

With respect to the luminous property of the other *fulgora*, we are not in possession of any particulars.

The *pausis spherocerus* has been discovered to yield light by Dr. Atzelius. On going to look at his specimen one evening, he says, he happened to stand between the light and the box in which it was contained, so that his shadow fell upon the insect; he observed, to his great astonishment, the globes of the antennæ, like two lanterns, spreading a dim phosphoric light. He examined the insect several times during that night, when the same appearance still presented itself; he was, however, disappointed in not having the opportunity of making further observations upon the animal, as it was so much exhausted it died before morning, and he was not able to procure another specimen. Linnæan Transactions, vol. iv.

The *scelopendra electrica* is an insect frequently found in this country, but is not observed to be luminous at all times. Degeer said he never saw it emit light, which was probably owing to the animal being only luminous under particular circumstances. It would appear that this species is incapable of shining unless after exposure to solar light. In several experiments that were made upon the *scelopendra electrica*, it was found, that the creature could not be excited to shine after it had remained all day in a dark situation, but a short exposure to the light appeared to be sufficient to restore the luminous property.

The light produced by the *scelopendra electrica* has a dull phosphoric appearance; it is a momentary emanation, which only takes place when the creature is disturbed or pressed.

The *scelopendra phosphorea* is but imperfectly known; in the edition of the *Sytlema Naturæ*, published in 1767, Linnæus states, that this insect is an inhabitant of Asia; that it yields, during the night, a light resembling that of the *glow-worm*, and that it is caught by falling from the sky on ships in the Indian and Æthiopian seas, 100 miles from the continent. Linnæus quotes as his authority, Car. Guell. Ekeberg, who, he says, saw, described, and delineated the animal.

Ekeberg was a Swede, and the captain of an East India-man. He made fourteen voyages, but, as far as we can learn, never published his discovery of the *scelopendra phosphorea*, and as we have no subsequent accounts of this insect by other voyagers, its real characters, and perhaps existence, must remain doubtful.

The *cancer sulgens* was discovered by sir Joseph Banks, during his first voyage with captain Cook, in the passage from Madeira to Rio de Janeiro. He observed, that its whole body was illuminated, and produced very vivid flashes of light. Phil. Trans. 1810, part ii.

Hablitzl relates, that a cable being on one occasion drawn up from the sea, it was found to exhibit light, and, upon closer inspection, it was perceived to be covered with the *cancer pulex*. Hablitzl ap. Pall. n. nord. Beytr. 4. p. 396.

Thules and Bernard, of the academy of Versailles, also reported, that they met with the *cancer pulex* entirely luminous.

In different systems of natural history, the property of shining is attributed to this species of cancer, probably only on the above authorities. The accuracy of the assertion might perhaps be still called in question, as the *cancer pulex* being frequently under our eyes, its luminous property, if it existed, could hardly escape more general observation.

In 1754, Godeheu de Riville discovered a luminous testaceous insect on the coast of Malabar, which appears to belong to that division of the Linnæan genus, *monoculus*, called by Muller *lyncus*.

Riville, perceiving the sea around his ship to emit a very brilliant light, procured some of the water and strained it; after which it ceased to shine, but the cloth was covered with luminous specks, that resembled in form and magnitude the ova of fish; on being examined in the light, with a magnifying glass, they were discovered to have an internal motion; some that were set at liberty in the water were seen to swim with great rapidity like water fleas. Riville seized one of these with a pair of forceps, which caused it to shed a luminous liquor of a blue colour, that illuminated the water to the distance of two or three lines.

Some of these animals were put into fresh water, which they survived only a few seconds, and descended, struggling, to the bottom of the vessel; many of them rendered much luminous fluid while dying.

Riville describes this creature as being enclosed in a shell resembling an almond, split along the side, and notched at the upper end, which is so transparent that all the internal parts are seen through it. The insect has four jointed antennæ, furnished at their extremities with long setæ. There are two feet armed with hooks; and below these, a thick foot terminating in several claws. The viscera are contained in a round sac; and at the lower part of the shell there is found a number of azure-coloured globules, which Riville considered as reservoirs of the luminous fluid, because they became of a dull yellow colour when the animal was about to die; but they are more probably the ova, which are also visible in this situation in other testaceous insects.

The luminous liquor shed by the animal does not, Riville says, mix with water, but floats on the surface like globules of oil. By straining some water from which the animals had been removed, similar globules were left in a distinct form upon the cloth. From these circumstances, he was disposed to believe that the globules he saw were really of an oily nature: which opinion he was in a great measure induced to adopt, from a preconceived theory, that all the luminous appearances of animals depend upon the occasional presence of an oily fluid. *Memoire sur la Mer lumineuse*. Mem. Etrang. de l'Acad. des Sciences, tom. iii.

A few years ago, captain Horsburg presented sir Joseph Banks with some notes on the luminous appearance of the sea, and a drawing of a phosphorescent marine insect, which have been published in a paper of Mr. Macarty's communicated to the Royal Society in 1810.

Captain Horsburg remarks, that the luminous state of the sea between the tropics is generally accompanied with the appearance of a great number of marine animals, of various kinds, upon the surface of the water; to many of which he does not, however, attribute the property of shining.

shining. At other times, when the water which gave out light was examined, it appeared only to contain small particles of a dusky straw colour, which dissolved under the slightest touch of the finger.

Captain Horsburg likewise observes, that in Bombay, during the hot weather in the months of May and June, he has frequently seen the edges of the sea much illuminated by minute sparkling points. These, whilst in the water, always avoided seizure, by moving away from the hand, so that it was with difficulty he procured any of them. Upon two occasions, he succeeded in detecting the animals that caused the light of the sea. At sun-rise, on April 12th, 1798, in the Arabian sea, he perceived several luminous spots in the water, which conceiving to be animals, he went in the boat, and with some difficulty caught one. This insect, he says, resembled the wood-loose in appearance, and was about one-third of an inch in length. When viewed with the microscope, it seemed to be formed by sections of a thin crustaceous nature. During the time any fluid remained in the animal, it shone brilliantly like the fire-fly.

In the month of June of the same year, he picked up an insect on a sandy beach, which gave light. This was also covered with a thin shell, but was of a different shape and a larger size than the animal taken in the Arabian sea.

Mr. Macartney entertains no doubt that both these insects were monoculi. The first he refers to the genus *Limulus* of Müller, and gives it the specific name of *Nœtilucus*. See Phil. Transact. 1810, part ii.

The light of the sea has been most frequently ascribed to the presence of a minute species of worm, the *nercis noëtiluca* of Linnæus, even by those who did not pretend to have seen the animal.

This creature was first described under the name of *Luciola marina*, in a small pamphlet published by Dr. Vianelli at Venice, in 1749. He found about thirty of them on the leaf of an alga, taken up from the lake of Chioggia. By shaking the leaf, he succeeded in procuring one of these on a piece of white paper. To the naked eye it appeared, in form and magnitude, like the half of the hair of the eye-lid. It had a yellow colour, and was formed of very tender substance. When it was examined under the microscope, he discovered that it had the figure of a worm, and consisted of joints or segments. It had two antennæ; a number of setaceous processes along each side of the body, which he considered as fins; and under these, other twisted processes analogous to feet. *Nuove Scoperte Intorno le Luci notturne dell' Acqua marina fatte da Guseppee Vianelli.*

Vianelli's observations were repeated soon after by Griseolini. He procured some of these animals upon the seaweed, on which they are usually found; and having placed one of them in some water, between two concave glasses, he subjected it to microscopic examination with the highest magnifying powers: by which means, all the parts of the worm were very evident. He describes the head as having two short antennæ, and a horn-shaped process between these, and two dark coloured eyes. The lateral processes, he says, form transparent cases, which terminate in a denticulated manner, and contain each a tuft of hair. The other processes are also transparent, extensile, and sometimes entwined together.

He observed that the light is shed at all seasons, but is most striking and most frequently seen in summer. When the wind is about to change from the S. E. into the E., the light is increased; and in the dark winter nights which succeed a warm sun, the luminous appearance is produced as in summer.

Griseolini further mentions the shining of another marine insect, which appears to be the *monoculus* discovered by Riville. Observations de François Griseolini sur la Scolopendre marine luisante, Venise 1750.

The same animal has likewise been described and figured by Adier, under the name of the *nercis phosphorans*. His description coincides with that of Griseolini. He states that this species is found in the African and Indian oceans, but that it is rarely met with in the Northern seas. *Annotates Academicæ Carol. Linne.*

The *nercis noëtiluca* was seen by the abbé Nolle, M. Rigaud, and Fougereux de Bondaroy. The latter, however, describes it to be the size of the head of a small pin. He says it increases, diminishes, or extinguishes its light at pleasure, which commonly issues from the posterior part of the body; but when fully illuminated, the head only is opaque. The colour of the light is blueish. When squeezed, it sheds a train of luminous fluid; which appearance is also seen, in a degree, when it is agitated in the water. He mentions having observed two sizes of the animal, but cannot determine whether these are different ages, sexes, or species. *Mem. de l'Acad. des Scien. 1767.*

The abbé Diquequere states, that he saw the luminous animals discovered by Vianelli; that he exhibited them to his pupils during his lectures, and delineated them at the same time. These drawings he sent to Rigaud, who returned for answer, that the designs were precisely the same of those which he had himself executed. *Journal de Physique, tom. vi.*

Spallanzani also asserted that he had seen the *nercis noëtiluca*.

After such a striking concurrence of testimony, we cannot presume to doubt the existence of this species of luminous animal: but we are led to think that it never visits the coasts of this country; as in numerous examinations we have made of sea-water in a luminous state, we have not met with it. Judging from our own experience, and comparing it with the observations of others, we are led to conclude that the *nercis noëtiluca* is, generally speaking, a rare species, and that the light of the sea is most frequently occasioned by *medusa*.

The largest and most splendid of the luminous *medusa* is the *pellucens*, which was discovered by Sir Joseph Banks, in the first voyage of captain Cook. It was taken up from the sea, at the same time with the *cancer fulgens* already mentioned, in the passage from Madeira to Rio de Janeiro. This species measures six inches across the crown or umbella, which is marked by a number of opaque lines that pass off from the centre to the circumference. The edge of the umbella is divided into a number of lobules, which succeed each other, one large and two small ones alternately. From within the margin of the umbella there is suspended a number of long cord-shaped tentacula. The central part of the animal is opaque, and furnishes four thick irregularly shaped processes, which hang down in the midst of the tentacula.

The *medusa pellucens* throws out flashes of light during its contractions, which are so vivid as to affect the sight of the beholders. When the water in which these animals, and some of the *cancer fulgens*, were contained, was emptied out of a bucket, it appeared like a stream of fire, or fused gold. *Phil. Trans. 1810, part ii.*

The *medusa noëtiluca* is described by Forstæl, as measuring about three inches in diameter, and about one and a half inch in depth. Its surface is convex, of a reddish glab colour, with brown spots. The margin is notched into 16 lobules.

The

The central part, containing the vilcra, hangs down for some way, and is surrounded by eight somewhat broad tentacula. Forskal, *Descriptiones Animalium*.

This species is reported to be extremely luminous, particularly round the margin.

Forskal has described also a species of luminous animal under the name of *medusa densa*. It appears to be a beroc, and corresponds most nearly with the *medusa pileus* of Gmelin.

A luminous species of *medusa* was discovered by Spallanzani in the strait of Messina. Its form is convex, with a fibrated margin. There are four thick tentacula, and eight which are long and slender. These are each hollow. In the concavity of the umbella there are four small groups of long thin bodies, entwined together like intestines, and adhering to an entangled mass of small tubes of a silver colour, that are extremely transparent and elastic. At the internal edge of the cavity of the umbella there is a thin muscular lamina. The pulse communicates with four lateral orifices, and has an aperture besides. Spallanzani represents this species as being exceedingly luminous. He says it shines like a torch, and is visible 35 feet below the surface of the water. The light is variable; sometimes it continues for a quarter or half an hour, or longer; at others it becomes suddenly extinct, and re-appears after a considerable interval. He supposes that the cessation of the light depends upon the animal being at perfect rest. *Memoria sopra le meduse fosforiche*. Mem. della Soc. Ital. tomo vii. and Spallanzani's Travels in the Two Sicilies.

Spallanzani further states, that he discovered in that part of the sea next the eastern coast of Genoa, in addition to the nereis nothilica, five other species of *sea glow-worms*, as he calls them, two of which he met with again in returning from Messina to Lipari. He proposed to give a description of these animals in his Voyage to Constantinople, which book, as far as we can learn, was never published. We must, however, confess, that Spallanzani's known fondness for the wonderful, would lead us to receive these discoveries with some degree of distrust, particularly as they have not been confirmed by the observations of others.

One of the most brilliant of the whole tribe of luminous creatures has been lately discovered by Mr. Peron in the Atlantic ocean. Most naturalists would, from the general appearance and structure of the animal, consider it as a species of *beroc*, but Peron has created a new genus, of which this is the only species yet discovered, and which he calls the *Pyrosoma atlanticum*. The animal has an elongated and nearly cylindrical figure, truncated at one extremity, and rather conical at the other. The body is hollow, and does not contain any organ, except a very delicate net-work of vessels, which is spread over the internal surface of the cavity. The circular aperture, or mouth, is surrounded internally by a number of tubercles. The external surface is studded with some thick elongated tubercles, and others of a smaller size. They are the principal seat of the light, and shine like polished diamonds. The interior of the substance of the body contains a number of small elongated glands, which are also more luminous than the transparent part.

The colour of this animal when at rest, or after death, is an opalesc yellow mixed with a disagreeable green; but during the contractions of its body, the creature appears, as it were, to kindle, and becomes instantly of the red colour of fused iron; it afterwards passes through different tints, as aurora, orange, green, and azure blue, according to the strength of its illumination.

The *pyrosoma*, when at the same depth in the sea, gives the appearance of a red-hot bullet, but when floating on the

surface of the waves, resembles a cylinder of incandescent iron. It was observed to perform regular and alternate motions of contraction and dilatation. The light is evolved during the contractile motions, and these may be excited irregularly, by touching the animal, or merely by agitating the water in which it is contained. The *pyrosoma*, like all the other luminous marine animals, exhibits no light after death.

Mr. Peron only met with this species in a certain latitude, and observes that the mollusca and zoophytes, which are found at great depths in the sea, or at great distances from any shore, always inhabit particular regions of the ocean, out of which they are very rarely met with. *Annales du Museum d'Histoire Naturelle*. Mem. par Peron. 24 Cahier.

The *penatula phosphorea* is well known to exhibit light, which, Dr. Shaw states in his History of Algiers, is so strong, that it directs the fishermen in their occupation.

The luminous effect is confined to the plumule of the *penatula*, or that part which is inhabited by the polyps. Spallanzani, in a letter to Bonnet, states that the light is only emitted when the *sea pin* is in motion, and that there is a mucous luminous substance furnished by the polyps, which is soluble in water, and becomes mixed with the sea-water, that is admitted into the pin by means of a hole situated at the extremity of its stalk. (Mem. Soc. Ital. tomo ii.) Other species of *penatula* are said to be luminous, particularly the *grisea*, *argentea*, and *grandis*. The light exhibited by the last is reported to be an ash colour.

In a paper upon luminous animals communicated by Mr. Macartney to the Royal Society in 1810, he gives an account of three species he discovered on our own coasts. One is a *beroc* not described by authors. Another agrees so nearly with the *medusa hemispherica*, that he conceives it to be the same, or at least a variety of it. The third is a minute species of *medusa*, which he believes to be the luminous animal so often seen by navigators, although it has never been distinctly examined or described.

Mr. Macartney first met with these animals in the month of October 1804, at Herne bay, a small watering place upon the northern coast of Kent. Having observed the sea to be extremely luminous for several nights, he had a considerable quantity of the water taken up. When perfectly at rest, no light was emitted, but on the slightest agitation of the vessel in which the water was contained, a brilliant scintillation was perceived, particularly towards the surface; and when the vessel was suddenly struck, a flash of light issued from the top of the water, in consequence of so many points shining at the same moment. When any of these sparkling points were removed from the water, they no longer yielded any light. They were so transparent, that in the air they appeared like globules of water. They were more minute than the head of the smallest pin. Upon the slightest touch, they broke and vanished from the light. Having strained a quantity of the luminous water, a great number of these transparent corpuscles were obtained upon the cloth, and the water which had been strained, did not afterwards exhibit the least light. He then put some sea-water that had been rendered particularly clear, by repeated filtrations, into a large glass, and having floated in it a fine cloth, on which he had previously collected a number of luminous points, several of them were liberated, and became distinctly visible in their natural element, by placing the glass before a piece of dark coloured paper. They were observed to have a tendency to come to the surface of the water, and after the glass was set by for some time, they were found congregated together, and when thus collected in a body, they had a dusky

draw colour, although individually they were so transparent, as to be perfectly invisible, except under particular circumstances. Their substance was indeed so extremely tender and delicate, that they did not become opaque in distilled vinegar or alcohol, until immerfed in these liquors for a considerable time.

On examining these minute globules with the microscope, he found that they were not quite perfect spheres, but had an irregular depression on one side, which was formed of an opaque substance, that projected a little way inwards, producing such an appearance as would arise from tying the neck of a round bag, and turning it into the body.

The motions of these creatures in the water were slow and graceful, and not accompanied by any visible contraction of their bodies. After death they always subsided to the bottom of the vessel.

From the sparkling light afforded by this species, he has given it the name of *medusa scintillans*.

The night following that, on which he discovered the preceding animal, he caught the two other luminous species. One of these he has called *beroe fulgens*.

This most elegant creature is of a colour changing between purple, violet, and pale blue; the body is truncated before, and pointed behind; but the form is difficult to assign, as it is varied by partial contractions, at the animal's pleasure. He has represented the two extremes of form that this creature assumes: the first is somewhat that of a cucumber, which, as being the one it takes when at rest, should perhaps be considered as its proper shape: the other resembles a pear, and is the figure it has in the most contracted state. The body is hollow, or forms internally an infundibular cavity, which has a wide opening before, and appears also to have a small aperture, posteriorly through which it discharges its excrement. The posterior two-thirds of the body are ornamented with eight longitudinal ciliated ribs, the processes of which are kept in such a rapid rotatory motion, while the animal is swimming, that they appear like the continual passage of a fluid along the ribs. The ciliated ribs have been described by professor Mitchell, as arteries, in a luminous *beroe*, which probably was no other than the species we are now speaking of.

When the *beroe fulgens* swam gently near the surface of the water, its whole body became occasionally illuminated in a slight degree; during its contractions, a stronger light issued from the ribs, and when a sudden shock was communicated to the water, in which several of these animals were placed, a vivid flash was thrown out. When the body was broken, the fragments continued luminous for some seconds, and being rubbed on the hand, left a light like that of phosphorus; this however, as well as every other mode of emitting light, ceased after the death of the animal.

The *hemispherical species of medusa* had a very faint purple colour. The largest individuals measured about three quarters of an inch in diameter. The margin of the umbrella was undivided, and surrounded internally by a row of pale brown spots, and numerous small twisted tentacula: four opaque lines crossed in an arched manner from the circumference, towards the centre of the animal; an opaque irregular-shaped process hung down from the middle of the umbrella; when this part was examined with a lens of high powers, it was discovered to be inclosed in a sheath in which it moved, and that the extremity of the process was divided into four tentacula, covered with little cups or suckers, like those on the tentacula of the cuttle fish.

This species of *medusa* bears a striking resemblance to the figures of the *medusa hemispherica*, published by Gronovius and Muller; indeed it differs as little from these figures, as

they do from each other. Its luminous property, however, was not observed by these naturalists, which is the more extraordinary, as Muller examined it at night, and says it is so transparent, that it can only be seen with the light of a lamp. If it should be still considered as a distinct species, or as a variety of the *hemispherica*, Mr. Macartney proposes to call it the *medusa lucida*.

In this species, the central part and the spot round the margin, are commonly seen to shine on lifting the animal out of the water into the air, presenting the appearance of an illuminated wheel, and when it is exposed to the usual percussion of the water, the transparent parts of its body are alone luminous.

In the month of September 1805, Mr. Macartney had again frequent opportunities of witnessing the luminous appearance of the sea at Herne bay, and of making observations upon the animals which occasion it. He found that they always retreated from the surface of the water, as soon as the moon rose, and that exposure to the day light took away their property of shining, which was revived by placing them for some time in a dark situation.

In that season he had two opportunities of seeing an extended illumination of the sea, produced by the above animals. The first night he saw this singular phenomenon was extremely dark, many of the *medusa scintillans*, and *medusa hemispherica* had been observed at low water, but on the return of the tide they had suddenly disappeared. On looking towards the sea, he was astonished to perceive a flash of light, about six yards broad, extend from the shore, for apparently the distance of a mile and a half along the surface of the water. The second time that he saw this sort of light proceed from the sea, it did not take the same form, but was diffused over the surface of the waves next the shore, and was so strong, that he could for the moment distinctly see his servant, who stood at a little distance from him; who also perceived it, and called out to him at the instant. On both these occasions the flash was visible for about four or five seconds, and although he watched for a considerable time, it was not repeated.

A diffused luminous appearance of the sea, in some respects different from this, has been described by several navigators.

Godeheu de Riville saw the sea assume the appearance of a plain of snow on the coast of Malabar. Mem. Etrang. de l'Acad. des Sc. tom. iii.

Captain Newland, in a paper published in the Journal de Physique, states that he has seen the sea appear like milk for a few nights. Cook and Perouse also observed it to be a straw colour.

Father Bourzes, in his voyage to India in 1704, saw what he called luminous vortices in the sea, which he said appeared and disappeared suddenly at certain periods, like flashes of lightning.

Captain Herburg, in the notes he gave to sir Joseph Banks, says there is a peculiar phenomenon sometimes seen within a few degrees distance of the coast of Malabar, during the rainy monsoon, which he had an opportunity of observing. At midnight the weather was cloudy, and the sea was particularly dark, when suddenly it changed to a white flaming colour all around. This bore no resemblance to the sparkling or glowing appearance he had observed on other occasions in seas near the equator, but was a regular white colour, like milk, and did not continue more than ten minutes. A similar phenomenon, he says, is frequently seen in the Banda sea, and is very alarming to those who have never perceived or heard of such an appearance before.

This singular phenomenon appears to be explained by some observations communicated to Mr. Macartney by Mr. Langstaff. In going from New Holland to China, about half an hour after sunset, every person on board was astonished by the milky appearance of the sea: the ship seemed to be surrounded by ice covered with snow. Some of the company supposed they were in soundings, and that a coral bottom gave this curious reflection, but on sounding with 70 fathoms of line no bottom was met with. A bucket of water being hauled up, Mr. Langstaff examined it in the dark, and discovered a great number of globular bodies, each about the size of a pin's head, linked together. The chains thus formed did not exceed three inches in length, and emitted a pale phosphoric light. By introducing his hand into the water, Mr. Langstaff raised upon it several chains of the luminous globules, which were separated by opening the fingers, but readily re-united on being brought again into contact, like globules of quicksilver. The globules were so transparent, that they could not be perceived when the hand was taken into the light.

This extraordinary appearance of the sea was visible for two nights. As soon as the moon exerted her influence, the sea changed to its natural dark colour, and exhibited distinct glittering points, as at other times.

This account of Mr. Langstaff is very important, as it proves that the diffused light of the sea is produced by an assemblage of minute *medusa* on the surface of the water.

In June 1806, at Margate, Mr. Macartney collected a great number of the small *luminous medusa*. A bucket of the water being set by for some time, the animals sought the surface, and kept up a continual sparkling, which was occasioned by the motions of individuals, as the water was perfectly at rest. A small quantity of the luminous water was put into a glass jar, and on standing some time, the *medusa* collected at the top of the jar, and formed a gelatinous mass, one inch and a half thick, and of a reddish or mud colour, leaving the water underneath perfectly clear.

In order to ascertain if these animals would materially alter their size, or assume the figure of any other known species of *medusa*, Mr. Macartney kept them alive for 25 days, by carefully changing the water in which they were placed; during which time, although they appeared as vigorous as when first taken, their form was not in the slightest degree altered, and their size but little increased. This experiment confirmed his opinion of their being a distinct species, as the young *actinia* and *medusa* exhibit the form of the parent in a much shorter period than the above.

In September 1806, he took at Sandgate also a number of the *beroe fulgens*: they were of various dimensions, from the full size down to that of the *medusa scintillans*: they could, however, be clearly distinguished from the latter species by their figure.

In April 1809, Mr. Macartney caught a number of the *beroe fulgens* in the sea at Hastings; they were of various sizes, from about the half of an inch in length, to the bulk of the head of a large pin. Many of them adhered together in the sea; some of the larger sort were covered with small ones, which fell off when the animals were handled, and by a person unaccustomed to observe these creatures, would have been taken for a phosphoric substance. On putting a number of them into a glass, containing clear sea-water, they still shewed a disposition to congregate upon the surface. It was observed that when they adhered together, they shewed no contractile motion in any part of their body, which explains the cause of the pale or white

colour of the diffused light of the ocean. The flashes of light which Mr. Macartney saw come from *tno* sea at Herne bay, were probably produced by a sudden and general effort of the *medusa* to separate from each other, and descend in the water.

The *medusa scintillans* almost constantly exults in the different branches of Milford haven that are called pills. Mr. Macartney sometimes found these animals collected in such vast numbers in those situations, that they bore a considerable proportion to the volume of the water in which they were contained: thus, from a gallon of sea-water in a luminous state, he strained above a pint of the *medusa*. The sea under such circumstances yields more support in swimming, and the water tastes more disagreeably than usual; probably the difference of density, that has been remarked at different times in the water of the sea, may be referred to this cause.

Mr. Macartney concludes that the *medusa scintillans* is the usual cause of the luminous appearance of the sea, not only around this country, but in other latitudes. Besides the places already mentioned, he has found this species on different parts of the coasts of Sussex, at Tenby, and in the bays of Dublin and Carlingford in Ireland. Many writers, he observes, have mistaken this species of *medusa* for the *neris nobiluca*, and some navigators have actually described the *medusa scintillans*, without being aware of its nature. Mr. Bajon, during his voyage from France to Cayenne, collected many luminous points in the sea, which he says, when examined by a lens, were found to be minute spheres. They disappeared in the air. Dr. Le Roy, in sailing from Naples to France, observed the sparkling appearance of the sea which is usually produced by the *medusa scintillans*. By filtering the water, he separated luminous particles from it, which he preserved in spirits of wine: they were, he says, like the head of a pin, and did not at all resemble the *neris nobiluca*, described by Vianelli; their colour approached a yellow-brown, and their substance was extremely tender and fragile. Notwithstanding this striking resemblance to the *medusa scintillans*, Le Roy, in consequence of a preconceived theory, did not suppose what he saw, were animals, but particles of an oily or bituminous nature. Observe sur un lumiere produite par l'Eau de la Mer. Mem. Estrang. des Sc.

The minute globules seen by Mr. Langstaff in the Indian ocean, in all probability, were the scintillating species of *medusa*; on his seeing some of these animals that had been preserved in spirits, he entertained the same opinion.

Professor Mitchell, of New York, found the luminous appearance on the coast of America, to be occasioned by minute animals, that, from his description, plainly belonged to this species of *medusa*, notwithstanding which, he supposed them to be a number of the *neris nobiluca*. Phil. Mag. vol. x. p. 20.

The *luminous animalcule*, discovered by Forster off the Cape of Good Hope, in his voyage round the world, bears so strong a resemblance to the *medusa scintillans*, that there is every reason for believing them the same. He describes his animalcule as being a little gelatinous globule, less than the head of a pin; transparent, but a little brownish in its colour; and of so soft a texture, that it was destroyed by the slightest touch. On being highly magnified, he perceived on one side a depression, in which there was a tube that passed into the body, and communicated with four or five intestinal sacs.

Many writers have ascribed the light of the sea to other causes than luminous animals. Martin supposes it to be occasioned by putrefaction; Silberchlag believed it to be phosphoric;

phosphoric: professor J. Mayer conjectured, that the surface of the sea imbibed light, which it afterwards discharged. Bignon and Gentil thought the light of the sea was electric, because it was excited by friction. Forster conceived that it was sometimes electric, sometimes caused from putrefaction, and at others by the presence of living animals. Fongeroux de Bondary believed that it came sometimes from electric fires, but more frequently from the putrefaction of marine animals and plants.

It is unnecessary to enter into a discussion of the above opinions: their authors have not attempted to support them by any argument or experiments; they merely gave them as speculations. It is sufficient to state, that they are contradicted by all the best observations upon the subject.

The only animals which are known to possess distinct organs for the production of light are, the luminous species of *lampyris*, *elater*, *fulgora*, and *passus*. Of these Mr. Macartney has given the following description.

The light of the *lampyridæ* is known to proceed from some of the last rings of the abdomen, which, when not illuminated, are of a pale yellow colour. Upon the internal surface of these rings, there is spread a layer of a peculiar soft yellow substance, which has been compared to paste, but by examination with a lens, I found it to be organized like the common interstitial substance of the insect's body, except that it is of a closer texture, and a paler yellow colour. This substance does not entirely cover the inner surface of the rings, being more or less deficient along their edges, where it presents an irregular waving outline. I have observed in the glow-worm, that it is absorbed, and its place supplied by common interstitial substance, after the season for giving light is past.

The segments of the abdomen, behind which this peculiar substance is situated, are thin and transparent, in order to expose the internal illumination.

The number of luminous rings varies in different species of *lampyris*, and, as it would seem, at different periods in the same individual.

Besides the luminous substance above described, I have discovered in the common glow-worm, on the inner side of the last abdominal ring, two bodies, which to the naked eye appear more minute than the head of the smallest pin. They are lodged in two slight depressions, formed in the shell of the ring, which is at these points particularly transparent. On examining these bodies under the microscope, I found that they were sacs containing a soft yellow substance, of a more close and homogeneous texture, than that which lines the inner surface of the rings. The membrane forming the sacs appeared to be of two layers, each of which is composed by a transparent silvery fibre, in the same manner as the internal membrane of the respiratory tubes of insects, except that, in this case, the fibre passes in a spiral, instead of a circular direction. This membrane, although so delicately constructed, is so elastic as to preserve its form after the sac is ruptured, and the contents discharged.

The light that proceeds from these sacs is less under the controul of the insect, than that of the luminous substance spread on the rings: it is rarely ever entirely extinguished in the season that the glow-worm gives light, even during the day; and when all the other rings are dark, these sacs often shine brightly.

The circumstance of these being points, which give a more permanent light than the other parts of the luminous rings of the abdomen, has been noticed before by the Comte G. de Razoumoufki. He states the number of these luminous points to vary from two to five. *Mém de la Soc. de Lauenne*, tom. ii.

I must however remark, that I never saw more than two of these luminous points, which were always upon the last ring of the body, and that the figures which accompany the memoir of the Comte de Razoumoufki, bear scarcely any resemblance to the insect they are intended to represent, from which we may fairly suspect him of inaccuracy in other particulars.

As far as my observation has extended, the small sacs of luminous substances are not found in any species of *lampyris*, except the glow-worm of this country. Thunburg mentions that the *lampyris japonica* has two vesicles on the tail, which afford light.

The organs for the production of light in the genus *elater* are situated in the corcelet; these likewise consist of a peculiar yellow substance, placed behind transparent parts of the shell, which suffer the natural colour of this substance to be seen through them in the day, and when illuminated, give passage to the light.

On dissecting the organs of light in the *elater noctilucus*, I found that there is a soft yellow substance, of an oval figure, lodged in the concavity of the yellow spots of the corcelet, which parts are particularly thin and transparent in this species. This substance is so remarkably close in its structure, that at first view it appears like an inorganic mass, but with a lens it is readily perceived to be composed of a great number of very minute parts or lobules closely pressed together. Around these oval masses, the interstitial substance of the corcelet is arranged in a radiated manner, and the portion of the shell that immediately covers the irradiated substance is in a certain degree transparent, but less so than that which lies over the oval masses; it is therefore probable, that the interstitial substance in this situation may be endowed with the property of shining. A fasciculus of the muscles of the corcelet arises in the interior of the oval masses of the luminous substance, but not apparently with any design, as it contributes, with the adjacent fasciculi, to move the anterior feet.

In the *elater ignitus*, the masses of luminous substance are extremely irregular in their figure: they are situated nearly at the posterior angles of the corcelet, and are more loose in their texture than the oval masses of the *noctilucus*, resembling rather, in composition, the interstitial substance which surrounds these masses in that species. The shell of the corcelet is somewhat thinner, and more transparent along both sides of the margin, than at other places, but it is not, as in the *noctilucus*, elevated, and peculiarly clear and thin immediately, over the seat of the luminous organ; consequently, the light emitted by the *elater ignitus* cannot be very brilliant.

I have not been able to procure any specimen of the *elater phosphorea*, but from the accounts of naturalists, it appears to resemble in every respect the *elater noctilucus*.

I have had an opportunity of examining, preserved in a moist way, two species of *fulgora*, the *candelaria* and *lanternaria*. The light in this genus has been observed to issue from the remarkable proboscis on the fore part of the head. This part has always been described by authors as hollow or empty, which I have found to be perfectly correct; and what is more extraordinary, that the cavity communicates freely with the external air, by means of a chink or narrow aperture, placed on each side of the root of the proboscis. This projection is covered internally by a membrane, between which and the horny part or shell, there appears to be interposed a pale reddish coloured soft substance, that is arranged in the *candelaria* in broad lines or stripes; but it is so thin, that I could not distinctly examine its structure, or absolutely determine, whether it should be considered as a substance

ance intended to furnish the light of these insects, or the pigment upon which the colour of the proboscis depends.

The globes of the antennæ constitute the organs of light in the *pauflus spherococcus*. Dr. Azeilius, who discovered the luminous property in this species, compares them to lanterns spreading a dim phosphoric light. (Linn. Transf. vol. iv.) The rarity of the insect put it out of my power to examine its structure, but from the form and situation of its organs of light, it is most probable they are constructed like those of the *fulgoræ*.

It has been conjectured by Carradori and others, that the *lampyrides* were enabled to moderate or extinguish their light, by retracting the luminous substance under a membrane; but neither in them, nor any of the other luminous insects, have I found an apparatus of this sort. The substance furnishing the light, is uniformly applied to corresponding transparent parts of the shell of the insect from whence it is not moved; indeed a membrane, if it did exist, would have but little effect in obscuring the light, and never could serve to extinguish it. The regulation of the kind and degree of the luminous appearance, does not depend upon any visible mechanism, but, like the production of the light itself, is accomplished by some inscrutable change in the luminous matter, which in some animals is a simple operation of organic life, and in others is subject to the will.

It is worthy of remark, that in all the dissections I have made of luminous insects, I did not find that the organs of light were better, or differently supplied with either nerves or air tubes, than the other parts of the body. The power of emitting light likewise exists in many creatures which want nerves, a circumstance strongly marking a difference between animal light and animal electricity. Phil. Transf. 1810, part ii.

With the exception of the animals above-mentioned, the exhibition of light depends upon the presence of a fluid matter.

In the *pholas dactylus*, the luminous fluid is particularly evident, and in vast quantity.

The shining of the *scelopendra electrica* is observed to be accompanied by the appearance of an effusion of a luminous fluid upon the surface of the animal, more particularly about the head, which may be received upon the hand, or other bodies brought into contact with the insect at the moment, and these exhibit a phosphoric light for a few seconds afterwards. This fluid, however, it is impossible to discover in the form of moisture, even upon the clearest glass, although examined immediately with the most scrupulous attention by a lens; it mutt therefore be extremely attenuated.

The same appearance has been observed during the illumination of the *neris noctiluca* by Fougereux de Bondaroy. Mem. de l'Acad. des Sc. 1767.

The animal discovered by Riville shed a blue liquor, which illuminated the water for a distance of two or three lines. Mem. Etrang. de l'Acad. des Sc. tom. iii.

Spallanzani relates, that the *medusa* which he examined, communicated the property of shining to water, milk, and other fluids, on being rubbed or squeezed in them. Spallanzani's Travels in the Two Sicilies, vol. iv.

The luminous fluid is in some instances confined to particular parts of the body, and in others is diffused throughout the whole substance of the animal.

In the *scelopendra electrica*, it appears to reside immediately under the integuments. In the *lyncus* discovered by Riville, it is contained in the ovary. Mr. Macartney believes that every part of the body of the *medusa* is furnished with this fluid, as there is no part that is not seen illuminated

under different circumstances, but Spallanzani affirms that it is only found in the large tentacula, the edges of the umbrella, and the purse or central mass; which he proved, he says, by detaching these parts successively, when they shone vividly, while the rest of the body neither gave light nor communicated any luminous appearance to water. Memoria sopra le meduse fosforiche. Mem. della Soc. Ital. tom. vii.

Spallanzani discovered a mucous luminous fluid in the plumule of the *penatulæ phosphorea*. Mem. della Soc. Ital. tom. ii.

The phenomenon of animal light has been attempted to be explained in different ways. By many persons it was formerly ascribed to a putrefactive process, but since the modern theories of combustion became known, it has been generally believed to depend upon an actual inflammation of the luminous substance, similar to the slow combustion of phosphorus. Others have accounted for the luminous effect, by supposing the matter of light to be accumulated, and rendered latent under particular circumstances, and afterwards evolved in a sensible form.

The opinion of the light of living animals being the consequence of putrefaction, is evidently absurd, and contradictory to all observation on the subject. It has been proved by the experiments of Dr. Hulme and others, that even the luminous appearances of dead animals are exhibited only during the first stages of the dissolution of the body, and that no light is emitted after putrefaction has really commenced.

Spallanzani, who was the most strenuous advocate for the phosphorescent nature of animal light, stated that glow-worms shone more brilliantly when put into oxygen gas; that their light gradually disappeared in hydrogen or in azotic gas, and was instantly extinguished in fixed air; that it was also lost by cold, and revived by the application of a warm temperature. He conjectured that the luminous matter of these insects was composed of hydrogen and carbonated hydrogen gas.

Forster relates, in the Lichtenberg Magazine for 1783, that on putting a *lampyris splendidula* into oxygen gas, it gave as much light as four of the same species in common air.

Carradori has made some experiments upon the *luciole*, (*lampyris italica*) which led him to deny its phosphorescence. He found that the luminous portion of the belly of the insect shone in vacuum, in oil, in water, and different liquids, and under different circumstances, where it was excluded from all communication with oxygen gas. He accounts for the result of Forster's experiment, by supposing, that the worm shone more vividly, because it was more animated in oxygen gas than in common air.

Carradori adopts on this subject, the doctrine of Brugnatelli, and ascribes the luminous appearances of animals to the condensation and extrication of light in particular organs, which had previously existed in combination with the substance of their bodies. He supposes the light to be originally derived from the food, or the atmospheric air taken into the body; in short, that certain animals have the peculiar property of gradually imbibing light from foreign bodies, and of afterwards secreting it in a sensible form. Annal di Chimica. tom. xiii. 1797.

The following experiments, which were lately made upon this subject by Mr. Macartney, would lead to different conclusions than those of the preceding authors.

Experiment 1.—A glow-worm was put into a glass of water, in which it lived nearly two hours, and continued to emit light as usual, until it died, when the luminous appearance entirely ceased.

*Experiment 2.*—The luminous substance was extracted from the before-mentioned *glow-worms*, and from others killed in different ways, but it afforded no light.

*Experiment 3.*—The faces containing the luminous matter were cut from the bellies of living *glow-worms*, and shone uninterruptedly for several hours in the atmosphere, and after their light became extinct, it was revived by being moistened with water; some of these were put into water in the first instance, in which they continued to shine unremittingly for forty-eight hours.

*Experiment 4.*—The luminous substance of a *glow-worm* was exposed to a degree of heat which would have been sufficient to inflame phosphorus, without increasing the brilliancy of its light: and farther, it could not be made to burn by being applied to a red-hot iron, or to the flame of a candle.

*Experiment 5.*—A delicate thermometer was introduced amongst some living *glow-worms*, during the time they gave out much light: the temperature of the room being 69°, the instrument rose to 75°, 76°, and 77°, according to circumstances, as the warmth was reflected from the hand, or dissipated by the worm crawling over cold substances. The luminous portion of the tail, when very brilliant, appeared to raise the thermometer more quickly than the other parts of the body; but it was not invariably the case. When shining strongly, the luminous rings appeared to communicate the sensation of warmth to the hand; but this was probably a deception, as the actual degree of heat was not sufficient for such an effect. It should however be mentioned, that in Templar's observations on the *glow-worm*, he said his feelings deceived him, if he did not experience some heat from the shining of the insect. Phil. Trans. N° 72.

*Experiment 6.*—To ascertain how far the evolution of heat, during the shining of *glow-worms*, depended upon the life of the animals, the luminous portion of the tail was cut off from several living worms: if the thermometer was applied to them immediately, it was raised by them one or two degrees; but after these parts were dead, although they continued to emit light, they produced no effect whatever upon the instrument.

*Experiment 7.*—Some *hemispherical medusæ* were put into a spoon, containing a small quantity of sea-water, and held over a burning candle. As soon as the water became heated, the medusæ appeared like illuminated wheels; the spots at the margin and centre alone emitting light; in which manner they shone vividly and permanently for about twenty seconds, when they shrunk and died, after which they were no longer luminous.

*Experiment 8.*—Some of the same species were put into spirits: a strong and unremittent light was instantly given out, which issued from the central and marginal parts, as in the preceding experiment, and continued until they died.

*Experiment 9.*—Some of the *scintillating and hemispherical species of medusæ*, contained in a small glass jar, were introduced into the receiver of an air-pump, and the air being exhausted, they shone as usual when shaken: if any difference could be perceived, the light was more easily excited, and continued longer in vacuum.

*Experiment 10.*—A *medusæ hemispherica* was placed in a small glass dish, containing a quantity of water, merely sufficient to allow the animal to preserve its figure: being insulated, it was electrified, and sparks drawn from it, which had not the slightest effect. The experiment was repeated several times with different individuals, but without exciting the animals to throw out light.

*Experiment 11.*—Some *hemispherical medusæ* were placed in contact with the two ends of an interrupted chain, and

slight electric shocks passed through them. During the very moment of their receiving the shock, no light was visible; but immediately afterwards the medusæ shone like illuminated wheels, which appearance remained for some seconds. Upon the closest inspection with a magnifying glass, no contractile motion could be perceived to accompany the exhibition of the light. The application of electricity, in this instance, seems to have acted merely as a strong mechanic shock.

It seems proved by the foregoing experiments, that so far from the luminous substance being of a phosphorescent nature, it sometimes shews the strongest and most constant light, when excluded from oxygen gas; that it, in no circumstances, undergoes any process like combustion, but is actually incapable of being inflamed; that the increase of heat, during the shining of *glow-worms*, is an accompaniment, and not an effect of the phenomenon, and depends upon the excited state of the insect; and, lastly, that heat and electricity increase the exhibition of light, merely by operating like other stimuli upon the vital properties of the animal. Phil. Trans. 1810, part ii.

In addition to these opinions, we may mention that professor Davy has found that the light of the *glow-worm* is not rendered more brilliant in oxygen, or in oxygenated muriatic gas, than in common air; and that it is not sensibly diminished in hydrogen gas.

We may further add, that Spallanzani's experiments of diffusing the luminous liquor of the *medusæ* in water, milk, and other fluids, are in direct contradiction of his own theory, as is also the extinction of the light of these mixtures by the application of a high degree of heat.

If the light emitted by animals were derived from their food, or the air they respire, as supposed by Carradori, the phenomenon should be increased or diminished, according to the quantity of food or air that the creatures consume. But we do not find this to be the case; for in those situations where they are sometimes found to be most luminous, they are deprived, in a great measure, of these assumed sources of their light.

In fact, the luminous exhibitions of living animals are not only independent of all foreign light, but are frequently destroyed by the latter. The shining of the *medusæ* was always found by Mr. Macartney to cease upon the rising of the moon, or at the approach of day; and when out of the sea, he never could excite them to throw out light until they had been kept for some time in the dark: all the luminous insects likewise secrete themselves as much as possible during the day-time, and go abroad only at night. It is true that the *scelopendra electrica* will not shine, unless it has been previously exposed to solar light; but it is to be observed that it shone as brilliantly and as frequently, after being kept a short time in a light situation, as when left uncovered the whole day. The circumstance of the *scelopendra* requiring exposure previous to its giving out light, is very unaccountable, as the insect, when left to itself, always seeks as much as possible concealment during the day: indeed it is the opinion of some naturalists, that it is killed by the light of the sun.

We shall terminate this article with the following conclusions, drawn by Mr. Macartney from his own observations, and from a careful review of all that had been written on the subject.

The property of emitting light is confined to animals of the simplest organization, the greater number of which are inhabitants of the sea. The luminous property is not constant, but in general exists only at certain periods, and in particular states of the animal's body. The power of shew-

ing light resides in a peculiar substance or fluid, which is sometimes situated in a particular organ, and at others diffused throughout the animal's body. The light is differently regulated, when the luminous matter exists in the living body, and when it is abstracted from it. In the first case, it is intermitting, or alternated with periods of darkness; is commonly produced or increased by a muscular effort; and is sometimes absolutely dependent upon the will of the animal. In the second case, the luminous appearance is usually permanent until it becomes extinct, after which it may be restored directly by friction, concussion, and the application of warmth; which last causes operate on the luminous matter (while in the living body) only indirectly, by exciting the animal. The luminous matter, in all situations, so far from possessing phosphoric properties, is incombustible, and loses the quality of emitting light, by being dried, or much heated. The exhibition of light, however long it may be continued, causes no diminution of the bulk of the luminous matter. It does not require the presence of pure air, and is not extinguished by other gases.

The luminous appearance of living animals is not exhausted by long continuance, or frequent repetitions, nor accumulated by exposure to natural light: it is, therefore, not dependent upon any foreign source, but inheres as a property, in a peculiarly organized animal substance or fluid, and is regulated by the same laws which govern all the other functions of living beings.

The light of the sea is always produced by living animals, and most frequently by the presence of the *medusa scintillans*. When great numbers of this species approach the surface, they sometimes coalesce together, and cause that snowy or milky appearance of the sea, which is so alarming to navigators. These animals, when congregated on the surface of the water, can produce a flash of light, somewhat like an electric coruscation. When the luminous *meduse* are very numerous, as frequently happens in confined bays, they form a considerable portion of the mass of the sea, at which times they render the water heavier, and more nauseous to the taste: it is therefore advisable to always strain sea-water before it is drunk.

The luminous property does not appear to have any connection with the economy of the animals that possess it, except in the flying insects, which by that means discover each other at night, for the purpose of sexual congress.

In the plates for illustrating the present subject in this dictionary, the reader will only find figures of those luminous animals which are not generally contained in books on natural history, or which are necessary for the explanation of lately discovered facts.

Fig. 1. is the *nercis nobilucis*, discovered by Vianelli, of the natural size.

Fig. 2. shews the same animal greatly magnified: *a* is the head, furnished with two short antennae and a horn-like process; *b, b*, the two eyes; *c, c, c*, some of the lateral twisted processes proceeding from the segments of the body; *d, d, d*, some of the other lateral processes that contain the tufts.

Fig. 3. is the *crustaceous insect*, discovered by Riville: *a* is the transparent shell, through which the internal parts of the animal are visible; *b*, the sac containing the intestines; *c*, one of the four-jointed setaceous antennae; *d*, the two feet armed with hooks; *e*, the foot which terminates in claws; *f*, the ova, which Riville mistook for globules containing a luminous oily fluid.

Fig. 4. exhibits the *cancer fulgens*, discovered by sir Joseph Banks. It is given of the natural size.

Fig. 5. represents the *limulus nobilucis*, discovered by captain Horiburg, greatly magnified.

Fig. 6. is the *medusa pellucens*, discovered by sir Joseph Banks, shewn less than the natural size.

Fig. 7. is the *pyrosoma atlanticum*, lately discovered and described by Peron.

Fig. 8. shews the *medusa lucida*, described by Mr. Macartney, of the largest size he met with.

Fig. 9. is the *beroe fulgens*, discovered by Mr. Macartney. It is represented of the usual size, and in the elongated form the creature assumes when in the act of swimming. On the posterior part are seen the ciliated ribs, which constitute its instruments of locomotion.

Fig. 10. shews the *medusa scintillans*, discovered by Mr. Macartney, as it appears to the naked eye.

Fig. 11. is the same highly magnified, by which the opaque parts upon the side and in the centre of the animal are made apparent.

Fig. 12. is the animalcule, discovered by Mr. Forster, of the size it appears to the naked eye.

Fig. 13. exhibits a microscopic view of the same animalcule.

Fig. 14. is an enlarged view of the inferior surface of the abdomen in the *lampyris lucida*, after the integuments had been removed, as delineated by Mr. Macartney: *a, a, a*, represent the three masses of luminous substance, which are applied to the three last rings of the abdomen; *b, b, b*, the arrangement of the cellular or interstitial substance on the other abdominal rings, which gives the pale colour to the whole belly of this insect.

Fig. 15. represents the common glow-worm, with the lower portion of the back cut away, to expose the sacs of luminous matter in situ on the last ring of the belly: *a* indicates the sac of one side; the intestine is seen to lie between them.

Fig. 16. is one of the light sacs of the glow-worm, taken out and prodigiously magnified, in order to shew its structure, as described by Mr. Macartney: *a*, the external part of the sac, which is composed of the interweaving of a spiral fibre; *b*, the luminous substance seen at one end, when the sac has been ruptured to expose its contents.

Fig. 17. is the *elater nobilucis*, with the shell of the corcelet removed on one side, by which the organ of light, described by Mr. Macartney, is uncovered; *a*, the yellow transparent spot of the corcelet; *b*, the oval mass of luminous substance surrounded by an irradiation of the interstitial substance; *c*, the ends of the muscles which are on the inside of the corcelet.

Fig. 18. shews the luminous apparatus of the *elater nobilucis*, considerably magnified: *a*, the radiated appearance of the interstitial substance around the oval mass of luminous substance: this mass is seen to consist of a number of smaller parts; *b* shews the arrangement of the interstitial substance, when it passes down between the muscles; *c*, the ends of the muscles of the back; *d*, the shell of the corcelet.

Fig. 19. is the *elater ignitus*: *a* indicates the yellow part of the corcelet; *b* shews the small mass of luminous substance in this species, the shell being removed.

LIGHT is also used to signify the disposition of objects with regard to the receiving of light.

Thus we say, a painting is seen in its proper light, when its situation, with regard to the light, is the same with that for which it was painted.

LIGHT, in Agriculture and Gardening. Experience has shewn its infinite service to the growth of vegetables, contributing exceedingly to facilitate their vegetation, and in-

## L I G H T.

crease their perfection and duration; as it is obvious most plants are considerably more prosperous, and attain their perfection in a free exposure, fully open to the light and air, than in shady places; the same is observed of fruits. Those growing in a situation full to the light of the sun, are in general more large and fair, ripening sooner, and more perfectly, as to beauty and richness of flavour, than such as grow in the shade: these reasons should therefore determine us to cultivate most of the principal plants and fruits in situations open as much as possible to the full light and influence of the sun; though upon particular occasions, and in the heat of summer, shady places may be necessary for some sorts of plants, though not where shaded and darkened by spreading trees, &c. but a border open above to the full light, and only shaded from the immediate rays of the sun. For the general crops, a perfectly open, sunny, light situation, free from the shade of spreading trees, is always the most proper.

And its utility is very evident, from plants growing in garden-frames, green-houses, &c. in winter; when, in time of severe weather, covers or shutters have been continued long over the glasses, so as to exclude the rays of light, they become sickly, grow pale, and assume an unhealthy appearance for a long time; the leaves often decaying or dropping off; and frequently, when the covers are continued very long without the admission of light, the whole plant in many sorts gradually dwindles and perishes. Great attention is of course requisite in this case, when, from the severity of the weather, the use of other covers besides the glasses is necessary, to take every opportunity of a favourable day, or even an hour or two of a day, to admit the light as fully as possible. The same is also the case with plants in early hot-beds, such as cucumbers, melons, &c. which, early in the year, require a covering of mats over the glasses every night; as when these additional covers are applied too soon in the afternoon, and continued late in the morning, so as to keep the plants long in darkness, it is highly disadvantageous to their growth, causing them to grow weak, pale, and sickly.

As light is, therefore, so beneficial to plants in general, it should be increased as much as possible to those in frames, green-houses, stoves, &c. In these situations it may be useful to paint the inside of all such departments white, to reflect the rays of light as much as possible, and particularly in the nights, and in the day time, when the severity of the season requires covers or shutters to be placed over the glasses or other conveniences where plants are kept.

The author of *Phytologia* remarks, that the contest for light, as well as for air, which is so visible in the growth of vegetables, shews the former to be of great consequence to their existence, as well as the latter. Thus many flowers follow the sun during the course of the day, by the nutation of the stalks, not by the rotation of them, as observed in the sun-flower by Dr. Hales; and the leaves of all plants endeavour to turn their upper surface to the light, which is their respiratory organ, or lungs. The great use of all plants turning the upper surfaces of their leaves to the light is thus, he thinks, intelligible; the water perspired from those surfaces is, he conceives, hyper-oxygenated; and, as it escapes from the sharp edges of the mouths of the perspiring vessels, when acted upon by the sun's light, gives out oxygen; which oxygen, thus liberated from the perspired water, and added to that of the common atmosphere, presents to the respiratory terminations of the pulmonary arteries on the upper surfaces of leaves an atmosphere more replete with vital air. This necessity of light to the respiration of vegetables

is so great, that there is reason to believe that many plants do not respire during the night, but exist in a torpid state, like the winter sleeping insects. Thus the mimosa, sensitive-plant, and many others, close the upper surfaces of their opposite leaves together during the night, and thus preclude them both from the air and light; and the internal surfaces of innumerable flowers, which are their respiratory organs, are closed during the night, and thus unexposed both to light and air. It is, however, observed, that the *fungi*, which are termed vegetables, because they are fixed to the earth, or to the stones, trees, or timber, where they are found, can exist without light or much air; as appears in the truffle, which never appears above ground, and by other fungi, which grow in dark cellars; and in esculent mushrooms, which are cultivated beneath beds of straw. The etiolation, or blanching of vegetables, depends upon the keeping of the light from them.

It is further noticed that the element of light, as well as that of heat, is necessary to vegetation. In this climate they both seem, in general, to be injurious only by their defect, and seldom by their excess. But as light acts as a stimulus on the more irritable or sensitive parts of plants, which appears by the expansion of many flowers, and of some leaves, when the sun shines on them; and by the nutation of the whole flower, as of the sun-flower (*helianthus*), and by the bending of the summits of all plants confined in houses towards the light; there may be diseases owing to the excess of this stimulus, which have not been attended to; to prevent which the flowers of *tragopogon falsus*, and of other plants, close about noon. Other unobserved diseases may be owing to a defect of the stimulus of light; as a *nimfa*, sensitive plant, which had been confined in a dark room, did not open its foliage, though late in the day, till many minutes after it was exposed to the light. The excess of light has not, however, been observed to be attended by vegetable diseases in these more northern latitudes so much as in others.

**LIGHT, in the Manner.** A horse is said to be light, in French *un cheval léger*, that is, a swift, nimble runner. We likewise call a horse light that is well made, though he is neither swift nor active; for in this last expression we consider only the shape and make of a horse, without regard to his qualities.

*Light upon the hand*; a horse is said to be such, that has a good tractable mouth, and does not reit too heavy upon the bit.

A coach-horse is said to be light, when he stirs nimbly, and dreads the whip; or when he has a light trot.

**LIGHT-bellied.** A horse is thus called that commonly has flat, narrow, contracted sides, which make the flank turn up like that of a grey-hound.

**LIGHT-hand.** See **HAND**.

**LIGHT, in Painting,** refers only to those effects which light (properly so called) produces upon the surfaces of natural objects; as exhibited by its reflection from them to the eye of an observer.

With regard to that art, light may be considered in two distinct points of view; *viz.* as to the natural and the artificial effects arising from it. The former is simply the effect produced upon the objects in a picture, by the direction in which it is introduced; which being once chosen, becomes a positive rule; and from which no variation can be allowed. The latter is ideal, and requires only to be probable or possible.

It relates to the quantity of light employed to illustrate the character of a subject, and depends entirely upon the taste of the artist; who, by the use of ideal shadows and fictitious lights, may effect a diminution or augmentation to

any proportion he pleases. These, together with light and dark colours, form the basis of chiaro-scuro; one of the grand fundamental principles of painting, of which we have already treated under the article CLARO-OBSCURE.

As light, when acting upon substantial forms, is always accompanied by shadow, and as they are necessary adjuncts to each other, we shall here unite them, and treat of them together. It is by the contrast of each to the other, that the effect of either is produced by colours; and however paradoxical it may appear, it is nevertheless true, that light in the art of painting is not more necessary to produce shadow, than shade is for the production of light. The colours which give the appearance of the former, obtain that effect only when surrounded with darker ones, which constitute shade; without the latter, they would appear nothing more than an uninteresting mass of one plain tone, without any degree of the quality which is termed luminous; but contrasted by their opposites in tone, they become brilliant; and when form is superadded, obtain the character of light. The same, though in the contrary degree, is the effect of dark hues, which, without the contrast of lighter ones, produce only a heavy, dull, unmeaning mass, that merits not the appellation of shade, till opposed by other tones, and rounded into form by the assistance of light.

The management of light and shade is the most important of the practical parts of the art; since, without the true arrangement of them, vain must be every effort of the painter to produce a just resemblance of those things which nature offers to our view, and which are the immediate objects of his study. Outline is but as the section of a body; and colour, a simple, unvaried colour added to it, would still in no-wise increase its value as the representative of a substance; but let light and shade be superadded, and duly disposed, and what was a flat surface becomes apparently a rounded one, is relieved from its ground, and appears to start from the canvas.

The sources of light are in fact but two; viz. the sun and fire; but to the painter a variety of modifications of these two take place, and become equally separate sources, with distinct qualities, both as to power and colour. Such, for instance, are the moon's reflecting power; that of the atmosphere when the sun is hid; and likewise the illumination proceeding from a window into a room. The effects produced by each of these differ so widely from those of the two former, that we may fairly say there are five general sources of light, at least, applicable to the purposes of painting. Of that proceeding direct from the sun in full blaze, it can only be observed, that, except for landscape, its use is confined in the art; being too powerful, and producing shadows too harsh, for the more intermingling and agreeable subjects of fancy or history. The softer illumination reflected from those parts of the atmosphere opposed to the sun, is usually and reasonably preferred; or that which the heavens yield when the source of its light is hid in clouds, though not when it is too much lost in the gloom of tempest; for then the lights and shadows become too indistinct and confused. The open light of the air has another character distinct from the two just mentioned; which is, when the sun is but faintly obscured by thick clouds, through which its rays penetrate with diminished lustre, but still in direct lines. In this case the light, though direct and causing shadows the same in form as when its source is unobserved, is yet but weak and soft; and the shadows it produces being effected by the general light of the atmosphere, are tender in their outline and tone. When the reflected light proceeding from the northern parts of the atmosphere is ad-

mitted through a window into a room, it assumes a mid-way character. For while the light is weaker, and consequently softer than sun-shine; the shadows, owing to the smallness of the aperture, become distinct but not harsh; and their distinctness is heightened by the room wherein is the window, (which may be considered as an original source,) receiving only a partial quantity of light, and consequently little or no reflection takes place, except from surrounding and contiguous objects upon each other: whereas, when a figure is so placed in open air as to receive the light reflected from the sky, it partakes of it in every direction, and therefore has little or no shadow; for there will be few parts where some rays of light will not, under such circumstances, find admission.

When the light proceeds direct from the sun, it is usual, though not strictly correct, to consider its rays as parallel, and consequently no enlargement or diminution takes place in lengthened shadows. But, in reality, its distance, which diminishes its size apparently, added to the effect of perspective, produces a real variation in shadows of objects whose magnitude is at all considerable. This is always the case when the source of light is larger or smaller than the illuminated body. In the former case, the shadow of a suspended ball would diminish to a point; as that of the earth does from the light of the sun; and in the latter it would dilate as it was extended, and project a shadow at a certain distance, large in proportion to the comparative smallness of the luminous body; as of the flame of a candle, for instance, compared to a tennis-ball.

Shadows by day-light seldom become totally obscure: an object must be placed in a situation where it could receive very little indeed of that peculiar illumination, without having some reflections falling into its shades, and consequently yielding some visible effect of the forms on which they fell. But by fire and candle-light, owing to the confined issue of their rays, forms hid in the shadows they project are often totally lost; nevertheless, these shadows are not blacknets, but darknets, of a colour whose hue depends upon that of the larger mass of surrounding bodies. Under many circumstances they receive reflections, and have a consequent degree of colour in the bodies that lie within their range.

There are two causes which operate to weaken and even destroy the force of reflected light. The one is the distance at which the reflecting object is situated from the luminary; the other, the distance of the same from the observer. When these two circumstances combine, the effect of light and shade is very weak.

To comprehend the principle upon which the illumination and consequent shadows of objects are produced, and to imitate them the most effectually, the painter must recollect, that light, whencesoever it issues, proceeds rectilinearly from its source to the surface which intercepts it; and is reflected in the same way, at an equal angle with the plane of that surface, but in an inverse direction. In the language of optics, *the angle of reflection is equal to the angle of incidence*. This is the simple but general rule, which is inally to guide the artist through all the difficulties of light and shade in painting; whether arising from direct or reflected illumination; this one principle holds equally good in all; but the lines which it forms in the shadows, are subject to the variations produced by perspective on all solid bodies whereon light can act.

The most important application of this rule the artist will find to be, in fixing upon the precise point where he should dispose of his most brilliant hues; or what are technically termed his high lights; which are, in reality, those parts of

his objects, where, if the surface be a polished one, the image of the luminary is reflected; and is of course that one which, to the eye of an observer, is most illuminated. These reflections will always be found to take place only on that point from whence a line drawn to the luminary, and another to the eye of the artist, form angles equal to each other with the plane of the surface of the illuminated object. For though it may not in reality be the precise spot where the greatest number of rays of light are intercepted by that body, yet it is effectually so to him whose eye can only receive those which are thrown off in reflection towards him. It may be observed as a consequence of this rule, that the extreme edge of a rounded body can scarcely ever be its brightest part; it will, as it recedes from the observer, lose to him its lustre, and melt into the ground or object behind it; or, if relieved by a flat object equally white with itself, a dark line will be seen to mark its boundary, in whatever situation the source of light may be, within a right angle with a line drawn from the object to an observer; or somewhat beyond that, to nearly 135 degrees.

It is scarcely necessary here to speak of the refraction of light from its original course, when passing through various substances, as glass or water; except to deprecate paying any attention to it in a picture where any essential form is broken in upon by it; or choosing such subjects, where deviation from general rules serve rather to confound than to satisfy the common understanding of mankind. These copying the positive truth would create confusion, it is most just, at least most useful, to vary from it: as in painting the portrait of a man with spectacles on. What artist in his senses, and who had a true perception of the real object of art, would think of painting exactly that which presents itself to his view, a positive deformity, eyes misplaced, and of monstrous form; for such they are when seen through the glasses. Such procedure would totally defeat the object of portraiture; and it would be hardly possible to make a likeness of the person, with such a variation from the positive form of his face.

The direction in which the light falls upon the objects introduced into a picture, and which we proposed at the beginning of this article as one of the points of view in which to consider the subject, is of very great importance on many accounts, and calls for the most attentive consideration of the artist before he begins to colour his picture, and even in the composition of his forms. If, without previous attention to this, he proceeds to execute his composition, and complete the development of his ideas, he would be fortunate if he did not find in his progress, that the necessity he was under of making shadows to bring out his forms, very frequently destroyed his general shapes, which previously appeared well when in lines only. A due attention to this, in the first instance, would frequently suggest ideas of forms, and assist him in filling his canvas agreeably, and in expressing the character of his subjects appropriately. It is, however, utterly impossible to give precise rules upon this subject in historical paintings, as it depends so entirely upon the nature of the subjects, and the local situations of the actors introduced. One general rule only may be given, *viz.* that the disposition of the figures should be such, with regard to the source of light, as to produce ample masses of light and shadow: either of the one or the other predominant, accordingly as the subject is grave or gay. If the subject be of one single figure, then it is requisite (and more easily to be managed) that care be taken that the light falls upon it in such a manner as accords with the action, and produces no unpleasant shapes. For great grace may be added to

figures by light and shade when agreeably disposed; and on the contrary, an unfortunate disposal of them may diminish the effect, if not totally destroy the most beautifully drawn figure imaginable.

In portraiture, something more precise may be said upon this subject. Its object is to convey a resemblance of a person in the most agreeable manner, generally speaking; yet therein much must remain which the rules cannot attach to, particularly where the object is to convey character strongly, and not merely to render the picture agreeable. In the latter case, if a person be so placed with regard to the window or luminary, that the light falls upon him at an angle of about 45 deg., and the greater part of the face be exposed to it, the purpose will be answered. A still more acute angle will give greater relief, but the effect will not be so pleasing. Whether the face should be turned directly facing the light, or so as to receive it partially, must entirely depend upon the character of the features. If large, they will bear a full light; if of a smaller and more delicate nature, a little inclination from the light will give more force and variety. But where the object is to convey character strongly, to the disregard of positive beauty, there the character only is the guide, and every angle of illumination, with any turn towards or from it, may effect the object, according to the stamp which nature has laid upon the face to be painted.

The angle of 45 deg. or thereabouts, is also the best for the general illumination of a picture while the artist is employed upon it, with such an inclination from the source of light, that no reflection of it is presented to his eye. He will, in this situation of his work to the light, be left in his own way, and see the whole of it together most effectually; but this is an object of lesser moment; a good artist need not wait to have his picture precisely in the very best situation, to enable him to perform his task with pleasure or effect. Indeed he cannot always have it so, particularly when engaged in adorning walls and ceilings, &c.

With regard to the second division of our subject, or the quantity of light proper to be introduced into a picture, which is a matter that lies entirely at the discretion of the artist, we must principally refer our readers to what has been said under the articles *CLAIR-OBSCURE*, and *EFFECT*, in *Painting*; more particularly the latter, where we have shewn that various masters have adopted as various quantities, and shaded them all agreeable. The subject, the place, and the time, must govern this point, and the taste of the artist must lead him to decide the matter for himself; his only guide is, the most natural, and at the same time the most effective, illustration of his subject.

Another point for consideration, is the tone of colour which should be given to the light. Of this, also, we have treated under the words *EFFECT*, in *Painting*, and *HARMONY* in the same art, and need only state here, that whatever hue is adopted, the same should range through the whole picture, except when two kinds of light are introduced, as day-light and candle-light. In that case the former will be of a cold colour; and in situations where shadows from the candle fall over parts illumined by the day, those parts, if the object be white, will appear of a light blue, as may be seen when candles are lighted and placed on a table-cloth, where rays of twilight can reach. The warm colour thrown off by the flame of the candle, imparts its nature to whatever it illumines, and as it is nearly yellow, it renders white and yellow very nearly alike in hue, and makes green appear blue, and purple nearly so. This renders it a difficult matter to paint by candle-light for a day-light exhibition. The artist must

## L I G H T.

rely very much upon his judgment and previous knowledge of his colours who attempts it, or all the delicate admixture of tints and hues will escape him. Rubens has very frequently succeeded in the admixture of lights, and in one picture particularly, his beautiful work of "St. Roch interceding for the unhappy Sufferers from the Plague." And Titian has rendered most beautifully the effect of three lights, *viz.* those of the day, of fire, and of candle, in his grand work of "The Martyrdom of St. Lawrence;" and has contrived to produce one harmonious tone over the whole, while each part is characteristically maintained.

LIGHT, in *Sea Language*, is used in contradistinction to laden. A ship is accordingly called light, either when she has no cargo, or when she is not sufficiently ballasted.

LIGHT is also used for the luminous body that emits it. There are various kinds of lights; *general* lights, as the air; *particular* lights, as a fire, a candle, and even the sun.

LIGHTS, in *Architecture*, denote doors, windows, and other places, through which the air and light have a passage.

In the Pantheon, all the light comes from on high; it has no lights but in the dome.

LIGHTS, in *Gardening*, a term applied to the moveable glazed sashes which cover garden and other frames; and which, according to the number of lights, or separate moveable glasses, are denominated one-light, two light, and three-light frames; these being the most general different sizes of this sort of frame. See FRAME and GARDEN-FRAME.

LIGHTS, *Fest of*. See DEDICATION.

LIGHTS, *Stopping, of a house*, is a nuisance; but stopping a prospect is not, being only matter of delight, not of necessity. If a man has a vacant piece of ground, and builds thereupon a house, with good lights, which he sells or lets to another; and afterwards builds upon ground contiguous, or lets the same to another person, who builds thereupon to the nuisance of the lights of the first house; the lessee of the first house may have an action of the case against such builder, &c. And though formerly they were to be lights of an ancient messuage, that is now altered.

LIGHT-HORSE, an ancient term in our English customs, signifying an ordinary cavalier, or horseman lightly armed, and so as to enter a corps or regiment; in opposition to the men at arms, who were heavily accoutred, and armed at all points. See CAVALRY and HORSE.
