But as these learned philologists have only dissected our alphabet, and analysed the pronunciation of our language, as far as concerns its articulation in speech, we shall examine it with respect to lyric poetry and singing, to which our remarks will be strictly confined.

If it be considered that of the five vowels in European alphabets, only two, *a* and *e*, are favourable to the clear emission of vocal sound; that of the nineteen consonants eight are absolutely mute, as *b*, hard *c* and *g*, *h*, *k*, *p*, *q*, *t*; seven semi-mute, that is, allowing only a murmuring noise, but no musical found, as *f*, *m*, *n*, *s*, *v*, *x*, *z*; that the soft *g* and consonant *j* are likewise of this kind; and that *r*, though accounted a liquid, only admits of a snarling, canine kind of a noise; *l*, indeed, is a true liquid, allowing a continuation of sound after it is formed; and *w* and *y* may be accounted semi-vowels; yet so numerous are the impediments to a neat, clear articulation, as well as sweetness and purity of musical tones, that some care should at least be used by the lyric poet in the selection of words, as well as great precaution by the composer, who gives them a melody.

If our alphabet be critically examined, in order to discover the effect which each letter has upon the voice in singing; it will be found that peculiar letters, as well as combinations of letters, have peculiar vices and tendencies to impede or corrupt musical sounds, both in their formation and passage: that *f* admits only of a whisper; for though regarded as a semi-vowel on account of its allowing us to breathe after it has been pronounced, without altering the form of the mouth; yet, as Dr. Holder has well observed, "it is one thing to breathe, and another to vocalise that breath." *M*, *n*, and *ng*, likewise allow us to breathe; but as it is only nasal breath, the sound we are able to emit is *stuffy* and impure. *S*, and its substitute, soft *c*, are *hissing*; *v* and *z* afford only a *jarring* buzz, by the vibration of the teeth and underlip, like that of a wasp or bee; *th*, cannot be uttered without a *hiss*; and the Saxo-Norman syllables *ble*, *cle*, *fle*, *gle*, *kle*, *ple*, *tle*, are all unmusical, and of difficult utterance.

The vowel *a*, according to our manner of founding it in the words *all*, *ball*, *call*, &c. affords the purest and most open passage to the voice through the mouth; and long divisions and vocal effusions should be appropriated as much as possible to this vowel, which is still more convenient to the singer when combined with no other letter, which alters the form of the organ. *O*, a lows a free passage to found; yet, as it separates the lips and teeth less than the letter *a*, it is in less favour with singers: however, the English words *blow*, *slow*, *glow*, *flow*, *woe*, &c. are well calculated for musical divisions. *E*, *i*, and *u*, partake of the nature of consonants, by putting the organs of speech in motion when they are first founded; and in dwelling upon these vowels no *voce di petto*, no voice can be produced from the chest, as they confine it to a small part of the mouth, or render it nasal. Indeed, the *u*, by almost closing the lips, allows but a very narrow and inconvenient passage to the voice; the *i* and the *e* are more favourable to a falset, a *voce da testa*, or feigned voice, than to a true *portamento*, or conduct of the voice.

Tosi, in his "Opinioni de' cantori antichi e moderni, o sieno osservazioni sopra il canto figurato," or florid song, fourscore years ago, recommended the exercising of the voice upon the three open vowels, which, with the Italians,

are *a*, *e*, *o*, equivalent to our *aw*, *a*, *o*. The Italian *i*, founded like our double *e*, and *u* as our double *o*, are never honoured with divisions or long sounds by the best composers or singing masters of Italy.

As open vowels are the most desirable to singers; so distinct, determinate, and uncompounded consonants, are the best crutches for the voice to lean on; for a neat, clear, and articulate pronunciation of consonants is as necessary to the intelligence of what is singing, as open vowels are to its being well sung. The letters *p*, *t*, *k*, for instance, are such clear and distinct articulations, that the voice, after any one of them, is delivered with a gentle kind of explosion, which considerably augments its force.

The *i*, in English, as it is founded in the word *smile*, and which is so peculiar to English mouths, seems a diphthong, compounded of *e* feminine, and *y*, or the Greek diphthong *ei*, or rather the German *ei*, as founded in *eisenac*, *eichner*, &c. and not a simple, or original vowel. Indeed, most of the diphthongs in our language require action in the organ, and spring in the muscles, as *oy*, *oy*, *eu*, *ou*, in the words *boy*, *boy*, *Europe*, *our*.

As accent and emphasis have great influence in varying the found of oral language, they are not indifferent to vocal melody: the Italian tongue, though it is easy to pronounce, and soft and mellifluous to the ear, from the openness and frequency of its vowels; yet the articulations of its consonants are more firm, vigorous, and poignant, than in any other language; and as every dialect has peculiar inflections of voice which form a kind of *tune* in its utterance, the Italian seems to have a greater compass and variety of intervals in this colloquial *tune*, or *cantilena*, than any other with which we are acquainted.

Diomedes calls accent the soul of speech, *anima vocis*. And every word of more than one syllable in prose, must have one emphatic or accented syllable among the rest. However, in verse, this rule cannot be observed without absurdity.

"Of man's first disobedience, and the fruit  
Of that forbidden tree," &c.

"Awake my Saint John, leave all meaner things  
To low ambition, and the pride of kings"

In each of these two last verses, were they set in recitative, which is the best musical criterion of accenting any language, there can only be two emphatic, accented syllables: as in Handel's opening of "Alexander's Feast;"

"'Twas at the royal feast, for Persia won"

A syllable in English, as well as Latin, which has two consonants after a vowel, is long, except one of these consonants be mute, and the other a liquid, as in *rêgret*, *rêplète*. Indeed, the accented syllable in our words which have double consonants, is short: so that accent and long do not always imply the same thing. In the case of double rhymes this rule should be observed: as *pleasure*, *measure*, *manner*, *banner*; which should all have short notes. Here *accent* and *quantity* certainly differ. By applying Italian melody to English words, we seem to lose in sense what we gain in found. The universality of double rhymes in Italian poetry must have an influence upon vocal melody, which our single rhymes but awkwardly imitate.

Dacier, in a note to his translation of Plutarch's Life of Lycurgus, says, that "the progress of music, in all times, has ever been proportioned to the genius and language of the people." The ancient Romans, though great in arms, agriculture, and literature, were not successful cultivators

of the fine arts; and nothing was achieved in them, throughout their empire, but by Grecian artists. For this we may, however, account, by the slaves only being allowed to cultivate the polite arts, among the Romans; whereas, in Greece, on the contrary, they were wholly prohibited their use.

No visionary innovation, or fantastical change, is here intended, in a language so excellent as our own for every purpose of reason, science, philosophy, and we may surely add, poetry; all we would recommend, is care to our lyric poets in the selection and arrangement of syllables, as well as unity of subject (see Italian Tour. p. 48, and our articles SONG, SYMMETRY, and UNITY of *Melody*), and attentive observance to the composers who let them to music, not to dwell on harsh, mute, nasal, or guttural words, which either preclude or vitiate all musical sound.

*Song* and *sing*, unfortunately, the two most common words in our lyric poetry, begin by a *hiss*, and end with a sound entirely nasal; and if we examine the syllables which terminate each line in Dryden's Ode on St. Cecilia's Day, the best of our lyric poems, and perhaps the most noble production, to read, of modern languages, we shall find that the dead letter *d* predominates; terminating in the course of the poem no less than two or three and thirty lines; in more than half of which, this hard and dumb letter is preceded by *n*, which, though it does not wholly silence the voice, yet allows it no passage, but through the nose. However, this junction is not so injurious to vocalised sound, as *ng* in the words *sung*, *young*, *beginning*, *winning*, *destroying*, *enjoying*; or *z* and *z* in *ears*, *hears*, *spheres*, *comes*, *drums*, *prize*, *skies*, &c. which terminate each musical phrase or period with a hiss. The impervious consonant *t*, in *state*, *state*, *state*, &c. preceded by a vowel, is less difficult to pronounce, and less offensive to hear, than the sibilation in *breath*, *oppress*, &c.

Admirable and sublime as this ode is in the perusal, some of the lines are extremely difficult to sing, without injuring either the poet or musician; the first, by a languid and inarticulate utterance, or the latter by a pronunciation-too rough and violent. The recitatives may, with propriety, admit of strong accentuation, as only such a portion of sound is wanting as will render the words more audible, and nearer singing, than mere speech: but as recitative is the medium between declamation and musical air, some attention seems necessary in selecting the words, and polishing the verses, even for this narrative melody; in slurring harsh alliterations, such as in the lines, *thrice he flew the plain—the sweet embusiasm from her sacred shore*, &c. where there is a constant and unavoidable hissing upon all the accents; and in placing such words at the pause, or hiatus, in the middle as well as at the end of each line or verse, where the punctuation requires a repose, or long note, as will neither wholly silence the voice, nor impede its expansion. If such precautions should be thought necessary for words of quick utterance in recitative, still more solicitous should the lyric poet be in the choice and arrangement when he writes an air, where every syllable is lengthened and vocalised, and where the vowel in each is all that the composer can tune, or the finger sweeten and refine.

It is very natural for poets to wish that the language, in setting it to music, should be more respected than it has generally been, particularly in our church compositions, by old masters, which the late Mr. Mason, in his "Anthem Book for York Cathedral," has very justly censured; but he commends Tucker, who was gentleman of Charles II's chapel, for his very accurate attention to accent and length of syllables; and sums up the excellencies and defects of

our ecclesiastical composers brought up in the King's chapel, after the Restoration, by speaking with exact discrimination of "the pleasing melodies of Wile; pathetic airs of Clarke; majestic movements of Blow; and sublime strains of Purcell."

But Purcell, the pride of every Englishman who loves music, was, in general, not only accurate, but happy and touching in the expression of words. Many of his melodies are, however, now become wholly obsolete and uncatch, from the temporary graces, with which he overladed them, for the sake of ignorant fingers; and, indeed, he wrote for no other. But these being the firebells and flourishes of a particular period, are very short-lived, and soon disgrace that melody which they were intended to embellish.

LANGUAGES are in general divided into *original* or *mother-tongues*; as the Hebrew and Arabic, in the East; the Teutonic and Slavonic, in the west.

LANGUAGES, *Secondary*, or *derivative*, which are those formed out of a mixture of several others, as Latin, French, &c.

Kircher will have the Coptic a mother-tongue independent of all others. See *Coptic*.

Du Jon maintains the Gothic a primitive language, and the mother of all the Teutonic tongues; that is, of all those spoken in the north. See *Gothic*.

Some add the Basque, or Biscayan, and Bas Briton, to the number of mother-tongues, imagining them to have been those of the ancient Celtæ, or Gauls.

LANGUAGES, *Learned*, or *Dead*, are those which only subsist in books, and which must be learned by the rules of grammar; as the Greek, Hebrew, Syriac, and Chaldee.

Raymond Lully solicited the establishment of the study of the learned languages a long time, in the thirteenth and fourteenth centuries. At length, in the year 1312, pope Clement, and the council of Vienne, appointed, that in the court of Rome, and in the universities of Paris, Oxford, Bologna, and Salamanca, there should be instituted professors of each, who should have salaries from the respective courts. The monks, however, vigorously opposed the spreading of these studies; and with so much success, that Erasmus tells us, in his time, "Græce nosse suspectum, Hebraice prope hæreticum."

LANGUAGES, *Living*, are those still spoken in some country or other; and which may be learned by conversation. The most popular among these are the French, Italian, Spanish, and English.

The Spaniards seem to place the nobleness and gravity of their language in the number of syllables, and the swelling of words; and speak less to be understood, than to be admired. Their terms are sonorous; their expressions haughty; pomp and ostentation run through all they say; their language cannot paint a thought to the life; it always magnifies it; frequently distorts it; and does nothing, if it does not exceed nature.

The Italian tongue does not swell up things to that degree, but it adorns and embellishes them more; yet these ornaments and embellishments are not real beauties. The Italian expressions, thus rich and brilliant, are like those faces covered with patch and paint, which make a fine show; but the finery is all deceit.

The French language (as some of their authors express themselves) is simple, without lowness; bold, without indecency; elegant and florid, without affectation; harmonious, without swelling; majestic, without pride; delicate, without softness; and strong, without roughness. Though, as to the points of strength and majesty, the French must give

give way to the English; which in these, as well as in copiousness, exceeds most of the living languages; as far as it is inferior to some of them in smoothness and delicacy.

Of all the modern languages, the French is generally allowed to be the most clear, and fit for philosophical and critical subjects; the chaste and most reserved in its diction; the most judicious and severe in its ornaments.

The language of France, for vocal purposes, may be compared with that of Italy. That the Italian language is favourable to the pure emission of sound, and consequently to singing, and the French the contrary, none but a native of France will dispute. Yet M. Framery, a man of taste and knowledge of music, and who sometimes seems to feel and acknowledge the defects of French music and its language for vocal purposes, says in the *Encyclopédie Methodique*, p. 235: "de célèbres compositeurs, Messrs. Duni, Gluck, Piccini, Sacchini, ont dit, ont écrit, qu'ils aimoient mieux composer sur la langue Française que sur la langue Italienne!" *credat Judæus*. M. Framery never surprised us more, or convinced us less. These composers may have said something flattering to the French, in public about their language, while at Paris; but in private, Gluck and Sacchini, to our knowledge, spoke of French as a musical language with no great respect. The Italians have often pretended, in Scotland, to prefer Scots tunes, and in Ireland, Irish, to Italian music. Geminiani and Tenducci did this in both countries; but in England, and among their own countrymen, they turned to ridicule both these national musics, more than they deserved; for though, when sung by fine singers, they lose their chief merit of originality and simplicity, when sung by the natives, they are extremely pleasing, and often truly touching.

Of all others, the English is said to be the most honest, open, and undefining language. With all its sublimity, it is gay and pleasant on occasion; but its gaiety is still moderated and restrained by good sense; it hates excessive ornaments; and, for the greater simplicity, would almost choose, as some say of the French, to go naked; it never dresses more than decorum and necessity require.

The English language is derived from so many and such different sources, that, on this account, it is deficient in regularity and analogy. Yet we have this advantage to compensate the defect, that what we want in elegance, we gain in copiousness, in which last respect few languages will be found superior to our own. See ENGLISH.

Ennius and Cæcrops are celebrated for their knowledge of many languages. Mithridates, king of Pontus, it is said, understood twenty-two tongues, which was the number of different people over whom he commanded; and those languages he knew so well, that he was able to harangue each of his people in their own tongue. It was a saying of Charles V. "That so many languages as a man understands, so many times he is a man." Sultan Soliman's interpreter spoke perfectly well seventeen different languages. But among the moderns, none has been more remarkable in this way than Pottellius; who, besides a perfect knowledge of all the dead languages, was so well acquainted with the living, that it is said he could have made the tour of the globe, without the use of an interpreter. See our article JONES, *Sir William*.

Biblander has written of the analogy and proportion of languages and letters, *De Ratione Communi Linguarum*, in 1518. Gesner, of the *Difference of Languages*, in 1572. Lazius published an Introduction to the Learning of the politer Languages, in a common Method, in 1548. Messiaser, a scheme of forty different languages, and different dialects, specimens of each whereof he gives in the Lord's

prayer, in 1593. De Recols, in his Addition to the *World of Daviti*, has published the *Pater-noster* in all the languages spoken among Christians; and Mr. Chamberlayne proposed to do the same in a hundred languages, a specimen of which has been published. Albericus Gentilis wrote of the mixture of languages, in 1633. And father Reiznier's *Discourse on Etymologies*, is a work of the same kind. In 1613, Durer published a treasure of the history of all the languages in the universe. Guichart has a treatise of the etymological harmony of languages, published in 1619. Brewwer has given us curious enquiries into the diversities of languages and religions, published in 1635.

LANGUAGE, *Philosophical*. See CHARACTERS, *Universal*.

LANGUAGE is also used, in the order of Malta, for *nation*. The knights of Malta are divided into eight languages; three whereof are for France; *viz.* the languages of Provence, of Auvergne, and of France; two for Spain, those of Castile and Arragon; the other three are the languages of Italy, England, and Germany.

Each of these languages has its chief, who presides in assemblies of the language to which he belongs. See MALTA.

LANGUAGE, *Frank*. See FRANK.

LANGUAGE *Hellenistic*. See HELLENISTIC.

LANGUAGE, *Law*. See LAW LANGUAGE.

LANGUED, LANGUAGE, in *Herakly*, is applied to such animals whose tongues appear out of their mouths: being of a colour different from that of the body of the animal.

LANGUEDOC, OCCITANIA, in *Geography*, a portion of Gallia Braccata, a maritime province (as it was denominated before the revolution,) bounded on the N. by Guienne, Auvergne, and Lyonnais, on the E. by the Rhone, on the S. by Foix, Roussillon, and the Méditerranæan, and on the W. by the Garonne. It lies between 42° 40', and 45° 20' N. lat., and between 1° 20', and 4° 45' E. long. In 43° 30', the parallel of Toulouse nearly, it extends 53 leagues from W. to E.; but towards either extremity, it does not exceed 33. Its breadth, for the greatest part, is 33 to 38 leagues, except towards the middle, where it scarcely amounts to 40 miles. The coast from Agde eastward is considerably augmented, the sea having retired, as appears by comparing the situation of the maritime places in ancient and modern times. The surface of this province consists of mountains and vallies, hills and plains. In the mountains, called the Cevennes and its branches, which are partly covered with forests, there are lead and iron mines. The lower tracts are fertile, and well watered, yielding grain, wine, and fruit; but one-half of the province is of an ungrateful and unproductive soil. The principal rivers are the Rhone, Garonne, Loire, Gardon, Villed, Erault, Orbe, Aude, Arriege, Allier, Tarn, and Lot. In this province many canals have been formed for commercial purposes.

Languedoc has been sometimes divided into Upper, Lower, and the Cevennes; the Upper, including nine dioceses, the Lower, containing 11 bishoprics, and the Cevennes, comprehending three. Geographers have divided this province into Upper and Lower; containing three archbishoprics, 23 bishoprics, 61 abbies, 637 priories, 353 religious houses, 60 commanderies, 200 towns and villages, 2 universities, 6 academies, 1000 ecclesiastical, 342,758 families, and 1,560,000 inhabitants. The ecclesiastical division has been differently arranged since the revolution. The capital of Upper Languedoc was Toulouse, and of Lower Languedoc, Montpellier. It is now divided into seven departments, *viz.* the Ardèche, Lozere, Gard, Herault, Tarn, Upper Garonne, and Aude.

LANGUENBRUCK, a town of Switzerland, in the canton of Soleure; 14 miles N.E. of Soleure.

LANGUEPOUR, a town of Hindooſtan, in Bahar; 43 miles S.S.W. of Bahar.

LANGUET, JOHN BAPTIST JOSEPH, in *Biography*, ſon of Denis Languet, attorney-general to the parliament of Dijon, in which city he was born in the year 1675. He received the elementary parts of his education in his native place, and then went to purſue his ſtudies at Paris, where he reſided at the ſeminary at St. Sulpice. In the year 1698, he was admitted a licentiate of the faculty of the Sorbonne, and was ordained, ſoon after, a prieſt at Vienne, in Dauphiné. He returned to Paris, took the degree of doctor in 1703, and attached himſelf to the community of St. Sulpice, where, by the exertions of his benevolent labours, he rendered himſelf uſeful that he was choſen curate to M. de la Chetardie. The duties of this appointment he diſcharged ten years, and ſold his eſtate, that he might have it in his power to relieve the neceſſities of the poor. In the year 1714, he ſucceeded to the living of St. Sulpice, and finding the church much too ſmall for the number of his pariſhioners, he conceived the deſign of building a place that ſhould excel every other church in the world in magnificence, and architectural decorations. This great work he accompliſhed by means of donations, which poured in from all quarters the moment his intentions were made known. It was conſecrated, in the year 1745, with ſo much ſplendour, that Frederic II., king of Pruſſia, was induced, from an account which he read of the proceedings on that occaſion, to ſend a polite complimentary letter to M. Languet. He eſtabliſhed likewiſe “La Maifon de l'Infant Jeſus,” intended for the accommodation of 30 or 40 poor ladies of noble deſcent. Here they were boarded and educated in a manner ſuitable to them, but at the ſame time were taught to be uſeful. They were employed, by turns, in attending to domeſtic concerns, and in other offices that would render them ſerviceable to their relations in the country. Another object of this eſtabliſhment, was to afford an aſylum to more than eight hundred poor women and girls delitute of the means of ſupport, belonging either to the city or country. They were provided with daily food, and were made to earn their ſupport, chiefly by ſpinning cotton and linen. Without entering into the minutæ of the regulations of the place, it is ſufficient to ſay, that this eſtabliſhment has proved a moſt happy retreat for numerous unfortunate females, who had been abandoned, by infamous betrayals, to diſeaſe and wretchedneſs. Here, by good example and excellent moral inſtruction, they have been recalled to virtue, and habituated to induſtry, and many of them have proved uſeful and honourable members of the ſociety. For their encouragement when they quitted the houſe, they were paid in money the amount of what they had earned by their labour. Though the land attached to the houſe conſiſted of only fourteen French acres, yet it fed a ſufficient number of cows to give milk for upwards of two thouſand children in the pariſh; it alſo contained conveniences for pigs and all kinds of poultry, which were ſold for the benefit of the inſtitution; a bakehouſe, furniſhing more than a hundred thouſand pounds of bread monthly, which was diſtributed among the poor of the pariſh; ſpinning-rooms, an excellent and well cultivated garden, a noble diſpenſary, &c. The management and regularity with which every department in this houſe was conducted, either for the inſtruction, employment, or ſupport of ſuch a number of perſons, were to admirable, and gave ſo high an idea of the great directing hand, that cardinal Fleury propoſed that Languet ſhould be appointed ſuperintendent of all the hospitals in the kingdom; to whom he answered with a ſmile, “I have always ſaid, my lord, that the bounty of your eminence led me to the

hospital.” M. Languet's benevolent exertions were not confined to the objects already mentioned, but extended to the poor and wretched of every deſcription. No perſon was ever more active and ſucceſsful than himſelf in obtaining large alms and conſiderable legacies, which he diſtributed with admirable prudence and diſcretion. It is ſaid, on good authority, that he diſburſed about a million of livres in charity every year. Noble families reduced to poverty, were among the prime objects of his benevolent attention. At the time of the great dearth in 1725, in order that he might relieve the poor, he fold his houſhold furniture, his pictures, and curious and rare pieces of workmanſhip, and, in ſhort, ſcarcely left himſelf the bare neceſſaries of life. He was among the firſt to be preſent at fires, or any other ſcene of public calamity, where his prudence, ſelf-poſſeſſion, and univerſally reſpected character, rendered his advice and exertions eſſentially ſerviceable. He had a wonderful talent in diſcovering the different diſpoſitions of mankind, and he knew how to employ every perſon according to his capacity. This excellent man declined the offers made of ſeveral biſhoprics; his great ambition was to do good, and he had ample means for this as a pariſh prieſt. He died in the year 1750 at the age of ſeventy-five. His piety and application to works of benevolence did not prevent him from being a lively and cheerful companion. He poſſeſſed a fine genius, and was highly delighted with cheerful and amuſing ſociety. His younger brother, named John Joſeph, born at Dijon in 1667, roſe to conſiderable eminence in the church, and was 40 years archbiſhop of Sens. He died in 1753. He took a very diſtinguiſhed part as a controverſiaſt, in defence of the bull “Unigenitus,” and diſplayed much learning and acuteness in his polemical pieces, which were tranſlated into Latin, and printed in 1753, in two volumes folio. He was author of “A Tranſlation of the Book of Pſalms,” and of diſcourſes published in the collections of the French academy. Moreiri.

LANGUET, HUBERT, was born at Viteaux, in Burgundy, in 1518: after a preliminary courſe of inſtruction in his own country, he went to Italy for the ſtudy of the civil law, and took a doctor's degree at Pavia. Having met with a book of the reformer Melancthon's, he felt a great deſire of ſeeing the author, and, in 1549, procured an interview with him at Wittenberg, which terminated in his converſion to the Proteſtant faith. After this he ſpent ſeveral years in travelling over different countries in the north of Europe; in his tour he became acquainted with Gullavus, king of Sweden, who gave him a commiſſion to invite perſons ſkilful in the arts and ſciences from France to his dominions. In 1559, he accompanied Adolphus of Naſſau, prince of Orange, into Italy; after this he was nominated by the elector of Saxony to be his envoy to the court of France. He was deputed by that prince to the aſſembly of the ſtates of Augſburg in 1568, and was employed by him in other important negotiations. He was again ſent to France in 1570, when he pronounced a bold and eloquent harangue in the name of the Proteſtant princes of Germany before Charles IX. He reſided at Paris during the bloody maſſacre of St. Bartholomew, and expoſed his own life to danger by his efforts in ſaving his hoſt, Andrew Wechel, the famous printer, and his friend, Dupleſſis Mornei. After accompliſhing various other miſſions to the ſatisfaction of his employers, he died at Antwerp in September, 1581, at the age of 63, greatly regretted by all who knew him. The prince of Orange, in whoſe ſervice he had been employed, walked as chief mourner at his funeral. He was a man of pure virtue in corrupt and difficult times: “He was,” ſays one of his biographers, “ſuch as many would wiſh to appear; he

he lived as good men would wish to die." His works are "Collections of Latin Letters to the Elector of Saxony, to Camerarius, Father and Son, and to Philip Sidney;" "A Relation of the Expedition of the Elector Augustus against the Revolters of Saxony; with the History of the Proceedings of the Emperor against that Prince;" "Vindicia contra Tyrannos," which is a spirited attack upon tyranny, and a defence of the rights of the people. This appeared soon after Languet's death, and coming out with the name of Stephanus Junius Brutus, was attributed to various persons, but has been ascertained to have been the production of Languet. Bayle. Moreri.

LANGUETTE, *Fr.* the tongue of a jack in a harpsichord or spinnet; the valve which opens and shuts the wind chest in an organ to let the wind into the pipes, when a key is pressed down.

LANGUIDO and LANGUENTE, *Ital.* musical terms for a languid or languishing air.

LANGUOR, a faintness and indisposition to exertion, commonly accompanied with a lassitude or weariness, and arising from a feverish state, or from a general debility of the nervous and circulating systems.

LANGUR, in *Geography*, a mountain of Thibet; 40 miles E. of Tankia.—ALŌ, a river of Mingrelia, anciently *Astolpus*, which runs into the Black sea, about two miles from Anarghia.

LANGUT, a town of Prussia, in the province of Oberland; 10 miles S.E. of Morangen.

LANGWIESE, a town of Bohemia, in the circle of Leitmeritz; 20 miles W.N.W. of Leitmeritz.

LANJAN, LANDJAM, or *Lanjang*, a city of Laos, and capital of the kingdom, or at least of the southern division, to which it gives name, and the usual residence of the king; situated on the W. side of the river Mecon, and defended on the land side by ditches and high walls. The palace is of wide extent, and appears like a city, from its size and the number of people who inhabit it. The houses of the principal persons are high, elegant, and richly ornamented; those of the lower people are mere huts. The priests alone have the privilege of building their houses of brick or stone. N. lat. 18° 30'. E. long. 101° 38'.

LANIARDS. See LANNIERS.

LANJARON, in *Geography*, a town of Spain, in the province of Granada; 15 miles S. of Granada.

LANIERE, NICOLÒ, in *Biography*, was an Italian, who came into England early in the last century; there is a fine portrait of him at the Grange, in Hampshire, by Vanduyke. It was the sight of this portrait that determined Charles I. to employ that excellent painter. Lanieri professionally practised music, painting, and engraving; but his greatest excellence was in music. His own portrait, painted by himself, is in the music school at Oxford. He etched a considerable number of plates for a drawing-book; was an able connoisseur in pictures; and had the art of giving modern paintings an air of antiquity, and putting off copies for originals. Granger's Biog. Hist. of Engl. vol. i. p. 539.

It is recorded in the folio edition of Ben Jonson's works, printed 1640, that, in 1617, his whole masque, which was performed at the house of lord Hay, for the entertainment of the French ambassador, was set to music after the Italian manner, *silo recitativo*, by Nic. Lanieri, who was not only ordered to let the music, but to paint the scenes.

This short piece being *scabolly* in rhyme, though without variation in the measure, to distinguish airs from recitation, as it was all in musical declamation, may be safely pro-

nounced the first attempt at an opera in the Italian manner, after the invention of recitative.

But in the same year, in the masque, by the same author called "The Vision of Delight," presented at court during Christmas, there is a manifest distinction of *air* from *recitative*; in both which styles the whole piece, in verses of different measures, was performed. It is opened by Delight, personified, who, *silo recitativo*, "spake in song." Then Night, likewise personified, sung, "Break Fancy from thy cave of cloud, &c." This air ends in a chorus or *quire*. After which Fancy spake, in *silo recitativo*. Then Peace sung, "Why look you so, &c." After which an air that terminates in a *quire*. The song ended, "Wonder spake," in recitative. Then dancing, singing, and chorus.

Here we have all the characteristics of a genuine opera, or musical drama of modern times, complete: splendid scenes and machinery; poetry; musical recitation; air; chorus; and dancing.

Though the music of this masque is not to be found, yet of Lanieri's "Musica narrativa" we have several examples, printed by Playford in the collections of the time; particularly the "Ayres and Dialogues," 1653, and the second part of the "Musical Companion," which appeared in 1667; and in which his music to the dialogues is infinitely superior to the rest: there is melody, measure, and meaning in it. His recitative is more like that of his countrymen at present, than any cotemporary Englishman's. However, these dialogues were composed before the laws and phraseology of recitative were settled, even in Italy. His cantata of "Hero and Leander" was much celebrated during these times, and the recitative regarded as a model of true Italian musical declamation.

LANIGEROUS, any thing that bears wool. Hence, LANGEROUS, or *Languginus Trees*, among *Herbalists*, are those trees that bear a woolly downy substance; as, the black, white, and trembling poplars, oifers, and willows of all sorts.

LANINA, in *Geography*, a town of Russia, in the government of Irkutsk, near the Baikal lake; 80 miles N.E. of Irkutsk.

LANINI, BERNARDINO, in *Biography*, an historical painter, native of Vercelli, and a pupil of Gaudenzio Ferrari. He imitated the style of that master, in his first works, to a degree of illusion. As he advanced in practice he cast a bolder eye on nature, and, by equal vigour of conception and execution, proved to the first artists of Milano, that, like Ferrari, he was born for grand subjects: such is that of St. Catarini, near S. Celso; the face and attitude of the heroine anticipate the graces of Guido; the colour of the whole approaches the tones of Tiziano; the glory of the angels rivals Gaudenzio; a less neglected style of drapery would have left little to wish for. Among his copious works at Milano, and in its districts, the dome of Novara claims distinguished notice. There he painted those Sybils, and that semblance of the eternal Father, so much admired by Lomazzo, and near them certain subjects from the life of the Virgin, which even now in a ruined state of colour enchant by spirit and evidence of design. His versatile talent indulged sometimes in imitations of Leonardo da Vinci; and at the Basilica of St. Ambrogio, the figure of Christ between two angels, in form, expression, and effect, fully proves with what felicity he penetrated the principles of that genius. Fuseli's Pilkington.

LANIS *de crescentia Wallie traducuntis aliquæ custumæ,* &c. an ancient writ that lies to the customer of a port, to permit

permit one to pass wool without paying custom, he having paid it before in Wales.

**LANISCHLE**, in *Geography*, a town of Iliria; 16 miles S.E. of Capo d'Iliria.

**LANISTA**, in *Antiquity*, is sometimes used to signify an executioner, but more frequently for a master gladiator, who taught the use of arms, and had always people under them, ready to exhibit shows of that kind. For which purpose they either purchased gladiators, or educated children, that had been exposed in that art.

**LANISTA** was also used to denote one who taught game-cocks to fight.

**LANIUS**, in *Ornithology*, a genus of the rapacious tribe, having the bill rather straight, with a tooth, or notch, on each mandible near the end; the base naked; and the tongue jagged at the tip. To this character, assigned by Gmelin after Linnæus, may be added, that the nostrils are generally round, and covered with stiff bristles. Dr. Latham observes still further, that the birds of this genus are not furnished with a cere at the base of the bill, and that the middle toe is connected to the next as far as the first joint. Lastly, according to Scopoli, the segments of the tarsi are seven in number.

Linnæus, in the various editions of his *Systema Naturæ* and other works, has referred this genus of birds to several distinct families, having sometimes placed it with the chattering, sometimes with the titmice, and then again, from its habits of rapacity, with the accipitres, in which last-mentioned order it stands in the Gmelinian edition of that author's publication. Before the time of Linnæus, our countryman, Ray, had classed this tribe among the short-winged hawks: Buffon also had arranged it after the falcons; but Brisson, on the contrary, includes them with the thrushes and the chatters, two analogous genera, which obviously belong to the order passeræ. Kramer introduces it under the passerine order; Scopoli under the pies; and Pennant, in his "Genera of Birds," with the accipitres; from which, however, the latter writer removes it to the order pieæ, in a subsequent edition. Gmelin retains it still in the accipitrine order. In Latham's "Synopsis," and also in his "Index Ornithologicus," the example of Scopoli is followed; the shrikes are disposed at the head of the order pieæ, and this arrangement has obtained the sanction of the French ornithologists. We are far from wishing to intrude a solitary suggestion against established opinions, and those too of acknowledged merit; yet, on a point in which so much difference has prevailed, a suggestion may be allowed. The shrikes then appear to us, at least in a general view, less intimately connected with the pies than the falcon tribe, though confessedly allied to both; and in defining the precise line between, it is not impossible that a future era will concur in the accuracy of Gmelin, who incorporates them with the accipitres; or, in reverting still farther back to the example of Ray, our enlightened countryman, place them as the last of the falcon tribe.

The birds of this genus are dispersed throughout most parts of the globe: they are generally of a noisy, restless, quarrelsome, and ferocious disposition; prey on all the smaller kinds of birds as well as insects. The manner in which they destroy their prey is almost, if not entirely, peculiar to themselves, and evinces a degree of address and cruelty that has not inaptly obtained them the name of butcher-birds. Afterouncing upon their destined victim, which they usually seize upon in a defenceless state, while young, and in the nest, they bear it away to some thorny bush, and by the dint of dexterity force it upon one of the stoutest

and sharpest spines; after which they proceed to tear the yet living creature into pieces, separating its mangled remains by the assistance of their bill and talons, and dispersing on different spines of the bush such remnants of the flesh, after being for the present satisfied, as are reserved for future meals. In this manner, the shrike tribe also treat the larger kinds of insects, as well as birds.

#### Species.

**FORKICATUS**. Tail forked; frontal crest erect; body greenish-black. Linn. *Drongo*, Buff. *Gobe-mouche huppé de Malabar*, *ibid.* *Fork-tailed shrike*.

Length ten inches; size of a black-bird; tail long, and much furcated; crest sometimes wanting. Inhabits the Cape of Good Hope, Madagascar, and China.

**CÆRULESCENS**. Tail forked; body bluish-black; belly white. Linn. *La pie-grièche a queue fourchée de Bengale*, Briss. *Le fougab*, Buff. *Fork-tailed Indian butcher-bird*, Edwards.

Inhabits Bengal, where it is called fingham: the English settlers call it also the king of the crows, from the hostile disposition they constantly evince against those birds. Its length is seven inches and a half; the tail much forked, the outer feather spotted with dirty white.

**MALABARICUS**. Body bluish-black; quill and tail-feathers black; outer tail-feathers long, and without webs, except on the outer side near the tip. Lath. Ind. Orn. *Gobe-mouche de Malabar*, Son. *Drongo de Malabar*, Buff. *Malabar shrike*.

Length seventeen inches and a half. This species inhabits Malabar.

**CASTANEUS**. Tail cuneated; body above chestnut, beneath white; crown, nape, and hind-head cinereous. Lath. *Lanius castaneus*, Gmel. *Chestnut-backed shrike*.

Country unknown. The bill, wings, and legs black; front black. Length ten inches.

**LUÇIONENSIS**. Tail cuneated; body reddish-grey; tail-feathers banded with brown at the ends; a black spot on the head, behind the eye. *Lanius lucionensis*, Linn. *La pie-grièche de Luzon*, Briss. *Luzonian shrike*.

Length seven inches and a half; bill and body above grey-brown; beneath, and on the sides, reddish, with white lines; tail rufous-grey; the tip of each feather, except the two middle ones, rufous white; legs and claws brown. According to Brisson, the inhabitants of the island of Luçon, which it inhabits, call this bird *cabecote*.

**CRISTATUS**. Tail cuneated; head crested; body reddish, beneath waved with tawny and brown. Gmel. *Bengalensis rufus*, Briss. *Crested red, or rousset-coloured butcher-bird*, Edwards. *Crested red shrike*.

**CANADENSIS**. Tail cuneated; head crested; body reddish, beneath whitish. Gmel. *Lanius Canadensis*, Briss. *Pie-grièche huppé de Canada*, Buff. *Crested shrike*.

Length six inches and a half; the bill and claws black; crest reddish; cheeks dusky, with white spots; throat and breast yellowish-red; belly cinereous; wing-coverts black, edged with white; tail black, with white dots. This species inhabits Canada.

**LUDOVICIANUS**. Tail cuneated and cinereous; body above cinereous, beneath whitish. Gmel. *Pie grièche de la Louisiane*, Buff. *Louisiane shrike*.

Inhabits Louisiana. Length eight inches; under the eyes a black band; six middle tail-feathers black, the rest white at the base and tip.

**NEGETA**. Tail cuneated, white at the tip; body cinereous, beneath whitish. Linn. *Cotinga cinerea*, Briss. *Guiraru*

*Guiraru nhegeta*, Ray. *Guirarou*, Buff. *Grey pyc of Brasil*, Edw. *Grey shrike*.

Inhabits northern Europe, Brasil, Surinam, and other parts of South America, frequenting marshy places. Length nine inches. In this species the wings and tail are blackish; wing-coverts black, with the tips dull white; primary quill-feathers black, outer tail-feathers at the tip white.

**CVIROSTRIS.** Tail cuneated; body white; back black; first five quill-feathers with a white spot. Gmel. *Collurio Madagascariensis*, Briff. *Ecorcheur de Madagascar*, Buff. *Vanga ou beurde a ventre blanc*. Buff. *Hook-billed shrike*.

Both mandibles reflected at the tips; hind-head greenish-black; greater tail-coverts obliquely spotted with white; tail-feathers in the middle, within cinereous, without black, tip white; legs lead colour, claws blackish. A native of Madagascar, where the inhabitants distinguish it by the name of vanga. It feeds on fruits, and is said to whistle well.

**COLLURIUS.** Tail cuneated; body black, beneath white; first quill-feathers white at the base. Gmel. *Pie griefche du Cap de Bonne Esperance*, Buff. *Collured shrike*.

Native of the Cape of Good Hope. Length twelve inches.

**EXCUBITOR.** Tail cuneated, white at the sides; back hoary; wings black, with a white spot. Linn. *Lanius cinereus*, Briff. *Lanius cinereus major*, Cefn. *Caftrica palombina*, Olin. *Great cinereous shrike*, Arct. Zool. Donov. Brit. Birds, &c.

This species inhabits many parts of North America and Europe, and is the largest of its tribe found in Britain, where, however, it is extremely rare. The length is ten inches. The male differs very little from the female, except that the parts beneath in the former are entirely white, while those in the female are marked with fine semicircular brownish lines. The female makes her nest of heath and moss, lined with wool and other soft substances. The species chiefly inhabits woods: it feeds on insects and small birds, the latter of which it seizes by the throat, then fixes them on a sharp thorn, and tears them to pieces. When confined in a cage, it will often, if possible, contrive to affix its food against the wires, that in like manner it may pull it afunder with its claws and bill. In countries where these birds are abundant, the husbandmen treat them with regard, being especially useful in the destruction of rats, mice, and other vermin. There are some distinct varieties of this bird: in one the body is white, the legs yellowish, and the bill and claws blackish; and another in which the lesser wing-coverts and shoulders are reddish.

**COLLURIO.** Tail somewhat cuneated; back grey; four middle tail-feathers unicolour; bill lead colour. Linn. Fn. Succ. *Lanius minor rufus*, &c. Ray. *Merule congener alia*, Ray. *Ecorcheur*, Buff. *Lesser butcher bird, flyber, &c.* Will. *Red-backed shrike*, Donov. Brit. Birds, &c.

Length seven inches and a half; the head and lower parts of the back light grey; upper part of the back, with the wing-coverts, ferruginous; the tail black, with all the feathers, except the two middle ones, more or less white at the base; the outer web of the outer feather white; breast, belly, and sides blossom-colour; legs black. In the female, the head is dull ferruginous, mixed with grey; breast, belly, and sides dirty white, with semicircular dusky lines; tail deep brown, the outer feather only white on the outer web. This species is not very uncommon in Britain, where it is considered as a bird of passage. It lays six white eggs, marked with a rufous brown circle towards the large end.

The nest is generally placed in a hedge or low bush, near which, it is asserted, no small birds have the temerity to build, as it not only feeds on insects, but also on the young of other birds, which it seizes in the nest by the neck, and kills by piercing the skull with its bill, the brain and eyes being the parts it first devours. It is remarkably fond of grasshoppers and beetles, which it eats by morsels; and when satisfied, transfixes the remains on a thorn, to be eaten at another opportunity. This, like the grey shrike, has no note peculiar to itself: it is merely an adept in the imitative art, as its note is varied to that of any other birds it wishes to decoy within its power. Writers describe two or three varieties of this species, the most probable of which is the variegated shrike, l'Ecorcheur varie of Brisson. This is grey on the upper part of the body, and rufous-white beneath, the whole marked with transverse brown striations; the scapulars rufous-white, bounded by a parallel black stripe; the tail black, the three outer feathers rufous-white at the base and tips, the outer one wholly rufous-white on the outer edge. It is the lesser variegated butcher bird of Willughby, and is admitted as a variety by Gmelin and Latham. Gmelin is, however, mistaken in placing the following bird as another variety of the species collurio.

**RUTILUS.** Crown and nape rufous, surrounded with fuscous; front, scapulars, spot on the wing, and whole surface beneath whitish. Donov. Br. Birds. *Lanius rufus*, Briff. *Lanius rufus* (y *Collurio*), Gmel. *Lanius rufus*, Lath. *Lanius rutilus*, Ind. Orn. *Lanius pomeranus*, Mus. Carlsk. *Lanius minor cinerascens*, Ray. *Lanius minor rutilus*, Klein. *Ampelis dorjo griseo*, &c. Linn. Fn. Suec. *Pie-griefche rousse*, Buff. *Buferola*, Zinnar. *Wood-chat*, Albin, &c.

Extremely rare in Britain. Its size is equal to that of the common or red-backed shrike, and its manners, so far as we are acquainted with the species, are nearly the same, except that it never frequents woods, keeping constantly on the elevations or among the low bushes in the open plains; it inhabits Africa and Southern Europe chiefly. There is an apparent error among writers in considering the bird called by Buffon la pie-griefche rousse à tete noire du Senegal, as a variety of Lanius rufus. Levaillant describes Buffon's bird under the name of Tchagra, from the peculiar sound of its note, which resembles the repeated repetition of the words *teba-teba—teba-gra*, and assures us it is no other than a variety of the following species.

**SENEGALUS.** Grey, beneath whitish; crown, band through the eyes, and tail-feathers black; the last, except the two middle feathers, white at the tips. *Lanius Senegalus*, Linn. *Lanius Senegalensis cinereus*, Briff. *Senegal shrike*.

Length nine inches. Very common in Senegal.

**ANTIGUANUS.** Tail long and cuneated; body above yellowish rufous, beneath white, head, bill, wings, legs, and tail above black. Gmel. *Pie-griefche d'Antigue*, Sonnerat. *Antiguan shrike*, Lath.

Inhabits the Philippines and Panay ides.

**NIGER.** Black; tail somewhat cuneated. Gmel. *Black shrike*.

Native of Jamaica. Length seven inches.

**LEVERIANUS.** Tail long, cuneated, black at the tip; bill, head, neck, middle of the breast, and legs black, the rest white. Gmel. *Lanius picatus*, Lath. *Maggie shrike*.

Inhabits South America; length ten inches; greater wing-coverts and secondary quill-feathers white at the edge; two middle tail-feathers as long again as the rest, and which are black with white tips.

**RUFUS.** Rufous, beneath white; head greenish-black.

Linn. *Lanius Madagascariensis rufus*, Briff. *Schelt-bé*, Buff. *Rufous shrike*.

Length eight inches, the bill, legs, and claws lead-colour.

LEUCOEPHIALUS. Greenish-black; head, neck, and body beneath white. Gmel. &c. *Lanius Madagascariensis major viridis*, Briff. *Tcha-ebert-bé*, Buff. *White-headed shrike*.

Size of the last, and inhabits the same country.

ATRICAPILLUS. Tail cuneated, and with the neck, crown, shoulders, and wings black; body above mouse-colour, beneath blueish-ash. Merrem.

Native of Surinam. The length five inches; wings short; wing-coverts and secondary quill-feathers edged with white; tail-feathers, except the two middle ones, tipped with white.

POMERANUS. Body above black, beneath white, hind head and back of the neck dark rufous, furrounded with black; two spots on each side the wings and rump white. Sparmann.

Inhabits Pomerania; bill, legs, and wings black.

TYRANNUS. Body cinereous, beneath white; crown black, with a longitudinal tawny streak. Gmel. *Muscicapa tyrannus*, Briff. *Tyrant*, Buff. *Tyrant shrike*.

Native of America. Length eight inches. Builds in hollow trees, is fierce and audacious, and will even attack the eagle, fastening upon its back, and continuing to scream and peck with its beak till it forces the eagle to retreat. There are several varieties of this bird.

MAJOR. Grey; each side the head reddish; tail longer than the body, and pointed. *La grande pie-grièche*, Sonnini.

Size of the black-bird, the plumage greyish-ash; bill citron-yellow; legs brownish, claws black.

AFRICANUS. Body above black, beneath white, and a band of the same on the wings. *La pie-grièche silencieuse*, Sonnini.

Size of the common red butcher-bird of Europe, the bill horn-colour; iris and legs brown, and claws black. The female is rather smaller than the male, and the colours more obscure. The nest, which is constructed with much art, is placed among trees, and commonly contains from three to four eggs of a pale green colour. The young in plumage resemble the female. Inhabits Africa.

SCHACH. Body yellowish; front and wings black.

Linn. *Lanius a-foack*, Oibeck. *Chingé shrike*.

Native of Chi-na, in size resembling the species tyrannus. Head and neck on the upper part grey; neck beneath dull reddish-white; back and belly reddish.

PITANGUA. Body black, beneath yellow; crown with a tawny streak; band over the eyes white. Gmel. *Lanius pitangua*, Linn. *Pitangua guaca*, Ray. *Tyrannus Brasiliensis*, Briff. *Bentaveo*, ou *Cuiriri*, Buff. *Brafsian shrike*.

Length nine inches; bill thick, throat white; wings beneath yellow. Native of South America.

BARBARUS. Black, beneath red; crown and thighs tawny. Gmel. *Lanius Senegalensis ruber*, Briff. *Govolak*, Buff. *Pie-grièche du Seneegal*, *ibid*. *Barbary shrike*.

Length nine inches; the bill, wings, tail, feet, and claws black, head, neck, vent, and lower wing-coverts yellow. Inhabits Barbary.

SULPHURATUS. Fuscous, beneath yellow, head blackish, furrounded by a whitish band. Gmel. *Lanius Cayanensis luteus*, Briff. *Pie-grièche jaune de Cayenne*, Buff. *Beccarde a ventre jaune*, *ibid*. *Yellow-bellied shrike*.

Native of Cayenne, the length nine inches; chin and throat white; legs grey; bill and claws blackish; wings and tail brown, edged with rufous.

CAYANUS. Cinereous; head, tail, and primary quill-feathers black. Linn. *Lanius Cayanensis cinereus*, Briff. *Pie-grièche grise de Cayenne*, Buff. *Cayenne shrike*.

Size of a black-bird, the length eight inches and a half, bill at the base red, at the tip black; legs cinereous, claws black. Buffon describes a supposed variety, about the same size, that differs in having a longitudinal black streak down each feather. This is from Cayenne, as is likewise another variety of smaller size, with the front yellowish.

MADAGASCARENسيس. Cinereous, beneath whitish; lores black; tail-feathers reddish. Gmel. *Lanius Madagascariensis major*, Briff. *Calli-calie et Bruja*, Buff. *Madagascar shrike*.

Length scarcely five inches, and inhabits Madagascar. In the male, the chin and throat is black; in the female, white mixed with rufous.

AURANTIUS. Tawny yellow; chin, throat, and breast reddish; head, above the eyes, and nape black; wings and tail brown. Lath. Ind. Orn. *Orange shrike*.

Native of Cayenne. Length seven inches.

NOOTKA. Tail rounded; body above black, beneath white; crown black; collar white. Gmel. *Nootka shrike*, Lath.

Length seven inches; bill and legs black; above the eyes a white line reaching to the nape, and a black one beneath the nape; lesser wing-coverts black, greater white; tail-feathers black, the four outer white at the tips. Native of New Zealand.

EMERIA. Grey, beneath white, temples and rump red. Gmel. *Lanius Bengalensis fufcus*, Briff. *Muscicapa emeria*, Linn. *Rouge queue*, Buff. *Bengal red start*, Albin. *Bengal shrike*.

Length five inches and a half; the bill greyish-brown; crown and hind head black; abdomen and upper tail-coverts red; each side the neck four black curved spots. Native of Bengal.

JOCOSUS. Tail rounded; body grey; lower eye-lid purple; vent fanguineous red. Linn. Amæn. Acad. *Merula sinensis cristata minor*, Briff. *Jocose shrike*.

Size of a lark; length seven inches and a half, and inhabits China, where it is called Kowkai-kon.

BICOLOR. Blue, beneath white, frontlet black. Linn. Mant. *Loxia Madagascarina*, Syll. Nat. *Pie-grièche blue de Madagascar*. *Blue shrike*.

Length six inches and a half; the bill, head, margin of the quill-feathers, two middle tail-feathers, and outer margin of the four next blue, the feathers furrounding the bill, the quill-feathers, except at the base, outer tail-feathers, legs, and claws black; female beneath dirty white; tail slightly cuneated. Native of Madagascar.

LEUCORHYNOS. Body above blackish, beneath whitish; bill, breast, belly, and rump white. Gmel. *Lanius Manillensis*, Briff. *Pie-grièche de Madagascar*, Buff. *Longraien*, *ibid*. *White-bellied shrike*.

Inhabits Manila; length seven inches; wings, tail, legs, and claws black; tail equal.

FERRUGINEUS. Body above black-brown; throat and breast dirty-white; belly ferruginous. Gmel. *Ferruginous shrike*, Lath.

A native of the Cape of Good Hope; size the same as the cinereous shrike; the bill lead colour; tail dusky brown; legs black.

TABUENSIS. Body above olive; chin and breast cinereous; belly yellowish-brown; tail and legs brown. Gmel. *Tabuan shrike*.

Length eight inches; the bill brown; crown greenish; wings black on the outer edge. First described by Dr. La-

atham,

tham, from a specimen in the Leveerian Museum. It inhabits the Friendly isles.

**PACIFICUS.** Black; head and neck approaching to greenish; belly and tail more dusky. Gmel. *Pacific shrike*, Lath.

Described from an example of the species in the Banksian collection, found in one of the islands of the South seas. The bill is dusky; feathers of the head and neck very narrow; tail three inches long, dusky and even at the end; toes divided to the base, the middle one very long.

**SEPTENTRIONALIS.** Bill black; legs lead colour; body above brown; chin and breast cinereous; belly and vent brownish. Gmel. *Northern shrike*, Lath.

Length eight inches; four middle tail-feathers brown, the rest within white at the tip, and each two inches long; legs short; claws stout and brown. Native of North America.

**PILEATUS.** Head black and erected; body cinereous; throat and breast black; wing-coverts barred with white; tail black at the tip. Lath. Ind. Orn. *Black capped shrike*.

Native of Cayenne. Length six inches. Female without crest; throat and breast cinereous.

**VIRIDIS.** Head, wings, and body above dusky green, beneath white; tail black. Gmel. *Tcha-chert*, Buff. *Green shrike*.

Size of the last; the wings long; two middle tail-feathers dusky-green, the rest black at the outer edge; legs and claws black.

**VARIUS.** Body above cinereous brown; chin and breast yellow-buff; belly, rump, and vent dirty brownish-white; interfasculars white; tail and wings brown. Gmel. *White shouldered shrike*, Lath.

Described by Pennant as a native of Brazil; the legs and bill are black; front and cheeks with paler spots.

**LEUCOCEPHALUS.** White; body above greenish-black; head, neck, and under parts of the body white. Lath. &c. *Tcha-chert-bé*, Buff. *White-headed shrike*.

Length eight inches. This species inhabits Madagascar. **DOMINICANUS.** Black; belly and rump white. Gmel. *Pie-grieffche Dominicae*, Sonnerat.

Inhabits the Philippine islands; exceeds the sparrow in size; flies swift, is bold and troublesome to crows. Is by some presumed to be a variety of the preceding species.

**PANAYENSIS.** Bill and legs black; head, throat, breast, and belly red; crown, wings, and tail brown. Gmel. *Panay shrike*.

Seven inches in length, and inhabits the island Panay.

**ALBUS.** White; bill, tail, legs, and greater part of the wings, black. Gmel. *White shrike*.

Inhabits same place as the former.

**NÆVIUS.** Body above black; beneath cinereous; an oblong spot of white on the wing-coverts. Gmel. *Spotted shrike*.

Native of Cayenne; the bill and legs black; tail-feathers white at the tip.

**OBSCURUS.** Body above dusky-black, beneath white; over each eye a white line. Gmel. *Dusky shrike*, Lath.

Supposed to inhabit America; in size corresponds with *L. nævius*; the bill is horn-colour; wings and tail more dusky than the body, and the legs brown.

**FUSCUS.** Above brown, beneath white; lores, tips of the secondary quill-feathers, and edges of the primary, yellowish. Gmel. *Brown shrike*, Lath.

Bill at the tip, and legs black.

**RUBER.** Red; wings and tail with ocellar spots, black at the tips. Gmel. *Red lanius, or butcher-bird of Surinam*, Bancr. *Red shrike*.

Native of Surinam.

**AMERICANUS.** Black; spot on the first quill-feathers, cheeks, and chin white; breast and belly cinereous. Gmel.

Inhabits North America.

**MINOR.** Cinereous; chin white; breast and belly rosy; front, line over the eyes, and tail black. Gmel. *Pie-grieffche d'Italie*, Buff.

Native of Italy, Spain, and Russia, and resembles the grey shrike.

**MELANOCEPHALUS.** Bill, head, and chin black; body olive above, beneath paler; tail with a broad black band, at the tip yellow. Gmel. *Black-headed shrike*, Lath.

Length six inches, the legs dusky; and inhabits the South Sea islands.

**BRACHYURUS.** Head above rusty grey; eye-brows white; a black band from between the eyes to the ears; body above cinereous, grey, beneath yellowish-white; tail rounded. Pallas. *Short-tailed shrike*.

Size of the red-backed shrike; wings blackish; tail-feathers ten, brown-grey, and, except the middle ones, white at the tip. Native of Hungary.

**BOULBOUL.** Black; breast and belly tinged with cinereous; wings brown, with two white bands. Lath. Ind. Orn. *Boulboul shrike*.

Size of the field-fare; bill and legs yellow. Inhabits India.

**PHENICURUS.** Body above reddish-grey, beneath yellowish-white, tail long, rounded, and with the rump bright red; orbits crossed by a black band. Pallas.

Inhabits rocky places on the river Onon; size of the last.

**DOLIATUS.** Tail rounded; body closely varied with black and white lines. Linn. *Pied shrike*.

Native of Cayenne; the length six inches and a half; bill dusky, claws and legs brown; feather on the hind head long, and when erected form a crest; wings and tail with transverse white spots.

**FAUSTUS.** Grey, beneath ferruginous; a white line between the eyes; tail rounded. Linn. *Amœn. Acad.*

Size of the field-fare; bill and legs pale; wings rounded; quill-feathers brownish, grey at the edges, tail brown, and all marked with light brown decussating lines.

**LANKA,** in *Geography*, a position of some importance, referring both to the science and history of the Hindoos. It is the generally received opinion, that Lanka is Ceylon; but in a note of the *Ayin Acbaree* (vol. iii. p. 36, Calcutta ed.) it is asserted, that Lanka is not Ceylon, but a place determined by the intersection of the equator and the meridian of Delhi, answering to the southern extremity of the Maldevy islands. "Indeed," the note continues, "there are many reasons for concluding Lanka to have been part of the Taprobane of the ancients, and that Taprobane, or more properly Tapobon, which in Sanscrit means the wilderness of prayer, was a very large island, including the whole, or the greater part, of the Maldevy islands, which have since been destroyed by inundations. This agrees very well with Ptolemy's description, and his island of monies seems to relate to those of the Ramayana." See *RAMAYANA* and *TAPROBANA*.

On this note it is observed, in the *Hindoo Pantheon*, p. 328, whence this article is chiefly taken, that therein is an avowed obscurity, and an exiling error somewhere; for that many arguments, if not proofs, may be adduced in support of the identity of Lanka and Ceylon, and perhaps Taprobane. Lanka was the theatre of Rama's exploits against its tyrannical king Ravana, whose name is indifferently pronounced Ravan, Raban, Rabou, &c. nor can there be much

much doubt of the island that we now call Ceylon having formed a part, at any rate, of that theatre, which might in former times have been of greater extent than that island is at present.

It is said, that in Sanscrit books Ceylon is called Tapa Rawan; Tapa or Tapu, in that language, meaning an island, and it may be indifferently pronounced Taporaban, or indeed, in common discourse, Taproban, or Taprobane. Much stress is not perhaps to be laid on conjectural etymology, but it may be observed, that many names of places and things on Ceylon, and in its neighbourhood, correspond with the nomenclature of the Ramayan. In the fifth volume of the Asiatic Researches is an interesting account by the Hon. Mr. Duncan, of that extraordinary traveller Purana-Puri, who notices on Ceylon a lake called the "tank of Ravan or Raban (the *b* and *v* being pronounced indifferently in various parts of India), from whom this tapu, or island, may probably have received its ancient appellation of Taprobane (*i. e.* the isle of Raban): here also is a place called Sita Kooda, or the pool of Sita, where Rama is related to have left his wife Sita, on the occasion of the war with the ravisher Ravan." (See SITA.) In the poetical hyperbole of the Hindoos, the tears shed by Sita, in her lamentation for her lord's absence and her own captivity, are said to form this kooda, or pool, still called by her name.

Between Ceylon and the continent is a series of rocks, some of which appear above water, admitting a passage only in fine weather to vessels of small burden. This in our maps is called Adam's bridge, the Romish missionaries having placed the garden of Eden in Ceylon, and fancied this bridge his only mode of exit. In Hindoo writings this is called Rama's bridge, and in the Hindoo Pantheon a plate is given of the building of it by Rama's monkey-general Hanuman, and his Simian associates. The conspicuous part acted by those animals, in the wars of the Ramayan, reminds us strongly of Ptolemy's island of monies, and offers another mark of identity. On the continent of India, Ceylon is to this day popularly believed to be inhabited principally by monies, lions, and monsters; one of its names, Singala dwipa, whence Seilan diva, Selendeb, Ceylon, &c. means the country of lions. See CEYLON.

In Hamilton's account of the East Indies (vol. i. p. 142.) a map of the peninsula has one of the Maldive islands marked Hunnamandow, evidently the same with Hanuman devy, as it would be more correctly pronounced, meaning the island of Hanuman; and this name occurring conspicuously on those islands gives room for imagining a connection between them and the history of Rama, Ravana, Lanka, &c. that would be farther developed if we had more knowledge of the islands in question; a knowledge that might be abundantly obtained by a permitted admission to the records at the India House. Hamilton calls the southern extremity of the peninsula Ram's point; this, in our more modern maps, is named Cape Comorin, and it has derived this name, which is cited by Ptolemy, from a celebrated temple of the goddesses Isa, or Devi, in her character of Kumari, or the Virgin. These are names of *Parvati*, which see. Rami is another of her names, and the temple, which is generally imagined to be in honour of Rama, the avatara or incarnation of Vishnu, may perhaps originally have been dedicated to Rami, whatever rites may now obtain there: a point that we are uninformed on; and shall offer no more thereon in this place than the remark that the rites of the virgin goddess Kumari, (whose magnificent temple under the name of Ramiswara, or Ramisferam, at the southern extremity of the promontory of India, is still a much venerated shrine, and of great resort by pilgrims,) have a striking analogy with those of the Taurican

Diana, a virgin goddess also, whose temple similarly occupied the southern promontory of the Taurican Cheloneusis. See RAMI and RAMISWARA.

The first meridian of the Hindoo astronomers passed through Ujjeini (*Oojin*, which see) and Lanka; the latter cannot therefore be Ceylon if confined to its present extent, for Oojin lies in about 76°, and the westernmost part of Ceylon in 80° call of Greenwich. This difficulty seems reconcilable only by allowing what is asserted in India, that Ceylon was formerly of greater extent than at present, and it is said, that appearances between that island and the Maldivys, or Maldivas, as well as between it and the continent, justify the belief of their having once joined. See *As. Ref.* vol. iii. p. 44, also CEYLON and MALDIVES in this work.

LANKAYT', a small island near the W. coast of Celebes. S. lat. 4 57'. E. long. 119° 12'.

LANKE', a lake of Thibet, about 45 miles in circumference; 40 miles N. of Darmadjira.

LANMEUR, a town of France, in the department of Finisterre, and chief place of a canton, in the district of Morlaix; 6 miles N.E. of Morlaix. The place contains 2389, and the canton 13,170 inhabitants, on a territory of 182½ kilometers, in 8 communes.

LANNARIUS, in *Ornithology*, the name of a bird of the long-winged hawk kind; the *Falco lannarius* of Linneus, called in English the *lanner*, and the male *lannaret*. See *FALCO lanarius*.

LANNAS, in *Geography*, a town of Sweden, in the province of Angermannland; 35 miles N.W. of Hernofand.

LANNIERS, or LANIARDS, in a *Ship*, are small ropes reeved into the dead-men's-eyes of all the shrouds and chains. Their use is to slacken or fet taught the shrouds. The stays also of all masts are fet taught by lanners. That rope, which fastens the stopper of the halliards to them, is called also a lannier; and the term is generally applied to any short piece of cord or line, fastened to several machines in a ship, and serving to secure them in a particular place, or to manage them more conveniently; such are the laniards of the gun-ports, the laniard of the buoy, of the cat-hook, &c.

LANNION, in *Geography*, a town of France, and chief place of a district, in the department of the Northern Coasts. The place contains 3132, and the canton 14,983 inhabitants, on a territory of 105 kilometers, in 9 communes. N. lat. 48° 44'. W. long. 3° 22'.

LANNOY, a town of France, in the department of the North, and chief place of a canton, in the district of Lille; 6 miles E.N.E. of Lille. The place contains 923, and the canton 13,933 inhabitants, on a territory of 97½ kilometers, in 16 communes.

LANNSTROFF, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Thionville. The place contains 338, and the canton 13,615 inhabitants, on a territory of 397½ kilometers, in 44 communes.

LANO, a lake of the island Mindanao, from 15 to 20 miles broad, and about 60 miles round. See MINDANAO.

LANOUAILLE, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Nontron. The place contains 458, and the canton 9581 inhabitants, on a territory of 235 kilometers, in 10 communes.

LANPENCKEN, a town of Prussia, in the palatinate of Culm; 14 miles N. of Strasburg.

LANSARD, a town of Persia, in the province of Mazanderan,

zanderan, on the coast of the Caspian sea; 10 miles W. of Tcherabad.

**LANSINBURG**, New City, a town of America, in the township of Troy, county of Rensselaer, New York, pleasantly situated on the E. bank of Hudson's river, opposite to one of the mouths of the Mohawk; containing about 250 houses, a brick church for the joint use of the Dutch and Presbyterians, a court-house, gaol, and an academy, incorporated in 1796. The library of this town was incorporated in 1775; 9 miles N. of Albany. N. lat. 42° 46'. W. long 73 34'.

**LANS-LE-BOURG**, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of St. Jean-de-Maurienne. The place contains 874, and the canton 4675 inhabitants, on a territory of 742½ kilometres, in 7 communes.

**LANSMANS**, a town of Norway; 116 miles N. of Bergen.

**LANSPESSADE**, in *Military Affairs*. See ANSPESADE.

**LANSQUENET** is the name of a game at cards.

**LANTA**, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Villefranche; 9 miles E. of Toulouse. The place contains 1455, and the canton 5669 inhabitants, on a territory of 117½ kilometres, in 16 communes.

**LANTA-LEPTEN**, a small island on the coast of China, near the harbour of Macao.

**LANTANA**, in *Botany*, supposed to be derived from *lentus*, flexible, as in that sense originally applied to the Plant Mealy Tree, *Viburnum Lantana*. It is now used generically for a set of plants, rather agreeing with that in general aspect, than in this peculiar quality.—Linn. Gen. 316. Schreb. 413. Willd. Sp. Pl. v. 3. 315. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 1. v. 2. 350. Juss. 109. Lamarck Illustr. t. 540. Gært. t. 56. (Camara; Plum. Gen. 31. t. 2.)—Class and order, *Didymnia Angiospermia*. Nat. Ord. *Personata*, Linn. *Vitacea*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, very short, cohering, tubular, with four slight teeth. Cor. of one petal, nearly regular; tube cylindrical, slender, longer than the calyx, somewhat oblique; limb flat, unequally and bluntly four-cleft. Stam. Filaments four, extremely minute, situated in the middle of the tube, slender, two of them a little above the rest; anthers roundish. Pist. Germen superior, roundish, style thread-shaped, short; stigma bent backward like a hook, pointed downwards, and attached obliquely, as it were, to the top of the style. Peric. Drupa roundish, of one cell. Seed. Nut roundish, somewhat pyramidal, of three cells, the lowermost of which is barren; kernels solitary, oblong.

Obs. Linnæus observes that the essential character consists in the figure of the stigma. His *L. Africana* is now separated from the rest; and called *Spielmannia*. In the genuine *Lantana* there is a many-leaved involucre, according to Linnæus, (rather to be termed a number of bractæes,) and the common receptacle of the fructification is oblong, bearing many crowded sessile flowers, mostly very unequal.

Ess. Ch. Calyx obscurely four-toothed. Limb of the corolla unequally four-cleft, flat, with an open mouth. Stigma bent back like a hook. Drupa with a smooth nut of two cells.

The species in Willdenow are 15, but professor Martyn reckons up 19. Some uncertainty attends a few, even of those defined by Linnæus, at least he suspected his *trifolia* might not be distinct from *annua*, but in this he seems to have been mistaken. Medicus, indeed, who took some pains

with this genus, appears to have described *annua* for *trifolia*, which Reichard corrected. The *L. falsifolia* of Linnæus is properly referred in Port. Kew. to *Buddlea*.

Good examples of the genus are,

*L. aculeata*. Prickly-stalked Lantana.—Linn. Sp. Pl. 874. Curt. Mag. t. 96.—Leaves ovate, somewhat heart-shaped, downy underneath. Stem prickly. Bractæes lanceolate, with a broad base.—Native of the West Indies, where it is vulgarly called Wild Sage. It is one of the most commonly cultivated in our fives, being readily propagated by cuttings, and flowering almost all the year. The stem is shrubby, more or less rough, with projecting prickles. Leaves stalked, serrated, pointed, roughish, about two inches long. Flowers bright yellow at first, then orange, numerous, in flattened heads, on simple, solitary, axillary stalks.

*L. Camara*. Various-coloured Lantana.—Linn. Sp. Pl. 874. (Camara melissæ-folio, flore variabili; Dill. Elth. 65. t. 56. f. 65.)—Leaves ovate, rough on both sides. Stem unarmed. Bractæes ovate, small, downy.—Native of South America; an old inhabitant of our fives. The flowers are changeable in colour, being, at first opening, yellow, then orange, finally scarlet; which becomes dull or brownish as they fade, not purple, as in some other species.—Several of this genus are described under the Brazilian name of *Camara*, in Piso and Marcgrave. The word is now adopted by the Portuguese, as it seems, in a medical sense, suggested by the colour of the flowers, for the dysentery.

*L. annua*. Annual Lantana.—Linn. Sp. Pl. 874. Curt. Mag. t. 1022.—Leaves ovate, downy beneath. Stem unarmed, hairy. Spikes oblong. Bractæes ovate, pointed.—Native of the West India islands, as well as of the Spanish Main; rarely preserved long in our fives, to which it has from time to time been introduced, because the seeds do not ripen well here, and the plant, though shrubby in habit, is properly annual. The leaves are broad, almost heart-shaped. Flowers in oblong, stalked, axillary spikes, very beautiful. When cultivated in an airy light stove, being bright reddish-purple, or pink, with a white ring and yellow eye.

*L. trifolia* of Linnæus differs from the last very widely in appearance, and has the leaves growing three or four together, ovate, much more finely crenate; the heads of flowers rounder; bractæes larger, and more obtuse.—Plumier's Icones, t. 70, quoted for this, is not at all like the Linnæan specimen, but appears to be merely a three-leaved variety of the *annua*.

*L. nivea*. Venten. Malmaif. t. 8, appears to us a white-flowered variety of *L. aculeata*; at least we can discover no specific distinction, unless the flower-stalks, growing in pairs at each leaf, should prove to be such. This is a native of the West Indies, and was sent to the garden of Malmaison by Messrs. Lee and Kennedy. The leaves are of a full bright green; flowers snow-white, copious about the ends of the branches.

Jacquin has a few new or doubtful species in his Hortus Schoenbrundensis; amongst others

*L. hexandralacea*, t. 361. Willd. n. 11. White small-flowered Lantana.—Leaves elliptic-lanceolate, serrated, downy beneath. Stem roundish. Heads of flowers cylindrical, shorter than the leaves. Bractæes nearly orbicular.—Willdenow, who first described this, and Jacquin, had it in their gardens, without knowing whence it came. We have a native specimen, gathered by Dombey, in moist situations at Lima. It is *shrubby*, with round, slender, roughish branches. Leaves opposite, stalked, an inch long or more, rugose; rough above; downy, with numerous, branching, prominent ribs and veins beneath; the margin sharply serrated. Flower-stalks axillary, various in length, but always

much shorter than the leaves. *Spikes* oblong, with broad, roundish, pointed *bractææ*; the *flowers* white, unequally five-lobed, turning reddish-brown in decay. The dried leaves are aromatic, with somewhat of the flavour of sage. —This species is properly placed next to *L. odorata*.

LANTANA, in *Gardening*, comprehends plants of the shrubby, exotic, green-house, and stove kinds, of which the species cultivated are the various-flowered lantana, *L. mista*; the various-coloured lantana, *L. camara*; the round-leaved lantana, *L. involucrata*; baum-leaved lantana, *L. mellicifolia*; the prickly lantana, *L. aculeata*; and the golden-flowered lantana, *L. aurea*.

*Method of Culture*.—These plants are capable of being raised by seeds and cuttings of the young branches.

With regard to the seeds, they should be sown in pots of light mould in the early spring, plunging them in a bark hot-bed. When the plants have attained some inches growth, they should be removed into separate pots of a small size, and be replunged in the bark-bed, due shade and air being given. The plants should afterwards, when they have acquired strength, be removed into an airy glass-case, or dry stove, where they may have a large share of air in warm weather, but be protected from the cold. This is necessary for the young plants, which should not the first year be exposed to the open air, but afterwards they may be placed abroad in the warmest part of the summer, and in winter be placed upon stands in the dry stove, where they will continue long in flower, and many of the sorts ripen their seeds. In winter they should be sparingly watered, as much moisture rots their roots.

And the cuttings should be planted in pots in the spring and summer months, as in May and July, and be plunged in a moderate hot-bed, due shade being given. They soon take root, and should afterwards be removed into separate pots filled with light earth, and managed in the same manner as those raised from seed.

These plants afford ornament and variety among collections of stove and green-house plants.

LANTARGUR, in *Geography*, a town of Lamjung; 42 miles N. of Gorkah. N. lat. 29 5'. E. long. 84° 18'.

LANTCHANG. See LANJAN.

LANTER-LOO, or LOO, is the name of a common game at cards.

LANTERN, or LANTHORN, a cover for a luminary, made of some transparent matter; serving to transmit the light, and, at the same time, to screen it from the wind and rain.

The word is derived from the French *lanterne*; and that from the Latin *laterena*, of *later*, I am bidden; *eo quod lucem habet interius clausam*, because the light is hidden within, say Isidore and Lambin. But according to Pezron, *laterena* comes from the Celtic *latera*, and according to Salmonius *lantern* comes from *lato*, of *fero*, because it bears a lamp or a light.

Epictetus's lantern is said to have been sold for three thousand drachmas; that of Diogenes was held in great veneration among the ancients; and that of Judas is still preserved in the treasury of St. Denis, as a very curious piece of antiquity.

Lanterns are made of glass, horn, paper, &c. Formerly they were made of the horn of a wild bull, called *urus*; which, when cut into thin laminæ, Pliny tells us, was very transparent. Those of horn were first introduced into England by king Alfred, about the year 887, in order to preserve his candle time-measurers from the wind. See LENS. And Hist. Com. vol. i. p. 45.

LANTERN, *Dark*, is a lantern with only one opening or

light, which, too, may be closed up when the light is to be entirely hid; and may be presented to the person one would see without being perceived one's self.

The ancients had their dark lanterns, but they differed from our's: they were covered with four skins, one on each side, or light, three of which were black, and only the fourth transparent. Casaubon, who gives us the description, took it from a manuscript of Julius Frontinus. These were principally used in their armies, when they were to march privately off from their enemies in the night-time.

LANTERNS are used at sieges in the night-time, upon the batteries; but these must be blind or dark lanterns. There is always great provision of them in all store-houses.

LANTERNS for ships are made of tin and glass, to light those parts of a ship where naked candles would be dangerous, such as for lighting the magazine and store rooms. Those used at the stern are called poop-lanterns, and those aloft top-lanterns.

LANTERNS, *Fest of*, in China, is a celebrated feast held on the fifteenth day of the first month; and is so called from the great number of lanterns hung out of the houses and in the streets; insomuch that it rather appears a fit of madness than of feasting. On this day are exposed lanterns of all prices, some of which are said to cost two thousand crowns. Some of their grandees retrench somewhat every day out of their table, out of their dress, equipage, &c. to appear the more magnificent in lanterns. They are adorned with gilding, sculpture, painting, japanning, &c. and as to their size, it is extravagant; some are from twenty-five to thirty feet diameter; they represent halls and chambers, and two or three such machines together would make handsome houses; so that in China they are able to eat, lodge, receive visits, have balls, and act plays, in a lantern.

To illumine them, they should have bonfires; but as that would be inconvenient, they content themselves with lighting up in them a great number of torches or lamps, which at a distance have a beautiful effect. In these they exhibit various kinds of shows to divert the people.

Besides these enormous lanterns, there is a multitude of other smaller: these usually consist of six faces or lights, each about four feet high and one and a half broad, framed in wood finely gilt and adorned; over these they stretch a fine transparent silk, curiously painted with flowers, trees, and sometimes human figures: the painting is very extraordinary, and the colours extremely bright; and when their torches are lighted, they appear highly beautiful and surprising.

LANTERN, or LANTHORN, in *Architecture*, a turret raised above the roof with windows round the sides, in order to light the apartment below. Lanterns are much more convenient than skylights; as the surface of the glass stands vertical, they are not so liable to be broken, nor so subject to the rattling noise of heavy rains and hail.

LANTERN is also used for a square cage of timber, with glass in it, placed over the ridge of a corridor, or a gallery between two rows of shops to illuminate them.

LANTERN, *Magic*, in *Optics*, the name of a machine, which, in the dark, represents various images and spectres on a wall, or other white surface, so odd and surprising, that those who are not in the secret think them the effect of magic. See MAGIC.

LANTERN-Fly, in *Ichthyology*, the English name of a fish of the foal-kind, but smaller and smoother to the touch, called in Latin *amoglossus*.

LANTERN-Fly, in *Natural History*, the name of a very singular kind of insect produced in the West Indies, and

carrying a strong light with it in the night. The structure of the trunk in this insect is of the same kind with that of the cicada; and it wants the power of making the noise for which the cicada is so famous; it belongs, according to M. Reaumur's distinctions, to that species of insect called the *prociçal*, or *prociçada*.

The glow-worm and the luminous beetles, with all the other luminous insects we are acquainted with in this part of the world, diffuse their light from a part which is near the extremity of the body, and under the belly, but the lanternfly gives it from its head. It differs also greatly in the degree of light; for this, in all the insects we are acquainted with, is very feeble; whereas in this fly it is so strong, that Mrs. Merian, who is the first that well described it, says she could read a small print in a dark night by the light that one of them gave. The head of this creature, strictly speaking, is very short, not exceeding the length of one of the rings of the body, if it be measured from its joining with the corcellet to its joining with the lantern, but if that part be accounted a portion of the head, then the head is equal in length to the whole body. This lantern is wider than it is deep, or thick, and has near its origin a large protuberance, which gives it a bunched or humped look. There are several tubercles and lines on it, of a reddish colour. The ground colour is an olive brown, and underneath it has one large rib running all the way along it, from end to end, and dividing it into two, and by the sides of that there are some others. These are all reddish, and those nearest the edges have small rows of spines running along them. Over each of the eyes there is a round granulated prominence, which seems to have been a collection of smaller eyes; and if so, the animal is supplied with the organs of vision in a different manner from all other known creatures. But there requires an examination of the creature on the spot, and while alive, in order to find out this. The upper pair of wings are not perfectly transparent, they are dotted with white in some places, and are variegated near their origin with several blackish spots. The under pair are more transparent than the upper; they are much shorter, and are broader than the others: these have each a large and beautiful round spot near the extremity, resembling that on the wing of the peacock-butterfly. The colours of the circles of these eyes are brown and olive; the last colour very bright and clear, the other very dusky and obscure. The spots are so large, that they appear very beautiful. Reaumur's Hist. Inf. vol. ix. p. 247.

**LANTERNISTS**, a name assumed by the academicians of Thouloufe.

**LANTHONY**, in *Geography*, a hamlet in the parish of Cwmoy, and hundred of Abergavenny, county of Monmouth, England, is noted for the fine and picturesque ruins of its abbey-church. These are seated in a narrow, deep valley, called "The Vale of Eurus." The surrounding hills, called Hattal, are lofty and grand, and from their steep acclivities are almost impassable for travellers. In a sequestered dale among these hills or mountains, Hugh Lacy founded a priory of canons-regular of the order of St. Augustin, about the year 1108. A very particular history and description of this abbey, and the surrounding country, with several prints, are to be found in Coxe's "Historical Tour in Monmouthshire," 4to. 1801.

**LANTIGNANO**, a town of Etruria; 13 miles S. of Pisa.

**LANTO**, a small island in the Baltic, between the island of Aland and the coast of Finland. N lat. 60° 25'. E. long. 20° 36'.

**LANTOOR**, or **BANDA**, the chief island among those called Banda islands in the East Indian sea. See **BANDA**.

**LAN-TSAN**, a river of Asia, which rises in the N. part of the Chinese province of Yun-nan, on the borders of Tibet, traverses the province from N. to S., changing its name to Kou-long; enters the kingdom of Laos, assuming the name of Mecon, and afterwards discharges itself into the East Indian sea.

**LANIGINOUS**. See **LANIGEROUS**.

**LANUGO**, in *Botany*, down; that soft, hairy woolly covering, which grows on leaves, stalks, or fruits, of divers plants.

Such is that found on the leaves of the rose-campion, and on the fruit of the peach-tree.

**LANVOLLON**, in *Geography*, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brieuc; 11 miles N.W. of St. Brieuc. The place contains 1123, and the canton 15,296 inhabitants, on a territory of 147½ kilometres, in 12 communes.

**LANUVIUM**, in *Ancient Geography*, a town of Latium, in Italy, S.E. of Rome, and S.E. of Alba, situated on the brow of a mountain near the Appian way. Milo, who killed Clodius, was born in this town. Here was a temple of Juno, worshipped under the three names of Sospita, Moneta, and Regina.

**LANYARDS**, or **LANIARDS**, on *Ship-board*. See **LANNIERS**.

**LANZA**, in *Geography*, a town of Spain, in Navarre; 8 miles N. of Pamplona.

**LANZETTI**, in *Biography*, an eminent performer on the violoncello, during the early part of the last century. He was in England about the year 1740; but returned to Bologna, the place of his nativity, where he ended his days.

**LANZO**, in *Geography*, a town of France, in the department of the Po, on the Stura; 11 miles N.W. of Turin.

**LANZONI**, **JOSEPH**, in *Biography*, a physician, was born at Ferrara on the 26th of October 1663. From his early childhood he exhibited a strong inclination for literature, which his parents indulged, by obtaining for him the best masters. He distinguished himself particularly in the schools of philosophy and of medicine, and graduated in both these sciences in the year 1683. In the following year, at the age of 21, he was appointed ordinary professor, and displayed talents which did honour to the university of Ferrara, during the long period in which he filled that office. He died in February 1730, at the age of 66.

Lanzoni acquired a high reputation by the success of his practice, and obtained the confidence and esteem of many illustrious personages. His attachment to study increased with his years; and every moment, in which he was not employed in the duties of his profession, was devoted to literature, philosophy, or antiquarian research. His character as a physician and philosopher, indeed, ranked so high, that if any question upon these subjects was agitated in Italy, the decision was commonly referred to him. He was distinguished likewise by his genius in Latin and Italian poetry; and he was the restorer and secretary of the academy of Ferrara, and a member of many of the learned societies of his time. He left a considerable number of works, both published and in manuscript, in the execution of which he has been reproached with carelessness and incorrectness. It will be sufficient to state, that a collection of his works, as well of those published by himself as of his manuscripts, was

printed at Laufanne, in 1738, in 3 vols. 4to., with an account of his life, under the title of "Josephi Lanzoni, Philosophiæ et Medicinæ Doctoris, in Patria Universitate Lectoris primarii, &c. Opera omnia Medico-physica et Philologica." Eloy. Dict. Hist.

LAO, in *Geography*, a town of the island of Cuba; 25 miles W. of Havana.

LAOCOON, in the *History of the Arts*, is a celebrated monument of Greek sculpture, executed in marble by Polydorus, Athenodorus, and Agesander, the three famous artists of Rhodes. This remnant of antiquity was found at Rome, in the ruins of the palace of Titus, in the beginning of the sixteenth century, under the pontificate of Julius II., and since deposited in the Farnese palace. Laocoon, the priest of Apollo and Neptune, is here represented with his two sons, with two hideous serpents clinging round his body, gnawing it, and injecting their poison. Virgil has given us the following description of the fact:

"Serpens amplexus uterque  
Implicat & miseris moriuf depascitur artus:  
Corrumpunt, spirisque ligant ingentibus, & jam  
Bis medium amplexit, bis collo squamea circum  
Terga dati, superant capite, & cervice altis."

This statue exhibits the most astonishing dignity and tranquillity of mind, in the midst of the most excruciating torments. Pliny says of it, that it is "opus omnibus, picturæ & statuarie artis, preferendum" Lib. xxxvi. c. 5.

LAODICEA, in *Ancient Geography*, a town of Asia, in Caria, called "Laodicea ad Lycum," not that it was near this river, which passed to the west of it, and received, to the north of Laodicea, the river Caprus, which traversed the town, and the Apocys, which was cast of it. A little to the south of Laodicea was Hierapolis. This town was more anciently called *Diospolis*, and afterwards *Rhaas*. It was re-established by Antiochus, who gave it the name of his wife; and it became one of the most considerable and rich towns of Asia Minor.

LAODICEA *Cabiofa*, a town of Asia, in Syria, situated eastward near mountains, west of Emesa and the river Orontes. It was favoured by the emperor Severus, on account of its attachment to the interests of the empire. By way of distinction, it was called "Laodicea ad Libanum."

LAODICEA *ad Mare, Latikea*, a maritime town of Syria, situated on an eminence, near the sea-coast. Strabo says, that its environs furnished abundance of wine. In its present ruins may be seen columns of porphyry and granite, an aqueduct, and a triumphal arch, supported by columns of the Corinthian order. About a stadium west of this town are the ruins of a fine port, artificially constructed in the form of an amphitheatre, and capable of containing a considerable fleet.

LAODICEA *Combysta*, a town of Asia, in Lycaonia, east of Philomelium; supposed to have derived its name from traces of ancient volcanos.

LAODICEA, a town of Asia, on the confines of Media and Persia Propria.—Also, a town of Mesopotamia, according to Pliny; being one of the six towns built by Seleucus under this name.—Also, a town of the Peloponnesus, in the Megapolitide, according to Polybius and Thucydides; the fame with the *Ladonea* of Pausanias.

LAO-KUN-TIM, in *Geography*, a town of Chinese Tartary; 50 miles S.W. of Ning-yuen-tcheou.

LAON, a town of France, and chief place of a district, in the department of the Aisne; and before the revolution, the capital of a small country called Laonnois, and the see

of a bishop, who was a duke, and the second peer of France.—The place contains 6691, and the canton 14,958 inhabitants, on a territory of 215 kilometres, in 27 communes. N. lat. 49° 34'. E. long. 3° 42'.

LAOS, in *Ancient Geography*, a town of Italy, in Lucania, west of Bratium, and near it. It was situated on a small gulf, distant 400 stadia from the town of Hyole. It was founded by a colony of Sybarites.

LAOS, in *Geography*, a country of Asia, bounded on the north by the Chinese province of Yun-nan, on the east by Tonquin, on the south by Cambodia, and on the west by Siam and Ava. Kæmpfer represents it as a powerful state, surrounded by forests and deserts, and of difficult access by water, because the river is full of rocks and cataracts. The soil is represented as fertile in rice, and the merchants of Cambodia were furnished from hence with the best benjoin and lacca. Exquisite musk is also obtained from Laos, with some gold and rubies; and the rivers supply the fresh water mya, which yields pearls. The religion and manners of the people resemble those of Siam; but in personal appearance they are like the southern Chinese. In Kæmpfer's time, the chief towns were Landjan, or Lantchang, and Tsiamaja, whence the people take the name of Landjanese, to which, in modern maps, is added Sandepora. Duhalde has given some account of this country, the capital of which is denominated Mohang-Lang by the Chinese. (See MOHANG-LANG.) Laos, in his time, was tributary to Ava; but its chief trade was with the Chinese. It is said to have mines of gold, silver, and copper; near the capital is one mine of rubies; and its emeralds are of large size. The articles exported are tin and sulphur, (perhaps cinnabar or realgar,) cotton, tea, and sapan or Brasil wood. The chief river is denominated Meinan Krong, which passes through Cambodia; and its different branches bear different appellations. This grand stream, in Mr. Dalrymple's map of exterior India, is called the Kion-Long, or Maykaung. Mr. Arrowsmith derives it from the Tibetan Alps, where it is called the Satchou, and by D'Anville the Lantfangkiang. Of this country Turpin, cited by Pinkerton, (Geog. vol. ii.) has given the most recent account. The name Laos, he says, denotes 1000 elephants, with which animals the country abounds. The climate is so temperate, and the air so pure, that men are said to retain their health and vigour, in some instances, to the age of 100 years. The flat part of the country resembles Siam, but the soil on the east bank of the river is more fertile than that on the west. The rice is preferred to that of other oriental countries. The ivory is beautiful, but the horn of the rhinoceros is particularly esteemed from a superstitious notion, that the possessor, who keeps it, insures his felicity. The fields, abounding with flowers, afford food for numerous swarms of bees, which supply excellent wax and honey. In the mountains are found rich mines of tin, iron, and lead; but gold and silver are explored in the sands of the rivers. Musk, says this author, is not a product of the country. Before the irruption of the Tartars, the Chinese carried on a considerable commerce with Laos; exchanging their velvets, silks, cottons, and porcelain, for ivory, opium, and medicinal plants. In the province of Laos, whence the kingdom derives its name, is a deep mine, which furnishes rubies and beautiful emeralds, one of which, in the royal treasury, is said to be as large as a common orange. The inhabitants of this kingdom are celebrated for their honesty and fidelity; and so anxious are they to maintain their reputation in this respect, that if a traveller be robbed, the nearest town or village is obliged to indemnify him. At the

same time, they are indolent and luxurious, and addicted to the study and practice of magic. The army of Laos is estimated by Turpin at 500,000 combatants; but he adds a circumstance which somewhat affects his credibility, that a numerous army might be raised of men who have lived a century. The people of this country are not very distinguished for their sobriety and temperance, as they eat daily four repasts of rice, fish, and the flesh of the buffalo; the buffalo and venison being common in their markets. Marriages are easily contracted, and no less easily dissolved; and the rich entertain many concubines. A funeral resembles a festival; and a sum of money is deposited in the tomb, which is circulated, after a certain period, by the priests. The commerce of this country was chiefly carried on in former times with Siam; but after the irruption of the Birmas, it passed to Pegu; at a later period, the trade of Laos has been transferred to Cambodia. The inhabitants of Laos boast that the Siamese borrowed the art of writing on palm-tree leaves from them. The tongue and characters are the same; but it is said, that the Laotian cannot pronounce the letters L and R.

The ancient worship of these people is said to have been directed to one God, the creator of all, who was only to be pleased by the exercise of virtue, and not by sacrifices, ceremonies, and the observance of certain days. But the purity of their faith has been corrupted by their intercourse with the Chinese. They believe in regular renovations of the universe; and that our earth has attained the age of 18,000 years. Polygamy is one of the promised joys of paradise, and the women are assured, that if they lead a virtuous life, they shall be changed into men. The priests take comfort under the privations of celibacy, from a persuasion which they indulge, that in another world they shall be able, by the privilege of their order, to create females at their pleasure. Some of their ceremonies, like those of Thibet, seem to have been derived from the Nestorian Christians. To the rich they sell dispensations and pardons; while the poor alone are condemned to perpetual misery.

The king of Laos is said to be an absolute, independent prince, and to acknowledge no superior, either in temporal or spiritual concerns. In him is vested the whole property of lands, and he disposes at pleasure the effects of his subjects; nor can any family in the kingdom inherit or possess any thing left them by will.

LAOUR, a town of Hindoostan, in Bengal; 40 miles N.W. of Silhet. N. lat. 25° 7'. E. long. 91° 20'.

LAPA, one of the Sooloo islands. N. lat. 5° 25'. E. long. 120° 42'.—Also, a town of Circassia, on the Cuban. N. lat. 44° 50'. E. long. 58° 34'.

LAPACTICS, from *λαπαξ*, *I evacuate*, a term used by the old writers in medicine to express such things as purged by stool, or at least gently loosened the belly. It was sometimes applied to the cathartic medicines, and sometimes to those foods which were of this tendency.

LA PALISSE, in *Geography*. See *La PALISSE*.

LAPAROCÉLE, (from *lapara*, the flanks, and *κελειν*, a tumour,) a term, in *Surgery*, denoting a swelling, or hernia, at the side of the belly.

LAPARY, in *Geography*, a town of Hindoostan, in Allahabad; 7 miles N. of Jiohpour.

LAPATA, a chain of mountains in Africa, called the "Backbone of the World," extending from N. to S. about 600 miles. S. lat. 12° 30' to 20°. E. long. 27 to 33°.

LAPATHIOS, in *Ancient Geography*, a town of the island of Crete, on the northern coast.

LAPATHUM, in *Botany*, *λαπαθιον* of the Greeks, from *λαπαξ*, or *λαπαζειν*, to evacuate, alluding to its medical

qualities; a general name for various plants, mostly of the Dock kind, belonging to the *Rumex*, *Rheum*, *Chenopodium*, or *Spinachia* of Linnæus.

LAPATHIUS, LAPITO, in *Ancient Geography*, a town on the N. coast of the island of Cyprus, at the bottom of a small gulf, formed to the N.W. by the promontory called Cron'm'on. It was founded by the Lacedæmonians as a place of arms, and a port.

LA PAZ, in *Geography*. See *La PAZ*.

LAP-DOG, called also *malteux*, or *fotor*, and by Dr. Caius, in his System of British Dogs, the Spanish gentle or comforter, is a species of the most generous kind of dogs. See *Dog*.

Mr. Pennant observes, that the Maltese little dogs were as much esteemed by the fine ladies of past times as those of Bologna are among the moderns. Old Hollingshed is ridiculously severe on the fair of his days for their excessive passion for these little animals; which is sufficient to prove it was in his time, *viz.* in the reign of queen Elizabeth, a novelty.

LAPEYROUSIA, in *Botany*, received its name from the Abbé Pourret of Narbonne, in honour of M. Picot Lapeyrouse, author of a splendid botanical book on the genus *Saxifraga*, and who has paid great attention to the natural history of the Pyrenées. Thunberg has applied the same name to a Cape plant, *Osmites calycina*, Linn. Suppl. 380, which he separates in his *Prodrum*, p. 163, from *Osmites*, saying the receptacle is naked, and the corolla discoid. In this Willdenow follows him, Sp. Pl. v. 3, 2260. On examining the original Linnæan specimen, marked as communicated by Thunberg himself, we find ourselves obliged to declare that neither of these characters holds good. The lanceolate scales of the receptacle are numerously apparent between the florets of the disk, and the ligulate florets of the radius are no less visible within the calyx; though indeed the large membranous inner scales of the latter equal them in length. The habit of the shrub, too, is sufficiently like other species of *Osmites*. Such being the state of the case, and the right of priority moreover in favour of Pourret, we adopt his *Lapeyroufia* in preference.—Ker (Gawler) in Curt. Mag. v. 16, 595, and v. 3, 1246. Ann. of Bot. v. 1, 237. Dryand. in Ait. Hort. Kew. ed. 2. v. 1, 110.—Claf. and order, *Triandria Monogynia*. Nat. Ord. *Enstatz*, Linn. *Irides*, Jussl.

Gen. Ch. *Cal.* Spatha inferior, shorter than the corolla, of two, rarely but one, folded valves. *Cor.* of one petal, superior, valver-shaped, nearly or quite equal; tube long, slender, triangular, its throat a little enlarged; limb in six deep segments, shorter than the tube, either quite equal and regular, or slightly irregular, in the former case horizontal, in the latter inclining. *Stam.* Filaments three, inserted into the mouth of the tube, rather shorter than the limb, various in direction; anthers oblong, incumbent. *Pist.* Germen inferior, roundish; style capillary, as long as the stamens; stigma three, linear, deeply divided, spreading and recurved, downy. *Peric.* Capsule membranous, three-lobed, or with three compressed dilated angles, of three cells and three valves, with very short partitions. *Seeds* numerous, in two rows, nearly globose, or slightly angular from pressure.

Eff. Ch. Spatha of one or two folded valves. Corolla valver-shaped; limb in six deep segments, shorter than the tube. Stigmas three, deeply divided. Capsule membranous, triangular, with many globular seeds.

The most correct enumeration of the species of this genus, previously, by other writers, confounded with *Isia*, *Gladiolus*, or *Galaxia*, is given by Mr. Ker, in Curt. Mag. v. 31, above quoted as follows.

1. *L. corymbosa*. Level-topped Lapeyroufia. Curt. Mag. t. 595. (*Ixia corymbosa*; Linn. Sp. Pl. 51. Willd. Sp. Pl. v. 1. 199. Jacq. Ic. Rar. t. 288. *I. crispifolia*; Andr. Repot. t. 35.)—Flowers regular, corymbose; tube scarcely longer than the limb. Stamens widely spreading. Stem two-edged, somewhat branched.—Native of the Cape of Good Hope, from whence it was introduced by Mr. Masson, in 1791. It flowers in the green-house in May and June, and requires to be kept dry when out of blossom. The *bulb* is conical, with a broad base. *Stem* about a foot high, zig-zag, somewhat branched, leafy, corymbose. *Leaves* vertical, clasping the stem with their broad sheathing base. *Flowers* numerous, not an inch wide, blue, generally with a white itary central mark, bordered with darker blue, not very unlike another beautiful Cape plant, *Rocella ciliata*, however different in botanical affinity. Sometimes they vary to white.

Mr. Ker is now convinced that *Ixia fissigata*, Lamarck. Dict. v. 3. 337, is not specifically distinct from the above.

2. *L. falcata*. Falcate Lapeyroufia.—(*Gladiolus falcatus*; Thunb. Gladiol. n. 4. t. 1. f. 3.)—Flowers slightly irregular, racemose; tube twice as long as the limb. Stem compressed. Leaves nearly radical, falcate, obovato-lanceolate. From the same country; discovered by Thunberg. The *stem* is but five or six inches high. *Leaves* one or two. *Flowers* five or six, blue. *Spatha* of two valves.

3. *L. fasiculata*. Fasciculate Lapeyroufia.—(*Ixia heterophylla*; Vahl. Enum. v. 2. 57. *Galaxia plicata*; Jacq. Ic. Rar. t. 292.)—Radical leaves sword-shaped, erect; floral ones crowded, recurved, undulated, obtuse, longer than the clustered flowers. Corolla regular; tube above twice as long as the limb. *Spatha* of one valve.—Native of the Cape of Good Hope. The *stem* is very short. The *flowers* are clustered at its summit, white, with narrow equal segments, and remarkable for being encompassed with crowded floral leaves, which are longer than themselves, recurved, undulated and obtuse. The *foliage* is glaucous. Radical leaves few, long, erect, sword-shaped and acute.

Vahl and Ker appear to have adopted this species from Jacquin, and they both cite his t. 291, and instead of 292, apparently after Willdenow in Sp. Pl. v. 1. 199, quoted by Ker 159. Thus erroneous references accumulate, for want of turning to the original authorities.

4. *L. fissifolia*. Split-leaved Lapeyroufia.—(*Gladiolus fissifolius*; Jacq. Ic. Rar. t. 268. Vahl. Enum. v. 2. 107.)—Leaves deeply split, and clasping the stem at their base; with a short sword-shaped point; floral ones rounded. Spike leafy. Corolla somewhat irregular, drooping; tube thrice as long as the limb.—Received from the Cape of Good Hope by Messrs. Lee and Kennedy, with whom it flowered in Sept. 1809. Mr. Masson, however, is recorded as having sent the same to Kew in 1791. The leafy *spike* is peculiar, as well as the long deep fissure of the *stem-leaves*. The *flowers* are purplish, fragrant, varying in the size and colours of their limb.

5. *L. anceps*. Sword-leaved Lapeyroufia.—(*Gladiolus anceps*; Linn. Suppl. 94. Jacq. Ic. Rar. t. 269.)—Leaves sword-shaped, decurrent, toothed at the outer edge. Stem corymbose, spreading. Corolla irregular; tube thrice as long as the limb.—Native of the Cape. This appears to be the original species on which Pourret founded the genus, in the Memoirs of the Society of Thoulouse, vol. 3. It differs from the last in its branching corymbose *stem*, winged with the narrow, decurrent, toothed bases of the perfectly sword-shaped and vertical *leaves*. The *flowers* vary with different shades of blue, and have a very long tube. The *floral leaves* are either large, with toothed or crisped edges,

as Jacquin represents them; or small and nearly smooth or even.

6. *L. flenoides*. Campion-flowered Lapeyroufia.—(*Gladiolus flenoides*; Jacq. Ic. Rar. t. 270. Vahl. Enum. v. 2. 106. Willd. n. 33.)—Leaves linear-sword-shaped, entire; floral ones as long as the rest. Corolla irregular; tube five times as long as the limb, erect.—Native of the Cape, and, as it seems, known only to Jacquin, who has named it very happily from the aspect of the *flower*, which is red, with a spot of yellow at the base of three of the segments, all on one side. The *stem* is about a span high, branched from the bottom, and clothed with linear, glaucous, grassy leaves, from several of the uppermost of which the *flowers* proceed, and their white tube is about as long as the corresponding leaf, straight and rather tumid in its upper part.

Two other species are indicated as doubtful by Mr. Ker, *Gladiolus brazeatus* and *G. Fabricii* of Thunberg and Vahl, which are suspected to be possibly not distinct from *L. fissifolia*, or from *anceps*.

LAPPIORD, in *Geography*, a town of Sweden, in a bay of the gulf of Bothnia; eight miles S. of Christianstad.

LAPHAO, a town on the N. coast of the island of Timor, inhabited by Portuguese or their descendants, situated at the bottom of a bay, and containing a church and about 60 houses; the inhabitants are of a copper colour, with black hair; they carry on some trade with Batavia; and this port is visited by some Chinese junks and vessels from Goa, but the port is safe only from March till August; at other times the hurricanes render it insecure.

LAPHIATI, in *Zoology*, the name by which the people of Lemnos call a species of serpent, supposed by Bellonius to be the same with the elaps, or elaphis, of the ancients.

LAPHYSTIUS, in *Ancient Geography*, a mountain of Bœotia, 20 stadia from Coronna. It had a certain district consecrated to Jupiter Laphystius, in which there was a marble statue of this deity. Hercules Charops had also a temple at a little distance from it. Pausanius, l. ix. Bœotic. c. 34.

LAPIDARY, LAPIDARIUS, an artificer, who cuts precious stones. See GEMS.

The art of cutting precious stones is very ancient; but, like other arts, its original was very imperfect. The French have succeeded in it the best; and the lapidaries of Paris, who have been a corporation since the year 1290, have carried it, especially in cutting of diamonds called brilliants, to a very great perfection, but not superior to that of the English.

There are various machines used in the cutting of precious stones, according to the quality of the matter to be cut: the diamond, which is extremely hard, is cut and formed on a wheel of soft steel, turned by a kind of mill, with diamond dust tempered in oil of olives; and this serves to polish them as well as to cut them.

Oriental rubies, sapphires, and topazes, are cut and formed on a copper wheel, with oil of olives, and diamond dust: they are afterwards polished on another copper wheel with tripoli and water.

Emeralds, hyacinths, amethysts, garnets, agates, and other stones less hard, are cut on a leaden wheel, with flint and water, and polished on a tin wheel with tripoli.

Turquois, of the old and new rock, lapis girafol, and opal, are cut and polished on a wooden wheel with tripoli.

LAPIDARY is also used for a virtuoso skilled in the nature, kinds, &c. of precious stones; or a merchant who deals in them. See GEMS.

LAPIDARY *Style*, denotes the style proper for monumental or other inscriptions.

This is a kind of medium between prose and verse; the jejune and the brilliant are here equally to be avoided. Cicero has preferred the rules of it: "Accedat oportet oratio varia, vehement, plena spiritus. Omnium sententiarum gravitate, omnium verborum ponderibus, est utendum."

The lapidary style, which was lost with the ancient monuments, has been retrieved, at the beginning of this age, by count Emanuel Teforo: it is now used variously at the beginning of books; and even epistles dedicatory are composed in it, of which we have no example among the ancients.

LAPIDES PICTI, in *Natural History*, a term used by Languis, to express such stones as are found with the delineations of fishes, trees, and shells, as well as leaves of ferns and other plants, very perfectly representing the things themselves, but scarcely at all standing out above the surface of the stone, and having in themselves scarcely any thickness. It is very evident, that the bodies represented are not here, in reality, but the whole configuration is owing to the natural veins of the stone, and the coalescence of the several small masses of which each large stone is composed, and to the vapours from within the earth, getting into the natural fine cracks in the stones, and tinging their sides with blackness.

LAPIDESCENT, any thing which has the faculty of petrifying, or turning bodies to a stony nature.

Naturalists speak of a lapidescent principle, a lapidescent spirit, a lapidescent juice, &c

LAPIDESCENT *Waters*, or *Springs*, are such as, having stony particles dissolved and swimming in them, do deposit the same on wood, leaves, and other bodies immersed therein; which, being incruited herewith, are commonly mistaken for petrifications.

LAPIDIFICATION, in *Chemistry*, an operation where-by any substance is converted into a sort of stone.

Lapidification is practised in metals, fixed salts, and salts of plants.

The term is also used for the making of artificial stones.

LAPIN, in *Zoology*, the Rabbit. See LEFUS *Cuniculus*.

LAPIS, in the general sense. See STONE.

LAPIS *Arabicus*, in the *Natural History of the Ancients*, the name of a stone of a fine white colour, resembling the purest ivory; and which, though naturally of a firm, solid, and compact texture, yet, when burnt, became light, porous, and spongy, and assumed the figure and appearance of a pumice; and was used like it in the compositions of the ancient physicians for cleaning the teeth.

LAPIS *Ærofus*, in *Natural History*, a name given to several sorts of stones, and other fossils, which had lain in the neighbourhood of copper-mines, and been impregnated with particles of copper, though not in a sufficient degree to be thought worthy the name of copper ores. See PYRITES.

The same sort of stones were also sometimes called *chalchites*, which made some confusion, as it gave occasion to confound them with the true *chalchitis*.

LAPIS *Asbestosus*. See ASBESTOS.

LAPIS *Ætites*. See ÆTITES.

LAPIS *Armenus*. See ARMENIAN Stone.

LAPIS *Affinis*, in the *Natural History of the Ancients*, the name of a stone, called also *sarcophagus*, from its power of consuming flesh.

It was a stone much used among the Greeks in their sepulchres, and is recorded to have always perfectly consumed the flesh of human bodies, buried in it, in forty days. This property it was much famed for, and all the ancient natu-

ralists mention it. There was another very singular quality also in it, but whether in all, or only in some peculiar pieces in it, is not known; that is, its turning into stone any thing that was put into vessels made of it. This is recorded only by Mutianus and Theophrastus, except that Pliny has copied it from these authors; and some of the later writers on these subjects from him.

This effect might probably be a kind of incrustation, formed on substances inclosed in vessels made of this stone, by water passing through its pores, dislodging from the common parts of the stone, and carrying with it particles of such spar as it contained; and afterwards falling in repeated drops on whatever lay in its way, it might again deposit them in such substances, in form of incrustations.

The place from whence the ancients tell us they had this stone was Afso, a city in Lycia, in the neighbourhood of which it was dug: and De Boot informs us, that in that country, and in some parts of the East, there are also stones of this kind, which, if tied to the bodies of living persons, would, in the same manner, consume their flesh. Hill's Notes on Theophrastus, p. 14.

LAPIS *Atramentarius*, the *copier-stone*. See PYRITES.

LAPIS *Bezoardicus*. See BEZOAR.

LAPIS *Bononiensis*, the *Bolonian stone*, a peculiar species of stone found in Bologna. See BONONIAN stone.

LAPIS *Calaminaris*. See CALAMINE and ZINC.

LAPIS *Calcarius*. See LIME and LIMESTONE.

LAPIS *Cauda caneri*, in *Natural History*, a name given by Gesner, and some other writers, to the fossil shells, since called *tubuli marini concaerati*, and by some *polythalamii* and *ortho-ceratitis*. See TUBULI *concaerati*.

LAPIS *Ceratitis*. See UNICORN *suffit*.

LAPIS *Colicus*. See COLIC-stone.

LAPIS *Corneus*, *horn-stone*, a name given by many of the German authors to flint, which some of them have also very improperly called *pyrites*, or the fire-stone, because it is used to strike fire with. See HORNSTONE and PETROSILEX.

LAPIS *Divinus*. See NEPHRITIC stone.

LAPIS *Hæmatites*. See HÆMATITES, and ORES of IRON.

LAPIS *Hepaticus*, *liver-stone*, or *liberstein*, a species of the barytic genus of earths or stones, colour grey, greyish, or yellow-grey, or brown, or greyish-black; lustre, 2.1; transparency, 1; fracture, foliated and partly striated; hardness, from five to six; sp. grav. 2.666; emitting a smell of liver of sulphur when rubbed or heated to redness; not effervescing with acids. According to the analysis of Bergman, a specimen from Andranar in Scania contains 0.38 of barosefelenite, 0.33 of silice, 0.22 of alum, 0.07 of gypsum and 0.5 of mineral oil. Kirwan.

LAPIS *Hibernicus*. See IRISH SLATE.

LAPIS *Hyænius*. See HÆNIUS lapis.

LAPIS *Infernalis*. See LUNAR CAUSTIC.

LAPIS *Islebianus*. See ISLEBIANUS lapis.

LAPIS *Judaicus*. See JUDÆIC.

LAPIS *Lazuli*. See LAZULITE.

LAPIS *Lucis*, the *stone of light*, in the *Materia Medica of the Arabs*, a name given to the brassy marcasite or pyrites. The Arabians have adopted this. Avicenna supposes this substance to be called so, because it was used, after calcination, for diseases of the eyes. It is very probable, that where vitriolic medicines take place, the caput mortuum of this fossil, which is only a colcothar of vitriol, may be of use. But its virtues in this respect can never be supposed so eminent, as to have intitled it to the pompous name it bears. It seems more probable, that it was called the *stone of light*, either from its glittering appearance where fresh broken, or from its giving large sparks of fire, when struck against a

steel.

steel. It was from this quality that it obtained the name of *pyrites*, or fire-stone, it giving fire on the collision with steel much better than flint does.

LAPIS *Lydius*. See *LYDIUS lapis*.

LAPIS *Marmoreus*, a marble stone about twelve feet long and three feet broad, placed at the upper end of Westminster-hall; where was likewise a marble chair erected on the middle thereof, in which our kings anciently sat at their coronation dinner, and at other times the lord-chancellor. Over this marble table are now erected the courts of chancery, and king's-bench. Orig. Juridical. 37.

LAPIS *Melittes*. See *MELITTES*.

LAPIS *Morscabibus*, or *French chalk*. See *MORCHTHUS*.

LAPIS *Medicamentifus*, or the medicinal stone, is a composition of rock alum, litharge, colcothar of vitriol, Armenian bole, and vinegar, boiled to the consistence of a hard stone. It was used to fasten the teeth, preserve the gums, heal and dry up ulcers and wounds; and also in injections, and in compositions for sore eyes.

LAPIS *Musicalis*, the *music-stone*, in *Natural History*, a name given by Mr. Sivers to a stone found in Prussia, carrying naturally on it all the musical characters found on the shell, commonly called the *music-shell*. He describes the stone, which seems to have been a single specimen, and as this author is the only one who ever met with it, it is much to be suspected that either fraud or fancy has had a great share in the matter.

LAPIS *Nephriticus*. See *NEPHRITIC stone*.

LAPIS *Ollaris*. See *POSTONE*.

LAPIS *Specularis*. See *SPECULARIS*.

LAPIS *Thyites*. See *THYITES*.

LAPITHA, in *Ancient Geography*, a town of Cyprus, on a river of the same name; 24 miles W.N.W. of Nicolia. *N.* lat. 35° 23'. E. long. 32° 36'. See *LAPATHUS*.

LAPITHÆUM, a mountain of Laconia. Steph. Byz. *Paufanias* (l. iii. c. 20.) mentions a town of this name in the Peloponnesus, on mount Taygetus, in the same canton.

LAPLAND, in *Geography*, the most northerly country in Europe, extending from the North-Cape, latitude 71½° N., to the White sea, under the Arctic circle, is inhabited by the same people though the country is subject to different powers. When the name Lapland was first given to the country, and that of Laplanders to the people, is uncertain. Saxo Grammaticus, in his commentaries; Adam of Bremen, in his account of the Danes; and Sturleson of Iceland have been cited on this subject, as having named the people in question "Scritthannar," "Scricinnar," or "Finnar;" and at present they are generally called Finns by the Norwegians. The name of Laplanders has been supposed to originate from their attachment to forcery: *lepp*, in their language, signifying a wizard.

Lapland is bounded on the north by the North sea and Frozen ocean; on the east by the White sea; on the south by Sweden and the gulf of Bothnia; and on the west by Norway. On the northernmost side, are what have been denominated the Frozen Alps, or Alps of Snow, which compose that chain of mountains called Severnoi, the declivity of which, towards the east and south, consists of lower mountains, deserts, forests, fens, and lakes. The surface is supposed to contain from seventy to eighty thousand square miles, but its population cannot be ascertained with any degree of precision.

Lapland is divided into three parts, *viz.* 1. That which is subject to Denmark, and is called Norwegian Lapland; this part lies between the Northern sea, the river Pais, and the lake Enarak. 2. Swedish Lapland, which includes all the country from the Baltic to the mountains that separate

Norway from Sweden. It is divided into six districts, denominated *marks*, or territories, which are distinguished by the names of rivers, as Aungnerland, Elma, Peta, Lula, Torna, and Kimi. 3. The eastern part is subject to the czar of Muscovy, situated between the lake Enarak and the White sea: this part of Lapland is divided into three prefectures; namely, that of the sea-coast to the north, called "Mourmankoi Leporie;" that upon the coast of the White sea, denominated "Jerikoi Leporie;" and the inland part, known by the name of "Bellamerskoi Leporie." In Swedish Lapland, the provinces or marks are subdivided into smaller districts called *biars*, consisting each of a number of families, among which the land is parcelled out by government. The whole country consists of huge congeries of frightful rocks and stupendous mountains, interspersed, however, with many pleasant vallies, watered by an infinite number of rivulets that fall into the rivers and lakes, which discharge themselves into the gulf of Bothnia. The chief towns are Kola and Tornea. There are many considerable lakes, as the Great Uma; the Great Windel; the Stor-avan, &c. Some of them are said to extend 60 leagues in length, and contain a great number of islands. Stor-avan is computed to contain 365; and Enara contains so many, that it has been affirmed, that no Laplander has lived long enough to visit each particular island. For the history of this country, we must refer to that of those countries to which it is subject, and also to the article FINNS. The climate is exceedingly cold during the winter months; the lakes and rivers are at that season completely frozen over, and to a great thickness: the whole face of the country is covered with snow to the depth of four or five feet. While this continues loose, it is impossible to travel, but if a partial thaw takes place, the surface of the snow is formed by a succeeding frost into a hard impenetrable crust, over which the inhabitants, by means of their rein-deer, travel with the utmost celerity. While the thaw continues, the air is surcharged with vapours, and the climate is rainy, but so long as the north wind blows, the sky is beautifully serene, and the air is clear. The heat of summer is almost as intolerable in Lapland as the cold of winter. In the more northerly parts of the country, the sun never sets for three months in the summer, and in the winter there is an uninterrupted night of the same duration, but this is qualified by a constant revolution of dawn and twilight, by a serene sky, moon-light, and aurora borealis, so that the inhabitants are enabled to fish and hunt, and to proceed with their ordinary occupations. During the summer season nothing can be more enchanting in many parts, than the vast prospects of mountains, forests, lakes, and rivers. At this season, notwithstanding the climate, the roses are seen in full flower on the banks of the lakes and rivers, with all the beauties of colour which appear in those cultivated in our gardens. In the intervals between the mountains, great part of the country is flat, covered with brown dusky forests of fir and pine trees, and these are often skirted by wide extended morasses, the stagnating waters of which in summer produce myriads of mischievous insects, that are more intolerable than even the cold of winter. The soil of Lapland is very barren, owing chiefly to the want of cultivation. In some districts the land will bear large crops of rye; there are many varieties of berries, as currants, Norwegian mulberries, that grow on a creeping plant; raspberries, cranberries, juniper berries, and bilberries. There are very fine woods of birch, pine, and fir, in several instances disposed by nature, as if they had been planted in regular rows by the hand of art. The service-tree, the willow, the poplar, the elder, and the cornel are found here. Among plants, the angelica

## LAPLAND.

angelica is most cultivated, and highly esteemed: the sorrel is used as an antiscorbutic. They have likewise other kinds of herbs, different species of grafs, heath, fern and moss, but the vegetable which is in the greatest plenty is the lichen. This moss covers the whole ground; its colour is a pale yellow, which when dry changes to white; the regularity of its shape, and the uniform manner in which the surface of the ground is decked with it, appears singular and striking; it has the semblance of a beautiful carpet. These plants grow in a shape nearly octagonal, and approaching to a circle, and as they join each other, they form a kind of Mosaic work, or embroidery. As this moss is very dry, nothing can be more pleasant to tread upon, nor can there be any thing softer for a bed: Acerbi, and his companions, in their journey frequently slept upon it. In some places it seems to be the only herb that will grow; the neighbouring birches and firs appear to vegetate with difficulty, as if deprived of their nourishment by the moss: in short, says the writer, "this moss appeared to be a royal plant, which ruled absolute over the vegetable kingdom of the country, and distributed its bounty and influence among a particular race of men and animals." With respect to the mineralogy of the country; silver and lead have been discovered in the provinces of Pitha and Lula; in the district of Torna there are two copper mines, and some excellent veins of iron. Here are found crystals of a very large size, and so hard and fine, that when polished they resemble real diamonds. In some parts amethysts and topazes are found: also curious stones too hard to be worked by the common tools of the mason. In a few of their rivers they fish for pearls, which are generally pale; but some of them are as bright as the oriental pearls, though larger and more round. Lapland is infested with a great number of grey wolves and bears, with which the natives are perpetually at war. The country likewise abounds with elks, beavers, and otters, which live here unmoletted, and find plenty of fish for their subsistence. The forests of this country furnish haunts to a great number of beautiful martens and squirrels, which change their colour every winter from brown to grey. Here are also ermines, weasels, hares, large black cats which attend the Laplanders in hunting, and little dogs trained to the pursuit of game. But the most remarkable animal of Lapland is the rein-deer. The woods, mountains, and rivers, are well stocked with wild fowl, and all sorts of aquatic birds that build and breed in northern climates. Early in every spring the swans go glither in numerous flocks from the German ocean: the lapwings follow in such swarms that they darken the sky. The rocks and mountains are frequented with eagles, hawks, kites, falcons, and other birds of prey. The rivers abound with salmon, which ascend from the gulf of Bothnia, trout, bream, and perch of excellent flavour, and amazing magnitude. The insects are extremely numerous; they often obscure the face of day; and are so venomous that the rein-deer, to avoid them, fly to the tops of the highest mountains for shelter, and the inhabitants betake themselves to the seaside, which is less infested than other parts by these pestilent vermin.

The commerce carried on by the Laplanders is more considerable than one would expect in a desert country, inhabited by a savage and ignorant people. They export large quantities of fish to Bothnia and White Russia. They trade with the neighbouring countries of Norway, Sweden, Muscovy, and Finland, by the sale of rein-deer, fine furs, baskets, toys of their own manufacture, and cheese made of the rein-deer's milk. They receive in return rix-dollars, woollen cloths, linen, copper, tin, flour, oil, hides, cutlery, spirits, and tobacco. The Laplanders march in caravans to the

fairs in Finland and Norway; these are composed of a long string of 30 or 40 rein-deer tied to one another, the foremost being led by a Laplander who walks in front. At night, when they have fixed upon a spot to rest on, they form a large circle of their rein-deer and pulkas or sledges, ready yoked, and the animals lying down quietly on the snow, are fed with moss by their masters. The people kindle great fires, around which they sit and sup, and smoke and sleep. The revenue arising from this country is not of much consequence; it is partly paid in rix-dollars, but chiefly in furs, and the tribute from the poorer classes is taken in dried fish. Part of the taxes is allotted for the maintenance of the clergy.

The Laplanders are short, few of them being five feet high; in their dresses they use no kind of linen; the men wear a sort of pantaloons reaching to their shoes, and their doublet is made to fit the shape; over this is a close coat with narrow sleeves, which is fastened round them with a leathern girdle. To the girdle are attached their knives, their pipes, and their instruments for striking fire. The dresses of the women is very much like that of the men, but in addition to it they wear handkerchiefs, short aprons, rings on their fingers, and in their ears, from which among the rich are suspended chains of silver, which pass twice or thrice round the neck. They are much addicted to finery, and to the use of embroidery manufactured from brass wire. They change their habitations according to the season, living in houses in the winter, and in summer they make use of tents. Their household furniture consists of iron or copper kettles, wooden cups, bowls, spoons, and sometimes tin or even silver basons, to which must be added the implements of fishing and hunting. The inhabitants are chiefly divided into fishers and mountaineers. The former build their habitations near some lake, from which they derive their subsistence. The others seek their support on the mountains, possessing herds of rein-deer more or less numerous; these are very rich in comparison of the fishermen. It is usual to assign to every child at its birth a number of these animals, which, with their produce and increase are to belong to it, so that when he arrives at man's estate, he finds himself master of several hundred rein-deer. The following description of a Lapland family was given from the life by an intelligent traveller: "it consisted of an old man and his wife, with a child about two or three months old. The infant was trusted up in a kind of cradle, resembling, in shape, a fiddle case, made of the thick bark of a tree, so formed that it exactly contained the child, which was fixed in it with a kind of brass-chain. It was covered with fine and soft moss, over which was spread the skin of a young rein-deer. The cradle was swung on a rope, which was fastened to the top of the hut." The Laplanders are averse from war, and will forsake their homes, to which they are much attached, rather than engage in it. Their manners and habits are finely described by Thomson, who, in comparing them with the martial hordes of the north, says,

"Not such the sons of Lapland: wifely they  
Despise th' insensate barbarous trade of war;  
They ask no more than simple nature gives;  
They love their mountains, and enjoy their storms.  
No false desires, no pride-created wants  
Disturb the peaceful current of their time;  
And through the restless ever-tortured maze  
Of pleasure or ambition bid it rage.  
Their rein-deer form their riches. These their tents,  
Their robes, their beds, and all their homely wealth  
Supply: their wholesome fare and cheerly cups."

Great pains have been taken by the Danes and Swedes to improve

form the minds of the Laplanders on the subject of religion, but the majority of them continue to practise superstitions and idolatries, as grofs as any that are to be met with among the most uninftructed Pagans. They rely on augury and witchcraft, and have been confidered by many of our countrymen, who have vifited thofe parts, as skillful in magic and divination. Their magicians make ufe of what they call a drum, an inftrument like the tambourine. On this, thofe who profefs to be Chriftians draw the figures of their own gods, as well as thofe of Jefus Chrift, the apoftles, the fun, moon, ftars, rivers, &c. : on different parts of this inftrument and its ornaments are placed fmall brafs rings, which, when the drum is beaten with a little hammer, dance over the figures, and according to their progrefs the forcerer prognofitates. They retain the worfhip of many Teutonic gods, and have among them confiderable remains of Druidical infitutions. They believe in the tranfmigration of the foul, and have feftivals fet apart for the worfhip of certain genii, who, they imagine, inhabit the air, and have the diretion and fuperintendance of human aétions. A black cat is reckoned one of the moft valuable appendages in each houfe : they talk to it as to a rational creature, and in their hunting and fifhing parties it is their ufual attendant. To this animal the Danifh Laplanders communicate their fecrets ; they confult it on all important occafions ; and among the Swedifh Laplanders, the drum is kept in every family for the purpofe of confulting the devil.

The account given by M. Maupertuis of the rigour of this climate, when he went to the polar circle to ascertain the real figure of the earth, deferves to be noticed in this article. He obferves, that in the month of December fpirits froze within their houfes ; and if the door of a warm room were opened only for a moment, the external air infantly converted all the vapour within into a kind of fnow, whirling it round in vortexes. When they went abroad, they felt as if the air was tearing their breafts to pieces, and within doors, the cracking of the wood, of which the houfes were built, continually warn them by its contraction of an increafe of cold. In fpeaking of the atmofpheric appearances, and of the heavenly bodies ; he fays, the brightnefs of the moonlight, the twinkling of the ftars, and the effulgent corufcations of the aurora borealis, afford a light fufficient for moft of the occafions of life. No fooner, fays he, are the fhort days clofed, than fires of a thoufand figures and colours light the fky, as if intended to make up for the abfence of the fun. Thefe lights are perpetually variable. Sometimes they begin in the form of a great fear of bright light, with its extremities upon the horizon, which, with the motion refembling that of a fifhing-net, glides foftly up the fky, preferving a diretion nearly perpendicular to the meridian, and commonly after thefe preludes all the lights unite at the zenith, and form the top of the crown. It would be difficult to enumerate the different figures which thefe meteors affume, and the various motions with which they are agitated. Their motion is moft commonly like that of a pair of colours waving in the air, and the different tints of their light give them the appearance of fo many ftreamers of changeable filk. " I faw," fays the philofopher, " a phenomenon of this kind, that in the midft of all the wonders to which I was now every day accuftomed, excited my admiration. To the fourth a great fpace of fky appeared tinged with fo lively a red, that the conftellation of Orion looked as if it had been dipped in blood. This light, which was at firft fixed, foon moved, and changing into other colours, violet and blue, fettled into a dome, the top of which itood a little to the fourth-weft of the zenith. In this country, where there are lights of fo many different colours, I never faw

but two that were red, and fuch are always taken for prefages of fome great miffortune. It is not at all furprizing, if people, with an unphilofophic eye, difcover in thefe phenomena armies engaged, fiery chariots, and a thoufand other prodigies. To the enlightened and rational philofopher, Lapland every where preents fubjects of reflection and contemplation : no arts flourish here ; we no where meet with temples, houfes, wrecks of columns, or of other monuments, but a fine opportunity is afforded of ftudying among the wandering tribes the firft elements of focial life ; of fociety in its moft ancient form." Acerbi's Travels into Sweden, Lapland, &c. Conftet's Tour to Lapland.

LA PLATA. See *La PLATA*.

LAPMARK. See *FINMARK*.

LAPOUTI, a mountain of Afia, between Caffgar and Little Tibet.

LAPPA, in *Botany*, the Latin name for any kind of Bur, or feed that fticks to the coats of animals. See *ACTIUM*, *APARINE*, and *XANTHUM*.

LAPPAGO, a name for the *Galium Aparine*, or Goose-grafs, alluding to the bur-like nature of its feeds. (See *LAPPA*.) It is now appropriated by Schreber to a particular genus of grafses ; fee the next article.

LAPPAGO, fo named by Schreber, on account of the bur-like afpect of the feed invefted with its mucicated hulks. —Schreb. 55. Willd. Sp. Pl. v. 1. 484. Mart. Mill. Dict. v. 3. Sm. Prodr. Fl. Græc. Sibth. v. 1. 76. Ait. Hort. Kew. ed. 2. v. 1. 182. (Tragus ; Hall. Hist. v. 2. 203. Desfont. Atlant. v. 2. 386.)—Clafs and order, *Triandria Digenia*. Nat. Ord. *Gramina*, Linn.

Gen. Ch. Cal. aggregate, each glume of one valve, fingle-flowered, lanceolate, pointed, ventricofe, angular, furrowed, permanent, mucicated at the back with a triple row of cartilaginous prickles, hooked upwards. *Flori* folitary, leaflefs. *Cor.* of two valves, fmallier than the calyx, awnlefs, fmoother, membranous and whitifh ; its glumes lanceolate, acute, concave ; the outermoft oppofite to the calyx, ribbed, inner more delicate and but half the fize of the outer, embraced by the calyx. Nectary of two lanceolate acute leaflets. *Stam.* Filaments three, capillary, the length of the glumes ; anthers fhort, deeply divided. *Pift.* Germen fuperior, ovate ; ftyles two, capillary, rather fhort ; fignmas cylindrical, feathery. *Peric.* none, except the permanent corolla. *Seed* unconnected, elliptic-oblong, with a longitudinal furrow.

Eff. Ch. Calyx mucicated, of one valve, fingle-flowered, aggregate. Corolla of two valves, awnlefs.

The only known fpecies is

1. *L. racemofa*. Branching Bur-grafs.—Sm. Fl. Græc. Sibth. v. 2. t. 101. Hoff. Gram. Austr. v. 1. 28. t. 36. (Cenchrus racemofus ; Linn. Sp. Pl. 1487. Schreb. Gram. v. 1. 45. t. 4. Gramen caninum maritimum afperum ; Bauh. Prodr. 2. Theatr. 16.)—Native of the fandy fea-fhores of the fourth of Europe, as well as of Arabia and India. It is a hardy annual with us, flowering in the warmeft part of the fummer. The root confifts of downy fibres. *Stems* numerous, a fpan high, jointed, unbranched, leafy, round, fmoother, decumbent and taking root at the bottom. *Leaves* fpreading, lanceolate, very acute, flat, ftriated, fmoother, except the edge, which is fringed as well as toothed ; the bafe is heart-fhaped ; the upper leaves are very fhort ; theaths rather fwelling, ftriated, fmoother, the upper ones longeft. *Stipula* fhort, fringed. *Spikes* terminal, folitary, two or three inches long, erect, cylindrical, obtufe, many-flowered, generally purplifh, and of an unufual afpect on account of the prickly hulks. Their common *ftalk* is hairy. *Flowers* three or four on each little zig-zag partial ftalk, alternate, rather

rather distant, erect, the uppermost generally abortive. The lower part of the *spike* is thin and flagging.

**IAPPANO**, in *Geography*, a town of Naples, in Calabria Citra; four miles N. of Cosenza.

**IAPPO**, a small island in the Baltic, between the coast of Finland and the island of Åland. N. lat. 60° 20'. E. long. 20° 48'.—Also, a town of Sweden, in the government of Abo; 23 miles S. of Abo.—Also, a town of Sweden, in East Bothnia, and government of Wafå; 37 miles E.N.E. of Wafå.

**LAPPO Serfoi**, a town of Sweden, in East Bothnia; 60 miles S.E. of Wafå.

**LAPPOJOCK**, a river of East Bothnia, which runs into the sea, five miles below Ny-Karleby.

**LAPPÖREN**, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 23'. E. long. 20° 59'.

**LAPTRASK**, a town of Sweden, in the province of Nyland; 21 miles N.E. of Borgo. N. lat. 60° 37'. E. long. 26° 12'.

**LAPPULA**, in *Botany*, a name given by some to the great caucalis, or rough-fruited stone-parley, or bastard parley.

**LAPSANA**, by some written *Lampfana*, an old Latin name, usually derived from *λαπάρα*, to purge or evacuate, on account of a supposed quality in the plant. Ambrosinus deduces it, by antiphrasis, from *λαπαρηνος*, *delstitute of splendour*, because of the mean appearance of the herb.—Linn. Gen. 405. Schreb. 534. Willd. Sp. Pl. v. 3. 1622. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 842. Juss. 168. Tourn. t. 272. Lamarek. Illustr. t. 655. Gært. t. 157. (Rhadagiolus; Cæfalp. 511. Schreb. 534. Willd. Sp. Pl. v. 3. 1625. Mart. Mill. Dict. v. 4. Juss. 168. Tourn. t. 272. Lamarek. Illustr. t. 655. Gært. t. 157. Koelpinia; Pallas. It. v. 3. 755.)—Class and order, *Syngenesia Polygamia-aqualis*. N. O. d. *Compositæ Semisfoculose*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common Calyx* ovate, somewhat cylindrical, angular, of about eight equal, linear, keeled, channelled, acute scales, with a few small imbricated ones at the base, all permanent. *Cor.* compound, imbricated, uniform; the florets hermaphrodite, about 16, more or less, equal, each of one petal, ligulate, abrupt, with five teeth. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen rather oblong; style thread-shaped, as long as the stamens; stigma cloven, reflexed. *Peric.* none, except the permanent scales of the calyx. *Seeds* solitary, oblong, angular, contracted at the top, upright or spreading, destitute of wing or down. *Recept.* naked.

Eff. Ch. Receptacle naked. Calyx with scales at the base, its inner scales equal, channelled. Seeds without down, contracted at the top.

1. *L. communis*. Common Nipple-wort.—Linn. Sp. Pl. 1141. Engl. Bot. t. 844. Curt. Lond. fasc. 1. t. 59. Fl. Dan. t. 500.—Calyx of the fruit closed, unchanged, smooth. Seeds loose. Stem panicled.—Frequent in waste or cultivated ground throughout most parts of Europe, flowering in summer. The root is annual. *Stem* erect, two or three feet high, roundish, nearly smooth, much branched in a panicled manner, leafy in the lower part. *Leaves* soft and rather hairy, toothed; the radical ones lyrate, the others ovate, acute, alternate. *Flowers* small, yellow, on long, slender, alternate stalks. *Seeds* nearly straight and erect, angular and striated, surrounded by the dried, smooth, permanent, scarcely changed calyx, but unconnected with it, and at length falling out, leaving it empty. This plant is said to be called *Papillar*, in Prussia, a name synonymous with Nipple-wort; because it is said to cure ulcerated breasts.

A variety of this, with the margins of its leaves curled, and more deeply as well as unequally toothed, is *L. crispata* Willdenow, said by him to continue constant from seed. Linnaeus considered it a variety, nor do we find reason to swerve from that opinion.

2. *L. stellata*. Starry Nipple-wort.—Linn. Sp. Pl. 1411. Gært. v. 2. 354. (L. n. 3; Gerard. Gallopr. 175. Rhadagiolus stellatus; Willd. n. 1. Rhadagiolus altera; Cæfalp. 511. Hieracium stellatum; Bauh. Hist. v. 2. 1014. H. narbonense falcatum; Lob. Ic. 240. H. falcatum Lobelii; Ger. em. 298.)—Seeds awl-shaped, spreading, somewhat incurved, embraced by the mucricated calyx-scales. Stem widely spreading. Radical leaves obovate, somewhat runcinate.—Native of the south of Europe. *Root* annual. *Stems* several, widely spreading or decumbent, branched. *Leaves* thin and nearly smooth, except a little roughness about the edge; the lower ones obovate, rather acute; tapering and nearly entire at the base; more or less runcinate about the middle, with numerous sharp teeth, each tipped with a little pale callous point: the upper leaves are linear-lanceolate, undivided and nearly entire. *Flowers* small, yellow, on long spreading stalks. *Calyx* rough with minute ascending bristles or prickles. Perfect seeds generally eight,  $\frac{2}{3}$  of an inch long, widely spreading in the form of a star, awl-shaped, slender, smooth, each embraced by one scale of the calyx, which rather exceeds it in length, and is externally rough with little prominent prickles, especially towards the point. About two or three very much incurved, smaller, apparently abortive seeds are found in the centre, each in like manner invested with its rough calyx-scale. All the seeds, as well as the calyx, are firmly united together to the tumid receptacle, which they entirely cover, till they are loosened by time or decay.

We unite, without the least scruple, the *L. stellata* and *L. Rhadagiolus* of Linnaeus as one species, on the authority of his own specimens, as well as that of his and our learned friend Gerard. They differ only in having more or less toothed radical leaves. Every other part precisely accords. Whether the two following be distinct from this now described may admit of some doubt, but we are persuaded they are so.

3. *L. Rhadagiolus*. Bird's-foot Nipple-wort.—Scop. Carn. ed. 2. v. 2. 119. (Rhadagiolus edulis; Gært. v. 2. 354. Willd. n. 2. Rh. lampfanae foliis; Tourn. Cor. 36? Rh. alter; Tourn. Inf. 480. t. 272. Rh. fig. 1. Lamarek. Illustr. t. 655. Rhadagiolus; Cæfalp. 511.)—Seeds few, awl-shaped, widely spreading, somewhat recurved, embraced by the smooth calyx-scales. Stem spreading. Radical leaves deeply runcinate, with rounded lobes.—Native of the south of Europe. We have garden specimens, named *L. stellata*, from Mr. Davall. The radical leaves are deeply and regularly pinnatifid in a lyrate manner, with two or three pair of opposite lobes, all rounded and blunt like the terminal one, but each tipped nevertheless, as in the former, with a little callous or glandular point. The calyx is perfectly smooth, both in flower and fruit. Perfect seeds generally but four, shorter and thicker than in the last, coloured, recurved, or, as Scopoli observes, deflexed, well compared by Cæfalpinus to a bird's foot, from which description and Tournefort's figure there can be no doubt of this being the plant both these authors meant, though Tournefort appears to have reversed the two species of Cæfalpinus; and hence perhaps arose the almost inextricable confusion among following authors. Linnaeus could not correct this, as he never saw but one species. We believe the two to be truly distinct. The resemblance of the radical leaves of the present to *L. communis*, makes us retain the

synonym of Tournefort's Corolla, though with a mark of doubt.

4. *L. Koelpinia*. Linear-leaved Nipple-wort.—Linn. Suppl. 348. (*Koelpinia linearis*; Pallas It. v. 3. 755. t. 1, l. f. 2. *Rhagadiolus Koelpinia*; Willd. n. 3.)—Seeds numerous, awl-shaped, spreading, incurved, embraced by the mucricated calyx-leaves. Leaves all linear-lanceolate, entire.—Found by Pallas in only one moist valley, by mount Bogden, in the desert of Attraction. We have a wild specimen from Aleppo, given by sir Joseph Banks. It flowers in the middle of May, ripening seed by the end of the month. The yellow blossoms open to the morning sun, and close at noon. This is a very slender plant, with a small annual root. The stems are from ten to eighteen inches long, scarcely branched, loosely spreading, smooth; square and furrowed towards the top. Leaves distant, all linear lanceolate, acute, entire, pliable, smooth, obscurely three-ribbed. Flowers solitary, on short scattered stalks, from the very root to the extremity of each stem. Calyx clothed with incurved prickles. Ripe seeds numerous, about twelve or fourteen, spreading from their base, but strongly incurved, each invell'd with one of the calyx-leaves, whose numerous, incurved, hooked prickles are much more remarkable than in either of the two last, some of them forming a recurved star at the top of each seed. This species is more akin to *L. stiltata* perhaps than any other, but the characters given above seem sufficient to keep them distinct. Pallas suggested the propriety of separating the three last-described species from *Lapsana*, by the name of *Koelpinia*; see that article. Whether they ought to form a genus, is, to us at least, doubtful. Schreber has agreed with Pallas if this point, only properly preferring the name of *Rhagadiolus* for the genus, as given by Cæsalpines and Tournefort, and correctly derived from *ῥαγὰς*; *ῥαγὰδες*, a cleft or fissure, whether it alludes to the reputed virtues of these plants in healing cracks of the skin, or to the cut (or star-like) aspect of the seeds. In habit they sufficiently accord with the original *Lapsana*, and the difference in the position of the ripening seeds is their only distinction. We ought rather perhaps to admire the sagacity of Linnæus in perceiving their agreement, than the ingenuity of those who have distinguished them. Pallas himself, with great modesty, merely submits his opinion to the decision of those who take the lead in botany. In the same uncertainty we wish now to leave it.—*L. Zacyntna* seems to be separated from the rest with more propriety, as its seeds have a feathery crown, and the nature of the torose calyx is more like that of *Crepis*. Jussieu includes it under his genus *Hedynopsis*; see that article.

Three much more dissimilar plants are ranged under *Lapsana* by Willdenow. These are *Hyoferis fatida* and *minima* of Linnæus, with *L. virgata* of Desfontaines, Fl. Atlant. v. 2. t. 215.—The first is on the authority of Haller and Scopoli, who say the seeds are without down. We have never seen them, but the stemless habit of the plant, and its whole aspect, exactly like a *Leontodon*, are so foreign to *Lapsana*, that the natural characters of the genus would be overlet by its admission.—*Hyoferis minima*, Gærtner's *Arnoferis*, t. 157, is indeed less unlike in habit, though stemless; but the seeds have an elevated border, and do not agree with *Lapsana*.

The third, *virgata*, has so great a number of florets as to take off an important part of its generic affinity, and its habit is more like an *Hedynopsis*. Having seen no specimen, we can decide nothing as to this species. It is necessary to know whether the seeds have an elevated border, in which case it might very well be placed along with *Hyoferis minima*, wherever that remains; or whether they be truly all without

a crown, and contracted at the summit, as in the true species of *Lapsana*. S.

LAPSARIÏ. See INFRALAPSARIÏ, SUBLAPSARIÏ, and SUPRALAPSARIÏ

LAPSE, in Law, a slip or omission of a patron to present a clerk to a benefice within six months of its being void: in which case, the benefice is said to be in lapse, or lapsed, and the right of presentation devolved to the ordinary.

And if the ordinary neglect to present during the same time, the right of presentation accrues to the metropolitan, and to the king by neglect of the metropolitan. This right of lapse was first established in the reign of Henry II., when the bishops first began to exercise universally the right of institution to churches (Braët. l. 4. tit. 2. c. 3.); and therefore, when there is no right of institution, there is no right of lapse; so that no donative can lapse to the ordinary, unless it hath been augmented by the king's bounty (fl. 1 Geo. I. st. 2. c. 10.); but no right of lapse can accrue when the original presentation is in the crown. (St. 17 Edw. II. c. 8. 2 Inst. 273.) In case the benefice becomes void by death, or cession through plurality of benefices, then the patron is bound to take notice of the vacancy at his own peril; but in case of a vacancy by resignation, or canonical deprivation, or if a clerk presented be refused for insufficiency, these being matters of which the bishop alone is presumed to be cognizant, here the law requires him to give notice thereof to the patron; otherwise he can take no advantage by way of lapse. (4 Rep. 75. 2 Inst. 632.) Neither shall any lapse accrue thereby to the metropolitan or the king. If the bishop refuse or neglect to examine and admit the patron's clerk, without good reason assigned or notice given, he shall have no title to present by lapse (2 Roll. Abr. 639.); and if the right of presentation be litigious or contended, and an action be brought against the bishop to try the title, no lapse shall occur till the question of right be decided. (Co. Litt. 344.) If the bishop be both patron and ordinary, he shall not have a double time allowed him to collate in (Gibf. Cod. 769.); and if the bishop doth not collate his own clerk immediately to the living, and the patron presents, though after the six months are lapsed, yet the presentation is good, and the bishop is bound to institute the patron's clerk. (2 Inst. 273.) If the bishop suffer the presentation to lapse to the metropolitan, the patron also has the same advantage if he presents before the archbishop has filled up the benefice: yet the ordinary cannot after lapse to the metropolitan, collate his own clerk to the prejudice of the archbishop. (2 Roll. Abr. 368.) But if the presentation lapses to the king, the patron shall never recover his right, till the king has satisfied his turn by presentation; for *nullum tempus occurrit regi*. But to prevent the inconvenience of the church's continuing void for ever, unless the king shall be pleased to present, the law has lodged a power in the patron's hands of, as it were, compelling the king to present. For if, during the delay of the crown to present, the patron himself presents, and his clerk is instituted, the king indeed, by presenting another, may turn out the patron's clerk; or, after induction, may remove him by *quare impedit*; but if he does not, and the patron's clerk dies incumbent, or is canonically deprived, the king hath lost his right, which was only to the next or first presentation. 7 Rep. 28. Cro. Eliz. 44. Blackst. Com. vol. ii.

LAPSED LEGACY. See LEGACY.

LAP-SIDED, in Sea Language, denotes the state of a ship, which is built in such a manner as to have one side heavier than the other, and consequently to retain a constant

heel or tendency toward the heavier side, unless when the is brought upright by placing a greater quantity of the cargo or ballast on the other side.

**LAPTANA**, in *Geography*, a town of Prussia, in the province of Samland; 10 miles N. of Konigberg.

**LAPTCHOUT-HOTUN**, a town of Asia, in the country of Hami; 30 miles W. of Hami-Hotun. N. lat. 43°. E. long. 92° 48'.

**LAPUSZNA**, a town of European Turkey, in Moldavia, near a river of the same name; 50 miles E.S.E. of Jassi.

**LAPWING**, **CAPELLA**, in *Ornithology*, the black-breasted tringa, with a hanging crest, or *Tringa vanellus* of Linnæus, commonly known in England by the name of lapwing or bastard plover, and called by some, in Latin, *vanellus*. See **TRINGA**.

Were the lapwing less common, it would be highly esteemed for its beauty. It is very frequent in our sunny countries, and in the wet places of most other parts of Europe.

It lays four eggs, of an olive cast, spotted with black, in a slight nest made with a few bents. The young, as soon as hatched, run like chickens, and are preserved with great anxiety and clamour by their parents from apprehended danger; which are said to flutter along the ground to a considerable distance from their nest, to elude pursuers, and to become more clamorous when most remote from it. The eggs are much valued for their delicacy, and are sold by the London purveyors for three shillings per dozen. In winter, lapwings join in large flocks, and are very wild; their flesh is very good, their food being insects and worms. During October and November, they are taken in the fens in nets, in the same manner as ruffs are, but are not preserved for fattening, being killed as soon as caught. Ray and Pennant.

**LAQUEARIUS**, a kind of athlete among the ancients, who in one hand held a *laqueus*, i. e. a sort of snare, wherewith to embarrass and entangle his antagonist, and in the other a poignard to stab him.

**LAQUER**. See **LACQUER**.

**LAQUEUS**, in *Surgery*, a *noose* or *snare*; or a kind of ligature, so contrived, that when stretched, by any weight, or the like, it draws up close.

It is used to extend broken or disjoined bones, to keep them in their places, when they are set, and to bind the parts close together.

**LAQUILO**, in *Geography*, a small island in the Mediterranean, near the coast of Murcia, about 3 miles S.E. of Almagaran.

**LAR**, or **LAAR**, a city of Persia, and capital of Laristan, situated on a sandy soil, amidst barren mountains; but the gardens, of which each house has one, abound with dates, an excellent fruit, which particularly prospers in this part of Persia. The houses are low, and in the time of Chardin were about 200. The city also contains bazars, mosques, a castle on a rocky, and a palace, in which the governor resides. The Jews reside in a quarter by themselves, and carry on a silk manufacture; and the Dutch have a factory here. In the vicinity are plantations of oranges and tamarinds, as well as dates; and at the foot of a mountain, at a small distance from the city, is found the substance called "Mummy;" 120 miles W. of Ormus. N. lat. 27° 20'. E. long. 54° 10'.

**LARAA**, a town of Spain, in Old Castile, on the Arlenza; 13 miles S.S.E. of Burgos.

**LARACHA**, or **LARACHE**, a sea-port town of Africa, in the empire of Morocco, on the river Luccos, near the Atlantic

ocean. The environs are intersected by woods and marshes. A fort, built by the Spaniards, on the land side, still remains, and the castle on the side of the road is defended by batteries, which lie close to the water's edge. The river is of good depth; and some commerce was formerly carried on in this place by the Europeans; but in the year 1780, the emperor compelled the merchants to retire. The large vessels of the emperor usually winter here; but there are no docks for ship-building. The road of this harbour is insecure in winter, but it is free from danger between the beginning of April and the end of September; 33 miles S. of Tangiers. N. lat. 34° 58'. W. long. 6° 2'. Chénier's Morocco, vol. i.

**LARADA**, a town of Tripoli; 30 miles S.E. of Mesurada.

**LARAGNE**, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap; 9 miles S.S.E. of Serres. The place contains 664, and the canton 3673 inhabitants, on a territory of 192½ kilometres, in 8 communes.

**LARANDA**, in *Ancient Geography*, a town of Asia, in Cappadocia, belonging to Astiochiana, according to Ptolemy, who joins this canton to Lycocania, but by other authors it is united with Pisidia and Hauria.

**LARASSA**, a town of Asia, in Media, not far from Ecbatana. Ptol.

**LARBOARD**, in *Sea Language*, the left-hand side of the ship, looking forward from the stern.

**LARBORUM**, in *Ancient Geography*, an episcopal town of Asia, in Caria.

**LARCENY**, or **LARCINY**, in *Law*, is a theft of personal goods or chattels, in the owner's absence. See **THEFT**.

The word comes from the French *larcin*; and that from the Latin *latrocinium*, *theft*.

Larceny is distinguished by the law into two sorts; the one called *simple larceny*, or plain theft, unaccompanied with any other atrocious circumstance; and *mixed or compound larceny*, which includes in it the aggravation of taking from one's house or person.

In respect of the things stolen, *simple larceny* is either *great or small*.

**LARCENY**, *Great*, *Grand*, is when the things stolen, though severally, exceed the value of 12*d*.

**LARCENY**, *Petty*, or *Petit*, is when the goods stolen exceed not the value of 12*d*.

*Simple larceny* is defined the felonious taking, and carrying away, the personal goods of another: so that in order to constitute this crime, there must be a *taking*, which implies the consent of the owner to be wanting; and therefore no delivery of the goods from the owner to the offender, upon trust, can ground a larceny. By the common law it was no larceny in a servant to run away with the goods committed to him to keep, but only a breach of trust: but by statute 21 Hen. VIII. c. 7. if any servant embezzles his master's goods to the value of 40*s*. it is made felony, except in an apprentice and servants under eighteen years old. But if he had not the possession, but only the care and oversight of the goods, as the butler of plate, the shepherd of sheep, and the like; the embezzling of them is felony at common law. (1 Hal. P. C. 506.) By the declaratory act of 39 Geo. III. c. 85. entitled "An act to protect masters against embezzlements by their clerks or servants," it is enacted and declared, that if any servant or clerk, or any person employed for the purpose in the capacity of a servant or clerk, to any person or persons whomsoever, or to any body corporate or politic, shall, by virtue of such employment,

## LARCENY.

ployment, receive or take into his possession any money, goods, bond, bill, note, banker's draft, or other valuable security, or effects, for, or in the name, or on the account of his master or masters, or employer or employers, and shall fraudulently embezzle, secrete, or make away with the same, or any part thereof; every such offender shall be deemed to have feloniously stolen the same; although such money, goods, &c. was or were not otherwise received into the possession of such master or masters, &c. than by the actual possession of his or their servant, clerk, or other person so employed. And every such offender, his adviser, procurer, aider, or abettor, being thereby lawfully convicted or attainted, shall be liable to be transported to such parts &c. for any term not exceeding fourteen years, in the discretion of the court before whom he shall be convicted or adjudged. Several statutes have also, at various times, passed to protect public companies from deprivations by their officers and servants; as 15 Geo. II. c. 13. f. 12. with respect to those of the bank of England, rendering embezzlement a capital felony; 35 Geo. III. c. 66. f. 6. and 37 Geo. III. c. 46. touching certain annuities payable at the bank of England, and containing the same provisions as the 15 Geo. II. c. 13. f. 12. The 24 Geo. II. c. 11. f. 3. contains the same provisions respecting the officers and servants of the South Sea house. So if a guest robs his inn or tavern of a piece of plate, it is larceny (1 Hawk. P. C. 90.); and so it is declared to be by 3 & 4 W. & M. c. 9. if a lodger runs away with the goods from his ready furnished lodgings. There must also be a *carrying away*; and a bare removal from the place in which he found the goods, though the thief does not quite make off with them, is sufficient. But this must be *felonious*, i. e. done *animo furandi*, or, as the civil law expresses it, *lucri causa*. (Inst. 4. f. 1.) The ordinary discovery of a felonious intent, is where the party doth it clandestinely, or, being charged with the fact, denies it: besides which, there are other circumstances that evince a felonious intent, which are left to the consideration of the court and jury. Moreover, this felonious taking and carrying away must be of the *personal goods of another*. Of things that adhere to a freehold, as corn, grass, trees, and the like, or lead upon a house, no larceny could be committed by common law; but the severance of them was, and in many things is still, merely a trespass: however, if the thief severs them at one time, whereby the trespass is completed, and they are converted into personal chattels, in the constructive possession of him on whose soil they are left or laid, and comes again at another time, when they are so turned into personality, and takes them away, it is larceny; and also if the owner, or any one else, has severed them. (3 Inst. 109. 1 Hal. P. C. 510.) And by 4 Geo. II. c. 32. to steal, or sever with intent to steal any lead or iron fixed to a dwelling-house, or out-house, or in any court or garden belonging to it, is made felony, liable to transportation for seven years. And by 21 Geo. III. c. 68. he who shall steal, rip, cut, break, or remove, with intent to steal any copper, brass, bell-metal, utensil, or fixture, fixed to any building, or in any garden, orchard, court-yard, fence, or outlet, belonging to any building, or iron-rails, or fencing, &c. and also his aiders and abettors, and all who shall knowingly buy or receive the same, shall be guilty of felony, and transported for seven years, or detained in prison and kept to hard labour, not exceeding three years, nor less than one, and within that time, if the court shall think fit, shall be once or oftener, but not more than thrice, publicly whipped. Moreover, to steal underwood or hedges, and the like, to rob orchards or gardens of fruit growing therein, to steal or otherwise destroy any turnips, or the roots of madder

when growing, are, by 43 Eliz. c. 7. 15 Car. II. c. 2. 31 Geo. II. c. 25. 6 Geo. III. c. 48. 9 Geo. III. c. 41. 13 Geo. III. c. 32. punishable criminally by whipping, small fines, imprisonment, and satisfaction to the party wronged, according to the nature of the offence. Moreover, the stealing by night of any trees, roots, shrubs, or plants, to the value of 5s. is by 6 Geo. III. c. 36. made felony in the principals, aiders, and abettors, and in the purchasers knowing the same to be stolen: and by 6 Geo. III. c. 48. and 13 Geo. III. c. 13. the stealing of any timber-trees, as oak, beech, chestnut, walnut, ash, elm, cedar, fir, asp, lime, sycamore, birch, poplar, alder, larch, maple, and hornbeam, and of any root, shrub, or plant, by day or night, is liable to pecuniary penalties for the first two offences, and for the third is constituted a felony, liable to transportation for seven years. Stealing ore out of mines is no larceny, except the stealing ore out of mines of black lead, which is felony without benefit of the clergy by 25 Geo. II. c. 10. Stealing of writings relating to a real estate is no felony, but a trespass (1 Hal. P. C. 510. Stra. 1137.): bonds, bills, and notes are goods of which larceny cannot be committed by common law (8 Rep. 33.): but by 2 Geo. II. c. 25. they are put upon the same footing with respect to larcenies, as the money they were designed to secure. And by 7 Geo. III. c. 50. if any officer or servant of the post-office shall secrete, embezzle, or destroy any letter or packet, containing any bank-note, or other valuable paper, specified in the act; or shall steal the same out of any letter or packet, he shall be guilty of felony without benefit of clergy. Or if he shall destroy any letter or packet with which he has received money for the postage, or advance the rate of postage, and secrete the money, he shall be guilty of single felony. By 26 Geo. II. c. 19. plundering or stealing from any ship in distress, whether wreck or no wreck, is felony, without benefit of clergy. For the laws relating to fish and game, see *Stealing of FISH and GAME*.

Of all valuable domestic animals, as horses, and of all animals, *domite nature*, which serve for food, as swine, sheep, poultry, and the like, larceny may be committed; and also of the flesh of such as are *feræ nature*, when killed. 1 Hal. P. C. 511.

Although no larceny can be committed, unless there be some property in the thing taken, and an owner; yet, if the owner be unknown, provided there be a property, it is larceny to steal it; and an indictment will lie, for the goods of a person unknown. (1 Hal. P. C. 512.) This is the case of stealing a shroud out of a grave; which is the property of those, whoever they were, that buried the deceased; but stealing the corpse itself, which has no owner, (though a matter of great indignity,) is no felony, unless form of the grave clothes be stolen with it.

By the Roman law, the penalty of *simple* and *secret* larceny was the returning it two-fold; and of *manifest* larceny four-fold: *manifest* larceny was, where the criminal was taken in the fact; *simple*, where he was not. The Lacedæmonians never punished larceny provided the person was not caught in the fact; but, on the contrary, it was applauded as a mark of dexterity and address. See *LACEDÆMONIANS*.

The laws of Draco at Athens, which are said to be written in blood, punished it with death; but Solon afterwards changed the penalty into a pecuniary mulct: and so the Attic laws in general continued. By the Jewish law, theft was only punished with a pecuniary fine, and satisfaction to the party injured. (Exod. chap. xxii.) From these examples, as well as the reason of the thing, many learned and scrupulous men have questioned the propriety, if not lawfulness

## LARCENY.

fines, of inflicting capital punishment for simple theft; and proposed either a pecuniary or a corporal punishment. Sir Thomas More in his *Utopia*, p. 42, and more lately the marquis Beccaria, *Ess. on Crimes and Punishments*, chap. xxii. have proposed that kind of corporal punishment, which approaches nearest to a pecuniary satisfaction, *viz.* a temporary imprisonment, with an obligation to labour, first for the party robbed, and afterwards for the public, in works of the most slavish kind: nevertheless the punishment of theft still continues, through the greatest part of Europe, to be capital. Puffendorf (*Law of Nat. l. 8. c. 3*) and sir Matthew Hale (*1 Hal. P. C. 13*.) are of opinion, that this must be always referred to the prudence of the legislature; yet both writers agree, that such punishment should be cautiously inflicted, and never without the utmost necessity. It is observed, that our ancient Saxon laws nominally punished theft with death, if above the value of 12*l.* but the criminal was permitted to redeem his life by a pecuniary ransom: as, among their ancestors the Germans, by a stated number of cattle. (*Tacit. de Mor. Ger. c. 12.*) But in the ninth year of Henry I. this power of redemption was taken away, and persons guilty of great larceny directed to be hanged, which law continues in force to this day. (*1 Hal. P. C. 12. 3 Inst. 53.*) See FELONY. *Petit larceny* by common law is only punishable by whipping or imprisonment. (*3 Inst. 218.*) Or, by 4 Geo. I. c. 11. the punishment may be extended to transportation for seven years; but the punishment of *grand larceny*, or stealing above the value of 12*l.* which sum was the standard in the time of king Athelstan, eight hundred years ago, is, at common law, regularly death: upon which sir Henry Spelman observed, above a century since, when money was at twice its present rate, that while every thing else was risen in its nominal value, and become dearer, the life of man had continually grown cheaper. And though the jury may exercise a kind of unwarrantable clemency, by bringing in larceny under the value of 12*l.* and the benefit of clergy is allowed for the first offence; yet in many cases of simple larceny this is taken away by the statute: as from horse-stealing (*1 Edw. VI. c. 12. 2 & 3 Edw. VI. c. 33. 31 Eliz. c. 12.*), taking woollen-cloth from off the tenters (*Stat. 22 Car. II. c. 5.*), or linen, silks, calicoes, or cotton goods from the place of manufacture (*18 Geo. II. c. 27.*), stealing sheep or other cattle specified in the acts (*14 Geo. II. c. 6. 15 Geo. II. c. 34.*), thefts on navigable rivers above the value of 40*s.* (*24 Geo. II. c. 45.*), plundering vessels in distress, or that have suffered shipwreck (*12 Ann. Stat. 2. c. 18. 26 Geo. II. c. 19.*), stealing letters sent by the post (*7 Geo. III. c. 50.*), and stealing deer, hares, and conies under the circumstances recited in the *Waltham Black act*, *stat. 9 Geo. I. c. 22.*

The Circassians are said to honour theft at this day; inasmuch that at their public feasts, their youth are not suffered to drink, if they have not performed something remarkable in that way. Solinus tells us, that in Sardinia there was a fountain that had the virtue of discovering a person that had committed larceny.

*Compound or mixed larceny* is that, which, besides all the properties of the former, has the aggravation of taking from one's house or person. With respect to larceny from the house, see BERGLARY and HOUSE-BREAKING.

It may be here observed, that the benefit of clergy is denied: 1. In all larcenies above the value of 12*l.* from a church, or from a dwelling-house, or both, any person being therein. 2. In all larcenies to the value of 5*s.* committed by breaking the dwelling house, though no person be therein. 3. In all larcenies to the value of 40*s.* from a dwelling-house, or its out-houses, without breaking in, and

whether any person be therein or no. 4. In all larcenies to the value of 5*s.* from any shop, warehouse, coach-house, or stable, whether the same be broke open or not, and whether any person be therein or no: whether these offences are committed by day or by night.

Larceny from the person is either by privately stealing; or by open and violent assault, usually called *robbery*. The offence of privately stealing from a man's person above the value of 12*l.* as by privately picking his pocket or the like, without his knowledge, was debarred of clergy, so early as by the statute 8 Eliz. c. 14. For the other kind of larceny from the person, see ROBBERY. See also FELONY.

Persons who buy or receive any stolen goods, knowing the same to be stolen, shall be deemed accessaries after the fact; 3 W. c. 9; and by 4 Geo. c. 11. they may be transported for fourteen years: and by 5 Anne, c. 31. such persons, and those who conceal any felons or thieves, shall be deemed accessary to the felony, and being convicted on the testimony of one witness shall suffer death as a felon convicted: but within clergy. If the principal felon cannot be taken, so as to be prosecuted and convicted, yet the buyer and receiver of stolen goods may be prosecuted for a misdemeanour, and punished by fine and imprisonment, or other such corporal punishment as the court shall think fit; which shall exempt him from being punished as accessary, if the principal shall be afterwards taken and convicted. Receivers of stolen lead, iron, copper, brass, bell-metal, and solder, fixed to or being in any houses, out-houses, mills, &c. shall, on conviction by due course of law, and although the principal hath not been convicted, be transported for fourteen years. Suspected places may be searched, and suspected persons may be apprehended, and carried before two justices, and if the person from whom the goods were received be not produced, or some credible witnesses do not depose upon oath the sale or delivery of them, or no satisfactory account of them be given, they shall be adjudged guilty of a misdemeanour. Every person, to whom such goods shall be offered for sale, or to be pawned, shall apprehend the person offering them; and if it shall appear, to the satisfaction of two justices, that such person did not apprehend, &c. the person who brought or offered the same, then he shall be adjudged guilty of a misdemeanour. And persons for the two former misdemeanours, in having or carrying any of the said goods, shall forfeit for the first offence 40*s.*, for the second 4*l.*, and for every subsequent offence 6*l.*; and for not carrying a suspected person before a justice, he shall forfeit for the first offence 20*s.*, for the second 40*s.*, and for every subsequent offence 4*l.* (*29 Geo. II. c. 30*) By 21 Geo. III. c. 69 every person who shall buy or receive any pewter pot or other vessel, or any pewter, knowing the same to be stolen or unlawfully come by, or shall privately buy or receive any stolen pewter, he shall, though the principal person be not convicted, be transported not exceeding seven years, or detained in prison and kept to hard labour not more than three years nor less than one; and within that time be once or oftener, but not more than thrice, publicly whipped. Persons offering for pawn or sale goods suspected to be stolen, may be seized and conveyed by a constable or other peace officer before a justice, who may commit them for any time not exceeding six days for examination, and afterwards, if the goods were stolen or clandestinely obtained, to the common gaol or house of correction. (*30 Geo. II. c. 24*) Persons advertising a reward for helping to stolen goods, and also the printer and publisher of such advertisement, shall respectively forfeit 50*l.* with costs (*25 Geo. II. c. 36*.) And by 4 Geo. c. 11. those who receive such reward, without apprehending the felon and bringing

him to trial, shall be guilty of felony in the same manner as if they had stolen the same. The charges of prosecution and conviction, in respect of any grand or petit larceny, may, by order of court, and at the prayer of the prosecutor, be paid by the county treasurer, with a reasonable allowance for his time and trouble. (25 Geo. II. c. 36.) And by 18 Geo. III. c. 19. the same charges shall be allowed to the prosecutor, whether the person tried be convicted or acquitted, provided that in this latter case it shall appear to the court that there was reasonable ground of prosecution, and that the prosecutor had *bona fide* prosecuted. And by 27 Geo. II. c. 3. 18 Geo. III. c. 19. reasonable charges may be allowed and paid in the same manner, to a poor person who is required to give evidence: in Middlesex these charges shall be paid by the overseers of the poor where the person was apprehended. It is provided by statute, that every person who shall apprehend any one guilty of house-breaking or private stealing, to the value of 5s. and prosecute him to conviction, and all the executors or administrators of a person slain in endeavouring to apprehend a house-breaker or felon, shall have a certificate without fee, under the hand of the judge, certifying such conviction, &c. which certificate shall be enrolled by the clerk of the peace of the county where it is granted, and may be once assigned over and no more. By virtue of this certificate the original proprietor, or assignee of the same, shall be discharged from all parish and ward offices, within the parish or ward where the felony was committed. (10 & 11 W. c. 23.) Every such person, and also the executors and administrators of a person killed as before, shall also have another certificate, which, on being tendered to the sheriff, and demand made, shall entitle him to the sum of 40*l.* without fee, in one month after the tender and demand; on pain of forfeiting double with treble costs. (5 Anne, c. 31.) See *DISCOVERY of Accomplishes*.

The sheriff, on producing the certificates and the receipts for the said rewards, may deduct the same from his accounts; and if he have not money in his hands, he shall be repaid out of the treasury, on certificate from the clerk of the pipe; or he may immediately apply to the commissioners of the treasury, who shall pay the same without fee. 3 Geo. c. 15.

**LARCH-TREE**, *Larix*, in *Botany*. Linnæus refers this to the genus of pine. See *PINUS Larix*.

It is the common name of a kind of pine or fir tree, the leaves of which are long and narrow, and are produced out of little knots or tubercles, in the form of a painter's pencil; the cones are produced at remote distances from the male flowers on the same tree; the flowers are very like small cones at their first appearance, but afterwards stretched out in length. These trees are propagated by seeds, which should be sown in the beginning of March, upon a bed of light soil, exposed to the morning sun only; or they may be sown in pots or boxes of light earth, and placed near a hedge, where they may be exposed to it. The seed should be covered about half an inch thick with fine light earth, and in very dry weather should be gently refreshed with water. In about six weeks, if the seeds be good, the plants will come up, at which time they should be carefully guarded against rapacious birds, which would otherwise pull off the heads of the plants, as they thrust themselves out of the ground with their covers on them; and refresh them with water in dry weather, especially if they are sown in pots or boxes; also keep them clear from weeds, which, if suffered to grow among the young plants, will soon destroy them. In October, if they are in boxes or pots, remove them into a situation where they may be defended from sharp winds,

which are sometimes hurtful to them, while young; but afterwards they will endure the severest weather of our climate. These trees are very proper for the sides of barren hills, where few other sorts will thrive so well; nor are they very delicate in regard to soil, but will grow much better on poor, strong, stony land, than in rich ground; during the summer, they appear very beautiful; but in autumn they cast their leaves, and are not evergreen like the fir.

It has been observed in the fifth volume of the *Annals of Agriculture*, that "larch wood is possessed of so many valuable qualities, that to enumerate the whole would appear an extravagant hyperbole. It is known to resist water, without rotting, almost for ever. The piles of larch timber on which the houses of Venice were built many hundred years ago, when examined, are still found as fresh as when first put in. And he has been told, stakes of it have been tried in the decays of Lincolnshire, which, between wind and water, have already out-worn two or three sets of oak stakes, and do not yet discover any symptoms of decay. It is as far known to possess the valuable quality of neither shrinking nor warping, when put into work; nor is it liable to be pierced by worms in our climate, as many of the paintings of Raphael Urban, which are done on this wood, and are still perfectly entire, sufficiently prove. Experiments have not yet ascertained whether it will resist the sea-worm in tropical climates, like the Bermuda cedar; but there is reason to think it would, as, in many of its other properties, it resembles that wood very much. Along with these valuable properties, it is known to be one of the quickest growing trees in this climate, remarkably hardy, and extremely beautiful when growing. It is, besides, much more easily reared than the oak, and could be spread over a great extent of mountains, if sufficiently bare of herbage, at least to no expense, by the natural shedding of its seeds, like birch or fir in soils that favour them, merely by keeping out cattle from those fields in which small clumps of this kind of wood had been planted some years before. In this way very extensive tracts in the condition just described might be entirely filled with this valuable timber. The uses to which it might be applied are innumerable. It would be valuable not only for ship-plank, but even crooked timbers might be obtained by using a little art, when young, to bend it, as the Bermudians do their cedar; for flood-gates in navigable canals and wet-docks it would exceed every thing that can be obtained in this climate. For barrel-staves it would be inimitable, and would enable us to furnish that article as cheap as any other nation whatever; and in building it would answer all the purposes to which fir is now applied, being much stronger and more durable than that wood. And when it is also adverted to, that it is next to incombustible, the reader will not think it strange that he in this manner so strongly recommends it to the attention of his countrymen, particularly those in the most rugged and barren districts; for, in such situations, it would be easy to shew, that, at a very trifling charge, they might, in a short period of years, bring their estates to a hundred times the value they bear at present, or even can be made to bear by any other kind of improvement. This would be a much more eligible plan of bettering their fortunes than that of trying to squeeze, with difficulty, from a poor people, a raised rent, for a subject that does not admit of proportionable improvement. See *PLANTING*.

The common cone-bearing larch-tree grows naturally upon the Alps and Apennines, and has been lately much propagated in England. Those trees raised from seeds thrive best in the worst soil and situation. There are two varieties of this tree, one of which is a native of America, and

and the other of Siberia; neither of which thrive well in this climate. In Switzerland the wood of the common larch-tree is used for building and covering the houses; and in other countries, where it abounds, it is preferred for every purpose to all the kinds of fir. In many places there are ships built of this wood, which are said to be durable; and, therefore, this may be a very proper tree for planting upon some of the cold barren hills in many parts of England, which, besides the profit they would yield to their proprietors, would also conduce to national benefit. The Venetian turpentine is extracted from the larch-tree. See TURPENTINE.

LARCIE, in *Geography*, a town of France, in the department of Corrèze, and chief place of a canton, in the district of Brives. The place contains 536, and the canton 6679 inhabitants, on a territory of 135 kilometres, in nine communes.

LARCIANO, a town of Etruria; five miles S. of Pistoia.

LARDNER, NATHANIEL, in *Biography*, was born at Hawkherif, in the county of Kent, on the 6th of June, 1684. He probably received his grammatical learning at Deal, which was his father's residence, and where he was pastor of a congregation of Protestant Dissenters; and from school he was removed to a dissenting academy in London, under the care of the Rev. Dr. Joshua Oldfield; but after staying here a short time, he was sent, in the year 1699, and when he was only in his sixteenth year, to prosecute his studies at Utrecht, under professors D'Uries, Graevius, and Burman. In his journey he was accompanied by Mr. Martin Tomkins, and on their arrival they found there Mr. Daniel Neal. After spending somewhat more than three years at Utrecht, Mr. Lardner removed to Leyden, where he studied about six months. In 1703, he returned to England, and from this time to 1709, we have no memorials concerning him. In the last mentioned year he preached, for the first time, at Stoke Newington, from the words of the Apostle Paul, "For I am not ashamed of the gospel of Christ," &c. "There could not," says his biographer, the excellent Dr. Kippis, "have been a more proper text, for a man who was destined, in the order of divine providence, to be one of the ablest advocates for the authenticity and truth of the Christian revelation that ever existed." In 1713, Mr. Lardner undertook the tuition of Mr. Brindley Treby, son of sir George Treby, knight, late lord chief justice of the common-pleas. Having conducted the studies of the young man, about three years, in lady Treby's house, where he was domestic chaplain, he accompanied him in an excursion into France, the Austrian Netherlands, and the United Provinces, which employed them about four months. It does not appear how long his connection, in lady Treby's family, as tutor, lasted, but he continued to reside in the house till the died, in 1721. In 1723, Mr. Lardner was engaged with a number of ministers, in carrying on a course of lectures, on a Tuesday evening, at the Old Jewry. The gentlemen who conducted these lectures preached a course of sermons on the evidences of natural and revealed religion. The proof of the credibility of the gospel history was assigned to Mr. Lardner, and he delivered three sermons on this subject, which probably laid the foundation of his great work, as from this period he was diligently engaged in writing the first part of the *Credibility*. In 1727, he published, in two volumes octavo, the first part of "The *Credibility of the Gospel History*; or the facts occasionally mentioned in the New Testament, confirmed by passages of ancient authors who were contemporary with our Saviour, or his Apostles, or lived near their time." This has been esteemed by persons of all parties an invaluable performance, that has rendered the most essential service to the cause of

Christianity. It has passed through several editions. In the year 1728, Mr. Lardner's life was long despaired of, by the attack of a violent fever, from the effects of which he slowly recovered. With all his great merit, Mr. Lardner, desirous of a settlement as a dissenting minister, did not receive an invitation for this purpose till he was 45 years of age. It was in 1729 he became assilant to Dr. Harris, minister at Crutched or Crouched Friars. About this period he published "A Vindication of three of our blessed Saviour's Miracles; viz. The Raising of Jairus's Daughter, The Widow of Nairn's Son, and Lazarus," in answer to Mr. Woolston's attack on the scripture account of Christ's miracles. In 1733, appeared the first volume of the second part of "The *Credibility of the Gospel History*;" this volume comes down to the year 178, and is prefaced by an introduction, giving a clear and very luminous history of the New Testament. It was immediately translated into the Low Dutch and Latin languages. The second volume was published in 1735, and concludes the author's remarks out of Christian writers of the second century. In 1736, he was attacked with another dangerous fever, the effects of which prevented him from preaching for several months. In 1738, Mr. Lardner published the third volume of the second part of "The *Credibility*," ending with the year 233; in 1740, the fourth volume, which comes down to the year 248; and, in 1743, he published the fifth volume, which concludes with the year 306. About the same period he sent into the world another performance, entitled "The Circumstances of the Jewish People, an Argument for the Truth of the Christian Religion, in three Discourses." He brought out the remaining volumes of "The *Credibility*," at intervals between this period and the year 1755, and in the next two years he added to this great and valuable work a supplement, in three volumes, comprising a history of the apostles and evangelists, with remarks and observations upon every book of the New Testament. Our author, on account of his very high merit as a writer, had, in 1745, received a diploma, conferring upon him the degree of doctor of divinity. In the year 1751, he resigned the office of preacher at Crutched Friars, having, during the preceding year, published a volume of Sermons, the subjects of which are entirely of a practical nature; and, in 1760, he gave the world a second volume of these sermons. He had also published many other smaller pieces which were well received by the public; such was a sermon entitled "The Counsels of Prudence, for the Use of young People," for which he was thanked by Dr. Secker, at that time bishop of Oxford. The discourse has been very frequently printed, and has at the present moment a large sale. Lardner had also published "A Dissertation upon the two Epistles ascribed to Clement of Rome, &c.;" "An Essay on the Mosaic Account of the Creation and Fall of Man;" "The Case of the Demoniacs, mentioned in the New Testament;" "A Letter to Jonas Hanway, Esq.," to shew that Mary Magdalen was not the sinner mentioned in the seventh chapter of St. Luke's gospel, but a woman of distinction and excellent character, who for a while laboured under bodily indisposition, which our Lord miraculously healed; and that, therefore, houses intended for the reception of penitent prostitutes, ought not to be denominated Magdalen houses. In 1762, he published "Remarks on the late Dr. Ward's Dissertations on several Passages of the sacred Scriptures;" to which succeeded, in 1764, "Observations upon Dr. Macknight's Harmony, so far as related to our Saviour's Resurrection." Amidst these various productions of a smaller nature, Dr. Lardner continued the prosecution of his grand object, and in the last mentioned year he gave the world the first volume of "A large Collection of ancient Jewish and Heathen Testimonies

"Testimonies to the Truth of the Christian Religion," comprising the Jewish and Heathen authors of the first century. The remaining three volumes were published in intervals between this and the close of the year 1767, and in them the biblical student is presented with a noble treasure of curious and valuable information, and of able and judicious criticism, for which the Christian world is deeply indebted to the author. They complete the grand design which had occupied a large portion of forty-three years of Dr. Lardner's valuable life; and by them, though far from profitable, he has raised a monument to his fame, which can never perish. Dr. Lardner lived to a very advanced age, and with the exception of his hearing, retained the use of his faculties to the last, in a remarkably perfect degree. In the year 1768, he fell into a gradual decline, which carried him off in a few weeks, at Hawkehit, his native place, at the age of eighty-five. He had, previously to his last illness, parted with the copy-right of his great work for the miserable sum of 150*l.* but he hoped if the booksellers had the whole interest of his labours, they would then do their utmost to promote the sale of a work that could not fail to be useful in promoting the interests of his fellow creatures, by promulgating the great truths of Christianity on a rational foundation. After the death of Dr. Lardner, some of his posthumous pieces made their appearance; of these the first consist of eight sermons, and brief memoirs of the author. In 1776, was published a short letter, which the doctor had written in 1763, "Upon the Personality of the Spirit." It was part of his design, with regard to "The Credibility of the Gospel History," to give an account of the heretics of the first two centuries. In 1780, Mr. Hogg of Exeter published another of Dr. Lardner's pieces, upon which he had bestowed much labour, though it was not left in a perfect state; this was "The History of the Heretics of the first two Centuries after Christ, containing an Account of their Time, Opinions, and Testimonies to the Books of the New Testament; to which are prefixed General Observations concerning Heretics." The last of Dr. Lardner's pieces was given to the world by the late Rev. Mr. Wiehe, then of Maidstone in Kent, and is entitled "Two Schemes of a Trinity considered, and the Divine Unity asserted;" it consists of four discourses; the first represents the commonly received opinion of the Trinity; the second describes the Arian scheme; the third treats of the Nazarene doctrine; and the fourth explains the text according to that doctrine. This work may perhaps be regarded as supplementary to a piece which he wrote in early life, and which he published in the year 1759, without his name, entitled "A Letter written in the Year 1730, concerning the Question, Whether the Logos supplied the Place of the Human Soul in the Person of Jesus Christ;" in this piece his aim was to prove that Jesus Christ was, in the proper and natural meaning of the word, a man, appointed, anointed, beloved, honoured, and exalted by God, above all other beings.

For the many testimonies given of Dr. Lardner's character, the reader must be referred to Kippis's life, prefixed to a complete edition of his works, published in 1788, in eleven very large volumes, by the late J. Johnson. One or two only shall be quoted in this place. "The name of Lardner is well known in the literary world. No writer, from the very excellence of Christianity, ever conferred so essential service upon true religion, or contributed more to clear up its evidence and elucidate its antiquities. Accordingly, there is no country, where the Christian religion is professed, in which his name is not held in the greatest esteem. Every church would have been proud to boast of him as their member, and his voluminous productions

have been translated into almost all the languages of Europe."

"Dr. Lardner," says his most excellent biographer, "may be held out, in particular, as a fine example to those of his own profession. As the Dissenters had the honour of producing Dr. Lardner, he will naturally be the object of emulation to the dissenting clergy." They will so far look up to him as their pattern, as to endeavour to qualify themselves for appearing, when occasions call for it, in the great departments of literature, and especially in the cause of religious truth and liberty, and in defence of the sacred writings."

The piety of Dr. Lardner was sincere and ardent; it was the governing principle of all his actions, and founded on just and enlarged views concerning the nature of religion. The love of truth appears manifestly in all his works; and no one ever seems to have preserved a greater impartiality in his enquiries, or to have been more free from any undue bias. He followed truth wherever it led him; and for the attainment of it he was admirably qualified, both by the turn of his disposition and his understanding. The candour and moderation with which he maintained his own sentiments, constituted a prominent feature of his character. Benevolence, as well as piety, entered deeply into Dr. Lardner's character; he was ready to promote every good work; and to persons in distress he was ever willing to contribute, to the highest degree which his fortune would admit. His manners were polite, gentle, and obliging; and he was attentive in every respect to the laws of decorum.

We may observe, that Dr. Lardner's great works were unquestionably indebted for Dr. Paley's "View of the Evidences of Christianity;" nor is it too much to say that if the former had not been published, the latter, probably, would never have appeared; and justice requires us to add, that sufficient acknowledgments were not made for the assistance which was derived from the labours of the excellent Lardner. It must, however, be admitted, that the deficiencies of the amiable Paley have been supplied by his biographer Mr. Meadley; who, in speaking of his "View of the Evidences of Christianity," which appeared in 1794, in three volumes, 2*mo.* but which have in all subsequent editions been printed in two volumes, 8*vo.* Mr. Meadley says, "the direct historical testimony for the authenticity of the Christian revelation, already adduced by the indefatigable Lardner, is admirably selected and arranged in this important work; and the general argument drawn up with great clearness and felicity. The most striking of those collateral proofs of the credibility of the gospel history, produced by the same writer, are also here again presented, in a novel and impressive manner, and established by auxiliaries of a different kind." Of Dr. Paley's works, and of his motives in the publication, too high eulogiums cannot be paid, and it is to be regretted that in his preface he had not acknowledged his obligations to our author. Paley's View is capital as an abridgment of Lardner, Douglas, &c. and his work has been twice, at least, abridged or analysed; one of these abridgments was published at Cambridge in 1795, and another in London in 1810. Lardner's Works, and Life by Kippis; Meadley's Life of Dr. Paley; and private information.

LARE, in *Geography*, a town of the principality of Georgia, in the province of Carduel; 80 miles S. of Teflis.

LARE Point, a cape on the E. coast of Madagascar. S. lat. 16° 40'.

LAREDO, a sea-port town of Spain, in the province of Biscay, with a good harbour, in a gulf of the same name; 20 miles E. of Santander. N. lat. 43° 25'. W. long. 3° 21'.

LAREK,

LAREK, or LARESH, a small island in the Persian gulf; the soil of which is bad and the water brackish. The Persians have prevented the attempts of the Dutch for settling a factory in this island; 12 miles S.S.E. of Gambron. N. lat. 26° 50'. E. long. 56° 38'.

LARENDEBA, a town of Asiatic Turkey, in Carmania; 40 miles S.S.E. of Cogni.

LARENSIS, in *Ancient Geography*, an episcopal see of Africa, in the Proconular province.

LARENTIALIA, in *Antiquity*, a feast held among the Romans on the 23d day of December, but ordered to be observed twice a year by Augustus; by some supposed to have been in honour of the Lares, but by others, with more probability, in honour of Acca Laurentia; and to have been the same with Laurentalia.

LA REOLA, in *Geography*. See *La REOLA*.

LARES, among the *Ancients*, derived by Apuleius, De Deo Socratis, p. 689, from *lar, familiaris*; a kind of domestic genii, or divinities, worshipped in houses, and esteemed the guardians and protectors of families; supposed to reside more immediately in the chimney corner.

The Lares were distinguished from the Penates, as the former were supposed to preside over house-keeping, the servants in families, and domestic affairs; and the latter were the protectors of the masters of families, their wives and children: accordingly, the Lares were dressed in short succinct habits, to shew their readiness to serve, and they held a sort of cornucopia in their hands, as a sign of hospitality and good house-keeping. According to Ovid there were generally two of them, who were sometimes represented with a dog at their feet. *Fast.* v. 146.

Plutarch distinguishes good and evil Lares, as he had before done good and evil Genii.

There were also some public, others private Lares.

Apuleius tells us the domestic Lares were no more than the souls of departed persons, who had lived well, and discharged the duties of their station; whereas, those who had done otherwise, were vagabonds, wandering about, and frightening people, called *Larvæ* and *Lemures*; which see.

The Lares were also called *Penates*, and were worshipped under the figures of little marmosets, or images of wax, silver, or earthen-ware.

The public Lares were also called *Compitales*, from *compitum*, a cross-way; and *Viales*, from *via*, a way, or public road; as being placed at the meetings of roads, and in the highways, and esteemed the patrons and protectors of travellers.

Their private Lares took care of particular houses and families: these they also called *Præsitæ*, from *præsitæ*?

“Quod præstant oculis omnia tuta suis.” Ovid. *Fast.*

They gave the name *Urbani*, i. e. Lares of cities, to those who had cities under their care; and *Hospitalis*, to those who were to keep their enemies off. There were also Lares of the country, called *Rurales*, as appears by several antique inscriptions.

The Lares were also genii gods, and were supposed to take care of children from their birth. It was for this reason that when Macrobius tells us the Egyptians had four gods who presided over the birth of children, *viz.* the Genii, Fortune, Love, and Necessity, called *Præsitæ*, some interpret him as if he had said, the Egyptians had Lares; but they have mentioned that there was a great difference between the Lares of the Romans, and the *Præsitæ* of the

Egyptians. However, the learned Mr. Bryant affirms that they were the same.

The ancients differ extremely about the origin of the Lares. Varro and Macrobius say, that they were the children of Mania: Ovid makes them the issue of Mercury, and the naiad Lara, whom Lactantius and Aufonius call *Larunda*; Apuleius assures us they were the posterity of the Lemures; Nigidius, according to Arnobius, made them sometimes the guardians and protectors of houses, and sometimes the same with the Curetes of Samothracia, which the Greeks call *Idei dætyli*. Nor was Varro more consistent in his opinion of these gods; sometimes making them the names of heroes, and sometimes gods of the air.

T. Tatius, king of the Sabines, was the first who built a temple to the Lares. The chimney and fire-place in the house were particularly consecrated to them.

Tertullian tells us the custom of worshipping the Lares arose from this, that they anciently interred their dead in their houses; whence the credulous people took occasion to imagine their souls continued there also, and proceeded to pay them divine honours. To this it may be added, that the custom being afterwards introduced of burying in the highways, they might hence take occasion to regard them as gods of the highways.

The victim offered to the Lares, in the public sacrifices, was a hog: in private, they offered them wine, incense, a crown of wool, and a little of what was left at the table. They also crowned them with flowers, particularly the violet, myrtle, and rosemary. Their symbol was a dog, which was usually represented by their side, on account of its fidelity, and the service it does to man, in watching his house. They were sometimes also represented as clothed in a dog's skin.

See farther on the Lares, in Arnobius, Lactantius, Augulline de Civit. Natalis Comes, Lambin. on Plaut. *Aul.* and on Hor. *Casaubon* on Sueton. &c.

The term Lares, according to Mr. Bryant, was formed from *laren*, an ancient word by which the ark was represented; and he supposes that the Lares and Manes were the same domestic deities under different names; and that by these terms the Etrurians and Latins denoted the *dii arkitæ*, who were no other than the arkite ancestors, or the persons preserved in the *laren* or ark; the genius of which was Isis, the reputed parent of the world. He observes farther, that they are described as dæmons and genii, who once lived on earth, and were gifted with immortality. Arnobius, lib. iii. p. 124. styles them *Lares quosdam genios & sanctorum animas*; and he says, that according to Varro de Ling. Latin. lib. viii. p. 113, they were the children of Mania. Huëtius *De monst. Prop.* 4. p. 139. adds, that Mania had also the name of Larunda; and she is styled the mother of the dæmons. By some she is called Lara, and was supposed to preside over families; and children were offered at her altar in order to procure her favour. Macrobi. *Sat. lib. i. c. 7. p. 154.* In lieu of these they in aftertimes offered the heads of poppies, and pods of garlick. *Anal. of Ancient Mythol.* vol. ii. p. 449, &c.

The pantheons, or images representing several gods at once, were also called Lares. Harpocrates was one of these.

LARES, or *Laris*, in *Ancient Geography*, a town of Africa Propria, according to Ptolemy, who places it in the territory of Circha.

LARG, in *Geography*, a small island near the W. coast of Sumatra. S. lat. 3° 30'. E. long. 100° 3'.

**LARG Fell**, a mountain of Scotland, in the county of Kirkcubright; 13 miles W. of New Galloway.

**LARG Kirk**, a town of Scotland, in the county of Sutherland; 18 miles N.W. of Dornock.

**LARGA**, a small island in the Spanish Main, near the coast of South America. N. lat.  $10^{\circ} 11'$ . W. long.  $76^{\circ} 6'$ .

**LARGE**, a *Sea Term*, applied to the wind, when it crosses the line of a ship's course in a favourable direction, particularly on the beam or quarter. Thus, if a ship steer well, then the wind in any point of the compass to the eastward of the fourth or north, may be called *large*, unless when it is directly east, and then it is said to be right aft. *Sailing large*, is, therefore, advancing with a large wind, so as that the sheets are slackened and blowing, and the bow-lines entirely difused. This phrase is generally opposed to *sailing close-hauled*.

**LARGE**, in the *Mennege*. A horse is said to go large, or wide, when he gains or takes in more ground in going wider from the centre of the volt, and describing a greater circumference. To make a horse go large, you must give him the aid of your inner heel. See ENLARGE.

**LARGE**, synonymous with *maxima*, the longest note in the first time table, equal to two *longs*, four *breves*, and eight *semibreves*. Its form is an oblong square, with a tail on the right side, thus . See CHARACTER.

**LARGE River**, in *Geography*, a river of Louisiana, which runs into the Mississippi. N. lat.  $38^{\circ} 25'$ . W. long.  $95^{\circ} 7'$ .

**LARGENTIERE**, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Briançon. The place contains 978, and the canton 5871 inhabitants, on a territory of  $462\frac{1}{2}$  kilometres, in 7 communes.

**LARGENTIERE**, a town of France, and chief place of a district, and seat of a tribunal, in the department of the Ardèche: 18 miles W. of Privas. The place contains 1006, and the canton 9543 inhabitants, on a territory of  $177\frac{1}{2}$  kilometres, in 14 communes. N. lat.  $44^{\circ} 32'$ . E. long.  $4^{\circ} 42'$ .

**LARGHETTO**, *Ital.* the diminutive of *largo*.

**LARGO**, in the *Italian Music*, a slow movement, one degree quicker than *adagio*, and two than *grave*. See TIME.

*Resoluto* makes *largo* flow in the first degree; but we think erroneously. *Adagio* is the slowest time in Corelli, and all the old masters; *grave* the second; and *largo* the third. In *adagios* and *largos*, the time is usually counted by quavers, and in *grave* by crotchets.

**LARGO Gulf**, in *Geography, a bay on the coast of Istria, near Trieste.*

**LARI**, a town of Etruria; 10 miles E. of Leghorn.

**LARIBUS COLONIA**, in *Ancient Geography*, *Laribus*, a Roman colony in Africa, situated on an eminence, five leagues N.E. from Siaca.

**LARICAXAS**, a province of South America, in the government of Buenos Ayres, about 240 miles from E. to W., and 75 from N. to S. Its climate varies in different parts, and its products are the same with those of Carabaya, which terminates it northward. It abounds in gold mines, the metal being 23 carats and 3 grains fine. The celebrated mountain of Su. bulli in this province, about half a century ago, yielded old in great quantity of this standard, but its mine was overflowed, and no labour could recover it.

**LARICE**, in *Ancient Geography*, the name given by Ptolemy to the province of India, now called Guzerat.

**LARICOT**, *Fr.* an acute stop in the organs of France, a 3d above the major 17th, and an octave above the 12th in our organs, which would be a 19th above the diapason.

**LARIK**, in *Geography, a town of Asiatic Turkey, in the government of Sivas; eight miles N.N.E. of Amahel.*

**LARINO**, a town of Naples, in the Molise; the see of a bishop, suffragan of Benevento; 25 miles N.E. of Milife. N. lat.  $41^{\circ} 47'$ . E. long.  $14^{\circ} 50'$ .

**LARINUM**, in *Ancient Geography*, *Larino*, a town of Italy, in Sannium, towards the south; it had the title of municipal.

**LARIO**, in *Geography, a department of Italy, occupying the whole of the W. coast of the lake of Como, anciently "Larius lacus." Its population amounts to 137,264 persons, who elect 12 deputies. The capital is Como.*

**LARIOZO**, a town of the island of Cuba; 48 miles E. of Spirito Santo.

**LARISSA**, in *Ancient Geography, a town of Thessaly, upon the right bank of the Peneus, 10 miles above Atrax, E. of the mouth of the Apidanos or the Peneus, 44 miles from Demetrias, and 24 from Diium. Acrisius, king of Argos, retired to this town, in order to avoid the death which the oracle had menaced; but taking a part in the games which were celebrated in this place, he was killed by a stroke of the diletus of Perseus. Larissa always maintained a distinguished rank among the towns of Thessaly; but it declined from the time of Lucan. However, it still subsists under the same name in European Turkey, near the celebrated mount Olympus, and is inhabited by Christians, Turks, and Jews; the former having an archbishop and several churches; and the Turks having several mosques. The number of inhabitants is estimated at about 25,000.*

Its situation, on an eminence, is pleasant. By the Turks it is called *Genijahar* or *Janzijehabir*. N. lat.  $39^{\circ} 45'$ . E. long.  $22^{\circ} 29'$ .—**ALIO**, a town of Eolia, in Asia Minor, situated E. of Phocæa and S.E. of Cyre, forming with these two towns the vertex of a triangle. Xenophon calls it the Egyptian Larissa, because it was one of the towns which Cyrus, the first king of Persia, gave to the Egyptians.—**ALIO**, a town of Asia, on the banks of the Tigris. Xenophon says, that it had been large, but deserted, and that it had anciently been under the dominion of the Medes.—**ALIO**, a town of Triphylia, in the northern part, upon the river Larissus, near the frontiers of Arcadia.—**ALIO**, a town of Crete, according to Strabo.—**ALIO**, a town surnamed *Cremossis*, according to Strabo; who says, that it was called Pelagisa, though situated out of the Pelagian territory. Livy places it on the sea-coast, between Echinus and Antron. Eulathius and Porphyrogenitus say, that it had been anciently called Argos.—**ALIO**, a town of Italy, in Campania; said to be built by the Pelagians, but deserted and ruined in the time of Dionysius Halicarnassus.

**LARISTAN**, a small province of Persia, formerly a kingdom conquered by Abbas the Great, in 1612; bounded on the N. and E. by Kerman, on the S. by the Persian gulf, and on the W. by Farlatan or Fars, of which some have regarded it as a part. The subdivision seems not to have been known in ancient times, though the long ridge of mountains on the S. of Fars, and generally about 60 British miles from the Persian gulf, naturally indicates a maritime province; which, if the ancient Persians had been addicted to commerce, would have been the seat of great wealth by intercourse with Arabia, Africa, and India. But the Persians were high-spirited horsemen and warriors, totally averse from maritime enterprize, either of war or trade, from a contempt of the Arabian fish-eaters on their coast, or more probably, from particular precepts of Zoroaster, the founder of their faith, which rendered a maritime life incompatible with the practice of their religion. The air of this province

is insalubrious, and varies frequently from extreme heat to extreme cold; water fit for use is scarce; that which is drunk being found, as it is said, to breed worms in the legs and thighs of those who use it. Camels are the principal articles of trade. The capital is *Lar*, which see.

LARIX, in *Botany*, an ancient Latin name, the Larch. See PINUS. The older botanists distinguished *Larix* as a genus by its fuciated leaves, but no difference is discoverable in the fructification, at least between it and *Abies*, which all Linnean botanists refer to *Pinus*. Jussieu keeps the two latter distinct, and hints at separating *Larix*.

LARK, in *Ornithology*. See ALAUDA.

LARK, *Sea*. See CHABADRIUS *Hiaticula*.

LARK'S POINT, in *Geography*, a cape on the coast of Canada, on the river St. Lawrence, at the mouth of the Saguenay river.

LARKENTING, a town of Thibet; 55 miles E.N.E. of Tchiatam.

LARKSPUR, in *Botany*. See DELPHINIUM.

LARMIER, *Fr.* in *Architecture*, the same as *Corona*; which see.

LARNE, in *Geography*, a sea-port and post-town of Ireland, in the county of Antrim. It is situated on the north-western extremity of Larne Lough, and has a good yarn market once a month. There are great salt-works here, and its exports consist of salt, lime, limestone, and some provisions. It is 97 miles N. by E. from Dublin. N. lat. 54° 51'. W. long. 5° 44'.

LARNE Lough, a bay on the east coast of the county of Antrim, Ireland, called Oldfleet haven by Boate, and Wolderfrith in the enumeration of the havens by Stanburft. It is formed by the peninsula called Island Magee, and is said by M'Kenzie to be a small but safe harbour, where vessels that draw not above ten feet water may ride on clean good-holding ground. It is about six miles long and one wide.

LARNIC, or LARNICA, a sea-port town on the coast of the island of Cyprus, the see of a Greek bishop, and the residence of several European consuls. The Turks have a mosque, and the Greeks have three churches. It is now a poor place, though the roadstead is good; 30 miles S.W. of Famagosta.

LARNTUKA, or LARUNTUKA, a sea-port town on the S. side of Ende, one of the Molucca islands, with a good harbour. S. lat. 8° 15'. E. long. 123° 57'.

LAROA, a town of Hindoostan, in Guzerat; 10 miles E. of Baroach.

LAROCHE, a town of France, in the department of the Sambre and Meuse, and chief place of a canton, in the district of Marche. The place contains 1006, and the canton 6167 inhabitants, on a territory of 250 kilometres, in 20 communes.

LAROS, a town of Turkish Armenia, on the coast of the Black sea; 18 miles S.W. of Gonieh.

LAROTAVA, a town of the island of Teneriffe.

LAROW, a town of Hindoostan, in Bahar; 10 miles S. of Gayah.

LARRAGA, a town of Spain, in Navarre; 11 miles E. of Estella.

LARRASOANNO, a town of Spain, in Navarre; 12 miles N.E. of Pamplona.

LARREA, in *Botany*, named by Cavanilles, in honour of Don John Anthony Hernandez de Larrea, dean of Saragossa, a liberal encourager of chemistry, botany, and agriculture. The author had, in his fourth volume of *Icones*, p. 63, suppressed this name, given by his countryman Ortega to another genus, and had changed it to *Hoffmannia*;

being then, as it seems, not so sensible of the dean of Saragossa's botanical merits as he afterwards became.—Cavan. Ic. v. 6. 39.—Class and order, *Decandria Monogynia*. Nat. Ord. *Grinales*, Linn. *Rutaceae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, concave, rather unequal, deciduous leaves. *Cor.* Petals five, equal, ovate, with claws. *Stam.* Filaments ten, rather shorter than the corolla, awl-shaped, equal, each furnished at its base, on the inside, with a cloven scale, applied close to the germin; anthers heart-shaped, erect, simple. *Pist.* Germen superior, globose, with five deep furrows; style awl-shaped, with five angles, nearly equal to the stamens; stigma simple. *Peric.* Drupes five, dry, cohering by their acute inner margin, externally convex, of one cell. *Nuts* solitary, ovate-oblong.

Obf. There are the rudiments of several seeds in the young fruit, though only one of them comes to perfection in each nut. The genus comes near *Zygophyllum* and *Pagonia*.

Eff. Ch. Calyx of five leaves. Petals five. Nectary of five cloven leaves, covering the germin. Drupes five, single-seeded.

1. *L. nitida*. Shining-leaved Larrea.—Cavan. Ic. t. 559. Leaves pinnate. Fruit smooth.—Gathered at Buenos Ayres by Louis Née, flowering in April. It has been raised with good success in the garden of Madrid, and we have specimens from Cavanilles himself. The stem is shrubby, nine feet high in its native country, hard, knotty, very much branched, the branches round, rather zig-zag, repeatedly subdivided, spreading, two-ranked, leafy, rough, viscid. Leaves opposite, sessile, twice as long as broad, about half an inch in length, shining, glutinous, smoothish, minutely dotted, each composed of about seven or eight pair of crowded, two-ranked, oblique, sessile, oblong, obtuse, entire leaflets, of which the two uppermost are unequal and very small, looking as if there were an odd one at the end. *Stipulas* opposite, triangular, acute, reddish. *Flowers* axillary, solitary, alternate, deep yellow, on roughish stalks, shorter than the leaves. The *germen* is hairy, though the fruit is naked, or only clothed with fine short down. Its outer coat is coriaceous and rugged. *Nuts* without valves or futures.—The whole plant exudes a copious glutinous resin, of a strong scent, still very powerful in the dried specimens, and intercalars so on their being moistened with proof spirit, which extracts from them abundance of a yellow fetid solution.

2. *L. divaricata*. Spreading-lobed Larrea.—Cavan. Ic. t. 560. f. 1.—Leaves simple, with two deep spreading lobes. Fruit hairy. Found with the former, flowering at the same season. The stem is shrubby, six feet high, with much of the habit of the foregoing; but the leaves are simple, very deeply cloven into two spreading acute lobes. The flowers are yellow, larger than those of *L. nitida*, with obtuse petals; and the fruit is beset externally with long prominent hairs.

3. *L. cumifolia*. Wedge-leaved Larrea.—Cavan. Ic. t. 560: f. 2.—Leaves wedge-shaped, cloven at the end, with an intermediate bristle.—This appears to differ in foliage only from the last, along with which it was found.

These plants promise to be not unworthy of attention for their dyeing qualities. Cavanilles says, ten leaves of the *divaricata*, boiled in a quart of water, with the little branch on which they grew, uted the whole liquid of a deep saffron colour.

LARREY, ISAAC DE, in *Biography*, born of a noble French family in 1638, was brought up to the profession of the law. He acted some time as an advocate in his na-

tive province, but having been educated in the reformed religion, he was obliged to quit his country at the repeal of the edict of Nantes. He went from France to Holland, and obtained the office of historiographer to the States-general. An invitation from the elector of Brandenburg induced him to remove to Berlin, where he died, in 1719, at the age of eighty-one. His principal works are "Histoire d'Angleterre," 4 vols.; "Histoire de Louis XIV." 3 vols. quarto; "Histoire d'Angleterre;" "Histoire des Sept Sages," 2 vols. 1713. Of these his History of England is most esteemed, and was in high reputation on the continent till that of Rapin was published. Larrey was a man of great integrity, zealous for his religion, and warm both in praise and censure, Moreir.

LARRISOUN, in *Geography*, a town of Persia, in the province of Mazanderan; 65 miles S.W. of Fehrad.

LARROQUE, MATTHEW DE, in *Biography*, an eminent French Protestant divine in the 17th century, was born at Leirac, a small city of Guienne, near Agen, in the year 1619. He was educated with a view to the church, and applied himself, in early life, with great diligence to the study of the belles-lettres, philosophy, and theology. Having made great progress in all the various branches of useful knowledge, he was admitted a minister with great applause in the province of Guienne. He was afterwards appointed, by the duches de la Tremouille, minister of the church of Vitre, in Brittany. Here he officiated nearly thirty years, during which time he applied himself most earnestly to the study of the fathers, and Christian antiquities. He was next invited to become both minister and professor of divinity at Saumur: he readily accepted the former office, but declined the latter, not thinking it to be consistent with the course of study in church-history, to which he had a prevalent inclination. Before he could take possession of his office, he received a prohibition from the intendant of the province, forbidding him to enter upon its duties. He therefore continued at Vitre, and employed his time very usefully in composing works of merit. In a short time he received three invitations at once, from three of the most considerable churches in the kingdom, viz. those of Montauban, Bourdeaux, and Rouen. He made choice of the latter, at which place he died in 1684, at the age of sixty-five. His works are numerous, and they acquired for the author a high reputation for real learning, as a theologian. He was a pious and faithful pastor in the church; and in the world an honest man. Moreir.

LARRY-BUNDER, in *Geography*, a sea-port of Hindoostan, in the province of Sindy, on a branch of the Indus, called the Pitti, about 20 miles from the sea. It has a good road for shipping, and the river is navigable for small vessels. The town contains about 100 houses, and is defended by a fort; 48 miles W.S.W. of Tatta. N. lat. 24° 45'. E. long. 66° 42'.

LARRY-BUNDER is also the name of a branch of the Indus; which see.

LARS, a town of Russia, in the government of Caucasus; 56 miles S.E. of Ekaterinograd.

LAKSMO, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 46'. E. long. 22° 39'.

LARVA, in *Natural History*, a name given by Linæus to insects in that state, called by other writers *eruca* or *caterpillar*. See ENTOMOLOGY and INSECTS.

LARVÆ, in *Antiquity*, derived from the Etruscan word *lar* or *lars*, signifying *prince* or *lord*, denoted the ghosts of the deceased, considered as wicked and mischievous. Hence is formed the term *larvatus*, i. e. *larva indutus*, or *demoniac*.

The ingenious Mr. Farmer urges the etymology and use of this term to prove, that the heathen demons were deified human ghosts. The term *lar* was applied not only to their *dæmæstic*, but also to their *collocal* gods, the *dii majorum gentium*, who were all natives of this lower world; and answers to the word *δαιμον*. Quos Græci δαιμονας; noltri, opinor, lares. Cicer. in Timæo. 3. (See LARES.) The larvæ were considered as mischievous spirits; and this author says, that the larvati were demoniacs; but the larvæ, with which they were possessed, were human ghosts; such also as demons were. Ess. on the Demoniacs, p. 27, &c.

The larvæ were also called *lemures*.

LARUCACHI, in *Geography*, a town of Peru, in the diocese of La Paz; 110 miles N. of Chucuito.

LARVIGEN, or LAURWIG, a sea-port town of Norway, in the diocese of Christiania, and capital of a county, deriving from it its name, situated at the conflux of two rivers near the sea. Its trade is considerable, and its iron-works are the most valuable in Norway; 56 miles S.S.W. of Christiania. N. lat. 59° 3'. E. long. 10° 15'.

LARUNS, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Oleron; 18 miles S. of Pau. The place contains 1607, and the canton 3855 inhabitants, on a territory of 445 kilometres, in 8 communes.

LARUS, in *Ornithology*, a genus of the order Anseres. In this tribe the bill is straight, acute at the edges, hooked at the tip, and destitute of teeth; the lower mandible gibbous below the point; nostrils linear, broader on the fore part, and placed in the middle of the bill. These are the gulls of English writers, a race of birds very widely diffused throughout the globe, some of the species inhabiting Asia, Africa, and Europe, others Europe, Asia, and America, but the far greater number of species are natives only of the northern regions of America and Europe, as Hudson's bay, Iceland, Greenland, and the north of the European continent, beyond which, towards the southward, their number materially diminishes. Many of the species found in northern latitudes inhabit the British isles, residing on our shores the whole year; others are extremely rare with us, or at least can be considered only as accidental visitors driven from more northern countries in severe winters. The haunts of the gull tribe are the borders of the sea, and marshes immediately in its vicinity, or in the depth of winter they sometimes retire inland, but only into such parts as are abundantly supplied with water, their food consisting principally of fish and worms. The gulls have a light body, the wings long; tongue rather cloven; legs short, naked above the knees, and the hind toe very small. They are very voracious, and when terrified are said to cast up the indigested food they have lately swallowed. The species of this genus are not very clearly discriminated, owing to the variations that prevail in the colours of the plumage in different states of growth, till the birds have attained their third year. This genus is divided into two sections, in the first of which the nostrils are without a cere, and in the other are covered by one.

Species.

\* *Nostrils without a Cere.*

ICTHYÆTUS. Snowy; head entirely, and neck to the middle, deep black; eyelids white. Pallas. *Larus albus*, &c. Oedem. *Die grosse Lachmöve*, Gmel. *Great black-headed gull*.

A native of the borders of the Caspian sea. The size that

## L A R U S.

of the bernacle goose, or larger. The bill is scarlet, with yellow base, the tip yellow with a brown spot; the inside of the mouth red; tail white, even at the end, and reddish brown. This species lays its eggs on the bare sands; the eggs are of an elongated oval form, marked with brown spots intermingled with others pale. When in flight it utters a hoarse cry like that of a raven.

**RISSA.** Whitish; back hoary; quill-feathers white; posterior toe unarm'd. *Larus rissa*, Linn. Gmel, &c. *Larus tridactylus*, Lath. *Kittiwake* Penn. Donovan. Br. Birds, &c.

Length fourteen inches; the bill yellowish; mouth saffron within; head, neck, belly, and tail snowy; wings hoary, the outer edge of the first and tips of the four or five feathers next succeeding white; legs dusky; posterior toe resembling a wart. It varies in sometimes having behind the ear a dusky spot.

This kind of gull inhabits the cliffs on the north coasts of Wales and Scotland, from whence it extends as far as Greenland, Spitzbergen, and Iceland, the arctic coast of Asia, and Kamtschatka. The Icelanders call it Rissa. Fabricius, in his Faun. Groen. describes this as the adult issue of the Tarrock, an affirmation contradicted by some authors and admitted by others, while again some few are of opinion they may be the two sexes of the same species.

**TRIDACTYLUS.** Whitish, back hoary; tips of the tail-feathers, except the outer one, black; feet three-toed. Linn.

**LARUS TRIDACTYLUS** ♂, Lath. *Kauke-gef*, Klein. *Tarrock*, Will. Donovan. Br. Birds, &c.

Frequents the fine rocky coasts of the sea as the former. The eggs, two in number, are greenish-ash, spotted with brown; they are noisy, swim well, and remain on the wing for a considerable time. The flesh and eggs are esteemed by the natives of Greenland, and their skins used as garments. Length fourteen inches; bill and legs dusky; head, neck, and body beneath white; wings varied black and white; tail black at the tip.

In the Bankian collection is a supposed variety of this species exceeding the common tarrock in size, being five inches longer; in this the wings are marked by an oblique black band, and the chin white; the outer tail-feathers entirely white. This inhabits Kamtschatka.

**MINUTUS.** Snowy; head, and beginning of the neck black; back and wings rufes; bill brown-red; legs scarlet. Pallas. Gmel. *La plus petite des mouettes*, Vieill. *Little gull*, Lath.

Size of a thrush; irides blueish; tail equal and white; inhabits near rivers in Siberia and Russia.

**EBURNEUS.** Entirely white; bill and legs lead colour. Gmel. Phipps, &c. *Larus niveus*, Act. Holm. *Larus candidus*, Fabr. Fu. Gr. *La mouette blanche*, Buff. *Rat-sber*, or *Ratzer*, Ray. *Ivory gull*, Arct. Zool.

The length of the species is sixteen inches, the breadth thirty-seven; the bill paler at the tip; wings much longer than the tail; legs lead colour, the claws black. This bird inhabits the Frozen sea between Asia and America. From its fatly gait when walking on the ice, and the strength of its voice, it is said to have obtained the name of *Ratzer*, or Senator. The flesh of the morse constitutes its favourite food; besides which it subsists on worms and fishes. During the summer, it visits the little isles and lakes in the interior, where it forms a nest composed of dried herbage, and lays four eggs of a white colour. The young are spotted with black principally on the back and wings, and the beak is of the same colour.

**CARUS.** White; back hoary; primary quill-feathers,

black at the ends, the fourth and fifth with a black spot at the tip, the outer one black without. Lath.—*Larus Canus*, White, back hoary. Linn. Fn. Succ. *Larus cinereus minor*. *Common sea-mew or mall*, Ray. *White web-footed gull*, Albin. *Common gull*, Arct. Zool. Donovan. Brit. Birds, &c.

Common on the coast of Britain, and in various parts of Europe and America. The length seventeen inches; bill yellow; legs greenish-white, or sometimes reddish. It forms a nest chiefly of sea-weeds; the eggs are large, deep olive, and marked with dark irregular blotches. (Vide Brit. Birds.) This kind of gull extends as far north as Iceland and the Russian lakes, and occurs also on the borders of the Caspian sea, the various shores of the Mediterranean, and those of Greece. Its breeding places are the hollows in rocks and cliffs near the sea.

**HYBERNUS.** Cinereous; beneath snowy; head white, varied with fuscous spots; neck above fuscous; wings varied; tail-feathers white, with a black band.—*Larus Hybernus*, Gmel. *Larus canus* ♂, Lath. *Gavia hyberna*, Brill. *Larus maculatus*, Brun. *Mouette d'hiver*, Buff. *Gnaea-guacu*, Ray. *Winter mew*, *coldly muddy*, Will. Donovan. Brit. Birds. *Winter gull*, Lath. Synop.

Feeds on reptiles and small fishes. This kind is very common in England, and is observed to inhabit farther inland than any other of the gull tribe. In Ind. Orn. of Latham it is described as the young of the foregoing species. Length seventeen inches.

**RUBIBUNDUS.** White; head blackish; bill and legs red. Ed. Nov. Aët. Stockh. *Larus rubibundus*, Linn. *Larus albus erythrocephalus*, Klein. *Brown-headed gull*, Albin. Donovan. Brit. Birds, &c.

Length fourteen to fifteen inches; the eye-lids the same colour as the bill and legs; first ten quill-feathers white, with the edge and tip black. Inhabits Europe and America, and makes a laughing kind of noise. The eggs, three in number, are greenish-brown, spotted with tawny. Gmelin admits two varieties of this species: one of a white colour, with hoary back, and the head and bill blackish, as described by Nozema; the other is white, with blue legs, the bill at the base blue, at the tip yellow. Latham in Ind. Orn. considers as varieties of *rubibundus* the Linnæan *larus cinerarius*, and also *larus erythropus* of Gmel., both which are placed as distinct species in the preceding publication. Gen. Syn.

**MARINUS.** White; back black. Linn. It. Wgoth. *Larus dorjo nigro, palibus rubris*, Ed. *Goeland noir*, Buff. *Great black and white gull*, Ray. *Black-backed gull*, Arct. Zool. Donovan. Brit. Birds, &c.

Native of the maritime parts of Europe and America, the Cape of Good Hope, New Holland, &c. The length twenty-nine inches; the bill yellow, with a red spot near the tip, and in the middle black; quill-feathers black, with the tips white, and the legs flesh-colour. Feeds on fish and young birds.

**NÆVIUS.** White; back cinereous; tail-feathers at the tip black. Gmel. *Wagellus cornubiensium*, Ray. *Wagel gull*, Will., &c. Donovan. Brit. Birds, &c.

This species inhabits the shores of European seas. Its length is about two feet; the bill black; legs dirty flesh-colour. This is by some esteemed the female of the foregoing (*marinus*), and by others as either a variety rather than a distinct bird, or as the younger bird. The bird described by Brunnich under the name of *larus argentatus*, the silvery gull of Latham, is likewise considered as a variety of *L. marinus*.

**FUSCUS.** White; back brown. Linn. Fn. Succ. *La-*

*gris-brun*, Briss. *Larus cinereus maximus*, Marsd. *Göland à mantau gris-brun*, Buff. *Herring gull*, Will. *Donov. Brit. Birds*, &c.

Inhabits Europe, America, and Asia. The length twenty-three inches; bill and legs in the adult bright yellow; eyes straw colour. The birds feed on the herring, the shoals of which it purveys, and thus directs the fishermen to the capture of that fish. The eggs, three in number, are whitish, spotted with black.

**GLAUCUS.** White; back and wings hoary; quill-feathers tipped with white; bill yellow, at the angle saffron. *Ced. Larus albus*, Olaf. *Goeland cendré*, Buff. *Burgermeister*, Martens. *Glaucous gull*, Arct. Zool.

Inhabits Sweden; is larger than the herring gull, very voracious, and feeds on smaller birds, fish, and carrion.

**ATRICILLA.** Whitish; head blackish; bill red; legs black. *Ced. Gavia radibunda*, Briss. *Larus albus*, Scop. *Larus minor*, Sc. Klein. *Baltner's great ash-coloured sea-mew*, Will.

Length eighteen inches. Flies in flocks, with a continual clamour; builds in pine trees, and inhabits America and Europe.

**ATRICILOIDES.** Reddish-white; head, orbits, and neck black; back and wings cinereous; legs scarlet. Falck. *Gmel. Siberian gull*.

Smaller than the former. This inhabits the salt marshes of Siberia.

**\*\* Nostrils covered with a Cere.**

**PARASITICUS.** Two middle tail-feathers very long. Linn. *Sterna*, Sc. It. Wgoth. *Catarracta parasitica*, Brünn. *Stercorarius*, et *stercorarius longicaudatus*, Briss. *Avia Norwegica kyniffa*, Ol. *Lalbe à longue queue*, Buff. *Arctic bird*, Edwards. *Arctic gull*, *Donov. Brit. Birds*, &c.

Length twenty-one inches; the bill and legs dusky; body above dusky, beneath, with the temples, and front white; breast with a dusky band; female brown beneath. Very rare in Britain. The species is found in the north of Europe, and also in Asia and America. It is of a rapacious disposition, and will pursue the lesser gulls in the air till they mute, when, instantaneously darting down, it dexterously catches the excrement before it reaches the water, and devours it. The eggs are cinereous, spotted with black.

**CREPIDATUS.** Dusky-white and brown, varied; two middle tail-feathers longer; anterior half of the feet black. *Donov. Br. Birds. Larus crepidatus*, Gmel. *Hawkesw. Catarracta cephus*, Brünn. *Stercorarius striatus*, Briss. *Black-toed gull*, Arct. Zool. &c.

This, like the former, is very scarce in Britain; its length is sixteen inches; the bill black, with the tip orange; breast and belly whitish, with numerous darkish lines. The two middle tail-feathers longer than the rest; and the anterior half of the feet black; the posterior, with the legs, paler and yellowish, or, as it sometimes appears, bluish.

The description of the black-toed gull in Dr. Latham's Synopsis, is an extract from Pennant's British Zoology, besides which Dr. Latham mentions another bird of the same kind in the late Leverian museum, which had the lighter half of the feet, with the legs, yellow instead of blue. In the description of this latter bird Dr. Latham observes, however, that "the two middle tail-feathers are not particularly longer than the others;" and again in Ind. Orn., this author hesitates apparently from this circumstance, in addition to the yellow colour of the legs, whether it should be admitted as a variety of *larus crepidatus*, or be esteemed a distinct species. It becomes therefore desirable to add that the description afforded us by Dr. Latham is not, in this

respect, entirely free from error; that able ornithologist was, in some manner, deceived, perhaps from the situation of the bird itself, which might preclude the possibility of an attentive inspection. Be this as it may, the Leverian specimen recorded by Dr. Latham, and also another from the same collection, are both in the museum of the writer of this article; in one of these (which we conceive to be the male) the two middle tail-feathers are nearly as conspicuously longer than the rest, as in the Arctic gull projecting beyond them scarcely less than two inches; and in the other, which we apprehend must be the female, they are advanced above an inch beyond the rest; in other particulars they accord pretty generally with Dr. Latham's description, and, as that writer observes, the lighter parts of the feet, with the legs, are yellow. We have besides this another example of this bird, a specimen recorded as being found near Oxford, in which the legs are black and yellow, as in the former, from whence we may conclude those to be the true colours, except perhaps in certain varieties.

**CATARRACTES.** Greyish; quill and tail-feathers white at the base; tail sub-queal. Gmel. *Catarracta skua*, Brünn. *Larus fuscus*, Briss. *Catarractes*, Gelin. *Ska boyeri*, Claf. *Goeland-brun*, Buff. *Cornish gannet*, Ray. *Brown gull*, Albin. *Skua gull*, *Donov. Brit. Birds*, &c.

Length two feet; the bill dusky, and much hooked; upper mandible covered half way down with a black cere; body brown; beneath rufous-cinereous; legs blackish, rough, and warty; claws hooked and black; posterior toe short, and armed with a sharp hooked claw. This voracious bird inhabits Europe, Asia, and America, and is remarkable for its voracity and ferocious disposition, especially in the breeding season. It feeds on fish, and all the smaller kinds of water-birds, and is the terror of the lesser birds of its own tribe, which it haunts on the wing, till they mute or vomit up what they have eaten, and then devours it.

**KEEASK.** Brown; wing-coverts variegated with white; tail black, spotted and tipped with white. Lath. Ind. Orn. *Esquimaux gull*, Arct. Zool. &c.

Inhabits America, as far as Hudson's bay; the length is twenty-two inches; the bill and legs black; toes and membrane half black, half white. It arrives at America in April, constructs a slight nest of grass, and lays two pale ferruginous eggs spotted with black.

**LARYNGEAL**, in *Anatomy*, an epithet applied to parts belonging to the larynx. The laryngeal arteries are the vessels more commonly described under the name of thyroid arteries. The laryngeal nerves, superior and inferior, are branches of the par vagum. See NERVE.

**LARYNGOTOMY**, (from *λαρυγξ*, the upper part of the windpipe, and *τομή*, to cut,) an operation in Surgery, which consists in making an artificial opening into the larynx with a knife, a measure sometimes necessary in certain cases of disease to prevent suffocation, as well as to enable the practitioner to inflate the lungs in instances of suspended animation. The incision is now generally made in the windpipe itself, and the operation called tracheotomy. See TRACHEOTOMY.

**LARYNX**, in *Anatomy*, a hollow organ, placed between the root of the tongue and the trachea, giving passage to the air into and out of the lungs in respiration, and producing the voice.

The organs of locomotion, whether those of the limbs or of the trunk, are the principal means by which man reacts on those external objects which have acted on him through the medium of the senses. They are particularly destined, in the natural state, to provide for the wants of digestion, of which they collect the materials. They also furnish the animal with the

## LARYNX.

the means of offence and defence, of which digestion is in general the immediate object. But social man has vastly extended the domain of this function. Submitted, through the cerebral nerves, to the direction of intellect, it is the instrument by which most of the conceptions of the latter are executed: and if the vast field of activity opened to our view in the arts shews the extensive agency of this power, it proves no less clearly how greatly the sphere of action of the locomotive organs has been increased. Man in society not only derives from his voluntary muscles, by acquiring extreme precision in their motions, much greater advantages than those to which the limited operation of instinct confines animals, but he has also given to them another direction—they serve him as a silent language, and a mode of intellectual communication. The head, the arms, the eyes indicate to us what the voice does not disclose; but gestures are in general only supplementary to the latter function.

Speech is the chief means of our intellectual communications: and here we have occasion to observe how vastly the functions of the larynx are extended by man in society. This extension is still greater than that which the locomotive agents offer to our view in the arts where industry has been pushed the farthest. Originally nature bestowed on man merely a voice, the chief object of which was, to establish those relations which bring together the sexes. Hence the close connection between the voice and the generative organs: it has, like them, a true period of puberty, whether in animals in whom it does not exist at all until that epocha, or in those, where, existing antecedently, it undergoes at this time a remarkable change. Remove these organs, and a new and peculiar modification of the voice soon shews itself. Each sex has a voice distinguished by particular characters: energy and force belong to that of the male; flexibility, delicacy, and grace to that of the female. Most animals employ their voice chiefly at the rutting season; many are dumb at all other times. We cannot therefore avoid the conclusion, that, in the natural state, the communications of the two sexes relating to generation are the particular object of the production of sound. Man in society has destroyed this original destination, and at the same time created another, of which the extent is bounded only by the limits of his intelligence. The mere voice, which sufficiently enables the individuals of both sexes to express the mutual wants connected with the generative functions, is inadequate to the conveyance of those which have arisen out of the state of society. It has therefore been modified; speech is the result of that modification; and thenceforth the larynx has performed a part in society not less important than that of the locomotive organs. These two modes of communication, which man enjoys, are almost equally employed, and produce, each in its way, nearly equal effects. If one be the organic instrument of all the arts, and of all the affections which the mind experiences in the social state through the eyes, the other is the agent of all that belongs to the domain of intelligence, of all that the mind perceives through the ears. Compare the vast stock of ideas, which are transmitted from man to man, with the material objects employed in their reciprocal commerce, and you will find the amount of each nearly the same. Yet, although the sum of the locomotive agents forms more than half of the entire volume of the body, the vocal instrument takes up a little room in a small part of the same body. The great disproportion between the organs of the voice and the important effects which they produce in society, is very striking.

The voice, from its destination, would naturally fall under the immediate empire of the brain. Hence the struc-

ture of the larynx has much analogy to that of the locomotive apparatus. It is composed of cartilaginous pieces, moved in various directions by voluntary muscles, on the motions of which the habits of society have conferred a precision foreign to the natural state, as it has on those of the fingers in certain arts, and on those of the lower limbs in others. Thus the voice is to speech, in relation to the muscles of the larynx, what the rude movements of the fingers of the savage are to the precise and delicate motions of the man who has employed himself on a mechanical art, in relation to the muscles of the upper extremity. The principle is the same, the results only are different. It is a general law in the organs of voluntary motion, that they acquire perfection by exercise, that they are in short susceptible of education.

This dependence of the functions of the larynx on the brain is not only marked in the state of health, but also in diseases. Paralysis, convulsions, and spasms of the muscles of this cavity have the same characters as in the locomotive organs, and have no analogy to the affections of involuntary parts. Hence Bichat has followed the indications of nature, in separating the vocal organs from the lungs in his physiological and anatomical arrangement: their proximity has generally led to their being considered together, in treatises of anatomy and physiology.

The following arrangement will be adopted, in considering the vocal organs: 1st, General considerations on the larynx; 2dly, Particular description of the component parts; 3dly, The assemblage of these parts in the general conformation of the cavity; 4thly, Mechanism of the larynx; 5thly, Its development in various ages; 6thly, The organs of speech; 7thly, The physiology of the voice and speech.

*General Considerations.*—The larynx is a cavity composed of moveable pieces, of a form not easily defined, and occupying the anterior and superior region of the neck. It is situated on the median line, and consequently regular and symmetrical in its form, like all the organs of the animal life. It terminates the trachea above, and forms a striking contrast with the lower extremity of that organ, which, formed by the bronchi, and concerned merely with the functions of the organic life, is made up of two lateral portions not resembling each other. The lateral portions of the larynx are, on the contrary, exactly similar. This symmetry of the larynx is necessary to the harmony of its functions: a discordant voice would inevitably result from different organizations of the two sides, or from inequality in the powers of the muscles of the right and left sides. The organ is placed below the os hyoides, to which it is fixed: it is superficial in front, and rests behind on the vertebral column, from which the pharynx alone separates it.

Designed, on the one hand, to allow a continual passage to the air in respiration, which is to a certain point involuntary; and concerned, on the other, in producing the voice entirely under the influence of the will, the larynx offers to our view a structure accommodated to these two very different phenomena. Several cartilages united together form its cavity, and their elasticity prevents it from being ever closed: hence a free passage is secured for the air. To these moveable cartilages are attached muscles, of which the voluntary contraction may increase or diminish the dimensions of the cavity; circumstances which are essential to the production of the voice. One of these cartilages, very different in its structure from the others, can close the cavity momentarily, by being depressed on its aperture. Lastly, a mucous membrane, continuous with that which lines the mouth, lines all these parts, and is prolonged into the lungs, following all the ramifications of the bronchi.

## L A R Y N X.

The size of the larynx does not follow the proportions of the general stature: it may be as large in a little person as in one of considerable height; and this corresponds to what we know of the voice, the force or weakness of which do not depend on the size of the individual. It would be an interesting research to compare the different kinds of voice with the organization of the larynx. We cannot doubt that the tenor, counter-tenor, &c. are produced by some peculiarities in the laryngeal structure; but the impossibility of knowing, in the case of subjects employed for dissection, what kind of voice the individuals possessed, prevents us from ascertaining any thing concerning this point. The difference in the voices of man and woman cannot but have been always observed; and their larynxes exhibit, on a merely superficial inspection, a great disproportion in size. The organ is large and broad in man: it appears contracted in woman, so as to be about one-third less: often it is not more than half as large as that of the male. This does not depend on stature: a large woman and a short man have this distinguishing character, as well as two individuals of equal size, or as a tall man and short woman. The same circumstance runs through all parts of the larynx: it is observed also in the neighbouring organs, as the trachea, the os hyoides, and their dependencies; and it takes place also constantly.

The general form of the organ is nearly the same, or at least the differences are much less remarkable than those which affect the size. However, the sexes are distinguished in several points. The two plates of the thyroid cartilage are much more oblique and proportionally less separated in man than in woman: hence they form in the former, where they are united in front, a much more considerable prominence under the integuments, and a much more acute angle. This projection is named *promontorium Adami*: in women the angle is very obtuse. The excavation which terminates it above is superficial and rounded in the female; much deeper and terminated by an acute angle in the male. The cricoid cartilage shews no difference in the two sexes in front. The male and female larynxes are distinguished almost solely by their size behind; yet, as the two sides of the thyroid are more widely separated in women, there is in them a greater relative breadth in the triangular spaces which separate this cartilage from the proper cavity of the larynx. The organ is surmounted in man by a much broader and thicker os hyoides than in woman. The epiglottis is also broader, more prominent above, and thicker: its general form is the same in both sexes. The glottis is also of the same form in both, and distinguished merely by its dimensions. As the arytenoid cartilages are longer, and consequently more elevated in man, the ventricles of the larynx are more deeply seated, and more distant from the external opening. The only difference observed below is the greater circumference of the cricoid in man. The trachea corresponds in size to the larynx, and is consequently smaller in women than in men. From the preceding observations it appears that the form of the larynx, although differing slightly in the two sexes, as well as the texture, which is the same in both, cannot be the essential cause of the differences in the key or pipe of the voice, which appear much rather to depend on the striking disproportion in size. It will be seen afterwards, that the particular character of the voice in the infant depends on the same cause.

*Description of the Parts of the Larynx.*—We may distinguish, in this organ, the cartilages which essentially compose its cavity, and give it solidity; 2. The ligaments which tie these together; 3. The muscles moving the cartilages, and thereby constituting the active instruments of the voice;

4. The glandular bodies situated in the neighbourhood of the cavity; 5. The membranous lining. The first four divisions must be examined in detail; the common membrane will be described with the larynx taken altogether.

*Cartilages of the Larynx.*—These are five in number. The first, named the thyroid, is broad and tolerably thick; it covers the organ in front, but is no farther concerned in forming the cavity than by the attachment it affords to certain ligaments and muscles. The second or cricoid cartilage, which possesses, as its name implies, an annular figure, forms the solid part of the cavity. Two arytenoid cartilages, situated behind, and much smaller than the others, give to the glottis that mobility which makes it the seat of the voice. Lastly, the epiglottis, a true fibro-cartilage, has the office of closing the larynx occasionally.

The thyroid or scutiform cartilage occupies the front and lateral part of the larynx, measuring more from side to side than from above downwards, and being broader above than below. It consists of two lateral portions obliquely united in front, where they form a more or less prominent acute angle, corresponding to the median line, and producing a conspicuous prominence in the neck of the male, already mentioned by the name of *promontorium Adami*. This angular prominence is bifurcated above, simple and rounded below. Each of the lateral divisions offers in front a nearly plane surface, slightly concave, covered principally by the thyro-hyoideus muscle. An oblique line bounds this surface externally, and affords attachment to the thyro-hyoideus, sterno-hyoideus, and the inferior constrictor of the pharynx. Behind it is a small surface covered by the two latter muscles. This cartilage presents behind a concavity in the median line, corresponding to the front prominence: the ligaments of the glottis and the thyro-arytenoid muscles are attached to this. Two plane surfaces, sloping backwards, correspond above to these muscles, from which a fatty cellular substance separates them, and below to the lateral crico-arytenoid muscles, and to some fibres of the crico-thyroidei.

Four edges terminate the surfaces of the thyroid cartilage. The superior is the largest, affords attachment throughout to the thyro-hyoideal membrane, has in its middle the notch surmounting the angle of union of the two pieces, then proceeds onwards on each side nearly horizontally, presenting a slight prominence corresponding to the external oblique line, and terminates beyond this by an appendix which will be mentioned. The inferior edge is shorter, concave in the middle, and has on the sides two convex prominences corresponding to the lower ends of the external oblique lines, and then two depressions. It affords attachment to the crico-thyroid membrane and to the crico-thyroidei muscles. The posterior margins, two in number, are directed obliquely, and rest against the spine: rather concave above and convex below, they afford attachment to some fibres of the stylo and palato-pharyngei. A rounded process, of different lengths in different subjects, directed obliquely backwards, surmounts each of these margins, and is connected by a ligament to the extremity of the os hyoides: these are the superior cornua of the thyroid cartilage. A similar rounded process, shorter than the former, directed rather forwards, terminates each of the perpendicular margins below: these are the inferior cornua, and are articulated by their extremities to the sides of the cricoid cartilage.

A round opening is sometimes seen on each side of the cartilage, towards its upper part, transmitting an artery and nerve to the cavity of the larynx.

The cricoid or annular cartilage occupies the lower and

branous connections: we shall consider at present only those of the first kind, the others belong to the general description of the organ.

The thyroid is connected to the cricoid cartilage in front and on the sides. In the former situation, a membrane, called the crico-thyroid, proceeds from the upper edge of the cricoid cartilage, and is attached to the middle of the lower border of the thyroid; it is lost insensibly on each side on the mucous membrane of the larynx. It is deepest in front, and grows narrow and less distinct towards the sides; it has a fibrous appearance in the former, which it loses in the latter of these situations. Covered on the sides by the crico-thyroidei muscles, it is subcutaneous in front, and corresponds to the laryngeal membrane behind. It allows a considerable motion between the two cartilages. On the sides there are two small articulations, formed between the inferior cornua of the thyroid, and the lateral articular faces of the cricoid: they are lined by loose fibrous membranes, and lubricated by a tolerably copious synovial secretion. The surfaces, which admit readily of a gliding motion on each other, are held together by very distinct ligamentous fibres. An anterior fasciculus is continued obliquely downwards and forwards from the front of the thyroid cornua to the side of the cricoid cartilage. A posterior goes from the back of the same process, and ascends to be fixed to the back of the cricoid under the arytenoid cartilage. There are some irregular fasciculi, besides the two first described.

The opposed surfaces of the arytenoid and cricoid cartilages are covered by very loose synovial membranes, lubricated by a copious secretion, and strengthened by ligamentous fibres at some parts. The most remarkable of these fibres are on the inside and behind; externally they are little apparent, and seem often hardly to exist at all.

Each of the arytenoid cartilages is connected to the thyroid by a fibrous fasciculus, particularly important on account of its concern in the production of the voice. They are called the aryteno-thyroid ligaments, ligamenta glottidis, or chordæ vocales. The ligament composed of parallel fibres, and about half an inch in length, arises from the anterior prominence of the basis of the arytenoid cartilage, passes horizontally forwards and inwards, and is fixed to the concavity of the angle formed by the junction of the two sides of the thyroid, uniting at this point with that of the opposite side. It is covered externally by the thyro-arytenoid muscle, and corresponds every where else to the mucous membrane. The slit-like aperture left between the right and left ligaments is the glottis, or rima glottidis.

The two arytenoid cartilages are connected together merely by the membrane of the larynx, and by the arytenoid muscle. It is said that a transverse fibrous fasciculus is sometimes placed in front of the latter, to prevent the two cartilages from being separated too widely.

The acute and elongated angle, which terminates the epiglottis below, gives origin to a narrow fibrous fasciculus, about half an inch in length, which is covered in front by the epiglottic gland, and is fixed to the angle of the thyroid, just above the attachment of the ligamenta-glottidis.

The arytenoid cartilages are not connected to the epiglottis by any fibrous union; two considerable membranous folds, forming the principal part of the upper aperture of the larynx, proceed from the former to the sides of the latter; they seem to be the ligamenta thyroidea superiora of Soemmerring.

*Muscles of the Larynx.*—The organ is moved by two kinds of muscles, of which one is common to it with other parts, the other belongs particularly to it. The first are the mus-

cles of the os hyoides, and move the whole organ together; these, as well as the os hyoides, are described in the article DEGLUTITION. The others are concerned in moving on each other the parts of the larynx.

The *crico-thyroideus* is a thin quadrilateral muscle, situated in front of the larynx, and often divided into two parts by a fatty line. It is attached to the front and sides of the cricoid, and proceeds upwards and outwards to the inferior edge of the thyroid, to which, as well as to a little of the posterior surface, the internal fibres are fixed. The external are longer, and reach to the front of the inferior thyroid cornua. An interval appears between the right and left muscles, in which the crico-thyroid membrane is visible. It corresponds in front to the sternum thyroideum, and to the inferior constrictor of the pharynx; behind to the crico-thyroid membrane, and to the crico-arytenoideus lateralis.

The *crico-arytenoideus posterior* is a strong muscle, flattened on its surface, triangular, and placed at the back of the larynx. Its origin fills the lateral excavation of the posterior surface of the cricoid. The superior fibres are the shortest, and proceed nearly transversely; the following are longer, and gradually more and more oblique from below upwards and outwards; they are attached to the posterior and outer part of the basis of the arytenoid, between the insertions of the arytenoideus, and of the crico-arytenoideus lateralis. In front it corresponds to the cricoid cartilage, and behind to the membrane of the pharynx.

The *crico-arytenoideus lateralis* is a thin and flattened muscle, rather elongated and quadrilateral, proceeding from the side of the cricoid to the side of the arytenoid cartilage. It arises from the superior margin of the former, passes obliquely backwards and upwards, and is fixed externally to the basis of the arytenoid. It is connected in front with the thyro-arytenoideus, separated on the outside from the thyroid cartilage by cellular substance, and lined on the inside by the laryngeal membrane.

The *thyro-arytenoideus* is a thin and flattened muscle of irregular figure, situated within the concavity of the thyroid cartilage. It arises near the angle of that cartilage, from the lower part of its posterior surface, proceeds backwards and outwards, becoming rather narrower, and is inserted in the front of the arytenoid cartilage, below the preceding, to which it is closely connected. It corresponds externally to the thyroid cartilage, and internally to the laryngeal membrane.

The *arytenoideus* is the mass of muscular fibres filling the posterior concavities of the arytenoid cartilages, and occupying the interval between them. The fibres arise from the concave surface of one cartilage, go across, and are inserted into the corresponding part of the opposite cartilage. They are partly oblique and partly transverse; the former consist of a few superficial fibres crossing respectively from the basis of one to the apex of the other cartilage, and consequently decussating like the two parts of the letter X. The great mass of the fibres has however a transverse direction. From the different courses of these two descriptions of fibres, two arytenoid muscles have been distinguished; viz. an obliquus and a transversus. These fibres are placed between the membranes of the larynx and pharynx; in front they are also partly in contact with the arytenoid cartilages.

Under the names of *thyreo-epiglotticus, major* and *minor*, some anatomists have described a few slender fibres proceeding from the posterior surface of the thyroid cartilage to the side of the epiglottis. Others do not admit the existence of these muscles, which are allowed by all not to be found generally. Haller regards these fibres, when they

exit, as a part of the thyro-arytenoideus. The motions of the epiglottis, in the human subject, are all entirely of a mechanical nature, and not performed by muscular action.

*Glands of the Larynx.*—There are three bodies of this description in the neighbourhood of the organ; viz. the epiglottic, the arytenoid, and the thyroid.

*Glands of the Epiglottis.*—In front of, and below the epiglottis, a triangular space is left, bounded behind by this cartilage, in front by the thyro-hyoidean membrane, below by the thyro-epiglottic ligament, and on the sides by the lateral folds of mucous membrane which line the two spaces left between the sides of the thyroid and the cricoid cartilage. This space is filled by a body, manifestly cellular and adipous for the most part, but covering below small granular glands, sometimes united together, sometimes insulated, and sending prolongations into the holes with which the epiglottis is pierced. The latter open on the laryngeal surface of the organ by very distinct apertures. The glandular bodies are sometimes so much covered and concealed by the surrounding fat, that they can hardly be distinguished. In all cases we may remove by dissection these bodies from the openings in the epiglottis, which then appear as empty spaces. We may distinguish as many as thirty of these. The superior excavations of the epiglottis contain small distinct grains: the epiglottic gland and its cellular tissue belong only to the inferior half of the organ. The openings in the epiglottis are of different sizes; they are very regularly formed, with rounded edges, and penetrate always straight through, never obliquely.

*Arytenoid Glands.*—In the fold of mucous membrane, proceeding on each side from the epiglottis to the arytenoid cartilage, a small body is found, evidently of a glandular nature, presenting small distinct grains, very analogous to those which compose the lacrymal gland, and generally of a greyish hue. It may be compared in form to a carpenter's square. The perpendicular branch, which is rounded, and may be felt by the finger, when we seize the fold that contains it, lies against the front of the arytenoid cartilage, and is loose above. The horizontal branch runs along the superior fold of the ventricle of the larynx, and is less prominent than the other. The situation, at which the two branches form their angular union, is in front of the base of the arytenoid. The glandular grains of this small body, probably, have excretory ducts terminating on the edge of the superior aperture of the larynx: but these apertures are not visible like those of the ducts of the last-mentioned glands.

These epiglottic and arytenoid glands furnish a mucous secretion, and are of the same nature as the others which belong to the laryngeal membrane. The passage of the food in deglutition, and of the air in respiration, requires that these organs should be defended by a mucous fluid.

The *thyroid gland* is one of those organs, of which the use is entirely unknown to us, although its constant existence, through all periods of life, and the great number of vessels which it receives, do not allow us to doubt that it performs some important office. Its situation immediately below and in front of the larynx, leads us to connect its history with that of this cavity, although we are ignorant whether it has any concern in the same functions. This organ, as well as the spleen, capsula renales, &c. suggests a very important reflection; viz. that our notions concerning the general relations of the functions of the animal economy must still be necessarily very imperfect, and that we should deceive ourselves if we suppose that we can embrace the plan of nature in one general view, and represent it accurately in our physiological classifications. Can we

doubt that the unknown functions of these viscera are connected to the general plan, and make an essential part of it? How then can we be certain that a knowledge of them would not either partly overturn, or considerably modify our present notions on those subjects. Why is the theory of foetal existence still so obscure? Because the functions of several organs, at that time perfectly developed, and in a very active state, escape our observation, and we cannot arrive at general results when the particular facts are unknown.

The bulk of this gland, which is always very considerable, varies much in different individuals: perhaps no organ presents more striking variations. No particular condition of the body, no modification of any particular function, no differences in stature, in the state of the larynx, trachea, lungs, &c. have been observed to accompany these varieties. Its form is tolerably constant; but in this respect there are also varieties. It is composed of two distinct portions, nearly pyramidal in their figure, occupying the sides of the larynx, and of the upper extremity of the trachea, so that the base is placed downwards and forwards, and the apex stretches upwards and backwards. Variations are observed in the extent and direction of these two lateral portions. They are united in front by a small flattened transverse band, which may be large and thick, small and narrow, or made up of distinct tubercles; indeed, we scarcely find it the same in two individuals successively. In a few instances this part does not exist, so that there are two distinct thyroid glands, one on each side. It does not extend above the trachea, so that the whole larynx is uncovered in front, nearly subcutaneous, and embraced by the curve formed by the two lateral portions of the gland united by the intermediate band.

In front the thyroid gland is covered by the sterno-thyroidei, sterno-hyoidei, omo-hyoidei, and latissimi colli. It rests behind and towards the outside on the vertebral column, to which a loose cellular substance connects it, and where, according to its bulk, it conceals or leaves exposed the nerves and blood-vessels of the neck. Internally, or towards the middle line, it covers the sides of the first rings of the trachea, part of the cricoid and thyroid cartilages, the crico-thyroidei, thyro-hyoidei, and inferior constrictor of the pharynx. Exactly in the middle and front it conceals the two first rings only of the trachea. A loose tissue separates it from all these parts.

It is surrounded by no membrane: the exterior cellular tissue is rather more dense and compact than the rest, as in the pancreas and salivary glands; but it forms no proper membrane. It never contains any fat.

With this external covering some muscular fibres are blended; not noticed by Albinus, nor by most other anatomists, but forming the levator gland. thy. of Haller, the musculus gland. thy. of Soemmerring. It does not exist constantly; is generally a single muscle, situated in the middle of the larynx, sometimes is placed towards the right or left, and sometimes, but very rarely, is double. It arises by a narrow tendinous slip from the basis of the os hyoides; descends in a straight course, growing broader, and has its fibres expanded on the front of the gland, and blended with the covering of the organ. It must apparently have the effect of suspending and supporting the gland. Muscular fibres have sometimes been seen, extending over the surface of the gland from the crico-thyroideus. Besides the effect, which these and the fibres just described may produce on the gland, it will be exposed to powerful compression against the larynx and trachea by the sterno-hyoidei and sterno-thyroidei, which embrace it very closely.

The proper tissue of the thyroid gland varies considerably

in colour and density : it is often red, and even dull brown, like the spleen, sometimes yellowish or greyish. It may be flabby or compact ; but its density varies less than its colour. The substance of the organ, like that of other glands, is disposed in distinct lobules, which are collected into more or less voluminous lobes. This conglomeration is never so perceptible as in the salivary glands, the pancreas, &c. ; excepting, however, certain cases of increased volume without organic change, where the surface of the organ is tuberculated and irregular from the unequal prominence of the lobes. In the natural state of the part, we may distinguish the lobes by dissection, as the great vascular trunks run in their intervals ; the latter, which are hardly perceptible at first view in consequence of the lobes being pressed against each other, become apparent by the use of the knife. A fine cellular tissue, never containing any fat, and small in quantity when compared to what is found between the lobes of other glands, is seen in these intervals.

The lobes of the thyroid gland are mixed in some subjects with rounded vesicles, containing sometimes a yellowish, sometimes a transparent and colourless fluid. In most subjects these cysts do not exist, and in many we cannot observe the slightest traces of them. Yet slices of the gland recently cut give us a peculiar feeling of viscosity, not observed in other glandular bodies, and proceeding from the fluid just mentioned. If an acid be poured on the cut surface, a slight white effluvia is produced, as in most other organs.

Although provided with a great number of blood-vessels, the thyroid gland contains in its capillary system less blood than the liver, the kidney, &c. It only discolours the water of maceration once or twice, which arises evidently from the small number of its capillaries. It is not by the large vessels, in which the blood is influenced by the heart's action, but by the capillaries, that we may judge of the quantity of blood habitually contained in an organ. As putrefaction generally proceeds more quickly, in proportion as the quantity of blood remaining in the organs after death is greater, the thyroid gland undergoes this change less readily than most others. Slices of it dried are greyish and friable. When boiled, they curl a little before ebullition, and then become considerably harder and corrugated as almost all the animal solids do. But, instead of growing soft again, like the muscles, tendons, &c. they are rendered still harder, like the glands, by a continuance of the boiling. Acids and alkalies have no peculiar operation on the tissue of the thyroid gland.

Nothing like an excretory duct has hitherto been discovered in this body : no communication has been pointed out between it and the trachea or larynx. The emphysema, of which it is sometimes the seat, proves nothing in this question ; for the air is contained in the cellular tissue which unites the glandular lobes, and is introduced in consequence of its general diffusion in the cellular tissue of the neck. By inserting a blow-pipe into the substance of the organ, and inflating forcibly, it may generally be distended so as to form an artificial emphysema. The air, in this case, is not contained in the vesicles, but in the cellular interstices : it follows the course of the vascular trunks.

Some sexual differences may be noticed in the thyroid gland. It is generally larger in the female, and its lateral divisions are more prominent in front ; which diminishes the apparent prominence of the thyroid cartilage. In man, on the contrary, the two lateral portions are thinner and proportionally flatter ; and lie more close on the sides of the larynx, below the external oblique line of the thyroid cartilage. But there are so many varieties in other points, that this sexual difference is often little observable.

The differences from age are few. The gland is proportionally larger in the fœtus and child than in the adult. Its front prominence is more striking at the first period : and its colour is deeper and brownish. Its proportional excess of volume cannot, however, be compared to that of the thymus, capsule renales, &c. : indeed, it is not sufficiently remarkable to authorize us in concluding that the use of the part is particularly relative to fœtal existence, although several authors seem to have believed this.

The thyroid gland has four large arteries, two on each side, one of which is derived from the external carotid, the other from the subclavian trunk. No part in the body has so considerable an arterial supply as this organ ; that of the brain is very much less in proportion. The inferior thyroid artery in the child is as large as the remaining trunk of the subclavian after its origin. These vessels are connected in the gland by large and numerous anastomoses. The veins correspond in number and magnitude to the arteries, and terminate in the jugular and subclavians. The absorbing vessels are also considerable, and join the jugular glands. The thyroid arteries are accompanied by nervous filaments from the great sympathetic ; but it cannot be easily decided whether the proper substance of the gland receives any nervous supply.

As we have stated already that the use of this organ is unknown, we shall not fatigue the reader with mentioning and refusing the assigned offices. Although they are very numerous, they are not grounded on any facts worthy of attention. Soemmerring, in his 6th vol. *De corporis humani fabrica*, § 56, gives a long list of "opiniones de glandulæ thyroideæ usu," and there is a similar catalogue in Haller's *Elementa*, lib. ix. sect. 1. § 22

#### *Of the Larynx in general.*

*General Conformation.*—The larynx is a cartilaginous cavity moved by various muscles. It is broad above, narrower below, and possesses an external figure, which does not correspond to that of the internal hollow. In fact, the latter, being essentially formed by the cricoid and arytenoid cartilages, and the membranous coverings belonging to them, possesses nearly a uniform diameter throughout ; and it is most contracted towards the upper part. This arises from what we have said of the thyroid cartilage, which rather protects than forms the larynx, although it is essential to its structure and action, from the attachment which it affords to muscles and ligaments. We may consider, in our view of this organ, the external and internal surfaces, the superior and inferior extremities.

The external surface, considered in front, presents, on the median line, the prominence formed by the union of the two portions of the thyroid, which exhibits, above, a considerable depression, particularly in man ; then the membranous interval, which separates the two crico-thyroides, and below it the convexity of the cricoid : on the sides we see the two flat surfaces of the thyroid cartilage, covered by the hyothyroides, the external oblique line, the triangular surface covered by the inferior constrictor, and terminated by the inferior cornu, lower down the crico-thyroides, which, at this point, almost entirely covers the cricoid cartilage. Behind, the external surface of the larynx, more depressed in the middle than towards the sides, presents, on the median line, the middle prominence of the cricoid : on the sides of this, the hollows lodging the crico-arytenoidæ postici, then a triangular space, broad above and narrow below, filled with a more or less adipous cellular substance ; lastly, two rounded edges, bounding the spaces just mentioned, more prominent than any other parts in this aspect, and resting on the vertebral column, so as to allow a free motion

to all the essential parts of the organ, particularly to the arytenoid cartilages.

The internal surface of the larynx, lined throughout by the mucous membrane, may be divided into two parts, one solid, the other moveable. The first is inferior, in point of situation, and formed entirely by the cricoid ring. The proportions of this part are constantly the same; and it contains nothing worthy of notice. The moveable portion is above, formed behind by the arytenoid cartilages, in front by the thyroid and epiglottis, on the sides by the folds of mucous membrane, continued between the epiglottis and the arytenoid cartilages. In the ordinary state this is triangular, broad in front, and narrow behind; but the motions of the epiglottis and arytenoid cartilages change its figure considerably. This part forms the opening by which the larynx communicates with the pharynx: the aperture is placed just behind and below the root of the tongue, and is often called the glottis, although it has no share in the formation of the voice. Of its relation to the pharynx, in respect to deglutition, see a further account in that article. The part, at which these two divisions of the larynx are united, is remarkable for the two membranous folds, called ligamenta glottidis, or chordæ vocales. These arise from the bases of the arytenoid cartilages, and pass obliquely, forwards and inwards, to meet together at the concavity of the thyroid, where they are fixed just under the epiglottis. They leave between them a triangular space, of which the basis is behind, and the apex forwards: this is the true glottis, and is placed about half or three quarters of an inch lower down than the opening described above: as the measurement of the opening from behind forwards considerably exceeds the transverse diameter, it has a slit-like appearance, from which the name of *rima glottidis* has been applied to it. The folds, which form the sides of the upper opening, differ essentially in their composition from those of the inferior aperture. The former are merely membranous: the latter contain the fibrous fasciculi, described already under the name of the thyro-arytenoid ligaments. The interval left on each side between the superior and inferior folds constitutes the ventricles of the larynx, or *fasciculi laryngis*. Their form must correspond to the direction of the folds, which have been just described; their depth is inconsiderable. Sometimes the mucous secretion of the internal lining accumulates here for a short time: sometimes foreign bodies become engaged in them, and produce suffocation by stopping the *rima glottidis*, or cause great distress until they are removed. The ventricles, as well as the superior laryngeal folds, correspond on the outside to the thyro-arytenoid muscles: the inferior folds separate these muscles from the crico-thyroides, which complete towards the outside the space separating these folds from the circumference of the cricoid.

The inferior extremity of the larynx, formed by the inferior circumference of the cricoid cartilage, is exactly circular. It is united to the first ring of the trachea by a fibrous membrane, similar to those which unite to each other the remaining rings of this tube. Behind, the posterior tracheal membrane is attached to it.

The superior extremity, much larger than the inferior, is formed in front and at the sides by the upper edge of the thyroid cartilage. This edge is connected to the os hyoides, which is immediately above it, by the loose and soft thyro-hyoidæal membrane: this is thicker in front than towards the sides, has very little fibrous appearance, but seems rather of a cellular nature. It is covered by the hyo-thyroides and sterno-hyoides; it corresponds behind to the epiglottis, from which the epiglottic gland separates it, and to the la-

ryngeal membrane. It is shorter in the middle than at the sides; consequently the cornua of the os hyoides can be elevated to a greater distance from the thyroid cartilage than the basis of the same bone, and the basis of the tongue, which is supported by the os hyoides, can be drawn up higher at the sides than along the middle line; which disposition of parts is favourable to the formation of the channel, along which the food is conveyed towards the œsophagus. The two extremities of the os hyoides are connected to the superior cornua of the thyroid cartilage by long, dense, and round ligaments, generally containing granular bodies of a cartilaginous or bony nature. These are named ligamenta hyo-thyroidea lateralia, to distinguish them from the former, which is called lig. hyo-thyroid. medium. The length of these lateral ligaments, in addition to that of the thyroid cornua, measures the distance between the os hyoides and the thyroid cartilage behind, which is about double the front interval.

Behind the edge of the thyroid cartilage, and in front of the epiglottis, there is a triangular space filled by the epiglottic gland, and its adipous cellular substance. This space is bounded above by the fold of mucous membrane continued from the basis of the tongue to the epiglottis, and, moreover, by a kind of fibrous membrane, which lies immediately under the former, and over the gland. The membrane in question is stronger in the middle than at the sides: it arises from the concavity of the os hyoides, and is attached to the middle of the epiglottis. Behind this space we see the epiglottis, and behind it the superior opening of the larynx, already mentioned. As the breadth of the epiglottis, which forms the front of this opening, is always the same, while the arytenoid cartilages, which compose the back part, admit of considerable motion, the figure of the aperture can undergo little change in front, while it may vary much more considerably behind. The position of the opening is rather oblique, from before backwards and downwards.

*Membrane of the Larynx.*—The interior of the cavity is lined by a mucous membrane, forming part of the general system common to the respiratory and digestive organs. It proceeds backwards from the basis of the tongue over the front of the epiglottis, forming, as it passes, the three folds already described: it is reflected over the loose edge of this fibro-cartilage, covers its posterior surface, and then enters the larynx. On each side it is continued directly backwards to the arytenoid cartilages, being loose and unconnected at its edge, and corresponding only to the thyro-arytenoid muscles. At the posterior edge of the opening of the larynx, it is continuous with the membrane of the pharynx. When it has arrived in the cavity of the larynx, and towards the basis of the arytenoid cartilage, it forms on each side a horizontal fold, directed obliquely forwards to the concavity of the thyroid, to which it is fixed, joining that of the opposite side. Below this point it lines the cavity of the ventricle, then forms another fold, which bounds this cavity below, and embraces the thyro-arytenoid ligament: it afterwards lines the lower portion of the larynx, and is continued into the trachea. In the whole of its extent the mucous membrane is of a pale rose-colour, and distinguished by that character from the lining of the mouth, of which it is a prolongation, and which is much redder. Its density is considerable, particularly on the cartilages, where it is united with the perichondrium: in other parts it is more thin and loose in its texture. On the laryngeal surface of the epiglottis, it is perforated by several holes, which are the terminations of excretory ducts. Mucous glands are apparent in several points of its surface. The capillary system of this membrane is not very considerable, and hence arises its paleness.

palaeus. It possesses very acute sensibility from the superior opening to the glottis; but is much less sensible below. For an account of the relation, which this property bears to the functions of the part, see *DEGLUTITION*. The sensibility is not excited by the contact of air, as that is habitual; but it is quickly roused by vapours disseminated in the atmosphere, particularly when they are at all acrid.

*Mechanism of the Larynx.*—The motions of this part are of two kinds, general and particular. The former, in which the whole larynx is moved, take place in deglutition, and in the pronunciation of different sounds. For an account of the former, and of the powers which act at that time, see *DEGLUTITION*.

The larynx is moved in the same way, and by the same muscles, in the pronunciation of different sounds. When an acute sound is uttered, it ascends very sensibly; and this ascent, which is gradual, according to the tone, may be felt by placing the finger on the thyroid cartilage, while we go through the gamut. In the formation of grave sounds, there is, on the contrary, a very sensible depression. These motions can be very clearly seen in the throat of a finger: the rapid and considerable changes which take place in that mode of exerting the voice, render the motions very perceptible. The ascent of the larynx is necessarily accompanied by an elongation, and its descent by a shortening of the trachea; in the former case its diameter is diminished, and in the latter increased. Some have supposed that these changes in the trachea are concerned in producing the alterations of tone; but if they produce any effect on the sounds, it is very slight, and they seem rather to be merely consequent on the movements of the larynx.

What connection is there between the sounds uttered and the general motions of the larynx? We know very little on this subject. We may observe that they have no relation to the force or weakness of the sound; so long as the voice remains at the same tone, the larynx does not move, however the sound may be changed in strength or weakness.

The thyroid and cricoid cartilages admit of reciprocal motion; the former can be brought downwards and forwards upon the latter; in this case the chordæ vocales are relaxed. The crico-thyroideus muscle has this effect.

But the motions of the arytenoid cartilages are the most important, on account of their connection with the chordæ vocales. They may be brought towards each other, until, indeed, they come into actual contact; this is attended with a proportionate approximation of the chordæ vocales. When the cartilages touch each other, the rima glottidis is completely closed; this is done by the arytenoid muscle. This shutting of the aperture is sometimes produced spasmodically, as when the parts are irritated by acrid vapours, or by foreign bodies coming into contact with them. Respiration must experience a temporary obstruction under such circumstances. When these cartilages are moved away from each other, the chordæ vocales are separated, and the rima glottidis proportionally enlarged; this is the action of the crico-arytenoides pollicis. The arytenoid cartilages admit also of being moved forwards and backwards; the chordæ vocales are rendered tense in the former state, and are relaxed in the latter. The thyro-arytenoidei and crico-arytenoidei laterales carry them forwards; and the crico-arytenoidei pollicii backwards.

*Development of the Larynx.*—The differences of this organ, according to the age of the individual, are not less conspicuous than the sexual distinctions in the adult. They refer to two principal periods; viz. the years which precede, and those which follow puberty; for the great changes in the structure of the larynx, which in this respect follows the

development of the sexual organs, take place about this epocha. In the fœtus and child there are no differences in the larynxes of the two sexes: until the period of puberty, the same size, the same rounded form, and the same want of prominence are observed both in the male and female. At this time the organ is much smaller in proportion in both sexes, but more particularly in the male, than it will be in the sequel. This will appear in a more striking point of view, if we compare the larynx to the os hyoides, which surmounts it. That organ, already much advanced, in consequence of its connection with the tongue, which is developed early in life, projects before the larynx; while in the adult, and especially in the male subject, the larynx projects before it. The thyroid cartilage can hardly be said to have a prominent angle in the child. It is rounded at this part in either sex. Nothing particular is to be observed of the cricoid cartilage; and all the parts at the back of the larynx present the same dispositions as in the sequel, excepting the difference in size.

The nature of the voice is influenced by this diminutive size of the larynx, and by the sameness of its conformation in the two sexes. At this period of life we remark that its pipe or key is slender, and that its character is the same in both sexes. If there is any difference, it is not such as that which in the sequel distinguishes the voice of man from that of woman.

As the growth proceeds, the larynx approaches to the state in which we find it in the adult. Yet it does not follow the same course of development as most other organs. In children of six months it is often as large as in those of two years. Sometimes in a subject of three years it will be smaller than in one of a year, although the stature of the two may be suitable to their respective ages.

A change almost sudden, or at least much less gradual than any which had occurred before, in the functions of the larynx, is remarked at the epocha of puberty: this indicates an alteration in the organization of the cavity, and a more rapid development of its structure. The change is much more remarkable in man than in woman, because the larynx remains much smaller in the latter than in the former, even after puberty. At this time the larynx is enlarged in all its dimensions by a speedy growth analogous to what is observed in the generative organs. But while this change is going on, for several months, the voice has a peculiar pipe, which is neither that of infancy nor of adult age.

After puberty the larynx undergoes no well marked change: its form becomes more fixed, and the prominence of its thyroid cartilage more considerable in man.

In the old person, as the cartilages are constantly receiving fresh depositions of earthy matter, they at last nearly equal bone in hardness. This change affects the thyroid first; then the cricoid, and lastly the arytenoids. The epiglottis is hardly ever affected, probably on account of its peculiar organization, which resembles that of the cartilages of the nose, ears, &c. This exemption is very favourable to its functions, which require pliancy. The voice always becomes weak and broken in the aged; the weakness of the muscles and the stiffness of the joints account for this, as analogous changes explain similar phenomena in the organs of locomotion.

The remarkable change in the pipe of the voice produced by the removal of the testicles has been mentioned in the article *GENERATION*. It has not been ascertained whether there is any change in the organization of the larynx in these cases.

The parts hitherto described are the instruments by which the voice is produced: the action of other organs is required,

quired, in order to modify this, so as to form it into articulated sounds or speech. Of these the tongue and the os hyoides are the most important: the latter bone is the basis of the tongue, the fixed point from which its muscles proceed, as also the point of attachment of the chief muscles of the larynx. The description of these organs, and of the muscular powers employed in moving them, will be found in the article *DEGLUTITION*. A knowledge of the parts about the throat, which anatomists generally term the fauces, is also essential in considering the subject of the voice. The larynx opens into a large membranous cavity, descending from the basis of the skull in front of the six upper cervical vertebrae, and named the pharynx. A large opening in the front of this, and between the tongue and soft palate, leads into the mouth: this aperture may be either free or closed. Another passage goes above the palate into the nose; but this is not so changeable in its dimensions as the former. Thus the air, expelled from the larynx, must proceed either through the mouth or the nose, or both. The mouth is the large space bounded by the lips and cheeks, the tongue and palate. Into it the tongue projects below, with free power of motion in every direction, and in the ordinary state nearly fills the cavity. The two rows of teeth form a kind of division into an outer and an inner cavity. For the more particular description of all these parts, see *DEGLUTITION*.

It was formerly held that the palate and uvula had a considerable influence on the voice: but this seems doubtful. The softness of the part, which is drawn down against another soft part, the tongue, renders it unfit for producing any modification in the sound. Animals, for the most part, have no uvula, and we know that the organ may be variously diseased without affecting the speech: "Wherefore," says Haller, (*Elem. Physiol. lib. ix. sect. 2. § 17.*) "if affections of the uvula have produced any considerable alterations in the voice, I should be rather inclined to ascribe them to some undue passage of the sound from the velum palati being at the same time injured. Thus, when the nose is diseased, a peculiar modification of the voice takes place, not because the nostrils are moved in the vocal functions, but because they transmit or reflect the sonorous tremors of the air. Thus, too, when the voice is injured by destruction of the bony palate, an artificial plate, which restores the power of reflection, without adding any motion, remedies the deficiency. I have the same opinion concerning speech. The guttural letters may be less perfectly formed, when the organs about the throat are diseased, because the allusions of parts cannot take place in the natural way: but the uvula is concerned in the pronunciation of no letter, and we might quote numerous authors who have seen it entirely cut away, or destroyed by disease, or originally deficient without the speech being impaired."

The passage from the pharynx, above the velum palati, leads into a large and irregularly formed bony cavity, lined with a soft membrane, and increased by many excavations in the neighbouring bones. This is the cavity of the nose, divided by a nearly perpendicular partition into two halves, the right and left nostrils. This cavity is described under the articles *CRANIUM* and *NOSE*. The air emitted from the larynx, rushes into these bony hollows, when they are not filled with mucus, strikes their sides, and throws the whole of the surfaces into vibrations, from which important modifications of the voice ensue.

*Physiology of the Voice and Speech.*—The voice, like all other sounds, is a vibration communicated to the air; and it offers to our observation, like them, three distinct kinds of qualities, independent of each other. 1. The tone, or the various degrees of acuteness and graveness, which depend on the ve-

locity of the vibrations. 2. The intensity, or the degrees of force, which depend on the extent of the vibrations. 3. The character or key, which arises from circumstances hitherto undetermined, and relating to the structure, the substance, or the figure of the sonorous body. The human voice is susceptible of a fourth order of modifications; viz. that which we represent by the letters of the alphabet, and which is itself divided into two other orders; the one relative to the principal sounds, which we represent by the vowels; and the other to their articulations, which constitute the consonants. We do not exactly know on what the two latter modifications depend: and although we perceive to a certain point the circumstances under which they are executed, we are not yet able to imitate them by artificial instruments.

The sound is produced by the passage of air through the rima glottidis, or the slit-like opening left between the two chordæ vocales. Almost invariably it is the passage of the air from the lungs, in expiration, that produces the sound; but there are some rare exceptions to this. In hiccup, and under some circumstances in coughing, sound is produced during inspiration. Many conceive, moreover, that the phenomena of ventiloquism are to be explained by the exertion of the vocal organs, when air is admitted into the chest.

That the larynx is the primary organ, in which the original sound is produced, is proved by the circumstance, that diseases and accidents affecting it destroy or modify the voice. If an opening be made in the trachea, below the larynx, so that no air shall pass through the latter, no voice is produced. When, on the contrary, an opening is made immediately above the glottis, the voice is not affected. Bichat made an incision between the os hyoides and the thyroid cartilage, and through the membrane, which connects the tongue to the epiglottis: through this transverse opening he drew out the epiglottis with a hook, so that the sound, instead of passing through the mouth and nose, came directly by the external wound. The voice was as strong as before, and very little changed in character. He drew the glottis between the sides of the wound, so that the sound could not pass at all into the mouth and nose: the result was still the same. In these experiments the epiglottis may be completely confined, or even cut away, without affecting the phenomena, so that it can have no concern in the formation of the voice. When the arytenoid cartilages were cut through, or the thyroid divided longitudinally, as in the operation of bronchotomy, the voice was destroyed.

The two elastic ligamentary and membranous bodies, which form the chordæ vocales, are analogous, in the human instrument of the voice, to the various provisions for producing vibration in the different wind instruments. No sound is produced by blowing into a tube through a simple opening; the only effect is a motion of the air, incapable of producing sound, unless it meets with a body susceptible of being thrown into vibration. It is, moreover, ascertained that the sides of the instrument are not the vibrating parts: for the substance of which they are composed, or the manner in which they are held, produces no change in the tone or key. On examining the parts, to which the mouth is applied, in the various wind instruments, it appears, that vibrations are produced in the air contained in the tube, as they are in the external air; that is, the intervention of an elastic body is necessary, which the blowing of the player agitates, and the vibrations of which are communicated to the air in the tube; or at least some angular body, against which the air may break as it passes with violence, and thereby be thrown into vibration. In the flute with a mouth piece, in organ-pipes of various kinds, in the hautboy,

hautboy, bassoon, &c. in trumpets, horns, &c. there are different provisions of this kind, to which the chordæ vocales are perfectly analogous. The tube then produces no found itself, it only modifies, directs, or augments that which it produced at its embouchure by the sonorous body against which the air breaks. The trachea of an animal is a continuous tube without any contraction, or any piece susceptible of vibration, except at its upper extremity, or the glottis. As the found is only formed at the end of the trachea, that tube cannot serve to modify it; it can only be compared to the pipe of the bellows of an organ, or to any canal which may convey air to the embouchure of the instrument; and the only part of the vocal organ in the mammalia, which can be compared to the tube of one of our wind instruments, is that placed in front of the glottis, *viz.* the mouth and nasal cavity. If we consider, not only the want of resemblance between these two cavities and all the instruments which we are acquainted with, but also the almost infinite number of means by which we can change their length, diameter, figure, and vents,—means which it is almost impossible to determine with sufficient exactness to deduce from them physical consequences, we shall not be surprised at the difficulties which the theory of the human vocal organ presents.

But the mere passage of the air through the glottis is not sufficient for the purposes of this function. The voice connects us with the individuals of our own species, enables us to communicate our thoughts to them, and must, consequently, be under the regulation of the will. Hence it is produced by voluntary motion, and does not take place except under the influence of volition. We are constantly breathing during sleep, without the production of any found: and we may expire, as strongly as we please, in the waking state without the voice being formed, until we exert a particular act of volition. Again, although the whole structure of the larynx is entire, the ligature or section of the recurrent nerves, or of the nerves of the eighth pair, destroys the voice. An injury of one nerve destroys half the vocal powers, but the voice is completely lost by operating on both. Galen performed this experiment repeatedly on pigs: Vesalius, and other more modern physiologists, have ascertained that the effects are correctly stated by Galen. In short, all the changes and conditions of the vocal organs, of whatever description, necessary to the production and modification of found, are produced by the muscles of the part, under the influence of the will. The exact nature of the muscular motions, required for producing the voice, is not known. Bichat observed, in the experiments already alluded to, that the rima glottidis was contracted whenever a found was uttered; and that this contraction was the more sensible, in proportion as the found was stronger. He states that it never was dilated during the formation of found. He observed, moreover, that inspiration and expiration were constantly attended respectively by dilatation and contraction of the glottis.

The air expelled from the lungs through the opening, prepared for its passage by the action of its proper muscles, throws the sides of this aperture, the chordæ vocales, into a state of vibration: the same effect is produced in the larynx, whose cartilaginous structure renders it particularly susceptible of such vibrations, and in all the surrounding organs. The found produced by the tremulous motions of all these parts is the voice. Hence we understand why hoarseness and smallness of the voice accompany catarrhs, in which the unusual coverings of mucus render the parts less susceptible of vibration; why those animals which have the greatest quantity of cartilage and the least membrane in

their vocal organs, have the strongest and most sonorous voices, and *vice versa*? We see also that all animals provided with a pulmonary organ will have a voice; since nothing more is required, for the production of this found, than the accumulation of air in some receptacle, its expulsion in a mass, with a certain force, and its meeting on its passage with elastic and vibratory organs. Fishes, which have gills, and insects, in whom the distribution of air is by means of tracheæ, produce no found.

It seems impossible to explain how the passage of air through the human glottis should produce vocal sounds distinguishing man from all other animals, and how each animal should have his peculiar and characteristic voice, where the differences of structure, in a part of such simple formation, must be very slight. Yet it seems true that the glottis alone produces the specific character of the voice in each animal. Numerous and respectable authors affirm, that the inflation of air through the glottis is sufficient, even in the dead animal, to produce its particular voice: this has been asserted of the human subject, the cow, pig, cat, rabbit, hare, goose, and frog. It is directly adverse to what we have already stated concerning the necessity of some muscular action to the production of the voice, and is so contrary to those principles, by which these functions are subjected to the will, that we cannot help doubting the whole assertion. After reciting what others have stated, Haller adds, “with me these experiments have not been so successful: I have sometimes obtained a found, that might be recognised as the voice of the animal, but could never imitate the character of the voice in the pig or dog, and much less in man.” *Elem. Physiol. lib. ix. sect. 3. § 4.*

As the found, formed in the larynx, or the voice, proceeds through the mouth and the multiplied hollows of the nostrils, it undergoes various modifications, according to the nature of these parts, which produce in it changes affecting its key or pipe.

Ventriloquism is, perhaps, one of the most singular phenomena connected with the vocal functions; and certainly one, of which the nature is very little understood. This name, as well as the Greek term of *engaltri-muthism*, proceeds on the supposition that the found comes from the abdomen: but we cannot doubt, in general, that the vocal organs alone are concerned, however unable we may be to explain the exact nature of the process. Ammann, the Swiss, whose philosophical labours on the subject of language, and particularly in the instruction of the deaf and dumb, entitle him to much confidence, says, that he saw an old woman who could speak during inspiration, and others have explained ventriloquism in the same way. We believe that the point has not been sufficiently ascertained by actual observation: and others, in their attempts at explanation, even suppose that it is produced, like ordinary speech, during expiration. Some conceive that the tongue is fixed, and that some motions of the pharynx and velum palati do the business. Richerand observed, that a man who could give a dialogue between two speakers, with different voices, as if placed at some distance from each other, did not inspire while he was doing this, but that he expelled air in much smaller quantity than usual. The same author observes, that a Mr. Fitz-James, who possesses the power of ventriloquism in wonderful perfection, does it by means of an extremely gradual expiration, in which the air is brought out in a very slender stream. He precedes this by a very deep inspiration: hence a full state of the stomach renders the exertion of his talent difficult, which all individuals, who have had the art in question, seem to experience. By accelerating or retarding the exit of this air, Mr. Fitz-James

## L A R Y N X.

can imitate different voices, make his auditors believe that the interlocutors in a dialogue, which he carries on alone, are placed at different distances, and produce the most complete illusion on these points. See Richerand, *Elemens de Physiologie*, § 2, p. 339.

In hawking the air is violently forced, by a kind of interrupted action, through the trachea, larynx, and fauces, so as to detach the secretions of the parts, or any thing else which lies on the surface. The peculiar noise is produced by the air thus violently dashed against the parts.

Snoring is produced by a kind of tremulous oscillation of the velum palati, generally in inspiration, but sometimes also in expiration. Whining, or the plaintive sound produced in weeping, is the consequence of tremors of the soft palate, gradually diminished in force as the air is expired.

In humming the mouth is closed, and the expired air enters the nasal cavities with tremulous motions of the muscles of the fauces.

When the tongue is drawn upwards and pressed against the palate, and then suddenly depressed, so as to allow the air to pass quickly, the noise called chuckling takes place. By drawing the lips between the teeth, and then quickly separating them, we can imitate the trot of the horse; and by exercise we can even produce a sound like the clapping of hands.

When we wish to ascertain the odorous properties of any body, we sniff at it; that is, the inspired and expired air is conveyed through the nose with a tremor of the alæ nasi causing a particular noise.

Hissing is produced by expelling the air between the teeth, when brought close together.

In whistling, the tongue is rendered concave on its superior surface, and applied to the bony palate, and upper teeth, so as to have a passage for the air between it and those parts; the lips are at the same time contracted into a round aperture; and the point of the tongue is in contact with the front lower teeth. The vibrations of the parts through which the sound passes produce the peculiar effect, and the motions of the tongue and lips increase or diminish the dimensions of the openings through which it passes. The production of a loud sound requires a large quantity of air, a strong and accelerated expiration, and a considerable tremor of the chordæ vocales. The lungs must therefore be large and admit easily of distention; the trachea and larynx must also be ample, and the reflexion of the sound in all the passages unimpeded. A distended state of the stomach is unfavourable to the production of such sounds, as it impedes the descent of the diaphragm. The impervious state of the lungs in the consumptive must be equally unfavourable; and we accordingly find that the voice becomes weaker, as the disease advances.

In forming high or acute sounds, a contracted state of the glottis, with tension of its ligaments, are required; the air passes rapidly through the narrow opening, and numerous oscillations of its sides are produced. The whole larynx is carried upwards and forwards; and, in uttering the most acute sounds, the head is thrown backwards, that the larynx may be elevated through a wider range. This elevation equals nearly half an inch for one octave. That the changes above-mentioned take place, is proved, by placing the finger on the larynx, which gives us immediate demonstration of its ascent, when we utter acute sounds; by the comparatively acute voice of children and women, in whom the larynx is small, and the glottis consequently narrow; by comparative anatomy, which shews us that the glottis is small and narrow in singing birds, large and relaxed in ani-

mals which utter deep sounds; by the blowing of wind instruments, in which the opening for the passage of the air is always contracted in order to produce the high notes; and also by this general fact, that the sounds are always more acute in proportion as these instruments are of smaller size.

If we talk too impetuously, the quick passage of the air throws the chordæ vocales into too rapid oscillations, and the voice suddenly becomes exceedingly shrill. These changes have nothing to do with the loudness of the sound; a weak as well as a strong sound may be either acute or grave in its tone.

In the production of deep or base tones, an opposite state of parts is required; the larynx is carried downwards, and the head itself brought towards the chest. This descent, like the ascent, is about half an inch for an octave. In the male sex, where the larynx is larger, and the glottis consequently more ample than in the female, the voice is habitually deeper toned. Eunuchs and women may be taught to sing soprano, but not bass. When very low tones are formed, in which the chordæ vocales are greatly relaxed, the production of sound ceases altogether.

A human voice that has been much exercised, can pass through about two octaves and a half in either direction from the middle; and consequently it has a range in the neck of nearly three inches.

The question has been much agitated among physiologists, whether the changes of tone in the voice depend on alterations in the diameter of the opening, or in the state of tension of the ligaments forming its sides. By the advocates of the former opinion, the organ of the human voice is compared to wind instruments, in which the enlargement of the aperture renders the sound grave, and its diminution acute; and by those of the latter to stringed instruments. We admit, in the preceding account, the efficacy of both kinds of changes, but we consider the alterations in diameter as the most efficient. The change of the voice from acute to grave, at the time of puberty, when the larynx undergoes a remarkable development, as well as its acuteness in females, whose glottis is less by one-third than that of man, shew that the size of the aperture has a great influence. Observing, on the other hand, that the chordæ vocales admit of considerable tension and relaxation, we must allow that these variations will render them susceptible of executing, in a given time, vibrations more or less extensive and rapid. And although they are neither dry, stretched, nor isolated, which are necessary conditions to the production of sound in those stringed instruments to which the larynx has been compared, yet they are analogous to vibrating bodies placed at the top of wind instruments, as the reed in hautboys, the mouth piece in flutes, &c. and equally contribute to the formation and varied inflexion of vocal sounds. Haller, in his *Elementa Physiologie*, lib. ix., has given a long and very instructive account of the whole controversy. We shall be surprized at seeing how very small a change can alter the tone, when we reflect that the breadth of the rima glottidis does not exceed a line at its broadest part, and that there is an almost innumerable variety of tones distinctly perceptible.

Singing is the expression of love and joy, common to birds with the human subject. The pronunciation of words or letters is not essential to its nature. It includes the greatest variety of acute and grave sounds, and the most rapid transition from the one to the other. In general the tone of singing is more acute than that of talking. The great difference between these two modes of vocal exertion is in the transitions of singing; in order to execute these, the larynx, instead of resting, is sustained in a kind of equilibrium between the elevating and depressing powers. A person will soon

perceive this by placing his finger on the larynx while he sings, or by observing the throat of another. As singing requires the exertion of many muscles, it soon fatigues. It also exercises the muscles of respiration; as a large quantity of air is frequently required. The rapid passage of the air in singing dries the parts quickly.

Speech is the formation of the voice, produced, as we have already described, by means of the organs about the throat, nose, and mouth, into articulated sounds, by which men communicate their thoughts to each other. All animals have a voice, but man alone speaks in the sense now alluded to. Some, indeed, which have a broad tongue, have been taught to pronounce a few words; but they express no thoughts by these sounds. We believe that no sufficient reason can be drawn from organization, why man invariably should possess, and animals invariably want the power of speech.

The tones are not so quickly changed as in singing, consequently the larynx is much less moved. Recitative is a kind of mixture of singing and speaking, partaking equally of the characters of each.

If we consider a letter to be a sound, that cannot be resolved into more simple elements, speech is the formation of the voice into the sounds expressed by letters, and the composition of words from these.

Letters are divided into vowels and consonants. The former (vocales) are produced simply by the voice passing through the mouth opened to a greater or less degree, without the tongue being applied to the lips or to any other part. These sounds are produced in laughing, and something like them may be observed in the voices of animals.

In the formation of the vowels, the passage through the nose is closed; the voice proceeds straight through the tongue and lips, and the mouth is open. The larger the space left for the voice along the tongue and through the lips, or the lower the tongue is placed in the mouth, and the wider the lips are apart, the more deeply do the vowels sound. These sounds are the most clear and distinct, because the canal, through which they proceed, is free and unconfined in every direction.

The consonants are sounds pronounced with the vowels, and modifying or limiting them. They must therefore have vowels either before or after them. The sound of the vowel in these cases is altered by the tongue being applied to some part in the cavity of the mouth, striking against the teeth or lips, &c.

The consonants are distinguished into different classes according to different principles of arrangement. Soemmering gives the four following classifications.

I. 1. Nafales; *m, n, ng.* 2. Orales; *l, r.* 3. Sibilantes; *f, g, b, ch, s.* 4. Explosivæ; *b, d, k, p, q, t.* 5. Composite; *x, z.*

II. 1. Nafales; *m, n, ng.* 2. Liquidæ; *l, r.* 3. Mutæ; *f, b, ch, s, z, sch, th, v, w.* 4. Explosivæ; *b, p, d, t, k, g.*

III. 1. Mutæ; *k, p, t.* 2. Explosivæ et vocales; *g, r.* 3. Explosivæ; *f, h, s, sch.* 4. Vocales; *b, d, g, l, m, n.*

IV. 1. Gutturales; *g, ch, h, th.* 2. Palatinæ; *d, l, n, r.* 3. Labiales; *b, f, m, p, w.* De corp. hum. fabrica, t. 6. p. 110.

To point out the motions by which all these sounds are produced, would lead us into too wide a field. We refer the reader to the work of Soemmering already quoted, and to Haller's *Elementa Physiologiæ*, lib. ix.

The remarkable change which occurs in the voice, at the time of puberty, must be referred to the sudden development which the organ undergoes at that time, as we have already stated. The various affections of the mind are accompanied

by the utterance of particular sounds; and this is strongly seen also in animals. In them, the wants connected with the generative functions, afford the most frequent cause for the exertion of the vocal organs. But we may observe further, both in birds and quadrupeds that certain modifications of the voice express fear and anger, affection for the off-spring, joy and pain, that others are used in calling the assembly together, and, in the case of gregarious animals, in imparting to each other something which we do not understand. Similar vocal expressions of what is passing internally are observed also in the dumb, who have not learned to speak; and even animals distinguish in man the sounds denoting anger, approbation, &c. In the sounds which we utter, on many of these occasions, in civilized society, there may be something arising from imitation or habit, or referable in some way to a conventional origin; but much of it is so completely inartificial, that we seem to obey merely a species of instinct, and to express the simple voice of nature. Various malformations and diseases of the organs concerned in speech impair or entirely destroy the power of pronunciation. From the important share which the tongue has, in producing articulated sounds, we should expect that extensive injuries of it would be very injurious in this way. But experience shews us that it may be very extensively injured without greatly impairing the powers of speech. Indeed several letters may be pronounced without its aid. Mr. Louis has collected several cases in his "Mémoire physiologique et pathologique, sur la Langue;" in proof of this point, he states, that after very serious injuries the power of speech was at first greatly impaired; but that it gradually returned. *Mémoires de l'Acad. de Chirurgie*, t. v.

Stammering may be caused by too large and thick a tongue, by great length of the frænum; by any causes that impair the motions of this organ, whether they be referrible to organization, or to the state of the nervous system, as in drunkenness, apoplexy, &c.

Too great confinement of the organ, by its frænum, sometimes prevents children from learning to speak.

Want of the front teeth, as well as undue size of the tongue, produces lisping.

The confinement of the tongue in the aged, consequent on the diminution of the cavity of the mouth from the loss of the teeth, very much impedes the powers of pronunciation.

When we assign certain organical defects, as the causes of defective pronunciation, we do not mean to assert that this is constantly true. A person who stammers, for example, will often be able to speak clearly, if he will speak slowly.

The obstruction of the passage of the sound through the nose, either by closing the front openings of the nostrils, or by the elevation of the velum palati behind, produces a peculiar modification of the voice, which is strangely enough termed, in common language, speaking through the nose. Diseases of the palate, or its velum, ulcerations, and preternatural openings in them, have also very considerable effect on the voice; the same may be observed of disease affecting the bones of the nose.

Dumbness may be accidental, or may subsist from birth. In the former case, it arises from organic injury, which either affects the mechanism of the parts, or which intercepts the communication between the vocal muscles and the brain. In dumbness from birth, deafness seems to be always the cause; so that the absence of speech should here rather be called silence. This, at least, is constantly the case, according to the observation of Sicard on the numerous pupils committed to his care. Here there is an absolute ignorance of sounds, and of their representative value in letters of the alphabet. The vocal organs exhibit no marks of deficiency; they

they are fit, in short, to fulfil the uses for which nature has destined them, but they remain in a state of inaction, because the deaf infant is not conscious that he has the means of communicating his thoughts. See the article DUMBNESS.

Dichat, *Anatomic Descriptive*, t. ii. Soemmering, *De Corporis humani fabrica*, t. vi. Haller, *Elementa Physiologiae*, lib. ix.

LASAIÀ, in *Geography*, a town of Naples, in Principato Citra; 21 miles S.S.W. of Cangiano.

LASANON, a word used by different authors in very different senses; some applying it to the trivet commonly used in kitchens; others to a close-stool; and others, among whom are Hippocrates, and the ancient physicians, for a sort of chair, contrived for a woman in labour to sit in, as being so made, that the weight of the child, when born, shall help to draw away the fecundines.

LASCARIS, CONSTANTINE, in *Biography*, a learned descendant of the imperial family of that name, was born at Constantinople. He quitted his native city when it was taken by the Turks in 1454, and went to Italy, where he was most amicably received by duke Francis Sforza of Milan, who placed his own daughter, a child of ten years of age, under the care of Lascaris for instruction in the Greek language. For her use he composed his Greek grammar. From Milan he went to Rome, and from thence, at the invitation of king Ferdinand, he repaired to Naples, where he opened a public school for Greek and rhetoric. Having spent some years in this employment, he was desirous of repose, and embarked with the intention of settling at a town of Greece; but having touched at Messina, he was urged by such advantageous offers to make it his residence, that he complied, and passed there the remainder of his days. Here he received the honour of citizenship, which he merited by his virtues as well as his learning, and by the influx of scholars which his reputation drew thither, among whom was the celebrated Bembo. He lived to a very advanced age, but the time of his death has not been exactly ascertained. He bequeathed his library to the city of Messina. His Greek grammar was printed at Milan in 1476, and was the first book that issued from the Italian press. A better edition of it was given in 1494, by Aldus Manutius: Erasmus considered it as the best Greek grammar then extant, excepting that of Theodore Gaza. Lascaris was author likewise of two tracts on the Sicilian and Calabrian Greek writers.

LASCARIS, JOAN ANDREW, a learned Greek of the same family with the preceding, came over to Italy, on the ruin of his country. He studied at Padua, obtained a high reputation for his knowledge in the learned languages, and received the patronage of Lorenzo de Medici, who sent him into Greece with recommendatory letters to sultan Bajazet, in order to collect ancient manuscripts. After the expulsion of the Medici family from Florence, in 1494, he was carried to France by Charles VIII., after which he was patronized by Louis XII., who sent him, in 1503, as his ambassador to Venice, in which office he remained till 1508. He joined the pursuit of literature with his public employment, and held a correspondence with many learned men. After the termination of his embassy, he remained some years at Venice, as an instructor in the Greek language. On the election of pope Leo X. to the papedom in 1513, he set out for Rome, being persuaded that he should meet with a favourable reception from that patron of learning. At the invitation of Lascaris, Leo founded a college for noble Grecian youths at Rome, at the head of which he placed the author of the plan. In 1518, he quitted Rome

for France, whither he was invited by Francis I.; here he was employed by the monarch in forming the royal library. He was also sent as his ambassador to Venice, with a view of procuring Greek youths for the purpose of founding a college at Paris similar to that of Rome. After the accomplishment of other important missions, he died at Rome in 1535, at an advanced age. As an author he composed epigrams in Greek and Latin; he translated into the Latin language, a work extracted from Polybius, on the military constitutions of the Romans; and he printed at Florence a magnificent edition of the Greek Anthologia. By his contemporaries he was greatly praised, on account of the eminent services which he performed for the extension of literature.

LASCHE, in *Geography*, a town of Bohemia, in the circle of Chrudim; eight miles E. of Chrudim.

LASCHI, in *Biography*, an admirable singer and actor in the first burletta band of singers which arrived in England during the autumn of 1748, when serious operas were discontinued by the abdication of lord Middlesex, who was as unsuccessful in his opera regency, as James II., in endeavouring to establish the Roman Catholic religion in this country.

The new troop consisted of Pertici, as *buffo caricato*, Lafchi, *tenor*, and Guadagni, *counter tenor*, (then very young,) as serious men. Frasi, and afterwards, Mellini, for serious women; and the comic female parts by the wives of Pertici and Lafchi, the two best comic actors we ever saw on any stage, formed a very good troop, and in the comic operas of "La Comedia in Comedia," "Orazio," "Don Colafione," "Gli tre Cicisbei Ridicoli," &c. composed by Latilla, Mitale Resta, and Ciampi, who came over as maestro to the company, pleased the public and filled the theatre very successfully during the whole winter. Lafchi was certainly the best first buffo, except Lovatini, that has ever appeared on our stage; and the acting of him and Pertici was undoubtedly the most amusing and ingenious that can possibly be imagined.

LASCIGO, in *Geography*, a town of Naples, in Principato Citra; 18 miles W. of Policastro.

LASCO, JOHNS A., in *Biography*, a zealous promoter of the Reformation, was born in Poland, of a noble family, about the close of the fourteenth century. He received the early part of his education in his own country, and then travelled into foreign parts for improvement. In Switzerland he became acquainted with the celebrated Zuingli, by whose influence he determined upon studying divinity, and having by the example of his friend imbibed the spirit of the reformation, he returned home with the design of propagating the principles which he regarded as having their foundation in important truth. At first he was promoted to a high station in the Catholic church, and at length was nominated bishop of Vespriem, in Hungary. His honours, probably, did not sit easy upon him, and he determined to make an open avowal of his sentiments; by this decided course he drew upon himself the vengeance of the Catholic bishops, who did not hesitate to pronounce him an heretic. He appealed to the king, but the sovereign was either unable or unwilling to extend the shield of his authority in protecting his bishop, and he was obliged to quit Hungary in the year 1540. In 1542, he was chosen minister of a church at Embden, and in the following year he went to Oldenburgh, to establish the doctrines and discipline of the reformation in that district. In 1544, he was invited into Prussia, by duke Albert, for the same purpose, but as he was not altogether a Lutheran, he was obliged to relinquish this mission and to return to Friesland. Here he resided about ten years,

when the publication of the Interim by the emperor Charles V. compelled him to seek another asylum, which he found in England, on the invitation of Edward VI., which was conveyed to him by archbishop Cramer. Here he became minister to a German Protestant church, which assembled for divine worship at Auln-Fryars. Of these Protestants, almost four hundred were admitted to the honour of citizenship; they were not tolerated, but guaranteed by royal patent, in the conscientious discharge of their duties to God, while numbers of his majesty's natural born subjects were grievously persecuted on account of their inability to join in all the ceremonies enjoined by the established religion. The preamble to the patent referred to, is a curious document considering the times; it admits that the German church made profession of pure and uncorrupted religion, and was instructed in truly Christian and apostolical opinions and rites, and it was permitted them to enjoy and exercise their own rites, ceremonies, and discipline, though they were different from those used in this kingdom. Lasco avowed the same opinions as those held by Hooper, Latimer, and other illustrious divines of that day: he was, however, permitted to live in peace during the reign of the youthful monarch; but upon the accession of the infamous Mary, he and his congregation were ordered to leave the kingdom. They embarked with their families and property, and at the commencement of a very severe winter arrived off the coast of Denmark, but were not permitted to land on account of their known tenets. For the same reason they were refused an asylum at Lubec, Hamburg, and some of the cities of Saxony; at length, after they had been driven from place to place, they were hospitably received at Embden in March 1554. In the following year Lasco went to Frankfort upon the Maine, and obtained leave from the senate to build a church for foreign Protestants. In 1556, he wrote a letter to Sigismund, king of Poland, in vindication of himself and his doctrines, from certain misrepresentations which had been circulated by his enemies. In 1557, he published an apology for the church of the reformed Protestants at Frankfort, on the subject of the variation in their creed from that of the confession of Augsburg with respect to the Eucharist. He was answered by Westphalus, who, feeling that he had the weakest side of the argument, exhorted the senate to interpose its power, and to withdraw its protection from the disciples of Zuingle, whom he denominated rank heretics, and the Devil's martyrs. Lasco, after a thousand vicissitudes, returned to his native country; but scarcely had he arrived, when the bishops and other ecclesiastics set about every method to ruin him. A synod was convoked to meet at Warlaw; the result of their deliberations was, that Lasco was a heretic; he was accused before the king, and a petition was drawn up praying that he might be banished. The sovereign nobly rejected their demand, and he was permitted to live free from persecution, though he was daily assailed by the dark calumnies of his enemies. He died in 1560, leaving behind him many works which testify that he was a man of great talents and profound learning. He was the friend of Erasmus, who acknowledged the obligations he was under to him; and Peter Martyr calls him his most learned patron. He was highly esteemed, and frequently consulted by Sigismund, king of Poland; and he is commended by contemporary historians as a man possessing many virtues, and the most unaffected piety. Gen. Biog.

LASCORIA, in *Ancient Geography*, a town of Asia, in Galatia, belonging to the Trocmi. Ptolemy.

LASDIPELEN, in *Geography*, a town of Prussian Lithuania; nine miles N. of Pilkabena.

LASER CYRENAICUM, in the *Materia Medica*, a name supposed to be given by the ancient Greeks to the gum we at this time call *assa fetida*. The word *assa*, or, as it was originally written, *asa*, was evidently formed on the *laser* of the Greeks; but there was also an *asa* mentioned by the old authors very different from this, being a fragrant and sweet-scented gum. This sweet gum was evidently the *laser* and *asa*, or *assa*, of the ancient Greeks: and the *silphium* was the plant which produced it. This plant grew in Cyrene, and furnished it a long time; but in the days of Pliny it was in a manner lost. The people of Cyrene found it more profitable to feed their cattle upon the *silphium*, than to gather its gum.

Pliny continues to tell us, that by the feeding cattle on this plant, it was perfectly destroyed, in a course of years, that there had been, of a long time, only one plant of it seen, and that reckoned to great a curiosity, that it was sent as a present to the emperor Nero.

When Cyrene no longer afforded the *silphium*, it was sought for in other places. The original *asa*, or *laser*, had the smell of myrrh, but more mild and agreeable; and the *asa* of succeeding times had that of leeks or garlic, and thence was distinguished by the name *scorado laserum*.

LASERPITUM, in *Botany*, *Laserwort*; an ancient name of uncertain derivation, synonymous with the *σαλπις* of the Greeks. *Lac serpitum*, alluding to its milky juice, or *lactipitum*, because that milky juice has a pitchy smell, both suggested by etymologists, afford little satisfaction. The word is evidently compounded of *Laser*, the name of the gum which it produces, and from which *Asa* is by some thought to have been corrupted. Hence *Asa fetida* has been supposed the true *Laser*, or gum of the *σαλπις*, which is known to be of a fetid nature. Ambrosinus asserts *Laser* to be a corruption of *Lactir*, from *lac*, milk. Whatever the *σαλπις* of the Greeks, or the *Laserpitium* of the Latins may have been, the *Silphium* of modern botanists is a genus of the syngenesious class, and the *Laserpitium* is one of the umbelliferous tribe, of which we are now to speak. It so far accords with the ancient plant, that several of its species discharge, when wounded, an acrid and strongly scented resinous gum.—Linn. Gen. 136. Schreb. 186. Willd. Sp. Pl. v. 1. 1414. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 138. Sm. Prodr. Fl. Græc. Sibth. v. 1. 191. Juss. 222. Tourn. t. 172. Lamarck Illust. t. 109. Gært. t. 85. (Siler; Gært. t. 22.)—Class and order, *Pentandria Digenia*. Nat. Ord. *Umbellate*, Linn. *Umbellifera*, Juss.

Gen. Ch. *General umbel* very large, of from twenty to forty rays; *partial of many rays*, flat. *General involucreum* of many leaves, small; *partial of many leaves*, small. *Petioles* of five teeth, scarcely discernible. *Cor. Universal* uniform; and all the flowers fertile; *partial of five spreading*, nearly equal, petals, their points bent in so as to form the shape of a heart. *Stem*. Filaments five, bristle-shaped, the length of the corolla; anthers simple. *Pist.* Germen inferior, roundish; styles two, rather thick, pointed, distant; stigmas obtuse, spreading. *Peric.* Fruit oblong, with eight longitudinal membranous angles, separable into two parts. *Seeds* two, very large, oblong, semicylindrical, flat on the inner side, furnished each with four dorsal and marginal membranes on the other.

Eff. Ch. *Involucreum* both general and partial. Fruit oblong, with membranous angles. Petals uniform, inflexed, emarginate, spreading.

The species of *Laserpitium* are in general of a larger proportion, with more ample foliage, than most other umbelliferous plants. To this nevertheless there are some exceptions,

## LASERPITUM.

tions, for we perceive a prodigious difference between the gigantic *L. aquilegifolium*, Jacq. Austr. t. 147, and the little *L. simplex*, Jacq. Misc. v. 2. t. 2. The 14th edition of Syll. Veg. has fourteen species, comprehending Forster's genus *Alephylla*; Willdenow has twenty-three. In each of these lists, however, there are some ambiguous or doubtful plants, which, from variations incident to this tribe, relative to the occasional absence or presence of an involucre, are supposed to be described twice over in the Linnæan system. Such is the case with *L. Chironium*, suspected to be the same as *Pastinaca Opopanax*, we believe justly. Willdenow doubts whether *L. Archangelica* of Jacquin, Ic. t. 58, be distinct from this plant of Linnæus, but we are quite clear on this point, and are almost as perfectly satisfied that *L. Chironium* is *Pastinaca Opopanax*, which last name Linnæus, in his note on the subject, has accidentally written *Coffina*, apparently from having Bauhin's synonym in his head; yet Reichard, Willdenow, and Laicharding copy him without reflection or remark.

Indubitable species of *LasERPitum*, which will serve to give a competent idea of the genus, are the following. None are natives of Britain.

*L. latifolium*. Broad-leaved Laserwort. Linn. Sp. Pl. 356. Jacq. Austr. t. 146. (*Libanotis Theophrasti* major; Ger. em. 1010.)—Leaflets obliquely heart-shaped, undivided, with sharp-pointed teeth.—Native of mountainous dry woods in various parts of Europe, flowering in July, ripening feed late in autumn. Jacquin observes that it varies greatly in size and roughness, being only a foot or two high on the Alps, while in less elevated situations it rises to four or five feet, with ample and handsome foliage. He asserts also that wild plants of a very rough habit, on being brought into the garden, became smooth the next season. Hence he determines the *L. asperum* of Crantz, Diff. fasc. 3. 50. t. 1. f. 2, and *glabrum* of the same author, 54, to be one and the same species. This f. 2. of Crantz very correctly expresses a leaflet of our plant, such as is preserved in the Linnæan herbarium, and exhibited by Jacquin as above. The radical leaves are twice or thrice compound, with large, heart-shaped, stalked, undivided leaflets, unequal at the base, veiny, from one to two or three inches long; smooth and dark green above; paler, and more or less rough with rigid bristles, beneath; the margin beset with strong broad sharp serratures, the base entire. The stem is smooth and round, bearing a few smaller more entire leaves, whose common stalk is greatly dilated and inflated at the base. The umbels are broad. Flowers small, white. Wings of the seeds, according to Jacquin's plate, even, and scarcely at all undulated, rounded not angular at their summit, agreeing very well with the first figure of the seed annexed to Morison's Sect. 9. t. 19. f. 1, so that, if he be right, his whole fig. 1. must belong to our plant, though it is not a very good one. We cannot help thinking too that the *LasERPitum* of Rivinus, Pentap. Irr. t. 21, is the same species. Professor Willdenow, however, seems to have been led by Crantz and Lamarck to establish another species, by the name of *L. Libanotis*, for which he quotes this plate of Rivinus, as well as another figure of Morison, Sect. 9. t. 19. f. 6. This he supposes to be the *glabrum* of Crantz, who cites as a certain though rude figure *Libanotis alpina latifolia, semine crispis*, Bocc. Mus. 24. t. 3. The plant of Boccone, according to all appearance, we have from Italy, and can aver its being totally different from *L. latifolium* and all the synonyms of Willdenow's *L. Libanotis*, being, as far as we can tell, not yet defined by any systematic author. The wings of its seeds, though called *crispis*, are nearly even, and terminate in a lateral angle at

the top, like Morison's t. 19. f. 6, which may possibly be a bad delineation of Boccone's plant. Willdenow does not mark his *L. Libanotis* as one that he had seen, and he might well be led into confusion by the writers on whom he has depended. Among these the most blameable is Crantz, who roundly asserts his *asperum*, (our *latifolium*), to be *L. Chironium* of Linnæus, which we can positively contradict, and which nobody but Lamarck has believed. The latter seizes with alacrity the opportunity of censuring Linnæus on the subject of his synonymy, though in this instance unjustly, while he himself describes under the name of *L. Libanotis*, with extremely confused synonyms, what appears clearly by his account to be *L. trilobum* of Linnæus, of which we shall now speak.

*L. trilobum*. Three-lobed Broad Laserwort. Linn. Sp. Pl. 357. (*L. Libanotis*; Lamarck Dict. v. 3. 423, by the very excellent description. Ligusticum Rauwollii, foliis aquilegiæ; Bauh. Hist. v. 3. p. 2. 148. Pluk. Phyt. t. 223. f. 7. Siler foliis aquilegiæ; Rivin. Pentap. Irr. t. 64.)—Leaflets broad-ovate, three-lobed, cut and sharply ferrated.—Native of Italy, and we believe also of Switzerland; though Professor Lachenal, from whom we have a specimen of the true plant, assigns the n. 793. of Haller, taken for this, to be only a variety of *latifolium*, which according to him has occasionally two or three lobes in its lower leaflets. A Swiss specimen from Schleicher seems to be the real *trilobum*, but it wants the lower leaves, and therefore cannot be absolutely determined. The leaflets of *L. trilobum* differ from the foregoing, in being by no means heart-shaped at the base, but either ovate or tapering, and more or less deeply three-lobed, sometimes to the very base; as well as cut and sharply ferrated. The umbel is very large and spreading, with long purple rays. Flowers small, white. Wings of the seeds even, and very narrow. Lachenal seems, when he wrote his remarks above alluded to, in Ag. Helvet. v. 8. 145, not to have distinguished this from the following, though they are widely different.

*L. aquilegifolium*. Great Columbine-leaved Laserwort. Jacq. Austr. v. 2.—Leaflets sessile, rounded, bluntly lobed and cut. Wings of the seed very narrow.—Native of Austria, Switzerland, and the Bithynian Olympus, first well determined by Jacquin. It is five or six feet high, with ample leaves, much resembling those of a Columbine in their rounded obtuse form and segments. The umbels are very large and spreading. Flowers white. Wings of the seeds even, and very narrow. Crantz makes it a *Siler*, and misquotes under it synonyms which belong to the last, and which he therefore justly says "could never be guessed to belong to the present." Why then, as they certainly do not, are they quoted?

*L. Siler*. Mountain Entire Laserwort. Linn. Sp. Pl. 357. Jacq. Austr. v. 2. 27. t. 145. Sm. Prodr. Fl. Græc. Sib. v. 1. 191. (*Siler montanum officinarum*; Ger. em. 1. 48.)—Leaflets elliptic-lanceolate, entire, stalked.—Found on the mountains of Austria, Switzerland, France, Greece, and other parts of the south of Europe. It is of more humble growth than any of the former, and distinguished by the form of its leaflets. The seeds are shaped and winged much as in the last. They are aromatic and very bitter. Haller complains of its being neglected as a medicinal plant, though strong in aromatic virtues.

*L. prutenicum*. Prussian Laserwort. Linn. Sp. Pl. 357. Jacq. Austr. t. 153. Ehrh. Herb. 93. (*L. minus*; Rivin. Pentap. Irr. t. 23.)—Leaflets pinnatifid; their segments lanceolate, acute, decurrent, entire. Stem hispid.—Found in Prussia, Austria, Switzerland, &c. The stem is about two feet high, erect, hairy, as well as the leaf-stalks.

*Leaves:*

*Leaves* light-green, smooth, bipinnate; their leaflets pinnatifid, with elliptic-lanceolate, decurrent, pointed segments. *Umbels* rather large, white, with white-edged involucreal leaves. *Seeds* small, their wings broadish and wavy.

*L. hirsutum*. Hairy Fine-leaved Laferwort. Lamarck Dict. v. 3. 425, with a wrong reference to Linnæus. (*L. Halleri*; Villars. Dauph. v. 2. 625. *L. n.* 705; Hall. Hist. v. 1. 353. t. 19.)—Leaves hairy, many times decomposed, with lanceolate decurrent segments, often three-lobed. Involucreal leaves with membranous fringed edges.—Native of the alpine parts of Switzerland, Savoy, and France. We gathered it on Mount Cenis, flowering in August. The broad, extremely compound, finely cut and hairy leaves, at once distinguish this species. The umbels are large, dense, and white. Wings of the seeds rather broad, pale, and slightly crisped.

**LASERPITIUM**, in *Gardening, &c.* The plants of this genus grow naturally in the south of France, in Italy, and Germany, and are preserved in botanic gardens for the sake of variety; they have no great beauty. It has been generally supposed, that the silphium of the ancients was procured from one species of this genus, but from which of them (if any) we are at present ignorant. All the species, if wounded, drop a very acrid juice, which turns to a resinous gummy substance, very acrimonious. This was externally applied by the ancients to take away black and blue spots that came by bruises and blows, as also to take away excrescences: it was also by some of the ancients prescribed in internal medicines, but others have cautioned people not to make use of it this way, from the effects which they mention to have been produced from the violence of its acrimony.

All these plants are extremely hardy, so will thrive in moist soils and situations. They are propagated by seeds, which, sown in autumn, will afford plants in the spring, that may be transplanted in the following autumn. Miller.

**LASERRA**, in *Geography*, a town of Corsica; 10 miles N.E. of Sarcena.

**LASERWORT**, in *Botany, &c.* See **LASERPITIUM**.

**LASGRUFVA**, in *Geography*, a town of Sweden, in Helplingland; 58 miles E. of Hudwickfwal.

**LASH**, or *to lash*, is to make fast the booms, anchors, &c. by several turns of rope, to prevent their moving by the motion of the ship.

*Lashing*, which also denotes a piece of rope used to fasten or secure any moveable body in a ship, or about her masts, sails, and rigging, is chiefly used for binding up to the ship's side, mulkets, butts of water or beer, or pieces of timber to make spare top-masts.

**LASHERS** are properly those ropes only which bind fast the tackles, and the breeches of the ordnance, when they are haled or made fast, within board.

**LASHOM JAMNAS**, in *Geography*, a town of Egypt, on the coast of the Mediterranean; 12 miles N.W. of Damietta.

**LASIA**, in *Ancient Geography*, an island situated on the coast of Lycias. Pliny.—Also, an island on the coast of the Peloponnesus, over-against Troezen.—Also, one of the names of the isle of Andros.

**LASIA**, in *Botany*, from *λασιος*, hairy or bristly, because the plant is beset with numerous little bristles or prickles. Loureiro. Cochinch. 81.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Piperite*, Linn. *Aroides*, Juss.

Gen. Ch. *Cal.* Spatha awl-shaped, twisted, coloured, very long. Spadix shorter than the spatha, entirely covered with florets. *Cor.* Petals four, fleshy, obtuse, concave, clovel-embracing the organs of impregnation. *Stam.* Filaments

four, short, flat, hidden by the petals; anthers two to each filament, rounded, concave, protruding beyond the corolla. *Pist.* Germen superior, roundish; style none; stigma rather abrupt. *Peric.* Berry small, roundish, unequal. *Seed* solitary, roundish.

Eff. Ch. Spadix covered with florets. Petals four, fleshy, inferior. Anthers two to each filament. Berry with one seed.

1. *L. aculeata*. Cu chaotic gai, of the Cochinchinese. Native of the moist plains of Cochinchina. A stemless plant, six feet high, with large, pinnatifid, leaves, on long, round, upright stalks. *Flower-stalk* radical, quite simple and naked, about as tall as the leaves. The leaves, and all the stalks are covered with numerous little short curved prickles. Loureiro justly indicates the affinity of this plant to *Pathos*, and no less justly prefers placing it in the fourth class, rather than in *Gynandria*. The prickly pubescence, if we may so term it, is very curious in this family. It is to be presumed the anthers are each of one cell only, or rather that each filament bears one anther, of two separated lobes and cells.

**LASIO**, in *Ancient Geography*, a town of the Peloponnesus, or Triphylia.—Also, a mountain in the island of Crete, on which was the tomb of Jupiter.

**LASIOPETALUM**, in *Botany*, from *λασιος*, hairy, and *πεταλον*, a petal, alluding to the hairiness of the flower.—Sm. Tr. of Linn Soc. v. 4. 216. Venten. Malmais. 59. Billard. Nov. Holl. v. 1. 63. Ait. Hort. Kew. ed. 2. v. 2. 36.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rhamnii*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, wheel-shaped, hairy, in five deep, equal, ovate, folded, at length expanded segments, permanent, often coloured. *Cor.* Petals five, minute, roundish, inserted into the base of the calyx between its segments. *Stam.* Filaments five, very short, opposite to the petals; anthers terminal, ovate, two-lobed behind, opening by two pores at the top. *Pist.* Germen superior, globose, with three furrows, very hairy; style short, straight, smooth; stigma simple, acute. *Peric.* Capsule invested with the calyx, nearly globose, with three angles, downy, of three cells and three valves, partitions from the centre of each valve. *Seeds* few, roundish, inserted into the inner edge of the partitions.

Eff. Ch. Calyx wheel-shaped, in five deep folded segments. Petals five, minute, opposite to the filaments. Anthers opening by two terminal pores. Capsule superior, of three cells, and three valves, with the partitions from their centre.

Obs. The late excellent M. Ventenat, erroneously quoted as the author of this genus in the new edition of Hort. Kew. has justly corrected its original describer, who mistook for a corolla what is truly the calyx. This correction is the more important, as it leads to a knowledge of the true natural order to which the genus belongs, as given above. M. La Billardiere has observed a species with five intermediate abortive filaments, and no petals.

1. *L. ferrugineum*. Rusty Woolly-blossom. Andr. Repof. t. 2c8. Venten. Malmais. t. 59.—Leaves alternate, linear-oblong, dependent. Flowers racemose.—Native of marshes in New South Wales, from whence the seeds were received in 1791, by Messrs. Lee and Kennedy. It flowers during most part of the summer, being sheltered in winter in the green-house, and allowed but a small supply of moisture. *Stem* shrubby, upright, slender, round, leafy, clothed with dense, rusty, stary pubescence, and, in its native situations, throwing out long, slender, extremely tough branches, to the extent, as it is reported, of many yards, amongst other shrubs.

shrubs. *Leaves* alternate, stalked, dependent, linear-oblong, bluntish, entire or slightly wavy, from two to four inches in length, and half an inch broad; heart-shaped, rather dilated, and often somewhat angular at the base; deep-green and smoothish above; white and downy, with a rusty rib, beneath. *Flowers* in short, lateral, deflexed clusters, nearly opposite to the leaves, with three or more linear rusty bractæa close to each flower. *Calyx* half an inch broad, light green, besprinkled on both sides with dense, flarry, rather rusty down. *Petals* and *anthers* brown. The whole shrub is more remarkable for singularity than beauty. Sometimes, according to Ventenat, the flowers are four-cleft and tetrandrous only.

2. *L. ledifolium*. Rosemary-leaved Woolly-blossom. Ventenat. Malm. at p. 59.—Leaves opposite, linear-lanceolate, spreading. Stalks single-flowered. Bractæa remote from the flower.—Seen by M. Ventenat in the herbarium of M. Thibaud, professor of botany at Strasburgh. We presume it must be, like the former, and all the known species besides, a native of New Holland. It is described as varying with broader and crowded, or narrower and more distant, leaves; and as being remarkable for the situation of its bractæa, in the middle of the flower-stalk.

3. *L. purpureum*. Purple Woolly-blossom. Ait. Hort. Kew. n. 2.—Leaves oval, entire.—Found in New Holland by Mr. Brwn. Sent to Kew in 1803 by Mr. Good. It is a green house shrub, flowering from April to July. Of this we have no further knowledge, not having seen any specimen.

4. *L. a-borefcens*. Nettle-tree-leaved Woolly-blossom. Ait. Hort. Kew. n. 3.—Leaves heart-shaped, deeply toothed.—Native of New South Wales, from whence it was sent by Mr. George Calcy in 1802, through Sir Joseph Banks, to Kew. It flowers from May to July, and is sheltered in the green-house.

5. *L. triphyllum*. Three-leaved Woolly-blossom. Billard. Nov. Holl. v. 1. 63. t. 88.—Leaves three together; the middle one largest and lobed. Stamens ten, the intermediate ones abortive. Petals wanting.—Gathered by M. La Billardiere in Van Lewin's land; by Mr. Menzies at King George's found, on the west coast of New Holland. We received a specimen in flower, by favour of Mr. Aiton, from Kew garden in May last. It is a shrub, kept, like others of its genus, in the green-house. The whole plant is clothed with rather soft flarry pubescence, like some of the mallow tribe, which assumes a rusty hue on the stalks, and on the veins of the leaves. The foliage is remarkable. Three leaves grow on stalks from one spot, (at the sides of the branches), of which the middlemost is much the largest, from one to two inches long and nearly as wide, heart-shaped at the base, more or less distinctly five-angled, or five-lobed, and somewhat sinuated, its footstalk nearly its own length; the side ones are unequally heart-shaped and entire, on very short stalks, and resemble stipulas. Long simple clusters, of several flowers, grow solitarily, opposite to the large leaves, between the small ones. The calyx is bluish-coloured, hairy, with pointed segments. Anthers dark brown, with yellow tips; the barren ones smaller and paler.

6. *L. quercifolium*. Oak-leaved Woolly-blossom. Andr. Repof. t. 459. Ait. Hort. Kew. n. 4.—Leaves three together, all sinuated; the middle one largest and three-lobed, somewhat pinnatifid. Stamens five. Petals wanting.—Gathered by Mr. Menzies, at King George's found, on the west coast of New Holland. Mr. Brown also observed it in that country. Seeds were sent to Kew, by Mr. Peter Good, in 1803. This is most akin to the last, but abund-

antly distinct. The leaves are smaller, somewhat glaucous, and much more harsh, owing to the more rigid and prominent flarry bristles on their upper surface; the three which grow together are more similar in size and figure, being all sinuated, though the middle one is much the most deeply lobed; the edges are slightly revolute. The flowers have their calyx of a deeper rose-colour, with less pointed segments. We perceive no barren stamens, nor any petals.

7. *L. coriocalatum*. Horned Woolly-blossom.—Leaves three together, cut and crenate; the lateral ones very small. Petals with linear points as long as the calyx.—Gathered by Mr. Menzies, at King George's found.—The leaves are more densely and uniformly hairy than in the last, as well as softer to the touch. The flowers are racemose, as in that, but much smaller, and are essentially distinguished by the long prominent linear appendages, or horns, of their petals, which equal the calyx in length, and in its dry shrivelled state extend much beyond it.

Several more species of this genus are in our possession, but we forbear to attempt their definition from imperfect dried specimens, as they will doubtless be more correctly and amply illustrated in the *Prodromus* of Mr. Brown, who has had the advantage of seeing them alive, and whose meritorious labours we never feel a desire to forestall. S.

LASIOSTOMA, so called by Schreber, from *λασιος*, hairy, and *στος*, the mouth, in allusion to the hairiness which covers the upper side of the flower, and surrounds its orifice. Schreb. 75. Willd. Sp. Pl. v. 1. 624. Mart. Mill. Dict. v. 3. (Rouhamon; Aubl. Guian. 93. Lamarck. Illustr. t. 81.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Apocynæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very short, in five deuplicate segments, with two small opposite scales at its base. *Cor.* of one petal, funnel-shaped tube cylindrical; limb in four acute equal segments, villous on their upper side. *Stam.* Filaments four, capillary, villous at their base, inserted into the tube of the corolla; anthers oblong. *Pist.* Germen superior, ovate; style longer than the corolla; stigma obtuse. *Peric.* Capsule orbicular, of one cell, with a brittle bark. Seeds two, hemispherical.

Ess. Ch. Calyx five-cleft. Corolla funnel-shaped, hairy about the mouth. Capsule superior, brittle; of one cell, with two seeds.

1. *L. cirrofa*. Willd. (Rouhamon guianensis; Aubl. Guian. 93. t. 36. Lamarck. Illustr. 322.)—Gathered by Aublet on the banks of rivers in Guiana, bearing fruit as well as flowers in November. *Rouhamon* is the Caribbean name. The woody trunk is seven or eight feet high, with many very long, knotty, opposite branches, climbing over the neighbouring trees, and clothed with reddish down. Leaves opposite, on short stalks, elliptical, pointed, entire, pale, smooth, three-ribbed. Tendrils axillary, simple, rather longer than the leaves, recurved and thickened at the extremity, not always present. Flowers small, white, in axillary tufts. Capsule rather large in proportion, an inch in diameter, yellow.—Jussieu refers this plant to the genus *Strychnos*, apparently with great reason.

LASK, a term used by *Farriers*, for a looseness in horses, often fatal to them.

LASK, or *Lako*, in *Geography*, a town of the duchy of Warlaw; 30 miles N.E. of Siradia.

LASKETS, or LATCHES, in a *Ship*, are small lines, like loops, fastened by sewing into the bonnets and drablers, in order to lace the bonnets to the courses, or the drablers to the bonnets.

LASKING, a sea-term for going large, or veering.

LASNEDOURG, in *Geography*, a town of France, in the department of Mont Blanc, on the Arc, at the foot of mount Cenis, the passage of which is the principal support of the inhabitants. The fun is hidden from this town by the mountain during two months in the year; 20 miles N.N.W. of Sufa.

LASOY, a town of Thibet; 40 miles N.N.W. of Tacpoy.

LASSA, the capital of Thibet, is called by different names, which have occasioned no small degree of confusion. Its proper name, in the language of Thibet, is said to be Baronthala; but the Tartars call it Lassa or Lahassa. Others call it Tonker, and apply the names Lassa and Baronthala to the district which contains Lassa and Putala. Others again give the name of Putala, instead of Lassa, to the capital of Thibet. Rennell says that we ought to apply the name Lassa or Lahassa, to the capital, and to consider Putala as the cattle and palace of the Lama, and his ordinary place of residence. Lassa, which is not considered as a large city, is situated on an extensive plain; the houses are of stone, and are spacious and lofty. The mountain of Putala (La Puta, the hill of Puta or Boodh, *la* signifying a hill in the native tongue), on the summit of which stands the palace of the grand lama, the high priest and sovereign of Thibet, (see LAMA), is about seven miles E. of the city. On the north of Lassa stands another range of mountains, covered with snow, which are clearly seen from Kambala, a very high mountain on the N. of the lake of Palte. Lassa is in the province of Ou, and almost in the centre of Thibet. The river Sanpoo Burrampooter runs at the distance of 24 miles from the city. The royal palace at Lassa is called Laprang, where, among other ornaments, are maps of the various provinces, painted about 1665, by the orders of the king Tifri, on 16 walls. Laprang is also one of the celebrated academies or schools of Thibet, which are frequented by the youth of many surrounding countries, as far as Cashgar, Yarkend, Camul, Turfan, and some from Kokonor, Amdoa, and China. The course of studies employs twelve years, occupied in logic, astronomy, philosophy, medicine, and, above all, the theology of Boud, or Xaca. In the city of Lassa are many foreign merchants, and the women have been recently polished by their conversation with the Chinese. A beneficial traffic is carried on with Lassa, by exchanging gold dust for silver bullion. N. lat. 30° 30'. E. long. 91° 40'.

LASSAN, or LESSAN, a town of Anterior Pomerania, on a lake formed by the Peene; 38 miles S.S.E. of Stralfund. N. lat. 53° 58'. E. long. 13° 52'.

LASSAY, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Mayenne; 9 miles N.N.E. of Mayenne. The place contains 2976, and the canton 14,258 inhabitants, on a territory of 132½ kilometres, in 14 communes. N. lat. 48° 27'. W. long. 0° 24'.

LASSEUBE, a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the district of Oleron; 6 miles E. of Oleron. The place contains 2884, and the canton 4974 inhabitants, on a territory of 130 kilometres, in 5 communes.

LASSIELL, a town on the E. coast of the island of Bouro. N. lat. 3° 30'. E. long. 127° 34'.

LASSIGNY, a town of France, in the department of the Oise, and chief place of a canton, in the district of Compiègne; 6 miles W. of Noyon. The place contains 718, and the canton 10,575 inhabitants, on a territory of 135 kilometres, in 24 communes.

LASSIRA, in *Ancient Geography*, a town of Spain, in the Tarragonensis, in the interior of the country of the Edetani. • Ptolemy.

LASSITI, in *Geography*, a town of the island of Candia; 22 miles S.E. of Candia.

LASSITUDE, in *Medicine*, a sense of weariness and debility, independent of fatigue, by which a person is induced to seek for repose and quiescence.

A lassitude is felt in almost all febrile diseases; and in many chronic affections, in which the circulation is feeble and unequal, as in scurvy, chlorosis, &c.; and in disorders of the stomach, liver, and alimentary canal. This feeling of weariness and indisposition to exertion, is indeed often the first and only perceptible symptom of approaching illness, as was remarked by Hippocrates: "Lassitudines spontanea morbos prænuunciant." (Aph. ii. 5.) It is a consequence also of most acute diseases, which leave the strength considerably impaired; and in this case it diminishes in proportion as the system regains its vigour in the progress of convalescence. As it is to be considered only as a symptom of various morbid states of the body, it requires no particular remedies to be specifically adopted for its removal; and the cure of it will be effected by remedying the particular morbid conditions with which it is connected.

LASSONE, JOSEPH MARIA FRANCIS DE, in *Biography*, an eminent French physician, was born at Carpentras, on the 3d of July, 1717. His parents quitted their native province, to procure him the advantages of education afforded by the capital; and the ultimate success of the plan evinced their wisdom and prudence. In his early years, however, young Lassone was not remarkable for his perseverance in study: on the contrary, his family were frequently alarmed by the propensity which he shewed for the gay pleasures of youth; but he as often raised their hopes by some ingenious performances, which merited academic honours, as well as the esteem of his preceptors. He wrote a comedy, which his parents insisted that he should suppress, and sacrifice the imprudent production: he submitted, and was never afterwards willing to declare the title of the piece, which had severtheless been acted with much success, under a different name, and still remains on the theatre. This juvenile work, foreign as it was to his studies, gave an extraordinary proof of the facility and flexibility of his genius, which afterwards enabled him to acquire in the different sciences a just and elevated reputation. Determining upon a strict attention to study, he devoted himself wholly to the pursuits of anatomy, in which he made such rapid progress, that, at the age of twenty-five, he was received into the Academy of Sciences as associate-anatomist. He examined, with great care and perseverance, the structure of the bones, and of the arteries, and demonstrated the muscular coat of the latter. He also investigated the structure, and inquired into the economy and use of the spleen, attempting to reconcile the different accounts given of that viscus by Ruyfch and Malpighi. He had strong hopes of discovering the office of this viscus, when an extraordinary event put a period to his anatomical pursuits. In selecting among some dead bodies a proper subject for dissection, he fancied he perceived in one of them some very doubtful signs of death, and endeavoured to reanimate it: his efforts were for a long time vain; but his first persuasion induced him to persist, and he ultimately succeeded in bringing his patient to life, who proved to be a poor peasant. This circumstance impressed so deep a sense of horror on the mind of the anatomist, reflecting on the consequences of his having selected this unhappy object for dissection, that he declined these pursuits

in future. Natural history succeeded the study of anatomy, and mineralogy became a favourite object of his pursuit: he published his observations on the crystallized free-fluors of Fontainebleau. But chemistry, a science to which he was thus led, finally became the beloved occupation of M. de Laffone. His numerous memoirs, which were read before the Royal Academy of Sciences, presented a valuable train of new observations, useful both to the progress of that study, and to the art of compounding remedies; and in every part of these he evinced the sagacity of an attentive observer, and of an ingenious experimentalist.

M. Laffone, although he had, by the number of his works, given every one reason to suppose that he had devoted himself exclusively to the sciences, had not neglected the practice of medicine. After having exercised it for a long time in the hospitals and cloisters, he was sent for to court; and he was the only example, except the celebrated Fernel, of one individual holding the office of first physician at Versailles, successively to two queens, and afterwards to the king: the ministers and the courtiers had been all changed, but he preserved the friendship of his sovereigns. He lived in friendship with Pontenelle, Winflow, D'Alembert, Buffon, and other scientific characters; and the affability of his manners, and his ardent zeal for the advancement of knowledge, among the young scholars, whose industry he encouraged, and whose reputation was become one of his most satisfactory enjoyments, gained him general respect. When from a natural delicacy of constitution, M. de Laffone began to experience the inconveniences of a premature old age, he became sorrowful and fond of solitude; yet reconciled to his situation, he calmly observed his death approaching, and expired on the 8th of December, 1788. Laffone, at the time of his death, held the appointment of first physician to Louis XVI. and his queen; he was counsellor of state, doctor-regent of the faculty of medicine at Paris, and pensionary-veteran of the academy of sciences, member of the academy of medicine at Madrid, and honorary associate of the college of medicine at Nancy. Hutchinson, Biog. Med. Eloy. Dict. Hist. Mil. de l'Acad. Roy. des Sciences, 1788.

LASSOTH, in *Geography*, a town of Silesia, in the principality of Neisse; 10 miles N. of Neisse.

LASSOUR, a town of Hindoostan, in the circar of Aurungabad; 32 miles N.W. of Aurungabad.

LASSUS, ORLANDUS, or, as he is called by the Italians, Orlando di Lasso, was a native of Mons, in Hainault, born in 1520, and who not only spent many years of his life in Italy, but had his musical education there, having been carried thither surreptitiously, when a child, on account of his fine voice. The historian Thuanus, who has given Orlando a place among the illustrious men of his time, tells us that it was a common practice for young singers to be forced away from their parents, and detained in the service of princes; and that Orlando was carried to Milan, Naples, and Sicily, by Ferdinand Gonzago. Afterwards, when he was grown up, and had probably lost his voice, he went to Rome, where he taught music during two years; at the expiration of which, he travelled through different parts of Italy and France with Julius Cæsar Brancatius, and at length, returning to Flanders, resided many years at Antwerp, till being invited, by the duke of Bavaria, to Munich, he settled at that court, and married. He had afterwards an invitation, accompanied with the promise of great emoluments, from Charles IX., king of France, to take upon him the office of master and director of his band; an honour which he accepted, but was stopped on the road to Paris by the news of that monarch's death. After this event he returned to Mu-

nich, whither he was recalled by William, the son and successor of his patron Albert, to the same office which he had held under his father. Orlando continued at this court till his death, in the year 1593, at upwards of seventy years of age. His reputation was so great, that it was said of him: "Hic ille Orlando Lassus, qui recreat orbem."

As he lived to a considerable age, and never seems to have checked the fertility of his genius by indolence, his compositions exceed, in number, even those of Palestrina. There is a complete catalogue of them in Draudius, amounting to upwards of fifty different works, consisting of masses, magnificantes, passions, motets, and psalms: with Latin, Italian, German, and French songs, printed in Italy, Germany, France, and the Netherlands.

As Orlando di Lasso was the contemporary of Cypriano Rore, a composer of equal renown in the 16th century, and who so much resembled him in genius, abilities, and reputation, we shall here draw a parallel between them, as the two principal masters of Flemish and Netherlandish counterpoint. To form a comparative idea of the style of these two composers, with that of Palestrina, the specific difference seems to be this: that the two Netherlanders, by having spent the chief part of their time in the courts of princes, had acquired a lighter and more secular cast of melody than Palestrina, who, residing constantly at Rome, and writing chiefly for the church, had a natural and characteristic gravity in all his productions. Indeed, the compositions *a capella* of Cyprian Rore and Orlando Lasso are much inferior to those of Palestrina in this particular; for by striving to be grave and solemn, they only become heavy and dull; and what is unaffected dignity in the Roman, is little better than the strut of a dwarf upon stilts in the Netherlanders. They were, however, great masters of harmony, and, out of the church, prepared the colours, and furnished the musician's pallet with many new tints of harmony and modulation, which were of great use to subsequent composers, particularly in dramatic painting.

In the same collection of songs, printed 1555, we have a Latin poem, set by Orlando di Lasso, in the manner of a madrigal, in which the modulation is curious; and though elaborate and *recherché*, it is pleasing, and has had many imitators.

Cyprian and Orlando were the first who hazarded what are now called chromatic passages. At the end of the fourteenth book of songs in four parts, printed at Antwerp by Tylman Sufata, there is an irregular Latin ode by Cypriano, set likewise in the madrigal style, in which not only an A ♯, but an A ♭, appear, for the first time, in the same movement, and almost every accident incident to modern music. Part of this curious composition is inserted in Burney's General History of Music, vol. iii. as a specimen of the author's frequent attempts at new harmonies and modulation, which, as it is laid before the learned musical reader in score, it will afford him much better information concerning the real history and progress of the art of counterpoint at this time, than all the catalogues of books, and descriptions of their contents, which diligence and language could furnish. Many of the forced, crude, and unexpected modulations in the motet of Cyprian Rore, however they may have been admired for their boldness and novelty, were never adopted by subsequent composers. Beautiful, natural, and pleasing passages and effects are soon rendered common by plagiarism and imitation; whereas the unnatural and difficult are long left in the possession of the original proprietor. Perhaps in a series of years, some other composer, unable to astonish by his inventions in a natural way, and determined

to produce something that shall, at least, *seem* new, will propose them again to the public, who will again reject, and so *on, ad infinitum*. But these musical hunters after novelty, without genius to find it, forget that such passages or modulations must have presented themselves to thousands in the course of their studies and *ricercate*, but that good taste and sound judgment had rejected them. It is at all times easy to produce *new* arrangements and combinations of sounds, if nature, grace, and propriety be renounced; but at once to be *new* and *natural*, belongs only to genius of the first order.

The songs in the same collection by Orlando, are said by the publisher to have been composed "à la nouvelle composition d'anciens d'Italie." We find but little melody in any of them, though much modulation, different from the other Flemish masters of this period. There is another essential difference in the notation, as the diminutions into crotchets and quavers, particularly in the songs *alla Napolitana*, are more frequent than in any other compositions of the middle of the 16th century. The chromatic accidental semitones are expressed by a sharp, and no longer left to the mercy and laxity of the finger, as was before the constant custom. The occasional changes in the intervals, which are necessary in counterpoint, though formed upon ecclesiastical melodies, were at first smuggled into harmony, perhaps by fingers whose good ears suggested them, though the composer had not dared to point them out, lest he should be accused of corrupting the modes. Orlando seems the first who, in spite of ancient prejudice and pedantry, when he wished to alter a note, dared to express his intentions in writing. In his more gay and comic style, however, the modulation is overcharged with wanton and unnecessary transitions from one key to another, without remaining long enough in any one to fix it in the hearer's attention.

Of the two compositions by Orlando di Lasso, and Cypriano di Rore, to Latin words, the first is in hexameter and pentameter, and the second an irregular ode, partly in the choral measures of the Greek tragedies. At this mark +, in Orlando's compositions, the first A ✕ occurs that we had ever seen used in counterpoint of equal antiquity; and this seems to have been suggested by the words *novumque melos*. Which of these productions was first composed, we know not, as they were both published together at Antwerp, in 1555. The only copy of this work which we have ever seen, is preserved in the British Museum. The madrigals, in general, of both Cypriano and Orlando, to Italian words, are excellent, in the style of the times. But as the singularities in the two compositions before us seem innovations, and preparatory to that revolution in the art, which takes place soon after, they seemed proper subjects of discussion; for the laboured and equivocal modulation, attempted by these composers, who, though often learned and ingenious, by abandoning the simplicity of their contemporaries, these productions border sometimes so much on caprice and affectation, as to fatigue the attention and offend the ear.

The pedantry of crude harmonies, and learned modulation, only suits depraved ears, that have grown callous to every thing that is easy and natural. The Italians, when they quitted madrigals, and no longer aspired at the applause of fastidious chamber-critics, whose approbation was bestowed on no compositions that did not smelt of the lamp, simplified their secular music, and instead of puzzling and goading the hearer with complicated contrivances and extraneous modulation, aimed at grace and facility in their melodies, which they clothed with such plain and tranquil harmony, as, instead of disguise and suffocation, added greatly to their ener-

gy and effect. Dramatic music was not yet even in idea, and *concerts*, or other assemblies of gay and unlearned hearers, seem now not to have existed; so that musical composers could not be said to write for the public, who will ever prefer such pleasure and amusement as give them the least trouble. Authors of all kinds, who seek for applause, conform to the taste of their judges; and we find, in our own times, that those musicians who are qualified by their genius and abilities, to direct and govern the public opinion, think it necessary, however false and corrupt it may be, to humour and flatter it, by all the concessions in their power. The art never long remains stationary at any one point of cultivation; and if perfection could be attained, its reign would inevitably be short. In music, the learned are few and silent; the ignorant numerous and noisy: in the chamber it was right to please the former, and in the theatre, where

"——— the fair, the gay, the young  
Govern the numbers of each song,"

there is no choice. A public and mixed audience is such a many-headed monster, that all its ears cannot be pleased at the same time; and whether the good or the bad predominate, the greater number must be gratified at the expence of the less.

Two of Orlando di Lasso's sons, Ferdinand and Rodolph, were able musicians, and both in the service of Maximilian, duke of Bavaria; the eldest as chapel-master, and the other as organist to that prince. These collected their father's motets, as well those which had been published during his life, as those which remained unpublished at his decease, and printed them in a very splendid and sumptuous manner at Munich, in seven volumes, large folio, 1604, with a dedication to their patron, the sovereign of Bavaria. The general reception, however, of these compositions, seems not to have equalled the expectations of the editors. Other productions had taken possession of the public ear and favour. It is, we fear, in vain to hope for the revival of old music; too many are interessed in the success of the new; and such are the vicissitudes of what are called taste and expression in this art, that if sufficient probity and zeal could be found in fashionable performers to incline them to attempt doing justice to the productions of former times, it is hardly possible for them to succeed; the accent, energy, and expression are either lost in the execution, or unintelligible to the hearers. There is, indeed, as little chance for a musician of the present age to perform such productions in the manner of the times in which they were composed, as to pronounce a foreign language as well as his own; and if, against all calculation, he should succeed, this music will still be an unknown tongue to the public.

LAST, or LEST, in general, signifies the burden or load of a ship.

LAST is also used for a certain weight and measure, which is various in various countries; though, in the general, the last is estimated at four thousand pounds weight. A last of cod-fish, white herrings, meal, and ashes for soap, is twelve barrels; of corn, or rape-seed, ten quarters; of gunpowder, twenty-four barrels, or two thousand four hundred pounds weight; of red herrings, twelve cades; of hides, twelve dozen; of leather, twelve diekers; of pitch, or tar, fourteen barrels; of wool, twelve facks; of stock-fish, a thousand; of flax, or feathers, one thousand seven hundred pounds weight.

LAST, in the marshes of Kent, a court held by the twenty-four jurors, and summoned by the bailiffs; wherein orders  
are

are made to lay and levy taxes, impose penalties, &c. for the preservation of the said marshes.

**LAST Heir**, is he to whom lands come by escheat, for want of lawful heirs; which, in many cases, is the lord of whom they are held: but in others the king.

**LAST Will**. See **WILL**.

**LAST, Part**. See **POINT-Laff**.

**LASTAGE**, or **LESTAGE**, according to Rastal, is a duty exacted in some fairs and markets, for carrying things bought whither one will.

**LASTAGE**, according to another author, is properly that custom which is paid for wares sold by the laff.

In the law of Richard II. lastage is taken for the ballast, or for lading of a ship. See **BALLAST**.

**LASTAGE** is sometimes also used for garbage, rubbish, or fuch filth.

**LASTEIN**, in *Geography*, a town of Prussia, in the province of Samland; 15 miles S.E. of Ragnitz.

**LASTISANA**, a town of Italy, in Friuli; 7 miles E. of Concordia.

**LASTRES**, a sea-port town and cape of Spain, on the N.E. coast of Asturia; 30 miles N.E. of Oviedo. N. lat. 43° 33'. W. long. 5° 19'.

**LASTRINGE**, a town of Sweden, in Sudermanland; 12 miles N. of Nykoping.

**LASULA**, a small island near the E. coast of Luçon. N. lat. 13° 27'. E. long. 123° 57'.

**LASUS**, in *Biography*, was born at Hermione, a city of Achaia, in the time of Darius Hyftaspes, in the 58th Olympiad, 538 years B. C. Diogenes Laertius says, that he deserves to be ranked among the seven sages. He was generally allowed to be the first among the Greeks who wrote about music, and was not only a theorist and great practitioner, but a dithyrambic poet, perhaps the inventor of that kind of poetry in honour of Bacchus, which was sung in the Phrygian mode at the public games, and partook of all that fire and hilarity which the god to whom it was addressed inspired.

Plutarch says, that he introduced new rhythms in his poetry and dithyrambic music, and upon the lyre, imitated the compass and variety of the flute; for which he is mentioned, in the Dialogue on Music, as a great innovator. Among the corruptions complained of, in the *new* music, the frequent and licentious transitions from one mode and genus to another, was not the least. If the object for multiplying the strings of the lyre, and the holes in the flute, so much complained of by the adherents to the old school, may be supposed to have occasioned the convenience by having an instrument nearly tuned for all the modes, like our harpsichords, it seems probable, that Lasus and other innovators might have been *temperers*, and have accommodated their *doctrine* to their *practice*.

Theon of Smyrna testifies that Lasus, as well as the Pythagorean Hippasus of Metapontus, made use of two vases of the same size and tone, in order to calculate the exact ratio or proportion of concords. For by leaving one of the vases empty, and filling the other half full of water, they became octaves to each other: and filling one a fourth part full, and the other a third, the percussion of the two vessels produced the concords of 4th and 5th; from which process resulted the proportions of these three concords contained in the numbers 1, 2, 3, 4.

This assertion, which has been taken upon trust, like the anvil story of Pythagoras, is equally false: to tune glasses by water has been lately practised, and thought a new discovery; but that their tones are altered in the proportions given above, is by no means true. Most glasses are lowered

about a whole tone, by being half filled with water, and not more than a major 6th if quite filled.

**LATA**, **LIGAMENTA**, in *Anatomy*. See **LIGAMENTUM**.

**LATABI**, in *Geography*, a town of Africa, in the kingdom of Aquamboe.

**LATAC**, or **LADAK**, a town and country of Thibet, forming a kind of detached sovereignty. The town is seven miles N. of the river Lachu, which falls into the Ganges. N. lat. 30° 55'. E. long. 74° 34'.

**LATACUNGA**, a town of South America, and a jurisdiction in the audience of Quito. This jurisdiction is called *Asiento* Latacunga; *asiento* denoting a place less than a town, but larger than a village. This place is situated on a wide plain, having on the E. side the eastern Cordillera of the Andes, from which projects a very high mountain, at a small distance from the foot of which is situated Latacunga, in S. lat. 55° 14'. W. long. 78° 16'; 50 miles S. of Quito. This *asiento* is large and regular; the streets broad and straight; the houses of stone, arched and well contrived; but on account of the dreadful earthquakes to which it is subject, consisting only of one story; one of these happened in June, 1668, and its effect was such, that of 600 stone houses, which the *asiento* then contained, only a part of one, and the church of the Jesuits, were left standing in a damaged state, and most of the inhabitants were buried under their ruins. The stone of which the houses and churches are constructed, is a kind of pumice, or spongy stone, ejected from volcanoes; inexhaustible quarries of it being found in the neighbourhood. This jurisdiction contains seventeen principal villages. The temperature of the air is cold: as this *asiento* is only six leagues distant from the mountain of Cotopaxi, which, not being less in extent and height than those of Chimborazo and Cayamburo, is, like them, covered with ice and snow; but the temperature is very different in the several villages of this jurisdiction; being hot in the vallies, temperate on the plains, and often excessively cold in places bordering on the mountains. The villages are generally larger, and more populous, than those of the other jurisdictions in the same province. Their inhabitants are Indians, Mellizos, and a few Spaniards. The *asiento*, besides a parish church, served by two priests, one for the Spaniards, and the other for the Indians, has convents of Franciscans, Augustines, Dominicans, the Fathers of Mercy, and a college of Jesuits. The inhabitants amount to between ten and twelve thousand, chiefly Spaniards and Mellizos. The Indians live in a separate quarter, as they do at Quito. In this *asiento* all kinds of trades and mechanic arts are carried on; and, as in all the other parts of this jurisdiction, it has a considerable number of manufactories of cloth, bays, and tucnyos. Great quantities of pork are salted here for exportation to Quito, Guayaquil, and Riobamba. The neighbouring country is sowed with clover, and interspersed with plantations of willows, the perpetual verdure of which gives a cheerful aspect to the country. The Indians of Puguli and Saquifili, two villages in this jurisdiction, are noted for making earthenware, as jars, pans, pitchers, &c. which are much valued. The clay of which they are made is of a lively red colour, and emits a sort of fragraney. The workmanship is very neat and ingenious. Juan Ulloa's Voyage to South America, vol. i.

**LATAKIA**, the ancient *Laudicea* (which see), a sea-port town of Syria, in the pachalic of Tripoli, is situated at the base, and on the southern side of a small peninsula, which projects half a league into the sea. Its port, like all the others on the same coast, is a sort of basin, environed by a mole, with a very narrow entrance. It is capable of

containing twenty-five or thirty vessels, but the Turks have suffered it to be choked up, so that it can scarcely admit four. Ships of above 400 tons cannot ride here; and hardly a year passes in which one is not stranded in the entrance. Nevertheless, Latakia carries on a very great commerce, partly of olives, but chiefly of tobacco, of which upwards of twenty cargoes are annually sent to Damietta; the returns from thence are rice, which is bartered in Upper Syria for oils and cottons. In the time of Strabo, instead of tobacco, the exports consisted of its famous wines, the produce of the declivities of its hills. Even then, Egypt was the market by way of Alexandria. Neither Latakia nor Tripoli can be mentioned as places of strength; they have neither cannon nor soldiers: a single privateer would conquer them both. Each of them is supposed to contain from four to five thousand inhabitants; 50 miles S. of Antioch. N. lat. 35° 36'. E. long. 35° 50'. Volney's Travels in Egypt, &c. vol. ii.

LATALATTA, one of the Molucca islands. S. lat. 0° 3'. E. long. 127° 5'.

LATANG, a town of Thibet; nine miles S. of Dsa-prong.

LATANIA, in Botany, a name given by Commerfon to a kind of palm, found in the Ile de Bourbon, and which seems to be barbarously constructed of the French word *late*, a lath, this palm being called in that language *latanier*.—Juss. 39. Lamarck. Dict. v. 3. 427.—Class and order, *Diececa Monadelphica*. Nat. Ord. *Palme*.

Eff. Ch. Male, Spatha of numerous imbricated leaves. Spadix branched, its branches fingered at the top, catkin-like, somewhat cylindrical, of many imbricated single-flowered feales. Corolla in six deep segments; the three outer ones smallest. Stamens 15 or 16; anthers oblong, two-celled. Female unknown.

1. *L. Borbonica*. Lamarck.—Its trunk is straight, simple, cylindrical, leafy at the top. Leaves stalked, fan-shaped, glaucous; their ribs cottony at the back. *Foodstalk* without spines. *Spatha* at the base of the foliage. The flowers are yellow, imbedded in each feale of the catkin. Filaments united at their lower part into a thick column.

LATATSI, in Geography, a mountain of Thibet. N. lat. 31° 35'. E. long. 77° 14'.

LATCHA, a lake of Russia, in the government of Olonetz, about 32 miles long and eight broad. N. lat. 61° to 61° 20'. E. long. 38° 30'.

LATCHETS. See LASKETS.

LATCHOU, or LACHU, in Geography, a river of Thibet, which runs into the Ganges, N. lat. 30° 50'. E. long. 77° 40'.

LATE, a town of Peru, in the jurisdiction of Lima.

LATEEN SAUL, in Sea Language, a long triangular sail extended by a lateen-yard, frequently used by bebecs, polacres, settees, and other vessels navigated in the Mediterranean sea.

LATERAL. See COLLATERAL, MULTILATERAL, and QUADRILATERAL.

LATERAL Equation, in Algebra, denotes a simple equation; an equation whose root is of one dimension.

LATERAL Ligaments, in Anatomy, are those placed at the sides of the joints. See JOINT.

LATERAL Line. See LINE.

LATERAL Operation for the Stone. See LITHOTOMY.

LATERAL Palsy. See PALSY.

LATERAL Sinuses, in Anatomy, the right and left; are the two branches into which the superior longitudinal sinus of the dura mater is divided at the internal transverse ridge of the occipital bone. See VEIN.

LATERALIS MORBUS, a name given by some writers to the pleurisy.

LATERALIS NARIS MUSCULUS, a name given by many authors to that muscle of the face which Albinus has called, from its office, the levator labii superioris alicque nasi. It is also called the obliquus nasi.

LATERALIS RECTUS CAPITIS. See RECTUS.

LATERAN was originally the proper name of a man, whence it descended to an ancient palace in Rome, and to the buildings since erected in its place; particularly a church called St. John of Lateran; which is the principal see of the popedom.

LATERAN, Councils of the, are those held in the basilica of the Lateran: of these there have been five, held in 1123, 1139, 1179, 1215, and 1513.

LATERAN, Canons regular of the Congregation of the, is a congregation of regular canons, whereof that church is the principal place, or seat.

It is pretended there has been an uninterrupted succession of clerks, living in community from the time of the apostles; and that a number of these were established in the Lateran in the time of Constantine. But the canons were not introduced till the time of Leo I. and these held the church eight hundred years, till the reign of Boniface, who took it from them, and placed secular canons in their room: one hundred and fifty years after, the regulars were reinstated.

LATERCULUM, among the Romans, was used for a roll or list of all the magistrates and military officers under the Roman emperors, with an account of their respective offices and fees.

LATERE, A, a Latin term used to denote the qualification of cardinals, whom the pope sends as legates into foreign courts; who are called cardinals *à latere*, as being his holiness's counsellors in ordinary, and assistants. See LEGATE.

The guards of princes were heretofore called *latrones*, because always attending at their sides, *à latere*.

Du Cange, in his Glossary, says there were anciently counts *à latere*, and monitors *à latere*.

LATESA, in Geography, a town of Naples, in Abruzzo Citra; 10 miles S. of Lanciano.

LATEWA, a town of Bengal; 45 miles N.W. of Rangur.

LATEX, in Chemistry, a name by which Van Helmont has, in some of his writings, called the famous menstruum, which he boasts Paracellus and himself to have been possessed of, and which he usually calls *alkebest*.

LATH, in Building, slips of wood used in plastering, tiling, and slating. These are what Festus calls *ambrices*; in other Latin writers they are denominated *templa*; and by Gregory of Tours, *ligaturæ*.

In plastering, the narrower the laths are the better they are for the purpose, so as they are of sufficient breadth to hold the nails, as the number of interstices are increased, the lime or luff will hang more readily, and the thicker they are they will be the better adapted to resist violence; but then they would be much more expensive. The laths are generally made of fir, in three, four, and five feet lengths, but may be reduced to the standard of five feet. Laths are single or double; the latter are generally about three-eighths of an inch thick, and the former barely one quarter, and about an inch broad. Lath is sold in bundles; the three feet are eight score to the bundle, four feet, six score, and the five feet, five score. The lath for plain tiling is the same as that used in plastering. Laths are also distinguished into heart and sap-laths; the former should always be used

in plain tiling, and the latter, of an inferior quality, is most frequently used by the plasterer. Heart-of-oak laths, by the statute Edw. III., should be one inch in breadth, and half an inch in thickness; but now, though their breadth be an inch, their thickness is seldom more than one quarter of an inch; so that two laths, as they are now made, are but equal to one lath. According to the said statute, pan-tile laths are nine or ten feet long, three-quarters of an inch thick, and one and a half inch broad, and should be made of the best yellow deal: the bundle consists of twelve such laths. A square of plain tiling will require a bundle of laths, more or less, according to the pitch. The distance of laying laths, one from another is various, differing more in some places than in others; but three and a half, or four inches, are usual distances, with a counter-lath between rafter and rafter: but if the rafters stand at wide intervals, two counter-laths will be necessary. Laths are employed for various other purposes as well as plastering and tiling, as in filleting for sustaining the ends of boards; in naked flooring and roofing; for furring up the surfaces; and in every kind of small work, where the dimensions of the parts do not exceed the scantling of laths.

In lathing for plastering, it is too frequent a custom to lap the ends of the laths upon each other, where they terminate upon a quarter or batten, in order to prevent cutting them; but though this practice saves a row of nails, it leaves only a quarter of an inch for plaster, and if the laths are very crooked, which they frequently are, there will be no space whatever left to straighten the plaster: the finished surface must, therefore, be rounded, contrary to the intention and to the good effect of the work; but if the ends are to be laid upon each other, they should be thinned at the lapping out to nothing at the extremity, or otherwise they should be cut to exact lengths.

Laths should be as evenly split as possible: those that are very crooked should not be used, or the crooked part should be cut out; and such as have a short concavity on the one side, and a convexity on the other, not very prominent, should be placed with the concave side outwards.

The following is the method of splitting laths: the lathe-cleavers having cut their timber into lengths, they cleave each piece with wedges into eight, twelve, or sixteen pieces, according to the scantling of the timber: the pieces thus cloven are called bolts; then, in the direction of the selvain, with their dowl-ax, into fizes for the breadth of the laths: this operation they call felting; and, lastly, with their chit they cleave them into thickness by the quarter-grain.

**LATH Bricks** are bricks made much longer than the ordinary sort, and used instead of laths for drying malt upon; for which purpose they are extremely convenient, as not being liable to catch fire, and retaining the heat much longer than those made of wood, so that a very small fire is sufficient after they are once heated.

**LATHAM**, in *Geography*, is a township in the parish of Ormskirk, hundred of Well Derby, Lancashire, England, situated 210 miles from London, and containing 434 houses, and 2179 inhabitants. In this township is Latham-house, the seat of Edward Wilbraham Bootle, esq. M. P. This place is noted in the Topographical Annals of Lancashire as the ancient seat of the Lathams in the reign of Edward III., and afterwards of the Stanleys, and lastly, of the Bootles. In the civil wars of the 17th century, Latham-house was heroically and gallantly defended by Charlotte, countess of Derby, who was besieged here by colonels Egerton, Rigby, Ashton, and Holcroft, from the 28th of July, 1644, to the 27th of the following May. This is a memorable instance

of feminine courage and fortitude: a similar example, however, was manifested in Blanch, lady Arundel, at Wardour-castle, in Wiltshire. A particular account of the former is recorded in the "History of the House of Stanley," 8vo. 259; and of the latter in Britton's "Beauties of Wiltshire," 8vo. vol. i. Latham-park is about five miles in circumference, and contains some fine forest scenery. Nearly in the centre is the house, built of stone, after a design of Leoni. In this township is also Cross-hall, once belonging to the earls of Derby, but is now the property of colonel Stanley, M. P. Near it is Blythe-hall, the seat of Thomas Langton, esq. Beauties of England, vol. ix.

**LATHE**, an engine of the most extended application in the mechanic arts, for forming wood or metal into any article of a circular figure. The mode of action in a lathe is essentially different from any other method of cutting, as the work is caused to revolve in a circle, while the tool is held upon a fixed support, and presented to it to cut away any parts projecting beyond the circle described by the motion of the work. To the mechanic the lathe is an invaluable machine, as a very great proportion of all the parts of machines is formed in it, and as it is the only method of working metal which may be considered as perfect. All things which can be turned are made in the lathe, both for accuracy and expedition. The common wooden lathe, in use among wood-turners for making articles of household furniture, is so generally understood, that it is needless to give a minute description of it; we have, therefore, given drawings in *Plate (Lathe)* of a metal lathe, the most perfect of its kind, proper for turning accurate and delicate works. For mathematical instruments, or machinery: it was made by Mr. H. Maudslay, London, who has a great number of different fizes, but on a similar construction, in constant use, at his manufactory for steam-engines, and other machinery, in the Westminster-road. *Figr.* 1. and 2. of the plate are a front and end elevation of the whole lathe, where A is a strong mahogany bench, supported on iron standards B, B, which are shewn fully in *figr.* 2; beyond these are fuits of drawers C, C, to contain the tools, &c.: the standards B carry the axis D of the great foot-wheel E, which gives motion to the work when it is turned by its crank D and treadle F, on which the workman presses his foot, at intervals, to turn the wheel round. The lathe itself, which is fixed upon the bench, consists of a triangular bar G. See also *figr.* 3, which is an enlarged figure of it; it is supported on small standards *a, b, c*, fixed to the bench A by screws going through it: upon this bar the puppets H, I, and K, are fitted with perfect accuracy, and H, which is called the back puppet, can be fastened at any part of the bar by a screw beneath it; the other two puppets, I, K, are screwed down upon the standards *a* and *b*, and are connected together by a piece of metal *d* fitting upon the bar, and call in the same piece with them: these two puppets support the mandrel, or spindle L, one having a screw with a conical steel point to enter a hole in the end of the spindle, and the other having a hard steel collar to receive the neck of the spindle, which fits it with the most perfect accuracy, to turn round freely (by a band encompassing *g* its pulley M), but without any shake in its collar; on the end of the spindle, beyond the collar, is a small screw to fix on the work to be turned. The back puppet H has a hole through the top of it, exactly in a line with the spindle, and a steel pin *e*, with a conical point fitted into it to support the end of a long piece of work; the point is fastened by a screw *g* in the top of the puppet, and has a screw *f* behind it to force it forwards: the bar G, also, has the rest, or support, for the tool fixed upon it, by a piece of metal *g*, (*figr.* 1.) fitted upon

the bar; a slider is fitted upon this piece to slide in a direction perpendicular to the bar, and the same screw beneath fattens the rest upon the bar at any place, and the slider at any length across the bar. On this slider is a socket to receive a pin, on the top of which is a cross-piece, formed like a T, upon which the tool is laid; this T can be adjusted to the height of the work the tool is to be applied to, and can be fattened at any height by the screw in the side of the socket. The various kinds of work to be turned are fattened to the end of the spindle, so as to be turned round with it, by means of what are called chucks: these are pieces of wood, or metal, fitted to screw fast upon the end of the spindle, and a hollow, like a dish, being turned out in it; the piece of wood or metal to be turned is driven into this hollow, and thus held to be turned, by holding a tool over the T of the rest, which is previously fixed close to the work, and presenting the edge to the work as it revolves by the treadle F, turning the foot-wheel, &c.: this, by its band turning the pulley M, and the work with an increased velocity. A chuck of this description is shewn mounted in *fig. 1*, with what is supposed to be a plate of brass, held in it to turn the flat face. Some chucks are flat, with holes through them, and the work is held by screws against it; others are provided with three jaws, like a vice, which can be altogether caufed to advance to, or recede from, the centre, by turning a screw, so as to encompass a piece of work of any dimensions. This method of chucking is adopted to form all kinds of flat or hollow work, as cups, boxes, circular rings, or plates, wheels, &c. which are, therefore, termed chuck-work; but articles of considerable length are supported at both ends, which method is called turning between centres. In this method the puppet H is slid along the bar to the length of the work, and fixed there by its screw: the point *e* is now, by its screw *f*, thrust forwards, and its point enters a small hole, previously drilled in the end of the work: the screw *g* is now tightened, to fasten the point *e*, upon which one end of the work revolves as a centre, the other end is received into a square hole in the end of a chuck screwed to the spindle. In other cases, the spindle has a chuck screwed to it, terminating in a conical point similar to that at *e*; this forms a support for the end, and an arm, projecting from the chuck, intercepts a pin or arm fixed to the work, and by this means turns it round with the spindle. This method of turning between centres is employed to turn spindles of wheels, bolts, serews, rollers, the outfiles of cylinders, or any other articles of greater length than their diameter. When a piece of work is to be turned, which is larger than the lathe will admit, the bar is to be drawn out, as in *fig. 1*, and supported by an additional standard *c* screwed to the bench. In the same state it will admit longer work.

The particular manner of holding the tool to the work is not easy to describe in words, but is soon acquired by practice. The tools for brass are square or flat bars of steel, the ends of which are cut off obliquely, to form an edge like a chisel, but with a very obtuse angle. It is held in such a position, that its upper flat surface points to the centre of the work to be turned: it is to be held down as firmly as possible to the rest, and advanced to the work at intervals, whenever it ceases to cut, by having removed all the projections of the work without the circle it describes. For turning with extreme accuracy, the slide-rest is a very useful addition to the lathe. It is a rest with two sliders in different directions, to one of which the tool is fixed; by means of screws with handles, the sliders and the tool can be moved in either direction, to bring the tool to the work. *Figs. 3, 4, and 5*, explain the ingenious piece of mechanism. N A

is a piece of metal, fitted to the bar of the lathe, and provided with a serew to fasten it at any place: upon the upper surface, which is flat, two pieces of brass are screwed, to form a dove-tailed groove, in which a slider, *b*, is fitted, to move with freedom and precision; a screw, *i*, is mounted in the frame N, and is lapped into a piece projecting from the lower side of the slider, so that the serew, when turned round by a handle fitted on its square, advances or draws back the slider in its groove. Upon this slider, *b*, is a frame *k*, having at the top of it a slider *l*, provided with a serew *m*, as the former, to move it, and carrying a piece *n*, with square holes through it in two directions to receive the tool *o*, and a serew at top to fasten it in. The slide-rest being mounted, in the manner of *fig. 3*, upon the bar, the upper slider, *l*, is parallel with the spindle, and the lower one, *b*, perpendicular thereto. For turning flat work, the tool is put in as there shewn: now by turning the serew, *m*, of the upper slider, the tool is advanced in contact with the work, which is mounted as in *fig. 1*; then by the other serew, *i*, it is drawn across the face of the work, turning it as it proceeds, to a perfectly flat surface. For turning a cylinder between centres, the tool, *o*, is put through its holder *n*, in a direction perpendicular to that shewn in *fig. 3*; and then the lower slider, *b*, is moved to adjust the tool to the diameter of the intended work; and the upper slider is moved, to carry the tool along the length of the cylinder, and cut it as it goes. The slide-rest will also turn cones, by the following contrivance: the frame *k*, supporting the upper slider, is fitted to the lower slider by one pin, upon which the whole frame and upper slider may be turned round and fattened at any inclination, by two serews passing through circular grooves. By this means the upper slider is inclined in any angle to the spindle, to turn a cone either hollow or solid, as the tool is put into its holder in one or other direction.

The slide-rest can be made to cut serews by an ingenious application, which is explained in *figs. 6 and 7*. A short bar P, exactly of the same dimensions as the large one, is fitted thereon, and fattened by its serew *p*. Upon this the slide-rest is placed: its sliders now stand in a direction perpendicular to what they did before, though on the same level. The serew to be cut, represented by Q, *fig. 6*, is mounted between the centres, and turned to a true cylinder by a tool put in the holder *n*, and carried along parallel to the spindle, by turning the serew, *i*, of the lower slider: this being done, a cog-wheel, V, is fitted on the chuck, at the end of the spindle, and another, W, is attached to the end of the serew, *i*, of the lower slider, so that it will be turned round at the same time with the spindle. A tool, with a point of the proper form to cut the thread of the serew, is put in the holder *n*, and advanced by the serew, *m*, of the upper slider to touch the cylinder Q. The lathe being now put in motion, the tool is moved along by the serew of the lower slider, at the same time the work revolves, and upon which it traces a spiral groove. When it arrives at the end of the serew, which it only scratches the first time, the tool is drawn back clear of the work, and the lathe turned the contrary way, to return the tool to the place where it first set out. The tool is then set by the serew *m*, to cut deeper than the first time, and the serew is cut over again: this being repeated four or five times, the serew is completed. By this method a serew of any degree of fineness may be cut, by merely changing the proportion of the cog-wheels, V, W, which connect the spindle and the serew of the lower slider. It is plain, if these wheels are of equal size, a serew will be formed of the same width of threads as the serew of the slide-rest at *i*; and if the wheel, W, on the serew, is the largest,

largest, the screw cut will be finer; if, on the other hand, the smallest wheel is fixed on the screw at W, it will cut a screw of a coarser thread than the screw *i*. The lathe is provided with wheels of all the different sizes, shewn by the dotted circles V, *fig. 7*, any of which may be fixed on at pleasure, either on the screw or the chuck. The screw cut in this manner will have its threads inclined in a contrary direction to the screw of the slide-rest; and if that is a left-handed screw, it will cut a right-handed screw, because the slider-screw revolves in an opposite direction to the spindle. That the lathe may cut screws of either kind, an intermediate cog-wheel is introduced between the two, to cause them to turn the same way. This gives another advantage, *viz.* that any two wheels may be used together; the intermediate wheel communicating motion from one to the other, though they are considerably distant from touching each other. The application of the intermediate wheels is explained in *figs. 8* and *9*, where *r* is a projecting shelf from the standard *a*; upon this a piece of metal, *x*, is fastened by a screw, and a short hollow spindle, *v*, is fitted into it, and fastened by proper screw-collars which admit its rotation; upon the end of this the cog-wheel W, which turns the screw of the slide-rest, is fastened by a nut: an arm, *co*, is fitted on the short spindle *v*, so as to have an angular motion round the centre: the arm has a groove in its length, in any part of which the centre pin of the intermediate wheel, *x*, can be fastened; and by these two motions this wheel may be fixed at any joint, so as to connect the wheels of any size. The hollow spindle, *v*, is adapted to receive an arbor or axis *y*, which has a socket in the end adapted to the square, upon the end of the slide-rest screw *i*: by this method the slide-rest may be set at any part of the lathe bar; when it is required to cut a screw at the end of a long bolt; the arbor *y*, forming the connection between the cog-wheel, W, and the screw, for which purpose it slides through the hollow spindle *v*, but is caused to revolve with it, by a feather or fillet projecting from one side; the socket of the hollow spindle may be set and fastened at any required distance from the lathe bar, and fastened by its screw; the slide-rest being set at a correspondent distance from the spindle of the lathe, by moving it upon the bar P, will admit a large piece of work, when a screw is required to be cut upon it. R, *fig. 7*, is an iron frame, fastened to the lower slider of the slide-rest, to support the screw from bending by the pressure of the tool, when it is long and slender. The frame is shewn in plan in *fig. 10*, where the holes are shewn for the two screws which hold down the frame upon the lower slider.

The methods of holding various pieces of work in the lathes to turn them are endless, and depending in a great measure upon the ingenuity of the workman to adapt them to the particular occasions he meets with. This subject, as well as the figure and manner of holding the tools, will be resumed under the article TUNING; an art which, from the facility with which it produces so many beautiful forms, has become a fashionable amusement among gentlemen, who may require many practical instructions, which would be needless to the mechanic regularly educated in the workshop. We shall also describe the method of turning elliptic work, as well as circular.

LATHIE, in *Lavo*. See LETTIE and LATIREVE.

LATHE, in *Rural Economy*, a provincial term used in some countries to signify a barn.

LATHRÆA, in *Botany*, (*λάρυξ*), *clandestina* or *concealed*, because the herbage is mostly under the ground, or at least covered with dead leaves of trees.) Toothwort. Linn. Gen. 375. Schreb. 402. Willd. Sp. Pl. v. 3. 200. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 654. Juss. 102. La-

marck Illustr. t. 551. Gærtn. t. 52.—Class and order, *Didymia Angiosperma*. Nat. Ord. *Personata*, Linn. *Pedicularæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, erect; its orifice deeply four-cleft. Cor. of one petal, ringent; tube longer than the calyx; limb ringent, swelling; its upper lip concave, helmet-like, broad, with a narrow hooked point; lower lip smallest, reflexed, obtuse, mostly three-cleft. Nectary a very short notched gland, depressed on both sides, inserted into the receptacle of the flower at one edge of the germen. Stam. Filaments four, awl-shaped, the length of the corolla, and concealed under its upper lip, two rather shorter than the rest; anthers oblong, two-lobed, barbed, flattened, cohering in pairs. Pist. Germen superior, globose, slightly compressed; style thread-shaped, of the length and situation of the filaments; stigma tumid, abrupt, drooping. Peric. Capsule roundish, obtuse with a point, invelled with the enlarged spreading calyx, of one cell and two elastic valves, each bearing a central, longitudinal, fungous receptacle. Seeds few, nearly globular, inserted into the receptacles.

Obf. The nectariferous gland shews its very near affinity to *Orobanchæ*. Linn.

Ess. Ch. Calyx four-cleft, inferior. A depressed gland at the base of the future of the germen. Capsule of one cell, with lateral fungous receptacles. Seeds globose.

1. *L. Clandestina*. Subterraneous Toothwort. Linn. Sp. Pl. 843. Lamarck, *fig. 1*. (*Clandellina flore subcæruleo*; Tourn. Inst. 652. t. 424. *Orobanche, five Dentaria aphyllæ purpureæ, cespitæ densæ*; Morif. Sect. 12. t. 16. f. 15.)—Stem branched, subterraneous. Flowers erect, solitary.—Native of shady woods in France, Italy, and the Pyrenees, growing parasitically on the roots of trees. The stem is subterraneous, at first short, and densely clothed with crowded, sessile, rounded, convex, very fleshy, entire, whitish leaves. In this stage of the plant the flowers rise above the ground, and are at first nearly sessile, very large, the corolla being two inches long, of a blueish colour, sometimes white, and they grow in rather close tufts. Afterwards the stem is greatly elongated, the leaves become remote, and shrivelled, the corolla falls, and each calyx is elevated on its own separate simple stalk above an inch long. This latter state is represented in Rudbeck's Elys. p. 229. f. 2. As we find no correct account of the growth of this singular plant, the above may not be unacceptable. It seems to shew the herb, if not the root, to be but of annual duration. What have been called scales of the root in this genus, seem equivalent to leaves, and we have fo denominated them above.

2. *L. Anblatum*. Oriental Toothwort. Linn. Sp. Pl. 844. (*Anblatum orientale, flore purpurascente*; Tourn. Cor. 48. t. 491.)—Lips of the corolla undivided.—Found by Tournefort in the Levant. Linnæus has taken up this species entirely from the plate and short definition of the great French botanist. It should appear to be most akin to the following, with which it constitutes Tournefort's genus of *Anblatum*, whose name is of German etymology, and adopted from Valerius Cordus.

3. *L. Squamaria*. Greater Toothwort. Linn. Sp. Pl. 844. Fl. Dan. t. 136. Engl. Bot. t. 50. (*Squamaria*; Rivin. Monop. Irr. t. 89. f. 2. *Dentaria major Matthioli*; Ger. em. 1585.)—Flowers racemose, pendulous. Lower lip three-cleft.—Native of shady woods throughout Europe, flowering in March or April, and growing parasitically on the roots of the hazel, for the most part. The subterraneous portion of the stem is branched, clothed with fleshy-white leaves, as in the first species; what rises above-ground is simple, purple, downy, racemose, bearing numerous drooping purple flowers, with a pale calyx, each partial flower

stalk attended by a leaf like those that grow below the surface.

LATHRÆA *Phelypæa*. See OROBANCHE.

LATHREVE, LEIDGREVE, or *Trithingreve*, was an officer under the Saxon government, who had authority over a third part of the county; and whose territory was therefore called trithing, otherwise a leid, leithin, or lathe, in which manner the county of Kent is still divided; and the rapes in Suffex seem to answer to the same. As to the jurisdiction of this officer, those matters that could not be determined in the hundred court, were thence brought to the trithing; where all the principal men of the three or more hundreds being assembled by the lathreve, or trithingreve, did debate and decide it: or if they could not, then the lathreve sent it up to the county court, to be there finally determined.

LATHRUS, in *Entomology*. See SCARABÆUS.

LATHYRIS, in *Botany*, a name given by many authors to a species of tithymal, or spurge, commonly known by the name of *tithymalus latifolius*, the broad-leaved spurge, and called by some also *cataputia*.

LATHYRUS, a name adopted from Theophrastus, whose *λαβυρος* appears evidently to be, like ours, something of the pea or vetch kind, though it is impossible precisely to determine what.—Linn. Gen. 375. Schreb. 497. Willd. Sp. Pl. v. 3. 1077. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 763. Juss. 359. Lamarck. Illustr. t. 632. Gærtn. t. 152.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Perianth inferior, of one leaf, bell-shaped; its segments lanceolate, acute; the two uppermost shortest, the lower one longest. *Cor.* papilionaceous. Standard very large, inversely heart-shaped, reflexed at the sides and summit. Wings smaller, oblong, somewhat crescent-shaped, short and obtuse. Keel semicircular, the size of the wings but broader, separating about the middle inwards. *Stam.* Filaments in two sets, one simple the other in nine divisions, curved upwards; anthers roundish. *Pist.* Germen compressed, oblong, linear; style in its upper part erect, flat, broader upwards, acute at the summit; stigma on the upper or inflexed side of the style, extending from the middle to the top, hairy. *Peric.* Legume very long, cylindrical or compressed, pointed, of two valves and one cell. *Seeds* several, either cylindrical, globose, or slightly angular.

Eff. Ch. Style flattened, downy above, broader upwards. Two upper segments of the calyx shortest.

Tournefort divides this genus into four by the foliage. His *Lathyrus*, t. 216, 217, has only a single pair of leaflets on each footstalk, the latter terminating in a compound tendril; his *Clymenium*, t. 218, has many leaflets to each stalk; his *Nissolia*, Inl. 656, has simple leaves without any tendril; and his *Alphaca*, t. 223, bears stipulas without leaves, at least in the adult plant. These, however, are very justly deemed by Linnæus mere differences in habit, among the species of one great genus, which is on the whole sufficiently natural. His 14th edition of Syst. Veg. enumerates 21 species, Willdenow 36, in three sections. The first section, with single-flowered stalks, now and then varying to two flowers, embraces 13 species; the second, with two-flowered stalks, has six; the third, with many flowers on each stalk, has 17.—Seven of the genus only are natives of Britain. The rest grow either in the warmer countries of Europe, or in the north of Africa, some in America, and one it is said in Japan. They are stationed for the most part in cultivated fields, in meadows, or about hedges and thickets. Those referable to the first and second sections are, perhaps

without exception, always annual plants, many of them capable of being used as pulse; those of the third are generally perennial, with very tenacious, deep or creeping roots, and more calculated for fodder. Examples are here subjoined.

\* *Stalks single-flowered.*

*L. Alphaca*. Linn. Sp. Pl. 1020. Curt. Lond. fasc. 5. t. 51. Engl. Bot. t. 1167. (Alphaca; Raii Syn. 320, Ger. em. 1250.)—Flowers solitary. Tendrils leafless. Stipulas between heart and arrow-shaped.—Found in the borders of gravelly corn-fields, but rarely. The *stem* is weak, a foot or two high, supported by its numerous simple tendrils, each springing from between two large, angular, almost halbert-shaped *stipulas*, which give the plant a peculiar aspect. One or two of the very first stipulas only are accompanied by a pair of small leaflets, with or without any elongated tendril. The *flowers* are small and yellow, very rarely two together on each flower-stalk.

*L. arabicarpus*. Linn. Sp. Pl. 1029. (L. minimus penennis  $\alpha\mu\alpha\rho\alpha\rho\omega\tau\omega\varsigma$ , seu supra infragie terram siliquas gerens; Morif. Sect. 2. Append. t. 23. f. 1.)—Stalks single-flowered, longer than the calyx. Tendrils two-leaved, quite simple.—Native of Syria. A humble plant, remarkable for producing many of its pods, with perfect seed, immediately from the root, or rather from the subterraneous part of the stem; yet these are the offspring of perfect flowers, (at least as to stamens and pistil,) though born under ground; as we have verified by examining the plant in Kew garden 30 years ago. Whether the roots be annual or perennial, we are not certain, but this subterraneous mode of fructifying is seen in two or three more species of *Lathyrus* or *Vicia*. Morison's figure exhibits the present plant very tolerably. What rises above ground bears linear-lanceolate rather glaucous leaflets, in pairs, with half arrow-shaped *stipulas*, and a dull solitary dull-purple *flowers*, which also produce feed.

*L. articulatus*. Linn. Sp. Pl. 1031. Curt. Mag. t. 253.—Stalks with one or two flowers. Tendrils accompanied by many alternate lanceolate leaflets, on a winged stalk.—Native of France and Italy. A common hardy annual in our gardens, to a place in which it is recommended by its elegant though scentless *flowers*, whose crimson standard is prettily contrasted with their white wings.

\*\* *Stalks two-flowered.*

*L. obovatus*. Common Sweet Pea.—Linn. Sp. Pl. 1032. Curt. Mag. t. 60.—Stalks two-flowered. Leaflets ovate-oblong, two to each branched tendril. Legumes hairy.—Native of Sicily, and some say of Ceylon; but the latter may perhaps be doubted, the plant being in the English gardens so hardy an annual, as frequently to survive our winters, when it comes up in autumn. Its great beauty, delicious fragrance, and variety of colours, render it a general favourite. More than two flowers are frequent on each stalk, though the uppermost are commonly blighted.

\*\*\* *Stalks many-flowered.*

*L. tuberosus*. Linn. Sp. Pl. 1033. Curt. Mag. t. 111.—Stalks many-flowered. Leaflets oval, in pairs. Stem without wings. Roots tuberous.—A troublesome weed in some parts of Germany and Italy, spreading widely over all kinds of cultivated ground, by means of its tuberous fleshy perennial roots, hardly to be extirpated. In our gardens it is a beautiful hardy plant, conspicuous for the peculiarly delicate rose-colour of its *blossoms*, and we have never heard of its being troublesome in its increase. The *seeds* rarely

rarely ripen. The *knobs* of the root are eatable when boiled.

*L. latifolius*. The Great Everlasting Pea. Linn. Sp. Pl. 1033. Engl. Bot. t. 1108. Mill. Illustr. t. 62.—Stalks many-flowered. Leaves elliptical, in pairs. Stem winged.—Very commonly cultivated in gardens, where its roots endure for a long course of years, throwing up tall climbing *stems*, which bear large bunches of beautiful crimson *flowers*, well known to most people. We rather doubt whether the plant be truly wild in England, yet it appears in some places to be so, and finds a place in all our British Floras.

*L. sylvestris*. Narrow-leaved Everlasting Pea. Linn. Sp. Pl. 1033. Engl. Bot. t. 805. Curt. Lond. fasc. 6. t. 52.—Differing from the last in the narrowness of its *leaves*, and less gaudy hues of its *flowers*, is perhaps a more elegant plant, and certainly wild in many parts of England in low bushy spots.

LATHYRUS, in *Gardening*, contains plants of the herbaceous climbing flowery kinds, of which the species chiefly cultivated are the sweet lathyrus, or pea, *L. odoratus*; the tangier lathyrus, or pea, *L. tingitanus*; and the broad-leaved lathyrus, or everlasting pea, *L. latifolius*.

But several other species may be cultivated where variety is wanted.

The first of these sorts has several varieties; as the purple-flowered, the white-flowered, the variegated or painted lady, sweet-scented, and the scarlet.

The second sort is a showy plant for shrubberies, wilderness quarters, arbours, and trellis-work; but too large and rampant for borders of the common flower-garden.

It has many varieties; as the red-flowered, the purple-flowered, the scarlet-flowered, and the large-flowered.

*Method of Culture*.—These plants may be readily raised, by sowing the seeds of the different sorts in the autumn or spring seasons, at different times in patches of six or eight together, in the places where they are to grow. Where the soil is light and dry, the autumn is the best season, as the plants appear more early, but in other cases the spring should be preferred. The plants afterwards only require to be kept clean from weeds, and be properly supported by branchy sticks.

The last sort may likewise be increased by transplanting the roots in the autumn; but the plants in this way are seldom so good as by seeds.

And the two first sorts must be sown annually, but the last will remain many years.

It may be noticed that it is the practice with the gardeners who raise the first sorts for the London markets, to sow them in the autumn in pots, and secure them from severe weather, by placing them in hot-bed frames: by which means they can bring them much more early to market. They may be continued in flower the whole of the summer by repeated sowings in the spring. When sown in pots, they should be watered frequently in a slight manner.

All these plants are highly ornamental in the borders, clumps, and other parts of pleasure-grounds, when properly intermixed in their species and different varieties in such compartments.

LATIANO, in *Geography*, a town of Naples, in the province of Otranto; five miles E. of Oria.

LATIAI, a feast or ceremony, instituted by Tarquinus Superbus, in honour of Jupiter Latiaris, or Latialis.

Proposed, having made a treaty of alliance with the Latins, to perpetuate it, to erect a common temple, where all the allies, the Romans, Latins, Hernici,

Volsci, &c. should assemble themselves every year, hold a kind of fair, exchange merchandizes, feast, sacrifice, and make merry together. Such was the institution of the Latian. The founder only appointed one day for this feast; the first consul added another to it, upon concluding the peace with the Latins; and a third was added, after the people who had retired to the Mons Sacer were returned to Rome; and a fourth, after appealing the sedition raised on occasion of the plebeians aspiring to the consulate.

These four days were called the *Latin feriae*; and all things done during the course of the *feriae*, as feasts, sacrifices, offerings, &c. were called *Latiare*.

LATICLAVIUM, or LATUS-CLAVUS, a garment which was a distinction and dignity among the Romans, contradistinguished from the angusticlavium.

The lati-clavium was a kind of tunic or long coat, faced with one or two slips of purple, applied lengthwise to the two sides of the tunic.

In the latus-clavus these slips were pretty broad, and in the angustus-clavus narrower; though there is nothing about which the learned differ more than the difference between those two habits.

There were buttons set on the latus-clavus, which appeared like the heads of large nails; whence some think it took its name.

The senators, prætors, and the chief magistrates of colonies and municipal cities, had a right to wear it. The robe called prætexta was worn over the latus-clavus. When the prætor pronounced sentence of death, he put off the prætexta; but retained the latus-clavus.

LATICZOW, in *Geography*, a town of Poland, in the palatinate of Braclaw; 60 miles N.W. of Braclaw.

LATILLA GAETANO, in *Biography*, an excellent Neapolitan composer, much esteemed by connoisseurs, in every species of vocal music. His comic operas, however, were the most ingenious and successful of all burletta compositions, till the Buona Figliuola of his nephew Piccini came out, which surpassed all preceding comic operas so much, that no other excited any curiosity in the public; till Pacifiello's superior fertility was known and felt.

Latilla's comic operas, that were performed in London, from 1748 to 1753, when the Mingotti first arrived, were "La Comedia in Comedia," "Orazio," and "Don Calafino," which were admirable. The melodies new, easy, and pleasing; humour without buffoonery; and the actors considered as well as the singers, in allowing time for Pertici and Laschi, those nice observers of whatever was ridiculous in the voice, countenance, or gesture of man, to convey their observations to the spectators.

We met with poor Latilla 20 years afterwards at Venice, "fallen from his high estate," and shrunk into an humble deputy organist, at the church of St. Maca; but found him an intelligent and well informed man, on other subjects than that of his own profession, which, however, he had cultivated in all its departments.

LATIMER, HUGH, the son of a respectable Leicestershire yeoman, was born about the year 1470. He was initiated in school learning in the country, and making a very rapid progress in his youthful studies, he was, at the age of fourteen, sent to Christ's college, Cambridge, where he was distinguished for his rapid proficiency in the studies of the place. Here he took his degrees, entered upon holy orders, and was at this period a zealous Papist, read the scriptures and the schoolmen with the same reverence, and held Thomas à Becket and the apostles in equal honour. He had taken alarm at the progress of Lutheranism, and inveighed with great bitterness, publicly and privately, against those principles,

ciples, of which he was hereafter to become a most zealous defender. His zeal as a Papist was so distinguished in the university, that he was elected cross-bearer in all public processions, an employment which he is said to have accepted with a high degree of reverence, and to have discharged with much solemnity. Our good divine was a Papist from conviction, and had a mind open to arguments on all sides of the question; he fortunately met with Mr. Thomas Bilney, a clergyman of great piety, and who, by the perusal of Luther's works, had become a secret favourer of the reformation. By degrees he infused into the mind of Latimer all those doubts which he had formerly felt respecting the discordance of Popery with pure Christianity. Latimer heard the arguments of his friend, and was prepared at first to dispute the ground inch by inch. At length he found the ground on which he stood absolutely untenable; and acknowledged the errors in which he had been educated. But the temper of the scholar was not like that of the matter: he could not be a Protestant in secret: he must come forth boldly and declare the convictions of his heart: he had fought truth as the pearl of great price, and having, as he believed, found it, was determined not to conceal its beauty from his friends and the world. He became an active apostle in the cause of Protestantism; he preached in public, he exhorted in private, and every where enforced the necessity of a holy life, in opposition to the superstitious ceremonies and observances inculcated by the Romish religion. He soon became obnoxious to the generality of the clergy, but being contented to go through evil as well as good report, he continued on his course with more ardour in proportion to the outcry made against him. He inveighed against the ceremonies which encumbered true religion, and exposed the pride and usurpation of the Romish hierarchy: but what he most insisted on was the right of the people to read the Scriptures in their native tongue. Dr. Buckenham, one of the Black-friars, was selected to answer, from the pulpit, the arguments of Latimer: he performed the task with great pomp, but not to the complete satisfaction even of his own party, and in a short time afterwards the whole university met to hear what the reformer had to say in his defence. Mr. Latimer at first recapitulated Dr. Buckenham's arguments; placed them in the strongest light, and gave them much greater importance than the friar had been able to do: he then attacked them with so much force of reasoning, and such abundance of wit, as to render the learned doctor truly ridiculous: he next appealed to his hearers, urging them to respect their own understandings, and not to submit to be led by the priests, who had ever been accustomed to treat the people at large with contempt; and he concluded with ardently hoping, that his honest countrymen might be permitted to have the use of the scriptures, till they shewed themselves to be as absurd interpreters of them as the learned friar. Latimer, by this exertion, and by an answer to Venetus, greatly increased the credit of the Protestant party at Cambridge. Bilney and Latimer were regarded as the heads of the party, and to them the students looked with respect, attachment, and even veneration. The heads of the colleges, and the senior members of the university, were alarmed, and determined to withstand the progress of heresy. Frequent convocations were held, and the strictest injunctions were laid on all the tutors to be watchful of the opinions of their pupils; but these efforts were in vain, and the bishop of Ely was applied to, and entreated to crush, by his authority, the new opinions. The prelate, though a Papist, was not a true perfectionist: he was willing to judge for himself, and though he went to Cambridge and preached against the heretics, yet he did not scruple to attend himself

the sermons of Latimer, and with much candour declared, that the reformer was the best preacher he had ever heard. Latimer's enemies next appealed to the court, and transmitted very heavy complaints respecting the increase of heresy; and Wölsey, contrary, it is thought, to his own inclination, instituted a court, consisting of bishops and other divines, to put the laws in execution against heresy. Bilney and Latimer were called to answer for their conduct, and as the former was regarded as the most guilty, by being the first promulgator of the new doctrines, his examination was the most severe, and he was pronounced guilty; but not having a mind formed for the sufferings prepared for him, he recanted, and after some ignominious treatment was dismissed. Latimer, and others who were involved in the charge, were, by the management of the cardinal, and the merciful disposition of Tunstall, bishop of London, dismissed probably without a reproach: the cardinal even granted Latimer his licence to preach throughout England. The friends of the reformers received them with open arms; but the fate of Bilney was truly wretched; he was struck with remorse at the thought of his recantation, and the agonies of his mind deprived him for a time of his reason. In a few years he returned to a sane state, and determined to expiate his abjuration by his death. He accordingly left his friends at Cambridge, went into Norfolk, his native country, and preached most earnestly against the corruptions of the established religion; he was seized, imprisoned, and executed, at Norwich, exhibiting, at his closing scene, a most admirable example of composure, firmness, and Christian courage. Latimer, in the mean time, exerted himself more than ever: he was constant in his exertions, and once or twice he had the honour to preach before the king at Windsor. Encouraged by the gracious reception afforded him by Henry, he took the liberty of writing a very bold letter to his majesty, against a proclamation which the clergy had prevailed upon the king to publish, forbidding the use of the bible in English. The king received the letter with good temper, and even thanked Mr. Latimer for his well-meant advice. When measures were taken for the establishment of the king's supremacy, Latimer exerted all his powers in forwarding his majesty's designs. His zeal in the business procured for him the presentation of the rectory of Westkinton, in Wiltshire, and, notwithstanding the remonstrances of his friends, who considered this as the first step only to higher dignities in the church, he went to reside on his living. His preaching rendered him very popular, and he was soon after appointed by the mayor of Bristol to preach on Easter Sunday. Public notice of this appointment had been given, and received by the people with great joy; but an order was suddenly issued by the bishop of Bristol, prohibiting any one to preach there without his licence. This was but the first instance of opposition which the clergy in that neighbourhood excited against him; they traduced his character, and inveighed against him with the greatest violence; and at length they drew up a set of articles, in the form of an accusation, which was laid before Stokesley, bishop of London, who immediately cited Latimer to appear before him. To this mandate he was not obedient, but on a citation from the archbishop he instantly submitted. He set out in the midst of winter, and at a moment when he was grievously afflicted with the stone and other acute disorders. On his arrival in London he found the court sitting, but instead of being examined as to any particular charges, he was ordered to subscribe a paper put into his hand, containing the obnoxious doctrines against which he had been preaching. This he positively refused, and he was dismissed, for the present, with an exhortation to reflect upon his conduct, and submit.

Frequently was he brought before the court, and as frequently he rejected the proposal. At length he remonstrated against their ill-treatment, and was probably refused by the interposition of the king. In 1534, he was appointed chaplain to queen Anne Boleyn, and in the following year he was offered the bishopric of Worcester, which he accepted, and discharged the duties of the office with zeal, piety, and diligence. In 1536, he was called on to attend the parliament and convocation; and it was hoped that this session would bring with it many important advantages for the Protestant cause. The convocation was opened by an eloquent Latin discourse from Latimer, who had been appointed to this office on account of his great talents, and because it was known that no other person could so ably expose the corruptions of the clergy as himself, and thus lead them to an active discharge of their duty. In a short time after this, an English translation of the bible was published and recommended by authority to a general perusal. During the sitting of the convocation, an animated but unsuccessful attempt was made to stigmatize archbishop Cranmer and bishop Latimer, by some public censure. As soon as the convocation broke up the bishop repaired to his diocese; he had no taste for state affairs, and he had a mind ill adapted to the manners of a court. It was the custom at that period for the bishops, at the commencement of every new year, to make presents to the sovereign, and many of them were very liberal in their donations; but Latimer, on this occasion, presented, instead of a purse of gold, a New Testament, with a leaf doubled down on this passage, "Whoremongers and adulterers God will judge."

Attempts were frequently made to ruin the bishop, but hitherto they were unsuccessful; and he continued in favour with the king. After the passing of the bloody statute, or the act of the six articles, the bishop protested against it by his conduct; he resigned his bishopric, and retired into the country. Here he intended to pass the remainder of his days, but an accident, which befel him, by the fall of a tree, obliged him to come to London for surgical assistance. His arrival was soon known in the metropolis, and the spies of the bloody-minded Gardiner watched him in every place. At length they obtained, or made, matter for accusation; he was charged with speaking against the statute of the six articles, and was, without hesitation, committed to the Tower, where he suffered a cruel imprisonment during the remainder of king Henry's reign. On the accession of Edward VI. Latimer, and all the others who had been imprisoned in the same cause, were set at liberty. He might have been reinstated in his bishopric, but he preferred a more private life, accepted an invitation from Cranmer, and took up his residence at Lambeth, where his chief employment was to hear the complaints, and to procure redress for the injuries, of poor people. No man was so well qualified for an office of this kind, and he continued in it during two years, interfering very little with public transactions. It was, however, known that he assisted the archbishop in composing the Homilies, which were published, by authority, in the beginning of king Edward's reign, and intended to supply the want of preaching, which was now at a very low ebb. Being one of the most eloquent preachers of the age, he was appointed to preach the Lent sermons before the king, during the first three years of his reign. After this he retired into the country, and made use of his majesty's licence, as a general preacher, in those parts where he thought his labours might be most serviceable. He continued in this practice till Popery was re-established in the reign of queen Mary, when he was cited to appear before the council in London. He immediately obeyed, and as he passed through

Smithfield, the scene of the most horrid cruelties exercised upon those who had been denominated heretics, he said, very cheerfully, to his attendants, "this place has long groaned for me." The next day he appeared before the council, who, after loading him with many reproaches, committed him to the Tower. His imprisonment was rendered uncommonly severe, but he endured every evil with resignation, and true Christian humility. The weather was exceedingly severe, but no fire was allowed him, which led him to tell the lieutenant of the Tower, that, however his enemies might expect he should be burned, unless he was permitted to have a fire this frosty weather, he should be first starved to death with cold. About this time archbishop Cranmer and bishop Ridley were committed to the Tower, which became so crowded with prisoners, that the three prelates were confined in the same room, a circumstance which, no doubt, they greatly enjoyed. The pleasure, however, was but of short duration; they were hurried to Oxford under the pretence of a public disputation to be held there by the most eminent divines on both sides. At this place they were most closely confined in the common prison, and deprived of every comfort, and of almost all the necessaries of life; hence they readily inferred what kind of disputation would be allowed them. They fully expected that the argument of power was the only one that would be resorted to, and having made up their minds to this, Latimer said he should give them very little trouble. "I shall," said he, "offer them a plain account of my faith, and say but little more; for I know that any thing more will be to no purpose. They talk of free disputation; but I am assured, their grand argument will be, as it was that of their forefathers, *We have a law, and by our law ye ought to die.*" When he was brought into court, he had a cap on his head, buttoned under his chin, a pair of spectacles hanging at his breast, a new testament under his arm, and a staff in his hand. He was exhausted in pressing through the crowd, and was permitted to sit down; after a sufficient pause, he was told he must dispute against the articles brought against him; he declared he was unable, through age, to do any such thing; "I am not able to debate," said the venerable old man, "I will avow my faith, and then do with me as you please." He was next ensnared, by the artful conduct of his accuser, to make concessions which were against him, and upon this the prolocutor arose, and exclaimed to the populace, "Here you see the weakness of heresy against the truth; here is a man, who, adhering to his errors, hath given up the gospel, and rejected the fathers." The good old man made no reply, but wrapping his gown about him, and taking his new testament and his staff, walked out with the greatest composure. On the following Friday he was again brought into court, was first excommunicated, and then condemned to death. As soon as the sentence was read, Latimer, lifting up his eyes to heaven, exclaimed, "I thank God most heartily, that he hath prolonged my life to this end."

No steps were taken towards putting the sentence against the prelates into execution, for nearly a year and a half; but, in 1555, new laws in support of the Romish religion having been enacted, a commission was granted by cardinal Pole, the pope's legate in England, to the bishops of Lincoln, Gloucester, and Bristol, empowering them to try bishops Latimer and Ridley for heresy. The prelates were ordered before the commissioners, and when Ridley had been examined, bishop Latimer was brought to the bar, whom the bishop of Lincoln addressed, in an eloquent, and very pathetic speech, earnestly exhorting him to accept the mercy that was offered, and to acknowledge the authority of the see of Rome. The good bishop was too firmly fixed in his

opinions to give them up through motives of timidity, and the desire of prolonging his life. He was, however, remanded, and on the next day judgment was passed on him and Ridley. Their execution was fixed for the 16th of October, and the place fixed on was the north side of the city, near Baliol college. Left the bloody scene should excite a tumult, the military were ordered to attend the place of execution. On the day appointed, the vice-chancellor of Oxford, and other persons of distinction, repaired to the spot which was to witness the sufferings of these worthy men; the prisoners, at the fixed hour, were sent for, and the concern of the spectators, which was apparent in every countenance, excepting in those who were actors in the scene, was greatly augmented by the striking contrast of their appearance. Ridley was dressed in his episcopal habit, shewing what they had formerly been, and bishop Latimer wore his prison attire, by which he exhibited the condition to which they were now reduced. Having heard a sermon, by a Popish doctor, in which they were treated with great inhumanity, they prepared for their last trial, and were chained to the stake. The fire was speedily kindled, and at the sight of the flames Latimer exclaimed, "Be of good cheer, master Ridley, and play the man, we shall this day light such a candle, by God's grace, in England, as I trust shall never be put out." He then recommended his soul to God, and a few minutes put an end to the sufferings of these noble martyrs. Such was the glorious and triumphant end of Hugh Latimer, who had been indefatigable in the discharge of the duties of life, and who exhibited the most astonishing firmness and composure in the several trials to which he was exposed. He was not learned, in the usual sense of the word, for he cultivated only useful learning, and he lived rather what the world calls a good than a great man. He was eminent as a preacher, but his sermons, that are extant, are not patterns of good composition; his manner of preaching was affecting, as he spoke from the heart, and made deep and lasting impressions on his auditors. He displayed at all times a noble and apostolic zeal in the propagation of the truth. No one had a higher sense of what became his office, or was less influenced by any sinister motive; and none ever reproved vice with more freedom, without any regard to the rank of his hearers. A collection of his sermons was published, in 1570, by Augustus Berniere, a Swiss, who dedicated them to Catharine, the duchess of Suffolk. It consists of forty sermons, and has been frequently reprinted. In Mr. Fox's Acts and Monuments, several of his letters are preserved, among which is the celebrated one to king Henry VIII. for restoring the free liberty of reading the holy scriptures. Biog. Brit.

LATIN, a dead language, first spoken in Latium, and afterwards at Rome, and still used in the Romish church, and among men of letters.

Some authors rank the Latin among the number of original languages, but by mistake: it is formed principally from the Greek, and particularly from the Æolic dialect of that tongue; though it has a great number of words which it borrowed from the languages of the Etruscians, Oscians, and other ancient people of Italy; and foreign commerce and wars, in course of time, added a great many more.

The Latin is a strong, nervous language, perfectly suitable to the character of the people who spoke it. The Romans were engaged in wars and commotions, foreign and domestic, which for seven hundred years engrossed all their thoughts. Hence, therefore, says the ingenious Mr. Harris, their language became like their ideas, copious in all terms, expressive of things political, and well adapted

to the purposes both of history and popular eloquence. But the Romans were no philosophers; and hence the unsuitness of their language to this subject; a defect, which even Cicero is compelled to confess, and more fully makes appear, when he writes philosophy himself, from the number of terms he is obliged to invent. Harris's *Hermes*, p. 411, &c.

The Latin is more figurative than the English, less plain than the French, less copious than the Greek, less pompous than the Spanish, less delicate than the Italian, but closer and more nervous than any of them.

We may here observe, that the prosody both of the Greeks and Romans was carried much farther than ours; or that they spoke with more, and stronger, inflexions of voice than we use. The quantity of their syllables was much more fixed than in any of the modern languages, and rendered much more sensible to the ear in pronouncing them. Besides quantities, or the difference of short and long, accents were placed upon most of their syllables, the acute, grave, and circumflex: the use of which accents we have entirely lost, but which, it is well known, determined the speaker's voice to rise or fall. (See ACCENT and PROSODY.) We may also observe, that strong tones and animated gestures always accompany one another. The action both of the orators and the players in Greece and Rome was far more vehement than that to which we are accustomed. (See ACTION and GESTURE.) When the Barbarians spread themselves over the Roman empire, these more phlegmatic nations did not retain the accents, the tones and gestures, which necessity at first introduced, and custom and fancy afterwards so long supported, in the Greek and Roman languages. As the Latin tongue was lost in their idioms, so the character of speech and pronunciation began to be changed throughout Europe. The same attention was no longer paid to the music of language, or to the pomp of declamation, and theatrical action. The arrangement which commonly obtains in the Latin language consists in placing, first in the sentence, that word which expresses the principal object of the discourse, together with its circumstances; and afterwards the person, or the thing that acts upon it. Thus Sallust, comparing together the mind and body, uses the following expression; "Animi imperio, corporis servitio, magis utimur;" in which the order renders the sentence more lively and striking than when it is arranged according to our English construction; "We make most use of the direction of the soul, and of the service of the body." The Latin order more gratifies the rapidity of the imagination, which naturally runs first to that which is its chief object; and having once named it, carries it in view through the rest of the sentence. But though the common arrangement in the Greek and Roman languages is to place that first which strikes the imagination of the speaker most, yet this does not hold without exception. Sometimes regard to the harmony of the period requires a different order, and to this the ancients attended. The Latin order is more animated; but the English is more clear and distinct. The Romans generally arranged their words according to the order in which the ideas rose in the speaker's imagination. We arrange them according to the order in which the understanding directs those ideas to be exhibited in succession, to the view of another. Our arrangement, therefore, appears to be the consequence of greater refinement in the art of speech; as far as clearness in communication is understood to be the end of speech. The limitation of arrangement in the modern tongues is, in a great degree, owing to the disuse of those differences of termination, which, in the Greek and Latin, distinguished the several cases of nouns, and

tenes of verbs; and which, by means of these, pointed out the mutual relation of the several words in a sentence to one another, though the related words were disjoined and placed in different parts of the sentence. As articles contribute very much to the clearness and precision of language, the want of them in the Latin tongue is unquestionably a defect, though they recur for the supply of this defect to the use of pronouns. (See ARTICLE and PRONOUN.) Blair's Lectures, vol. i.

For a while the Latin tongue was confined almost wholly within the walls of Rome; nor would the Romans allow the common use of it to their neighbours, or to the nations they subdued. Cicero observed, that even in his time, Greek was used almost among every people, but the Latin only confined to a very narrow compass. By degrees they were brought to grant the use of it as a favour; and, in time, became sensible of the necessity there was of its being generally understood, for the conveniency of commerce: and, accordingly, used their utmost endeavours, that all the nations subject to their empire should be united by one common language: so that at length they imposed that as a law, which they had before granted as a favour.

After the translation of the seat of the empire from Rome to Constantinople, the emperors of the East, being always desirous of preserving the title of Roman emperors, appointed the Latin to be still retained in use, both in their rescripts and edicts, as appears by the constitutions of the eastern emperors, collected in the Theodosian Code; but at length the emperors, neglecting the empire of the West, abandoned all care of the Latin tongue, and allowed their judges to pass sentence in Greek; and, accordingly, we find the emperor Justinian's Novels are composed in Greek.

Charlemagne, coming to the empire of the West, appointed the law proceedings in foreign courts to be made in Latin; and the notaries were to draw their acts and instruments in the same tongue: this practice continued a long time through a great part of Europe; but at length it gave way, and the French took place of the Latin, not only in France, but, in some measure, in England too; and the reason given for it was, that abundance of difficulties arose about the understanding of Latin terms. See *LAW LANGUAGE*.

The Latin, however, was prodigiously degenerated and corrupted, before it came to be laid aside. The incursions of the Goths and Vandals into Italy brought an inundation of foreign words and phrases into it; inasmuch that Valla and Naud call Boethius the last Latin author. By command of Theodoric, king of the Goths, it was the hard fate of this worthy man, says Mr. Harris, to suffer death; with whom the Latin tongue, and the last remains of Roman dignity, may be said to have sunk in the western world. But that was not all; when it once got into the courts of justice, it was still worse handled; till, at last, being introduced amongst the monks, and become the common language of missals and breviaries, it was debauched to that degree, that it was almost become scandalous to use it.

In this condition it was found at the time of the Reformation, when Vives, Erasmus, &c. began to open the way for its recovery; since which time monkish Latinity has been declining, and all endeavours have been used to retrieve the pure language of the Angulitan age.

It was said of cardinal Bembo, that he would never read the breviary for fear of corrupting his fine Latin.

LATIN Character. See CHARACTER.

LATIN Church, is a term used for the Romish or western church, by way of opposition to the Greek church. See CHURCH.

LATINÆ FERIÆ. See FERIÆ.

LATINI, BRUNETTO, in *Biography*, an early reviver of literature in Italy, was born at Florence in the early part of the thirteenth century; he was employed, about the middle of that century, by the Guelphs, in Florence, as ambassador to Alphonso, king of Castile, with the view of obtaining aid against Manfred, king of Naples and Sicily. By the prevalence of the opposite party he was driven from his country, and retired to France. At Paris he opened a school of philosophy, and wrote several books. We find him in his native country in 1284, and acting as syndic at Florence. He died in 1294. The most celebrated of his works was his "Teforo," a compilation from various authors, in history, philosophy, rhetoric, and morals. He translated into the Italian language part of the first book of Cicero de Inventione, and he was author of a moral work in verse, entitled "Il Teforetto." He is represented as a profound rhetorician and philosopher, and is said to have been the first who began to polish the language, and refine the understanding of his countrymen. Though he does not appear to have been a public instructor at Florence, he probably gave private assistance in the studies of his friends, and he is mentioned as having been, in some measure, the tutor of Dante.

LATINI, LATINO, a learned Italian, was born at Viterbo in 1513. He studied several years at Sienna, with a view to jurisprudence, which an ill state of health obliged him to relinquish. He then assumed the ecclesiastical habit, went to Rome, and became librarian to cardinal Rodolfo Pio, who, dying in 1564, left Latini the bequest of his copious library. He was employed in the reformation of the Decretal of Gratian, first undertaken by desire of pope Pius IV. and published under Gregory XIII. and committed to the care of many of the most learned ecclesiastics of the Roman court. He died in 1593, and bequeathed all his books to the chapter of Viterbo. He was highly esteemed for his learning and industry, though his modesty did not permit him to publish any thing during his life-time. After his decease there appeared two volumes of his "Latin Letters, Poems, and other small Pieces." He communicated many emendations of Tertullian to the edition of that father published by Pamelius. His MS. annotations on the fathers, and on other authors, were given to the public in the "Bibliotheca Sacra et Profana," printed at Rome in 1667. Moreri.

LATINI, the *Latins*, in *Ancient Geography*, comprehended in general all the people of Latium, and particularly those who inhabited the territory along the Tiber from Rome to the sea. They were formed, it is said, by the union of the Aborigines, or of people whose origin was not known, of the Pelasgi, who had migrated from Thessaly, and of the Arcadians, brought thither by Evander, 60 years before the war of Troy.

LATION is used by some for the translation or motion of a body from one place to another.

LATISSIMUS COLLI, in *Anatomy*, a muscle of the neck, often called platysma myoides. See DEGLUTITION.

LATISSIMUS DORSI, is a muscle of the back, described under DORSI.

LATITAT, in *Law*, a writ, whereby all men in personal actions are called originally to the king's bench.

It has this name, as supposing the defendant lurks, lies hid, and cannot be found in the county of Middlesex, to be taken by bill; but is gone to some other county, to the sheriff whereof this writ is directed. See BILL of Middlesex.

LATITUDE, in *Geography* and *Astronomy*. The latitude of a place on the terrestrial globe is its angular distance from

## L A T I T U D E.

from the equator. It is measured on the meridian, being that part of it which is intercepted between the zenith of the place and the equator. See **MERIDIAN**.

If the place is situated to the north of the equinoctial line, it is said to have north latitude; if on the other side, its latitude is south.

When the spherical figure of the earth was once admitted, obvious methods, founded on astronomical principles, were immediately invented, to determine the latitude of places, or their relative situation to the equator. Previous to the establishment of this theory, nothing could be more vague and unsatisfactory than the methods employed by the ancients of determining the relative situations of the principal cities of the world to each other. But the knowledge of the true figure of the earth, not only suggested a more scientific division of its surface by imaginary circles, supposed to be drawn on its circumference; but by referring these circles to corresponding ones in the heavens, astronomy and geography were combined, and the principles of the former were successfully applied to the improvement of the latter. Long before the apparent motion of the heavens was known to arise from the real motion of the earth, the two points which we now call the poles were referred to those two points in the heavens which were observed to be stationary; and a great circle of the terrestrial sphere, supposed to be every where equally distant from the poles, was called the equinoctial line, and assumed as a principal circle, to which geographical situations were to be referred; and as astronomers, in taking the ecliptic for their principal circle, had defined the positions of the heavenly bodies by their distances from this circle, and a perpendicular to it, calling these distances *longitudes* and *latitudes*; so, in imitation of this method, geographers assumed the equinoctial line as their standard, and taking another circle perpendicular to it, they referred all positions on the earth to these circles by the same name. Hence longitude and latitude, in geography, are not defined in the same terms as in astronomy, being in the latter always referred to the ecliptic, and on the terrestrial globe to the equator. This circumstance often embarrasses the young student in astronomy, who is naturally at a loss to comprehend why the same terms should have such different significations, when applied to the terrestrial and celestial globe. It being once clearly understood that every point of the convex surface of the earth has at any given instant of time its corresponding point on the concave surface of the heavens, a number of methods were immediately suggested (and quite independent of actual measurement), for determining the situation of places, or their latitudes and longitudes as defined above. The most obvious method of defining the situation of points on a sphere, is to refer them to two great circles perpendicular to each other. On the celestial globe, whether we assume the equator or the ecliptic for one of these circles, we can have no hesitation in the choice of the other, because the equinoctial points are so remarkable, that they naturally indicate the advantage of making the second circle pass through them. Still, however, it must be remembered, that this choice is to a certain degree arbitrary; we might have assumed the equator or ecliptic for one principal circle, and for the other, a great circle perpendicular to either of them, which should pass through any remarkable fixed star, as Sirius, or Arcturus. The preference, however, has always been given to the equinoctial points, and, accordingly, as we assume the equator, or the ecliptic, as the principal circle, we define the situation of the different points by *right ascension* and *declination*, or by longitude and latitude. See **RIGHT ASCENSION**, and **DECLINATION**.

There is likewise another method occasionally employed by astronomers, but which relates only to their own particular situation at the moment of observation: this is by altitude and azimuth. The place of a heavenly body determined by this method is not permanent, but changes at every instant; and since no two observers can have the same zenith, no star can have the same altitude and azimuth at the same instant of time to different observers. See **ALTITUDE**, **AZIMUTH**, &c. &c.

In this latter method the principal circle assumed is the *horizon*, and the great circle perpendicular to it is that which passes through any two opposite cardinal points, as the North and South, or the East and West.

Let us now consider the terrestrial globe. Here the equinoctial line presents itself as the great circle, of all others the most proper for our purpose; but what is to guide our choice in the selection of another great circle perpendicular to it? We are not here assisted, as in the celestial globe, by finding any one point possessing some remarkable property peculiar to itself; and even if there were such a point arising from local circumstances, it would have no representation in the heavens; and, therefore, would not facilitate the object of our present investigation, which is to shew by what method astronomers have contrived to determine the situation of points on the earth's surface, by finding their corresponding zenith points in the heavens.

Finding, therefore, but one great circle on the terrestrial globe indicated by nature, astronomers and geographers have been obliged to assume a second from circumstances entirely accidental. The first meridian has been differently assumed by writers of different countries. The French astronomers divide the terrestrial globe by two great circles; one of which is the equator, the other a great circle passing through the observatory of Paris, and to these great circles all other places are referred; hence, according to their definitions, if a great circle be conceived to pass through any place, and to be perpendicular to the equator, then the latitude of that place will be the arc of this secondary circle between the equator and the place, and its longitude will be the arc of the equator, intercepted between this great circle and that which in a similar manner passes through the observatory of Paris.

English geographers and astronomers, in like manner, suppose their first meridian to pass through the Royal Observatory of Greenwich.

Having thus minutely described what is meant by longitude and latitude, both on the celestial and terrestrial globe, it remains to explain the different problems connected with the subject, and, agreeably to the arrangement adopted in this work, we shall confine ourselves as much as possible to that part of the subject connected with *Latitude*, referring to *Longitude* that which more immediately belongs to it.

The theory of finding the latitude of a place by astronomical observation is so simple, that it may be understood by merely inspecting a celestial globe. See **GLOBE**.

The meridian (*Plate XVI. fig. 147. Astronomy.*) rises (in our latitudes) in the north point of the horizon *O*, passes through the pole *P*, through the zenith, and crosses the equator *Æ* before it meets the southern point of the horizon. It is thus divided into four parts:

*P O* = the latitude,  
*P Z* = the co-latitude,  
*A Z* = the latitude,  
*H Æ* = the co-latitude.

It is evident, that if the value of either of these four arcs can be determined, the latitude is known.

The most ancient method of determining the latitude was by

# LATITUDE.

by means of a gnomon; in this case the mean of the greatest and least altitude of the sun was taken, which is always equal to the co-latitude, or A.H. The altitude of the equator above the horizon, and the complement of this to 90°, is the latitude of the place. See GNOMON.

We shall first give the methods of determining the latitudes of fixed observatories on shore, and then describe those which are best adapted to perform the same operation at sea.

*Method of determining the Latitude of a fixed Observatory.*—The best method of determining the latitude of a fixed observatory, is by a long series of observations of the pole-star, made with an 18-inch repeating circle of Borda. The method of adjusting and observing with this instrument has been already sufficiently explained under CIRCLE and DECLINATION. But as this instrument is not in this country in very general use, we shall suppose the observer to be in possession of an astronomical circle or quadrant, or some equivalent instrument adapted to the determination of zenith distances by meridional observations.

The latitude of an observatory may be determined with very considerable accuracy by zenith distances of the sun when near the summer solstice, as the obliquity of the ecliptic is very correctly ascertained; but the most preferable method is certainly by a regular series of observations on circumpolar stars. Polaris, and  $\beta$  Ursæ minoris, are the most eligible stars for this purpose. They should be observed continually, both above and below the pole, and all the observations carefully reduced to the first of January, of the year in which the observations are made. It is evident, that the mean of the altitudes above and below the pole, will be the altitude of the pole itself. The accuracy of the result will depend on the goodness of the instrument, the skill of the observer, and the exactness with which the necessary corrections have been applied. When the altitude of a heavenly body is taken with an astronomical instrument, the observer must first consider what correction is required from the nature and construction of the instrument itself; such as the error of collimation, or index error, error of division, &c. This being properly allowed for, the observation is next to be corrected for refraction, and here attention must be paid to the state of the barometer and thermometer, and the mean refraction corrected accordingly. The true altitude, or zenith distance, being thus ascertained, the next step is to determine what would have been the true zenith distance if the observation had been made on the first of January, instead of the given day. For this purpose we must apply the precession, aberration, solar and lunar nutation, and likewise a correction arising from the proper motion of the star whenever this can be known. By a careful discussion of a series of observations thus corrected, the latitude is to be obtained, and with a good two-foot circle a skilful observer will never err above a second or two from the truth, except from the little remaining uncertainty which still attends the subject of astronomical refractions.

In the Philosophical Transactions for 1806, Mr. Pond suggested a method of correcting the respective latitudes of any two observatories, by means of the catalogues of stars made at each of them, and applied it with success to the correction of the latitude of Palermo. The principle of the method is this: If the declinations of a number of stars are observed at two observatories, subject only to the errors of division in the respective instruments, the positive and negative errors may be naturally expected to be nearly equal to each other: if, therefore, the declinations of one catalogue should be all either greater or less than in the other, it would

indicate that the error was in the assumed latitude, which enters as a common element of calculation, and not in the observations themselves. Now if such a correction be applied to the latitude of each observatory, as will make the sum of the positive differences equal to the sum of the negative, the latitudes thus corrected will be much more accurately determined than by any method that can be practised separately.

Examples of deducing the latitude from observations of the sun; taken from the Greenwich Observations of 1810.

This method is subject to whatever error may exist in the solar tables relative to the declination of the sun. The fol-

lowing method is, therefore, preferable, and is quite independent of the errors of the solar tables.

Let the sun be observed as often as possible within ten or twelve days of each solstice, and let each observation be reduced to the solstice, either by Guerin's tables or by direct calculation. Then, after the proper correction for nutation, parallax, and error of collimation has been duly applied, let the solstitial zenith distances be added together; half their sum will be the zenith distance of the equator, or the latitude of the place.

The following example is taken from Dr. Bradley's Observations, for the purpose of determining the latitude of the Royal Observatory at Greenwich.

# LATITUDE.

Winter solstice	-	74° 56' 54.26"
Summer solstice	-	28 00 21.96
Sum	-	102 57 16.22
Half sum or latitude		51 28 38.11

By taking half the difference, the obliquity of the ecliptic is determined at the same time.

		74° 56' 54.26"
		28 00 21.96
Sum	-	46 56 32.30
Half difference or obliquity of the ecliptic for 1753	-	23 28 16.15

Notwithstanding this method appears so unobjectionable in theory, the uncertainty of refraction at the winter solstice renders it less exact than a series of observations of the pole-star, observed constantly above and below the pole.

*Example.*—The mean of 94 zenith distances of the pole-star at Greenwich above the pole, reduced to Jan. 1, 1749, is, according to Dr. Bradley's observations,

Mean of 100° below the pole		36° 29' 48.3"
		40 33 39.29
Co-lat.	-	77 2 44.12
Or latitude of Greenwich	-	38 31 22.06
And polar distance of *	-	51 28 38
		2 2 17.23

*On the method of finding the latitude at sea.*—The method of finding the latitude at sea by a meridional observation of the sun or star, differs so little from that above explained,

and is so fully described in books which mariners are never unprovided with, that scarcely any thing need be added on the subject. Some of the nicer corrections used at land may be omitted, and others will be necessary; such as the correction for the depression of the horizon, and the index error of the sextant, all which are to be found in every book of navigation. (See DEPRESSION.) The latitude may be found either by taking the meridian altitude of the sun, moon, or fixed star. But it sometimes happens that, in the winter season, a meridian altitude cannot be taken for many days together: in that case, recourse must be had to two altitudes of the sun taken at different times, the interval between the two observations being supposed to be given by a pocket chronometer.

Many able mathematicians have successfully laboured to improve this problem, and to render it easy to mariners. Mr. Professor Lax of Cambridge presented a very valuable paper on this subject to the Royal Society in 1799, in which a method is given of finding the latitude by a double observation, with extreme precision; and Dr. Brinkley likewise constructed a set of very useful tables, which were for some time annually inserted in the Nautical Almanacs.

*Problems relating to the finding the longitude and latitude of the heavenly bodies, from their observed passage over the meridian, with their zenith distance.*

We have already explained, under DECLINATION and RIGHT ASCENSION, how these quantities are obtained. We shall now add an example of the calculation, by which the longitude and latitude are deduced from an observed right ascension and declination.

*Example.*—October 2, 1811. The right ascension of the comet was obtained from observation 6<sup>h</sup> 23<sup>m</sup> 42<sup>s</sup> 13", and its declination 49° 31' 2" N.; required its longitude and latitude.

*Example.*

When the moon's longitude and latitude are to be deduced from its observed right ascension and zenith distance, the process is much longer; and as the calculation is not given at length in any author we are acquainted with, we shall add an example, with the method of comparing it with the Nautical Almanac.

First, compute the mean time by Dr. Maskelyne's folio tables, or other equivalent solar tables. To the mean time of the transit thus found, apply the equation of time taken out of the Nautical Almanac with a contrary sign, and this will be true or apparent solar time. From the moon's horizontal equatorial parallax, taken from the Nautical Almanac, subtract the correction, page 75 of Mayer's Lunar Tables, (or, still more correctly, a quantity which will be given in a table we propose to annex to the article PARALLAX,) the remainder will be the moon's horizontal parallax. From the observed zenith distance of the  $\mathcal{D}$ 's U L or L L corrected for refraction, subtract the constant quantity  $10' 3''$ , which is the angle the vertical makes with the radius, (see DEGREE and Figure of the EARTH,) and add the log. sine of remainder to the log. sine of  $\mathcal{D}$ 's horizontal parallax, the sum will be the log. sine of  $\mathcal{D}$ 's parallax in zenith distance; which subtracted from the observed zenith distance, gives the corrected zenith distance. To this add  $\mathcal{D}$ 's horizontal semidiameter, (taken from Nautical Almanac,) if U L was observed; or subtract, if L L; and thus the correct zenith distance of the  $\mathcal{D}$ 's centre will be obtained. The difference of this quantity, and the latitude of the place,  $\pm$  error of collimation, will give the required declination north or south, as the first is greater or less than the second.

But if the  $\mathcal{D}$ 's zenith distance was not observed exactly at the time of the transit of the preceding or subsequent enlightened limb, this declination must be corrected by the following proportion

As 12 hours is to the interval of time between the two observations, so is the variation of declination on 12 hours by the ephemeris to the correction required, and which must be thus applied:

$\mathcal{D}$ 's zenith distance observed before transit of limb,	{	$\mathcal{D}$ 's declination increasing, add. $\mathcal{D}$ 's declination decreasing, subtract.
$\mathcal{D}$ 's zenith distance observed after transit of limb,	{	$\mathcal{D}$ 's declination increasing, subtract. $\mathcal{D}$ 's declination decreasing, add.

Thus the true declination will be obtained from observation.

From log. sine of  $\mathcal{D}$ 's horizontal semidiameter, subtract log. cosine of  $\mathcal{D}$ 's true declination, the remainder will be log. sine of  $\mathcal{D}$ 's semidiameter in A. R., which add, if preceding limb was observed, namely, before the full; or subtract, if  $\mathcal{D}$ 's subsequent limb was observed after the full, to or from A. R. of limb; and this will give the true A. R. of  $\mathcal{D}$ 's centre.

Next with the apparent time previously found, compute the  $\mathcal{D}$ 's longitude and latitude by proportion from the Nautical Almanac, and apply the corrections for a second difference (from Taylor's Sexagesimal Tables). N. B. Compute the proportional part of the moon's motions in longitude doubly by the rule of practice, by changing the second and third terms of the proportion for each other, for greater certainty.

Then from the true A. R. and declination found above, and the apparent obliquity of the ecliptic, compute the longitude and latitude by Dr. Maskelyne's rules, annexed to the precepts prefixed to Taylor's Logarithms, and the difference between this and the longitude and latitude, found as above by proportioning from the Nautical Almanac,

gives

# LATITUDE.

gives the error of the tables. N. B. Compute the longitude and latitude from A. R. and declination assumed to the nearest second over or under; and after the operation, correct it, that is, as much as the true A. R. exceeds or falls

short of that found. And as much as the true declination is north or south of that assumed, so much the true latitude may be north or south of that found; which correct accordingly.

Example of the calculation of the moon's longitude and latitude, January 6, 1811, and compared with the Nautical Almanac.

*On the secular variation in Longitude and Latitude of the fixed stars.*

We have already explained, under ECLIPTIC, the cause of the change of position in this circle, which produces a secular variation both in the longitude and latitude of the fixed stars. The following table by M. Zach is intended to facilitate the calculation of this quantity, and has not yet been published in this country.

The formulæ used for the construction of these tables are, Sec. var. north lat = 52".6318 fin. (long \* + 8 53' 13') Sec. diminut. in long. 52".6318 cof. (long \* + 8 53' 13') tang. lat. \*. See PRECESSION.

*Examples of the use of the following tables.*

Let it be required to find the secular variation in latitude and longitude of Aldebaran for 1700—1800.

## LATITUDE.

The long. of Aldebaran for 1750 =  $2^{\circ} 6' 16''$   
 Latitude fourth - - - - -  $5' 29'' 16''$   
 Var. in lat. by Table III. for  $2^{\circ} 6'$  +  $50.812$   
 Prop. part for 18' - - - - - +  $0.070$   

---

 Sum - - - - -  $50.882$

Arg. lat.  $5^{\circ} 29' 16''$ , Table I. — angle  $\alpha = 2^{\circ} 29' 27'' 0''$ .  
 This will give two arguments with which enter Tab. IV.  
 Arg. I. =  $2^{\circ} 6' 18' + 2^{\circ} 29' 27' = 5^{\circ} 5' 45' = + 253.75$   
 Arg. II. =  $2 6 18 - 2 29 27 = 11 6 51 = - 255.04$   

---

 —  $1.29$

But the latitude being fourth, the sign must be changed: the secular diminution of latitude is therefore  $-50''.882$ .

To find the secular variation in longitude.—First find the subsidiary angle  $\alpha$ .

Since the latitude is fourth, the sign must be changed: therefore the secular increase of longitude of Aldebaran is  $1''.29$ .

### Auxiliary Angle $\alpha$ for calculating the secular Variation in Longitude.

Arg. Lat.	Angle $\alpha$ + 11 $^{\circ}$	Diff.	Arg. Lat.	Angle $\alpha$ + 11 $^{\circ}$	Diff.	Arg. Lat.	Angle $\alpha$ + 11 $^{\circ}$	Diff.

Deg.	+ VI	+ VII	+ VIII	- IX	- X	- XI	Deg.

The sum or difference of the two quantities taken from this table by the two arguments, will be the secular variation in longitude, which, when the auxiliary angle  $\beta$  is used, is to be multiplied by 10.

**LATITUDE of a Planet**, is an angle, as PTR (*Platz XVI Astronomy, fig. 148.*) under which a planet's distance from the ecliptic PR is seen on the earth.

The sun never has any latitude, but the planets have; for which reason, in the common sphere, the zodiac has some breadth. The ancients only allowed six degrees on each side the ecliptic, but the moderns have extended it to nine.

When they have no latitude, they are said to be in the nodes of the ecliptic, or in the intersection of their orbit with that of the sun; and in this situation it is that they eclipse, or are eclipsed by, the sun.

**LATITUDE, Circle of**, is a great circle, MST *m*, passing through the poles of the ecliptic. See **CIRCLE**.

**LATITUDE of the Moon, north ascending**, is when she proceeds from the ascending node towards her northern limit, or greatest elongation.

**LATITUDE, North descending**, is when the moon returns from her northern limit to the descending node.

**LATITUDE, South descending**, is when she proceeds from the descending node to her southern limit.

**LATITUDE, South ascending**, is when she returns from her southern limit to her ascending node.

And the same holds good of the other planets. See **ASCENDING and DESCENDING**.

**LATITUDE, Heliocentric, of a Planet**, is its distance from the ecliptic, such as it is seen from the sun.

This, when the planet comes to the same point of its orbit, is always the same, and unchangeable.

**LATITUDE, Geocentric, of a Planet**, is the distance from the planet from the ecliptic, as it is seen from the earth.

This, though the planet be in the same point of its orbit, yet is not constantly the same, but alters according to the position of the earth, in respect to the planet. See **HELIOCENTRIC, and GEOCENTRIC**.

Dr. Halley has some considerations, in the Philosophical Transactions, which make it probable, the latitudes of some of the principal fixed stars, particularly *Polaris*, *Sirius*, and *Arcturus*, alter in time; whence it may be argued, the rest likewise alter, though the variation may be less conspicuous in these, because they are supposed at a greater distance from us. See **STARS**.

**LATITUDE, Difference of**, is an arc of the meridian, or the least distance of the parallels of latitude of two places; and it is found when these have the same name; by subtracting the lesser latitude from the greater; and when they have contrary names, by adding them together.

**LATITUDE, Parallax of**. See **PARALLAX**.

**LATITUDE, Refraction of**. See **REFRACTION**.

**LATITUDINARIAN**, among *Divines*, denotes a person of moderation, with regard to religious opinions, who believes there is a latitude in the road to heaven, which may admit people of different persuasions. This name was given by way of distinction to those excellent persons in England, who, about the middle and towards the close of the 17th century, endeavoured to allay the contests that prevailed between the more violent Episcopals on the one hand, and the more rigid Presbyterians and Independents on the other, with respect to the forms of church government and public worship; and also between the Arminians and Calvinists, with respect to certain religious tenets. Many of them were zealously attached to the forms of ecclesiastical government and worship that were established in the church of England, and they recommended episcopacy with all their eloquence; but they did not consider it as of divine institution, and absolutely necessary to the constitution of a Christian church; and therefore they maintained that those who followed other forms of government and worship were not, on that account,

to be excluded from their communion, or to forfeit the title of brethren. Others had no great liking for the liturgy or ceremonies, or, indeed, the government of this church, but yet, for the sake of peace and order, conformed. As to the doctrinal part of religion, they took the system of the famous Episcopius for their model, and, like him, reduced the fundamental doctrines of Christianity, *i. e.* those doctrines, the belief of which is necessary to salvation, to a few points. By this manner of proceeding they shewed that neither the Episcopals, who, generally speaking, embraced the sentiments of the Arminians, nor the Presbyterians and Independents, who as generally adopted the doctrine of Calvin, had any reason to oppose each other with such bitterness and animosity, since the subjects of their debate were matters of indifference with respect to salvation, and might be variously explained and understood, without any prejudice to their eternal interests.

The chief leaders of these Latitudinarians were Hales and Chillingworth: to them may be added the respectable names of More, Cudworth, Gale, Whitcomb, Wilkins, and Tillotson. The first fruits of their charitable zeal were the odious appellations of *Atheists*, *Deists*, and *Socinians*, liberally bestowed upon them by the Roman Catholics, and the more rigid of the Protestant contending parties. However, they were afterwards raised to the first dignities of the church, and deservedly held in general esteem. And at this time the church of England is chiefly governed by Latitudinarians of this kind; and the spirit of moderation and mutual charity has generally prevailed, with that of liberal enquiry, among the various sects and denominations of Christians. Mosheim's *Ecl. Hist.* vol. iv. and Birch's *Life of Tillotson*, p. 407. See **COMPREHENSION**.

**LATIUM**, in *Ancient Geography*, a considerable division of Italy, which acquired importance from its having given name to the Latins, and from its having Rome for its capital. Some authors have thought that this was a denomination given to the whole of Italy, or at least to a more considerable extent of territory, than that to which it was afterwards restrained. Several of the ancients have sought the etymology of Latium, in the verb *latere*, to conceal, and they have imagined that this name was given to the country, because Saturn retired thither in order to shelter himself from the fury of his children. M. Gêbelin, in his *Oriental Allegories*, suggests, that the primitive *lat* signifies to conceal, and that *terra alio* alludes to the application of the soil, for the concealment of the seed that was sown in it. Hence, he says, Latium might have signified the country where seed was sown, in contradistinction to that part which was mountainous and uncultivated. The ancients distinguished Latium into ancient and modern, and under these appellations it comprehended different territories. Ancient Latium extended from the Tiber to Circeii, and was estimated at 50 miles in length. Its inhabitants, in succession, were the Aborigenes, the Pelasgi, the Arcades, the Siculi, the Arunci, and the Rutuli; and besides these, the Circeii, the Volsci, the Osci, and the Ausones; and by degrees the name Latium extended as far as the river Liris. At the first, says Strabo, the Latins had possession of it, and were not subject to the Romans; but when these had vanquished the Æqui, Volsci, and Hernici, as well as the Rutuli, the Aborigenes, the Roeci, and the Argyrucii, and also the Privenates; the whole country, thus subdued, assumed the name of Latium; and it afterwards extended to Campania, and the country of the Samites. Among the original inhabitants we may reckon the Siculi; and it was afterwards occupied by various tribes, which migrated thither at different periods; being at this time an inconsiderable territory.

tory, along the coast of the Tuscan sea, south of the Tiber. Under the Latin kings, it extended southward to the Promontorium Circæum, as we have already stated, which was 50 miles beyond the Tiber. Under the consular government, the territories of the *Æqui*, *Volsci*, and *Hernici*, were annexed to this province, and the river *Liris* (Gari-gliano) was held to be the southern boundary. At the commencement of the Christian era, *Sinuccia*, now *Sinope*, and the circumjacent territory noted for its baths, were included in *Latium*; so that, in its greatest extent, it comprehended *Campagna di Romagna*, and a considerable part of *Terra di Lavoro*. The principal rivers in this province were the *Tiber* and *Liris*; which see respectively. The chief cities and towns were *Rome*, *Osia*, *Laurentum*, *Lavinium*, *Ardea*, *Tibar* or *Tivoli*, *Tusculum* or *Frescati*, *Gabii*, now extinct, between *Rome* and *Præneste*, *Præneste*, *Alba Longa* or *Albano*, *Aricia* near *Alba Longa*, on the *Apennian* way, &c. See *ITALY*.

**LATMOS**, or **LATMUS**, a mountain of *Asia Minor*, partly in *Ionian* and partly in *Caria*.

**LATMUS**, originally a village of *Asia*, in *Cilicia*, on the banks of a river of the same name, which afterwards became an episcopal town of *Iliaria*. The river had its source in mount *Latmus*, and discharged itself into the *Latic* gulf, near the town *Heraclea*. The *Latic* gulf was a gulf of *Ionian*, which commenced between the mountains *Latmus* and *Grius*, and extended from thence towards the N.W., communicating with another gulf at the mouth of the *Meander*—Also, a small island situated to the S.E. of the *Latic* gulf, near to and W.N.W. of *Heraclea*.

**LATOAN**, in *Geography*, a small island in the East Indian sea, near the N. coast of *Borneo*. N. lat. 7° 16'. E. long. 117° 21'.

**LATOMIA**, Λατομια, derived from the Greek λατ, *flans*, and τμια, *I cut*, properly signifies a quarry, or place where stones are dug. See *QUARRY*.

These were anciently used as goals for criminals. *Dionysius* had a place of this kind dug in a rock near *Syracuse*, where an infinite number of people were shut up. *Cicero* reproaches *Verres* with imprisoning Roman citizens in *latomia*; so that *latomia* became a general name for a prison; so the prisoners inclosed in them were called *latomarii*.

**LATOMIA**, in *Ancient Geography*, the name of six small islands in the Arabian gulf, according to *Strabo*.

**LATONA**, a town of *Egypt*, upon the Nile, which was the capital of a nome called the *Nomos Latopolites*. *Ptolemy*.

**LATONA**, in *Mythology*, a goddess of paganism, whose history is very obscure. *Hesiod* makes her the daughter of *Titan Cœus* and *Phebe*, his sister. The fable adds, that *Apollo* and *Diana* were her offspring by *Jupiter*, and that they advanced her to the rank of celestial deities in spite of *Juno*. According to *Herodotus*, she was an Egyptian deity, the nurse, and not, as the Greeks represented her, the mother of *Apollo* and *Diana*, and was worshipped at *Buto*, or *Buthos*, in *Egypt*. The inhabitants of *Delos* erected a temple for her, pretending that *Neptune*, with a blow of his trident, had made the island of *Delos* to rise up from the bottom of the sea, to secure to *Latona*, persecuted by *Juno*, a place where she might, without molestation, bring forth her children: but that at *Argos* was the most magnificent, and celebrated for her statue, executed by *Praxiteles*. *Latona*, *Venus*, and *Diana*, were the three goddesses most in veneration among the Roman women.

**LATOPOLIS**, in *Ancient Geography*. See *ESNEH*.

**LATOPOLITES NOMOS**, a district of *Egypt*, the capital of which was dedicated to *Latona*, and situated on

the left of the Nile. This nome is mentioned both by *Strabo* and *Pliny*.

**LATOPOLITES NOMOS**, or *Hermionites Nomos*, another district of *Egypt*, the capital of which was called the town of "Latonium," according to *Ptolemy*.

**LATORCZA**, in *Geography*, a river of *Hungary*, which rises near the *Carpathian mountains*, and runs into the *Theiss*, near *Tokay*.

**LATOCHE'S ISLAND**, an island in the North Pacific ocean, at the entrance of *Prince William's sound*, 13 miles long and three broad. N. lat. 60. E. long. 212° 30'.

**LATOVICLI**, in *Ancient Geography*, a people of Upper *Pannonia*.

**LATOUCR**, in *Geography*, a town of *Hindooostan*, in the circuit of *Aurangabad*; 25 miles W. of *Aurangabad*.

**LATOWIC**, a town of the duchy of *Warsaw*; 18 miles E. of *Czerlik*.

**LATRIA**, Λατρία, in *Theology*, a religious worship, due only to *God*.

The *Romanists* say, "They honour *God* with the worship of *latria*; and the saints with the worship of *dulia*;" but the terms, however distinct, are usually confounded.

The worship of *latria*, besides its inner characters, has its external marks to distinguish it; the principal whereof is sacrifice, which cannot be offered to any other but *God* himself, as being a solemn acknowledgment, or recognition, of the sovereignty of *God*, and our dependence on him.

*M. Dailé* seems to own, that some of the fathers of the fourth century allowed the distinction between *latria* and *dulia*. See *ADORATION* and *WORSHIP*.

**LATRIS**, in *Ancient Geography*, a town of *Germany*, at the mouth of the *Vistula*. *Pliny*.

**LATRONICA**, in *Geography*, a town of *Naples*, in *Basilicata*; 22 miles S.W. of *Turi*.

**LATSCHACH**, a town of the duchy of *Carinthia*; 14 miles S.W. of *Clagenfurt*.

**LATTANZIO**, *GAMBARA*, in *Biography*, a painter of history and portraits. He was the son of a taylor at *Cremona*; but being more inclined to painting than the use of the needle, he spent his youthful days in covering the walls and furniture of his father's house with drawings in charcoal, and thus drew upon himself the displeasure of his parents; who evinced their dissatisfaction by the unequivocal testimony of the scourge.

*Giulio Campo*, an artist of some celebrity, residing at *Cremona*, happened one day to pass by when the taylor was exerting his energies upon the back of his self-willed son *Lattanzio*; hearing the cause, he took the boy home with him, and for six years assisted and encouraged him in his pursuit of the art of painting. Such was the success accompanying this act of generosity, that according to *Vasari*, *Gambara* became the best painter of his time in *Brescia*, where he took up his residence; and where many ingenious artists practised painting in conjunction or competition with him.

His principal works are in fresco, and some are still to be seen at *Brescia*, particularly the cloister of *Santa Euphemia*, wherein he painted a series of scriptural and evangelical subjects. *Venice*, *Parma*, and *Cremona* all possess testimonials of his skill, which adorn their churches and many of their private houses. His style is very much like that of *Pordecone*, an attempt to unite the colour of the Venetian with the drawing and design of the Florentine school, but it is not so powerful. He married a daughter of *Romanno*, but died at the early age of 33, by a fall from a scaffold while painting

painting in the church of St. Lorenzo in Brescia, about the year 1570. Ridolfi. Vafari.

LATTIMO, in the *Gloss Trade*, a name for a fine milk-white glass. There are several ways of making it, but the best of all is this: Take four hundred weight of crystal frit, and sixty pounds of calcined tin, and two pounds and a half of prepared manganese; mix these well with the frit, and fet them in a pot in a furnace to melt and refine. At the end of eighteen hours this will be purified; then cast it into water, purify it again afterwards in the furnace, and make a proof of it. If it be too clear, add fifteen pounds more of calcined tin; mix it well with the metal, and let it stand one day to purify; it will then be of a whiteness surpassing even that of snow, and is fit to work into vessels. Neri's Art. of Glass, p. 98. See GLASS.

LATTIN, or LATTEX, a name by which we used to call the plates of iron covered with tin, and now usually called *tin*, of which our mugs, and such other things, are made. The principal part of the work is to prepare the leaves, beat out to a proper thinness, so as that they shall readily receive the tin; for if there be but the smallest particle of dust on them, or only the slightest rust in any part, the tin will never fix there.

This smoothing of the plates is effected by steeping them in acid water, till the surface is a little preyed upon by it, and then they are scowered with sand, which makes them very smooth and fine. By this means a woman cleans more plates in an hour, than the most expert workman can do otherwise in many days. M. Reaumur, to whom the world owes the discovery of this process, mentions several waters, any one of which will succeed, but the Germans themselves use nothing but common water, made eager with rye. This they make a great secret of, but the preparation is very easy. After they have ground the rye grossly, they leave it to ferment in common water for some time; and they are thus sure of a sharp and eager menstrum, excellently fitted for their purpose. With this liquor they fill certain troughs, or tuns, and into these they put several bundles of the plates of iron: and to make the liquor more eager, and to act the better on them, they keep it in stoves, where it has little air, and is kept warm with small charcoal fires.

There are several other ways of making iron rust, as keeping it in a moist cellar, exposing it to the dew, sprinkling it with simple water, or, which is still better, with water in which sal ammoniac has been dissolved, several times a day: and in those countries where the pyrites is common, the vitriolic waters, which partake of it, will do it very well. This water may be prepared at little or no expence, only by heaping up large quantities of the pyrites, and letting it moulder in the air, then putting it into common water, and making a lixivium of it. Whichever method of rusting the plates be used, it is always necessary to scower them with sand as soon as it is done; and when they are thus cleaned, they must be immediately plunged into water, to prevent their rusting again, and they are to be left in this water till the instant in which they are to be tinned, or, in the language of the workmen, *blanched*. The people employed in this part of the operation are called *blanchers*; and the others, who assist at the cleaning of the plates, the *scalers*. The blancher makes as great a secret of his art, as the scaler does of his; and it was with great difficulty that M. Reaumur obtained it. The manner of doing it is this:

They flux the tin in a large iron crucible, which has the figure of an oblong pyramid with four faces, of which two opposite ones are taller than the two others. The crucible is heated only from below, its upper part being luted with the furnace all round. The crucible is always deeper than the

plates, which are to be tinned, are long; they always put them in downright, and the tin ought to swim over them. To this purpose artificers of different trades prepare plates of different shapes, but M. Reaumur thinks them all exceptionable. But the Germans use no sort of preparation of the iron, to make it receive the tin, more than the keeping it always steeped in water till the time; only when the tin is melted in the crucible, they cover it with a layer of a sort of suet, which is usually two inches thick, and the plate must pass through this before it can come to the melted tin. The first use of this covering is to keep the tin from burning; as if any part should take fire, the suet would soon moisten it, and reduce it to its primitive state again. The blanchers say, this suet is a compounded matter. It is indeed of a black colour, but M. Reaumur supposed that to be only an artifice to make it a secret, and that it is only coloured with soot, or the smoke of a chimney; but he found it true so far, that the common unprepared suet was not sufficient; for after several attempts, there was always something wanting to render the success of the operation certain. The whole secret of blanching, therefore, was found to lie in the preparation of this suet; and this he at length discovered to consist only in the first frying and burning it. This simple operation not only gives it the colour, but puts it into a condition to give the iron a disposition to be tinned, which it does surprisingly.

The melted tin must also have a certain degree of heat, for if it is not hot enough, it will not stick to the iron; and if it is too hot, it will cover it with too thin a coat, and the plates will have several colours, as red, blue, and purple; and upon the whole will have a cast of yellow. To prevent this, by knowing when the fire has a proper degree of heat, they might try with small pieces of iron; but, in general, use teaches them to know the degree, and they put in the iron when the tin is at a different standard of heat, according as they would give it a thicker or thinner coat. Sometimes also they give the plates a double layer, as they would have them very thickly covered. This they do by dipping them into the tin, when very hot, the first time, and when less hot, the second. The tin, which is to give the second coat, must be fresh covered with suet, and that with the common suet, not the prepared. Philos. Trans. N<sup>o</sup> 466, p. 634. See TIN.

LATTYPOUR, in *Geography*, a town of Bengal; 20 miles N. of Kithenagur.

LATUS, in *Ichthyology*, the name of a fish of the coracinus, or umbra kind, caught in the Nile, and in the Adriatic and Mediterranean seas. It much resembles the common coracinus, but is larger, and has not the beard which hangs from the chin in that species; and its body is somewhat rounder. It is esteemed a very delicate dish. Rondelet. de Pisc. p. 130.

LATUS, in *Anatomy*, a name given by many authors to one of the muscles of the anus, now generally called the levator ani.

LATUS Rectum, in *Conics*, the same with parameter. See CONIC Sections, and PARAMETER.

LATUS Transversum of the hyperbola, is a right line, intercepted between the vertices of the two opposite sections; or that part of the common axis which is between the vertices of the upper and lower cone. See HYPERBOLA.

LATZKI, in *Geography*, a town of Aultrian Poland, in Galicia; 80 miles W.S.W. of Lemberg.

LAVA. This word, in its strict sense, denotes only the fused stony substance which issues from volcanoes during the time of their activity, and according to the degree of fluidity it has acquired, and the quantity in which it is discharged,

charged, either collects near the crater in amorphous groups, or extends its course to various distances. But much greater latitude (as we shall see hereafter) has been given to the term *lava* by several authors, for not only other volcanic ejections, to which the above definition cannot be applied, have been described under that name, but even such unaltered rocks as will be allowed by unbiassed observers to have scarcely any one character in common with real volcanic productions.

Werner has divided lava into two varieties only; viz. 1. Scorious or slaggy lava (*Schlackige Lava*), and 2. Foamy lava (*Schaumige Lava*.)

The colour of the *scorious lava* is greyish-black, which passes into smoke-grey, yellowish-grey, reddish-grey, greenish-grey, and through several shades of this into greenish-black. Decomposition, sulphuric and other vapours, frequently modify the principal colours, and often produce the lighter tints of yellow.

It occurs more or less knotty and vesicular, with vesicles of different size, sometimes glazed over, and empty. Internal lustre between glimmering and glistening, seldom shining. Fracture imperfectly conchoidal, also fine-grained, uneven. Is commonly opaque, sometimes faintly translucent on the edges. It is semi-hard, brittle, easily frangible, and not particularly heavy.

The colour of the *foamy lava* is generally dark greenish-grey, approaching to greenish-black. Its vesicular structure, brittleness, and lightness are indicated by its name.

This the Wernerian school carefully distinguishes from *pumice*; which see.

Lava is often porphyritic, but the crystals of hornblende, augite, &c. are, according to Werner, wrapped up, not imbedded, in its basis; and when they occur in the hollows or vesicles of lava, are not in the form of druses, but generally part of the crystals projects into the cavity, while the other is included in the lava.

Though the Neptunists profess to find characters sufficiently obvious to distinguish lava from unaltered rocks that might be mistaken for it, such as the rough aspect which it presents both internally and externally, &c.; yet their decision in dubious cases is known to be chiefly regulated by the mode of occurrence of the rock; and substances, that present regular strata, not seldom of very considerable extent and comparative thickness, and frequently conformable to all the sinuosities of the older formations, can never be expected to find a place in their catalogue of volcanic productions.

The question, whether lava ever occurs in a *compact* state, involves the various controversies with regard to the origin of basalt, which will be treated of at large in its proper place. But as it is necessary in this article briefly to advert to the reasons that have induced Werner, and other Neptunists, to exclude compact lava from their systems, we shall extract the excellent observations given on this subject by Mr. Kirwan, in the second appendix to his *Mineralogy*.

“By compact lava,” says this distinguished mineralogist, “volcanic writers denote an earthy substance, which, after having been fused, but not vitrified, becomes, on cooling, compact, close, and solid. Whether this degree of solidity is such as *totally* to exclude that evidently porous and cavernous structure, which cellular lava presents, is not perfectly agreed upon.

“Those who are guided by observation on modern and undisputed volcanic torrents, allow that no lava, absolutely compact and destitute of pores, in an extent of more than

a few square inches, is ever found. Thus Mr. Bergman defines compact lavas to be “those which, though not absolutely destitute of cavities, yet contain so few, that they may be cut into slabs with an almost entire surface, and polished like marble.” (3 *Bergin*. p. 201.) To this definition, Mr. Dolomieu, in his notes on Bergman’s Dissertation, makes no objection; from which we may conclude, that in a small extent, such as that of common marble slabs, they never exhibit an uninterrupted surface. This last mentioned philosopher, indeed, having unfortunately wished to comprehend, in his definition of compact lava, stony masses, not found in modern and undisputed beds of lava, but in *supposed* ancient currents, found himself much embarrassed: There is, says he, such uncertainty in the characters of compact lava, that, independently of local circumstances, the most experienced eye may be deceived. (Iles Poncez, p. 171.) Yet these circumstances, not properly attended to, are those which have seduced him into the most palpable mistakes.

“Gioeni, though in many instances misled by Dolomieu, yet acknowledges that lava, so compact as to be totally destitute of pores, is not found. (Lithol. Vefuv. p. 85). Padre Torre, who, independently of any system, has candidly and impartially examined the products of Vesuvius, expressly denies the existence of lava destitute of pores, none other but the porous being found in currents of modern date. Galeani, in his catalogue of the lavas of Vesuvius, drawn up in 1772, hardly mentions any compact lavas. Gioeni, in his catalogue, entirely omits this distinction; and Mr. Dolomieu acknowledges that not a single specimen of compact lava is to be found in the cabinet of prince Biscari.

“Those, on the other hand, who, guided by system, bestow the name of lava on stony masses, which they *suppose* to have anciently flowed, either from real still subsisting, or imaginary ancient extinct, volcanoes, find *compact* lava entirely destitute of pores, very scarce indeed in the *supposed* currents from modern, but in *great plenty* in those which they ascribe to their fictitious volcanoes now extinct, as well as in the very bowels of those volcanoes.

“Gioeni, after telling us, from Dolomieu, that compact lava occupies the centre of the beds of lava, and porous lava the upper part, acknowledges that this gradation seldom takes place; a few, however, says he, are the visible currents of lava on Vesuvius, in which we meet this gradation.” It seems, he should rather have said, none; for, some lines after, he tells us, that modern volcanoes have lost the power of producing any. (Lith. Vefuv. xlvii.) The detached masses that pass for compact lava, he acknowledges to have been ejected in their solid form by the explosive power of the volcano, and consequently are not real lavas, but rather natural stones, torn from the sides of the mountain. (Lith. Vefuv. li.) Mr. Dolomieu tells us, that compact lavas are stones which, after having been melted, re-assume their natural state and appearance without any change in their external or internal properties, or scarce any change; and that some are perfectly compact (that is, destitute of pores), namely, those that are buried under, not other lavas, but under an entire and immense volcano (De Prod. Volcan. p. 162. Poncez. 170. 179.) ; he, therefore, gives up the idea of finding these not only in the *beds* of modern, but even in those of extinct ancient volcanoes. Hence he tells us, that they are much more common in extinct volcanoes; and that in *Ætna* they do not constitute the  $\frac{1}{10}$  part of the whole; whereas in Vivarais and Auvergne they form whole mountains. Now most of these ancient volcanoes of the Vivarais appear to me and many others, to be mere creatures of imagination, and consequently, until the substances they contain are proved to have been in fusion, no definition, grounded on the appearance

ances of these substances, can pass for that of real compact lava.

"In beds, however, of real undisputed lava, some parts are found, that, having been pressed by the super-incumbent weight, are more compact than common porous lava; and these, comparatively to the former, may be called compact; but scarcely more than a few square inches of their substance is destitute of visible pores.

"Their colour is brown, yellowish, reddish brown, bluish, or black, more rarely grey. Their lustre *o. 1*. Transparency *o. 1*. Their fracture earthy, or fine splintery, more rarely foliated, and presents small internal pores, if of sufficient size, in some part of the substance. Hardness from 7 to 9. Specific gravity 2.75 to 2.88.

"Much circumspection is requisite in framing a description of compact lava, from a view of the specimens brought to us from volcanic countries, as they are all collected by persons, who take indiscriminately from real, and from supposed, volcanic currents, even from mountains in which no volcano ever existed.

"To form a true idea of these lavas we should attend to the following circumstances; 1. That the heat of most volcanoes (I exclude those that for the most part produce only vitrified substances) seldom reaches 100° of Wedgwood; the proof of which is, that almost all real lavas, whether cellular or compact, are vitrifiable at that degree. Since, therefore, they were not vitrified in the volcano, it is plain, that in it they did not attain that degree; 90 or 95 degrees may then be assumed as the average heat of most volcanoes. 2. In this heat many stones of the argillaceous genus, as trapps, hornblendes, and argillites, undergo a change; for they alter their colour, become porous, assume a porcelan grain, and consequently begin to vitrify, as I have found on repeated trials; but they never flow in this heat, nor consequently form a lava; but bitumen will flow in this heat, and even in one much inferior, and be decomposed. If, therefore, the argillaceous stones be mixed with and drenched in bitumen, they will be softened by it, and flow with it; and where the air, erupting both from them and the decomposing bitumen has most liberty to escape, it will tumify, burst through the liquid mass, and form cellular lava; but, where it is more compressed, less of it will be disengaged, and the lava will be compact, and resemble, in some degree, the original stone of which it is formed. 3. Stones of the siliceous genus undergo no change in this heat, nor even shorls or feldspar; and hence, though immersed in the fiery torrent, they cannot with propriety be called lavas, as they are not even softened by the mixture of bitumen, as stones of the argillaceous genus are.

"Between siliceous and argillaceous stones there are many gradations and various mixtures, which must occasion corresponding varieties in the effects which heat and various other circumstances may produce. It is sufficient here to establish the principles on which most of them may be explained. Compact lavas abound in heterogeneous substances which either have not been fused, or only partially fused or scorched, or decomposed by heat, as feldspar, shorls, garnets, zeolites, &c. Every volcano has some that are peculiar to it. Thus the lavas of Vesuvius abound in that called white garnet, and which I call Vesuvian, those of *Ætna* abound in feldspar, &c.

"Hence we must exclude from the rank of lavas all stones which do not appear, either from their external characters or local circumstances, ever to have been softened by heat; and consequently, all those detached pieces which are ejected at the beginning of an eruption without fusion, and many others which volcanic collectors enumerate among compact

lavas, merely from having found them in the vicinity of volcanoes. Thus Mr. Dolomieu (Lipari, p. 85.) reckons among volcanic stones one, in the interior of which he distinctly perceived a leaf of sea-weed. Few indeed are the stones contained in his catalogue which can be deemed really volcanic.

"All real lavas, except those of the vitreous kind, affect the magnetic needle, unless the iron they contain be much oxygenated, as it often is in those of a red colour; but even these are frequently magnetic by reason of the shorls embodied in them.

"The component ingredients of lavas are various, according to the nature of the original stones, and the accidents they meet with in their liquified state. Mr. Dolomieu found them to contain from 40 to 60 per ct. of silica, from 16 to 3 of magnesia, from 5 to 1 of calx, and from 2 to 25 of iron." Poncep, p. 184.

"Though the above, and several other remarks of the same tendency, which will be noticed under the articles TRAPP-FORMATION and VOLCANO, have much contributed to invalidate the testimony of those who contend for the existence of compact lava, and the igneous origin of many other substances apparently Neptunian, yet volcanists continue to classify over and over again those substances which they consider as belonging to their domain; and it is necessary to be acquainted as well with their mode of viewing the subject as with that of the opposite party. It is with this view that we give the following abstract of the most complete arrangement of, so called, volcanic rocks hitherto offered to the world, namely, that of the celebrated Faujas de Saint-Fon, which occupies nearly a whole volume of his "Essai de Géologie," published at Paris in 1809. It is almost superfluous to observe that this arrangement should be consulted *cum grano saltu*; as of course almost all the rocks belonging to the felsit-trapp formation of Werner are introduced into it, as well as other substances, which, although ejected, have probably not undergone any alteration by the agency of the fire, and are therefore to be considered as intruders into an arrangement of lavas.

CLASS I. *Lavas considered with regard to their form and external modifications.*

*Div. 1. Black, homogeneous, massive, compact lava.*—

1. Fine-grained; from Otaheite, Staffa, the neighbourhood of Rome, Darmstadt, the Euganean mountains, Auvergne, &c. 2. *Var.* of a coarse grain, from Meiffner, the vicinity of Göttingen, Hesse Cassel, Rochemaure in Vivarais, &c. 3. *Var.* of a scaly texture; from Stolpe in Meissen, the isle of Bourbon, Mont Meffin in Vivarais, &c.

*Div. 2. Homogeneous compact lava in prisms, with three to nine sides (the latter rare).—*1. Prisms without joints; Staffa, Expally in Vivarais. 2. *Var.* with prisms transversely divided or jointed; at the Pont de la Beaume in Vivarais, &c. 3. *Var.* with jointed prisms, joints concave at one side and convex at the other; Giant's Cauldway, Ireland, left bank of the Volane, &c. 4. *Var.* with prisms laterally compressed; Rochemaure in Vivarais. 5. *Var.* with arched prisms; Staffa, isle of Bourbon.

*Div. 3. Prismatic lava, with edges and planes so regular as to appear the result of crystallization.*—In pyramids of four sides, flattened, &c.; in Auvergne, &c.

*Div. 4. Tabular lava.*—1. *Var.* in thick tables; from Monts Meffin, Coneron, &c. in Vivarais. 2. *Var.* in thin tables; Rochemaure in Vivarais, isle of France, isle of Bourbon.

*Div. 5. Globular lava.*—1. *Var.* in solid balls; from Teneriffe. 2. *Var.* in hollow balls; isle of Bourbon. 3. *Var.* in balls composed of concentric layers; from Vesuvius, Castel-

Castel-Gombeto near Vicenza, Montechio Precalcino, &c. These lavas are the result of a particular kind of decomposition, which takes place in extensive beds of compact basaltic lavas, in which they appear as if implanted. Some globular lavas owe their origin to the joints of basaltic pillars, whose angles and edges decay, while the nucleus remains found, and appears to issue from the prism.

*Div. 6. Tear-shaped lava (lavas en larmes).*—Small oblong masses, imitating more or less the form of tears. They occur from the size of a hazel-nut to that of an egg, often enclosing within their centre the fragment of a foreign body, such as granite, olivine, &c. Found on Vesuvius, in the crater of Mont-Brül, in Vivarais, Auvergne, &c.

#### CLASS II. Porous lava.

*Div. 1. Heavy porous lava.*—1. *Var.* with large oblong pores; from Vesuvius, Etna, Hecla, Vivarais, Auvergne, &c. 2. *Var.* with large irregular pores; in all the above places. 3. *Var.* with pores less large, and generally round; in a partly porous, partly compact lava; from the Meissner in Hesse. 4. *Var.* with small, round, and oblong pores; in a lava remarkable on account of its hollows or depressions, which exhibit a regular structure, and, on being broken, convey the idea of parallelograms of different sizes, arranged side by side, as well externally as on the internal surface of the lava: some of these parallelograms are more than an inch long, and the fourth part of an inch deep. The origin of this lava, which occurs in the isle of Bourbon, is thus explained by M. Hubert:—A great eruption of the volcano of that island gave origin to a vast stream of lava, which in its progress came in contact with a plantation of palm trees. The trees were immediately set on fire; but being soon covered by the lava, combustion ceased, and the wood became converted into charcoal. Incandescence long time continued, afterwards produced in the fibrous wood, thus carbonized, contractions and clefts of a certain regularity. The lava next entering the clefts formed by contraction, and moulding itself over the nucleus of the coal, produced the hollows observable, as often as the coal is purposely detached, or destroyed by some accidental cause. 5. *Var.* of prismatic triangular form, with oblong and irregular pores; from the neighbourhood of Rochefaute, in Vivarais.

*Div. 2. Light porous lava.*—1. With round pores; from Vivarais, Auvergne, isle of Bourbon, Tunis, &c. Desfontaines has gathered at Tunis specimens of such a lava, which the natives apply in the preparation of their woollen stuffs, in preference to the fullers' thistle used in other countries. 2. *Var.* with oblong pores; from Vesuvius, Etna, Hecla, from Vivarais, Auvergne, &c. 3. *Var.* with irregular curved or twisted pores; from Vesuvius, the isle of Bourbon, Teneriffe, Stromboli, Vulcano, Vivarais, &c. 4. *Var.* with decussated pores; from the isle of Bourbon, Vesuvius, &c. 5. *Var.* with streaked pores; from Vesuvius, Etna, isle of Bourbon, and Mount Hecla.

The light striated lavas, appearing in the shape of cables, ribbands, &c. also belong to this class. In general, the porous lavas are nothing but the result of the more or less active or continued development of gases produced by the peculiar nature of the lavas, and by the more or less violent action of subterranean fire.

#### CLASS III. Scarified lavas.

A particular modification of porous lavas, produced when, under certain circumstances, the matter of which these consist undergoes the first degrees of vitrification, and becomes covered with a kind of shining varnish, which distinguishes them from ordinary porous lavas. These scarified lavas are found, 1, twisted; 2, cable-shaped; 3, ribband-shaped; 4, in bunches, with round or oblong grains; 5, lalacritical,

short elongated knobs, separated or united. All these varieties of forms are found at Vesuvius, Etna, Hecla, in Teneriffe, the isle of Bourbon, &c.

CLASS IV. Lavas considered with regard to their component parts, or to the different rocks from which they originated.

*Div. 1. Granitoid lava.*—These lavas, which, according to Faujas' system, must have been elaborated at a great depth in the bowels of the earth, owe their origin to rocks analogous to our granite, except that quartz does not enter into their composition; the substance formerly considered by Faujas and others as quartz, having proved to be feldspar.

*A. Coarse-grained granitoid lava.*—1. With base of a whitish-grey colour, composed of irregular whitish grains of feldspar, of a quartz appearance, but easily fused before the blowpipe; a great number of minute, thin, and hexagonal laminae of black mica, disseminated among the grains of feldspar, and large crystals of this substance, of a pearly white and parallelipipedic form, are imbedded in this quartz-fs granite. The grains of feldspar have suffered a little by the fire, and the crystals are slightly calcined. Some of them are even dissolved into capillary separations, and pass into a substance like pumice. This lava, which is strongly attracted by the magnet, is found at Mont-d'Or; but a similar variety occurs in the isles of Ponza and Lipari; at Santa Fiora, in Tuscany, &c. 2. *Var.* with base of whitish granular feldspar, spotted with dots of black mica, and hornblende of the same colour, and in small crystals with dull surface; from the Euganean hills, &c. 3. *Var.* with large laminae of a shining bronze coloured mica, some of more than an inch in diameter, in a rough uneven purplish black mass, which is melted without being glassy, and is pervaded by large pores. It is slightly attracted by the magnet. Found near Andernach. 4. *Var.* with base of reddish granular feldspar streaked like pumice, and of white slightly calcined feldspar crystals, with some hexagonal laminae of brown mica, minute reddish garnets, which are partly fused, and a black glassy substance appearing to be hornblende: it is faintly attracted by the magnet. From Santa Fiora, in Tuscany. 5. *Var.* with base of white feldspar, in irregular rather scaly grains, with a great quantity of needles of black hornblende, and altered garnets of a purplish hue. Very obedient to the magnet. From Teneriffe. 6. *Var.* of a white colour inclining to grey, composed of a multitude of very small and close grains of white feldspar; and of much larger grains of shining scaly feldspar, with rather pearly lustre, some of which grains show a tendency to crystallization. Blackish, dull dots, being common hornblende altered by the fire, are disseminated in the feldspar. Faujas mentions a specimen of this variety, from the Cantal, which is traversed by a bar of black and white granite, formed of small grains of very pure feldspar, and of small grains of black hornblende, unaltered by the action of the fire. 7. *Var.* with bluish-black base, having small brilliant points proceeding from the scaly particles of a white stony substance, with dull fracture; purplish red, semi-transparent garnets, partly flaved, partly fused, are indistinctly imbedded both in the black and white substances. The former of these, which is compact, and fuses before the blowpipe into a black glass, has all the characters of hornblende; the latter is compact feldspar. From the Cape de Gatte, in Spain.

*B. Fine-grained granitoid lava.*—8. *Var.* formed by a mixture of small, irregular, close grains of hornblende, and small grains and scales of white, rather pearly feldspar. The hornblende being predominant in this mass, it exhibits a black surface on being broken, or cut by a saw, in which case it resembles basalt; but when polished, small white dots and lines appear, which, though delicate, are still sufficiently visible on the

the black ground of the maf; found on the fummit of mount Mezin, where, by the action of the atmofphere, it undergoes a ftriking alteration; for while the particles of feldfpar at the furface become corroded and difappear, the hornblende remains unaltered and fresh, projecting over the reft as black granular particles. Lavas fimilar to this, fome of them prifmatic, Mr. Faujas pretends to have feen in the neighbourhood of Caffel, and near Gottingen. 9. *Var.* compofed of white feldfpar in fmall grains, rather mealy at the furface, and of a black fubftance diffeminated as dots in the maf; the latter appears to be altered hornblende. In this mixture are alfo imbedded large white feldfpar cryftals with pearly luftre. Occurs on the right bank of the Rhine, at the foot of the Seven Mountains, nearly oppofite Goderberg. 10. *Var.* with white grains of feldfpar, harder, frefter, and of clofer texture than thofe of the preceding variety, mixed with black hornblende, difpofed in dots, lineaments, and even as fmall prifmatic cryftals, more abundant, and lefs altered, than the hornblende of No. 9. Alfo garnet cryftals are diffeminated in it, but cannot be feen without the affiftance of a high magnifier. This variety is attracted by the magnet. It takes a good polifh, and is ufed for building. It is, together with the preceding, found at the foot of the Seven Mountains, where it is quarried. Large feldfpar cryftals have not been found in it. 11. *Var.* compofed of fmall irregular white cryftals, difpofed in diftinct lines appearing fealy, fhining, and as rather calcined when viewed through a lens; their length is about  $\frac{1}{4}$ th, their width  $\frac{1}{8}$ th of an inch; they are interfected by other prifmatic indeterminate cryftals of the fame dimenfions, of an intenf black colour, vitreous, almoft metallic external luftre, but rather dull on the furface of fracture. Alfo particles of iron mica, (for oligifte of Haüy,) and of magnetic iron-ftone, are found in this maf. Faujas has analyzed thefe two ores of iron; according to him they are combined with titanium, and the white cryftals belong to the fpecies of the latter, called *Sphene* or *Titane filiceo-calcaire*. This variety was found, in infulated blocks, near the top of the Meffier, in Heflia. 12. *Var.* differing from the preceding only by the *fer oligifte* it contains being in large laminae, marked with lines, the general difpofition of which produces fmall hexahedral laminae. The fphene, which forms the bafe of this maf, is harder, white, inclining to yellowifh; it confifts of cryftalline tranflucent particles; the magnetic iron interfects the fphene in all direftions, while the iron-mica is only diffeminated here and there; both thefe iron ores are, like the preceding, combined with titanium. This variety is found near the extinct volcano of Beaulieu, in the ci-devant Provence. Mr. Faujas remarks, that no fimilar rock is known to occur, that may be confidered as the original of this, and the preceding volcanic fubftances. He denominates them *granitic*, becaufe they have much the appearance of fuch a compound.

C. *Schiftfe granitoid lava*.—13. *Var.* compofed of minute, reddifh-brown grains of feldfpar, much larger, angular grains of white feldfpar, and a great quantity of fmall fix-fided laminae of fhining mica, difpofed in a fimilar manner as in gneifs. The white feldfpar is eafily feparated into laminae in the direftion of parallel lines observable on it, and which are produced by the action of the fire. Sometimes fome dots of hornblende are feen in the maf; but they are of rare occurrence. This is found in Lipari under the pumice defcribed by Dolomieu. 14. *Var.* with yellowifh-grey, granular, dull feldfpar, intermixed with white vitreous grains of feldfpar, and much black hornblende in fmall, fender cryftals, difpofed in horizontal lines, representing thin layers, and giving this fubftance a fillic appearance. From Vulcano.

CLASS V. *Porphyroid lava.*

Faujas' volcanic porphyries are compofed of a fufible pafte or bafe, in which more or lefs regular cryftals of feldfpar are imbedded, often accompanied by grains of quartz, hornblende, augite, &c. The bafe itfelf be confiders analogous to the "trapps of the Swedes." He fubdivides them as follows.

A. *Porphyroid lava with feldfpar cryftals*.—1. *Var.* with black, hard, and heavy, though rather porous, bafe, and with white feldfpar cryftals of loofe texture. Strongly attracted by the magnet. From mount Etna. 2. *Var.* with more compact bafe, of a deep violet brown colour, with a great quantity of fmall greyifh-white, rhomboidal, and parallelpipedic cryftals, and alfo grains of feldfpar. It is very magnetic, and takes a good polifh. Found by Dolomieu in the Ifle des Salenes, near the village Amalfi, where, according to this geologift, it appears in the form of iflets of flairs. Faujas adds that a fimilar rock is found in Auvergne, in thin tables, which are ufed in fome villages for roofing. 3. *Var.* with purplifh brown bafe, including white irregular feldfpar cryftals, without luftre. From Trizac, in the canton of Mauriac, Auvergne. 4. *Var.* with rather purplifh bafe, abounding with more or lefs regular feldfpar cryftals of a white colour. Though rather decompofed, it affects the magnetic needle. From Mauriac and fome other parts of Auvergne.

B. *Porphyroid lava with feldfpar and mica*.—5. *Var.* with rather purplifh grey bafe, very white irregular feldfpar cryftals, and fmall fometimes fix-fided laminae of an intenf black mica. It fometimes contains fmall cryftals of filiceo-calcareous titanium. From Leorens, part of the Cantal mountains. The bafe of this has quite a compact feldfpar appearance. 6. *Var.* with grey bafe, including white feldfpar cryftals and black mica, but lefs abundant than in the preceding. From Mont d'Or; occurs alfo in the ifles of Ponza and Lipari, &c.

C. *Porphyroid lava with feldfpar and pyroxene*.—7. *Var.* of a deep grey bafe, with dots, lineaments and cryftals of white feldfpar and black pyroxene, in fmall cryftals. Sufceptible of a good polifh. From the extinct volcanoes of Campania, the neighbourhood of Rome, Santa Fiora, &c.

D. *Porphyroid lava with cryftals of black pyroxene and fmall grains of green pyroxene*.—8. *Var.* with deep grey, containing a great number of cryftals of black pyroxene, and irregular dots of greenifh pyroxene. From Chimborazo, where it was found by Humboldt at the height of 1840 toifes. Faujas fo completely miftakes Humboldt, that he imagines the ftratum of this fubftance has 1840 toifes in thicknefs! The fame is found near Puzzuoli; and in the ancient lavas of Vefuvius. 9. *Var.* with the fame bafe as the preceding, and, like it, fufceptible of taking a good polifh. with angular grains, needles, and regular cryftals of green pyroxene. Found among the ancient lavas of Vefuvius.

E. *Porphyroid lava with hornblende and feldfpar*.—10. *Var.* with purplifh bafe, with a profufion of lineaments and more or lefs regular cryftals of black hornblende, irregular grains of white feldfpar, fome of which have penetrated into the hornblende cryftal. Found at Santa Fiora in Tufcany.

F. *Porphyroid lava with hornblende only*.—11. *Var.* of a blackifh-grey colour, with large cryftals of very black and fhining hornblende. From Mas de Puffanton, near Chamerae, in Vivara's. 12. *Var.* of deep reddifh-brown colour, with a profufion of brilliant needles and cryftals of hornblende. From the Peak of Teneriffe.

G. *Porphyroid lava with hornblende and olivine*.—13. *Var.* in which the hornblende, in irregular fragments, conftitutes

more than double the weight of the mafs, in which fome pores are obfervable. The grains of olivine which it includes are iridicent. From the Peak of Teneriffe.

H. *Porphyroid lava with leucite cryftals.*—14. *Var.* with opaque white leucites, with rather pearly luftre, the largelt of which have from three to five lines in diameter; they exhibit, when pieces of the lava are cut and polished, minute rents. The bafe in which they are imbedded is black, compact, hard, very obedient to the magnet, fufible before the blowpipe into a black, opaque glafs; it takes a fine polifh. From Capo di Bove, Caprarola, and the neighbourhood of Naples. 15. *Var.* with large leucites of a dull white colour, fome of them transparent, lamellar, and here and there fufed and vitrified. The enveloping lava is of a greyifh-black colour; it is dry, rough to the feel, full of irregular pores, and attracted by the magnet. From the ancient lavas of Veluvius. 16. *Var.* with white, opaque, dull cryftals, which, though they are fo friable as to be eafily reduced to powder by the preffure of the nail, have ftill preferved their original form; they are large and clofely grouped together. The lava which includes them is of a dull black colour, inclining to grey; it has loft part of its hardnefs, but ftill affects the magnet. In the midft of thefe decompofed cryftals are feen black lineaments and grains of a fubftance which appears to be that of the lava itfelf, and which was perhaps forcibly introduced into the body of the cryftals, through the rents that were produced when the mafs was ftill in a fluid ftate. Found in abundance in the vicinity of Viterbo. 17. *Var.* with white opaque leucites, having fome black points in their centre, and with irregular cryftals of black pyroxene diffeminated in the lava. It is black, hard, fufceptible of a good polifh, attracted by the magnet, and fufible into a black brilliant glafs. Found in large mafles, and fometimes in prifms, at Bolfena. A fimilar variety occurs at Civita-Caftellana, and another at Aquapendente, which latter, however, includes pyroxenes of a yellowifh-green colour. 18. *Var.* with transparent, hard, leucite cryftals, of a yellowifh-white colour, accompanied with black hornblende. The including lava is black, compact, hard, and attracted by the magnet. Found at Borghetto, Bolfena, Aquapendente, and Albano. 19. *Var.* with very fmall white opaque leucite cryftals, clofely grouped together, and accompanied by much larger, irregular cryftals of black hornblende; in a black, hard, compact and very magnetic lava, from Tivoli and Aquapendente. 20. *Var.* with almoft microfopic white, tranflucent leucite cryftals, fo clofely grouped together as to appear to be in contact with each other, intermixed with irregular black hornblende cryftals. Found abundantly at Bolfena, in the neighbourhood of Civita-Caftellana and of Viterbo. 21. *Var.* with very fmall, pellucid, white, leucite cryftals, and irregular hornblende cryftals, of a greenifh colour. In a purplifh, not very hard, lava, the iron of which has acquired a degree of oxydation, whence it fhews no effect on the magnetic needle. From Viterbo. 22. *Var.* with large, white, pellucid leucite cryftals, which are generally of a fealy nature and full of minute flaws, and fometimes with fmall lineaments of a very beautiful fky-blue colour, of a cryftalline appearance. This fubftance, comparable to blue fapphire, or, more aptly, to lazulite, appears to be of contemporary formation with the reft. The fame fubftance in minute particles is difcriminated alfo in the pafte of the lava, which is compact and of a blackifh-grey colour. Befides thefe, alfo black fhining dots are obfervable in this lava; they have the appearance of having been fufed, and may perhaps be grains of pyroxene, or black garnets. Some grains of arfenical pyrites are likewife obfervable in it. From Albano. Some-

times the leucite cryftals, in the lavas of this divifion, are accompanied by fome mica in fmall fcales; and in the neighbourhood of Rome large nodules are found, fometimes of the thicknefs of a man's fist, and entirely compofed of black cryftallized mica and leucite; the latter are clofely enveloped by the former, and both appear to have acquired their cryftalline form at the fame period. This is not confidered by Faujas as a true volcanic fubftance.

#### CLASS VI. *Variolitic lavas.*

The pafte is the fame as that of the porphyritic lavas, but inftead of cryftals, it includes globules of feldfpar.

1. *Var.* with pafte of a greenifh-grey colour, with numerous blackifh-grey globules, of the fize of a pea, and of a finer and harder texture than the bafe; both of them fufible. When the pafte is decompofed by the action of the atmofphere, the round fhots exhibit themfelves as projecting globules. From Teneriffe. 2. *Var.* with grey pafte, and very fmall round fhots of a darker grey colour. This variety, which attracts the magnet, is, like the preceding, compact, and takes a fine polifh. It has a tendency to feparate into thin laminae when ftruck with a hammer. From Veldrine, in Auvergne. 3. *Var.* with grey pafte, inclining to greenifh; fhots like thofe of No. 1, but four times fmaller. Is ftroingly attracted by the magnet. From Pui en Velai. 4. *Var.* with white orbicular fhots on a grey ground; attracted by the magnet. From Pas-de-Compain, Auvergne. 5. *Var.* like No. 4, but with much fmaller fhots, grouped clofer together, and lefs regularly orbicular. From Puy-Creux, Auvergne. 6. *Var.* of a blueifh colour, with very fmall pores, and numerous white orbicular fhots of about two lines in diameter. From the crater of Mon-Brûl, in Vivarais, where it often occurs in large irregular balls, which feparate into concentric layers when ftruck with a hammer.

#### CLASS VII. *Feldfpar lavas; or lavas with bafe of compafä feldfpar.*

Faujas remarks, after Dolomieu, that there are fometimes in the fame lava two different kinds of feldfpar, one of which is compact and fufible, and ferves as bafe to the other, which is more or lefs regularly cryftallized and refractory, fo that the bafe may have been in complete fufion, while the cryftals remained in their original ftate.

1. *Var.* Feldfpar lava of a black colour, opaque, of a very fine grain and conchoidal fracture; it fufes into a white tranflucent glafs, and is ftroingly attracted by the magnet. From Catajo in the Euganean mountains, and from Vulcano. 2. *Var.* of a light grey colour, inclining to fleft red, of a fine grain, tranflucent at the edges; fufible before the blowpipe, and faintly attracted by the magnet. From one of the Ponzaifles. 3. *Var.* of a white colour, heavy, partly vitrified. From the Euganean mountains. 4. *Var.* of the fame colour, but fhining; rather glaffy; compofed of fmall, rather ftreaked, and fometimes fwelled fcales; and, therefore, lighter than the preceding. Is not attracted by the magnet; but is fufible before the blowpipe. From Milo, an ifland in the Archipelago. 5. *Var.* of greyifh-white colour, here and there with a flight fhade of red, with numerous fhining fcales of mica; feldfpar rather calcined. Is not attracted by the magnet; but fufible into a femi-transparent glafs. From the ifle of Ponza, and from Puy-de-Dôme, in Auvergne. 6. *Var.* white, with fcales of brown fhining mica, and pellucid grains of feldfpar, more cryftalline than the bafe in which they are included. From Mont d'Or, in Auvergne; fimilar varieties are found in the Euganean mountain, and another from Mont Mezin, in Velai.

#### CLASS VIII. *Amygdaloid lavas, with bafe of trap.*

These are confidered, by Faujas, as having originally belonged

longed to rocks, whose base is generally the same as that of the porphyries; and whose globules and nodules of calcareous spar, zeolite, calcedony, &c. do not owe their existence as such, to infiltration, but are of a contemporaneous origin with the base. The volcanic fire which operated on such amygdaloid rocks, though it has rendered them soft and fluid, has but little changed their character; but all, in the opinion of that strenuous volcanist, bear clearly the stamp of igneous origin. They are subdivided as follows:

*A. Amygdaloid lava with calcareous globules.*—1. *Var.* with globules of translucent calcareous spar of a yellowish colour, of the size of a pea; in a black, compact mass; attracted by the magnet. From Vivarais; also from Vicenza. 2. *Var.* with white, translucent, sparholc globules, some with a thin, shining, reddish-brown, others with a steel-grey coating of the same kind, in a similar mass, affecting a triangular-prismatic form. From near Rochefave, in Vivarais. 3. *Var.* with white, compact, lenticular grains, translucent on the edges, the largest of them of the size of a common lentil; in a black compact mass, of a very fine grain. From the Isle of Ascension. 4. *Var.* with white, spherical globules; sometimes two, three, or four of them together; sometimes single in cells that are partly empty; base like that of the preceding variety. From the valley of Ronca, in the Veronese territory. 5. *Var.* with similar, very small globules, grouped closely together, and taking up the whole of the cell; in a reddish-brown, hard, compact mass, attracted by the magnet. From the same place. 6. *Var.* with small, perfectly orbicular, globules of equal size, in a deep-grey, compact, soft mass, containing numerous grains of olivine, with oxidized ochrey surface. From Vivarais. 7. *Var.* with white, translucent, shining, radiated globules of arragonite; in a black, hard, compact lava; obedient to the magnet. From the Isle of Ascension. A similar one, but with larger globules, from near Roche-Sauve, in Vivarais. 8. *Var.* with the same globules, but accompanied by grains and indeterminate crystals of black hornblende; in a brownish compact mass. From near Bais, in Vivarais. 9. *Var.* with radiated globules, and irregular grains of arragonite, intermixed with grains of olivine. From the Isle of Bourbon.

*B. Amygdaloid lava with globules of mesotype.*—1. *Var.* with solid globules of a white silky zeolite, composed of needles radiating from the centre; in a black, compact, hard mass, attracted by the magnet; including also grains of black hornblende. Between Roche-Maure and Meyffe, in Vivarais. A similar variety from Staffa, and the Isle of Mull. 2. *Var.* with very small solid globules, of a snow-white zeolite, and irregular, almost microscopic grains of the same substance, so numerous as to constitute half of the whole mass; the base like that of the preceding variety. From the valley of Ronca, in the Veronese territory. A similar one is found near Rome, in which grains of hornblende are lodged in the very substance of the zeolite. 3. *Var.* with numerous, white, pellucid, zeolitic grains, of about the size of a millet seed, and closely grouped together; in a greyish-black compact lava. From Montecchio-Maggiore, near Vicenza. Similar varieties occur in the Lipari islands, at mount Vesuvius, &c.

*C. Amygdaloid lava with stilbite.*—1. With globules of white nearly stilbite, in a black compact base, attracted by the magnet. From Feroc. 2. *Var.* with similar globules, surrounded by a crust of a green, rather friable, substance, very like the green earth of Verona; in a greyish-green mass, not attracted by the magnet. From Feroc. 3. *Var.* with white radiated stilbite, on crystals of calcareous spar; in a black mass. From Iceland. 4. *Var.* with white stilbite,

in indeterminate-shaped nodules, in a friable, brownish mass. From Dumbarton.

*D. Amygdaloid lava with analcime.*—1. With irregular globules of transparent analcime, partly crystallized; in a greyish-black lava, attracted by the magnet. From Mount Etna. 2. *Var.* with oblong globules of pellucid analcime; in a black compact lava, strongly attracted by the magnet. From one of the Cyclopean isles. 3. *Var.* with globules of white compact analcime; in a greyish-black lava, appearing rather altered. From Montecchio-Maggiore. 4. *Var.* with hollow nodules of white, dull, and opaque analcime, partly in the form of trapezoidal crystals; in an altered lava, as it is called by our author. From Dumbarton, Scotland. 5. *Var.* with small, insulated, semi-transparent, greyish, dodecahedral crystals; in a light grey lava resembling tripoli, and penetrated in all parts by numerous, very small, spherical grains of analcime, of a darker grey colour, and a little translucent on the edges; intermixed also with some small crystals of calcareous spar.

*E. Amygdaloid lava, with farsolite,* (referred by Häuy to analcime).—1. *Var.* with globules, and sometimes irregular nodules, of a reddish stony substance, similar to the farsolite of Thompson; in a greyish, hard, porous, but heavy lava; the red globules accompanied by analcime, white radiated zeolite, cuboid crystals of calcareous spar. From Montecchio-Maggiore. 2. *Var.* with radiated zeolite, trapezoidal analcime, cuboid calcareous spar, and semi-transparent crystalline celestine, or sulphat of strontian, of a light blue colour, passing, in some specimens, into white. In a similar mass, from the same place.

*F. Amygdaloid lava, with chabafie.*—1. White chabafie, in a porous, black, heavy mass, with small, blueish, elevated, rather mamillary spots, which are phosphate of iron. From Val di Noto. A similar substance is found at Clermont, in Auvergne. 2. *Var.* with small primitive crystals of chabafie, in the orbicular hollows of a black, hard, heavy, and compact mass. From the Peak of Teneriffe. 3. *Var.* with small globules, and very minute crystals of chabafie, in a black heavy mass, with shining black hornblende, and numerous grains of olivine, decomposed into a yellowish earthy substance. From Teneriffe. 4. *Var.* with primitive crystals of chabafie, lining the orbicular hollows of a close black lava. From Iceland.

*G. Amygdaloid lava, with calcedony.*—Here M. Faujas mentions eleven varieties of nodules of calcedony, some of them containing water, (known by the name of chydrous,) others solid; found principally in the decomposed lavas of Monte Tondo, Monte Galdo, San Florianio, Mont-Main, in the Vicentine territory. To these he adds, by way of appendix, some calcedonic and quartz substances, which he considers as owing their origin to infiltration, and to which he refers the hyalite of Francfort on the Mayne. In another appendix the same author places the masses including the granular peridot or olivine, and which he would consider of porphyritic origin, were the olivines ever found crystallized in them. He enumerates several varieties found in the basalts and lavas of Vivarais, Cassel, Isle of Bourbon.

#### CLASS IX. Volcanic breccias and tuffes.

*A. Volcanic breccias formed of more or less rounded fragments of different kinds of lavas,* seized and enveloped by other lavas in a state of fusion.—1. *Var.* composed of angular and blunt fragments of black, hard, compact lava, of rather porous black lava, and of grains of white feldspar; the whole intimately united by a brownish lava, with streaked pores. Peak of St. Michael, in Velay; as also near Roche Sauve, in Vivarais. 2. *Var.* with irregular fragments of scoriiform semi-vitreous lavas of a shining black colour, cemented by a

grey striated lava, approaching hard pumice. From Vivarais, and the Isle of Lipari. 3. *Var.* formed of numerous angular fragments of black porous lava, and some white opaque feldspar, cemented together by grey pumice with small pores: from Lipari and Ischia. 4. *Var.* with fragments of white, sometimes yellow and brownish lime-stone, in a grey hard lava, mixed with white, transparent, flawed crystals and grains of feldspar, some laminae of black hornblende, silvery mica, and grains of green augite; from the vicinity of Albano, and other parts of the Roman territory. 5. *Var.* composed of large fragments of white marble, fine-grained yellowish marble, and another hard stony substance formed of lime and silice: in a grey lava, including much black pyroxene; from the vicinity of Rome, and from near Vesuvius. 6. *Var.* composed of fragments of white and grey marble, and rounded pieces of black hornblende; others of black scaly mica; in a grey lava, mixed with particles of silvery mica, and numerous fragments of deep green pyroxene. From Ischia. 7. *Var.* with large nodules of olivine, of different colours; fragments of black compact lava, of porous, almost scoriated lava, of the same colour, cemented by a grey mass formed of more or less comminuted detritus of several kinds of lava. From the Isle of Bourbon, of Ascension, &c.

B. *Volcanic breccias formed by the sudden contact of fire and of water greatly heated.*—1. Breccia formed of fragments of brown porphyry, porphyry with red base, and crystals of white feldspar; of fragments of white marble, marked at their points of contact with the lava, with black lineaments that appear produced by an aqueous solution which intimately united all parts of this breccia, the base of which is a grey lava, mixed with melted grains of black pyroxene; it is attracted by the magnet. From the foot of Mount Etna. 2. *Var.* including angular fragments of black lava, with conchoidal fracture; of grey feldspar lava, with rough surface (both attracted by the magnet); of glassy blueish-green lava, fragments of ash-grey pumice, fragments of a whitish, semi-transparent, volcanic glass, and a colourless glass; the whole cemented by a blueish-grey, softish, coarse-grained lava. From the Lipari islands. 3. *Var.* composed of fragments of black, rather porous, basalt, including grains of olivine, of large fragments of a yellowish quartz sand-stone with red stripes, of fragments of grey or red indurated marble, and geodes of brown iron-stone; the whole cemented together by a grey lava, composed of the more or less comminuted grains of the substances that form the breccia, and of some black pyroxene. From the Habichtswald. 4. *Var.* composed of various fragments of black basaltic lava, intimately connected by white and shining calcareous spar, sufficiently hard to allow the breccia to be cut and polished; sometimes the compact lava adopts the reddish colour of ochre. From Roche-maure, Vivarais; also from Monte-Bolca. 5. *Var.* formed of more or less large fragments of intensely black, shining, volcanic glass, cemented by white calcareous spar, susceptible of a good polish. From Val di Noto. 6. *Var.* composed of very small fragments of a compact, greenish-black, decomposed lava, some of which include grains of black pyroxene; in a hard siliceo-calcareous paste, which is but little soluble in nitric acid.

C. *Volcanic tuffas, properly so called,* formed by the detritus of different species of granular, pulverulent, or earthy lavas. They appear to owe their origin to various circumstances. First, they may, according to Faujas, be considered as the result of the sudden contact of water with volcanic fire; when, at the time of great subterranean convulsions, a communication is suddenly opened between the sea and the igneous gulf. Secondly, the projected pulverulent lavas,

which are sometimes carried to a great distance, such as those which buried Herculaneum and Pompei, or those which accumulate at the bottom of the sea in the vicinity of volcanoes, and may, in the progress of time, produce depositions, and even more or less regular strata, of tuffa. Lastly, under some circumstances, the tuffas that were already deposited in the sea, may have been again displaced by currents, and mixed with shells and other marine productions, and sometimes even with land productions, swept into the sea by rivers, &c. the current may, at different intervals, have deposited these tuffas, as more or less regular layers.

1. Volcanic tuffa, composed of white and grey, very light pumice, in small fragments, adhering to each other. From Pleyth, near Andernach, where it covers the quarries of trafs. 2. *Var.* with base of pumice reduced to so fine a powder, as to appear like a clayey substance, serving as a cement to numerous grains of a very light pumice, but less rough to the touch than that of the base, which, moreover, includes small nodules of real porous lava, of a brown colour, and sometimes colourless. From the same place, where it forms a kind of trafs. 3. *Var.* formed of pumice in grains, and small angular fragments of black basaltic lava, scaly particles of a somewhat micaceous schistus, cemented by a paste of pumice reduced to powder. From the same place; where it forms another variety of trafs, being of greater solidity, and forming beds of upwards of fifty feet thickness, in which sometimes charred wood is found. 4. *Var.* formed of very small grains of lava, which is partly scoriated, of some grains of black pyroxene, and other grains of rounded yellowish olivine, cemented by grey and black pulverulent lava, resembling sand-stone. Is sometimes found in beds at Carlberg, in Hesse. A similar tuffa, of a dark grey colour, with white points, is found on an elevated part of the Cantal, in Auvergne. 5. *Var.* of a purplish-grey colour, and resembling, at first sight, a sand-stone, but in reality composed of the detritus of a purplish lava, of a less altered compact lava, and some grains of black pyroxene. Near Roche-sauve, in Vivarais, where it forms thick beds, resting on other tuffas, and overlaid by basalt. 6. *Var.* gold yellow, dotted with white, grey, and black, composed of small fragments of basalt, yellowish-brown friable lava, some grains of olivine, and small particles of black pyroxene; also yellow ochre nodules are found in it. This tuffa forms considerable beds, one above the other, at Roche-sauve, in Vivarais. 7. *Var.* of a purplish-brown colour, with yellow ochre, white and blackish dots, composed of small angular fragments of black compact lava, which has lost some of its hardness; of small fragments of a white marble, mixed with some iron; of particles of porous altered lavas of an ochre-yellow colour; of grains of shining black pyroxene, and some olivine in grains. It is attracted by the magnet. Found at the preceding place, where it forms considerable strata, overlaid by vast basaltic causeways. Also, in this tuffa large nodules of ochre are found. The tuffas of the vicinity of Roche-maure, in Vivarais, are similar to this; as likewise those of the neighbourhood of Rome, of Naples, Campania, of the Euganean mountains, of several parts of the Vicentine territory, &c.

M. Faujas enumerates, at the end of this section, the various animal and vegetable substances, shells, madrepores, and carbonized species of wood, that have been found imbedded in volcanic tuffas. A section is also set apart to volcanic pitch-stones, divided into three classes, *viz.* wood, converted into pitchstein, by volcanic fire; flint, which has undergone the same change; and porphyries converted into what Werner calls pitchstone porphyry. The places assigned to the first of these varieties are, Afferstein, near Frankfurt, and

and Upper Hungary; the locality of the second is principally Auvergne; which is also that of the specimens of volcanic pichstone porphyry, here enumerated. To the last of these substances Faujas refers most of such *laves résinites*, or *résinitiformes* of Dolomieu, as contain crystals of feldspar, and several of which are found at Vulcano. These are said to form a transition into

CLASS X. *Enamels (émaux), obsidians, and other volcanic glasses*.—The prototypes of these are the different varieties of trapp, compact feldspar, and porphyry, which, according as they are more or less fusible by volcanic fire, are, under circumstances favourable to vitrification, converted into the several kinds of glasses that are found among volcanic productions.

A *Enamel*.—1. Grey, with greyish-white, or greenish zones, opaque; some pores are visible in the paste, and, with the help of a lens, also crystals of feldspar, or traces of them. From the isle of Ascension. 2. *Var.* of dark-grey colour, besprinkled all over with small round spots of a much lighter grey, and produced by small globules in the substance of the enamel, which, in some places, displays an intense, vivid-black colour. This substance, which is from the island of Vulcano, bears distinctly the characters of a variolitic lava converted into enamel. 3. *Var.* of a blackish-grey colour, hard, opaque, in which some dots of fused black pyroxene are still visible. From the isle of Ponza. 4. *Var.* of an intense black colour, approaching obsidian, but more opaque, and of a rather greasy aspect. From the Peak of Teneriffe. This enamel is sometimes covered with a rust-coloured crust. In some specimens scarcely any foreign body is observable, except some traces of white feldspar; in others the mass is rather less intensely black and more marked with spots of white feldspar, melted together with the enamel without having entirely lost their original tint.

B.—*Real obsidian, or volcanic glass*.—1. Obsidian of a black colour, of conchoidal fracture, divisible into sharp fragments, of deep black colour, and translucent on the edges; thinner fragments almost completely transparent, with scarcely any traces of a fuliginous tint. It is fusible before the blowpipe into a very white, shining, translucent glass, with minute superficial vesicles. From Mount Hecla, Teneriffe, Ascension, Vulcano, Lipari, Ponza, &c. 2. *Var.* of a globular form, black, opaque, but sometimes transparent, and faintly turbid or smoky. From Cap de Gates. Faujas refers this substance (which has been called *luchs-saphire* by some writers) to the homogeneous volcanic glasses, because it easily melts before the blowpipe into a white enamel, and because the globules are sometimes found imbedded in a greyish enamel, approaching to lamellar pumice. These globules are not always spherical. Their size is from that of a small pea to that of a large hazelnut. They are very light, though not porous; their external lustre is unctuous. 3. *Var.* forming a very fine black glass, with well defined, conchoidal fracture; and fragments nearly transparent on the edges, and of a weak olive-brown colour. In some parts white points and some small hollows are seen, which latter are lined with a white fused, rather vitreous, substance, which appears to owe its origin to such grains of feldspar as did not experience a sufficient degree of fusion to amalgamate with the obsidian. From Cerro de las Marejas, in Mexico. 4. *Var.* with intensely black ground, and well defined fracture, yielding sharp-edged fragments; the whole of the brilliant mass is filled with small, white, opaque, globular, and oblong spots, closely grouped together, and appearing like melted enamel, but rather unctuous. From the Lipari islands. 5. *Var.* of

a black colour, inclining to olive-green, disposed in more or less elongated, rather flexible, capillary filaments, often terminated by very small, round, or oblong globules; fusible before the blowpipe into globules of a greenish-black. From the isle of Bourbon. Lavas with small filiform particles of volcanic glass have also occurred in the island Vulcano. These are by some mineralogists looked upon as filiform crystals of augite or pyroxene; but M. Faujas says he has subjected them to closer examination, and found them to be volcanic glass.

C. *Pumice fines*.—The true pumice, says Faujas, which we should be careful not to confound with the lightest lavas, keeps the midway between the volcanic glasses and the enamels: it generally derives its origin from a peculiar kind of vitrification of compact feldspar, and some porphyritic rocks. Those of Lipari and Vulcano are the only known volcanoes that have produced pumice in considerable quantity: the isle of Lipari, in particular, is the vast magazine that furnishes almost the whole of the immense stores of this substance, consumed for the purposes of different arts, in almost all parts of Europe. In small quantity and in insulated fragments it occurs in the neighbourhood of several other volcanoes.

1. Pumice of a white colour, porous, light, rough to the touch, and fusible. From Campo-Bianco, the Lipari isles, Valle-del-Aqua, near Otto-Jano, &c. 2. *Var.* of a silky appearance, fibrous, and with capillary lineaments. From the same place. 3. *Var.* of a dark grey or black, sometimes greyish-white colour, with twisted pores; fibrous, including, among its fibres, more or less indeterminate crystals of white feldspar, which, in some of the specimens, are only seen on the rifts. From Ichia, Procida, from the neighbourhood of Naples. At Lipari, the varieties of black pumice are found in the hillock of the tomb of the Nafos. 4. *Var.* of a whitish colour, scaly, light, silvery, and semi-transparent. From Lipari. 5. *Var.* the same, but heavy. *Ibid.* 6. *Var.* of a grey colour, light, fibrous, with blackish, shining, sometimes crystallized, mica. In a pumice from Herculaneum, from the neighbourhood of Naples, from Ichia, Procida, &c. 7. Light, porous, or fibrous variety, with more or less angular nodules, and grains of black volcanic glass. From Lipari, Stromboli, Capo di Monte, at Scutello, in the neighbourhood of Naples; from Teneriffe, &c. 8. *Var.* the same, but whiter, with small thin fragments of a silvery-grey shistus. In the tuffa from Pleyth and other places in the vicinity of Andernach. 9. *Var.* with very small angular and irregular fragments of a vitreous, stony substance, of a sky-blue colour (now called *Latialite*, or *Häünye*). Among the varieties of pumice from Pleyth, &c. 10. *Var.* of a greyish-white colour, light, with nodules of obsidian of various sizes. From Teneriffe and Lipari. 11. *Var.* of a dark grey, sometimes rather brownish colour, heavier than the preceding variety; with vesicles, all of which are elongated in one and the same direction: gives out some sparks when struck with steel. From Lipari. 12. *Var.* of a silvery-white, composed of small lamellæ, or scales. Found among the other varieties at Lipari: it is rather lighter than the common white pumice.

CLASS XI. *Sulphur, and various saline substances, found sublimated in volcanoes and solfataras.*

The salts are: Glauber salt, nitre, alum, Epsom salt, mineral alkali, rock salt, efflorescent, in filaments and cubes, fall ammoniac, in rhombic, or dodecahedral crystals, generally of a topaz-yellow colour. Also gypsum, and calcareous spar; muriate of copper, in small deliquescent crystals; red and yellow orpiment.

CLASS XII. *Volcanic iron*, viz. titaniferous iron, as sand, and in small octahedral crystals, from various places; specular iron from several volcanoes in Italy and France; phosphate of iron, as powder in porous lavas from Capo di Bove, Etna, Val di Noto; or in small laminae, from Bouche, in the department of Allier, &c.; iron pyrites, in fine grains; oxys of iron; muriate of iron, of a yellow colour, from Vesuvius and Etna; and iron-vitriol, found in volcanic grottos, in the island of Vulcano.

Several intercelling observations on the nature of lava, and the various phenomena it presents under different circumstances, are given by Sir William Hamilton, father della Torre, Bolis, Tata, Breilach, Buch, and others, which will be more particularly noticed under the article *Volcano*.

The purposes for which the lava of Vesuvius, Etna, and other volcanoes is employed, are particularly those of building and paving. Also the ancients made use of it for these purposes, as appears from the presence of Vesuvian lava in the architectural remains and pavements found in Herculaneum and Pompei. That of Etna appears to be still more generally used for building, since, according to Ferrari, there is not a house in its neighbourhood that is not constructed of it. The rapid progress in the rebuilding of Catania was, in a great measure, owing to the facility with which the building materials were procured. Also mill-stones are made of the lava of Etna, many of which are exported to Calabria and Malta; and it has even been manufactured into cannon balls.

LAUACA, in *Geography*, a small island near the S. coast of Sardinia. N. lat.  $39^{\circ} 4'$ . E. long.  $8^{\circ} 36'$ .

LAVACRUM, in *Botany*, a name given by some authors to the common wild teasel, or *disficus sylvestris major*, Ger. Emc. Ind. 2.

LAUADEROS. See *LAVATORY*.

LAVAGNA, in *Geography*, a sea-port town of Genoa, at the mouth of a river of the same name, which rises in the Apennines; 12 miles W.N.W. of Brugnato.

LAVAL, a city of France, and capital of the department of the Mayenne, situated on the river Mayenne. The number of inhabitants is estimated at 14,154; the eastern division containing 6658, and the canton 15,175, on a territory of 145 kilometres, in 9 communes; and the western division comprehending 7496, and its canton 15,000, on a territory of 122½ kilometres, in 6 communes. In the town and its environs are manufactures of linen, which yield a considerable commerce. N. lat.  $48^{\circ} 5'$ . W. long.  $0^{\circ} 41'$ .

LAVAMUND, a town of the duchy of Carinthia, on the Drave; the see of a bishop, suffragan of the archbishop of Salzburg; 24 miles E. of Clagenfurt. N. lat.  $46^{\circ} 44'$ . E. long.  $14^{\circ} 37'$ .

LAVANDULA, in *Botany*, Lavender; so called from the Latin word *lavo*, to wash or besprinkle, alluding to its ancient use in baths or fomentations, or to that of its distilled water in more modern times. Linn. Gen. 290. Schreb. 386. Willd. Sp. Pl. v. 3. 60. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 382. Sm. Prodr. Fl. Græc. Sibth. v. 1. 339. Juss. 113. Tournef. t. 93. Lamarck Illustr. t. 504. Gært. t. 66. (Stechas; Tourn. t. 95.)—Class and order, *Didymia Gymnosperma*. Nat. Ord. *Verticillate*, Linn. *Labiata*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, ovate, obscurely toothed at the orifice, short, permanent, with a bractea at its base. Cor. of one petal, ringent, reversed; tube cylindrical, longer than the calyx; limb spreading; its larger lip turned upwards, cloven, spreading; the other directed downwards, in three roundish, nearly equal, segments. Stam. Filaments four, within the tube of the corolla,

short, pointing downwards, two of them shorter than the rest; anthers small. Pisl. Germen four-cleft; style thread-shaped, the length of the tube; stigma of two obtuse cohering lobes. Peris. none, except the calyx, which protects the seeds, its mouth being closed. Seeds four, obovate.

Eff. Ch. Calyx ovate, obscurely toothed, attended by a bractea. Corolla reversed. Stamens enclosed in the tube.

Obs. The *Stechas* of Tournefort differs from his *Lavandula*, in having the flowers ranged in many rows on the spike, and the whole crowned with an ornamental tuft of floral leaves.

Six species are described in the latest edition of Linnæus, eight in Willdenow, all of them admitted into the new Hortus Kewensis, but the last in the list erroneously. The rest are for the most part known and esteemed in every garden or green-house. All are shrubby, with blue or purplish, fragrant, spiked flowers, and their foliage is likewise aromatic, generally of a grey or hoary-green, narrow, either simple or compound. The spike is supported on a longish, naked, square stalk.

1. *L. Spica*. Common Lavender, or Spike. Linn Sp. Pl. 800. Woody. Med. Bot. t. 55. (Lavandula; Ger. em. 583, 584. f. 1—3. Rivin. Monop. Irr. t. 54. f. 1, 2.)—Leaves linear-lanceolate. Spike interrupted, naked at the summit.—Native of the south of Europe, hardy with us, and cultivated for the sake of its scent when dried. To be “laid up in lavender” is become proverbial for any thing stored up with peculiar care. The essential oil and distilled water are so generally used in perfumery, as to be no unimportant articles of commerce. The compound spirituous tincture, or lavender drops, is a popular cordial, very commodious for those who wish to indulge in a dram, under the appearance of an elegant medicine. This plant varies in the breadth of its leaves, from linear to lanceolate, inclining to obovate; hence the old writers describe and figure two kinds. The flowers are occasionally white, which also they have not omitted to notice.

2. *L. Stechas*. French Lavender. Linn. Sp. Pl. 800. (Stechas arabica; Rivin. Monop. Irr. t. 55. Str. five Spica hortulana; Ger. em. 585.)—Leaves linear, revolute, hoary. Spike close, crowned with a coloured leafy tuft. Bractæas somewhat three-lobed.—Native of Spain, Greece, the south of France, and the north of Africa. It will not bear our winters without the shelter of a green-house. The leaves are much smaller than in the former, more strongly revolute. Spikes uninterrupted, short, and thick, on but shortish stalks, their bractæas more or less distinctly three-lobed, purplish and woolly; those which crown the top of the spike, greatly dilated, wavy, undivided, of a beautiful purple, much paler than the flowers; rarely wanting.

3. *L. viridis*. Madeira Lavender. L’Herit. Sert. Angl. 19. Ait. Hort. Kew. n. 3. Hoffm. and Link Lustf. v. 1. 91. t. 4.—Leaves linear, revolute, rugose, villous. Spike close, crowned with a leafy tuft. Bractæas undivided.—Native of Madeira, from whence it was sent to Kew by Mr. Masson in 1777. It differs from the last in its rugose, green and villous, not hoary, leaves, its undivided bractæas, and its green, not purple, crown of the spike.

4. *L. dentata*. Tooth-leaved Lavender. Linn. Sp. Pl. 800. Curt. Mag. 400. t. 401. (Stechas folio serrato; Ger. em. 586.)—Leaves linear, finely pinnatifid, pectinate. Spike close, with a leafy crown.—Native of Spain, the north of Africa, and some parts of the Levant, not of Greece.—The very neatly-toothed leaves distinguish this species. Its spikes stand on long stalks, and are crowded, pale, with all the bractæas large, coloured, and somewhat membranous, a few

## LAVANDULA.

low at the top being rather the largest, and destitute of flowers, as in the two last. The *corolla* is often white. This is one of the species that has been longest cultivated in England, having been preserved in the dwelling-house before green-houses or stoves were invented.

5. *L. pinnata*. Pinnated Lavender. Linn. fil. Diff. 9. t. 1. Am. Acad. v. 10. 52. t. 2. Curt. Mag. 401. t. 400. Jacq. Misc. v. 2. 318. Ic. Rar. t. 106.—Leaves deeply pinnatifid; their segments wedge-shaped, obtuse, nearly entire. Spike linear, somewhat branched.—Native of Madeira, from whence Mr. Masson sent it in 1777. The leaves are finely hoary, with little scent, elegantly pinnatifid, and distinguished by their obtuse wedge-like segments. The spikes stand on very long stalks, and are much more slender than any of the former, often compound. The bractæes are imbricated, uniform, ovato-lanceolate, pointed, coriaceous, not membranous, slightly coloured, and there is no leafy crown at the summit. The corolla is of a delicate blueish-purple, like the Common Lavender, but larger and more showy.

6. *L. multifida*. Cut-leaved Canary Lavender. Linn. Sp. Pl. 800. (L. folio multifido; Rivin. Monop. Irr. t. 54. f. 3. *Stachas multifida*; Ger. em. 585.)—Leaves doubly pinnatifid, hoary. Spike ovate, mostly simple. Bractæes woolly, elliptical, with distant ribs. Native of Spain, Barbary, and the Canary islands. One of the species longest cultivated in England, though it requires protection in winter. The Hortus Kewensis marks this plant as biennial, and we have a French specimen marked annual. It has certainly more of an herbaceous than shrubby appearance. The leaves are hoary, doubly and very deeply pinnatifid, with decurrent segments, whose extremities are acute, and in some measure elliptical. Spikes rather ovate and thick, very rarely, if ever, producing a small branch or two from the bottom. Bractæes membranous, broadly elliptical, besprinkled with wool, furnished with three strong ribs, equally distant from each other, and from the edge. There are no barren leafy bractæes at the top.

7. *L. abrotanides*. Southernwood-leaved Canary Lavender. Lamarec Dict. v. 3. 420. Willd. n. 7. (L. folio longiori, tenuis et elegantius dissecto; Tourn. Infl. 198. Comm. Rar. t. 27.)—Leaves doubly pinnatifid, with linear segments, nearly smooth. Spike linear, mostly branched and interrupted. Bractæes smoothish, ovate, with approximated ribs.—Native of the Canaries, long known in gardens. The stem is shrubby. Leaves with finer, more linear, and greener segments than in the last. The narrowness and branching nature of the spikes more accord with *L. pinnata* than with *multifida*, with which latter this species has long been confounded. The bractæes also most resemble those of *pinnata*, but are more membranous, and far less hoary. Their ribs generally three, sometimes five, are always closer together than in *multifida*.

The eighth species of Willdenow, *L. carnosa*, Linn. fil. Diff. 9. t. 2. Am. Acad. v. 10. 52. t. 3. (Katu-Kurka; Rheede Hort. Mal. v. 10. 179. t. 60.), found by Koenig on dry walls and rocks at Sadras in the East Indies, and sent to Kew in 1788 by sir Joseph Banks, where it is kept in the stove, being a tender biennial, is most certainly not a *Lavandula*, but a *Plectranthus*, as its habit, and the large deflexed upper segment of its calyx, both evince. See PLECTRANTHUS.

LAVANDULA, in Gardening, comprises plants of the shrubby evergreen kind, of which the species cultivated are, the common lavender (*L. spica*); the French lavender (*L. stachas*); the tooth-leaved lavender (*L. dentata*); and the Canary lavender (*L. multifida*).

The first fort has varieties with narrow leaves with blue

flowers, and with white flowers with broad leaves, and dwarf lavender.

It may be remarked that this species is the common lavender; but the narrow-leaved variety with blue flowers is the fort cultivated for its flowers for medicinal purposes.

And that the broad-leaved fort has much shorter and broader leaves, and the branches are shorter, more compact, and fuller of leaves; it continues several years without producing flowers; and when it does, the leaves on the flowering-stalks approach nearer to those of the common lavender, but are still broader; the stalks grow taller, the spikes are looser and larger, the flowers smaller, and appear a little later in the season.

The second kind has varieties with white flowers; and with purple flowers.

The fourth species has a variety which rises with an upright, branching, square stalk, four feet high; the leaves longer, and cut into narrower segments than the Spanish plant; they are of a lighter green, and almost smooth; the naked flower-stalk is also much longer, and terminated with a cluster of spikes of blue flowers; at two or three inches below these are two small spikes, one on each side; the flowers are smaller than those of the first fort.

*Method of Culture.*—All the forts are readily increased, by planting slips or cuttings of their young shoots in the spring. With the first two forts, a quantity of slips or cuttings should be taken off in the early spring, as March or April, from three or four, to six inches long, stripping off the under leaves, then planting them in a shady border, four inches asunder, giving a good watering, and repeating it occasionally in dry weather. When the plants are well rooted in summer, they should be transplanted into the places where they are to grow early in autumn, as September or October, with balls of earth about their roots.

And where the first fort is intended to produce flowers for economical purposes, it should be planted in rows, two or three feet asunder, and about the same distance in the rows, or in a single row one or two feet asunder, along the edges or divisions of garden-grounds, in a sort of edging or dwarf hedge; in either of which modes the plants grow freely, continuing in root, stem, and branches several years, and produce abundance of spikes of flowers annually for gathering in the latter end of summer; the culture afterwards is principally to cut down any remaining decayed flower-stalks in autumn, pruning or cutting away any disorderly out-growing branches at top and sides, and digging the ground occasionally in spring or autumn along the rows of plants.

In regard to the second fort, it may also often be raised from seeds, which should be sown in a bed of light earth in the early spring, and raked in evenly with a light hand. The plants rise in about a month, when, if there be dry weather, water should be given; and after they are three inches high, they should be pricked out in beds, half a foot apart, watering them as they require, until fresh rooted. They should stand here till the following spring, and then be thinned out, and planted where they are to remain.

The third and fourth forts may be increased by slips and cuttings, planted in pots, in the early spring months, and placed under frames, due water, and shade from the mid-day sun, being given till they are rooted; when a little advanced in growth, transplanted into separate small pots, and managed as other green-house exotic plants.

The two first forts are useful for their fine spikes or flowers, as well as ornamental in assemblage with other shrubby plants, in the borders and clumps of pleasure-grounds; and the two last forts in the green-house collection

with

with other plants. Those designed for shrubberies or other similar places, being previously raised to some tolerable bushy growth, and a foot high or more, should be planted either in the early autumn, or in the spring, disposing them singly at proper distances in the fronts of the clumps, borders, &c. See LAVENDER.

LAVANDULA, *Lavender*, in the *Materia Medica*. The common lavender, or *lavandula spica*, was formerly considered, says Woodville, as a species of *Nardus*, and appears to be the pseudo-nardus of Mattheolius and Pliny. This plant, which grows spontaneously in many of the southern parts of Europe, appears from Turner to have been cultivated in England previously to the year 1568. The fragrant smell of the flowers is well known, and to most persons is agreeable; to the taste they are bitterish, warm, and somewhat pungent; the leaves are weaker, and less grateful.

The flowers and summits of the narrow-leaved or common lavender are, in a very eminent degree, cephalic and nervine. They are often employed as a perfume, and medicinally as mild stimulants and corroborants, in palfies, vertigoes, lethargies, and tremors of the limbs, both internally and externally.

The flowers are sometimes used in the form of a conserve, into which they are reduced by beating them, while fresh, with thrice their weight of double refined sugar. Water extracts by infusion nearly all the virtue both of the leaves and flowers: in distillation with water, the leaves yield a small portion of essential oil; but the flowers, in their most perfect mature state, about one ounce from sixty. Woodville observes, that in order to obtain the largest quantity of essential oil from these and most other flowers of this kind, they should be allowed to grow to their full maturity, and be dried for some time. This oil is of a bright yellow colour, a very pungent taste, and possesses, if carefully distilled, the fragrance of the lavender in perfection: it is given internally from one drop to five, and employed in external applications for stimulating paralytic limbs, and for destroying cutaneous insects. It is also said, that if spongy paper be dipped in this oil, and applied to the parts, it immediately kills the pediculi inguinales. Rectified spirit extracts the virtue of lavender more completely than water. The simple spirit of lavender, prepared by pouring a gallon of proof spirit on two pounds of the fresh gathered flowers, adding water sufficient to prevent empyreuma, macerating for 24 hours, and distilling a gallon by a gentle fire, is richly impregnated with the fragrance of the flowers. More compounded spirits, in which other aromatics are joined to the lavender, have been distinguished by the name of English or palfy drops: the college of London (1809) directs three pints of the simple spirit of lavender, and one pint of spirits of rosemary, to be digested on half an ounce of cinnamon, half an ounce of nutmegs, both bruised, and an ounce of red sanders wood sliced as a colouring ingredient, macerating for 14 days, and then straining; the college of Edinburgh, to the same quantity of both spirits, orders one ounce of cinnamon, two drams of cloves, half an ounce of nutmegs, and three drams of red sanders. These preparations are taken internally on sugar or in any convenient vehicle, from ten to one hundred drops, and used externally in embrocations, &c.

The medicinal virtue of lavender resides in the essential oil, which is supposed to be a gentle corroborant and stimulant of the aromatic kind; and is recommended in nervous debilities and various affections proceeding from a want of energy in the animal functions. According to Dr. Cullen (*Mat. Med. vol. ii.*) it is, "whether externally applied or given internally, a powerful stimulant to the nervous system; and among the others of this order, named cephalics, the la-

vender has a very good and perhaps the best title to it." And he further says, "it appears to me probable, that it will seldom go farther than exciting the energy of the brain to a fuller impulse of the nervous power into the nerves of the animal functions, and seldom into those of the vital. It was, however, with great propriety, that professor Murray dissuaded its use where there is any danger from a stimulus applied to the sanguiferous system. It is however still probable, that lavender commonly stimulates the nervous system only, and therefore may be more safe in palfy than the warmer aromatics, especially if the lavender be not given in a spirituous menstruum, or along with heating aromatics, which however is commonly done in the case of the spiritus lavendulæ compositus." The official preparations of lavender are the essential oil, a simple spirit, and a compound tincture, already mentioned.

The broad-leaved lavender, a variety of the former, to which foreign writers have given the name of spike, is stronger both in smell and taste than the other, and yields in distillation almost thrice as much essential oil; but the flavour of the oil and of the plant itself is much less grateful: the oil is likewise of a much darker colour, incising to green. This oil, mixed with  $\frac{1}{4}$ ths of rectified spirit, or oil of turpentine, was the "*Oleum spicæ*," formerly highly celebrated as an application to indolent tumours, old sprains, diseased joints, &c. See *Oil of SPIKE*.

LAVANGE, in *Geography*, one of the Virgin islands in the West Indies; three miles S.E. from the island of St. Thomas.

LAVANSAARI, an island of Russia, on the coast of Livonia, 80 miles from the capital, four miles and a half long, and two broad, surrounded on the N.W. side by islets and shallows, having three tolerable harbours, and occupied by about 40 families. Some patches of soil are cultivated, and in the middle of the island is a small lake.

LAVANT SEE, a lake of Stiria; nine miles E. of Neumark.

LAVARA, in *Ancient Geography*, a town of Hispania, in the interior of Lusitania. Ptolemy.

LAVARDAC, in *Geography*, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Nérac. The place contains 928, and the canton 9482 inhabitants, on a territory of 182 $\frac{1}{2}$  kilometres, in 14 communes.

LAVARETUS, in *Ichthyology*, the name of a small fish called by some the *gang-fish*, and the *rhingau*, and by Marcgrave the *curimata*. It seems of a middle nature, between the trout and herring kind, and is caught in vast quantities, in the months of March and April, in several of the lakes in Germany, and is pickled, and sent to different parts of the world. It seldom grows to more than four inches long.

LAVARETUS. See SALMO *Lavaretus*.

LAVATER, JOHN GASPARD CHRISTIAN, in *Biography*, was born at Zurich in 1741. He was intended for the Protestant ministry, and entered upon holy orders in 1761. He acquired an early reputation by the eloquence of his pulpit discourses, and the zeal and benevolence with which he fulfilled the duties of his functions. He felt an early propensity to read the human countenance, and frequently exercised the pencil in sketching such features as had made a particular impression on him, which he studied with great attention. Accident led him to the study of physiognomy; standing at a window with Dr. Zimmerman, he was led to make some remarks on the singular countenance of a soldier that was passing by, which induced the physician to urge him to pursue and methodize his ideas. He accordingly

ingly began the pursuit, and in process of time, with the natural progress of an enthusiastic mind, acquired not only a fondness for the study, but a full conviction of the reality of the physiognomical science, and of his own great discoveries in it. In 1776, he published the first fruits of his labours in a quarto volume, entitled "Fragments." He took in them a wide range of inquiry, and carried his ideas of physiognomy beyond the observation of those parts of the countenance which exhibit to a common eye the impressions of mental qualities and affections, and maintained, as a leading position, "that the powers and faculties of the mind have representative signs in the solid parts of the countenance." Two more volumes appeared in succession, which presented a most extraordinary assemblage of curious observations, subtle and refined reasoning, delicate feeling, and philanthropical and pious sentiment, together with a large admixture of paradox, mysticism, whim, and extravagance. The whole is illustrated with a great number of engravings; many of which are highly finished and singularly expressive. The work was soon translated into the French and English languages, and for a time became the favourite topic of literary discussion. The work now is rarely referred to except for the plates; the science itself is gone into utter neglect. Lavater is well known for a work entitled "Aphorisms on Man," of which an English translation was published in 18mo. in the year 1788. He was a zealous Christian, and translated into the German language "Ronne's Enquiry into the Evidences of Christianity." His popularity as a preacher and pastor was extremely great at Zurich, where the people exhibited to him tokens of the highest respect and the most affectionate veneration, and he was applied to by persons of all ranks as the arbiter of controversies among them. His moral character was exemplary, and his ardent zeal for doing good was scarcely at any time surpassed. No man was ever a more determined opposer to tyranny and intolerance in every shape; he had the true Swiss zeal for liberty. This noble spirit rendered him a friend to the French revolution at the outset, but when the republican rulers began to display a system of rapine and extortion, and to extend this even to Switzerland, he was the boldest of their antagonists. When Zurich was stormed in 1797, he rushed into the streets, and received a severe wound in the breast from a Swiss soldier, on whom he had conferred important benefits. From the effects of this he never entirely recovered; but the activity of his mind was unsubdued till a short time before his death, which happened on the 2d of January 1801, when he was in the sixtieth year of his age. A warm desire to promote the honour of God, and the good of his fellow creatures, was the principal feature in his character, and the leading motive of all he did. Next to these were an indefatigable placability, and an inexhaustible love for his enemies. Monthly Mag. Ann. Regiller.

LAVATERA, in *Botany*, so named by Tournefort, in the Memoirs of the Academy of Paris for 1706, after Dr. Lavater, a physician of Zurich, who is said to have written nothing on the subject of botany, nor have we any information concerning him. Linn. Gen. 354. Schreb. 467. Willd. Sp. Pl. v. 3. 793. Mart. Mill Dict. v. 3. Sm. Fl. Brit. 742. Juss. 272. Cavan. Diss. 86. Lamarck. Illustr. t. 582. Czertn. t. 136.—Class and order, *Monadelphica Polyandria*. Nat. Ord. *Columbifera*, Linn. *Malvaceae*, Juss.

Gen. Ch. Cal. Perianth double; the outer of one leaf, three-cleft, obtuse, shortell, permanent; inner of one leaf, cut half way down into five segments, sharper and more erect, likewise permanent. Cor. Petals five, inversely heart-shaped, flat, spreading, their lower parts attached to the tube of the filaments. Stam. Filaments numerous, united

below into a tube, separating loosely at its top and sides, anthers kidney-shaped. Pysl. Germen superior, orbicular depressed; style cylindrical, short; stigmas several, from seven to fourteen, bristle-shaped, as long as the style. Peric. Capsules numerous, equal in number to the stigmas, of two valves, opening inwards, ranged in a depressed circle round the columnar receptacle, at length deciduous. Seeds solitary, kidney-shaped.

Eff. Ch. Calyx double; the outer three-cleft. Capsules numerous, ranged in a circle, single-seeded.

One of the most handsome of the malvaceous order, at least of those found in Europe, to which quarter of the world, and the north of Africa, the whole genus is confined; for the Linnæan *L. americana* is no other than *Sida abutiloides* of Jacquin, and Willdenow, n. 48. Eight species, exclusive of this, are detailed in Syst. Veg. ed. 14; Willdenow has twelve, seven of which are shrubby, five herbaceous and mostly annual.

In the first section are

*L. arborea*. Sea Tree-Mallow. Linn. Sp. Pl. 972. Cavan. Diff. t. 139. f. 2. Engl. Bot. t. 1841.—Stem arborescent. Leaves downy, plaited, with seven angles. Flower-stalks axillary, clustered, single-flowered.—Found upon rocky cliffs on the south-west coast of England and east coast of Scotland, as well as in other parts of Europe, flowering in July and August. It is naturally biennial, though of a shrubby habit and above six feet high, for it blossoms but once, though it will, in a garden, sometimes survive many winters before that event takes place. The stem is round and thick, branching at the top chiefly, where it forms a leafy head. The leaves are alternate, flaked, pliable and downy, of seven shallow crenate lobes. Flowers numerous, axillary, purple, very like those of the common *Malva sylvestris*, but rather more handsome.

*L. triloba*. Three-lobed Tree-Mallow. Linn. Sp. Pl. 972. Jacq. Hort. Vind. v. 1. 30. t. 74.—Stem shrubby. Leaves rounded, crenate, somewhat heart-shaped, slightly three-lobed. Stipules heart-shaped. Flower-stalks aggregate, single-flowered.—Found on the coasts of Spain and France. With us it is a greenhouse plant, not easily kept nor much valued, being far more beautiful on its native rocks, where the light hoary green of its copious foliage, is prettily contrasted with the large, very delicate, rose-coloured flowers. The broad stipules are remarkable.

*L. maritima*. Soft Single-flowered Tree-Mallow. Gouan. Illustr. 46. t. 21. f. 2. (*Althæa frutex* Clusii; Ger. em. 933f.)—Stem shrubby. Leaves rounded, crenate, bluntly angular, soft and downy. Stalks axillary, solitary, single-flowered.—Native of Spain and the south of France. Linnæus did not distinguish its synonyms from the last, though it differs abundantly in the much greater softness of the leaves, want of stipules, and the solitary flower-stalks. The flowers are large and elegant, of a light purple with dark claws. We have seen this species blossoming in Mr. Argericini's fine conservatory at Blackheath, but it finds no place in the 1st edition of *Hort. Kew.* or the 5th of *Hort. Cant.*

Of the second section are

*L. thuringiaca*. Great-flowered Lavatera. Linn. Sp. Pl. 973. Jacq. Austr. t. 311. Curt. Mag. t. 517.—Stem herbaceous, downy. Leaves somewhat downy; the lower ones angular; the upper three-lobed. Flower-stalks axillary, single-flowered.—Native of Hungary, Tartary, Germany, &c. about hedges; a hardy perennial in our gardens, flowering from July to September, and propagated either by root or by seed; yet as Curtis observes "it is rarely met with in any of our collections;" possibly because the *trimesis* is preferred. The stems are few, erect, three or

four feet high, clothed with short soft hairs. *Leaves* stalked, dependent, but slightly downy. *Flowers* on long solitary stalks, with large, pink, veiny petals, inversely heart-shaped, their sinuses "puckered" as Curtis says; but this is not represented by Jacquin in his wild plant, and is perhaps an indication of luxuriance only.

*L. cretica*. Small-flowered Lavatera. Linn. Sp. Pl. 973. Jacq. Hort. Vind. v. 1. 15. t. 41.—Stem herbaceous, rather hairy. *Leaves* acutely five-lobed. Flower-stalks axillary, aggregate.—Native of Crete, cultivated by Miller in 1768, and we believe still preserved in Chelsea garden, coming up spontaneously from seed, the root being annual. There is nothing to recommend it to general admiration, the *flowers* being far less ornamental than the wild *Malva sylvestris*, which the plant resembles in herbage. We have a specimen from the Göttingen garden named *Lavatera sylvestris* of Link.

*L. trimifris*. Spanish Annual Lavatera. Linn. Sp. Pl. 974. Jacq. Hort. Vind. v. 1. 29. t. 72. Curt. Mag. t. 109.—Stem herbaceous, rough with deflexed hairs. *Leaves* smoothish, heart-shaped, angular; the lower ones rounded. Flower-stalks solitary, shorter than the leaves.—Native of Spain, France, and the Levant, a hardy annual in our gardens, where it is raised without trouble, producing abundance of large, pink or white, very showy blossoms, all summer long. The *stem* is branched, two feet high, rough in the upper part especially, with simple deflexed hairs. The *leaves* are nearly smooth on the upper side, more or less downy beneath, all heart-shaped; the upper ones most angular, the lower more rounded, but still rather lobed. *Flower-stalks* hairy, shorter than the leaves.

*L. punctata*. Dotted-stalked Lavatera. Allion. Auſtr. 26. Willd. n. 11. (*Malva folio vario*; Bauh. Prodr. 137. t. 137.)—Stem herbaceous, rough with starry points. *Leaves* downy; the lower ones rounded, the upper hastate. Flower-stalks solitary, elongated.—Native of the country about Nice, according to Allion, who first, among modern botanists, determined this very distinct species, but did not advert to Bauhin's synonym, which Linnæus had referred to the preceding, but which, from the excellent figure and description, we have no hesitation in applying to this. *L. punctata* is an annual, distinguished from the last by its starry pubescence, much more downy *foliage*, and much smaller purple *flowers*, on longer and more slender stalks. The *leaves* also grow on long footstalks, and differ greatly in shape, the lower ones being heart-shaped, short and rounded, slightly lobed; some higher up deeply and sharply five-lobed; but most of the upper ones hastate; all are crenate. The *calyx* is soft and downy.

LAVATERA, in Gardening, comprehends plants of the herbaceous perennial kinds, of which the species most generally cultivated are the Cretan lavatera (*L. cretica*); the common annual lavatera (*L. trimifris*); the great-flowered lavatera (*L. thuringiaca*); the tree lavatera or mallow (*L. arborea*); the downy-leaved lavatera (*L. obliqua*); the three-lobed lavatera (*L. triloba*); and the Portuguese lavatera (*L. lusitanica*).

The first sort varies with red flowers, with white flowers, and with purple flowers.

The second kind has likewise several varieties.

*Method of Culture*.—The first two, or annual sorts, are readily increased, by sowing the seeds in a light soil in the places where the plants are to remain, or in pots, in the spring season, as about the latter end of March, in patches of four or five in each, giving them water occasionally when the weather is dry. When the plants have attained a little growth, they should be thinned out to one or two of the strongest plants. When any are to be removed to other

places, it should be done at this period, and with a little earth about the roots, due water and shade being given; but they seldom succeed well by transplanting.

All the other shrubby perennial sorts may likewise be increased by sowing the seeds, and managing the plants in the same manner. Most of these sorts will not last more than two years in this climate, unless the soil be dry, when they continue three or four.

They in general require a warm dry situation, or to have their roots covered by old tan, or the protection of the greenhouse during the severity of the winter season.

These plants are highly ornamental in different parts of pleasuring-grounds. The annual sorts have great beauty, in their flowers being large, numerous, and conspicuous, and are proper where large showy-flowering plants are required. The perennial kinds are also suitable for large borders and shrubby compartments, having large, straight, upright, durable stems, terminated by branched bushy heads, and very large soft foliage; that form a variety in assemblage with other plants, though their flowers are often hidden by their large leaves.

LAVATION, in Antiquity, a feast of the Romans, in honour of the mother of the gods, instituted in memory of the day when the worship of Cybele was transferred from Phrygia to Rome, and celebrated on the twenty-fifth of March.

LAVATORY, or LAVADERO, a name given to certain places in Chili and Peru, where gold is got out of earth by washing.

M. Frezier gives us the following description of the lavatories of Chili: they dig deep into the earth, in such places as they have reason to expect gold in; and, in order to facilitate this digging, they turn a stream of water upon the spot, loosening the earth as much as possible all the time, that the current may have the greater effect, and tear up the earth more strongly. When they are got to the earth they want, they turn off the stream, and dig dry.

The earth that they now get is carried on mules, and discharged into a basin, made somewhat in the manner of a smith's bellows, into which a little rivulet of water runs with a great deal of rapidity, dissolving the parts of the earth, and carrying every thing away with it, excepting the particles of gold, which, by their great weight, precipitate to the bottom of the basin, and mix with a fine black sand, where they are almost as much hidden as they were before in the earth. See *History of GOLD*.

Sometimes they find very considerable pieces in lavatories, particularly some pieces of 24 ounces each. There are several lavatories where they find these pebbles, or pieces of virgin gold, of a prodigious size. Among others, they tell of one that weighed 512 ounces, bought by the count de la Moncloa, viceroy of Peru.

Nine or ten leagues to the east of Coquimbo are the lavatories of Andacoll; the gold of which is 23 carats fine. Their work here always turns to great profit, excepting when the water fails them. The natives maintain that the earth is creative (*creatrix*); that is, it produces gold continually; because, after having been washed sixty or eighty years, they find it impregnated afresh, and draw almost as much out of it as at first.

LAVATRIS, in Ancient Geography, a place of Great Britain, mentioned in Antonine's 5th Itinerary, situated between Cataracton or Cataract, and Vertevic or Bough, and supposed to be Bowes in Yorkshire.

LAVAU, in Geography, a town of France, and chief place of a district, in the department of the Tarn, before the revolution the see of a bishop; 18 miles N.E. of Toulouse.

Houfe. The place contains 6237, and the canton 14,730 inhabitants, on a territory of 252½ kilometres, in 22 communes. N. lat. 43° 41'. E. long. 1° 53'.

LAUBACH, a town of Germany, in the principality of Solms Laubach; 40 miles N.E. of Mentz. N. lat. 50° 32'. E. long. 8° 50'.

LAUBAN, or LUBAS, a town of Lufatia, on the river Queifs, furrounded by a wall and fome battions. The trade of the place in cloth and linen is confiderable; 13 miles E.S.E. of Gorlitz.

LAUCHA, a town of Saxony, in Thuringia, on the Unfrutrit; 32 miles N.E. of Erfurt. N. lat. 51° 14'. E. long. 11° 47'.

LAUCHHEIM, a town of Germany, belonging to the Teutonic knights; 10 miles W. of Nordlingen. N. lat. 48° 32'. E. long. 10° 14'.

LAUCHSTÄDT, a town of Saxony, in the territory of Merfeburg; 4 miles W. of Merfeburg. N. lat. 51° 26'. E. long. 12° 1'.

LAUCKISSKEN, a town of Pruffia, in the circle of Samland; 25 miles E.N.E. of Königsberg.

LAUD, WILLIAM, in *Biography*, archbifhop of Canterbury, the fon of a clothier of Reading, in Berkfhire, was born in October 1572, and having received his grammar learning at the fchool of that town, he was fent to the univerfity of Oxford in 1589, where he was entered of St. John's college. Of this college he was admitted a fellow, and at the proper periods he took his degrees. In early life he was efteemed by all who knew him as a very forward, confident, zealous perfon. He was ordained deacon in 1600, and in the following year he took prieft's orders, and read a divinity lecture in the college. It was about this time that he maintained the conflant and perpetual vifibility of the church of Chrift, derived from the apoftles to the church of Rome, and continued in that church till the reformation. In 1605, he was chofen proctor of the univerfity, and in the fame year he was appointed chaplain to Charles Blount, earl of Devonfhire. In 1604, he took his degree of bachelor of divinity, and in the exercife which he performed on this occafion he maintained the neceffity of baptifm; and that there could be no true church without diocefan bifhops. From the drift of his difcourfe he was fuppofed to be ftrongly inclined to popery. Dr. Abbot had already been his antagonist, and on this occafion he made no fcruple of charging him with being a Papift in the moft public manner, fo that it was fcarcely fafe to be confidered his friend and companion. In the year 1605, Mr. Laud married the earl of Devonfhire, his patron, to Penelope, the late wife of lord Rich, who had been divorced from him for adultery. In juftification of himfelf, he contended that the innocent and guilty might lawfully marry again, after a divorce had been obtained. The part which he took in this affair expofed him to much cenfure from the public, gave great offence to the fovereign, and made fo deep an impreffion on the mind of Laud, that he ever afterwards obferved the anniversary of the marriage as a day of falling and humiliation. His firft preferment in the church was to the vicarage of Stamford, in Northamptonfhire, in the year 1607, which led to other fituations of more value and importance. In 1611, he was elected prefident of St. John's college, and very foon after was appointed one of his majesty's chaplains. He had now great hopes of rifing with rapidity to the higheft honours, but his expectations were fo completely difappointed, that in the year 1614 he had determined to withdraw from the court. By the perfuafion of Dr. Neile, bifhop of Lincoln, he was induced to remain there another year; to keep up his fpirits the pre-

late gave him a prebend in the church of Lincoln, and, in the following year, the archdeaconry of Huntingdon. In 1616, the king prefented Dr. Laud to the deanery of Gloucefter, and at the fame time required him to reform and fet in order whatever was amifs in that cathedral. He was diligent in obeying the royal mandate, and made great alterations in the church, which being effeeted, he recommended, that the members of that church fhould make their humble reverence to God not only at their firft entrance into the choir, but at their approaches to the holy table, which he had removed from the middle of the church to the eaft end of the choir. Thefe changes gave great offence to many perfons on account of their fuperftitious tendency, particularly to Dr. Miles Smith, bifhop of Gloucefter, who from that moment would never enter the church again fo long as he lived. Laud now began to take an active part againft the Puritans; and he was alfo very defirous to bring the church of Scotland to a uniformity with that of England; with this view he attended the king in a journey to Scotland, but nothing was gained by the expenfive tour, excepting that the king faw his commands neglected, and his authority contemned. Upon his return he was made a prebend of Weftminfter, and in the following year he was nominated to the bifhopric of St. David's, chiefly through the intereft of the lord-keeper Williams, at the infigation of the favourite Buckingham, to whom Laud had recommended himfelf. In the year 1622, bifhop Laud held a conference with Fifher, a Jefuit, before the marquis of Buckingham and his mother, in order to confirm them both in the Proteftant religion, with refpect to which they were then wavering. From this time a clofe intimacy fubfifted between Laud and Buckingham, who made the bifhop his confeffor and counfellor; and when he went with prince Charles into Spain, left him as his agent at court, with whom he maintained a frequent correffpondence. In the courfe of this, he infinuated fome heavy charges againft his friend, the lord-keeper Williams. This circumftance occafioned a fettered enmity between the two bifhops, Williams accufing Laud of the deepeft ingratitude on that account. Laud correffponded with the duke of Buckingham during his journey to France, to bring about a marriage between the princefs Henrietta-Maria and king Charles I. Supported by Buckingham's favour, to whom he is charged with having rendered himfelf too fubfervient, bifhop Laud gained the confidence of the new king, and it was faid that thefe two men ftopped up both the king's ears from any other doctrines in church or ftate, but what was infufed by them. Laud was defired by king Charles to make out a list of the eminent divines with their principles and qualifications, that from this list he might felect his chaplains, and others for promotion in the church. Laud quickly gave in his list, of whom his friends had the mark O againft their names, for "orthodox," but thofe whom he did not delight to honour, he branded with a P, fignifying, that they were Puritans, and, as fuch, ought not to be trufted with any power whatever. At the coronation in 1626, Laud officiated as dean of Weftminfter, by the king's appointment, in the room of bifhop Williams, who was in difgrace. In the fame year he was tranflated from St. David's to the bifhopric of Bath and Wells, and was alfo appointed dean of the chapel royal. In 1627 he was fworn a member of the privy council, and, in 1628, tranflated to the fee of London. By the advice of Laud all ecclefiaftical preferments were given away, and the whole country was almoft entirely governed. Upon the affafination of the duke of Buckingham he prevailed on the king to fend to the judges for their opinion,

“whether, by law, Felton might not be racked:” they returned a decided opinion, “that he could not be racked by the laws of England.” Bishop Laud was the most active and leading member of the high-commission court, the arbitrary and severe proceedings of which were justly odious to the nation. For an instance of the extreme rigour and cruelty of their proceedings, we refer to the article *LEIGHTON*, a learned Scotch prelate, who was sentenced to stand in the pillory, and to have his ears cut off, and his nose slit, and then to be imprisoned for life, on account of a book which he had written. No sooner was the savage sentence passed, than bishop Laud pulled off his cap, and gave God thanks for it. In the year 1630, bishop Laud was elected chancellor of the university of Oxford, to which he was a great benefactor. He adorned it with many noble buildings, and enriched it with books and curious MSS. in almost all the known languages of the world, procured at an immense expence. In 1631, bishop Laud undertook to repair and beautify St. Paul’s cathedral, which he accomplished in a very magnificent style; but to raise the money which was expended, he resorted to so many oppressive and unjustifiable methods, that it became the common proverb, and St. Paul’s was repaired with the fins of the people. Laud shewed great zeal in obtaining the utmost deference to all the external rites and ceremonies of the church, and he caused the several churches, in which he took an interest, to be adorned with all kinds of pictures, images, and altar-pieces, all which circumstances led the people to suspect, that he was too much inclined to the papal religion, if he were not already a Papist in his heart. This suspicion was still strengthened by his declaration, that in the disposal of all ecclesiastical preferments, he should give a most decided preference to single men, supposing the abilities of the single and married to be otherwise equal. In 1633, he attended the king in a journey to Scotland, and was present at his coronation for that country, which ceremony was performed in the abbey church of Holyrood-house. While in Scotland, he took every opportunity of urging the clergy to conformity with the church of England, but in this he was completely unsuccessful. Almost immediately after his return, Abbot, the archbishop of Canterbury, died, and Laud was instantly appointed his successor. He was, almost at the same moment, offered a cardinal’s hat, which he declined, but upon what grounds he refused the honour is not known, though various motives have been assigned. He now carried matters very high, drove many of the French and Dutch Protestants, to whose ancestors Edward VI. had given an asylum, out of the kingdom; and either imprisoned or silenced many worthy clergymen, who refused to read the king’s declaration for allowing lawful sports on Sundays after divine service. He was still more severe against those who were any ways suspected of puritanical principles. Some of them, by an exertion of arbitrary power, were fined, imprisoned, and even whipped, and kept to hard labour. Laud was, in 1635, nominated to other high offices, among which was the office of a commissioner of the treasury. He now procured the lord treasurer’s staff for his friend Dr. Juxon, the bishop of London, which gave great offence to the people. (See *JUXON*.) We cannot give any thing like a detail of the many prosecutions in which the archbishop was almost constantly engaged, they will be found in other articles of this work. (See *BASTWICK*, *PRYNNE*, &c.) It is sufficient to say in this place, that these prosecutions were cruel, illegal, and tyrannical; but they were not borne by the people without deep, though silent, complaints. Never was man more hated, or more detested so: there still existed in the country the printing press, by means of which his proceedings and character, and the arbi-

trary measures of the court, were exposed to the whole nation, in a secret manner. He accordingly procured a decree to be made in the star-chamber, which ordained, that the number of printers should be limited; and those who were allowed to follow the profession, should not be allowed to print any books of divinity, law, physic, philosophy, or poetry, till they had been licensed by the archbishop of Canterbury, or the bishop of London for the time being, upon pain of very grievous penalties. These proceedings, though they might be useful to the court for a short time, created so many enemies to the existing state of things, that there was great danger of some sudden convulsion. Many of the best men in the country, to avoid persecution, retired to America for an asylum, and a multitude of others would have followed their example, had not the archbishop obtained an edict to prevent any one from leaving the kingdom without a licence for that purpose. This was a degree of severity scarcely paralleled in the Christian world, but it answered no good end, for the people took a general disgust, and almost the whole of England was filled with Puritans. Laud did not confine his arbitrary measures to England, but was equally violent in his plans with regard to Scotland, so that he drew upon his head the hatred of that kingdom, and provoked the resistance which led to the renewal of the solemn league and covenant, subscribed by king James, and the whole nation in the year 1590. The attempt made in 1637, to force on the Scotch the new liturgy, was the first step which called forth the open opposition of all ranks. The king at first raised a powerful army to reduce the covenanters to submission, but when he had marched to the borders of Scotland, he found the preparations made to receive him so serious, and he knew that his Protestant nobility and soldiers were not zealously affected in his cause, that he found himself compelled to seek for a general pacification. It was soon discovered that the idea of war was not abandoned, but only deferred, and that the English court were resolved to subdue the spirit of the people in Scotland. Laud and Strafford were the advisers of this resolution, and to raise supplies, application was made to the English parliament, which, after an interval of twelve years, was summoned to meet at Westminster for that purpose. The commons not only refused to comply with the desires of the crown, but appointed committees to consider the grievances under which they laboured. The king wished them to commence with a subsidy bill, which they refused; he at length dissolved the parliament, in great anger, before a single act was passed. All the engines of arbitrary power were set to work to raise money for the war, and those who refused to comply with the demands made upon them were fined and imprisoned. The greater part of the odium of these oppressions fell upon the archbishop, of whom the populace expressed their detestation in the most open way that they dared. On one occasion, viz. on May 9th, 1640, a paper was posted up, exhorting the London apprentices to attack the palace at Lambeth, but the archbishop having had timely notice of their intentions, frustrated their designs, and dispersed the multitude, amounting to the number of 500 persons. One of them was taken in the act of breaking the windows, and was cruelly put to death as a traitor, but this extreme severity only served to inflame the mob still more against the archbishop. Another circumstance which contributed to encrease the number of the archbishop’s enemies, was his continuing the convocation of the clergy after the dissolution of the parliament, by which he obtained several subsidies granted by the clergy, which the Commons had refused till their grievances were redressed. At length the necessities of the state obliged the king to call a new parliament, and,

as soon as it met, the canons and constitutions of the late convocation came before the house of commons. These, being discussed, were declared "to contain many matters contrary to the king's prerogative, to the fundamental laws and statutes of the realm, to the rights of parliament, to the property and liberty of the subject, and matters tending to sedition, and of dangerous consequence." In the course of the debates the archbishop's character was warmly attacked, and in some of the speeches he was charged with the treasonable design of subverting the religion and laws of the country. On the next day articles against the archbishop, presented by the Scotch commissioners, were read in the house of lords, and then reported to the house of commons, in a conference between the two houses. The resentment of parliament broke out into a flame, and a motion was made and carried that he had been guilty of high treason. Upon this, Denzil Hollis, son of the earl of Clare, was immediately lent up to the bar of the house of lords, to impeach him in the name of the Commons of England, to inform their lordships, that, in convenient time, they would bring up the particulars of their charge, and to request, that in the mean time he might be committed to safe custody. His grace being now commanded to withdraw, he requested leave to say "that he was heartily sorry for the offence taken against him, but humbly desired their lordships to look upon the whole course of his life, which was such, that he was very sure not one man in the house of commons did believe, in his heart, that he was a traitor." He was now committed to the custody of the gentleman usher of the black rod; and on the 26th of February, fourteen articles were brought up from the Commons by sir Henry Vane, the younger. He was then committed to the Tower, and in his passage thither he had to undergo the loud and deep curses of an enraged populace. One of the first steps taken against him was levying upon his property a fine of twenty thousand pounds, for his proceedings in the convocation held in 1640. In June 1641, he resigned the chancellorship of the university of Oxford, and in the following October, the house of lords sequestered his archiepiscopal jurisdiction. His confinement in the Tower was very severe, and he began to feel in his own person such sufferings as must bring to his recollection what he, in the day of his power, had inflicted upon others. After an imprisonment of nearly three years, he was brought to trial upon the fourteen articles already mentioned, and upon ten additional ones, which were now, for the first time, brought forward. Many of the charges were ill supported, and much of the evidence was trifling and irrelevant. It sufficiently appeared, however, that he had laboured to extend the royal prerogative and the ecclesiastical power, to a degree that was utterly inconsistent with the liberties of the people; that he had been zealous in enforcing the illegal claim of ship-money; that he had committed persons to prison, and punished them without law; and that he had been guilty of many arbitrary, illegal, and cruel actions. Archbishop Laud defended himself with uncommon spirit, eloquence, and acuteness, and with extraordinary presence of mind. His counsel in their defence endeavoured to shew, that if the charges were true, they did not amount to treason by any established law of the kingdom. This justification had its weight, and the lords, who were staggered by the plea, deferred giving judgment, till the Commons thought fit to bring in a bill of attainder, which was, after much delay, passed. To stop the consequence of this, the archbishop presented the king's pardon under the great seal, but it was over-ruled by both houses. By this bill the archbishop was condemned to suffer death, as in cases of high treason, and

all the favour he could obtain was to have his sentence altered from hanging to decapitation. He met his death with great firmness on Tower hill, on the 10th of January, being then in the seventy-second year of his age. Mr. Hume, in speaking of the learning and morals of archbishop Laud, says "he was virtuous, if severity of manners, and abstinence from pleasure, could deserve that name. He was learned, if polemical knowledge could entitle him to that praise." In his government of the church, it has been justly observed, he displayed a total want of charity towards those who made the least opposition to the doctrines and ceremonies established by authority; and under his countenance, the star-chamber wore all the horrors, and exercised all the cruelties, of an inquisition. In state affairs his counsels were high and arbitrary, and he was very active in promoting those measures which ultimately proved his own ruin, and that of the king. He was in some cases generous and munificent: besides what he did for Oxford in her buildings and library, he founded an Arabic lecture, which began to be read in 1636, and he invited the university with many new privileges. He procured a charter for the town of Reading, founded in it an hospital, and endowed it with a revenue of 200*l.* per annum. The archbishop published some single sermons, which have been reprinted since in an octavo volume. He printed a conference between himself and the Jesuit Fisher. His diary has been printed since his death; and in the year 1700, was published "An historical Account of all the material Transactions relating to the University of Oxford, from Archbishop Laud's being elected Chancellor, to his Resignation of that Office," written by himself. His letters to Gerard John Vossius were printed in London in 1690, and some others may be found at the end of Dr. Parr's Life of archbishop Usher. Biog. Brit. Toulmin's Edit. of Neal. Hume.

LAUDA, in *Geography*, a town of the duchy of Wurzburg, on the Tauber; 28 miles S.S.W. of Wurzburg.—Also, a town of the duchy of Warfaw; 20 miles S.E. of Gnesna. It is called Laudica.

LAUDAMNAT, a town of Bengal; 12 miles S. of Nattore.

LAUDANUM, a name given by the chemists to certain preparations, chiefly extracts of opium, on account of their excellent qualities; the word being derived from *laudare*, to praise.

The "laudanum liquidum" of Sydenham, Thebaica tinctura, or wine of opium of the London Pharmacopœia of 1809, is prepared by macerating for eight days 1 oz. of extract of opium, bruised cinnamon bark and bruised cloves, of each a dram, in a pint of wine, and straining. It is observed, that the degree of narcotic power of this preparation is nearly the same as that of the ordinary tincture of opium, from which it differs, in having the extract for its basis, in the addition of aromatics, and in the vehicle employed. The extract of opium, it is supposed, produces less consequent affection of the brain and nervous system than crude opium, and the same effect seems to be further obviated by the aromatics which are joined to it. This is a composition of the same articles, in different proportions, as the Tinctura thebaica of P. L. 1745, and as the celebrated liquid laudanum of Sydenham. This is still in use, and it possesses such advantages by the modification of opium it affords, as to justify being restored to the Pharmacopœia. See OPIUM.

LAUDAVA, in *Geography*, a town of Prussia, in the palatinate of Culm; 20 miles N.E. of Thorn.

LAUDER, a royal borough, in Berwickshire, Scotland, is situated on a river of the same name, about 22 miles to the south of Edinburgh, and 24 from Berwick. It is

now only a place of a mean appearance, and entirely destitute of trade. Formerly, however, it was a place of very considerable note. It was constituted a royal borough at a very early period, and for many years was distinguished as the residence of royalty, and the seat of the Scottish parliament. In the reign of king James III., when the parliament was convened to consult upon the means of repelling the English invasion, the nobility were so enraged at the conduct of the favourite minister, sir Robert Cochrane, that they hung him and his associates over Lauder bridge, in presence of the king and his army. This town has five fairs during the year. It joins with Haddington, Salburgh, Dunbar, and North Berwick, in sending a representative to parliament. Near the town, on the side of the river, is Lauderfort, built by Edward I. of England, and now the principal seat of the earl of Lauderdale. In this mansion are several noble apartments, rich in stucco work. One of them is very carefully preserved, as a curious example of the taste of the age in which it was made. Many vestiges of ancient Pictish camps can still be distinctly traced in this neighbourhood. Several tumuli, also, are visible on Lauder-Muir, which has probably been the scene of some battles in ancient times, as many fragments of swords, bows and arrows, &c. have been dug up from this place. On a rising ground, not far from the town, are the remains of a Roman station, in which a number of coins of that people have been found at different periods. Some ancient Spanish, English, and Scottish coins have likewise been discovered in different fields in this vicinity. The soil in the parish of Lauder is light and sandy, and in a high state of cultivation. The country rises gradually from the river, on both sides, to hills of a moderate height, which afford excellent pasture for sheep. Copper ore has been discovered in different spots, but is not rich enough to admit of being wrought with any prospect of advantage. Slate is also in plenty, but of an inferior quality. Adderstones and arrowpoints of flint, commonly called *elf*, or *faery arrows*, and several other stones of the most fanciful shapes, are found here after heavy rains. The whole parish, according to the parliamentary returns in 1800, contained 349 houses, inhabited by 1760 persons. Sinclair's Account of Scotland, vol. i. by the Rev. Dr. James Ford.

**LAUDI SPIRITUALI**, *Ital.* the most ancient melodies that can be found in Italy, set to Italian words. It was the opinion of Father Mencltrier (sur les Drames en Musique) that hymns, canticles, and mysteries, in the vulgar tongues of Europe, had their origin from the pilgrims who went to the Holy Land. St. Francis d'Assise, born 1182, is mentioned by Crescimbeni, and other Italian writers, among the first pious persons of that country who exercised their genius in composing hymns and spiritual songs, called *Laudi*, in the form of canzonets. *Le Laudis*, which were likewise called *lalde*, *lodi*, *cantici*, or *canticles*, are compositions in praise of God, the Virgin Mary, or the saints and martyrs. They resemble hymns as to the subject, but not the character and verification: hymns having been originally constructed on Greek and Roman models; but the *laudi*, or spiritual songs, are entirely of Italian invention.

A society for the performance of these religious poems was instituted at Florence so early as the year 1310, the members of which were called *laudisti*, and *laudisti*. In the fifteenth century this species of sacred poetry was very much esteemed and practised, as is manifest by the various collections that were made of them, one of which was printed 1485. In the next century several volumes of them were published, among which there are many poetical compositions on sacred subjects by Politian, Bembo, Lodovico Martelli, and other eminent poets. (*Quadrio*, *Storia d'Ogni Poef*

rol. ii. p. 466.) In the 17th century, though their favour was somewhat diminished, yet, besides a large volume composed by Serafino RAZZI, and published by the author, 1608, there were many collections of these spiritual songs printed.

Crescimbeni tells us that the company of *laudisti* of St. Benedicet, at Florence, went to Rome during the time of the grand jubilee, in the year 1700, and sung through the streets in procession several ludi that were written by the celebrated Filicaja. In most of the ancient collections, the melodies were prefixed to each of these songs. They were at first little more than chants, and without base. However, according to the commentary on Boccaccio, by Sanfovino, published at Venice, 1546, they were afterwards sung in many different parts. "There are in Florence," says he, "several schools of artizans and mechanics, among which are those of Orfanmichele, and Santa Maria Novella. Every Saturday after nine o'clock these assemble in the church, and there sing five or six ludi, in four parts, the words of which are by Lorenzo de Medici, Pulci, and Giambellari; and at every ludi they change the singers, and to the sound of the organ discover a madonna, which finishes the festival. And these singers, who are called *laudisti*, have a preceptor, whom they denominate their captain or leader."

This company still subsisted in 1770, when we frequently heard them sing their hymns, through the streets, in three parts, and likewise in their church, accompanied by an organ. Of the antiquity of this institution, as a MS. volume of *Laudi Spirituali*, which we found in the Magliabecchi library at Florence, is an indisputable proof, the preface, and a specimen of those ancient melodies, bearing date MCCCXXVI. have been inserted in the General History of Music, vol. ii. p. 327.

**LAUDICOENI**, among the Romans, formed of *laus*, praise, and *cena*, supper or entertainment, applauders, or persons who, for a reward, attended the rehearsal of plays and orations, in order to raise, or join in the acclamation. See ACCLAMATION and APPLAUSE.

**LAUDON**, GIBSON ERNEST, baron, in *Biography*, was descended from a respectable family, originally from Scotland, a branch of which settled in Livonia, and there purchased an estate at Totzen, where the subject of the following article was born in 1716. He displayed, at an early age, a strong inclination for a military life, and being instructed with this view, he entered, at the age of fifteen, into the Russian army as a cadet, and, in 1733, he was at the taking of Dantzic, where the king of Poland had sought refuge, in consequence of the disturbances which then prevailed in that country. He served three campaigns under count Munich against the Turks, and was present at the taking of Azof, Oczakow, and Chotzim. On the restoration of peace, he staid some time at Petersburg, in hopes of higher promotion, but being disappointed in his expectations, he went to Vienna, and was appointed by the empress queen to a command in the corps of Pandours, then raised by baron Trenk, and with these he proceeded to Bavaria. While he belonged to this corps he was severely wounded, and taken prisoner by the French, but was rescued by his own corps before his wound was healed. After this he was engaged much in active service, but he employed every leisure moment in the study of the military art, and in preparing himself for the active situation in which he was afterwards placed in the seven years' war. In 1754, he was employed to reduce to obedience the rebellious Croats, which he did rather by his judicious conduct than by force of arms. During the seven years' war, which commenced in 1756, he performed the most noble exploits, which we cannot in this place give in detail. Towards the close of that war, he

termed to make an attack on Schweidnitz. The night appointed for the execution of this plan was the 30th of September. Every preparation being made, Laudon harangued his soldiers, forbade them, under the severest penalties, to plunder the town, and promised, in case of their obedience, to distribute among them the sum of 100,000 rix-dollars. The guards exclaimed with one voice, "No, general, lead us on to glory, we do not want money." At two in the morning the signal was given, and the first assault made, and in four hours Laudon was in possession of the whole fortrefs. Although this achievement had been undertaken without the order of the Aulic council, the empress congratulated the victor in a letter written by her own hand, and sent him her picture set round with diamonds. On the conclusion of peace in 1763, the general retired to his estates in Bohemia, but in 1766 the empress appointed him a member of the Aulic council of war, and in the following year he was elected a member of the equestrian order of the empire, and in 1769 he was made commander-in-chief in Moravia. In 1770, when Frederic the Great paid a visit to the emperor Joseph at Neustadt, the principal officers were invited to dine with the two monarchs. As the company were about to place themselves at table, his Prussian majesty said to Laudon, "come general, and sit near me, I would rather have you by my side than opposite to me." In the war of Bavaria, in 1778, he was promoted by the emperor to be field-marshal, and entrusted to the command of the Austrian army, which amounted to 50,000 men. The plans which he formed to counteract the designs of the enemy were worthy the reputation which he had before acquired. After the peace, Laudon again retired to his estates, from whence he was again called, on the breaking out of the Turkish war, in 1788. He had the command of the grand army when it was resolved to reduce Belgrade; the archduke Francis was to be present at the siege, and the emperor, in a letter to Laudon, said, that "his nephew could not be in a better school than under his Gideon." The attack commenced on the 15th of September, and on the 30th it was determined that the place should be carried by storm. The assault began about nine in the morning, and at one of the outworks was in possession of the besiegers. The fortrefs still refused to capitulate; but, after a dreadful bombardment, by which most of the enemy's cannon were silenced, the place surrendered. In consequence of this achievement, he was appointed generalissimo of the whole Austrian army, an office which had been conferred on no person since the time of prince Eugene, and which gave him an unlimited controul over all the Austrian generals, and even over the Aulic council of war. On his return to Vienna, he was received with every mark of distinction that his sovereign and the people, by whom he was idolized, could bestow. After the death of the emperor Joseph, he was confirmed in all his appointments by his successor Leopold, who continued the war; soon after this he was taken ill of a fever, of which he recovered, but having imprudently rode out, contrary to the advice of his physicians, he was seized with a suppression of urine, which put an end to his life in the month of June following. This great general was beloved by his troops, who, under his command, believed themselves to be invincible. The most striking feature in the character of Laudon was that dauntless presence of mind, combined with daring intrepidity, so essential to the hero, and which can turn to the best advantage any unexpected opportunity that occurs. Joseph II. had a bust made of him, to be erected in the hall of the Aulic council of war, with the following inscription, "Gideonis Laudoni, summi castrorum praefecti, semper strenui, fortis, felicis militis, et civis optimi exemplum, quod duces militaeque imitantur, Josephus II. Aug. in ejus effigie proponi

voluit, anno 1783." After the capture of Belgrade, the emperor took from the family repository of the house of Austria the large star of the Theresian order, and sent it to Laudon, with permission for him to wear it on his breast; though by the statutes it could only be worn by the grand master of the order. Gen. Biog.

LAUDS, LAUNES, the second part of the ordinary office of the breviary, said after matins, though, heretofore, it ended the office of the night.

The laudes consist principally of psalms, hymns, &c. whence they took their name, from *laus, laudis, praef.*

LAVELANET, in *Geography*, a town of France, in the department of the Arriège, and chief place of a canton, in the district of Foix; 12 miles N.E. of Tarascon. The place contains 1200, and the canton 12,831 inhabitants, on a territory of 327½ kilometres, in seven communes. N. lat. 42° 56'. E. long. 1° 55'.

LAVELLO, a town of Naples, in Basilicata, the see of a bishop, suffragan of Bari; six miles N. of Venofa.

LAVEN, a small island near the E. coast of Luçon. N. lat. 14 12'. E. long. 124 6'.

LAUENAU, a town of Westphalia, in the principality of Calenberg; 15 miles N. of Hameln.

LAUENBURG, a town of Hinder Pomerania, and chief town of a lordship of the same name, situated on the Lehe; 36 miles W. of Dantzic. N. lat. 54° 32'. E. long. 17° 42'.—Also, a town of Germany, in the duchy of Saxe-Lauenburg, on the right coast of the Elbe, built by Henry the Lion. Here is a toll on the Elbe; 30 miles S.E. of Hamburg. N. lat. 53° 22'. E. long. 10 48'. See SAXE-LAUENBURG.

LAVENDER, in *Agriculture*, a small shrubby plant, sometimes cultivated in fields near large towns for the spikes of flowers, which are either sold in small bundles, or distilled for lavender-water, and the essential oil of the plant.

The common spike lavender is mostly employed with this intention. According to some the method of cultivating it is by planting the slips or cuttings of the young shoots, after being struck, in rich shady borders or nurseries the preceding spring, about September or October, in rows, two, three, or more feet distance from each other, and about the same distance apart in the rows, the ground being kept clean by digging or hoeing in the spring or autumn, and the plants retained in order by proper pruning. And as they decay from age or other accidents, they are replaced from the nurseries; the slips of such plants as are wearing out being made use of for the purpose. The spikes of flowers begin to get ripe and ready for gathering about the end of June or July, when it is collected by women and children by cutting off the heads and tying them up in bundles, so as to be sent to the still-house, or other places, in proper baskets. When, for distilling, the lower parts of the stems are then cut off and the heads put into the still.

But this plant, when cultivated in the field, should, according to others, have the ground well prepared by digging, or repeated ploughing and harrowing; after which, in the spring season, as about March or beginning of April, a proper quantity of slips or cuttings of the young shoots or branches should be provided, and planted at once by means of a dibble, in rows of not more than two and a half or three feet apart, and one and a half or two feet distant in the rows, closing the mould well about them. They afterwards require to be kept clean by means of the hoe, and to have the mould brought up to them occasionally, particularly in the autumn, and the dead stems or leaves cleared away.

They will mostly afford spikes of flowers in plenty in the second summer, after being thus planted out.

Lavender succeeds best where the soil is rather of a dry quality, and not too stiff. In some parts of the southern districts near London, it is grown in the fields with much profit.

In the Agricultural Survey of Berkshire, it is stated, that the late field-marshal Conway, about twenty years ago, formed a large lavender plantation, and erected proper apparatus for its management at Park-place, near Henley. "There are about twenty acres planted with lavender, on the side, and at the bottom of a chalky hill, with a south-western aspect. The land at the bottom is very good, but that on the slope has only a thin covering of mould over the chalk, and the difference of soil is strongly marked by the luxuriance of the plants they respectively bear."

It is of such importance to keep crops of this sort perfectly clean, that three men are constantly employed in weeding this plantation; who, occasionally, use small hand-hoes, but not much, as they are liable, without great care, to break and injure the plants. When the state of the weather will not admit of this sort of business being done, they go over the plantation with large shears, and clip off all the stalks which were left by the lavender cutters.

Hot summers are very favourable to the productiveness of plantations of this kind.

LAVENDER, in *Botany*. See LAVANDULA.

LAVENDER *Cotton*. See SANTOLINA.

LAVENDER, *French*. See CASSIDONY.

LAVENDER, *Sea*, *Limonium*. See STATICE.

LAVENDER, *Hollow-leaved Sea*, or *Side-saddle Flower*. See SARRACENA.

LAUFENFRED, in *Geography*, a town of Westphalia, in Calenberg, on the Wefer; 15 miles N.W. of Gottingen.

LAVENHAM, a market-town and parish in the hundred of Babong, and county of Suffolk, England, was formerly considerable for its manufacture of woollen cloths and calimancoes. The making of yarn from wool is now, however, the principal employment of the inhabitants. The market is held here on Tuesday, and there are two fairs during the year; one for butter and cheese on the 10th of October, and another for horses on Shrove Tuesday. Six capital burghesses, chosen for life, constitute the governors of the town, and by them all the inferior officers are appointed. The land here is of that sort called Borough-English, whereby all heritable property descends to the youngest son, or, in default of issue, to the youngest brother. The town itself is agreeably situated on the banks of the river Brell, from which it rises in a gentle acclivity, and consists of nine streets or divisions, and a market-place, with a stone cross in the centre. At the south end stands the parish-church, one of the finest specimens of ancient ecclesiastical architecture in the county. This noble building was probably founded towards the close of the fifteenth century. Its walls are built of freestone, interspersed with very curious decorations of flint-work. On every side they exhibit a variety of arms of noble personages, who probably obtained that distinction by their benefactions towards the erection of the church. The inner roof is very finely wrought in carved work; and there are two pews of such exquisite workmanship, as to vie with any in Henry VIIIth's chapel. This town has, likewise, a meeting-house for Dissenters, two charity-schools, and two Sunday-schools, one of which is supported by the Dissenters. In the parliamentary returns for 1800, the houses are stated to amount to 339 in number, and the inhabitants to 1776 persons.

LAVENIA, in *Botany*, a genus formed by the late Dr. Solander, and adopted from his manuscripts by professor Swartz, of the *Cotula Verbesina*, and *Verbesina Lavenia* of

their common preceptor Linnæus. The name is of unknown origin, and suspected by professor Martyn to be vernacular in Ceylon. It first appears in the supplement to Ray's *Florida Plantarum*, v. 3, 217, on the authority of Sherard, for the species last mentioned, for which it was adopted by Linnæus as the trivial name. Whatever the derivation or meaning of this word may be, its euphony may uphold it, though, according to found principle, Swartz ought to have preferred *Adenostemma*, given to the same plant by the classical Forster, and constructed of *adon*, a gland, and *stemma*, a crown, the seed being crowned with three glands instead of the feather, hair or membrane appropriated to other genera of this family. Swartz. *Prod. Ind.* Schreb. 544. Willd. *Sp. Pl.* v. 3, 1724. Mart. *Mill. Dict.* v. 3. (*Adenostemma*; Forst. *Gen.* t. 45. Juss. 184.)—Class and order, *Syngenesia Polygamia-aqualis*. *Nat. Ord.* *Compositæ discoidæ*, Linn. *Corymbifera*, Juss.

*Gen. Ch.* *Common Calyx* ovate, somewhat imbricated, consisting of from 10 to 14 lanceolate, equal, permanent scales. *Cor.* compound, uniform, of from 15 to 20 equal hermaphrodite florets, which are funnel-shaped, dilated at the base, the limb in five regular spreading segments. *Stam.* Filaments five, thread-shaped, shorter than the tube; anthers oblong, flat-tish, didymous, slightly cohering laterally. *Pist.* Germen oblong; style thread-shaped, longer than its own corolla, deeply divided; stigmas flat-tish, club-shaped. *Peric.* none, except the permanent spreading calyx. *Seed.* rather club-shaped, slightly rugged, viscid with glands. Crown of three awl-shaped bristles, glandular at the tips. *Recept.* naked.

*Eff. Ch.* Receptacle naked. Seed-down of three bristles, glandular at their tips. Calyx ovate, slightly imbricated. Style divided.

Obf. Forster describes the florets as bearded or downy on their upper or inner surface.

1. *L. decumbens*. Decumbent *Lavenia*. (*Cotula Verbesina*; Linn. *Sp. Pl.* 1258. Mant. 473. *Chrysanthemum sylvaticum repens* minus, *chamædryos folio*, *floræ luteo* nudo, *femine rostrato*; Sloane *Jam.* v. 1. 262. t. 155. f. 2. *Tanaetum herbaricum erectum*, *foliis cordatis crenatis oppositis*, *capitulis paucioribus remotis terminalibus*; Browne *Jam.* 316. *Herb. Linn.*)—Stem decumbent. Leaves heart-shaped, obtuse, obtusely ferrated.—Native of the inland cool and shady woods of Jamaica. *Root* annual. *Stem* decumbent or prostrate, from nine to eighteen inches long, throwing out roots from the lower joints, simple, except now and then a short axillary shoot or two, leafy, nearly smooth, bluntly quadrangular. *Leaves* opposite, stalked, an inch or more in length and almost as broad, heart-shaped, nearly smooth, blunt, unequally and bluntly ferrated, three-ribbed, often cut away close to the lateral ribs at the base. *Flowers* few, terminal, convex, yellow, scarcely so large as a pea, on long, slender, in some degree panicled, stalks.

2. *L. erecta*. Upright *Lavenia*. (*Adenostemma viscosum*; Forst. *Prodr.* 54. *Verbesina Lavenia*; Linn. *Sp. Pl.* 1271. Swartz. *Obf.* 312. *Eupatoriophalacron scopulariaræ aquaticæ foliis oppositis*; Burm. *Zeyl.* 95. t. 42. *Pu-tumba*; Rheede *Hort. Mal.* v. 10. 125. t. 63.)—Stem erect. Leaves elliptical, pointed, sharply ferrated; tapering and entire at the base.—Native of Ceylon, the coast of Malabar in sandy ground, and the Society isles. *Root* annual, of many pale fibres. *Stem* a foot high, erect, somewhat branched, leafy, square, rough with ascending bristles. *Leaves* stalked, opposite, the uppermost less exactly so; all of a broad elliptical figure, tapering much at each end, three-ribbed, rough, two or three inches long, entire at the base, broadly and acutely ferrated upwards. *Flowers* on shortish, hispid, hoary, axillary stalks, accompanied by linear bractæ, and consisting

consisting of fewer florets than the preceding, of a palish blue colour, and externally downy.

**LAUVENSAR**, in *Geography*. See LAVANSARI.

**LAVENSTEIN**, or **LOEWENSTEIN**, a town of Germany, in the principality of Culmbach, near which is a copper-mine; 12 miles S. of Sanfeld.—Also, a town of Westphalia, in Calenberg; nine miles E. of Hanck.—Also, a town of Saxony, in the margravate of Meissen; 18 miles S. of Dresden. N. lat. 50° 42'. E. long. 13° 46'.

**LAVENZA**, a sea-port of Italy, in the department of the Apennines, with a harbour at the mouth of a small river; seven miles S.E. of Sarzana. N. lat. 44° 3'. E. long. 10° 1'.

**LAVER**, in *Botany*, perhaps from the verb to *lave*, alluding to its being washed up on the shore. See ULVA.

**LAVER Bread**, a sort of food made of a sea-plant, otherwise called the *oyster-green*, or *sea-liverwort*. It is said to be used in the county of Glamorgan, and other parts of Wales.

**LAVER**, in *Scripture History*, a sacred utensil placed in the court of the Jewish tabernacle, consisting of a basin, where they drew water by cocks, for washing the hands and feet of the officiating priests, and also the entrails and legs of the victims.

**LAVERNA**, in *Antiquity*, the goddess of thieves and cheats among the Romans, who honoured her with public worship, because she was supposed to favour those who wished that their designs might not be discovered. Varro says, that she had an altar near one of the gates of Rome; hence called Porta Lavernalis.

**LAVERNICK**, in *Geography*, a town of Prussia, in the territory of Culm, on the Drebenitz; 44 miles E. of Culm.

**LAVEZZO**, a name given by the Italians to a steatitic stone, of which vessels are made; called also *Lapis comensis* and *POTSTONE*, which fee.

**LAUF**, in *Geography*, a town of Germany, in the territory of Nuremberg; 8 miles E.N.E. of Nuremberg. N. lat. 49° 51'. E. long. 11° 13'.

**LAUFFEN**, a town of the archbishopric of Salzburg, on the Salza; 11 miles N.N.W. of Salzburg. N. lat. 47° 54'. E. long. 12° 52'.

**LAUFFEN**, a village and castle of Switzerland, which gives name to a bailiwick, in the canton of Zurich, near the Rhine, where is a celebrated cataract; 2 miles below Schaffhausen.

**LAUFFEN am Neckar**, a town of Wurtemberg, on the Neckar, formerly imperial; 16 miles N. of Stuttgart. N. lat. 49° 5'. E. long. 9° 18'.

**LAUFFEN**, a town of Prussia, in Natangen; 15 miles S. of Barteniten.—Also, a town of Austria, where the diet was held under Frederick I.; 18 miles S. of Gemunden.

**LAUFFENBURG**, a fortified town of Germany, and one of the four forest-towns of the late Austrian Swabia, situated on both sides of the Rhine, over which is a bridge; and at this place there is a fall in the river; 26 miles W. of Schaffhausen. N. lat. 47° 36'. E. long. 8° 4'.

**LAUFFON**, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Délémont, seated on the Barck; 16 miles N. of Soleure. The place contains 740, and the canton 7513 inhabitants, on a territory of 172½ kilometres, in 21 communes. N. lat. 47° 32'. E. long. 7° 20'.

**LAUGEON**, a town of Meckley; 42 miles W. of Munnypour.

**LAUGERIA**, in *Botany*, named by Jacquin, in honour of Robert Laugier, professor of botany and chemistry in the university of Vienna, where the botanic garden there was

first established. Jacq. Amer. 64. t. 177. f. 21. Linn. Gen. 102. Schreb 140. Willd. Sp. Pl. v. 1. 1081. Mart. Mill. Dict. v. 3. Juss. 206. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, tubular, small, deciduous, unequal at the orifice. Cor. of one petal, falver-shaped; tube very long; limb in five obovate segments. Stam. Filaments five, very short; anthers linear, long, within the tube. Pyl. Germen nearly ovate, inferior; style thread-shaped, rather longer than the tube; stigma capitate. Peric. Drupa roundish, umbilicated with a small depression. Seed. Nut roundish, with five furrows, and from two to five cells.

Ess. Ch. Corolla falver-shaped, five-cleft. Stamina within the tube. Drupa inferior. Nut of five cells.

Obf. Vahl suggests that this genus might with propriety perhaps be united to *Guettarda*; see that article.

1. *L. odorata*. Linn. Sp. Pl. 276. Jacq. Amer. 64. (Edelchi; Loefl. It. 259. 271. 306.)—Leaves elliptic-lanceolate, pointed, nearly smooth. Stem somewhat spinous. Clusters panicled. Nut with five cells.—Native of South America; observed by Jacquin in exposed bushy places on the sea shore, about the Havana and Carthagen. The stem is shrubby, ten feet high, erect, branching, the branches opposite and widely spreading. Leaves opposite, on short stalks, from one to two inches, or more, in length, elliptic-lanceolate inclining to obovate, pointed, entire, veiny, described by Jacquin as smooth, but a young branch sent by him to Linnæus, from the Vienna garden, has numerous hairs on the leaves, especially at the rib and edges, and its footstalks, like the twig itself, are very hairy. *Stipulas* axillary, opposite, lanceolate, recurved. Clusters axillary, panicled, lax, as long as the leaves. Flowers dirty red, very fragrant at night. Fruit copious, larger than a pea, very black, soft, when ripe falling off on the slightest shaking of the bush.

2. *L. lucida*. Swartz Ind. Occ. v. 1. 475. Vahl. Symb. v. 3. 40. t. 57.—Leaves oblong, obtuse, membranous, shining. Clusters forked. Nut with two cells.—Native of bushy places, in the warmer parts of Jamaica, as well as in St. Lucia and Santa Cruz. A shrub with round, smooth, spreading branches. Leaves two or three inches in length, oblong, with a blunt point, shining, smooth on both sides. *Stipulas* axillary, ovate, acute, deciduous. Clusters from the bosoms of the upper leaves, so as to appear terminal, foliary, rarely opposite, the length of the leaves, either simply forked, or twice divided, widely spreading. Flowers nearly sessile in a simple row on each branch of the cluster, with a solitary intermediate one, whitish, fragrant. Fruit black, its nut of two unequal cells. Dr. Swartz thinks this may be the *Ipnotraguapin* of Loefl. It. 270, with the description of which it agrees in many respects, but he never observed any spines on his *L. lucida*. We have, nevertheless, no doubt of their being one and the same species.

3. *L. coriacea*. Vahl. Ecol. v. 1. 26.—“Leaves elliptic-ovate, rather coriaceous, smooth on both sides, bluish. Spikes twice divided. Flowers tetrandrous.” Found on the summits of mountains in the island of Montserrat, where it was probably found by Von Rehr. A shrub or tree, but we know nothing further concerning it.

4. *L. resinosa*. Vahl. Ecol. v. 1. 27.—“Leaves broad-lanceolate, smooth; glaucous beneath. Spikes axillary, cloven. Branches resinous at the summit.” Native of lofty mountains in Montserrat.

5. *L. tomentosa*. Swartz Ind. Occ. v. 1. 477.—“Leaves ovate, acute; downy beneath. Clusters forked. Nut of two cells.” Native of shrubby places in the western part of Jamaica. A small tree, twice the height of a man, with subdivided.

subdivided downy *branches*. *Leaves* shining and smooth above, silky and soft beneath. *Flowers* whitish. It blossoms in autumn, and resembles a *Tournefortia* in habit and inflorescence. *Swarz*.

LAUGHER, a name given to a particular species of pigeon, called by Moore the columbaridens. It is about the size of the common pigeon, and much of the same make; but it has a very bright pearl-coloured eye, almost white, and is a mottled red, or blue. They are said to be brought from Jerusalem, and the country thereabouts. When the cock of this species courts the hen, he has a guttural cooing, not unlike the gurgling of a bottle of water, when poured out hastily; and after this he always makes a noise not unlike laughing, from the singularity of which he has obtained his name.

LAUGHLI, *Lx*, in *Geography*, a fief of Piedmont, which takes its name from a mountain; formerly held immediately of the empire, ceded, in 1746, to the king of Sardinia, or duke of Savoy, and now annexed to France.

LAUGHTER, an action or passion peculiar to man.

Authors attribute laughter to the fifth pair of nerves, which sending branches to the eye, ear, lips, tongue, palate, and muscles of the cheek, parts of the mouth, præcordia, &c. there hence arises a sympathy, or consent, between all these parts; so that when one of them is acted upon, the others are proportionably affected.

Hence a favoury thing seen or smelt, affects the glands and parts of the mouth, a thing seen or heard, that is shameful, affects the cheek with blushes; on the contrary, if it pleases and tickle the fancy, it affects the præcordia and muscles of the mouth and face with laughter; if it causes sadness and melancholy, it likewise affects the præcordia, and demonstrates itself by causing the glands of the eyes to emit tears.

Laughter, according to Hobbes, is "a sudden glory, arising from a sudden conception of some enmity in ourselves, by comparison with the infirmity of others, or with our own formerly." Dr. Campbell, on the contrary, maintains, that this emotion doth not result from the contempt, but solely from the perception of oddity, with which the passion is occasionally, not necessarily, combined. See **RIDICULE**.

L'Augier, Monsignor, in *Biography*, principal physician to the imperial court at Vienna in 1772; the most intelligent and best informed critic, among musical dilettanti, with whom we ever conversed. He had been in France, Spain, Portugal, Italy, and Constantinople, and was perfectly well acquainted with national styles of music, and the peculiar merits and defects of individual composers throughout Europe. This gentleman, in despite of uncommon corpulency, possessed a most active and cultivated mind. His house was the rendezvous of the first people of Vienna, both for rank and genius, and his conversation was as entertaining as his knowledge was extensive and profound. Among his other acquisitions he had arrived at great skill in practical music, had a most refined discriminating taste, and could give, vocally, specimens of the *national melody*, which he had heard with philosophical ears wherever he had been; in fine, he was a living history of music. In Spain he had been intimately acquainted with Dominico Scarlatti, who, at seventy-three, composed for him a great number of harpsichord lessons, the chief of which had never been printed. The book in which they had been transcribed contained forty-two pieces, among which were several *slow* movements, with which, for want of fortissimo and expression, in the old harpsichords, he seldom enriched his works. These lessons were composed in 1756, when Scarlatti was too fat to cross his hands, as he used to do; so that these are not so difficult

as his more juvenile works, which were made for his pupil and patroness, the late queen of Spain, while she was infanta of Portugal. M. L'Augier used to relate, that the empress queen Theresa had been a very notable musician, and that some years ago he had heard her sing very well. In the year 1739, when she was only twenty-two years of age, and very handsome, she sung a *duo*, with old Senefino, at Florence, so well, that by her voice, which was then a very fine one, and graceful and steady manner, she so much captivated the old man, that he could not proceed without shedding tears of satisfaction. Her imperial majesty had so long been a performer, that she one day, in pleasure, told the old Faustina, the wife of Haffe, who was then upwards of seventy, that she thought herself the first (meaning the oldest) virtuosa in Europe; for her father, at a rehearsal, brought her on the court stage at Vienna, when she was only five years old, and made her sing a song.

Metafasio, in a letter to Farinelli, calls M. L'Augier Monsignore, the physician of the pope, and we suppose the imperial physician is qualified with the title of Monsignore, my lord. The imperial Laurat tells Farinelli, that Monsignor L'Augier is charmed with him, with his heart, and with his conduct. And sporting with his rotundity, he says, "he often visits me, in spite of his immeasurable corpulency, and mounts to the altitude where I reside, with the lightness of the most slim dancer. I shall, for your sake, embrace as much as possible of his majestic circumference." This extraordinary personage, with a mind proportioned to his body, died at Vienna in 1774, to the great loss of society in that city, and of sound criticism and good taste.

LAVIANO, in *Geography*, a town of Naples, in Principato Citra; 27 miles E. of Salerno.

LAUJAR, a town of Spain, in Grenada; 18 miles N.W. of Almeria.

LAVIGEN, a town of Norway, in the diocese of Drontheim; 24 miles N. of Drontheim.

LAVIGNON, a name which the fishermen of the vicinity of Rochelle give to a shell-fish, which is used for food in that place, and is probably a species of *Solen*. It is common on the coast of Poitou, and has a very thin pair of shells for its covering, and which never can shut close, in the manner of the ciler or muscle, or other common bivalve shells: the fish, therefore, always buries itself in the mud by way of security. The shells are very smooth and polished, especially on the inside, and they are naturally white. This colour they always retain within, though their outer surface is often tinged black by the mud.

They are often buried five or six inches deep in the mud, but it is always easy to know where they are, because they must keep a free communication with the water above; by means of a round aperture, of about a tenth of an inch diameter, which opens from the surface of the mud to every shell-fish. When the shells of this fish are opened to their utmost width, it is easy to see a sort of arm with which each is furnished, in the manner of the common muscle, for its progressive motion. This part serves them to bury themselves in the mud, and to raise themselves out of it again, when they are inclined to seek a new habitation; into which they make their way in a more speedy manner than would easily be thought.

When the creature is plunged to its proper depth under ground, it receives the benefit of the water above, by means of two pipes, or proboscides, which have each a double aperture at their ends. These take in water, and throw it out again, alternately, for the uses of the animal, and either of the two is indifferently qualified to answer either purpose. The fish has a power of lengthening, or shortening these pipes

pipes at pleasure, and, when it pleases, takes them wholly into the shell. Mem. Acad. Par. 1710.

LAVIN, in *Ornithology*, a name given by the people of the Philippine islands to a species of hawk, a bird of great beauty, being variegated all over with yellow, black, and white. They call it also *scub*.

LAUINGEN, in *Geography*, a town of Bavaria, in the principality of Neuburg, on the Danube, supposed to have been a Roman colony; six miles above Hockfleit. N. lat. 48° 32'. E. long. 10 22.

LAVINGTON, EAST, or *Market Lavington*, a market-town and parish in the hundred of Swanborough, and county of Wilts, England, is situated at the northern termination of Salisbury plain. It was formerly called Steeple, or Staple, Lavington, and was a considerable town; having acquired the name of Cheaping, or Market Lavington, from its great corn market, which was established early in the sixteenth century, but is now much decreased, as the chief resort of the dealers is to Devizes. East Lavington is 8½ miles from London; the markets were on Monday and Wednesday. The population, as returned to parliament in 1800, was 918; the number of houses 167. Bishop Tanner, the celebrated author of "Notitia Monastica," was born in this town in 1674.

*West, or Bishop's Lavington*, is a parish within two miles of the foregoing, but is situate in the hundred of Whorlston; it was returned, in 1800, as containing 214 houses, and 978 inhabitants. Britton's Beauties of Wiltshire, 8vo.

LAVINIUM, in *Ancient Geography*, a small town of Latium, exactly S. of Rome, and eight miles S.E. of Laurentum, near the sea-coast, on the rivulet Numicus, between the mouth of which, and the Tiber, Æneas is supposed to have landed. According to Strabo, he built this town after the defeat of Turnus, king of Ardea; thus perpetuating his victory and the name of his wife Lavinia, daughter of king Latinus. According to the same author, he erected here a temple of Venus, the care of which he committed to the Ardeates. But as this city was not strong enough to resist the assaults of his enemies, who were jealous of his power, he built another on an eminence, E. of the first. See LANUVIUM.

LAVINO, in *Geography*, a town of Italy, in the Milanese; 18 miles W.N.W. of Como.—Also, a town of Naples, in the Molise; 24 miles N.E. of Molise.

LAVIS, a town of Tyrol, at the union of the rivers Lavis and Adige; eight miles N. of Trent.

LAVIT DE LOMAGNE, a town of France, in the department of the Gers, and chief place of a canton, in the district of Lectoure; 12 miles E. of Lectoure. The place contains 1330, and the canton 7606 inhabitants, on a territory of 10½ kilometres, in 15 communes. N. lat. 43 57'. E. long. 1°.

LAUKAS, a town of Sweden, in the government of Wafra; 124 miles E.S.E. of Wafra.

LAUKOWITZ, a town of Bohemia, in the circle of Bohehau; 10 miles N.N.E. of Jung-Buutzel.

LAUNAY, PENEU, in *Biography*, was born at Blois in the year 1573, and having considerable family interest, he obtained, in early life, a post under government, and was made secretary to the king. These honours he willingly renounced, in order that he might devote his time to the study of the sacred writings. His works prove how diligently he followed his new profession. He acquired the respect and esteem of the French Protestants, and he was chosen deputy to all the synods of his province, and to almost every national synod which was held in his time. He died in 1662, at the age of eighty-nine years. His works are paraphrases on the

books of Proverbs, Ecclesiastes, the prophet Daniel, all the epistles of St. Paul, and the Apocalypse, which were published at different periods. He published likewise "Remarks on the Bible, or an Explanation of the different Words, Phrases, and Figures of the sacred Writings;" and "A Treatise on the Lord's Supper."

LAUNCE, in *Ichthyology*. See AMMODYTES.

LAUNCEGAYS, in our *Old Writers*, a kind of offensive weapons now disused, and prohibited by the statute 7 Rich. II. cap. 13. Many of the commentators on our ancient laws profess themselves unable to explain what kind of weapons these were. Grose suggests, that the term lancegay may be a corruption of the words lance aigue, a sharp or pointed lance; and if the intention of the acts be considered, it will justify, in a degree, this supposition; as they were evidently framed to prevent those violent affrays that frequently arose among the gentry of that time, commonly attended by a numerous suite, who, if armed with mischievous weapons, might have spilt much blood. A lance fit for war was, perhaps, termed sharp, or pointed, in opposition to a blunt or tilting lance. See LANCE.

LAUNCESTON, in *Geography*, a populous borough and market-town in the hundred of East, and county of Cornwall, England, is situated on an eminence, at the distance of one mile from the river Tamer, near the central part of the eastern side of the county. Its ancient name was Dunheved, the Swelling Hill; but the present appellation, according to Borlase, signifies the "Church of the Castle." The castle is the most important object in the town, to which, in all probability, it gave origin. Its mouldering walls surround and cover a considerable extent of ground, and prove it to have been a fortress of great strength and importance. The principal entrance was from the south-west, through a fortified passage upwards of an hundred feet in length, and ten in breadth. At the end of this stood the great gate, the arch of which was pointed, but is now in ruins. This led to a smaller gate, with a round arch, opening into the baſe court, which formed a square of 136 yards, surrounded by thick walls and fortified with a deep ditch. At the south-west angle was a very strong round tower, whence a terrace extended to the keep or citadel at the south-east angle of the court. This consisted of an immense artificial hill, nearly ninety feet in perpendicular height, about 300 feet diameter at its base, and 93 at its summit. The ascent to this keep originally commenced at a semi-circular tower, and continued to the top through a covered way, seven feet wide, now in ruins. The keep consists of three wards, and is surrounded by a circular wall. The thickness of the outer wall, or parapet, is about three feet; the second wall is six feet from the former, nearly four times the thickness, and considerably higher. About eight feet within this wall is another, ten feet thick, and thirty-two feet high from the floor of the inclosed area, the diameter of which is about eighteen feet. In the baſe court formerly stood the county gaol, a spacious assize court, a chapel, and other buildings; but these have all been taken down, except the gaol, which retains its situation near the bottom of the hill. The building of this castle has been generally attributed to William, earl of Moreton and Cornwall, in the time of William the Conqueror; but this opinion is probably erroneous, as the style of workmanship exhibited in several parts of the remains, is apparently of a much earlier date. The walls of the keep, in particular, have every appearance of being considerably more ancient; and from a retrospective view of events that have occurred in this county, the conjecture appears to be fully warranted that the foundation of the castle is as remote as the time of the Britons. The era

in which the town was founded, or, at least, began to assume a regular form, is better determined; this was about the year 900. No remains of the original buildings are now extant. On the north side of the town was a priory of Augustinian monks, said to have been established by Warlewast, bishop of Exeter. As this town was a principal residence of the earls of Cornwall for many years after its foundation, its consequence continually increased, and many liberties and privileges were granted to its inhabitants. Soon after the conquest a weekly market was established on Sunday; in the reign of king John, the townsmen paid five marks for the removal of the market to Thursday, but it has since been changed to Saturday. In the reign of Henry III. Launceston was made a free borough by the king's brother, Richard, earl of Poitiers and Cornwall; he also granted the inhabitants some additional immunities, which were confirmed by several subsequent charters; and in the reign of Richard II. the assizes were ordered to be held at Launceston, and "no where else." This regulation was observed till the first year of George I. when an act was passed empowering the lord chancellor to appoint any other place in the county. Since that period the winter assizes only have been held here; those of the summer having been removed to Bodmin. By a charter of Philip and Mary, granted in 1555, which enumerates and confirms the various prior charters, the government is vested in a mayor, recorder, and eight aldermen, who, with the free burgesses, have the right of electing the parliamentary representatives. The whole number of voters is about twenty. This borough made its first return in the twenty-third of Edward I. and had a mayor as early as the time of Edward IV. Near the centre of the town is the church of St. Mary Magdalen, a handsome fabric, built with square blocks of granite, most of which are enriched with carved ornaments, executed in a very singular manner. At the west end is a lofty tower; and a figure of the Magdalen, in a recumbent posture, is placed in a niche at the east end. This church was originally only a chantry chapel; in the reign of Henry IV. it was re-edified and considerably enlarged; in Henry VI.'s reign it was constituted a parish church, and was again rebuilt in the time of Henry VIII. The town was formerly surrounded by a wall, of which some parts still remain. The streets are narrow; but the houses are well built; on the south side is a fortified gateway, containing an apartment used as the town gaol. The children of the poor are educated in two charity-schools maintained by voluntary subscription; and a free-school founded and endowed by queen Elizabeth. Launceston is distant from London 213 miles; has a weekly market on Wednesday, besides that on Saturday already mentioned, and six annual fairs; the return to parliament in the year 1801 stated the population to be 1483, the number of houses 226. The houses of this town are connected with those of Newport, which is a borough, though apparently only part of Launceston. See NEWPORT.

About two miles north of this town is Werrington, a seat of the duke of Northumberland. Polwhele's History of Cornwall, 4to. Beauties of England and Wales, vol. ii.

**LAUNCH**, in *Ship Building*, is the slip or descent whereon the ship is built, also the whole machinery used in launching.

To facilitate the operation of launching, the ship, when she is first built, is supported by strong platforms, laid with a gradual inclination to the water, on the opposite sides of her keel, to which they are parallel. Upon the surface of this declivity are placed two corresponding ranges of planks, which compose the base of a frame, called the *cradle*, whose

upper part envelops the ship's bottom, to which it is securely attached. Thus, the lower surface of the cradle, conforming exactly to that of the frame below, lies flat upon it, lengthways, under the opposite sides of the ship's bottom; and as the former is intended to slide downwards upon the latter, carrying the ship along with it, the planes or faces of both are well daubed with soap and tallow. The necessary preparations for the launch being made, all the blocks and wedges by which the ship was formerly supported, are driven out from under her keel, till the whole weight gradually subsides upon the platforms, which are accordingly called the ways. The shores and staunchions, by which she is retained upon the stocks till the time of launching, are at length cut away, and the screws applied to move her, if necessary. The motion usually begins at the instant when the shores are cut, and the ship slides downward along the ways, which are generally prolonged under the surface of the water to a sufficient depth, to float her as soon as she arrives at the farthest end thereof. When a ship is to be launched, the ensign, jack, and pendant, are always hoisted, the last being displayed from a staff erected in the middle of the ship. Ships of the first rate are commonly constructed in dry docks, and afterwards floated out, by throwing open the flood-gates, and suffering the tide to enter, as soon as they are finished. Falconer.

**LAUNCHING**, the act of conveying the ship into the water after she is built.

**LAUNCHING-Draft of Water**, the depression of the ship, when first launched below the water's surface.

**LAUNCHING-Planks**, form the upper surface of the platform on each side the ship, whereon the buldgeways slide in the act of launching the ship.

**LAUNDER**, in *Mineralogy*, a name given in Devonshire, and other places, to a long and shallow trough, which receives the powdered ore, after it comes out of the box, or coffer, which is a sort of mortar, in which it is powdered with iron pestles.

The powdered ore, which is washed into the launder by the water from the coffer, is always finest nearest the grate, and coarser all the way down. See **BUBBLE** and *Dressing of ORE*.

**LAUNDRY**, as if *Lavanterie*, Fr. the room in which clothes are washed; or, in a more restricted and appropriate sense, as the term is used in the subsequent article, it denotes the place where clothes are mangled, dried, and ironed. Under this head we shall include the *wash-house*, as it is necessarily connected with the laundry. Washing and getting up linen are employments of great importance in most families, and they have engaged the attention of many ingenious mechanics, who have contrived various washing-machines for the abridgment of labour and expence in this department of domestic economy. Most of the machines hitherto used are objectionable on many accounts, but principally because they operate by *friction*, instead of *pressure*. When the linen is properly prepared for washing, it may be thoroughly cleaned by *pressure* only. Rubbing it with the hands, or by any machine that operates by friction, injures it more than the wear it sustains in actual use. Hence it follows that the best method of cleaning foul linen is, first, to prepare it for the operation by soaping it where necessary, and putting it into soak for at least twelve hours. This will loosen the filth, and decompose the grease and other matter with which it is soiled, and it will then be readily removed by alternately soaking, and squeezing or pressing. The desideratum, therefore, is, to construct a machine that would, by a rotative motion, or an up-and-down stroke, (like pumping) alternately press and saturate the linen with

## L A U N D R Y.

the fuds, and lally with clear water. The machine that comes nearest to this, of any that has fallen under our notice, is one invented by Mr. Gould.

We shall now describe a wash-house and laundry, constructed upon scientific principles by John Bentley, esq. the present possessor of Highbury House, near London, being the completest of the kind we have met with.

The wash-house is 24 feet long, nine feet broad, and eight feet high. It is furnished with a filtering machine, a cistern for filtered water, two coppers, a copper cullender, a jack with pulleys, six washing tubs, a stone sink, a table, a wringing machine, and a pump of hard water.

The floor is rough Yorkshire-stone, laid upon a sharp current. Over two-thirds of the roof is a lead cistern containing 40 hogheads of rain water, supplied from the adjoining buildings. The other third of the roof is conical, surmounted with a cylinder for a steam-vent, which opens and shuts at pleasure. When open, besides emitting the steam, it admits both light and air. The cistern for filtered water holds 200 gallons, and supplies, by pipes and cocks, the copper tubs and sink.

The first copper is fixed so that the top of it is level with the bottom of the cistern, and the bottom of it is level with the top of the other copper, and the tops of the tubs and sink, all which it supplies with hot water. The tubs, coppers, and sink, are supplied with cold water from the cistern. Each of the tubs has a brass plug at bottom, to discharge the foul water. A nine-inch board runs along the front of the tubs and sink on the ground, to prevent the splashing of the water when discharged. Each tub is furnished with a small wooden strainer for soap.

The second copper is for boiling the linen, and has a copper cullender to hold the linen, which is drawn up by the jack and pulleys. The jack has a paul and ratchet wheel to keep the cullender suspended over the copper till the water is drained from the linen into the copper, which can then be turned out altogether into the rining-tub. By this contrivance, the usual mode of poking the linen out with a stick (which frequently damages it) is avoided. At the bottom of this copper is a large brass cock for discharging the fuds when they are done with.

Though the six tubs are supplied with both hot and cold water, there are only six cocks to the whole, one cock supplying two tubs, by means of a screw-joint in the nozzle, which turns at pleasure to either tub. There is also a screw-joint between the key and pipe in each cock, by which means it can at any time be repaired without the assistance of the plumber.

The filtering machine performs its operation by ascent. It has three cocks in one pipe: The uppermost is for regulating the quantity of water to be filtered, which can be varied at pleasure from 50 to 500 gallons in a day. The other is for cleansing the machine when saturated with filth, which is accomplished by only turning the cock, and will, in a few minutes, be as clean as it was at first, the mud, &c. being discharged at the third or middle cock, which also serves to draw unfiltered water when required. Under the cistern is a receptacle for coals, and under the filtering machine a place for pails and mops. Both cisterns have a surplus water-pipe to prevent running over, and in which are also plugs to discharge all the water when needful.

The table hangs to the wall, and may be put up and down at pleasure. It is for sorting and soaping the foul linen, &c.

The laundry adjoining the wash-house is 18 feet square, and 11 feet in height. It has two windows in front. The floor is level, of rubbed Yorkshire-stone, laid upon brick piers,

to keep it perfectly free from damp. It is furnished with one of Baker's large mangles; an ironing-board 12 feet by three feet, with four large drawers for the ironing-cloth, iron-holders, &c. with room for the clothes-baskets underneath; a stove or drying-closet, eight feet by six feet; a furnace for heating the closet and the irons, and a place for coals under the floor, close by the furnace. The closet contains four wooden horses, each with five rails or bars. Each horse runs in and out of the closet upon two small iron wheels, upon an iron rail-way. One horse holds six flurts, or a proportionable quantity of other linen, and the whole will dry off as much and as speedily as six women can wash in succession. It hardens the linen after being ironed, and is also useful for airing feather beds, &c. The linen, whilst drying, is kept free from smoke and dust, and there never can be any steam in the room.

The furnace for heating it is similar to those under coppers or in a hot-house, immediately over which, before it enters the flue to the closet, is an iron oven for heating the irons. The flue is continued round the bottom of the closet, and carried up the end of the building. The top of the horizontal part of the flue is of cast-iron plates; iron being a good, and brick a bad conductor of heat. A few inches above these iron plates, the iron rail-way before mentioned is laid, between which and the flue there is a flooring of wire work. This prevents any accident from the casual falling of linen upon the flues, but does not impede the ascent of warm air. Level with the rail-way, inside the closet, there is an opening 15 inches square, communicating with the external air. The ceiling of the closet is in the form of a hopper, terminating in a funnel of the same diameter (15 inches) as the external air-vent. Both these vents are furnished with a sliding door, which opens and shuts, as required, by pulley cords.

The principle upon which it acts is by heating it to a degree sufficient to excite a strong evaporation from the wet linen, and carrying off the moisture by means of the two vents. During the time of its acquiring this heat, both the vents, and also the horses, are kept closely shut, so that the closet is nearly air-tight. As soon as the proper degree of heat is obtained, both the vents are to be opened, when a strong current of air rushes in at the lower, carrying up all the vapour from the linen through the upper vent or funnel, when the drying will be very speedily completed. The linen is then removed, a fresh supply put in, and the operation repeated as before, beginning by closely shutting all up.

Besides the dispatch and economy attending this wash-house and laundry, the health and comfort of those employed in them are greatly promoted, by being entirely free from the pernicious effects of damp vapour, and in not being incommoded by any extra heat in hot weather.

Since this article was written, the gentleman above mentioned has made a considerable improvement in the wash-house. He has constructed an apparatus for performing the operation by *steam*. Although it is not yet (December 1811) quite completed, it is sufficiently so to have ascertained by experiment, that every species of *white* linen may be better cleansed this way than it is possible to do it by the hands, or any machine hitherto invented.—We say *white* linen, because the operation proves to be so powerful, that it discharges the colour from all dyed and printed articles that have been tried with it.

At the end of the wash-house a strong iron-boiler is fixed, three feet six inches long, one foot eight inches wide, and two feet nine inches deep, with fittings up the same as those for steam-engines, *viz.* a feeding-pipe with regulator, a

mercury gauge-tube, a three-inch steam-tube, two observation cocks, a safety valve, and a discharging pipe. From the steam-tube, a pipe of  $1\frac{1}{2}$  inch bore is continued the whole length of the building; and from this main steam-pipe, others of smaller dimensions, from  $\frac{3}{4}$  to  $\frac{1}{2}$  inch diameter, are laid on the different steaming vessels. These may be either of wood, tin, or copper; but the latter is certainly best, for the action of steam is so powerful, that it will soon render both wood and tin useless. They must be fitted with a loose grating inside, about two inches from the bottom; a cock at one end, to admit the steam; and another at the other end, quite at the bottom, to discharge the foul water. The process is as follows: Soap the linen where it is very dirty, and put it to soak; then place the linen upon the grating in the steam vessel; cover it up, and turn on the steam. The discharging cock must be occasionally opened, to draw off the condensed steam; and when it is found to come off perfectly clear, which it will do in half an hour, or less, the operation is finished, and the articles will come out perfectly clean, and most beautifully white.

By this simple and easy process, the drudgery of washing is entirely done away; and the saving in time, soap, and other expences, is greater than can well be conceived. The saving of water in many situations is a matter of consequence; but what is of still more importance, the linen will last double the time it otherwise would do: for as there is neither pressure nor friction, it cannot be injured in this process.

Washing by steam has been practised, but never before by this method. The way it has been done has been by steaming the linen *in the fuds*. Hence it is evident that the silt that is forced out of the linen is mixed with the fuds, and is again dispersed equally all through the linen; so that repeated changes of soap and water must be had recourse to, before the linen is made thoroughly clean. But by this new process, the linen being put into the steaming vessels, without any other liquor than it retains on being taken out of the soaking tubs, every particle of matter which is dislodged from it instantly subsides to the bottom of the vessel, and never can again come in contact with the linen. Our readers must excuse the prolixity of this article, on account of its great importance and usefulness in domestic economy to every family.

*Note.*—The boiler above described also heats an hot-house in an adjoining garden, besides boiling a copper, and thus does the work of six fires.

LAUNOY, JOHN DE. in *Biography*, was born at Val-de-He, a village of Lower Normandy, in 1603. He received the early part of his education at Constance, whence he was sent to the university of Paris, where he pursued his studies with great diligence for five or six years. In 1636 he was ordained priest, and soon after was admitted to the degree of doctor of divinity at the college of Navarre. For the sake of improvement he travelled to Rome, and became acquainted with the most eminent characters; but on his return to Paris, he applied with great intenseness to his studies, and composed a vast variety of works on subjects relating to history, criticism, and ecclesiastical discipline. At his own house he formed a kind of literary school, for the discussion of topics that tended to the improvement of the mind. He was an able defender of the rights of the Gallican church, in opposition to the pretensions of Rome. He attacked several false traditions with great intrepidity; and he contended so forcibly for expunging the names of several false saints from the calendar, that he was called the banisher of saints. It was said of him, that "he was a terrible critic, formidable both to heaven and earth; that he

had expelled a greater number of saints from paradise than ten popes have canonized. He suspected the whole martyrology; and he examined all the saints one after another, in the same manner as they do the nobility in France." By the freedom which he exercised in his writings, he provoked against him an host of enemies; and he was obliged, at the intimation of the king, to discontinue his assemblies, which were held at his own apartments. He met with an excellent friend in the abbé d'Élreves, who presented him with a very valuable preferment in the church, which he soon resigned, choosing to live contented on a small income rather than endure the cares of business. He said that it was much more difficult for a Christian to make a right use of riches, than to live without them. He died in his 75th year, in 1678. His works are very numerous, and have been collected and published in ten volumes, folio. Of one of his pieces, viz. "De Auctoritate negantis Argumenti," Bayle says, had he published nothing else, he would have established his fame as a benefactor to the republic of letters, by a thousand fine hints which it contains for distinguishing truth from falsehood in historical matters. He was a person of great simplicity, a good friend, disinterested, and laborious; an enemy to vice, void of ambition, charitable and beneficent, and ever observing the same tenor of life. Bayle. Moreri.

LAUNY, or LAUX, in *Geography*, a town of Bohemia, in the circle of Saatz, on the Egra, on the road from Leipzig to Prague; 9 miles E.N.E. of Saatz. N. lat. 50° 20'. E. long. 13° 54'.

LAVOISIER, ANTHONY LAWRENCE, in *Biography*, a distinguished chemical philosopher, was born at Paris, on the 13th of August 1743. His father, who was a man of opulence, spared no expence in bestowing upon him the advantages of a liberal education; and he displayed very early proofs of the extent and success of his studies, especially in the circle of the physical sciences. In the year 1764, the French government proposed a prize question, relative to the best method of lighting the streets of a large city. Lavoisier presented a dissertation on the subject, which he discussed upon the most enlarged and philosophical views. This was not only highly approved, and printed at the expence of the Academy of Sciences, but obtained for him the present of a gold medal from the king, which was delivered to him by the president of the Academy, at a public sitting, in April 1766. Two years afterwards, he was admitted a member of that learned body, of which he was constantly one of the most active and useful associates. About the same time, he was occupied in experimental researches on a variety of subjects; such as the analysis of the gypsum found in the neighbourhood of Paris; the crystallization of salt; the properties of water; and in exploring the phenomena of thunder, and of the aurora borealis; and he distinguished himself by several dissertations on these and other topics, practical and speculative, which appeared in different periodical works. In the Memoirs of the Academy for 1770 were published his observations on the nature of water, and on the experiments which had been supposed to prove the possibility of its conversion into earth. He proved, by a careful repetition of these experiments, that the earthy deposit, left after repeated distillations of water, proceeded solely from an abrasion of the vessels employed. Lavoisier performed several journeys into various parts of France, in company with M. Guettard; in the course of which he collected a store of materials for a lithological and mineralogical history of that kingdom, which he ingeniously arranged in the form of a chart. These materials were the basis of a great work on the revolutions of the globe, and on the formation of the strata of the earth: two interesting sketches of which were printed

printed in the Memoirs of the Academy for the years 1772 and 1787.

In fact, M. Lavoisier devoted his whole time and fortune to the cultivation of the sciences, the boundaries of which he seemed, by such an union of zeal, talent, and wealth, destined to extend. About this period, a new mine of experimental research, which promised the most curious and interesting results, had been opened out by the genius of Dr. Black, and already pursued with much sagacity and industry by Dr. Priestley.—We allude to the discovery of the properties of certain acrimonious substances, gases, or (as they have been called) factitious airs, which had hitherto escaped the attention of chemical inquirers. M. Lavoisier, struck with the beauty and importance of these discoveries, entered into the same field of research with all the scientific ardour by which he was characterized: and here the advantage of his ample wealth was manifest; for he conducted his experiments upon a large scale, with costly instruments of the most improved construction. The result of this course of experimental inquiry he gave to the world in 1774, in his “Opuscules Chymiques,” which contained not only a clear and elegant view of all that had hitherto been done, in regard to gaseous or acrimonious fluids, but also several original experiments, remarkable for their ingenuity and accuracy.

The existence of a gaseous body, in a fixed or solid state, in the mild alkalies and alkaline earths, which, when expelled from these substances, assumed an aerial form, and left them in a caustic state, as well as its production during the combustion of fuel, had been demonstrated by Dr. Black; and Bergman had shewn that this air possessed acid properties. Dr. Priestley had also submitted it to various experiments in the year 1767; but no progress had been made in ascertaining the real constituent parts of this acid gas, or fixable air. The honour of this discovery was left for Lavoisier; who, in 1772, by exposing a piece of charcoal, inclosed in a glass vessel, to the action of a lens, discovered that part of the charcoal was consumed, that a diminution of air had taken place in the receiver, and that the residue possessed the properties of the fixable air:—whence he concluded that charcoal was one of the constituent parts of this gas. The combustible nature of the diamond having been already proved by Macquer, d’Arcet, and others, Lavoisier was induced to submit this substance to the same treatment as the charcoal in the former experiment: and he found that precisely the same results took place: whence he inferred, that there existed a great analogy between charcoal and diamond. Both these conclusions have been amply confirmed by subsequent experiments: they were in every respect important; and seen, together with the facts previously known, of the production of acids by the combustion of sulphur and phosphorus, to have given the first hint to Lavoisier of his subsequent general theory of the formation of acids.

Lavoisier now turned his experimental researches to the subject of the calcination (as it was then termed, from its apparent similarity to the process of making lime) of metals. It had already been shewn by Rey and Homberg, that metals acquire an augmentation of weight during calcination. This additional weight was attributed by the latter to the fixation of heat and light; but was supposed by the former to proceed from the fixation of a part of the air. M. Lavoisier published the result of his investigation of this curious subject in 1774, in a memoir on the calcination of tin in close vessels, in which he demonstrated the following very important facts. He shewed, 1, that a given quantity of air was requisite for the calcination of a given quantity of tin; 2, that a part of the air is absorbed during this pro-

cess, by which not only the bulk, but the weight of the air is diminished; 3, that the weight of the tin is increased during the same process; and, 4, that the weight acquired by the tin is exactly equal to that which is lost by the air.

Thus by a few simple, accurate, and well-chosen experiments, Lavoisier had apparently arrived at the legitimate inference, that during the process of the formation of acids, whether with carbonaceous matter, sulphur, or phosphorus, and also during that of the calcination of metals, an absorption and fixation of air take place, and thus he gained a glimpse of principles, in the view of which his singular sagacity in devising experiments, and his accuracy in executing them, would in all probability have alone conducted him to those brilliant results, to which the active genius of Dr. Priestley so materially contributed. The synthetic proof, only of this union of air with the base had been as yet ascertained: but Dr. Priestley first furnished the analytic proof, by dissolving the combination; a discovery which at once advanced the nascent theory of Lavoisier, and, in his hands, became the source of more than one important conclusion. In August 1774, Dr. Priestley discovered, that by heating certain metallic calces, especially the calcined mercury, (the precipitate *per se*, as it was then called,) a quantity of air was separated, while the mercury resumed its metallic form; and this air, which he found was much purer than that of the atmosphere, he called, from the theory of the time, *dephlogisticated air*. The succeeding winter he spent at Paris, and communicated to Lavoisier, and the other philosophers there, his recent discovery: and the importance of this intelligence to the views of Lavoisier was manifest in a memoir published by him in the following year, 1775, on the nature of the principle which combines with metals during their calcination. In this paper he shewed, in conformity with the experiments of Dr. Priestley, that the mercurial precipitate *per se*, by being heated in a retort, gives out a highly respirable air, (since called *oxygen*), and is itself reduced to the metallic state; that combustible bodies burn in this air with increased brilliancy; and that the same mercurial calx, if heated with charcoal, gives out not the pure air, but fixed air:—whence he concluded that fixed air is composed of charcoal and the pure air. It has, therefore, since been called *carbonic acid*.

A second very important consequence of Dr. Priestley’s discovery of the pure or vital air, was the analysis of the air of the atmosphere: which was accomplished by Lavoisier in the following manner. He included some mercury in a close vessel, together with a known quantity of atmospheric air, and kept it for some days in a boiling state: by degrees a small quantity of the red calx was formed upon the surface of the metal; and when this ceased to be produced, the contents of the vessel were examined. The air was found to be diminished both in bulk and weight, and to have been rendered altogether incapable of supporting combustion or animal life: part of the mercury was found converted into the red calx, or precipitate *per se*; and, which was extremely satisfactory, the united weight of the mercury and the precipitate exceeded the weight of the original mercury, by precisely the same amount as the air had lost. To complete the demonstration, the precipitate was then heated, according to Dr. Priestley’s first experiment, and decomposed into fluid mercury and an air, which had all the properties of vital air; and this air, when mixed with the unrespirable residue of the original air of the receiver, composed an elastic fluid possessing the same properties as atmospheric air. The vital air was afterwards made the subject of various experiments in respect to the calcination of metals, to the combustion and conversion of sulphur and phosphorus into acids,

acids, &c. in which processes it was found to be the chief agent. Hence it was named by Lavoisier *oxygen* (or generator of acids), and the unrespirable residue of the atmosphere was called *azot*, (*i. e.* incapable of supporting life.)

The new theory thus acquired farther support and consistency: oxygen appeared to be one of the most active and important agents of chemistry and of nature; combustion, acidification, and calcination, (or, as it was now called, *oxydation*, the calces being also termed *oxyds*, *i. e.* something approaching to, or resembling acids,) were proved to be processes strikingly analogous to each other; all according in these points, that they produced a decomposition of the atmospheric air, and a fixation of the oxygenous portion in the substance acidified or calcined.

Time alone seemed now requisite to establish these doctrines, by exemplifying them in other departments of chemical research. In the year 1777, six memoirs were communicated to the Academy of Sciences by Lavoisier, in which his former experiments were confirmed, and new advances were made to a considerable extent. Our countrymen, Black and Crawford, in their researches respecting latent heat, and the different capacities of bodies under different circumstances, had laid a solid foundation, on which the doctrines of combustion, resulting from the foregoing experiments, might be perfected, and the cause of the light and heat connected with it might be explained. The first mentioned philosopher, Dr. Black, had shewn, that a solid, when it is made to assume a liquid form, and a liquid, when it assumes the form of vapour, absorbs or combines with, and renders latent, a large portion of heat, which is again parted with, becomes free and cognizable by the sense of feeling, and by the thermometer, when the vapour is again condensed into a liquid, and the liquid becomes solid. In like manner, it was now said by Lavoisier, during the process of combustion, the oxygen, which was previously in a gaseous state, is suddenly combined with the substance burnt into a liquid or solid. Hence all the latent heat, which was essential to its gaseous state, being instantaneously liberated in large quantity, produces flame, which is nothing more than very condensed free heat. About the same time, the analogy of the operation and necessity of oxygen in the function of respiration, with the preceding hypothesis of combustion, was pointed out by Lavoisier. In the process of respiration, it was found that, although atmospheric air is inhaled, carbonic acid and azot are expired. This animal operation, said Lavoisier, is a species of slow combustion: the oxygen of the air unites with the superfluous carbon of the venous blood, and produces carbonic acid, while the latent or combined *caloric* (the matter of heat) is set free, and thus supplies the animal heat. Ingenious and beautiful, however, as this extension of the analogy appeared, the subject of animal temperature is still under many obscurities and difficulties.

The phenomena of chemistry, however, were now explainable upon principles more simple, consistent, and satisfactory than by the aid of any former theory; and the Lavoisierian doctrines were every where gaining ground. But there yet remained a formidable objection to them, which was derived from a circumstance attending the solution of metals in acids; to wit, the production of a considerable quantity of inflammable air. If sulphuric acid (formerly called vitriolic acid, or oil of vitriol) consists only of sulphur and oxygen, it was said, and bar iron is nothing more than this metal in a simple state, how does it happen, that when these two substances, with a little water, come in contact, they should produce a large quantity of inflammable air during their reaction? This objection was unanswerable, and appeared to be fatal

to the whole theory; but it was most opportunely converted into an argument in its favour, by the great discovery of the decomposition of water, made by Mr. Cavendish, who resolved that element, as it was formerly esteemed, into oxygen and inflammable air. The latter has since, therefore, been called *hydrogen*, or generator of water. This experiment was repeated with full success by Lavoisier and his associates in 1783; and the discovery was further established by a successful experiment of the same chemists, carried on upon a grand scale, in which, by combining the oxygen with hydrogen, they produced water, and thus adding synthesis to analysis, brought the fact to demonstration.

This new view of chemical phenomena, together with the immense accession of new compounds and substances, which the labours of modern experimentalists had brought to light, appeared to demand a correspondent alteration in the nomenclature. Accordingly, a committee of some of the ablest of the French chemists, of whom Lavoisier was the most conspicuous, undertook the arduous task, and produced a regular system of nomenclature, derived from the Greek language, which, although far from being faultless, and notwithstanding much opposition with which it was at first treated, has become the universal language of chemical science, and has been adopted even in pharmacy and medicine. His work, entitled "Elemens de Chymie," which was published in 1789, was a model of scientific composition.

We have hitherto viewed M. Lavoisier principally as a chemical philosopher, in which character he has founded his great claims to the respect and admiration of posterity. But the other arts and sciences are indebted to him for considerable services which he rendered them, both in a public and private capacity. In France, more than in any other country, men of science have been consulted in matters of public concern; and the reputation of Lavoisier caused him to be applied to, in 1776, to superintend the manufacture of gunpowder, by the enlightened minister Thurgot. By the application of his chemical knowledge to this manufacture, he was enabled to increase the explosive force of the powder by one fourth; and while he suppressed the troublesome regulations for the collection of its materials from private houses, previously adopted, he quintupled the produce. The Academy of Sciences received many services from his hands. In addition to the communication of forty papers, relative to many of the most important subjects of philosophical chemistry, which were printed in the twenty volumes of *Memoirs*, from 1772 to 1793, he most actively promoted all its useful plans and researches, being a member of its board of consultation, and, when appointed to the office of treasurer, he introduced order into its accounts, and economy into its expenditure. When the new system of measures was proposed, he contributed some new and accurate experiments on the expansion of metals. The national convention consulted him with advantage concerning the best method of manufacturing assignats, and of securing them against forgery. Agriculture early engaged his attention, and he allotted a considerable tract of land on his estate in the Vendome, for the purpose of experimental farming. The committee of the constituent assembly of 1791, appointed to form an improved system of taxation, claimed the assistance of his extensive knowledge; and he drew up, for their information, an extract of a large work on the different productions of the country and their consumption, for which he had been long collecting materials. This was printed by order of the assembly, under the title of "Richesses Territoriales de la France," and was esteemed the most valuable memoir on the subject. In the same year, he was appointed one of the commissioners of the national treasury; and he introduced

into that department such order and regularity, that the proportion between the income and the expenditure, in all the branches of government, could be seen at a single view every evening. This spirit of systematic and lucid arrangement was, indeed, the quality by which he was peculiarly distinguished, and its happy influence appeared in every subject which occupied his attention.

The private life of this distinguished person was equally estimable with his public and philosophical character. He was extremely liberal in his patronage of the arts, and encouraged young men of talents in the pursuit of science. His house became a vast laboratory, where philosophical experiments were incessantly carrying on, and where he held conversazioni twice a week, at which all the votaries of learning and science, foreigners as well as Frenchmen, assembled. In his manners M. Lavoisier was mild, affable, and obliging; a faithful friend and husband, a kind relation, and charitable to the poor upon his estates; in a word equally claiming esteem for his moral qualities, as for those of his understanding.

The time was arrived, however, when distinction even by his talents and worth was so far from securing public respect, amid the tumults of the revolution, that it became a source of danger, and, when joined with wealth, was almost certainly fatal. All those especially, who had held any situation under the old administration, particularly in the financial departments, were sacrificed during the murderous reign of Robespierre, to the popular odium. Lavoisier was seized and thrown into prison, upon some charges fabricated against himself and twenty-seven other farmers-general. During his confinement he foresaw that he should be stripped of all his property; but consoled himself with the expectation that he would be able to maintain himself by the practice of pharmacy. But a more severe fate awaited him: he was capitally condemned, and dragged to the guillotine, on the 8th of May, 1794.

The name of Lavoisier will always be ranked among the most illustrious chemists of the present age, when it is considered what an extensive and beneficial influence his labours have had over the whole science. It has been said, indeed, that if he be estimated on the score of his actual discoveries, not only Scheele and Priestley, and Cavendish, but many more, will stand before him. But he possessed in a high degree that rare talent of discernment, by which he detected analogies, which others overlooked, even in their own discoveries, and a sagacity in devising and an accuracy in completing his experiments, for the purpose of elucidating every suggestion which he thus acquired, such as few philosophers have possessed. No one who did so much, probably ever made so few unsuccessful or random experiments. It was the singular perspicuity, simplicity and order to which he reduced the phenomena of chemistry, that claimed for his theory the general reception which it met with, and occasioned the abandonment of those doctrines which prejudice and habit conspired to support. Subsequent discoveries, however, and more especially those numerous facts which the genius of Mr. Davy has lately brought to light, through the medium of that most powerful agent of decomposition, galvanism, have rendered several modifications of the Lavoisierian theory necessary, and bid fair to produce a more general revolution in the language and doctrines of chemistry.

M. Lavoisier married, in 1771, the daughter of a farmer-general, a lady of pleasing manners and considerable talents, who partook of her husband's zeal for philosophical inquiry, and cultivated chemistry with much success. She engraved with her own hand the copper plates for his last work. Mad. Lavoisier has since given her hand to another eminent philo-

sopher, count Rumford. Gen. Biog. Hutchinso'n's Biog. Med.

**LAVONIA**, in *Geography*, a town of Naples, in Calabria Citra; 8 miles W.S.W. of Rossano.—Also, a town of Calabria Ultra; 14 miles W. of Squillace.

**LAVORA**, or **TERRA DI LAVORA**, a fertile and delightful province of Naples, diversified with hills and plains, lying between 40° 36' and 41° 45' N. lat.; and anciently Terra Laboria, Campana, and Campus Laboricus, and in the middle ages the Castellany of Capua. It received its present name in 1001 from Richard II., prince of Capua, on account of the fitness of the soil for every kind of cultivation. This province is populous, and abounds in corn, wine, oil, and other productions of Italy. It is bounded on the N.W. by Campagna di Roma, on the N. and E. by Abruzzo Citra and Contado di Molise, on the S.E. and S. by Principato Ultra and Principato Citra, and on the W. by the Mediterranean; being 90 miles from N.W. to S.E. and 30—45 in breadth; and in 1779 it contained 1,210,689 inhabitants. It is watered by the rivers Carigliano and Volturno; the former, which is a placid stream, rises in Abruzzo Ultra, and falls into the sea below Trajeto; the latter descends from the Apennines, passes by Capua, and loses itself in the gulf of Gaeta. The capital of this province is Naples.

**LAUPEN**, a town of Switzerland, in the canton of Berne, and chief place of a bailiwick: it is situated at the conflux of the Sannen and Senfe; 5 miles S.W. of Berne. It was once imperial.

**LAUQUEN**, called *Villarica* by the Spaniards, a lake of Chili, about 72 miles in circuit, with a beautiful conic hill in the centre. From this hill springs the river Tolten, which joins the Pacific ocean.

**LAUR**, a town of Persia, in Chulistan; 50 miles E. of Tostar.

**LAURA**, a town of Russia, in the government of Moscow; 36 miles N.E. of Moscow.

**LAURA**, a town of Hindoostan, in the circar of Nagore; 20 miles W. of Catchwana,

**LAURA**, *Λαυρα*, primarily signifying *village, street, or hamlet*, a name given to the residence of the ancient monks. Authors cannot agree about the difference between a laura and a monastery: some pretend, that a laura was a monastery, wherein there lived at least a thousand monks; but this is nowise credible. The more natural opinion is, that the ancient monasteries were the same with the modern, consisting of large buildings divided into halls, chapels, and cells, possessed by the monks, each of whom had his apartment; but the lauræ were a kind of villages, whereof each house was inhabited by one or two monks at the most; so that the houses of the Chartreux seem, in some measure, to represent the ancient lauræ, and those of the other monks proper monasteries. The term laura was only understood of the religious places in Egypt, and the East, where their houses stood apart from each other, and were not joined by any common cloister, the monks that inhabited them only meeting in public once a week.

**LAURADIO**, in *Geography*, a town of Portugal, in the province of Estramadura, on the S. side of the Tagus; 6 miles S.S.E. of Lisbon.

**LAURAGAIS**, the name, before the revolution, of a small county of France, in Upper Languedoc, of which Castelnaudary was the capital.

**LAURANA**, a sea-port of Istria, with a small harbour, in the gulf of Quarnero; 8 miles S. of Castua. N. lat. 45° 28'. E. long. 14° 17'.

**LAURE**,

LAURE, a town of Portugal, in the province of Alentejo; 30 miles W.N.W. of Evora.

LAUREAT, POET, is a well known office in the king's household. Sir John Hawkins observes, that there are no records which ascertain the origin of the institution of the office in this kingdom, though there are many that recognize it. It appears that as early as the reign of Henry III. there was a court poet, named Henry de Avranches, who is supposed to have had an appointment of a hundred shillings a year, by way of salary or stipend. In 1341 Petrarch was crowned with laurel in the Capitol by the senate of Rome; afterwards Frederic III. emperor of Germany, gave the laurel to Conrad Coltes; and ever since the counts palatine of the empire have claimed the privilege of solemnly investing poets with the bays. Chaucer, who was contemporary with Petrarch, and acquainted with him, when abroad, assumed the title of poet-laureat on his return to England; and in the 12th year of Richard II. obtained a grant of an annual allowance of wine. We read of persons under the same title in the reigns of Edward IV. Henry VII. and VIII. and of James I. who, in 1615, granted to his laureat an annual pension of 100 marks. In the year 1630, this pension was augmented, by letters patent of Charles I. to 100*l.* per annum, with an additional grant of one terle of Canary Spanish wine, to be taken out of the king's store of wines yearly. *Hawkin's Hist. of Music, vol. iv. p. 13.*

LAUREATION, a term in the Scottish universities, used for the act of taking up the degree of a master of arts, to which the students are admitted after four years' study in the universities.

LAUREL, in *Botany and Gardening*. See *Laurus* and *Prunus*.

LAUREL, *Common or Cherry, Prunus laurocerasus*, in the *Materia Medica*, is a native of the Levant, and has been long cultivated in Britain. The leaves have a bitter styptic taste, accompanied with a flavour resembling that of bitter almonds. The flowers also have a similar flavour. The powdered leaves, applied to the nostrils, excite sneezing, but less powerfully than tobacco. The kernel-like flavour of the leaves has caused them to be used for culinary purposes, especially in custards, puddings, blanc-mange, &c. and as the proportion to the quantity of milk is inconsiderable, this has been done without any noxious effect. However, as the poisonous quality of this laurel is now indubitably proved, the public should be cautioned against its internal use. The first and principal proofs of the deleterious effects of this vegetable upon mankind were communicated to the Royal Society by Dr. Madden of Dublin, in a "letter giving an account of two women being poisoned by the simple distilled water of laurel-leaves, and of several experiments upon dogs, by which it appears that this laurel is one of the most dangerous poisons hitherto known." He mentions also the case of a gentleman, who by mistake drank a quantity of this laurel water, and died in a few minutes, complaining of a violent disorder in his stomach. (*See Phil. Trans. N<sup>o</sup> 418. 426. vol. xxxvii.*) The case of Sir Theodosius Boughton is more recent. His death in 1780 was ascribed by an English jury to this poison. In this case the active principle of the laurocerasus was concentrated by repeated distillations, and given to the quantity of an ounce. It has been found by the experiments of Madden, Mortimer, Nicholl, Langrish, Vater, Fontana, and others, that to brute animals this poison is almost instantaneously mortal. These experiments also shew, that the laurel-water is destructive to animal life, not only when taken into the stomach, but also on being injected into the inter-

ines, or applied externally to different organs of the body. The most volatile is the most active part of the laurocerasus; and from its sensible qualities we may be led to judge, that an analogous principle seems to pervade many other vegetable substances, especially the kernels of drupaceous fruits; and in various species of the Amygdalus, this lapid principle extends to the flowers and leaves. It is observable, that it is much less powerful in its action upon human subjects than upon dogs, rabbits, pigeons, and reptiles. To poison man, the essential oil of the laurocerasus must be separated by distillation, as in the spirituous or common laurel water; and unless this is strongly imbued with the oil, or given in a large dose, it proves innocent. Dr. Cullen remarks, that the sedative power of the laurocerasus acts upon the nervous system in a different manner from opium and other narcotic substances, whose primary action is upon the animal functions; for the laurocerasus does not occasion sleep, nor does it produce local inflammation, but seems to act directly upon the vital powers. "Although this vegetable seems to have occupied the notice of Stoerck, its medicinal use has its advocates. From Linnaeus we learn, that in Switzerland it is commonly and successfully used in pulmonary complaints. Langrish mentions its efficacy in agues; and as Bergius found bitter almonds to have this effect, we may from analogy conclude, that this power of the laurocerasus is well established. Baylies found that it possessed a remarkable power of diluting the blood, and from experience, recommended it in all cases of disease supposed to proceed from too dense a state of that fluid; adjucing particular instances of its efficacy in rheumatism, asthma, and in scirrhus affections. Nor does this author seem to have been much afraid of the deleterious quality of the laurocerasus, as he orders a pound of its leaves to be macerated in a pint of water, of which he gives from 30 to 40 drops three or four times a day." *Woodville's Med. Bot.*

LAUREL, *Alexandrian, in Botany*. See *Ruscus*.

LAUREL, *Dwarf, of America*. See *Kalmia*.

LAUREL, *Sea-fule*. See *Phyllanthus*.

LAUREL, *Spruce, or Spurge*. See *Daphne*.

LAUREL Mountains, in *Geography*, a range of mountains W. of the Alleghany ridge, and part of the Alleghany mountains; extending from Pennsylvania to North Carolina, and giving rise to several branches of the Ohio river. The Great Kanlawha breaks through the Laurel ridge in its way to the Ohio. N. lat. 38° 30'. W. long. 81° 10'. About lat. 36°, in a spur of this mountain, is a spring of water 50 feet deep, very cold, and, as it is said, blue as indigo. The lands, within a small distance of the Laurel mountains, through which the Youghiogini river runs, are in many places broken and stony, but rich and well timbered; and in some places, and particularly on Laurel creek, they are rocky and mountainous. From the Laurel mountain to Monongalela, the lands for the first seven miles are good, level, and fit for farming, interspersed with fine meadows: the timber, white-oak, chestnut, hickory, &c. Morfe.

LAUREL RIVER, a river of Kentucky, which runs into the Cumberland. N. lat. 36° 34'. W. long. 83° 50'.

LAURELS, pieces of gold coined in the year 1610, with the king's head laureated, which gave them the name of laurels; the twenty-shilling pieces of which were marked with XX, the ten shillings X, and the five-shilling pieces with V.

LAUREMBERG, Peter, in *Geography*, a learned physician, was born at Rotterdam, where his father was professor of medicine and mathematics. Peter took the degree of doctor in the university of his native place, and afterwards travelled.

travelled into France, and settled for some time at Montauban, where he taught philosophy in 1611. In 1614, however, he was at Hamburg, and was professor of natural philosophy there until 1620; when he returned to Rollock, and was appointed professor of poetry in 1624. He died in this city on the 13th of May, 1639, at the age of 54. He left several works; those on anatomy, however, were esteemed by Riolan as of very indifferent worth. They are, "Disputationes Physicæ," Rollock, 1616. "Hæcogæ Anatomica Græcæ Interpretatio," Hamburg, 1616. "Proſceſſus Anatomica," *ibid.* 1619. "Laurus Delphica, seu, Conſilium quo deſcribitur Methodus perfacilis ad Medicinam," Leyden, 1621. "In Synopſin Aphoriſmorum Chymiatricorum Angeli Salæ, Vicentini, Notæ et Animadverſiones," Rollock, 1624. "Porticus Eſculapii, ſeu, generalis Artis Medicæ Conſtitutio," *ibid.* 1630. "Apparatus Plantarius primus, &c.," Francfort, 1632. "Palcomple nova, id eſt, delineatio Pulchritudinis," Leiſpic, 1634. "Anatomia corporis humani, ſive Collegium Anatomicum duodecim diſputationibus comprehenſum," Roſt. 1636.

William Lauremberg, the father of the preceding, who died in 1612, left an "Eſſay on the malignant, pectehial Fever," Rollock, 1605; and the following poſthumous works: "De Curatione Calculi," Leyden, 1610. "Botanotheca, ſive Modus conficiendi Herbarium vivum," 1626; and "Hiſtoria Deſcriptionis Aelitis, ſive Lapidis Aquila," 1627. His younger ſon, John Lauremberg, likewiſe was a phyſician, and author of ſeveral works, on the antiquities of Greece, algebra, and arithmetic, &c. Eloy. Dict. Hiſt. de la Méd.

LAUREMBERGIA, in *Botany*, ſo named by Bergius in honour of Peter Lauremberg, formerly an excellent gardener, who publiſhed a work on horticulture at Francfort in 1632, which is ſaid to have led the way to the modern improvements in that art. Berg. Cap. 350. t. 5. f. 10. See SERPICULA, to which the ſynonym of Bergius undoubtedly belongs, though cited with hesitation in Schreb. Gen. 628. Lamarck's figure of *Serpicula*, t. 758, is in fact a copy of that of Bergius.

LAURENCE, *Canons of St.*, an order of regular canons, ſo called from the monaſtery of St. Laurence d'Oulx, in Dauphiné.

This congregation is ſaid to have been founded by St. Benediſt. It was deſtroyed by the Vandals, and continued uninhabited till the middle of the 11th century. In 1057, Odo, count of Savoy, gave it to one Gerard, and his canons. This donation was confirmed in 1065, by Cunibert, biſhop of Turin, who added to it above forty other churches; by which means a very conſiderable congregation was formed, to whom the ſucceeding popes, and counts of Savoy, granted a great many privileges.

It had thirty priories; the chief, who is the prior of the congregation, bears the title of provost, and exerciſes a ſpiritual juriſdiction throughout his provostſhip.

LAURENCE, *Bay of St.*, in *Geography*, a bay on the E. coaſt of Ruſſia, at the entrance of Beering's ſtraits. N. lat. 63° 47'. E. long. 188° 15'.

LAURENCE *Creek*, a river of Kentucky, which runs into the Ohio, N. lat. 38° 30'. W. long. 83° 36'.

LAURENCE *Iſland*, a ſmall iſland in the gulf of Florida, near the coaſt of Eaſt Florida. N. lat. 25° 36'. W. long. 80° 22'.

LAURENCE *Iſland*, an iſland in the Pacific ocean, on the coaſt of Ruſſia, near Tſchukotſkoi Noſs; about three leagues in circuit. N. lat. 63° 47'. E. long. 188° 15'.

LAURENCE, *Gulf of St.*, a part of the North Atlantic ocean, ſituated between the iſland of Newfoundland, Labra-

dor, Canada, Nova Scotia, and the iſland of Cape Breton; 350 miles in length, and 150 in breadth. This is the eſtuary of the river of the ſame name, and is generally frozen from December to April. This noble gulf is cloſed by the iſland of Newfoundland, and by numerous ſand-banks, particularly by that which is called the Great Bank. N. lat. 47° 51'. W. long. 57° to 65°.

LAURENCE, *Harbour of St.*, a bay on the S. coaſt of Newfoundland, ſituated N.W. of the entrance into Placentia bay.

LAURENCE *Key*, a ſmall iſland in the bay of Honduras, near the coaſt of Mexico. N. lat. 16°. W. long. 89° 48'.

LAURENCE *Kirk*, a town of Scotland, in the county of Kincardine, in which have been lately eſtabliſhed manufactures of lawns, cambric, &c. In 1799 it was created into a burgh of barony, with the privilege of a market. The population in 1801 was 1215; 7 miles W. of Berwie.

LAURENCE, or *Lawrence, River of St.*, the laſt, or at leaſt the ſecond, river in North America, being not leſs than 90 miles wide at its mouth, and navigable for ſhips of the line as far as Quebec, a diſtance of 400 miles from the ſea. Near Quebec it is five miles wide; at Montreal, 560 miles from its mouth, from two to four miles broad. To this place it is navigable with perfect ſafety for ſhips drawing fourteen feet water. During the whole of its courſe to Kingſton on lake Ontario, 743 miles from its mouth, it is navigable for batteaux of two tons burden, except merely at the rapids above Montreal, at the Fall of the Thicket, and at the Long Fall, where it is neceſſary to lighten the batteaux, if heavily laden. Mr. Weld ſuggeſts, that at each of theſe places it is poſſible to conſtruct canals, ſo as to prevent the trouble of unloading any part of the cargoes of the batteaux; and that, at a future day, when the country becomes rich, ſuch canals will, without doubt, be made. The force of this river is not preciſely aſcertained; but the name is generally appropriated to the ſtream that iſſues from lake Ontario. From Ontario to Montreal it has the name of Iroquois, and afterwards it aſſumes the name of St. Laurence. This river cannot, conformably to geographical uſage, be traced beyond lake Ontario, to lake Superior; much leſs, with Mr. Weld, to lake Winipic, which, according to the beſt maps, has no communication with the ſea of Canada, or the connected lakes Superior, Michigan, and Huron. The length of the St. Laurence may be reckoned about 700 Britiſh miles, its chief characteristic being its breadth. Mr. Weld has made ſeveral obſervations on the importance of this river to the commerce of North America. The time required to aſcend this river, from Montreal to Kingſton, is commonly found to be ſeven days, but with a ſtrong and favourable wind the voyage may be performed in leſs time, and with an adverſe wind it will of courſe require longer time. The paſſage downwards is performed in four or five days, according to the wind. The current is ſo ſtrong, that a contrary wind ſeldom lengthens the paſſage in this direction more than a day. The channel of this river, inſtead of having been impaired by time, like thoſe of many others, and that of the Miſſiſſippi in particular, is found to be conſiderably better now than when it was firſt diſcovered; and there is reaſon to imagine that it will improve ſtill more in proceſs of time, as the clear water from lake Ontario comes down with ſuch impetuouſity during the floods in the ſpring of the year, as frequently to remove banks of ground and of looſe ſtones in the river, and thus to deepen its bed. To this purpoſe, it is obſerved, that the channel on the N. ſide of the iſland of Orleans, immediately below Quebec, which, in the year 1720, was not deep enough to admit a ſhallop

Mallof of small size, except at the time of high tides, is at present of sufficient depth for the largest vessels, and is the channel most generally used. This river, in its course, forms a great variety of bays, harbours, and islands, which are not only fertile and pleasant, but favourable for the purposes of commerce. It appears by a comparison of the St. Laurence with other rivers, connecting the lakes with the Atlantic ocean, that this river opens a shorter passage than any of the others, and that the portages are shorter than in any of the other routes; they are also fewer, and goods may be transported in the same boats the whole way from Montreal to the lakes. Besides, the St. Laurence will, on another account, be found a more commodious channel than any other for the carrying on of trade between the ocean and the lakes. Being constantly supplied from that immense reservoir of water, lake Ontario, it is never so low, even in the driest season, as not to be sufficiently deep to float laden bateaux.

The scenery along various parts of this river is very fine, as it winds for hundreds of miles through a rich country, diversified with rising grounds, woodlands, and cultivated plains. The attention, in going down the river, is particularly attracted by the beautiful disposition of the towns and villages on its banks. All the houses have a neat appearance at a distance; and in each village, however small, there is a church: the churches are kept in good repair, and most of them are covered, according to the custom of the country, with tin, which, from the manner in which it is put on, never becomes rusty.

LAURENS, ANDREW DU, or LAURENTIUS, in *Biography*, a French physician, was born at Arles. He was a disciple of Lewis Duret, at Paris; but after having taken his degree of doctor of medicine, he settled in a provincial town. He was induced, however, to accompany a lady of quality to court, and through her interest was appointed chancellor of the university of Montpellier, physician to the queen, and ultimately (in 1606) first physician to the king, Henry IV. He died in 1609. He left several works, the principal of which were upon anatomical subjects, and were more remarkable for elegance of style, than correctness in the detail of facts. His "*Historia Humani Corporis et singularum ejus partium anatomica*," folio, 1600, was often reprinted, and translated into French by Heliot, in 1741. The figures of this work are chiefly copied from Vesalius. He published also "*Discours de la Vue, des Maladies melancholiques, des Catarrhes, et de la Vieillesse*," 1596, which was translated both into Latin and English. Gen. Biog. Hutchinsof Biog. Med.

LAURENS, in *Geography*, a district of South Carolina, lying between Enoree and Saluda rivers; about 31 miles long and 22 broad, containing 12,809 inhabitants, of whom 1919 are slaves.

LAURENS Court-house, a place in the above county, 20 miles from Bush river, 32 from Newbury, and 40 from Greenville; in which is a post-office.

LAURENS, *St.*, a small island in the Indian sea. S. lat. 9° 35'. E. long. 52°.

LAURENT, *St.*, a town of Hispaniola, on the Ozema; seven miles N. of St. Domingo.—Also, a town of France, in the department of the Vendée; seven miles S.E. of Mortagne.—Also, a town of France, in the department of the Jura; 12 miles N. of St. Claude.—Also, a town of France, in the department of the Lower Seine; seven miles N. of Rouen.—Also, a town of France, in the department of the Aude; four miles E. of La Grasse.—Also, an island in the Pacific ocean, near the coast of Peru, at the entrance of the harbour of Callao.

LAURENT *d'Aigouze, St.*, a town of France, in the department of the Gard; 15 miles S. of Nîmes.

LAURENT *d'Arce, St.*, a town of France, in the department of the Gironde; eight miles S.E. of Bourg.

LAURENT *de Cerdans, St.*, a town of France, in the department of the Eastern Pyrenées; nine miles S.W. of Cerat.

LAURENT *de Chamouffet, St.*, a town of France, in the department of the Rhone, and chief place of a canton, in the district of Lyons; 15 miles W. of Lyons. The place contains 1255, and the canton 10,978 inhabitants, on a territory of 182½ kilometres, in 14 communes.

LAURENT *sur-Gorre, St.*, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Rochechouart; 15 miles W.S.W. of Limoges. The place contains 2313, and the canton 13,519 inhabitants, on a territory of 265 kilometres, in nine communes.

LAURENT *de Médoc, St.*, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Lesparre; 50 miles from Lesparre. The place contains 549, and the canton 3706 inhabitants, on a territory of 657½ kilometres, in six communes.

LAURENT *le Minier, St.*, a town of France, in the department of the Gard; six miles S.E. of Le Vigan.

LAURENT *du Motay, St.*, a town of France, in the department of the Mayne and Loire; nine miles S.E. of St. Florent.

LAURENT *des Mures, St.*, a town of France, in the department of the Here; nine miles S.E. of Lyons.

LAURENT *sur Oibais, St.*, a town of France, in the department of the Meuse; 12 miles N. of Eltain.

LAURENT *de la Plaine, St.*, a town of France, in the department of the Mayne and Loire; three miles S.W. of Chalonne.

LAURENT *du Pont, St.*, a town of France, in the department of the Here, and chief place of a canton, in the district of Grenoble; 12 miles N. of Grenoble. The place contains 3339, and the canton 11,551 inhabitants, on a territory of 182½ kilometres, in eight communes.

LAURENT *de Rividol, St.*, a town of France, in the department of the Aveyron; nine miles N. of Severac.

LAURENT *de la Salaque, St.*, a town of France, in the department of the Eastern Pyrenées; seven miles N.E. of Perpignan.

LAURENTALIA, or LARENTALIA, called also *Larentinalia, Laurentales, and Larentales*, feasts celebrated among the Romans on the tenth of the calends of January, or twenty-third of December, in memory of Acca Laurentia, wife of the shepherd Faustulus, and nurse of Romulus and Remus.

Acca Laurentia, from whom the solemnity took its name, is represented as no less remarkable for the beauty of her person, than her lasciviousness; on account of which, she was nick-named by her neighbours, *lupa, she-wolf*; which is said to have given rise to the tradition of Romulus and Remus being suckled by a wolf. She afterwards married a very rich man, who brought her great wealth; which, at her death, she left to the Roman people; in consideration of which they performed her these honours; though others represent the feast as held in honour of Jupiter Latiaris. See LARENTINALIA and LARES.

LAURENTEVA, in *Geography*, a bay or gulf of the Frozen sea, on the W. coast of Nova Zembla. N. lat. 72° 15'. E. long. 53° 14'.

LAURENTIA, in *Botany*, Mich. Gen. 18. t. 14, received its appellation from Micheli, in compliment to Dr. Mark

Mark Anthony Laurenti, a physician and professor at Bologna, whose botanical merits have not been transmitted to posterity, and the name is now sunk in that of *Lobelia*, to which article we refer the reader.

**LAURENTUM**, in *Ancient Geography*, a town of Italy, in Latium, of which it was for some time the capital; and supposed to have been the residence of king Latinus; situated upon the sea-coast, about eight miles S. of the capital.

**LAUREOLA**, in *Botany*, Spurge Laurel. See **DAPHNE**.

**LAURI**, FILIPPO, in *Biography*, painter of figures and landscapes. He was son of Baldassare Lauri of Antwerp, a landscape-painter of note, who settled at Rome, and died there in 1641.

Filippo was born in 1623; and became celebrated for cabinet pictures in the Flemish style of colour, but with a much more correct and refined taste of form than prevailed in that school; which most probably he acquired by residing with his father in Rome. His pictures are agreeably composed, touched with great spirit and freedom, of good colour and picturesque effect. Claude Lorraine paid him the compliment to employ him frequently to put figures in the fore-grounds of his landscapes; and in some of his best pictures, the hand of Lauri is discernible in the better proportion and beauty of touch with which the figures are wrought than in those completed by Claude's own hand.

The subjects he generally selected were those of nymphs, gods, and goddesses, and the like; where he could, with propriety, introduce much of the nude. To these he gave great ease in their actions, and composed them in a very agreeable manner. He died in 1694, at the age of 71.

**LAURI**, in *Botany*, a natural order of plants, to which *Laurus*, one of the number, gives its name; (the *Laurine* of Ventenat and Brown; see *Prod. Nov. Holl. v. 1. 401*.)—This is the 27th order of Jussieu's system, the fourth of his sixth class. There is nothing equivalent to it among the *Ordines Naturales* of Linnæus.

The characters of Jussieu's sixth class are.—Cotyledons two; petals none; stamens inserted into the calyx.—The calyx is of one leaf, either superior or inferior, entire or divided. Corolla wanting, but there are sometimes little scales, resembling petals, borne by the calyx. Stamens perigynous, or inserted into the calyx, definite or indefinite, both filaments and anthers distinct. Germen superior or inferior, or only invested with the calyx, simple, or rarely several in a definite number; style either solitary, or several in a definite number, or wanting; stigma simple or manifold. Seed naked, superior, or pericarp superior or inferior, often containing a single seed, rarely several. The situation of the embryo is various. Sometimes the flowers are of separate sexes.—The orders of this class are six; *Elaeagni*, *Thymelææ*, *Proteæ*, *Lauri*, *Polygonææ*, and *Atriplicææ*. It is one of those in which botanists differ most with respect to the application of the terms calyx and corolla. In the two first orders Linnæan botanists use the term calyx for what in the third and fourth is called corolla, and in the fifth and sixth again calyx. The analogy of one class, if truly natural, ought certainly to prescribe the use of the same term throughout, for the same part; but a question will but too frequently arise how far any class is really natural, or out of the reach of all exception; for, in every system, the leading sections, or classes, must be regulated by technical characters.

The order of *Lauri* is thus characterized:

Calyx divided into six parts, permanent. Stamens six, inserted into the lower part of each segment, or double that

number, six of them being interior; anthers combined with the filament, opening from the base upwards. Germen superior; style one; stigma simple or divided. Drupa or berry of one cell, containing a nut with one seed. Embryo destitute of albumen. Stem arboreous or shrubby. Leaves alternate, rarely opposite.

The genera are *Laurus*, *Porosfena*, Schreb. and *Douglasia*, Schreb. to which Mr. Brown has added *Endiandra*, *Cryptocarya*, *Tetranthera*, and the Linnæan genus *Cassipoua*.—Genera subjoined by Jussieu as allied to the *Lauri* are *Myristica*, *Virola* of Aublet, which Schreber properly reduces to *Myrsipica*, and *Hernandia*; to which list Mr. Brown adds *Cyrocarpus*; see that article. The excellent author last mentioned, accustomed, as has been said of Jortin and Goldsmith, to enrich every subject which he touches, has made the curious discovery of the cotyledons of the *Lauri* being peltate near their base. He has also remarked a strange inadvertence of Gærtner, who takes the cotyledons of *Cassipoua* for albumen, and the plumula for cotyledons. These parts, being rightly understood, admirably prove the true affinity of the genus, notwithstanding its parasitical and leafless habit.

**LAURI**, in *Geography*, a town of Naples, in Lavora; two miles S.W. of Sezza.

**LAURIA**, a town of Naples, in Basilicata; 17 miles E. of Policastro.

**LAURICAUCHA**, a mountain of Peru, abounding in silver ore; six miles N. of Paico.—Alfo, a lake of Peru; 80 miles N. of Lima.

**LAURIERE**, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Bellac; 18 miles E. of Bellac. The place contains 1407, and the canton 6502 inhabitants, on a territory of 145 kilometers, in seven communes.

**LAURINGEN**, a town of the duchy of Wurzburg, on the Laur; 30 miles N.E. of Wurzburg. N. lat. 50° 13'. E. long. 10° 32'.

**LAURISTO**, a town of Naples, in Principato Citra; 9 miles W.N.W. of Policastro.

**LAURINUM**. See **DAPHNELEON**.

**LAURISTAN**, in *Geography*, a town of Persia, in the province of Irak, on the Zenderoud; 90 miles W. of Ispahan.

**LAURO**, a town of Portugal, on a river of the same name, in the province of Alentejo; 27 miles W.N.W. of Evora.

**LAUROCERASUS**, in *Botany*, the Cherry-laurel, so called, from the laurel-like appearance of its leaves, as well as from the fruit; which is truly a cherry, and, though not wholesome, eatable, notwithstanding the very dangerous qualities of the rest of the plant. See **PRUNUS** and **LAUREL**.

**LAUROTAXA**, a name used by Columna, and some other authors, for the narrow-leaved kind of *rufus*, or butcher's broom, called by others *biflora*.

**LAUROW**, in *Geography*, a town of Hindoostan, in Bahar; 10 miles S.S.W. of Gayah.

**LAURUS**, in *Botany*, the ancient Latin name of the Bay-tree, for which it is retained by modern botanists, and along with which it now comprehends a great number of species, constituting one of the noblest genera in the whole vegetable kingdom. The origin of the word is lost in the obscurity of antiquity; and whether etymologists derive it from *lavo*, to wash, or from *laus*, praise or honour, they give us little more satisfaction in one case than the other.—Linn. Gen. 200. Schreb. 270. Willd. Sp. Pl. v. 2. 477. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 427. Sm. Prodr. Fl. Græc. Sibth. v. 1. 268. Juss. So. Journ. t. 367.

t. 367. Lamarec. Illustr. t. 321. Gærtn. t. 92.—(Borbonia; Plum. Gen. 3. t. 2. Perica; *ibid.* 44. t. 20.) Class and order, *Eucaendria Monogynia*. Nat. Ord. *Holeraceae*, Linn. *Lauri*, Jussl.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* in six deep, ovate, pointed, concave, erect, alternately external segments. Nectary consisting of three pointed coloured tubercles, each terminating in two bristles, surrounding the germen. *Stam.* Filaments nine, shorter than the corolla, compressed, obtuse, three in each row; anthers attached to the edges of each filament, in the upper part, at each side. There are two globular glands, on a very short stalk, attached to every filament of the innermost row, near its base. *Pist.* Germen superior, nearly ovate; style simple, of equal thickness throughout, the length of the filaments; stigma obtuse, oblique. *Peric.* Drupa oval, pointed, of one cell, contained within the corolla. *Seed.* Nut ovate, pointed, with a kernel of the same shape.

Obs. Most of the species, including the Cinnamon and Camphor have united, or hermaphrodite, flowers; several are dioecious, as *L. nobilis*, the Sweet Bay, which has mostly from 8 to 14 filaments, and a deeply four-cleft corolla. The glandular bodies attached to some of the filaments, afford a discriminating character.

Ess. Ch. Calyx none. Corolla calyx-like, in six deep segments. Nectary of three glands, bearing two bristles, and surrounding the germen. Innermost filaments bearing glands. Drupa with one seed.

Linnaeus's 14th edition of *Syst. Veg.* has 16 species, Willdenow has 34, the increase being chiefly from the works of Swartz and Thunberg. Several still non-descript are in the hands of most collectors of tropical plants. The genus is extremely interesting on account of several fine and valuable aromatic species, as the Cinnamon, Cassia, Camphor, Sassafras, &c. The habit of the whole is arborecent. *Leaves* stalked, almost without exception alternate, undivided, entire, smooth and evergreen, more or less ovate or elliptical. *Flowers* mostly panicle, small, pale or greenish, not ornamental, but very curious in structure. *Fruit* large in proportion to the blossom. Mr. Brown expresses an intention of separating *Cinnamomum*, as a distinct genus from *Laurus*, as indeed it originally stood, till Linnaeus united them. It is extremely probable that other species require more accurate generic investigation than they have hitherto received, in which predicament we suspect is the *Sassafras* of North America, a tree with deciduous and partly lobed leaves. There appears also to be an oriental Sassafras wood, of a much more permanent though similar flavour to the American, of which we formerly procured a specimen at Venice, but of the tree that produces it we know nothing.

The following may suffice for examples of *Laurus* as the genus at present stands.

*L. Cinnamomum*. Cinnamon-tree. Linn. Sp. Pl. 528. (*Cinnamomum foliis latis ovatis frugiferum*; Burm. Zeyl. 62. t. 27. Cassia cinnamomea, five Cinnamomum; Herm. Lugduno-Bot.; 129. t. 655, 656.)—Leaves triply-ribbed near the base, ovate; lateral ribs vanishing near the top. Panicles repeatedly compound. Native of Ceylon, where, as well as in Amboyna, its importance as an object of cultivation, for the sake of its precious bark, is universally known. (See CINNAMON.) Concerning the botanical determination of the present species, there has always been some doubt, Linnaeus having defined it *foliis trinerviis*, that is, with three ribs distinct at the base, which is only so far true, that they are united to the mid-rib at a much less distance above the base, which is rounded, than those of *L. Cassia*. It seems moreover that this Cinnamon, like other cultivated plants,

is liable to many varieties, not only in quality, but in external configuration, and it may very possibly have originated from the *Cassia*, like apples from the wild crab. For a long while the true Cinnamon was scarcely to be seen in the herbulariums of Europe, but we have a specimen from Amboyna, by favour of the late Mr. Christopher Smith, in which the *panicles* are copious, longer than the *leaves*, repeatedly subdivided, and somewhat umbellate. The *flowers* are silky externally, and rather small. Linnaeus says they are dioecious. Another specimen, from the garden at the Mauritius, has narrower *leaves*, and much smaller panicles. The true Cinnamon is now not rare in the stores of curious collectors. The bishop of Winchester, many years since, raised it from seeds ripened in his own garden.

*L. Cassia*. Cassia-bark-tree. Linn. Sp. Pl. 528. (Carua; Rheede Hort. Mal. v. 1. 107. t. 57.)—Leaves triply-ribbed far above the elongated base, elliptic-lanceolate; lateral ribs vanishing beyond the middle. Panicles corymbose.—Native of Malabar, Sumatra, Java, &c. The narrower *leaves*, tapering at each end, and the very different qualities of the bark, which is more mucilaginous and far less gratefully aromatic, distinguish this from the preceding, whether it be a species, or only a variety. Rheede says, the bark of the *root* yields camphor.

*L. Camphora*. Japanese Camphor-tree. Linn. Sp. Pl. 528. Jacq. Coll. v. 4. 221. t. 3. f. 2. Kämpf. Amoen. 770. t. 771. (Arbor camphorifera japonica; Commel. Hort. Amit. v. 1. 185. t. 95.)—Leaves elliptical, pointed, triply-ribbed far above the elongated base. Clusters axillary, somewhat compound, shorter than the leaves. Native of Japan, often to be seen flowering in the English robes. The curious structure of the *blossoms* may be seen in Jacquin. The Japanese camphor is believed to be obtained by distillation from this tree, that of Borneo and Sumatra being the produce of one of a different species, if not genus, of whose botanical characters little is known. This latter is erroneously called *Laurus Camphora* in our article CAMPHOR, to which we refer the reader.

*L. nobilis*. Common Bay-tree. Linn. Sp. Pl. 529. (Laurus; Camer. Epit. 60. Ger. em. 1407.)—Leaves lanceolate, veiny, finely reticulated, evergreen. Flowers four-cleft, dioecious, in short axillary clusters. Native of Italy and Greece, almost perfectly hardy in our climate, being one of the most desirable evergreens we have, though of slow growth. The *leaves* are of a rich deep green, highly and pleasantly aromatic. *Flowers* born by old trees only, pale yellow. *Fruit* black, the size of an unripe olive, strongly aromatic, never, as far as we know, perfected in England, but plentiful in Italy. This is certainly the *δαφνη* of Dioscorides, and consequently the classical laurel. It is still called by the same name among the modern Greeks. There is a broad-leaved variety, called *δαφνη πλαυιτιχη* in Dioscorides.

*L. aestivalis*, *Benzoin* and *Sassafras*, three North American species, have deciduous leaves. The true Benjamin tree, or Gum Benzoin (see those articles) is not, as Ray supposed, this *Laurus Benzoin*, but a species of *Styrax*, as was first shown by the late Mr. Dryander in the Philosophical Transactions for 1787, p. 307. t. 12. See STYRAX.

L A U R U S, in Gardening, comprises plants of the evergreen and deciduous tree kinds, for borders, green-houses, and sloop, of which the species cultivated are the common sweet bay (*L. nobilis*); the willow-leaved bay (*L. ætivalis*); the common Benjamin-tree (*L. benzoin*); the sassafras-tree (*L. salifras*); the royal bay, or Indian laurel (*L. indica*); the broad-leaved Carolina bay, or red bay (*L. borbonica*); the camphor, or camphire-tree (*L. camphora*);

phora); the cinnamon-tree (*L. cinnamomum*); the cassia, or wild cinnamon-tree (*L. cassia*); and the alligator pear (*L. persea*).

The first sort has several varieties, as the broad-leaved, which is almost too tender for the open air in this climate, with leaves much broader and smoother than those of the common sort: the common, which is seldom hurt in this climate, except in very severe winters, of which there are two subvarieties, one with plain leaves, the other with leaves waved on the edges: the narrow-leaved, with very long narrow leaves, not so thick as those of the preceding two sorts, and of a light green, the branches covered with a purplish bark, and the male flowers come out in small clusters from the axils of the leaves, fitting close to the branches; of which there are subvarieties in the nurseries with variegated leaves. What is now called bay, was formerly called laurel, which has introduced some confusion.

It may be noticed, that the chief of the camphor used in Europe is prepared from this tree in Japan, by splitting the wood into small pieces, and subliming or distilling it with water in an iron retort, covered with an earthen or wooden head, in the hollow of which they fasten hay or straw, to which the camphor, as it rises, adheres. This camphor is brownish or white, but in very small semi-pellucid grains. It is packed up in wooden casks, and thus sent to India and Europe, where it is purified by a second sublimation, and reduced into the solid mass as found in the shops. Native camphor, or the Capoor Baroos of the Malays, is a production obtained in Sumatra and Borneo, by cutting down the trees, and splitting them with wedges into small pieces, the camphor being found in the interstices in the flate of a concrete crystallization. Some have asserted that it is from the old trees alone that this substance is procured, and that in the young trees, if it is in a fluid state, it is called Meenio Capoor, or camphor oil; but this is a mistake: the same sort of tree that produces the fluid does not produce the dry, transparent, flaky substance, nor ever would. They are readily distinguished by the natives. Many of the trees, however, produce neither the one nor the other. The traders usually distinguish three degrees of quality, by the names of head, belly, and foot, according to its purity and whiteness. Some add a fourth sort, of extraordinary fineness, of which a few pounds only are imported to Canton, and sell there at the rate of two thousand dollars the pekul.

The common camphor will evaporate till it wholly disappears; while that of Sumatra and Borneo, called native camphor, though subject to some decrease, does not appear to lose much in quantity from being kept.

Camphor oil is obtained by the Sumatrans by making a transverse incision into the tree, to the depth of some inches, and then cutting slopingly downwards from above the notch, till a flat horizontal surface be left. This they hollow out, till it is of a capacity to receive a quart: then put into the hollow a bit of lighted reed, and let it remain for about ten minutes, which acting as a stimulus, draws the fluid to that part. In the space of a night the liquor fills the receptacle previously made. The trees are soon exhausted.

The eighth sort has several varieties; but it is the Ceylon cinnamon that is chiefly used as a spice.

*Method of Culture.*—The first sort may be increased by feed, layers, and suckers. The feed should be sown soon after the berries are ripe, or early in the spring, either in beds, covering them with earth near an inch deep, or in drills half a foot asunder, the same depth. When the plants are come up, they should be supplied with frequent waterings during the summer, and in winter defended from severe frost by the

shelter of mats, or some other covering, being tender while young; and after having two summers' growth in the feed-bed, in the spring following the strongest should be removed into nursery rows, one or two feet asunder, and a foot apart in each row, giving water in dry weather, till they have taken good root, and keeping them clear from weeds. When they are half a yard, or two or three feet high, they are of proper growth for transplanting into the shrubbery in autumn or spring. The berries may also be sown in pots, and plunged into a hot-bed in spring, which brings the plants forwarder, being careful to inure them to the full air in the summer season.

In the layer, some of the lower branches that are well furnished with young shoots, may be laid down in the early spring, or in August, but the latter is the best season; each shoot being slit-layed; they become rooted in one year, when in spring following they may be taken off, and planted in the nursery, in the manner directed for the seedlings.

Where suckers are had recourse to, they should be taken up with good roots in autumn or spring, and be planted in the nursery like the seedlings and layers.

This sort is also capable of growing by cuttings, planted in the beginning of April on a moderate hot-bed of tanners' bark covered eight inches deep with rich loose fresh earth, five inches deep, and eight or nine asunder, rubbing off their leaves, and watering them gently every evening while the bed continues warm, covering the glasses with mats during the heat of the day. When the cuttings have shot roots, they should receive all mild gentle showers, and the evening dews. In the beginning of August, the glasses may be taken off, being replaced when the weather begins to be frosty; keeping them open every mild day. In the beginning of the April following, or as soon as the weather becomes temperate, both glasses and frames should be removed, continuing frequent and plentiful waterings during the summer months, as the weather may require; and in the succeeding April the plants will be strong, well rooted, and fit for planting out.

At the period when the plants raised in these ways are removed to the nursery, they should have their superfluous roots and branches cut away, encouraging the leading shoots; planting them in a well sheltered quarter of light mould. The ground should be dug over in autumn and spring, keeping it clean, loose, and mellow in summer, and the plants be annually pruned in April.

The gold-striped variety is tender, being commonly kept in pots, and housed with hardy green-house plants. When it stands in the open ground, it is sometimes much injured in severe winters. The method of increasing it is by budding it on the plain foot.

And the broad-leaved and narrow-leaved varieties are not so hardy as the common sort, being scarcely able to live abroad whilst young, in common winters, without shelter. As in severe winters the old trees are frequently killed, or at least the branches much injured, the plants are frequently kept in tubs, and housed in the winter season.

The second, third, and fourth sorts may be increased by feed, by layers, and sometimes by suckers and cuttings. The feeds or berries procured from America, and preserved in sand, should be sown, as soon after they arrive as possible, in a bed of light earth an inch deep, or in largish pots the same depth, plunging them in mould, in an eastern border, up to their rims, till the spring following; when they should be placed in a hot-bed, which greatly forwards the germination of the feed, and soon brings up the plants. They must be timely inured to the full air. The plants raised by either method should, while young, be watered during summer,

and sheltered from the frost in winter, and when two years old be planted out in nursery rows, as directed for the other plants. They may also be increased by layers and suckers in the same manner as directed for the fir-tree; but it is sometimes long before the layers are rooted.

They are likewise sometimes capable of being increased by cuttings, by the aid of a good hot-bed.

And the fifth, sixth, and seventh forts may be increased by layers, but they are sometimes two years before they are sufficiently rooted. They may also be raised from seeds, procured from the places of their natural growth, sowing them in pots, and plunging them in a hot or bark-bed; but without this aid they do not always grow freely the first season; in which case they should be placed in the open air in summer, and in a frame, or in the green-house, near the windows, in winter; and in spring the pots be plunged in a hot-bed, which will bring up the plants, giving air daily, and frequent waterings, and injuring them by degrees to the open air as the summer advances; placing them in shelter in winter, and in the following spring planting them out in separate small pots, managing them as other green-house shrubs.

The eighth, ninth, and tenth forts are also raised by layers and seed, sown and managed as above, generally assisted by the bark-bed of the stove; the plants being planted off into separate pots, and managed afterwards as other hot-house plants.

It may be noticed that the first, second, third, and fourth forts are highly ornamental in the borders and clumps of pleasure grounds; the three following in green-house collections; and the three last among other stove plants.

**LAURUSTINE**, a name often given to a fine evergreen flowering shrub. See *VIBURNUM TINUS*.

**LAUS**, in *Ancient Geography*, a town of Italy, in the territory of the Laconians; founded by the Sybarites, but afterwards taken possession of by the Lycaonians, a colony of the Samites.

**LAUS POMPEIA**, a town of Gallia Transpadana towards the S.E.; founded by the Boii, and afterwards belonging to the Infubrians. It was a Roman colony and municipal.

**LAUS KAUREN**, in *Geography*, a peninsula of Finmark, in the Frozen sea. N. lat.  $70^{\circ} 45'$ . E. long.  $30^{\circ} 24'$ .

**LAUSANNE**, a city of Switzerland, in the canton of Berne, and the largest town in the Pays de Vaud, and by the French division of 1798 the capital of the department and canton of Leman, is beautifully situated on the declivities of three hills, and in the intermediate vallies, environed by an old wall, and distant two miles from the lake of Geneva, and 37 miles N.E. from Geneva itself. The district to which it gives name was once a republic itself, but afterwards annexed to the canton of Berne, and is a considerable tract, lying below the border of Vevey and Venoge, about 13 miles in length and five in breadth. The ascent upon which the town is built is so steep, that in some places the horses cannot, without great difficulty, draw up a carriage, and foot passengers ascend to the upper part of the town by steps. These inconveniences, however, are amply compensated by the sublimest views in nature, commanding the lake of Geneva, the Pays de Vaud, and the rugged coast of Chablais.

The church is a magnificent Gothic building, having been formerly a cathedral, while the Pays de Vaud was subject to the house of Savoy. It stands on the most elevated part of the town; and contains, among many other sepulchres, the tomb of Amadeus VIII. duke of Savoy, styled the Solomon of his age, but more known by the name of the anti-pope Felix V., who exhibited a singular instance in the annals of Europe of a personage twice abdicating the pomp of

sovereignty, and twice retiring to a private station. The number of inhabitants, according to Coxe, is about 7000; Pinkerton states them at 9000. In the year 1536, when part of the Pays de Vaud was conquered from the house of Savoy, the bishop of Lausanne retired from the town, and the inhabitants put themselves under the direction and sovereignty of the canton of Berne, which granted to it new privileges, in addition to those which it had formerly possessed. The reformation was introduced by Pierre du Viret in the same year. The bishop's diocese formerly comprehended the greater part of the cantons of Berne, Soleure, and Friburg, the Pays de Vaud, the principality of Neuchâtel, Bienna and its territory, and the country of Erguel, and extended almost to Franche Comté. Since the reformation, it has been reduced to little more than the canton of Friburg and a part of that of Soleure. Lausanne chooses its own magistracy, which consists of a burgomaster, five bannerets, the town council, the council of sixteen, and the great council. An academy was established here in 1537, and a college in 1540. Professors in every science are appointed by government, and there is a tolerable library for the use of the public. The bailiwick of Lausanne is extensive; the bailiff, who is chosen every six years, succeeded to the bishop, and has equal jurisdiction. The air of Lausanne is very pure and healthy; and it has plenty of excellent water, with every necessary of life in the greatest abundance. Lausanne is not only governed by its own magistrates, and has its own courts of justice; but the burghers, who possess houses in the principal street, enjoy the right of pronouncing sentence in criminal causes. The criminal is tried by the civil power; if he is found, and acknowledges himself guilty, one of the magistrates pleads in defence of the prisoner, and another against him; the court of justice gives an opinion upon the point of law, and the majority of the burghers above-mentioned determine the penalty. If the punishment is capital, there is, according to the letter of the law, no pardon, unless obtained within twenty-four hours from the sovereign council of Berne, although it generally happens that eight days are granted for that purpose. When the criminal is seized within the jurisdiction of the town, the fact is tried, and the burghers pronounce sentence in the town-hall; in this case there is no appeal. But when he is taken within the district of the bailiff, they assemble in his house, and an appeal lies from their determination to Berne. Lausanne is 41 miles S.W. of Berne. N. lat.  $46^{\circ} 33'$ . E. long.  $6^{\circ} 28'$ . Coxe's Travels in Switzerland, vol. ii.

**LAUSSIG**, a town of Saxony, in the circle of Leipzig; 14 miles S.E. of Leipzig. N. lat.  $51^{\circ} 7'$ . E. long.  $12^{\circ} 36'$ .

**LAUSSNITZ**, a town of Saxony, in the margravate of Meissen; 13 miles N. of Dresden.

**LAUSZA**, a town of Samogitia; 44 miles N.W. of Miedniki.

**LAUT**. See *PULO LAUT*.

**LAUTAKARI**, a small island in the N. part of the gulf of Bothnia. N. lat.  $65^{\circ} 35'$ . E. long.  $24^{\circ} 34'$ .

**LAUTENBURG**, a town of Prussia, in the territory of Culm; 48 miles E. of Culm.

**LAUTER**, a town of Germany, in the county of Henneberg; 11 miles N.E. of Meiningen.

**LAUTERBACH**, a town of Bohemia, in the circle of Saatz; 65 miles W. of Prague. N. lat.  $50^{\circ} 2'$ . E. long.  $12^{\circ} 45'$ .—Also, a town of Upper Hesse; 13 miles N.W. of Fulda.

—Also, a town of Saxony, in the circle of Erzgebirg; five miles N.W. of Zwickau.

**LAUTERBERG**, a town of Westphalia, in the Hartz

Hartz forest, near which are mines and forges of copper and iron; 14 miles S. of Gosslar.

LAUTERBOURG, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Wissembourg, situated on the Lauter. The place contains 1941, and the canton 9782 inhabitants, on a territory of 180 kilometres, in 10 communes; 29 miles N.N.E. of Straßburg. N. lat. 49°. E. long. 8° 14'.

LAUTERBRUENNEN, a valley of Switzerland, in the canton of Berne; six miles S. of Interlachen, and about 15 miles in circuit, embosomed in the midst of the Alps, and celebrated for its picturesque and romantic scenery. The western boundary, from which the Staubbach falls, forming a cataract, would, in any other country, be called an enormous mountain; it here appears only a trifling hill, in comparison with the opposite chain, of which the highest point is the beautiful Jungfrau-horn, that stretches in a semi-circular direction, and, towering above the adjacent peaks, rises to a stupendous height. At the extremity of the vale, there are some noble points of view, and glaciers which stretch from the foot of the Breithorn and Gros-horn. In this delightful valley, many streams of the clearest water gush from the earth like small rivers, and numberless torrents precipitate themselves from the mountain. From this circumstance the valley derives its name; *Lauterbrunnen* signifying, in German, *many springs*. One of the peaks, adjoining to this valley, which is called the Gros-horn, is of a pyramidal shape, and capped with frozen snow; another, the Breithorn, is conical, and seems crowned with an enormous mass of transparent ice, from which the reflection of the sun-beams is inexpressibly beautiful. But the most elevated and the most majestic of the whole group, is the Jungfrau-horn. (See JUNGFAU.) The hollows between the mountains are filled with large valleys of ice, broken into various shapes, and several torrents, bursting from the snow, and uniting in their course, form the Weits-Lutchine, a river which rolls rapidly through the valley of Lauterbrunnen, joins the Schwartz-Lutchine, which flows from Grindewald, and swells the Aar. This valley is bordered by calcareous rocks to its furthest extremity. Wengenalp is the last of a group of calcareous and schistous mountains between Lauterbrunnen and Grindewald, which there joins the Jungfrau, the summits of which appear to be of granite. Cox's Travels, vols. i. and ii.

LAUTERKEN, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the district of Kaiserslautern; 24 miles N. of Deux Ponts. The place contains 627, and the canton 4594, inhabitants, in 21 communes. N. lat. 49° 39'. E. long. 7° 35'.

LAUTERHOFEN, a town of Bavaria; 12 miles S.W. of Sulzbach.

LAUTERN, a town of Prussia, in the province of Ermeland; 14 miles S.S.E. of Heilsberg.

LAUTERSHAUSEN, a town of Germany, in the principality of Anspach, on the Altmuhl; eight miles W. of Anspach.

LAUTERSTEIN, a town of Saxony, in the circle of Erzgebirg; 17 miles S.S.W. of Freyberg.

LAUTREC, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Castres; 12 miles N.N.W. of Castres. The place contains 3238, and the canton 7548 inhabitants, on a territory of 147½ kilometres, in 12 communes.

LAUTTE, a town of Prussia, in Oberland; 16 miles E.S.E. of Marienwärdner.

LAUVNS, a town of France, in the department of the Lower Pyrenæes; 15 miles S.E. of Oleron.

LAUZERTE, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 17 miles N.W. of Montauban. The place contains 3608, and the canton 12,176 inhabitants, on a territory of 232½ kilometres, in 16 communes. N. lat. 44° 15'. E. long. 1° 13'.

LAUZES, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors. The place contains 444, and the canton 7139 inhabitants, on a territory of 237½ kilometres, in 11 communes.

LAUZET, LE, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Barcelonnette; 10 miles W. of Barcelonnette. The place contains 857, and the canton 5038 inhabitants, on a territory of 295 kilometres, in seven communes.

LAUZUN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande; 14 miles N.E. of Marmande. The place contains 1809, and the canton 12,852 inhabitants, on a territory of 220 kilometres, in 17 communes. N. lat. 44° 38'. E. long. 0° 32'.

LAW, EDMUND, in *Biography*, a learned English prelate, the son of a clergyman, in the neighbourhood of Cartmel, in Lancashire, was born in the year 1701. He received the greater part of his classical learning at the free grammar school of Kendal, from which place he was sent to St. John's college, Cambridge. He was admitted to the degree of B. A. in 1723, and soon afterwards was elected fellow of Christ's college. During his residence in this college, he became known to the public by a translation of archbishop King's "Essay upon the Origin of Evil," with notes. To this work was prefixed "A preliminary dissertation," by the Rev. Mr. Gay of Sidney college. In the controversy which took place in consequence of Dr. Clarke's "Demonstration of the Being and Attributes of God," Mr. Law took a part, and among other things published his "Enquiry into the Ideas of Space, Time, &c." In the year 1735, a new and improved edition of Robert Stephens' "Thesaurus Linguae Latinae" was given to the public, and in the preparation of this valuable work, Mr. Law had a considerable share. In 1737, he was presented by the university to the living of Graystock, in the county of Cumberland, worth about 300*l.* per annum. In 1743, he was promoted by sir George Flemming, bishop of Carlisle, to the archdeaconry of that diocese, and, in 1746, went from Graystock to reside at Salkeld, a pleasant village upon the banks of the river Eden, the rectory of which is annexed to the archdeaconry. During his residence at this place, he published his "Considerations on the Theory of Religion;" to which he subjoined "Reflections on the Life and Character of Christ;" and an appendix concerning the use of the words "Soul and Spirit." In 1749, Mr. Law proceeded doctor of divinity; in his public exercise for which degree, he defended the doctrine of what is usually denominated "The sleep of the soul." In 1754, he was elected master of Peter-house, in Cambridge, and in the following year appointed head librarian of the university; a sinecure place, with a salary of fifty pounds a-year. He received almost every year some additional preferments, which were rather honourable expressions of regard from his friends, than of much advantage to himself: in 1767, he obtained a stall in the church of Durham, and in 1769, on the recommendation of the duke of Grafton, he was nominated bishop of Carlisle, and was permitted to hold, in connection with the bishopric, the mastership of Peter-house, and the rectory of Graystock. In 1774, he published a very valuable treatise, entitled "Considerations on the Theory of Religion,"

Religion," which has passed through at least eight editions. The object of this work was to shew that arts and sciences, natural and revealed religion, have upon the whole been progressive, from the creation of the world to the present time; as also that they have been suited to each other, as well as to the circumstances of mankind, during each eminent period of this their progression. In 1777, Dr. Law gave the public a handsome edition, in four vols. 4to. of the works of Mr. Locke, with a life of the author, and a preface. In the edition of the "Considerations," published at Carlisle in 1784, he made such alterations as shewed that he had given up the doctrine of the pre-existence of Christ, a fact which he noticed to a friend in pretty strong language. Dr. Law died in August 1787, in the 84th year of his age. The life of Dr. Law was a life of incessant reading and thought, almost entirely devoted to metaphysical and religious enquiries. The leading peculiarity of his religious sentiments is, that "Jesus Christ will, at his second coming, by an act of his power, restore to life and consciousness the dead of the human species, who, by their own nature, and without his interposition, would remain in the state of insensibility, to which the death, brought on mankind by the sin of Adam, had reduced them." Dr. Law published, besides the articles already mentioned, some single sermons; a tract on "The Nature and Necessity of Catechising;" "A Defence of Mr. Locke's Opinion concerning personal Identity;" and "Observations occasioned by the Contest about literary Property." See life prefixed to an edition of his Reflections printed by Johnson in 1803.

LAW, JOHN, a famous projector, the son of a goldsmith in Edinburgh, was born about the year 1681. It appears that he was not brought up to any profession, but having a turn for calculation, he made himself a proficient in numbers, and in the speculations depending upon them. He obtained, while very young, the confidence of the king's ministers for Scotland, and was employed by them to arrange the revenue accounts, which were at that time in great disorder. To remedy the want of a circulating medium he proposed the establishment of a bank, which, according to his plan, might issue paper-money to the amount of the value of all the lands in the kingdom. This was not adopted. At the death of his father he succeeded to a small estate, and commenced the fine gentleman, supplying the deficiency of his income by gaming. In consequence of a duel, in which he killed his antagonist, he was obliged to leave the country. He visited Venice and Genoa, from which cities he was banished as a sharper; he wandered through Italy, supporting himself by his wits, chiefly by the success of singular wagers, in which, by his skill in calculation, he always took care that the chances should be in his favour. He proposed his financial scheme to Louis XIV. who listened to his plans. A bank was established, composed of 1200 shares of 3000 livres each; to this was annexed a Mississippi company, who had grants of land in Louisiana, and was expected to realize an immense sum by planting and commerce. To this were afterwards joined the trade of Senegal, and the privilege of the old East India company. In 1718, it was declared a royal bank; and by a number of advantages arbitrarily conferred upon it, such were the extent of its business, and the magnitude of its funds, that its shares rose to twenty times their original value. All France was seized with the rage of gambling in the funds. Money and valuables of all kinds were brought to the market and invested in bank paper, and those thought themselves truly happy who could strip themselves of every thing for a participation in this imaginary wealth. In 1720, Law was made comptroller-general of the finances. Regarded as the Plutus of the kingdom, he saw

at his levee dukes, peers, and marshals of France. At length the baseless fabric of this prosperity began to give way: the shares sunk daily in value, and the ruin of the system seemed to be inevitable. He was obliged to resign his post, after holding it only five months; and loaded with the public execrations, retired first to an estate in the country, and then, for further safety, quitted the kingdom. He now passed the remainder of his days in obscurity, occupied, however, with his projects, fully convinced of the solidity of his system, the failure of which he attributed to the opposition it met with. He died at Venice in 1729.

LAW, WILLIAM, a learned and pious divine of the church of England, was born at King's-Cliffe, Northamptonshire, in 1686, and educated at Oxford, where he took his degrees. He entered into holy orders, but it does not appear that he ever had the cure of souls, owing probably to his adherence to non-juring principles, which he maintained to the close of his life. He was some time a private tutor in a gentleman's family at Putney, after which he chiefly resided in a very retired way at the house of Mrs. Hester Gibbon, aunt of the celebrated historian, in Northamptonshire, where he died in 1761. He was author of a great many theological publications, of which the most important is "The serious Call to a devout and holy Life, adapted to the State and Condition of all Orders of Christians." His "Practical Treatise on Christian Perfection" was likewise very much esteemed. He entered the lists against bishop Hoadley; and was a zealous disciple of the doctrines of Jacob Behmen, whose works he published.

LAW, in its most general and comprehensive sense, signifies a rule of action; and is applied indiscriminately to all kinds of action; whether animate or inanimate, rational or irrational; in which sense it is used when we say, the laws of motion, of gravitation, of optics, or mechanics, as well as the laws of nature and of nations. Accordingly law is a command or precept, constituting a rule of action, and coming from some superior authority, which an inferior is obliged to obey; or, according to some, law is a command, or mandate of some person, or power, whose precept carries with it the reason of obedience: or, it is a rule of action, that obliges by virtue of its being the will of a superior. See OBLIGATION.

The word is formed from the Saxon *lab, laga*, which signifies the same.

Thus, the commands of God with respect to men, of a city with respect to the citizens, and universally of all powerful beings in respect to those who cannot resist, are called their laws.

The nature of a law will be most clearly discovered by shewing wherein it differs from *covenant, counsel, and right or equity*; with all which it is frequently confounded.

Law is confounded with covenant, or compact, by those who take laws to be nothing else but *συνδοχαιματα*, or forms of living determined by the consent of mankind; among whom is Aristotle, who defines a law, "a declaration determined by the common consent of a city, shewing in what manner things are to be done:" which is not so much the definition of a law, as of a *civil law*; nor yet properly of a civil law; for this common consent is no more than a mutual covenant, which does not oblige any person, and consequently is not any law, till some supreme power be constituted with a power to compel, and to make it penal to transgress it. Here then the covenant is confounded with the law, which leads into absurdities; for a covenant or compact is a promise proceeding from us; a law, a command directed to us.

The difference between a counsel and a law is this :

A counsel is a precept, wherein the reason of obedience is taken from the thing itself prescribed; a command is a precept, wherein the reason of obedience depends on the will of the prescriber; for we cannot properly say, *ſic volo, ſic jubeo*, unleſs *ſit pro ratione voluntas*. A law comes from a perſon who has a power over thoſe whom he commands; a counſel, from him who has no ſuch power. To do what is enjoined by a law, is an act of duty; what by a counſel, an act of choice, or freewill. Counſel is only matter of perſuaſion, law is matter of injunction; counſel acts only upon the willing, law upon the unwilling alſo.

Law is confounded with right or equity, by thoſe who perſiſt in doing what is permitted by the *divine* law, though prohibited by the laws of the country. What is prohibited by the *divine* law, cannot be permitted by the *civil* law; nor what is commanded by the *divine* law, be prohibited by the *civil* law; but what is permitted by the *divine* law, may, notwithstanding, be prohibited by the *civil* law: for the inferior laws have a power of reſtraining the liberty left by the ſuperior laws, though they cannot enlarge it. Now right or equity is a natural liberty, not conſtituted by laws, but free of them; for take away laws and liberty is complete.

This liberty is firſt reſtrained by the *natural* and the *divine* law, the reſt reſtrained by the *civil* laws; and what remains unreſtrained by the *civil* law, may be again reſtrained by the conſtitution of particular cities and ſocieties. There is a great difference, therefore, between law and right, *lex & jus*; for law is a chain; but right a liberty; and they differ as two contraries. See *Civil or Municipal LAW, infra*.

Law may be divided, with reſpect to its different original, into *divine* and *human*.

Law, *Divine*, may be conſidered as twofold, with reſpect to the two different manners in which God notifies or announces his will to man; *viz. natural (or moral), and poſitive*.

Law, *Natural*, is that which he has made known to all mankind, by an innate light, called *natural reaſon*.

*Natural* law may be divided into that natural law of men, which, in a peculiar ſenſe, is called the *LAW of nature*; and the natural law of countries, commonly called the *LAW of nations*. (See each of theſe articles.) The precepts are the ſame in both theſe; but becauſe, when ſocieties are once inſtituted, certain perſonal properties become veſted in men; that law, which, when we ſpeak of the duties of men ſeverally, we call the *natural law*, when transferred to cities or countries, we call the *law of nations*.

M. Regis ſays, that the laws of nature are the dictates of right reaſon, which teach every man how he is to uſe his natural right; and the laws of nations, the dictates, in like manner, of right reaſon, which teach every ſtate how to act and behave themſelves toward others.

Law, *Poſitive*, is that which God has revealed by his prophets, or by perſons ſupernaturally commiſſioned and inſpired and found only in the holy ſcriptures: ſuch are thoſe laws delivered to the Jews, relating to the divine worſhip and polity, which may be called *divine civil* laws, as being peculiarly directed to that people. As the matter of *natural* laws is ſomething in its own nature good and neceſſary, theſe laws are founded in the immutable natures and relations of things, carry with them their own recommendation, and if it were not for the depravity of mankind, would not need a ſupernatural light for the diſcovery of their reaſonableneſs and obligation. Whereas poſitive laws differ from the former, both with regard to the *matter* of them, as well as the *manner* of their publication. Theſe may be diſtinguiſhed into ſuch as are *purely* poſitive, or *partly* ſo. The matter of

*purely* poſitive laws is indifferent; ſo that the poſitive decree of the legiſlator alone makes them to be laws, mere reaſon being then ſilent. Such were the ceremonial laws of the Jews, and ſuch are the ſacraments of the Chriſtian religion. Nevertheless, every poſitive law is founded in reaſon, though reaſon may not be able, antecedently to their promulgation, to diſcover their fitneſs and utility. But the reaſons that recommend them, when they are actually promulgated, would not give them the authority and ſanction of a law, without the expreſs intention of the ſupreme lawgiver. Laws that are *partly* poſitive may be reſolved into the law of nature, or the moral law as revived, improved, and enforced by revelation. Several particulars of this law derive a greater degree of evidence from this new mode of promulgation, and alſo a ſtronger enforcement. The law concerning the ſabbath is in a peculiar ſenſe a law of this kind, the matter of it being of a mixed nature. That ſome part of our time ſhould be conſecrated to the worſhip of our creator, the light of nature dictates; but that it ſhould be a ſeventh part rather than any other, or the laſt ſeventh rather than the firſt, or the third, is not natural but poſitive.

Law of Nature, as it reſpects intelligent, moral, and accountable beings, is the will of God, relating to human actions, grounded in the moral differences of things; and becauſe it is, in ſome meaſure, diſcoverable by natural right, it is obligatory upon all mankind. It is thus defined by Cicero (D: Legibus, lib. i) “Lex eſt ratio ſumma inſita in natura quæ jubet ea quæ faciendæ ſunt, prohibetque contraria.” It is called the law of nature, on account of the manner of its promulgation, which is by natural reaſon; on account alſo of its ſource or foundation, this law reſulting from the reſpective natures of beings and things, of beings, as God and man, and of things or actions, as morally good or evil, and having different physical effects; and, moreover, becauſe it is the law of God. Nature is but a fictitious perſon; and all that is ſaid of the wiſdom of her deſigns and operations, of her power, or of her laws, is to be aſcribed to him who is the author of nature. “Quid enim eſt aliud natura, quam Deus et divina Ratio, toti mundo, et partibus ejus inſerta?” Seneca de Benef. l. vi. c. 7. The demonſtration of this law of nature has been attempted by ſeveral learned men, who commonly urge the conſent of the more civilized nations, as a good argument for the exiſtence of this law. “Omni autem in re conſenſio omnium gentium lex natura putanda eſt,” ſays Cicero; i. e. “as to any point, the agreement of all nations in it is to be eſteemed a law of nature.” Others have erroneouſly alleged, as a proof of the law of nature, innate ideas or practical principles, impreſſed on the ſoul of man by its creator: but of ſuch ideas and principles we have no evidence. A more direct and concluſive demonſtration of the law of nature may be deduced from the conſideration both of the divine and human nature; which beheld in one view and in the relation they bear to each other ſupply unequivocal evidence of the exiſtence and obligation of this law. To this purpoſe we ſhall avail ourſelves of ſome appropriate reflections and reaſonings of the learned judge Blackſtone in immediate connection with this ſubject. “As God,” ſays this learned writer, “when he created matter, and endued it with a principle of mobility, eſtabliſhed certain rules for the perpetual direction of that motion; ſo, when he created man, and endued him with freewill to conduct himſelf in all parts of life, he laid down certain immutable laws of human nature, whereby that freewill is in ſome degree regulated and reſtrained, and gave him alſo the faculty of reaſon to diſcover the purpoſe of thoſe laws.”

Conſidering the Creator only as a being of infinite power, he

he was able unquestionably to have prescribed whatever laws he pleased to his creature, man, however unjust or severe. But as he is also a being of infinite *wisdom*, he has laid down only such laws as were founded in those relations of justice, that existed in the nature of things antecedent to any positive precept. These are the eternal, immutable laws of good and evil, to which the Creator himself in all his dispensations conforms; and which he has enabled human reason to discover, so far as they are necessary for the conduct of human actions. Such among others are these principles: that we should live honestly, should hurt nobody, and should render to every one his due; to which three general precepts Justinian has reduced the whole doctrine of law.

But if the discovery of these first principles of the law of nature depended only upon the due exertion of right reason, and could not otherwise be obtained than by a chain of metaphysical disquisitions, mankind would have wanted some inducement to have quickened their inquiries, and the greater part of the world would have rested content in mental indolence, and ignorance its inseparable companion. As therefore the Creator is a being, not only of infinite *power*, and *wisdom*, but also of infinite *goodness*, he has been pleased so to contrive the constitution and frame of humanity, that we should want no other prompter to inquire after and pursue the rule of right, but only our own self-love, that universal principle of action. For he has so intimately connected, so inseparably interwoven the laws of eternal justice with the happiness of each individual, that the latter cannot be attained but by observing the former; and, if the former be punctually obeyed, it cannot but induce the latter. In consequence of which mutual connection of justice and human felicity, he has not perplexed the law of nature with a multitude of abstracted rules and precepts, referring merely to the fitness or unfitness of things, as some have vainly surmised; but has graciously reduced the rule of obedience to this one paternal precept, "that man should pursue his own true and substantial happiness." This is the foundation of what we call ethics, or natural law. For the several articles into which it is branched in our systems, amount to no more than demonstrating, that this or that action tends to man's real happiness, and therefore very justly concluding that the performance of it is a part of the law of nature; or, on the other hand, that this or that action is destructive of man's real happiness, and therefore that the law of nature forbids it.

This law of nature, being coeval with mankind and dictated by God himself, is of course superior in obligation to any other. It is binding over all the globe in all countries, and at all times: no human laws are of any validity, if contrary to this; and such of them as are valid derive all their force, and all their authority, mediately or immediately, from this original.

But in order to apply this to the particular exigencies of each individual, it is still necessary to have recourse to reason: whose office it is to discover, as was before observed, what the law of nature directs in every circumstance of life; by considering, what method will tend the most effectually to our own substantial happiness. And if our reason were always, as in our first ancestor before his transgression, clear and perfect, unruled by passions, unclouded by prejudice, unimpaired by disease or intemperance, the task would be pleasant and easy; we should need no other guide but this. But every man now finds the contrary in his own experience; that his reason is corrupt, and his understanding full of ignorance and error.

This has given manifold occasion for the benign interposi-

tion of divine providence; which, in compassion to the frailty, the imperfection, and the blindness of human reason, hath been pleased, at sundry times and in divers manners, to discover and enforce its laws by an immediate and direct revelation. The doctrines thus delivered we call the revealed or divine law, and they are to be found only in the holy scriptures. These precepts, when revealed, are found upon comparison to be really a part of the original law of nature, as they tend in all their consequences to man's felicity. But we are not from thence to conclude that the knowledge of these truths was attainable by reason, in its present corrupted state; since we find that, until they were revealed, they were hid from the wisdom of ages. As then the moral precepts of this law are indeed of the same original with those of the law of nature, so their intrinsic obligation is of equal strength and perpetuity. Yet undoubtedly the revealed law is of infinitely more authenticity than that moral system, which is framed by ethical writers, and denominated the natural law. Because one is the law of nature, expressly declared so to be by God himself; the other is only what, by the assistance of human reason, we imagine to be that law. If we could be as certain of the latter as we are of the former, both would have an equal authority; but, till then, they can never be put in any competition together.

Upon these two foundations, the law of nature and the law of revelation, depend all human laws; that is to say, no human laws should be suffered to contradict these. There are, it is true, a great number of indifferent points, in which both the divine law and the natural leave a man at his own liberty; but which are found necessary for the benefit of society to be restrained within certain limits. And herein it is that human laws have their greatest force and efficacy: for, with regard to such points as are not indifferent, human laws are only declaratory of, and act in subordination to, the former. To instance in the case of murder: this is expressly forbidden by the divine, and demonstrably by the natural law; and from these prohibitions arises the true unlawfulness of this crime. Those human laws that annex a punishment to it, do not at all increase its moral guilt, or superadd any fresh obligation in *foro conscientie* to abstain from its perpetration. Nay, if any human law should allow or injoin us to commit it, we are bound to transgress that human law, or else we must offend both the natural and the divine. But with regard to matters that are in themselves indifferent, and are not commanded or forbidden by those superior laws; such, for instance, as exporting of wool into foreign countries; here the inferior legislature has scope and opportunity to interpose, and to make that action unlawful which before was not so.

We might further add, that, as there is a natural and necessary difference between virtue and vice, and the several actions and dispositions which are denoted by these two opposite terms, natural reason discovers it to be the will of God, that every man should look upon this difference in the nature of things and actions, as a law or rule, which he is religiously to observe, under pain of his Maker's displeasure. Among those writers who have alleged arguments in proof of the law of nature, some have founded it upon the reason and fitness of things, others, on our moral sense, and social affections; and others, again, on the good effects of virtue, and evil effects and consequences of vice; but, however they may differ in the principles upon which they have founded their reasoning, they have ultimately arrived at the same conclusion. These principles are illustrated under their proper heads in the course of this work. The names and works of the different writers are cited by Grove,

in his "System of Moral Philosophy," vol. II. p. ii. n. 5. The law of nature, says the author last cited, is eternal and necessary; so that it always did, and always could not but exist. It is universal, inasmuch that all mankind are born the subjects and objects of this law, notwithstanding the difference of climate, of government, of language, and of opinions and customs that have prevailed in different parts of the world. Moreover, the law of nature is immutable, for the divine nature is immutable. The first principle, or law of nature, according to Hobbes, is self-preservation. Thomasius will have in to be our own happiness, which falls in at last with the sentiment of Hobbes. Puffendorf maintains it to be sociality. Valentine Alberti, the belief that we are the image of God. Henry and Samuel Cocceius, the will of God. Grotius, right reason. Velthemius, the intrinsic decency or turpitude of actions. Strimefus and Janus, that we are to love God, ourselves, and our neighbour.

Laws, *Human*, comprehend all those rules of conduct, which originate in the wisdom of man, individually or collectively considered, and which are designed to regulate their behaviour to one another in more limited or more enlarged societies, and which are enforced by human authority and worldly sanctions. Human laws are necessary as a remedy, partly to the generality, and partly to the inefficacy of the divine. The laws of God are too general to ascertain all the duties of society, without some additional interpretations of men. That no man by fraud or violence injure another, and take his property, is a divine law; which notwithstanding, human laws are in many cases needful to settle the bounds of property, and assign every member of the community his rights and duties; what he may expect from others, and what he is to do to them. "Salus populi suprema lex esto." "To secure the welfare of the society be the supreme law" is really a divine precept; but the geniuses and interests of nations are so various, yea, so liable to change are the interests and circumstances of the same people, that different laws are necessary to suit this diversity of tempers, occasions, and emergencies. Nor is it any reproach to the divine law that it is no more particular; since it must be infinite to reach all the particular circumstances of mankind: and God hath given men reason, by which they may build upon the foundation that he hath laid such further laws and constitutions, as the course and posture of human affairs shall require. Nor is the inefficacy of the law of God, which is the other thing that makes human laws necessary, any more a dishonour to it. For what is the cause of this inefficacy, but the wilful corruption of men? It was most fit, that the chief rewards and punishments annexed to the divine laws should be unseen and future; that the trial of human virtue might be more conspicuous. And were not mankind sunk into an extreme degeneracy, the prospect of an eternal world would make all other considerations useless. But as it is now, the torments of an after-life are not a bridle strong enough upon the lusts and passions of men. It is therefore necessary, that every society, to secure its own peace, should insert as much of the divine law into their respective constitutions, as concerns the welfare of the body politic; and enforce these laws, not as divine, but as laws of the state, with civil sanctions; that they who will not be made honest by the fear of God, may be so by the fear of the laws of their country. The difference between the philosophers and others was said to be this, *Μορὸν ποιεῖσθαι ἐκείνων ἀ πρᾶξι ἀκούειν αἱ δικασαί*, "that they praised from choice that honesty and virtue, which others observed through fear of the laws;" agreeably to that of the apostle, "that the law is not made for a righteous man, but for the lawless and

disobedient." All human laws are of the nature of those called *civil*; and these, with regard to the difference of their subject matter, may be sub-divided into the law of nations, civil law, and canon law.

*Law of Nations, Jus Gentium*, is that rule, or measure, which all or several nations, either by a tacit or express agreement, are obliged to observe towards one another, whether in peace or war. If, indeed, men were to live in a state of nature, unconnected with other individuals, there would be no occasion for any other laws, than the law of nature, and the law of God. Neither could any other law possibly exist: for a law always supposes some superior who is to make it; and in a state of nature we are all equal, without any other superior but him who is the author of our being. But man was formed for society; and, as is demonstrated by the writers on this subject, is neither capable of living alone, nor indeed has the courage to do it. However, as it is impossible for the whole race of mankind to be united in one great society, they must necessarily divide into many; and form separate states, commonwealths, and nations, entirely independent of each other, and yet liable to a mutual intercourse. Hence arises a third kind of law, to regulate this mutual intercourse, called "the law of nations:" which, as none of these states will acknowledge a superiority in the other, cannot be dictated by any; but depends entirely upon the rules of natural law, or upon mutual compacts, treaties, leagues, and agreements between these several communities: in the construction also of which compacts we have no other rule to resort to, but the law of nature; being the only one to which all the communities are equally subject: and therefore the civil law very justly observes, that "quod naturalis ratio inter omnes homines constituit, vocatur jus gentium."

*Law, Civil or Municipal*, is the rule by which particular districts, communities, or nations are governed; being thus defined by Justinian, (Inst. 1. 2. 1.) "Jus civile est quod quisque sibi populus constituit." Judge Blackstone calls it "municipal" law, in compliance with common speech; for though, strictly speaking, that expression denotes the particular customs of one single *municipium*, or free town, yet it may with sufficient propriety be applied to any one state or nation, which is governed by the same laws and customs. Accordingly, municipal law, thus understood, is properly defined to be "a rule of conduct prescribed by the supreme power in a state, commanding what is right and prohibiting what is wrong." It is a "rule;" not a transient order from a superior to or concerning a particular person, but something permanent, uniform, and universal. It is thus distinguished from advice or counsel, and also from a compact or agreement. (See the beginning of the article *LAW*.) It is a rule of "civil conduct," by which it is distinguished from the natural or revealed law. (See *LAW of Nature*.) The municipal or civil law regards man as a citizen, and bound to other duties towards his neighbour than those of mere nature and religion; duties in which he has engaged, in consequence of enjoying the benefits of the common union; and which amount to no more than that he do contribute, on his part, to the subsistence and peace of the society. It is likewise a rule "prescribed," because a bare resolution, confined in the breast of the legislator, without manifesting itself by some external sign, can never be properly a law. This resolution must be notified to the people who are to obey it. This may be done by universal tradition and long practice, which suppose a previous publication, and is the case of the common law of England. It may be notified, *visa voce*, by officers appointed for that purpose, as is done with regard to proclamations, and such acts of parliament

parliament as are appointed to be publicly read in churches and other assemblies. And, lastly, it may be notified by writing, printing, or the like; which is the general course taken with all our acts of parliament. This notification, however, should be made in the most public and perspicuous manner; and not like the mask of Calgula, who (according to Dion Cassius) wrote his laws in a very small character, and hung them up upon high pillars, the more effectually to enslave the people. That, without doubt, can never be a rule to any person, which is not liable to his cognizance, or which he neither does nor can know. Agreeably to this circumstance, some have derived "lex" a *legendo*; because the law was to be publicly read, that it might be known to all and observed by all. The matter of *divine* laws being usually of great importance, and the author a sovereign who has an absolute propriety in us, and on that ground an unquestionable right to the most entire devotedness, and zealous concern to please him; we ought to use all the means in our power to come at the knowledge of his will. But as *human* laws proceed from the will of those who, by nature, are upon a level with the rest of mankind, and have the consent of others to govern them purely for their temporal or political good; such a provision ought to be made for their publication, that by an ordinary care, and without taking up much of their time and thoughts, which are to be spent in their private callings, people may be able to know the pleasure of their governors. There is another circumstance, which is worse than the non-promulgation of a law; and that is the making of laws "ex post facto:" when after an action (indifferent in itself) is committed, the legislator then for the first time declares it to have been a crime, and inflicts a punishment upon the person who has committed it. All laws should be made to commence "in futuro," and be notified before their commencement. When the laws or rules of conduct are properly notified or prescribed, it is the business of the subject to be thoroughly acquainted with them: for if ignorance, of what he might know, were admitted as a legitimate excuse, the laws would be of no effect, but might always be eluded with impunity. On this head we shall only add, that it is requisite to the very essence of a law, that it be made by the supreme power. Sovereignty and legislature are convertible terms; one cannot subsist without the other. That the law may answer the purpose of a complete rule, "commanding what is right and prohibiting what is wrong," it is necessary that the boundaries of right and wrong be established and ascertained by law: and it is then the business of the law, considered as a rule of civil conduct, to enforce these rights, and to redress these wrongs. For this purpose every law may be said to consist of several parts: one, *declaratory*, whereby the rights to be observed, and the wrongs to be eschewed, are clearly defined and laid down; another, *directory*, whereby the subject is instructed and enjoined to observe those rights, and to abstain from the commission of those wrongs; a third, *remedial*, whereby a method is pointed out to recover a man's private rights; or redress his private wrongs; to which may be added a fourth, usually termed the *sanction*, or *vindictory* branch of the law, whereby it is signified what evil or penalty shall be incurred by such as commit any public wrongs, and transgress or neglect their duty. (Blackst. Com. book i.) For the interpretation of the law, see INTERPRETATION.

*Civil* laws, considered with regard to the two offices of the legislator, viz. to judge and to compel, may be divided into two branches; the one *distributive*, the other *vindictive* and *penal*.

**LAW, Distributive**, is that by which every man has his

right; or, it is that which constitutes the rules and measures of things, whereby we know what belongs to us, and what to others; so as we may not disturb or interrupt others in the enjoyment of their own, nor be interrupted by them; and what each man may lawfully do or not do.

**LAW, Vindictive**, is that branch by which the punishments to be inflicted on those who violate the laws, are determined.

The distributive and vindictive are not two species of laws, but two parts of the same law. For if a law say no more than "Whatever you catch in your net, in the sea, shall be your's," it is in vain; for though another take from you what you have caught, it is still your's; in regard, in the state of nature, where all things are common, your's and another's are the same thing. So that what the law defines to be your's, was your's before that law, and will be your's after it, though possessed by another.—A law, therefore, is but an empty sound, unless it determine the thing to be your's in such a sense as to forbid every body else from disturbing you in the possession of it. But such prohibition will be vain, unless there be a penalty annexed to it. A law, therefore, must contain both these parts, that which prohibits, and that which punishes. The first whereof, which is called *distributive*, is prohibitory, and speaks to all; the latter, called *vindictive* or *penal*, is mandatory, and speaks only to the public officers. Whence it follows, that to all civil laws there is annexed a penalty, either implicitly or explicitly; and where that punishment is not ascertained, either by writing or by example, it is supposed to be arbitrary, and to depend on the pleasure of the legislator: for that is no law, which may be violated impune.

*Civil* laws, considered with regard to the different manners of promulgating them, are of two kinds; *scripta* and *non scripta*, or *written* and *unwritten*.

**Laws, Written**, are those which require either the voice, or some other sign of the legislator's will to become laws. The written laws of England consist of statutes, acts, or edicts, made by the king's majesty, by and with the advice and consent of the lords spiritual and temporal, and commons, in parliament assembled. The oldest of these now extant is the famous "magna charta," as contained in parliament 9 Hen. III. See **MAGNA CHARTA** and **STATUTES**.

**Laws, Unwritten**, are such as need no other promulgation besides the voice of nature, or natural reason; of which kind are all natural laws.

Hence it appears, that though the natural laws be described in the writings of the philosophers, they are not therefore to be called *written* laws; nor are the writings of lawyers, laws, for want of the supreme authority; nor the *responsa prudentum*, or opinions of judges, laws, excepting so far as they are allowed by the supreme power to pass into use; and then they are called *leges scripta*, written laws; not because of their use, but because of the will of the supreme power, which is argued from their passing into use.

The unwritten law of England includes not only "general customs," as the *common laws*, properly so called; but also the "particular customs" of certain parts of the kingdom; and likewise those "particular laws," that are by *custom* observed only in certain courts and jurisdictions. When these parts of the municipal law of England are called "leges non scripta," we are not to understand that these laws are at present merely *oral*, or communicated from the former ages to the present solely by word of mouth. Indeed, during an age of profound ignorance of letters, all laws were entirely traditional, because the nations among which they prevailed had but little idea of writing. Thus the British

as well as the Gallic Druids committed all their laws, as well as learning, to memory; and it is said of the primitive Saxons here, as well as their brethren on the continent, that "leges sola memoria et usu retinebant." But with us, at present, the monuments and evidences of our legal customs are contained in the records of the several courts of justice, in books of reports and judicial decisions, and in the treatises of the learned sages of the profession, preserved and handed down to us from the times of highest antiquity. But these parts of our law may be fitly styled "leges non scriptæ," because their original institution and authority are not set down in writing, as acts of parliament are, but they receive their binding power, and the force of laws, by long and immemorial usage, and by their universal reception throughout the kingdom. In like manner as Aulus Gellius defines the "jus non scriptum" to be that, which is "tacito et illiterato hominum consensu et moribus expressum." See *COMMON LAW* and *CUSTOM*.

Having considered the *civil* law in its more general acceptance, as denoting the statutes and ordinances of every state for its own good government, we shall refer for the statement of its more special acceptance to the article *CIVIL LAW*.

*LAWS*, *Canon* or *Ecclesiastical*, in a more extensive sense, denote laws relating to the worship, discipline, and government of the church. For an account of that which is by way of eminence called *canon law*, see *CANON LAW*.

There is another division of the law of England besides that which we have above stated, more large and particular; as into the prerogative or crown law; the law and custom of parliament; the common law; the statute law; reasonable customs; the law of arms, war, and chivalry; ecclesiastical or canon law; civil law, in certain courts and cases; forest law; the law of marque and reprisal; the law of merchants; the law and privilege of the stannaries, &c. But this large division may be reduced to the common division; and all is founded on the law of nature or reason, and the revealed law of God, as all other laws ought to be. 1 Co. Inst. 11.

Law is also applied to the several policies of states and people, or the maxims and rules they have agreed upon, or received from their magistrates, whereby to live in peace and mutual society.

The laws of the twelve tables were the ancient laws of the Romans, for which the Decemviri were sent into Greece, and which served them for the ground-work of all their jurisprudence.

The celebrated laws of the more modern days, are those of the Angli, the Werini, or Thuringi; of the Boii, or Bavarians; those of the Burgundi, Germans, Danes, and Norwegians; of the Franks, the Frisians, the Lombards, the Gothic law, the Martina, or Merician law; of the laws of the Saxons, Scots, Sicilians, Visigoths; the laws of Oleron, the Moimatin law, and the Salic law.

*LAW*, *Lex*, among the first Romans properly signified an ordinance of the people, made at the request of a magistrate, particularly a consul.

These ordinances differed from the plebiscita and senatus consulta, and even from other ordinances made at the request of any other magistrate beside a consul, though those too bore the name of laws.

Thus, though Aquilius and Falcidius were only tribunes when they made their request, yet we still say, the *Aquilian* law, the *Falcidian* law, &c.

The several laws of the Romans are distinguished, 1. By the name of him at whose request they were passed; as the *Cornelian* law, the *Julian* law, &c. 2. By the matter or

subject of the law; and hence came the terms, *testamentary* laws, as the *Furian*, *Voconian*, &c. *judiciary* laws, *Agrarian* laws, &c.

3. Sometimes by the crimes against which they were made. For instance: the laws touching *poisoning*, *parricides*, &c. the laws of *concession*, *peculate*, &c.

The *Codex* and *Authentica* are the laws and constitutions of the Roman emperors; and the *Digest* is a compilation, made by the emperor Justinian's order, of the several opinions and judgments of the most learned in the Roman law; to which he gave the sanction of laws, as appears by the epistle prefixed to the work; and it is this that properly constitutes the Roman law. See *CIVIL LAW*.

The *lex talionis*, or *law of like for like*, is the most ancient and equitable law in the world. It was observed by the Hebrews.

*LAW* has also a more special signification, wherein it is taken for that which is lawful with us, and not elsewhere: as "tenant, by the courtesy of England."

Thus we also say, to *swage law* (*swadare legem*), and to *make or do law* (*facere legem*). See *WAGER*, and *MAKE*.

*LAW of Arms*, is that law which gives precept how rightly to proclaim war, to make and observe leagues, to attack the enemy, and to punish offenders in the camp.

Common things concerning arms and war are under the cognizance of the constable and marshal of England. 13 R. II.

*LAW*, *Assignee* by. See *ASSIGNEE*.

*LAW*, *Covenant* of. See *COVENANT*.

*LAWS of Estates*, such acts and regulations as relate to their natures and managements. See *ESTATE*, and *FARM*.

*LAW*, *Forest*. See *FOREST*.

*LAW*, *Frank*. See *FRANK*.

*LAW of Honour*, denotes a system of rules, constructed by people of fashion, and calculated to facilitate their intercourse with one another; and for no other purpose. Nothing is adverted to by the law of honour but what tends to incommode this intercourse; and hence it only prescribes and regulates the duties betwixt equals, omitting such as relate to the Supreme Being, as well as those which we owe to our inferiors. For which reason, profaneness, neglect of public worship or private devotion, cruelty to servants, rigorous treatment of tenants or other dependants, want of charity to the poor, injuries done to tradesmen by insolvency or delay of payment, with numberless examples of the same kind, are accounted no breaches of honour; because a man is not a less agreeable companion for these vices, nor the worse a deal with, in those concerns which are usually transacted between one gentleman and another. Again, the law of honour, being constituted by men occupied in the pursuit of pleasure, and for the mutual conveniency of such men, will be found, as might be expected from the character and design of the law-makers, to be, in most instances, favourable to the licentious indulgence of the natural passions. Thus it allows of fornication, adultery, drunkenness, prodigality, duelling, and of revenge in the extreme; and lays no stress upon the virtues opposite to these. *Paley's Principles of Moral and Political Philosophy*, vol. i.

*LAW*, *Insurance* of. See *INSURANCE*.

*LAW*, *Intendment* of. See *INTENDMENT*.

*LAW Language* was formerly, in this kingdom, Norman or law French; and in this barbarous dialect were all public proceedings written and recorded. Nothing could be a more humiliating and ignominious badge of tyranny and foreign servitude; being introduced under the auspices of William the Norman, and his sons; and thus the ironical observation of the Roman satirist came to be literally verified, that

"Gallia

“*Gallia caudicos docuit facunda Britannos.*” (Juvén. xv. 111.) This continued till the reign of Edward III., when by stat. 36 Ed. III. c. 15, it was enacted, that for the future all pleas, &c. should be conducted in the English tongue; but entered and enrolled in Latin. The practitioners, however, being used to the Norman language, which was more familiar to them, continued to take their notes in law French; and when these notes were published, under the denomination of reports, they were printed in that barbarous dialect; which, joined to the additional terror of a Gothic black letter, has occasioned many students to throw away their Plowden and Littleton, without venturing to attack a page of them. But in reality, says Blackstone, on a nearer acquaintance, they would have found nothing formidable in the language; which differs in its grammar and orthography as much from the modern French, as the diction of Chaucer and Gower does from that of Addison and Pope. Besides, as the English and Norman languages were concurrently used by our ancestors for several centuries, the two idioms have naturally assimilated, and actually borrowed from each other; for which reason the grammatical construction of each is so very much the same, that an Englishman (with a week’s preparation) would understand the laws of Normandy, collected in their “grand coutumier,” as well, if not better, than a Frenchman bred within the walls of Paris.

The Latin, which succeeded the French for the entry and enrolment of pleas, and which continued in use for four centuries, answers so nearly to the English, that it has been generally imagined to be totally fabricated at home, with little more art or trouble than by adding Roman terminations to English words. Whereas, in reality, it is a very universal dialect spread throughout all Europe at the irruption of the northern nations, and particularly accommodated and moulded to answer all the purposes of the lawyers with a peculiar exactness and precision. These northern nations, or rather their legislators, though they resolved to promulge their laws in the Latin tongue, have frequently intermixed in it some words of a Gothic original; which is more or less the case in every country of Europe, and ought not, therefore, to be imputed as any peculiar blemish in our English legal Latinity. The truth is, that which is generally denominated law Latin, is in reality a mere technical language, calculated for eternal duration, and easy to be comprehended both in present and future times; and on those accounts best suited to preserve those memorials which are intended for perpetual rules of action. As to the objection of locking up the law in a strange and unknown tongue, this is of little weight with regard to records, which few have occasion to read, but such as do, or ought to, understand the rudiments of Latin. The learned Blackstone suggests, that the terms of the “law are not more numerous, more uncouth, or more difficult to be explained by a teacher, than those of logic, physics, and the whole circle of Aristotle’s philosophy, nay even of the politer arts of architecture and its kindred studies, or the science of rhetoric itself.” The technical Latin continued in use from the time of its first introduction till the time of the subversion of our ancient constitution under Cromwell, when, among many other innovations in the law, the language of our records was altered and turned into English. But, at the restoration of king Charles, this novelty was no longer continued; the practitioners finding it very difficult to express themselves so concisely or significantly in any other language but the Latin. Thus it continued without any sensible inconvenience till about the year 1730, when it was again thought proper that the proceedings at law should be done into English; and it was accordingly so ordered

by statute 4 Geo. II. c. 26. This provision was made, according to the preamble of the statute, that the common people might know and understand what was alleged or done for and against them, in the process and pleadings, the judgment and entries in a cause. Several inconveniences arose from this alteration; so that in two years it was found necessary to make a new act, 6 Geo. II. c. 14, which allows all technical words to continue in the usual language, and has thereby almost defeated every beneficial purpose of the former statute. Blackst. Com. b. iii.

LAW, *Marine*, denotes that law which serves to regulate the interests of navigation and maritime commerce. (See NAVIGATION, and COMMERCE.) This law has undergone various alterations and improvements, in consequence of the extension of naval intercourse between different nations for the purposes of commerce. Several codes have been formed by different states primarily for the regulations of navigation, and for defining the authority of the masters and other officers of ships, and the duty and rights of the seamen; and afterwards for the regulation of maritime contracts. The earliest system of marine law, which history records, was that compiled by the Rhodians, after they had, by their commerce and naval victories, obtained the sovereignty of the sea, about 900 years before the Christian era. These laws exist at present only in a detached and imperfect state, as they have been preserved and incorporated in other subsequent institutions of a similar nature. It has been supposed by some that the Rhodian laws were adopted by the Romans during the first Punic war, when they first became a naval power; but others affirm that they were incorporated with the Roman law by Justinian and others. As for the Phœnicians, Carthaginians, Athenians, Corinthians, and other maritime states of antiquity, it does not appear whether they had any marine laws of their own institution. If they had any, they have not been transmitted to our times. The first code of modern sea-laws was compiled, says Serjeant Marshall, about the time of the first crusade, towards the end of the 11th century, by the people of Amalfi, who had then become considerable for their commerce and maritime power. It is not improbable that the code consisted principally of the Rhodian institutions, which were found still in force in the countries bordering upon the Mediterranean; and being collected into one regular system, were generally received, for a considerable time, as law in those countries. In process of time, other states, as they acquired importance and distinction, formed new collections of marine laws, in which the old institutions were altered and modified to suit the improvements of the times, or their own particular interest. But when inconveniences were found to arise from a diversity of rules pertaining to a subject that had been long regulated by one general system, it became necessary for the different maritime states to form a new code out of all these discordant materials, which was done, as Grotius informs us, (De Jure Bell. l. iii. c. 1. § 5. n. 6.), by the authority of almost all the sovereigns of Europe. This new digest was denominated “*Consolato del Mare.*” It was first published, by order of the ancient kings of Aragon, in the Catalan tongue, and therefore probably composed at Barcelona, the capital of Aragon. In the 13th century this code was revived as law in Italy, the Greek empire, France, and Germany; and Vinnius says, that most of the marine laws in Spain, Italy, France, and England are borrowed from it. It seems to have been considered as a branch of the public law, and its regulations are still of very high authority in every maritime state of Europe. The next collection of sea-laws in point of time, as well as of celebrity, is that of Oleron,

Oleron. (See OLERON.) This was succeeded by a collection of the ordinances made by the "Merchants and masters of the magnificent city of Wisbuy, in the island of Gothland, formerly very famous for its commerce, but now reduced to an obscure and inconsiderable town." Many of the regulations contained in this code of laws are precisely the same with those of Oleron. These laws were for some ages, and indeed still remain, in great authority in the northern parts of Europe. In 1507, the deputies of the Hanseatic league, in a general assembly at Lubeck, drew up a system of laws relating to navigation, for the use of their confederacy, to which, in 1614, they added several new ordinances. But the most complete and comprehensive system of this kind is the famous ordinance of the marine of Louis XIV. published in 1681. This excellent code was compiled and arranged by a very masterly hand, under the inspection of Colbert, the celebrated minister of that prince, upon an attentive revision of all the ancient sea-laws of France and other countries, with the assistance of the most learned men of the time, and upon consultation with the different parliaments, the courts of admiralty, and the chambers of commerce in France. It forms a system of whatever experience and the wisdom of ages had pronounced to be most just and convenient in the marine institutions of the maritime states of Europe. Notwithstanding new regulations, suggested by motives of national interest, it has hitherto been esteemed a code of great authority upon all questions of maritime law. From this ordinance, and from the elaborate and useful commentary of Valin, Lord Mansfield is said to have derived much of his extensive and accurate acquaintance with the principles of marine. Marshall's Law of Insurance, vol. 1. See INSURANCE.

**LAW of Marque**, a law by which those who are driven to make use of it, take the goods, or shipping of the party that has done them wrong, and of whom they cannot get ordinary justice, whenever they can take him within their own bounds or precincts. 27 Edw. III. cap. 17.

**LAW, Martial**. See MARTIAL.

**LAW Merchant**, a summary sort of law, originally differing from the common law, though now adopted, and become a part of the laws of the kingdom. This decides the causes of merchants on the general rules which obtain in all commercial countries; and that often, in matters relating to domestic trade, as, for instance, with regard to the drawing, the acceptance, and the transfer, of inland bills of exchange. (Co. Litt. 172. Lord Raym. 181. 1562.) One point of it consists in this, that if there be two joint merchants of wares, and one of them dies, his executor shall have the moiety; which is not allowed in the case of others, not merchants. See CUSTOM.

The law of merchants not being founded in the particular institutions, or local customs of any particular country, but consisting of certain principles which general convenience has established to regulate the dealings of merchants with each other in all countries, may be considered as a branch of public law.

**LAWs of Molmutius**. See MOLMUTIN *Laws*.

**LAWs of Oleron**. See OLERON.

**LAW of Parliament**. See PARLIAMENT.

**LAW, Poyning's**. See POYNING.

**LAW, Release in**. See RELEASE.

**LAW, Salic**. See SALIC.

**LAW, Spiritual**, is the ecclesiastical or canon law, allowed and authorized in this realm, so far as it is not against the common law, nor against the statutes and customs of the kingdom. And according to such ecclesiastical laws, the

ordinary and other ecclesiastical judges proceed in cases within their cognizance.

**LAW Staple**, the same with law merchant.

**LAW Suit**. See SUIT.

**LAW, Sumptuary**. See SUMPTUARY.

**LAW, Surrender in**. See SURRENDER.

**LAWs, By**. See BY-LAWS.

**LAWs, Cock-pit**. See COCKPIT.

**LAWs of the Stage**. See STAGE.

**LAW** is also used figuratively in speaking of the rules or order wherein any thing is performed.

Thus we say, the laws of motion, the laws of mechanics, the laws of fluids, the laws of chance, of a game, &c. laws of friction, of resistance, of descent of bodies, &c. laws of elasticity, rarefaction, reflexion, refraction, &c.; all which see under their proper heads.

**LAW**, in *Scripture History*, one of the three divisions of the Old Testament, comprehending Genesis, Exodus, Leviticus, Numbers, Deuteronomy. See CANON.

**LAW-Day, Lagedayum**, in our old *Law Writers*, was any day of open court, and commonly used for the courts of a county or hundred. It is also called *view of Frank-pledge, or court-leet*. "Et quieti sint de festis comitatum & hundredorum nostrorum, de visu franci plegii & laudavorum, &c."

**LAWA**, in *Geography*, a town of the island of Bornoeo, situated on a river of the same name. N. lat. 0° 40'. E. long. 110° 42'.

**LAWEND**, in the military language of the Ottoman empire, the appellation of cavalry, called also *Delibaches*. (See *DELIBACHES*.) From *Lawend* we have formed *Laventi*. Their arms are short sabres, pistols, muskets, and lances. They wear a kind of cap, which is a long cylinder of black felt, nine or ten inches high, and without any projecting rim. Their saddles are made in the English manner, of a single skin, stretched upon a wooden tree; in the rest of their accoutrements and clothing, they resemble the Mamlouks. Their ragged clothes, their rusty arms, and their horses of different sizes, give them the appearance of banditti more than of soldiers; and, in reality, they have first distinguished themselves under the former character, nor have they much changed their habits by adopting their second occupation. Almost all the cavalry in Syria are Turkmans, Curds, or Caramanians; who, after exercising the trade of robbers in their own country, seek employment, as well as an asylum, near the person of the pacha. Throughout the empire, their troops are, in like manner, formed of plunderers, who roam from place to place. From want of discipline, they retain their former manners, and are the scourge of the country, which they lay waste, and of the peasants, whom they often pillage by open force. Volney's Travels, vol. ii.

**LAWER KIRK**, in *Geography*, a town of Scotland, in the county of Perth; 15 miles S.E. of George Town.

**LAWES, WILLIAM**, in *Biography*, the eldest son of Thomas Lawes, a vicar-choral of the cathedral church of Salisbury, and a native of that city, was placed early in life under Copernario, for his musical education, at the expense of the earl of Hertford. His first preferment was in the choir of Chichester, but he was soon called to London, where, in 1602, he was sworn a gentleman of the chapel royal; which place, however, he resigned in 1611, and became one of the private, or chamber-musicians, to Charles, then prince, and afterwards king. Fuller says, "he was respected and beloved of all such persons as cast any looks towards virtue and honour;" and he seems well entitled to this praise. He manifested his gratitude and loyalty to his royal master by taking up arms in his cause against the parliament.

liament. And though, to exempt him from danger, lord Gerrard, the king's general, made him a commissary in the royal army, yet the activity of his spirit disdaining this intended security, at the siege of Chester, 1645, he lost his life by an accidental shot. The king is said, by Fuller, to have been so affected at his loss, that though he was already in mourning for his kinsman lord Bernard Stuart, killed at the same siege, his majesty put "on particular mourning for his dear servant William Lawes, whom he commonly called the father of music."

His chief compositions were fantasias for viols, and songs and symphonies for masques. Though his brother Henry, in the preface to the Choice Psalmes for three voices, which they published jointly, boasts that "he composed more than thirty several sorts of music for voices and instruments, and that there was not any instrument in use in his time but he composed for it as aptly as if he had only studied that." In Dr. Aldrich's Collection, Christ-church, Oxon, there is a work of his called Mr. William Lawes's Great Consort, "wherein are six fettes of musicke, six books." His Royal Consort for two treble viols, two viol da gambas, and a thorough-bass, which was always mentioned with reverence by his admirers in the 17th century, is one of the most dry, awkward, and unmeaning compositions we ever remember to have had the trouble of scoring. It must, however, have been produced early in his life, as there are no bars, and the passages are chiefly such as were used in queen Elizabeth's time. In the music-school at Oxford are two large manuscript volumes of his works in score, for various instruments; one of which includes his original compositions for masques, performed before the king, and at the inns of court.

His anthem for four voices, in Dr. Boyce's second volume, is the best and most solid composition that we have seen of this author; though it is thin and confused in many places, with little melody, and a harmony in the chorus, p. 201, which we are as unable to understand, or reconcile to rule, or to our own ears. He must have been considerably older than his brother Henry, though they frequently composed in conjunction. We are, however, unable to clear up this point of primogeniture: Henry's name is placed first in the title to Choice Psalmes, published in 1648, in the preface to which he says, "as to that, which is my part in this composition, it takes precedence of order only, not of worth." And yet he says of his own tunes just before, "they had their birth at the same time as his." Besides the psalms at the end of sir William Davenant's masque, called "The Triumphs of the Prince d'Amour," 1635, it is said, that "the musick of the songs and symphonies were excellently composed by Mr. William and Mr. Henry Lawes, his majesty's servants."

Several of the songs of William Lawes occur in the collections of the time, particularly in John Playford's Musical Companion, part the second, consisting of dialogues, glees, ballads, and airs, the words of which are in general coarse and licentious. The dialogue part, which he furnished to this book, is a species of recitative, wholly without accompaniment: and the duet at last, which is called a chorus, is insipid in melody, and ordinary in counterpoint. His boated canons, published by his brother Henry at the end of their psalms, as proofs of his great abilities in harmony, when scored, appear so far from finished compositions, that there is not one of them totally free from objections, or that bears the stamp of a great master.

LAWES, HENRY, the brother of William, was likewise a disciple of Coperario. By the cheque-book of the chapel royal, it appears that he was sworn in Pisteller, in January, 1625, and, in November following, gentleman of the chapel;

after this, he was appointed clerk of the cheque, and one of the public and private musicians to Charles I. William and Henry Lawes were at this time in such general favour, that though the kingdom was divided into factions, and were not only varied more in their principles, but disputed them with more violence than at any other period of our history, there was but one opinion concerning the abilities of these musicians. Yet as the reputation of Henry was still higher, and more firmly established than that of his brother, it seems to require more ample discussion. We have examined with care and candour all the works which we could find of this composer, which are still very numerous, and are obliged to own ourselves unable, by their excellence, to account for the great reputation which he acquired, and the numerous panegyrics bestowed on him by the greatest poets and musicians of his time. His temper and conversation must certainly have endeared him to his acquaintance, and rendered them partial to his productions; and the praise of such writers as Milton and Waller is durable fame. Tallis, Bird, or Gibbons, who were all infinitely superior to Lawes, never had their abilities blazoned by contemporary poets or historians of eminence. Fenton, the editor of Waller's works, tells us, that "the best poets of his time were ambitious of having their verses set to music by this admirable artist;" and, indeed, he not only set some of the works of almost every poet of eminence in Charles I.'s reign, but of young noblemen and gentlemen who seem only to have tried their strength on the lyre for his use, and of whose talents for poetry no other evidence remains than what is to be found in Lawes's publications.

Waller has more than once bestowed his fragrant incense on this musician. Peck says, that "Milton wrote his Masque at the request of Lawes;" but whether Milton chose Lawes, or Lawes Milton for a colleague in Comus, it equally manifests the high rank in which he stood with the greatest poets of his time. It would be illiberal to cherish such an idea; but it does sometimes seem as if the twin-sisters, Poetry and Music, were mutually jealous of each other's glory: "the less interesting my liter's offspring may be," says Poetry, "the more admiration will my own obtain." Upon asking some years ago, why a certain great prince continued to honour with such peculiar marks of favour an old performer on the flute, when he had so many musicians of superior abilities about him? We were answered, "because he plays worse than himself." And who knows whether Milton and Waller were not secretly influenced by some such consideration? and were not more pleased with Lawes for not pretending to embellish or enforce the sentiments of their songs, but setting them to sounds less captivating than the sense.

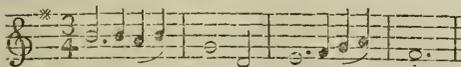

But bad as the music of Lawes appears to us, it seems to have been sincerely admired by his contemporaries in general. It is not meant to insinuate that it was pleasing to poets only, but that it was more praised by them than any other music of the same time. Though that of Lanier, Hilton, Simon Ives, Dr. Child, and others, seems preferable; and the poets, whose praise is fame, perhaps taught others to admire.

The time was now come for simplifying harmony and purifying melody in England, as well as in Italy; and the beginning of this enterprize was not fortunate here any more than in that country: harmony and contrivance were relinquished without a compensation. Simplicity, indeed, was attained; but devoid of accent, grace, or invention. And this accounts for the superiority of church music over secular at this period in every part of Europe, where canon, fugue, rich harmony, and contrivance, were still cultivated; while the first attempts at air and recitative were awkward, and the bases thin and unmeaning. Indeed, the composers of this kind

kind of music had the single merit to boast of affording the singer an opportunity of letting the words be perfectly well understood; as their melodies, in general, consisted of no more notes than syllables, while the treble accompaniment, if it subsided, being in unison with the voice-part, could occasion no embarrassment or confusion.

But there seems as little reason for sacrificing music to poetry, as poetry to music; and when the sentiments of the poem are neither enforced nor embellished by the melody, it seems as if the words might be still better articulated and understood by being read or declaimed, than when drawn out in such psalmodic ayres as those of Henry Lawes and his contemporaries. It has, however, been asked "whoever reads the words of a song but the author?" And there are certainly many favourite songs, which nothing but good music and good singing could ever bring into notice. These are, however, poems, we will not call them songs, on subjects of wit and science, which must ever be enfeebled by music; while others, truly lyric, and confined to passion and sentiment, travel quicker to the heart, and penetrate more deeply to the soul by the vehicle of melody, than by that of declamation. But we want not to set up one art against another, or to give a preference to singing over declamation; but to assign to each its due place and praise. There are passages in our best plays which could never be sung by the finest performer that ever existed, to so much effect as they have been spoken by a Garrick or a Siddons; while in Metastasio's charming dramas, there are lines and stanzas, by which an audience has been often more completely enrapt, when well set and well sung by a mellifluous and touching voice, than by the most exquisite declamation of the greatest actors that ever existed. Though Henry Lawes severely censures the admirers of Italian music in his preface, yet his first cantata, "Thetis and Ariadne," is both in poetry and music, an imitation of the famous scene in Monteverde's opera of "Arianna," which was afterwards formed into a single heroic song, entirely like this, in *stilo recitativo*, without any air from beginning to end. After the operas of Rinuccini, which had been set by Jacopo Peri, Giulio Caccini, and Monteverde, in that manner, at the beginning of the 17th century, had met with such universal applause in Italy, from the lovers of poetry and simplicity, and enemies to madrigals and music of many parts, this kind of composition had many imitators, not only in Italy, but throughout Europe. All the melodies of Henry Lawes remind us of *recitative* or *psalmody*, and scarce any thing like an air can be found in his whole book of Ayres. As to his knowledge and resources in counterpoint, we are certain that they were neither great nor profound. His works were chiefly published under the title of "Ayres and Dialogues," of which he printed three several books, the first in 1653; the second in 1655; and the third in 1658. Besides these, many of his songs and dialogues were published by Playford in collections, entitled "Select Musical Ayres and Dialogues," by Dr. Wilson, Dr. Charles Colman, Nicholas Laniers, and others. Though most of the productions of this celebrated musician are languid and insipid, and equally devoid of learning and genius, we shall point out one or two of them that seem the most meritorious.

Book the First, p. 11.

Careless of love, and free from fears, &c.

is one of the most pleasing airs that we have seen of this author. We should insert another of his songs entire, in the musical plates, had we room; "A Lover once I did espy;" not so much on account of the beauty of the melody and harmony, though it is one of the best in those particulars, as for the singularity of the measure, which is such as seldom occurs. Harry Carey's ballad "Of all the girls that are so smart, &c." which is a slower kind of hornpipe, resembles it the most of any air which we can recollect. "Little love serves my turn," p. 18. of the same collection, is the gayest air which we have seen of H. Lawes. His other most pleasing ballads are those beginning, "If when the sun," p. 18. and Ben Johnson's song, "Still to be neat, still to be dressed;" see Playford's Collection. But the best of all his songs seems "Come from the dungeon to the throne," p. 107. of Playford's second part; and "Amidst the myrtles as I walk," is pleasing psalmody.

The tunes which he set to Sandys's excellent version of the psalms, as well as those to the Choice Psalms of the same paraphrase, which were composed by Henry Lawes and his brother, in a kind of anthem or motet style, though ushered into the world, in 1648, by such innumerable panegyrics in rhyme, are so far from being superior to the syllabic psalmody of their predecessors who clothed Sternhold and Hopkins in Narcotic strains, that they seem to possess not only less pleasing melody, but less learned harmony, than may be found in anterior publications of the same kind. And this seems to be the opinion of the public: as they were never adopted by any vociferous fraternity, or admitted into the pale of a single country church, that we have been able to discover, since they were first printed. One of these, first published by Henry, to the seventy-second psalm, has, indeed, long had the honour of being jingled by the chimes of St. Lawrence Jewry, six times in the four-and-twenty hours, in a kind of *Laus perpetua*, such as was established in Psalmody island, mentioned in the General History of Music, vol. ii. p. 9.

During the civil war, Henry Lawes supported himself by teaching ladies to sing; however, he retained his place in the chapel royal, and, at the Restoration, composed the coronation anthem. Yet he did not long survive this event, for, in October, 1662, he died, and was buried in Westminster Abbey.

LAWFUL. See UNLAWFUL.

LAWFUL Naam. See NAAM.

LAWING of Dogs, a phrase used in our ancient law-writers. Thus, mastiffs must be lawed every three years, Crompton, Jurisd. fol. 163, that is, three claws of the fore-foot shall be cut off by the skin, or the ball of the fore-foot cut out. See EXPEDITATION.

LAWLESS COURT, a court held on King's Hill at Rochford in Essex, every Wednesday morning next after Michaelmas day, at cock-crowing; at which court they whisper, and have no candle, nor any pen and ink, but a coal. He that owes fuel of service there, forfeits double his rent every hour he is missing.

This court is called lawless, because held at an unlawful hour; or, perhaps, *quia dicta sine lege*; because opened without any form. It is mentioned by Camden; who says, this servile attendance was imposed on the tenants, for conspiring, at the like unseasonable time, to raise a commotion.

LAWLESS Man, *ex-lev.* See OUTLAW.

LAWN, in Gardening, an open space of short grass-ground, in the front of a residence, or in a garden, park, or other pleasure-ground. These, when extended in the principal fronts of habitations, add considerably to the neatness and grandeur of their appearance, by laying them open, and admitting more extensive prospects. Where there is a sufficient

cient scope of ground, they should be as large as the nature of the situation will admit, always being planned in the most conspicuous parts immediately joining the houses, and extended outward as far as convenient, allowing width in proportion; having each side or verge bounded by elegant shrubby compartments in a varied order, separated in some parts by intervening spaces of grass-ground, of varied dimensions, and serpentine gravel-walks, gently winding between and through the plantations, for occasional shady, sheltered, and private walking; or similar walks carried along the fronts of the boundary plantations, and immediately joining the lawns, for more open and airy walking in; and in some concave sweeps of the plantations there may be recesses and open spaces both of grass and gravel, of different forms and dimensions, made as places of retirement, shade, &c.

Though the usual situations of lawns are those just mentioned; yet if the nature of the ground admit, or in cases where there is a good scope of ground, they may be continued more or less each way; but always the most considerable on the principal fronts, which, if they be to the south, or any of the southerly points, they are the most desirable for the purpose.

With respect to the dimensions, they may be from a quarter of an acre, or less, to six or eight acres, or more, according to the extent and situation of the ground. Sometimes lawns are extended over ha-has, to ten, twenty, or even to fifty or sixty acres, or more. But in these cases they are not kept mown, but eaten down by live stock.

The form must be directed by the nature of the situation; but it is commonly oblong, square, oval, or circular. But in whatever figure they are designed, they should widen gradually from the house outward to the furthest extremity, to have the greater advantage of prospect; and by having that part of them within the limits of the pleasure-ground, bounded on each side by plantations of ornamental trees and shrubs, they may be continued gradually near towards each wing of the habitation, in order to be sooner in the walks of the plantations, under shade, shelter, and retirement. The terminations at the farther ends may be either by ha-has to extend the prospect, or by a shrubby or plantation of flatly trees, arranged in sweeps and concave curves. But where they extend towards any great road, or distant agreeable prospect, it is more in character to have the utmost verge open, so as to admit of a grand view from and to the main residence.

But the side-boundary verges should have the plantations rurally formed, airy, and elegant, by being planted with different sorts of the most ornamental trees and shrubs, not in one continued close plantation, but in distinct separated compartments and clumps, varied larger or smaller, and differently formed, in a somewhat natural imitation, being sometimes separated and detached less or more, by intervening breaks, and open spaces of short grass, communicating both with the lawns and interior districts; and generally varied in moderate sweeps and curves, especially towards the lawns, to avoid stiff, formal appearances, both in the figure of the lawns and plantations. In planting the trees and shrubs, which should be both of the deciduous and evergreen kinds, where intended to plant in distinct clumps, either introduce the deciduous and evergreens alternately in separate parts, or have some of both interspersed in assemblage; in either method, placing the lower growth of shrubs towards the front, and the taller backwards, in proportion to their several statures, so as to exhibit a regular gradation of height, that the different sorts may appear conspicuous from the main lawns. They may be continued backwards to a considerable

depth, being backed with trees and shrubs of more lofty growth. The internal parts of the plantations may have gravel or sand walks, some shady, others open; with here and there some spacious short grass openings, of different dimensions and forms.

It is seldom that extensive lawns in parks or paddocks, &c. have any boundary plantations close to what may be considered as a continuation of them beyond the pleasure-ground, but are sometimes dotted with noble trees, dispersed in various parts, at great distances, so as not to obstruct the view; some placed singly, others in groups by twos, threes, fives, &c. and some placed irregularly, in triangles, sweeps, straight lines, and other different figures, to cause the greater variety and effect, each group being diversified with different sorts of trees, all suffered to take their natural growth. Where final, these kinds of openings should always be kept perfectly neat, by being often poled, rolled, and mown, but where they are of large extent, this is scarcely ever the case. See GRASS, GROUND, and TURFING.

LAWNS, in *Commerce*. See CAMBIC.

LAWOROW, in *Geography*, a town of Austrian Poland, in Galicia; 24 miles W. of Lemberg.

LAWRENCE, PETER JOSEPH, in *Biography*, an engineer, was born in Flanders in the year 1715. He distinguished himself, when he was only eight years old, by a considerable turn for mechanics. Cardinal Pelignac being shewn a machine that he had at that early age constructed, predicted that he would one day arrive at eminence in the science of practical mathematics. Before he had attained to manhood, he had executed drains in different parts of Flanders and Hainault, which till that time had been deemed impracticable. He constructed many curious and very ingenious sluices and locks for rivers and canals; and he invented machines that were found of great utility in fortification, and a carriage on which the colossal statue of Lewis XV. was brought to Paris with great ease. He contrived engines, which at once cleared mines of their water, and, at the same time, raised the metallic ores. He formed a junction of the Scheldt and the Somme, which he effected by a subterraneous canal, three leagues in length, the level of which was 45 feet above the source of the Scheldt, and 15 feet below the bed of the Somme. The various mechanical inventions and undertakings of M. Lawrence have been celebrated in a poem by Delille, intitled, "The Treasury of Parnassus."

LAWSONIA, in *Botany*, dedicated by Linnæus to the honour of John Lawson, a native of North Britain, who visited Carolina, and published an account of his voyage, with much information concerning the plants of that country, at London in 1709, in quarto.—Linn. Gen. 191. Schreb. 257. Willd. Sp. Pl. v. 2. 344. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 2. v. 2. 354. Juss. 331. Lamarck. Illust. t. 296. (Alcanna; Gært. t. 110.)—Class and order, *Oëandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Salicaria*, Juss.

Gen. Ch. *Cal.* Perianth inferior, four-cleft, small, permanent. *Cor.* Petals four, ovato-lanceolate, flat, spreading. *Stam.* Filaments eight, thread-shaped, the length of the petals, and standing in pairs between them; anthers roundish. *Pist.* Germen superior, roundish; style simple, as long as the stamens, permanent; stigma capitate. *Peric.* Berry dry, globose, pointed, of four cells. *Seeds* numerous, angular, with a spongy coat.

Obs. Gærtner, who justly esteems the fruit to be rather a dry berry than a capsule, chuses to call the genus *Alcanna*, a word corrupted from *Al Henna*, the Arabian appellation of the first species.

Eff. Ch. Calyx four-cleft. Petals four, regular. Stamens approaching each other in four pairs. Berry dry, superior, of four cells, with many seeds.

1. *L. inermis*. Henna, or Smooth Lawsonia. Linn. Sp. Pl. 498. Suppl. 219. (L. alba; Lamarck. Dict. v. 3. 106. *L. spinosa*; Hasselq. It. 464. Alienna, five Henna Arabum; Walth. Hort. 3. t. 4. Rauwolf. It. 60. t. 7.)—Thorns none. Leaves obovate, acute. Segments of the calyx as long as its base.—Native of various parts of the Levant. Miller is said in the Hortus Kewensis to have cultivated it in 1759, but it is never preserved long, even in a stove, by our gardeners. The writer of this article obtained seeds in 1787 at Paris, from M. Desfontaines, who had brought them from Barbary. These vegetated at Chelsea, and in some other gardens, producing shrubby plants of a humble stature, which in the ensuing autumn and winter were laden with flowers, whose delicate aspect, and exquisite scent, attracted the admiration of all who saw them. The habit of this species is not unlike Privet, but the leaves are more obovate, and of a lighter green. The flowers are yellowish-white, with purplish stamens, and grow in opposite clusters about the tops of the branches. Hasselquist in his travels, English edition 246, says, "the leaves are pulverized, and made into a paste with (hot) water. They (the Egyptians) bind this paste on the nails of their hands and (soles of their) feet, keeping it on all night. This gives them a deep yellow, which is greatly admired by the eastern nations. The colour lasts for three or four weeks, before there is occasion to renew it. The custom is so ancient in Egypt, that I have seen the nails of the mummies dyed in this manner. The powder is exported in large quantities yearly, and may really be reckoned a valuable commodity. The Arabians call it *Cheenna*. The dried flowers afford a fragrant smell, which women who have conceived cannot bear."

2. *L. spinosa*. Prickly Lawsonia. Linn. Sp. Pl. 498. (Cyprus; Alcanna; Rumph. Amboin. v. 4. 42. t. 17. Mail-anfchi; Rheede Hort. Mal. v. 1. 73. t. 40. Pluk. Phyt. t. 220. f. 1.)—Branches becoming spinous. Leaves obovate, with a small point. Segments of the calyx as long as its base.—Native of the East Indies. It differs from the former, of which many have not unjustly thought it a variety, in having the permanent lateral branches hardened into a spine at their extremities. The fruit answers to Gartner's description of a dry berry rather than a valvular capsule. The leaves seem to vary in shape. Rumphius says they are used to dye the nails in the island of Celebes, &c., and that the Malay women are particularly fond of the flowers, with which they deck their persons and strew their beds. Hasselquist's own specimen, called in his travels, by Linnaeus, *L. spinosa*, proves not to be this plant but the former. Indeed, as we have before hinted, they are most probably but one species.

3. *L. coccinea*. Scarlet Lawsonia. Branches becoming spinous. Leaves elliptic-obovate, acute. Segments of the calyx twice as long as its base.—Sent from Banda by the late Mr. Christopher Smith, as "a *Lawsonia* with scarlet flowers." It is very nearly related to the last, and we find nothing to discriminate this, our specimen being but imperfect, except a difference in the relative proportions of the parts of the calyx, of the certainty or constancy of which we have some doubt.

One might suppose this plant to be the *L. purpurea*, Lamarck. Dict. v. 3. 107, Willdenow's n. 2; but on turning to the *Pouletsjie*, Rheede Hort. Mal. v. 4. 117. t. 57, cited for it, which Linnaeus very erroneously quotes for *L. inermis*, the plant of Rheede will be found widely different

from every *Lawsonia*, as Jusseu well observes, p. 332. The flowers are monopetalous and tetrandrous, with an inferior germen, and this great French botanist suspects it may be a *Pectia*. Of its belonging to his order of *Rubiaceae* there can be little doubt. The *L. purpurea*, therefore, of which Lamarck had seen only leaves, and Willdenow nothing, falls to the ground.

4. *L.?* *Acronychia*. Broad-leaved Lawsonia? Linn. Suppl. 219. Forstl. Prodr. 27. (Acronychia laevis; Forst. Gen. 27. t. 27.)—Leaves obovate, on long stalks. Petals inflexed at the point. Stamens fringed.—Gathered by the Forsters in New Caledonia. A smooth shrub, with round branches. Leaves opposite, an inch or two long, obovate, obtuse, broad, entire, slightly revolute, veiny, smooth. Foxtalks half an inch long, straight, channelled, smooth, united to the leaf by a joint. Clusters axillary, forked, much shorter than the leaves. Calyx with very fine, rounded, pale-edged segments. Petals linear-oblong, hooked inward at the point. Stamens fringed at the base, scarcely so long as the corolla. The fruit is positively described by Forster as "an inflated capsule of four valves." This character, and the totally different form of the petals and calyx, persuade us that the species in question ought to stand as a genus by itself, as Forster originally made it.

LAWSONIA, in Gardening, contains plants of the exotic tree kind for the stove, of which the species are the smooth Lawsonia (*L. inermis*), and the prickly Lawsonia (*L. spinosa*).

*Method of Culture*.—These two plants may be raised by sowing the seeds in pots of light mould, in the early spring, and plunging them in the bark bed of the stove. When the plants have acquired a few inches growth, they should be removed into separate small pots filled with light sandy earth, replunging them in the bark-bed, and giving a little water, with proper shade. They afterwards may be placed so as to have pretty free air, but be constantly kept in the stove at all seasons.

They afford a variety among other stove plants.

LAWYER, (*legista, legisperitus, jurisconsultus*), by the Saxons called *labman*, is a counsellor, or one learned in the law; and lawyers, such as counsellors, attornies, &c. are within the act 3 Jac. I. against extortion; but it has been held only to extend to officers. See COUNSELLOR, ATTORNEY, &c.

LAX, in Geography, a town of Switzerland, in the Valais; 33 miles E. of Sion.

LAXA, a town of the island of Lewis, situated on a bay, on the east coast; 9 miles S.S.W. of Stornamay.—Also, a town of Peru, in the diocese of La Paz; 20 miles S.W. of La Paz.

LAXATIVE MEDICINES, are those purgative or cathartic substances, which operate gently, without producing any considerable discharge from the mucous glands and exhalants of the intestines; such as manna, magnesia, rhubarb, the neutral salts in small doses, sulphur, electuary of senna, &c. For an account of the operation and use of these medicines, see CATHARTICS.

LAXATOR, in Anatomy, a name applied to two muscles of the ossicula auditus. The *laxator tympani major* is the externus mallei of Albinus; the *laxator minor* is simply laxator tympani of that anatomist. The existence of the latter muscle is doubted by some. See the article EAR, where they are described by the names of Albinus.

LAXEMBURG, in Geography, a town of Austria; 7 miles S. of Vienna.

LAXEY BAY, a bay on the east coast of the Isle of Man, in the Irish sea, which affords a shelter from westerly winds,

winds, in about 7 to 10 fathom water. The cape at the southern extremity is called "Laxey Point."

LAXIOR TOGA. See TOGA.

LAXMANNIA, in *Botany*, a name originally given by Forster, in his *Genera*, t. 47, to a syngeneis tree of St. Helena, which Solander considered as a *Banksia*, but which George Forster in his *Plante Atlanticæ*, 56, subsequently referred to *Spilanthus*. We have not discovered it in Willdenow, nor can we ascertain what Schreber decided concerning this plant; but the latter has adopted the name for another genus, of which we are now to speak. It is designed to commemorate the Rev. Eric Laxmann, a native of Finland, Professor at Petersburg, who made many botanical discoveries in Siberia, and died in 1796.—Schreb. 800. Mart. Mill. Dict. v. 3. (Cuminofma; Gært. t. 58.)—Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Aurantiæ*; Juss.

Gen. Ch. Cal. Perianth inferior, very small, of one leaf, bell-shaped, in four roundish segments, permanent. Cor. Petals four, longer than the calyx, linear, coriaceous, equal, spreading, inflexed at the point, marked on the upper side with a triply villosus line. Stam. Filaments six, linear in their lower part, awl-shaped upwards, straight, spreading, rather shorter than the corolla; anthers roundish, incumbent. Pist. Germen superior, roundish, very hairy; style shorter than the stamens, thick, angular; stigma simple, obtuse, furrowed. Peric. Berry nearly globose, of four cells lined with a membrane. Seeds solitary, oblong, compressed.

Ess. Ch. Calyx four-cleft, inferior. Petals four, linear, downy on the upper side. Berry with four cells. Seeds solitary.

1. *L. Cuminofma*. Globose Ankænda. (Cuminofma Ankænda; Gært. Sem. v. 280. t. 58. f. a.—H.)—Fruit globose, slightly depressed. Petals twice the length of the calyx.—Native of Ceylon. Of this we know nothing but from Gærtner, who confounds its synonyms with the following, though he distinguishes it as a species by the shape of the fruit, and relative proportions of the calyx and petals.

2. *L. Ankænda*. Pointed Ankænda. (Cuminofma baccis ovato-acuminatis; Gært. v. 1. 281. Jambolifera; Linn. Zeyl. 58, excluding the synonyms. Ankænda; Herm. Mus. Zeyl. 23. Perin-Panel; Rheede Hort. Mal. v. 5. 29. t. 15.)—Fruit ovate, pointed. Petals many times longer than the calyx.—Native of Ceylon and Malabar. A shrub about four feet high, with round, smooth, leafy branches. Leaves opposite, without stipules, stalked, four or five inches long, and nearly two in breadth, obovate, entire, veiny, smooth and shining, full of pellucid dots. Panicles axillary, stalked, repeatedly three-cleft, corymbose. Flowers greenish-white. Berry ovate, pointed, dark-green, with an aromatic flavour of Cumin.

Mr. Dryander in Tr. of Linn. Soc. v. 2. 232, has well illustrated the synonymy of this plant, which Linnaeus had confounded with the Jambolana, or Jambolains of Acosta, a species of *Calyptanthus*; see that article. This mistake is supposed to have arisen from the tickets of *Madan* and *Ankænda* in Hermann's herbarium having been changed.

LAY, ALLAMPI, or *Alampou*, in *Geography*, a town of Africa, in the kingdom of Niugo, on the Gold Coast.

LAY, or *Lai*, the title of the most ancient kind of songs in the French language. It was not till the reign of Philip Augustus that songs became common in that country. Gautier de Coigny, an ecclesiastic of St. Medard de Soissons, composed a considerable number, which are still preserved in MS. among his other writings. "Lays were a kind of elegies," says M. l'Evêque de la Ravaliere, (An-

cient des Chançons, tom. i. p. 225.) "filled with amorous complaints. The origin of this species of composition is such as rendered it necessarily plaintive: as the word *lai* is imagined to have been derived from *liffus*, Latin, which signifies complaints and lamentations. However there are some lays which describe moments of joy and pleasure more than sorrow or pain; and others upon sacred subjects.

Chaucer, who frequently uses the word *lay*, confines it wholly to songs of complaint and sorrow:

"And in a letter wrote he all his forwe  
In manere of a complaint or a lay,  
Unto his faire freshe lady May."

Cant. Tales, v. 9754.

"He was dispeired, nothing dord he say,  
Sauf in his songes somwhat wold he wray  
His wo, as in a general complaining;  
He said, he loved, and was beloved nothing.  
Of swiche matere made he many layes,  
Songes, complaintes, roundels, virolays—"

Tran. t. 11255.

"Thus end I this complaining or this lay."

Ibid.

In Spencer's time, however, its acceptance was more general, and as frequently applied to songs of joy as sorrow:

"To the maiden's founding timbrels fung  
In well attuned notes, a joyous lay."

Fairy Queen.

Shakspeare and Milton use it likewise indiscriminately for every kind of song.

Lai seems a word purely Francic and Saxon: it is neither to be found in the Armoric language, nor in the dialect of Provence. The French poetess Marie, who in the time of St. Louis, about the middle of the thirteenth century, translated several tales from the Armoric language of Bretagne, calls them *lais*; but the term is of much higher antiquity. After its adoption by the English poets, it soon became a general term in poetry for every species of verse, as song is now: but both these words still retain their particular acceptance as well as general; for by a song is understood a short poem set to a tune, and this was the particular meaning of *lay*, in the last century, among our musical writers.

Tales and songs, says the editor of ancient Fabliaux et Contes François, were the most common and ancient species of poetry. The French, naturally gay, cheerful, and sportive, were more attached to this species of composition than any other nation, and communicated this love for lyric poetry to their neighbours. They must have been in possession of a great number of these songs and tales, because in all social meetings the custom was for every one present either to sing a song or tell a story, as appears by the end of the fable of the priest, "qui ot Mere a force," where we read these verses:

"A cest mots senist cis fabliaux  
Que nous avons en rime mis,  
Pour conter devant nos amis."

And according to John li Chapelain, in his ditty of the Sacrifician of Clugny, it was customary for a bard to pay his reckoning with a story or a song.

"Usage est en Normandie,  
Que qui hebergiez ell, qu'il die

Fable

Fable ou chanson a son oste  
Celle costume pas n'en oste  
Sire Jehans li Chapelains."

" In Normandy a song or tale  
Is current coin for wine or ale;  
Nor does the friendly host require  
For bed and board a better hire."

In the thirteenth century, the songs in vogue were of various kinds; moral, merry, and amorous; and at that time, melody seems to have been little more than plain-song, or chanting. The notes were square, and written on four lines only, like those of the Romish church, in the clef of C, without any marks for time. The movement and embellishments of the air depended on the abilities of the singer. The compass of modern music is much extended since by the cultivation of the voice; for it was not till towards the end of St. Lewis's reign that the fifth line began to be added to the staff. The singer always accompanied himself on an instrument in unison. *Poesie du Roi de Navarre*, tom. ii.

LAY, in *Agriculture*, a term applied to such land as is in the state of grafs, or sward. This sort of ground is frequently dilinguished into such as has been long in the state of sward, and such as is newly laid down to grafs, or into old and new lays. The proper method of managing the latter is of great importance to the farmer, and which, Mr. Young thinks, should be by keeping them perfectly free from all sorts of stock for the following autumn and winter after their being laid down, when, in the spring, they will afford a flow of young grafs highly valuable for sheep, with which they should only be well stocked, and kept down then, and during the whole of the summer: "nothing," in his opinion, "being more pernicious than mowing a new lay, as directed by certain authors. They may," he supposes, "have succeeded in spite of such bad management, but never by it." The most suitable method of managing these new lays, under different circumstances, will be described in speaking of laying lands down to the state of sward or grafs. See LAYING down to Grafs.

It may be observed, that the treatment necessary for old lays must vary much, according to their nature and the particular circumstances under which they are placed, as will be shewn under the management of meadow and pasture lands, as well as in considering the nature of grafs. See GRASS-GROUND, MEADOW, and PASTURE.

It has also been observed, that, on many farms, there are often "tracts of barren lays, from mofs, poverty, neglect, and bad herbage, upon which a very great improvement may be made by a single ploughing in August. For this purpose, a strong four-horse plough must be used with a skim-coulter; then going over it twice, in different directions, with the scarifier, so as not to disturb the flag; harrowing it once, and immediately sowing a quarter of a peck of coleseed, two bushels of cock's foot, and one bushel of Yorkshire white *per* acre; adding some of whatever seeds may be procured at the moment cheaply." It is then advised to be left "unfed and untouched till the March following; in which month, and through April, it should be loaded well with sheep: the use will then be very great. Keeping sheep feeding it heavily through the year, the cole will be killed, and you will have a pasture worth treble what it was before. The expence is said to be small, and the improvement rapid." Various modes of improving land, in the states here described, will be explained under the heads above mentioned.

And the same writer also thinks, that, by December, old lays will be wet enough to begin to break them up: "a

work that should not be done while the land is dry; for it will not then turn up in clean well-cut furrows. Ploughing grafs-land is, it is said, a very good piece of husbandry, when they are worn out and over-run with mofs and other rubbish, or hide-bound. To keep land under such unprofitable turf is bad management. It should, by all means, be broken up, and kept in a course of tillage for three or four years, and then laid down again: by which conduct, four times the profit will arise that could be gained from keeping it in lay."

LAY-BROTHER, among the *Romanists*, a pious, but illiterate person, who devotes himself, in some convent, to the service of the religious.

The lay-brother wears a habit different from that of the religious, nor ever enters into the choir, or the chapter. He is not in any orders, nor does he make any vow, excepting of constancy and obedience.

These lay-brothers make the three vows of religion.

In the nunneries are also lay-sisters, who never enter the choir, &c. and who are only retained for the service of the convent.

The institution of lay-brothers began in the eleventh century. The persons on whom this title was conferred were such as were too ignorant to become clerks, and who therefore applied themselves wholly to bodily labour.

It seems to have taken its rise from hence, that the laity in those days had not, for the generality, the least tincture of learning; whence also those came to be called *clerks*, by way of distinction, who had studied a little, and were able to read.

In some orders they are only retained by a civil contract, which, however, binds them for life; in other orders they are to pass through four years of probation, as among the Jacobins; or seven, as among the Feuillants. The Capuchins admit none before nineteen years of age. The Jesuits call them *coadjutors*.

LAY-Canon. See CANON.

LAY-Communities. See COMMUNITY.

LAY-Corporation. See CORPORATION.

LAY-Fee, *feodum laicum*, land held in fee from a lay-lord, by the common services to which military tenure was subject, as distinguished from the ecclesiastical holding in *frank-almoign*, discharged from those burdens.

LAY the land, in *Sea Language*. See LAND.

LAY-patronage. See PATRONAGE.

LAYS, *vide*. See SIDE-lAYS.

LAY, *vaunt*. See VAUNT-lay.

LAYAU, in *Geography*, a town of the island of St. Vincent, on the W. coast, in a bay at the mouth of a river, to both of which it gives name. N. lat. 13° 8'. W. long. 61° 18'.

LAYBACH, a town and capital of Carniola, on a navigable river of the same name, dividing it in such a manner, that part of the town lies in Upper, and the other in Lower Carniola. The citadel is ancient and has a church; it is inhabited by a countable, who has the title of burgrave, and 12 foldiers. Laybach is the see of a bishop, who is a prince of the empire. The town contains, besides the cathedral, several churches, and about 500 houses; 28 miles N.E. of Trieste. N. lat. 46° 12'. E. long. 14° 30'.

LAYCOCK, or LACOCK, a parish, formerly a market-town of Wiltshire, England, is seated in a fine, fertile valley, on the western bank of the river Avon, three miles from Chippenham, and 95 west of London. In the year 1800 this place contained 147 houses, and 1408 inhabitants. Here was formerly an abbey of large extent, and rich endowment. A large pile of the old buildings still remains in their former monastic

monastic style; particularly the cloister, kitchen, cellars, gallery, &c.; with the fish-ponds and terrace walk. At the S.E. angle of the building is a tower, which contains, among other records, an original copy of the Magna Charta. See Blackstone's "Dissertation on Magna Charta," &c. Some account of the abbey, with a view of the cloisters, is published in "The Architectural Antiquities of Great Britain," vol. ii.; and a full description of the place, and other objects in the vicinity, will be found in Britton's "Beauties of Wiltshire."

**LAYDE**, a town of Africa, in the country of the Foulis, on the Senegal; 45 miles S.E. of Goumel.

**LAYER**, in *Building*. See **COURSE**.

**LAYER**, in *Gardening*, the young shoot or branch of such trees as are capable of being raised by being laid into the ground. It is the part which is placed in the earth in order to strike root, and from the new plant layers are made from different kinds of shoots and young branches, according to their natures and habits of growth.

**LAYERING**, the act of placing layers into the ground. This is performed in different ways, as may be seen under the proper head. See **LAYING**.

**LAYES**, or **LEYES**, a term used in many parts of England for such pasture ground as has been formerly tilled and sown.

**LAYING**, in *Gardening*, the process or operation of placing layers in the soil. It is a method adapted to most sorts of trees and shrubs, and many herbaceous plants. It is effected by laying branches and young shoots of trees and plants in the earth, from two or three to five or six inches deep, leaving their tops out, that the part laid in the earth may emit roots, and become a plant. The layers, when well rooted, should be separated from the parent, and planted in the nursery, or other proper place, to acquire due strength and size, for the purposes for which they are designed. And they require different lengths of time for becoming rooted, from a few months to two or more years.

There are great numbers of shrubs and trees that are capable of being increased by layers, but the practice is more particularly applicable to the shrubby kind; as their branches grow near the ground, convenient for being laid down. It may, however, be practised with success on fruit-trees and forest-trees, when their branches are situated low enough for being laid, though the varieties of many fruit-trees are better propagated by grafting and inoculation. The vine and fig, however, often admit of being increased by layers; and forest-trees, for the continuance of varieties; as the plants raised in this method continue exactly the same as the parent plant from whence they were raised. This is a certain method to continue any approved variety, as well as to increase such shrubs or trees as do not produce seeds here, and which cannot be easily obtained. It is likewise an expeditious and easy mode of propagation; as by it many new plants are often raised in a few months, which would take two or three years to bring them to the same size from seed. In many sorts it is so easy that all the shoots of any branch situated near the ground, or convenient for laying down, may be made distinct plants.

It may be noticed that, for all sorts of the tree or shrub kinds, it is generally performed on the young shoots of the preceding summer, which should be laid down in spring or autumn; but sometimes on shoots of the same year, in summer, especially in the hard-wooded evergreen trees and shrubs, that do not strike root readily in the older wood. Many sorts of trees that have their wood of a loose soft texture often grow pretty freely by layers of them, of two or several years growth.

But in herbaceous plants capable of being propagated by layers, such as carnations, pinks, double sweet-williams, &c. the young shoots of the same year, laid down in June and July, are commonly the most successful.

In regard to the season for performing this sort of work, in most sorts of trees and shrubs, it is autumn and spring, though it may be performed at almost any time of the year.

Many kinds of under-shrubby and herbaceous plants also succeed, if layed any time in spring or summer till the end of June; though that and the following month are the most successful for the herbaceous tribe, as carnations and others usually propagated by laying, as they then root the same season in from three or four to five or six weeks, so as to be proper for transplanting.

When it is intended to lay trees or shrubs that naturally run up to stems, without furnishing any considerable quantity of lower branches for laying, a sufficient number of strong plants should be set in the nursery, at proper distances, and headed down in the autumn or spring after, within a few inches of the ground, that they may throw out a good quantity of young shoots the following summer, near the earth, so as to be convenient for laying down in the succeeding autumn; or, by waiting another year many more shoots for the purpose of layers will be provided, by the first shoots throwing out many lateral ones, each of which when layed will form a plant. And on the layers being rooted, and all cleared away, the stool remaining will furnish another crop of shoots for laying next year, and the same in succession for many years.

Where layers are wanted from trees that are grown up, and whose branches are at a distance from the ground, a temporary stage or scaffold is erected, on which pots or tubs of mould are placed to receive the layers.

The general method of merely laying the branches or shoots in the earth, is practised for all sorts; but previous to laying, they are often prepared in different ways to facilitate their rooting, according as the trees of different natures require; as by simple laying, twisting, flitting, cutting the bark, piercing the shoot, wiring, and other modes.

*Simple Laying*.—This is merely laying the shoots in the earth, as directed below, without any previous preparation of twisting, flitting, &c. and is sufficient for a great number of trees and shrubs of the soft-wooded kinds; but for such as do not readily root by this simple method, recourse must be had to some of the following ways.

*Twisting the Layer*.—By giving the shoot a gentle twist in the part designed to be laid in the ground, it greatly promotes and facilitates the emission of fibres from the bruised part.

*Slitting or tonguing the Layer*.—This is the most universal and successful mode, where any preparation of the shoot is necessary to promote its rooting; it is performed by flitting the shoot at a joint underneath, up the middle, half an inch or an inch or more long, according to the size and nature of the layer, forming a sort of tongue nearly the same as directed for carnation layers; laying that part in the earth, and raising the top upright, or rather pointing inwards, so as to separate the tongue of the slit from the other part, and keeping the slit open, as directed below.

*Cutting the Bark of the Layer*.—This is performed by cutting the bark all round at a joint, taking out small chips all the way below the cut, and laying that part in the earth, by which it readily emits roots.

*Piercing the Layer*.—This is done by thrusting an awl through the shoot, at a joint, in several places, laying that part

## L A Y I N G.

part in the ground, by which it will emit fibres from the wounds more readily.

*Wiring the Layer.*—This is by twisting a piece of wire hard round the shoot at a joint, and pricking it with an awl on each side of the wire in several places, laying it in the earth, by which it breaks out into roots at the confined and wounded parts; often proving successful in such trees and shrubs as do not readily emit fibres by the other methods.

It may be observed that by some of these methods almost all sorts of trees and shrubs may be propagated.

*Method of Laying.*—The general method of laying all sorts of trees or plants, either by simple laying, or any of the other methods, is the following.

The ground about each plant must be dug for the reception of the layers, making excavations in the earth to lay down all the shoots or branches properly situated for the purpose, pegging each down with a hooked stick, laying also all the proper young shoots on each branch or main shoot, fixing each layer from about three or four to six inches deep, according to their length, though some shorten their tops down to an eye or two only above the earth, raising the top of each layer somewhat upright, especially the slit or tongued layers, to keep the slit part open. As all the layers of each plant or stool are thus layered, all the mould should be levelled in equally in every part, close about every layer, leaving an even smooth surface, with the top of each layer out.

It sometimes happens that the branches of trees are so inflexible as not to be easily brought down for laying; in which case they must be plashed, making the gash or cut on the upper side; and when they are grown too large for plashing, or the nature of the wood will not bear that operation, they may be thrown on their sides, by opening the earth about the roots, and loosening or cutting all those on one side, that the plant may be brought to the ground to admit of the branches being laid down into the earth.

Where layers are to be made from green-house shrubs, or other plants in pots, the work should generally be performed in pots, either in their own, or others placed for that purpose.

After laying in either of the above methods, there is no particular culture necessary, except in the heat of summer giving occasional waterings to keep the earth moist about the layers, which will greatly forward them, and promote a good supply of roots against autumn, when those that are properly rooted should be taken off and transplanted.

The layered branches or shoots should be examined at the proper season, October and November, and those that are rooted be cut from the mother plant, with all the root possible, planting them out in nursery rows a foot or two asunder, according to their nature of growth, there to remain till of due size for their several purposes; but those of the tender kinds must be potted, and placed among others of similar nature and growth.

When the layers are all cleared from the stools or main plants, the head of each stool, when to be continued for furnishing layers, should be dressed; cutting off all decayed and scraggy parts, digging the ground about them, working some fresh mould close about their heads, to refresh and encourage their producing a fresh supply of shoots for the following year's laying down. This sort of care preserves them many years.

*Laying-down to Grass, in Agriculture,* the means of bringing such land as has been under the plough into the state of grass or sward. This is a part of husbandry which is of much importance to the farmer, and which requires much care and attention to accomplish it in a proper manner,

under different circumstances of soil, climate, situation, and preparation of the ground. It is well known by practical farmers that some sorts of soil are much more difficult to be brought into the state of good grass or sward than others, and that, when this point has been accomplished, some are much more profitable and advantageous than others, as affording a much better, and more lasting herbage. In some places, too, the business of bringing the land into the state of sward, after it has been in that of arable cultivation, is effected with the greatest ease and facility: the ground, on being left in an unploughed condition, from its natural tendency to the production of herbage, returns to the state of sward, almost without trouble, seed, or expence; while in others, all the art of the most careful agriculturist is found insufficient for accomplishing the purpose. It has been stated by Mr. Davis, that “after twenty years fruitless expectation and expence, the landholders have frequently been obliged to restore the land again to a state of tillage.” But besides this disposition or tendency in soils for taking on the growth and establishment of grass crops, there are other circumstances to be attended to in bringing them to the state of grass or sward, after they have been under the plough; such as those of their possessing neither too much nor too little moisture, and that of their having a sufficient staple or depth of mould for the full and secure establishment of the grass plants. As where the soils are too wet, or too retentive of moisture, they will sustain much injury, if not be wholly destroyed, during the winter season, when there is much rain and frost, as well as be quickly superfered by plants of the coarse aquatic kind, such as the rush, &c.

And where they are too dry, the grasses will be liable to be destroyed by heat during the summer months, by the little moisture which they contain being thus carried away, and of course leave their places to be supplied by other sorts of coarse plants, such as those of the moss, fern, and heath kinds, according to the nature of the ground. A good depth of mould or soil is likewise requisite, in order that the roots of the grass plants may penetrate or run down to such a depth below the surface, as to be in a great measure out of danger from the effects of heat and evaporation in the summer season. On these as well as other accounts, it is therefore better that the lands intended for grass, especially where they are to be kept in a permanent state of sward, should incline in some measure to a state of moisture, or be in such a degree retentive of it, as to preserve that state of humidity which is necessary for the healthy and vigorous growth of the plants, without endangering the destruction of their roots by putrefaction, from its stagnating in too large a proportion about them. It is chiefly on this principle, it is added, that the more light, thin, dry, descriptions of soil are better suited for the production of grain, or the occasional practice of convertible husbandry, than for that of permanent grass or sward.

And there are still other circumstances connected with the nature of the soils, which are necessary to be particularly attended to in the laying of lands down to the state of grass, as those of properly adapting the grass plants to their qualities, some sorts of grasses being much more impatient of wet than others, consequently more proper for the drier sorts of lands; some more capable of resisting the effects of heat and drought, and of course more suitable for the thinner and more porous kinds of soil: while others delight in a moist or wet soil, and are incapable of being grown with any success, on such as are of a dry quality. They likewise differ much in respect to their hardness; some resisting the effects of cold much more effectually than others, and of course more adapted to high exposed situations. Besides these,

these, they vary in other respects, some succeeding to the most advantage in soils of the clayey kind, others in those of a loamy quality, while others delight in those of a sandy nature, a few in those of the calcareous kind, and some in those which partake much of the nature of peat.

In addition to these different natural propensities, there are some grasses that have the property of rising to a great height in the stem, and of course affording a large coarse produce, while others are more limited in this respect, but spread and extend themselves more in a lateral direction, affording a less proportion of produce, but which is of a finer quality. The former, with certain restrictions, would seem better adapted to the purpose of hay, though the latter may be applied to the same use, where the fineness of quality is preferred to quantity of produce. There are likewise some sorts of grasses that contain much larger proportions of saccharine matter in their compositions than others, as well as more leaves and fewer flower stems; and which, from the avidity with which they are fed upon by different sorts of live stock, and the success that attends their being thus consumed in the improvement of such stock, would appear to possess the largest proportion of nourishment; and of course to be the most proper for being introduced where the lands are intended for the purpose of grazing, or fattening animals by means of vegetable food in its grassy state. And further, there is another property of grasses in which they differ considerably; and which is of so much consequence as to require being regarded in the laying of lands to the state of sward. This is that of early growth, which is a circumstance of vast importance in a grazing point of view, as there is in general a great deficiency of grass for the support of stock in the early part of the spring. See *Practical AGRICULTURE*.

It is the opinion of Mr. Curtis, that in the forming of good meadows, or other grass-lands, there should be a combination of these different circumstances, as it is chiefly by the sward, or the quantity of produce, that the cultivator is enabled to support his live stock, and pay his rent; of course no expence in labour or manure is spared to obtain it by the prudent farmer. It does not, however follow, that this should be solely regarded, or that to attain it the coarsest sorts of plants should be cultivated; nor will the grasses that are recommended merely for their being relished by cattle, or for the sweetness of their foliage, if they are found to be deficient in the quantity of produce, fully answer the views of the farmer or grazier, as, to constitute a good meadow or pasture, an abundant produce is necessary. And that, though animals prefer some sorts of food to others, it is not possible to indulge the live stock that is to be supported constantly with the finest and most delicate hay or herbage. Besides, it is not improbable but that the productive grasses may in some cases be highly nutritious, or that cattle may eat as eagerly the herbage or hay made from the coarse as the fine grasses. And cattle are frequently known to thrive on food to which they are habituated by necessity, though at first they could scarcely be prevailed on to eat it. It is suggested, that in making experiments, persons are apt to conclude too hastily from the appearance which a plant assumes on its being first planted or sown; as the most insignificant plant or vegetable will often make a great show, when its fibres have fresh earth to shoot into: "but the trial comes when the object of the experiment has been in a meadow or pasture several years, when its fibres, from long growth, are matted together, and it meets with powerful neighbours, to dispute every inch of ground with it;" if "it then continue to be productive, it must have merit." It is well known, that "lucern, when left to itself, is soon

overpowered; and if broad-leaved clover, which is undoubtedly a perennial, the first year be sown, a great crop is produced; but let the field be left to itself, and the clover, like the lucern, will yearly diminish,—not because it is a biennial, as has been often supposed, but because plants hardier, or more congenial to the soil, usurp its place: this shews, "that at the same time that a good plant is introduced, it should be a powerful one, and such as is able to keep possession, and continue to be productive." Further, that "in respect to the property of cattle's thriving on the food they eat, it is unquestionably of great consequence; and it is to be regretted, that our knowledge of the most nutritious kinds of herbage is so confined: but of those plants which have been in cultivation, we are enabled to speak with some certainty: it is well known, that "clover, lucern, sainfoin, tares, and several other similar plants, have a great tendency to fatten cattle; but what natural grasses, or other plants, which have not been subjected to separate culture, have this particular tendency, and in what degrees, remains to be ascertained by the test of experiment." But, "that as leguminous plants are in general found to agree with cattle, it may be reasonably concluded, that a certain quantity of them may be proper and beneficial in pastures. It is well known that certain pastures are more disposed to fatten animals than others: but how far this depends on situation, and their particular produce, remains to be ascertained." With respect to the property of early growth, it is suggested that the "want of early herbage in the spring is the general complaint of farmers and graziers in all the best grass districts of the kingdom: those plants, therefore, which are found to shoot at an early period, and to put forth early foliage, especially when it is such as is grateful to cattle, must be deserving of great attention. As far as grasses have to do in this business, those mentioned hereafter may effect all that can be expected in this way: much must, however, depend on seasons; if the winter should be severe, or north-easterly winds prevail in the spring months, grassy herbage will be backward, in spite of all that can be done; but in order to counteract the bad effects of such seasons as much as possible, pastures and grass-lands should be warmly situated, and not drenched too much with moisture, being sheltered by thick hedges, and divided into small inclosures." But where early pasturage is the great object of the farmer, there are other plants that may deserve a place among them, such as those mentioned below. And that "though early herbage is highly valuable for pasturage, it is not less so for the purposes of hay; as by the middle of May at the latest, a meadow of this sort would be fit for cutting; and the second hay-making begin by the time that hay-making usually takes place in other cases; and by this means the double advantage be obtained, of a larger produce, and less risk in securing or making it."

It is stated in a late work on *Practical Agriculture*, that "on the principles that have been already explained, there can be little doubt but that by a judicious and due attention to the different circumstances and uses for which grass-lands are intended, as well as to the selecting and mixing of the best and most proper grass-seeds, and adapting them to the particular nature and circumstances of the soils, after they have been brought into a suitable condition for receiving them, those grounds which have been in a state of tillage may be laid down to the state of sward, in a much better and more beneficial manner than has been the case under the indiscriminate use of such as were in, or which have sown themselves on the lands from the contiguous pastures." It has "been long since remarked as extraordinary, by Mr. Stillingfleet, that cultivators should have neglected

to make a proper advantage of plants of such importance, and which, in most situations, constitute the principal food of live stock, from the want of properly distinguishing and selecting such as are the most advantageous and useful under different circumstances of the land." Some have likewise contended, that "the best grass-seeds cannot be collected at too high a rate; as it is possible, by such means, to render lands, which are suited for the production of grass, much more valuable than can be done by the common modes of laying them down."

It cannot, however, but be confessed that much difficulty has been thrown in the way of introducing the most proper sorts of grasses, in laying lands down to sward, from their near resemblance to each other, in many instances, requiring the nicest discernment to distinguish them, and from the want of other means of procuring them."

It has been stated by Mr. Curtis, in his tract on Grasses, that "if grass-lands, such as downs, pastures, and meadows, be carefully examined, they will all, except such as have been recently laid down with rye-grass or clover, be found much in a state of nature, replete with an indiscriminate mixture of plants, some of which produce cattle food of a good kind, others such as is of a very indifferent description; some affording good crops, while others scarcely yield any thing at all." And in the system of Practical Agriculture it is suggested as sufficiently obvious, "that by a careful attention to the procuring of the best and most suitable sorts of grass-seeds, and applying them according to the principles which have been given above, much superiority may be attained in the forming of pasture, or other sorts of grass-lands." See GRASS.

*Method of Preparation of the Land.*—The proper preparation of land for grass-seeds is a part of management, according to the same writer, "that is of vast importance to the success of forming good grass-lands, but which has been much neglected in the practice of laying them down. From the smallness of the seeds, and the fibrous nature of the roots of the grass-plants in most cases, it is evident that lands which are intended for being laid down to the state of sward, whatever their quality may be in respect to soil, should constantly be brought into as fine a state of pulverization and mellowness as possible, before the seeds are put in: as where the contrary is the case, from the lumpiness of the surface mould, the seeds can neither be sown with so much regularity, vegetate in so equal a manner, or extend their roots, and establish themselves at first so perfectly in the land, they are of course more liable to be destroyed by hot seasons coming on afterwards. It is probable that in this way much new laid down grass-land is greatly injured the first summer, especially when it turns out to be hot and dry. The necessary fineness of mould may be obtained in different modes, according to the nature of the lands. In the more stiff and heavy ones, by ploughing before winter, and leaving them to be exposed to the action of frosts and other causes during that season; having recourse to severe harrowing, and occasional rolling, in the early spring months; and by the frequent interposition of such sorts of crops, in the courses that precede those of grass, as have a tendency, from the peculiar nature of their roots, to loosen and render the soils fine, such as those of the bean, cabbage, rape, and clover kinds. The lighter sorts of land may be brought into a proper condition for the reception of grass-seeds, by repeated ploughing and harrowing, or scuffing, and the frequent introduction, in the previous crops, of such sorts of green fallow crops as have a power, by the great degree of shade and stagnation which they afford, as well as by the culture which they require while growing, of bringing the

soil into a fine friable state. These are turnips, potatoes, tares, saintfoin, and others of a similar description." It has been contended by Mr. Clofe, "that where the grass-seeds are to be put into the ground with grain crops in the spring, the tillage should be performed with more than ordinary attention; which, in the case of turnips, will depend greatly upon their being consumed at such an early period as will admit of the ground being thoroughly broken down and reduced; for if there be much delay, and the season prove unfavourable, a bed of mould, sufficiently loose and mellow, will not be procured for the reception of the seeds: and when grown with spring corn, the lands should be ploughed over three times; and where the first of these earths can be given early enough to be influenced by the vernal frosts, it will be found to be much more beneficial." The use of the harrow and the roller will be occasionally necessary, after the different ploughings, according to the nature and state of the land. "But when the sowing is executed in August, the same degree of attention is not believed by the Rev. Mr. Young to be so necessary, as the time and season afford so full an opportunity of bringing the ground into suitable order, that the most inattentive cultivator can scarcely experience any other difficulty than what originates from an unusual wetness of season."

In the System of Practical Agriculture noticed above, it is mentioned that, "besides this fineness of preparation in the soils, it is necessary that the method of cropping and application of manure in the preceding courses be such as to leave them in a state of high fertility and richness; as no good grass-land can be supposed to be produced, where the lands have been worn out and exhausted by the previous crops:—a practice which has, however, been too general in the returning of arable lands to the condition of grass. Mr. Marshall has, he says, indeed very justly observed, that the want of proper condition in the lands at the time of their being laid down to sward, added to those of improper sorts of grasses and bad seeds, is the chief cause of their not succeeding." According to some cultivators, "manure ought to be applied with every other crop, and always with that which immediately precedes the grass. This is," he says, "a practice that should be adopted as much as possible." And "in order to have grass-lands of the best kind, it is likewise of great utility to have them so managed in the preparation, as to be rendered perfectly clean and free from all sorts of weeds; as by their rising with greater rapidity than the sown grass-plants, they are often liable to shade and destroy them, or greatly injure their growth."

And it has been advised by Mr. Billingfley, "in restoring old worn-out lands to the state of good pasture, to clear the land from injurious weeds by means of a full winter and summer fallowing; or, instead of the latter, by a crop of potatoes, well manured for, and kept in a perfectly clean state by attentive culture while growing, succeeded by winter vetches fed off in the early spring." And "in all the more light sorts of soil, it is unquestionably the most beneficial practice to bring the ground into that sort of fine tilth, which is proper for the reception of grass-seeds, by a judicious mixture of green crops of different sorts with those of the corn kind, according to the nature of the soil." The most appropriate methods of combining and intermixing these with each other are fully explained in considering the modes of cropping different sorts of ground. See *Course of Crops, and Rotation of Crops.*

Further: "when the lands have been, by these methods, brought into a good state of fertility, and reduced into a sufficiently mellow and friable condition of mould, the surface should be made as fine, loose, and even as possible"

## L A Y I N G.

And that "where the grounds are much inclined to moisture, the ridges may be preserved, which should be of considerable breadth, with very slight furrows; but in the more light and porous descriptions of land, the whole should be laid as even as possible, without any ridges or furrows. In the former cases, in some districts, they prefer making the ridges six, eight, or more yards in breadth; which, when the land is to be under the scythe, is in a much better state for being mown; and if for pasture, there will be less danger of the animals being injured by being cast in the furrows. But in the latter, the surface will not only be more agreeable in its appearance, but be more advantageous for all the purposes of grass management," when thus laid down.

*Most proper natural Grasses.*—In respect to the kinds of natural grasses, the circumstances that have been observed above render it sufficiently plain, that the proper choice and application of grasses must be a matter of great consequence, in the laying down lands to the state of sward or herbage.

In fact, it is, according to the author of Practical Agriculture, "a business attended with uncommon difficulty, from the number of trials that have been yet made being very inadequate for affording the means of fully deciding

upon their properties, advantages, and uses, in many cases, as well as from their habits, and the soils to which they are the best suited, being often very imperfectly known; and also from the great trouble and inconvenience of obtaining their seeds genuine, and in a proper state of healthy vegetation."

But it is suggested that the plants of the natural grass kind, which have been found by experienced cultivators most useful in the different intentions already mentioned, are "the sweet-scented vernal grass, meadow fox-tail grass, smooth-stalked meadow grass, rough-stalked meadow grass, meadow fescue grass, hard fescue grass, tall fescue grass, crested dog's-tail grass, ray or rye grass, Yorkshire white, cock's-foot grass, tall oat grass, timothy grass, yarrow, burnet, white clover, trefoil, cow grass, rib grass, and a few others;" most of which will be found useful in laying lands to grass, under different circumstances of soil, situation, moisture, and dryness. See GRASS, and these several heads.

The Rev. Mr. Young, in the third volume of Communications to the Board of Agriculture, advises the varying of grass-seeds, according to the nature of the soil, in this way:

### Soils and Seeds.

Clay.	Loam.	Sand.	Chalk.	Peat.
"Cow-grass.	White clover.	White clover.	Yarrow.	White clover.
Cock's-foot.	Ray.	Ray.	Burnet.	Dog's-tail.
Dog's-tail.	York white.	York white.	Trefoil.	Cock's-foot.
Fescue.	Fescue.	Yarrow.	White clover.	Rib.
Fox-tail.	Fox-tail.	Burnet.	Saintfoin.	York white.
Oat-grass.	Dog's-tail.	Trefoil.		Ray.
Trefoil.	Poa.	Rib.		Fox-tail.
York-white.	Timothy.			Fescue.
Timothy.	Lucerne.			'Timothy.'

With regard to the proportions or quantities which are necessary per acre, it is hinted, that "in situations where women and children are fully employed, it may be difficult to procure large quantities gathered by hand: in such places a man must be content with what can be bought. Credited dog's-tail is so very generally to be thus procured, that he cannot but suppose it in a good measure at command.

However, without adverting to this point, he may remark, that from the lands which he has laid down to grass to a considerable extent, and in which he has used every one of these plants largely except the poa, and that on a smaller scale, he is inclined to think that the quantities stated below may be safely employed."

### Soils and Seeds.

Clay.		Loam.	
Seeds.	Substitutes.	Seeds.	Substitutes.
"Cow-grass - - - 5lb.		White clover 5lb.	
Trefoil - - - 5lb.		Dog's-tail 10 lb.	Ray - 1 peck 5;
Dog's-tail - - 10lb.	Yorkshire white 2 bush.	Ray 1 peck.	Rib-grass 4lb.
Fescue - - - 1 bush.	Timothy - 4lb.	Fescue 2 do.	Yorkshire white
Fox-tail - - - 1 do.	Do. - 4 do.; or,	Fox-tail 3 do.	Timothy 4lb.
	Yorkshire white 1 bush.	Yarrow 2 do.	Cow-grass 5lb.

Sand.		Chalk.	
Seeds.	Substitutes.	Seeds.	Substitutes.
White clover 7lb.		Burnet - 10lb.	
Trefoil - 5lb.		Trefoil - 5 lb.	
Burnet - 6lb.		White clover 5 lb.	
Ray - 1 peck.		Yarrow - 1 bush.	Ray - 1 bush.
Yarrow = 1 bush.	Ray 1 peck. Rib 4lb.		

## LAYING.

Seeds.	Peat.	Substitutes.	
White clover	- 10lb.		
Dog's-tail	- 10 lb.	Yorkshire white	6 pecks.
Ray	- 1 peck.		
Fox-tail	- 2 do.	Rib	5lb.
Fescue	- 2 do.	Cow-grafs	4lb.
Timothy	- 1 do."		

*Method of sowing Grafs-seeds.*—In respect to the time and manner of sowing grafs-seeds, they are different in practice according to the preparation and the particular circumstances of the land. The most usual period of putting in grafs-seeds has been the spring, at the time the grain crops are sown: but where the land has been brought to a suitable state of preparation by means of green and other fallow crops, the latter end of the summer, as about August, has been the more general time. In the former case they are most commonly put in with the grain crops; but in the latter without any other sort of crop. The author of the System of Practical Agriculture remarks, that "there has been much diversity of opinion among agricultural writers with regard to the superior utility of these different seasons of introducing the seeds, as well as with regard to their being sown with or without other sorts of crops. The advantages of the autumnal over those of the vernal sowings are contended to be, those of the grafs-plants being less exposed to danger from the shade, closeness, and choking, that must necessarily occur at the latter season, there being less risk of flocking the ground with noxious weeds in case of the seeds of hay-chambers being indiscriminately sown; their being put in upon a better preparation and more mellow and fertile state of the land; their growth being more strong and vigorous from their not being robbed of their proper nourishment by other exhaulting crops, and the great superiority of the hay produce: while, on the contrary, it is maintained in support of the vernal sowings, that besides their being less precarious, shade is necessary in the early growth of the grafs-plants to protect them from the effects of heat; the moisture is better preserved in the soil for their support; small annual weeds more effectually prevent it from rising to injure them; and the loss the farmer must sustain from the want of grain crop guarded against."

But in regard to the objection on the ground of weeds being produced, Mr. Clofe has remarked, that "sowing rubbish in August is not of so great importance as in the spring. In the former season all the annual seeds vegetate, and if the beginning of the winter be mild, they will blossom; but they cannot perfect their seeds, and thus stock the land with noxious weeds."

Upon which the first of these writers observes, that "though some of the arguments urged on both sides of this controverted point may be objected to, the autumnal sowings not preventing the perennial weeds from rising and seedling their seeds in the following summer, nor the great closeness of grain crops being without injury to the growth of the young grafs-plants; there are facts which render it probable that each method may have advantages under particular circumstances. In the more southern districts, where the severity of the winter season is later in its approach, the autumnal season may frequently be made use of with advantage, after fallow crops, for sowing grafs-seeds, especially in cases where the lands are in too rich a condition for the successful growth of corn. But in the more northern

parts of the kingdom, and exposed situations, where the frost sets in at an early period, it may be in general the most advisable practice to put the seeds in, in the vernal months, with suitable crops of the grain kind." And the Rev. Mr. Young has observed, that "grafs-seeds answer almost equally well in either method: he prefers, however, the August sowing without corn, though the success of his trials in the different seasons has not justified any decisive conclusion." It is even admitted, that "in moory and mountainous situations, where the snows come early, autumnal sowings are not advisable, or to be performed later than the very early part of August; the vernal season with oats, for being cut young for foiling or hay, is constantly to be preferred." Mr. Dalton, in Yorkshire, after trying other methods, also recommends the autumnal season without corn as the most advisable. And the Rev. Mr. Clofe states, that "a friend of his, wishing to procure good meadow or pasture around his house, fallowed the land for barley; but the spring proving wet, and the soil being a strong loam, he could only put half of it in order for that crop, which was sown and laid with clover and rye grafs. The other part was fallowed and sown in August with the sweepings of hay-chambers. The barley was a good crop, and the clover and rye-grafs were probably equal to the first year's cut of hay. The second year the artificial grasses began to fail; worse the third, fourth, and fifth; the sixth year, after having received two dressings, the spontaneous product of the soil began to give a fleece over the surface of the land. About ten years after these lands were sown, Mr. Clofe saw this field, when the part sown in August was worth at least fifteen shillings per acre more than the part which had been sown with artificial grasses in the barley. Thus from actual experiments, numbers of which he could adduce, he concludes that sowing the sweepings of hay-chambers in August, is preferable to sowing any artificial grasses in the spring with any crop of corn. Suppose the corn worth five pounds per acre, the difference in the produce of hay or feed in the second, third, fourth, and fifth years, would more than counterbalance this; and the proprietor would find a permanent improvement in his land of from fifteen to twenty shillings per acre." Mr. Young thinks, the best season in the whole year for this purpose is August, and the only one admissible for it on strong, wet, and heavy soils, in forty years' experience having never failed at that period. It is stated in the System of Practical Agriculture already noticed, that "on comparative experiments being made with corn in the spring months, and without it in August, the latter was found by much the best mode by different cultivators." But that in the experiment of an accurate agricultor, mentioned by the Rev. Mr. Young, in his paper in the communication to the board, "in comparing different methods of vernal sowings, in which four acres were sown with seeds alone, on pease and buck-wheat ploughed in the preceding autumn; five acres with barley, and five more with the seeds put in alone without corn or manure: the portions sown alone were over-run with weeds, and only preserved from being smothered and destroyed, by being eaten down by a dairy of cows." And others, after repeatedly trying the experiment of sowing in the spring with corn, and the autumn without, and from long and extensive practice, conclude, "that, even if we were to have no regard to any other circumstance, except the grafs crop alone, it would be always best to sow it with some kind of grain; but when we consider likewise the loss that the farmer thus sustains for want of a crop of grain, the practice of sowing alone must be looked upon as highly pernicious to the farmer."

And he supposes, that it is probably in this last respect that the greatest disadvantage of the practice consists, as without it the farmer can derive no immediate recompense for his great expence of tillage and preparation of the land."

In cases where the vernal sowing with other sorts of crops had recourse to, barley is that, according to Mr. Cartwright, which is most usually recommended, and "there seems to be no question that barley is in general the fittest grain to be sown with grass-seeds. The same tillage which answers for the one is requisite for the other. Barley has a disposition to loosen the texture of the ground in which it grows; a circumstance highly favourable to the vegetation of grass-seeds, which require a free and open soil to extend their roots in; the tender and delicate fibres of which have much difficulty in contending with the resistance of a stubborn soil. And this points out the reason why grass-seeds so frequently fail on strong land not in a proper state of cultivation. In the choice of barley, that sort should be preferred which runs least to straw, and which is the soonest ripe." But the writer of the System of Practical Agriculture observes, that as from the grassy nature of the stem, and the large size of the ear in this sort of grain, a considerable degree of closeness and shade must constantly be kept up, it should never be sown so thickly as in other cases where there are no grass-seeds. Some object to sowing grass-seeds with barley on other principles, as those of its drawing its nourishment from the surface, which is also the case with the grass-plants, and that in consequence they must be greatly retarded in their growth from the want of due support. Where the land is in a proper state of preparation and tillage, if sown with oats, they will be apt to become so luxuriant as to greatly injure, if not wholly destroy, the young grass-plants by the closeness of their shade. In some cases they, however, succeed tolerably with this sort of crop. On the stronger kinds of land the sowing of grass-seeds has been found to answer well with thin crops of beans. In an experiment of this kind, it is stated that Mr. Dalton found that the beans did not "rob, but sheltered and nourished the grass-plants, the plan answering beyond expectation."

It is suggested, that in order to effect the purposes of distribution and perfect vegetation in the most complete manner, the seedman should "be accustomed to the business, and the seeds, as being of different weights, &c. as little mixed with each other as possible. It is much better to have more casts than to blend the seeds together for the sake of dispatch. For all the smaller sorts of seeds, it has been supposed by the Rev. Mr. Young, preferable to deliver them by means of the Norfolk turnip trough, which has lately been adapted to clover and ray-grass. And this operation should always be performed as soon after the land has been ploughed as possible, as under such circumstances the seeds vegetate in a much more quick and vigorous manner. But it should never be attempted in such a wet state of the land as produces any great degree of tenacity or adhesiveness in the mould, as in such circumstances the seeds would be apt to come up in a tufty unequal manner. Nor for the same reason should the lighter sorts of grass-seeds ever be sown in windy weather; as the delivering them in an equal and regular manner is a point of consequence to the forming of good grass-land. In the covering in of the seeds, the author just mentioned observes, that care should be taken that none are left in an exposed state on the surface of the ground, as where that is the case many of them will be destroyed or picked up by birds, and the sward appear patchy. This business is executed in the most complete

manner by a pair of light short-tined harrows at one tining. The practice of employing bush-harrows is improper, as in that way the seeds are liable to be drawn into lumps. In all the lighter and more spongy descriptions of land, it may be advantageous to pass a light roller over the surface immediately after the seeds have been well harrowed in." And "in cases where the tenants and not the proprietors of the land are to lay them down to grass, it may be the most advisable practice for the latter to procure the seeds, but at the expence of the former, especially where they have a sufficient interest in such lands; as, without this precaution, from their general propensity to keep the ground under the plough, and their indifference in respect to the obtaining of the most proper sorts of seeds, there may be danger of the business being improperly performed."

*Proper Management after being laid down.*—It may be remarked, that the proper conducting of this business is a matter of considerable importance, and a point upon which much of the success of forming good grass-land must in most circumstances depend. It is advised by some, as soon as the crop with which the seeds have been sown has been removed, to have recourse to rolling the land with a moderately heavy roller, when it is in such a state of dryness as just to admit the impression of the implement; as by this process, from the mould being pressed closely about the roots of the plants, their early growth may be much benefited, and the danger of drought in some measure obviated. The practice is, however, in the opinion of others, the most necessary in the more light and porous descriptions of land. There are still others, likewise, who recommend the application of manure at this period, in order to promote the growth and support of the young grass-plants; a point which would seem quite unnecessary where the above mode of preparation has been had recourse to. The writer of the System of Practical Agriculture, however, states that "as the surface of such grounds as have been newly laid down to the state of sward is, from the previous tillage which they require, extremely tender, and readily broken into holes for some time even in the drier descriptions of land, the turning-in of the cattle with the view of feeding them down till, in most cases, be highly prejudicial by the treading which they cause. The best practice is, therefore, probably to suffer no sort of stock to be put upon such lands till the spring after their being laid down; or where the farmer finds it absolutely necessary to turn upon the lands, the lightest sort of stock should constantly be selected for the purpose." And "it has been observed by the Rev. Mr. Young, that the advantage of feeding such lands during the autumn and winter seasons, is scarcely matter of any consequence, as the spring feed for sheep, where it is omitted, is of so much greater utility, a very early pasturage being in this way afforded for ewes and lambs." Mr. A. Young is also decidedly of the same opinion in his Farmer's Calendar.

There are much diversity and contradiction in the opinions of experienced cultivators as to the future management in different states and circumstances of the lands, some supporting the superiority of keeping the ground closely fed down by sheep or neat cattle, while others consider mowing or feeding as preferable. "There seems little reason to doubt but that feeding by some sort of stock is a much better practice than those of either mowing or feeding; the chief difficulty is in respect to the sort of stock that is the most proper. On the dry and more firm sorts of ground, a mixed flock may be the most advantageous, as neat cattle and sheep, as in that way the new pasture may be fed down in the most regular manner; but on those that are of a more open,

## LAYING.

open, porous, and less firm quality, sheep, by their eating so closely, may do much harm, especially in the first years of the new lay, by pulling up the young and imperfectly established grafs-plants. Several instances of this kind have been noticed in such soils. In lands that are more inclined to moisture, the confining of the produce by neat cat's milt constantly be liable to do mischief, except in very dry seasons; they must of course be principally fed down by sheep. And in all cases where the new lay is chiefly constituted of the more coarse sort of grasses, sheep would seem to be the most proper kind of stock, as the grasses are thereby constantly becoming more fine and sweet. Many facts of this nature have been noticed by cultivators. The sweetness of the pasturage on many sheep-downs has been remarked to depend more on their being kept closely fed down than any other circumstances, as on being neglected in this respect it becomes coarse, and is rejected."

*System of Practical Agriculture.*—It has been well observed by the Rev. Mr. Young, in a valuable paper, in the third volume of Communications to the Board, that "sheep-feeding not only ameliorates by enriching the soil, and fixing the herbage, but also by destroying weeds." And Dr. Dickson has "been assured by a very extensive and experienced cultivator in Somersetshire, that under this sort of management, not only many coarse grasses, but other sorts of plants become fine, and eagerly fed upon by animals." It is still farther stated, that "Dr. Wilkinson, who has been much in the habit of comparing different practices, advises the grazing constantly with sheep, and for the first six years never to permit the scythe to touch the lays;" but this is certainly longer than is necessary to preclude the scythe in many sorts of soil. And the Rev. Mr. Young has remarked in addition, "that it is not merely the first year that feeding with sheep is the best practice on new lays, but it may be so managed the second, and if it extend to the third it is the better: and though there is not any necessity for adhering to it any longer, it has been found to answer well in his practice, four, five, or even six years; and in general it may be concluded, that the more the land is fed with sheep, the greater the improvement will be. But in this management the impoverishing absurd system of removing the animals to be folded in other places, is not to form any part of the practice."

In the Agricultural Report of the North Riding of Yorkshire it is suggested, that "it has been long the practice in that district, with the most improved cultivators, to have recourse to the method of sheep-feeding for some time after laying the lands down to grafs, as two years or more. Where ray grafs and white clover are intended to remain some years, it is found by some advantageous to eat them the first year by the sheep, in closing, thickening, and rendering them more permanent." These facts are all in evidence of the great propriety and utility of the practice of feeding new grafs-lands. It must, however, be observed, that in order to render the practice perfectly safe and beneficial, the new lays should not be fed during the autumn, or the stock turned into them at too early a period in the spring. "Nor should they be too heavily stocked, or the stock kept in the pastures too long, especially when it consists principally of sheep, as they may do much harm by paring and eating the plants so closely down as immediately to kill them, or expose their roots too much to the destructive effects of drought. And in cases where the grasses have run up much to stem, if the lands be sufficiently stocked with plants, it may be beneficial to cut them over, by means of a strong scythe, before their seeds are formed, as

by this means they will become more strong and vigorous; but, in the contrary circumstances, they are better left for the purpose of providing a more abundant supply of young grasses, as the benefit obtained in this way will more than counterbalance the injury sustained by the running up of the old plants." But the author of the System of Practical Agriculture states, that "though the practice of feeding new laid grasses in the first years appears to be the most advantageous and proper mode of management, especially for lands intended for pasture, there are many cases in which they may be mown with great success. This practice is perhaps always the most beneficial and proper, and indeed the only one that can be adopted, in such soils as possess any great degree of moisture; as, under such circumstances, the feeding them down with any sort of live stock must, in most seasons, be injurious to the sward. And, besides, where the object and intention of the farmer is chiefly hay, the grafs-plants, by being kept closely eaten down by live stock for a considerable length of time before the scythe is applied, may, from their becoming thereby disposed to a low and lateral spreading growth, be afterwards more unfit for the production of hay crops. Several facts of this nature are related by writers on husbandry. In one case, where different divisions of land of the same kind were laid down in the same manner, on one of them being kept in the state of pasture, and the other alternately mown and pastured; after some years, both being shut up for hay, that which had been pastured afforded a much inferior produce to the other. The same thing has happened in other cases of old pastures being converted into hay lands, even when the most favourable season prevailed." It is consequently concluded, that "on these principles, it may be a more judicious practice to manage lands designed for hay, without having them for any great length of time, previously to their being mown, fed down closely with stock; as in this way a larger produce of hay may be afforded." And it is supposed, that "where the new lays are mown the first year after being laid down, which is not a method to be recommended, it is an excellent practice to apply a moderate coat of manure over them in the autumn, especially when the state of the land and the season is such, in respect to dryness, as to admit of its being done without injuring the surface sward; as by this means the grafs-plants not only become more strong and vigorous, but better established in the soil, and of course bear cutting with much less injury."

But as it may be the case sometimes, though seldom, where these modes are fully attended to, that the farmer may fail either in part or wholly of producing a good lay; it has been observed, that, "in the first case, it is the best practice to have recourse to sowing fresh seeds, which should be performed in the early part of the spring, when the weather is in a moist state; the seeds being advised by some to be trodden in by putting sheep upon the land, either indiscriminately, or by very open ploughing, as the use of the roller will not be effectual, and that of harrowing cannot be practised without injury." It is stated that a large cultivator at Enfield found advantage from putting the seeds in before the manure was applied in the new lays, which are sometimes too hastily ploughed up. By either method, the sward of such lays may often be much thickened, as well as benefited in other respects. And that, in cases where the grasses have run up much to stem, if the lands be sufficiently stocked with plants, it may be beneficial to cut them over, by means of a sharp scythe, before their seeds are formed; as by this means they will be more strong and vigorous, and the lands be less injured; but, under the contrary circumstances,

stances, they are better left for the purpose of providing a more abundant supply of young grasses, as the benefit obtained in this way more than counterbalances the injury sustained by the old plants being left upon the land. But that where there is a complete failure from particular causes, the most advisable method is, where the feeds have been put in, in the spring, with grain crops, to take off these crops as soon as they admit of it; and, after giving the land one ploughing, to harrow in directly fresh feeds, which should be accomplished as early in the beginning of August as it can be performed; and a roller may be applied over the land, when in a suitably dry condition, about October. But that where the latter end of summer has been the time of sowing, it is advised "that the land should have three ploughings performed upon it in the early spring months, when the weather is sufficiently dry, and the grass-seeds be again put in with the crop of buck-wheat in May, which, though it is not a suitable crop for the heavy wet sorts of land, sometimes answers well in dry seasons, and in wet ones, as affording but little feed, may be mown when in blossom as green food for the cows." From the land not being much robbed of its fertility in this way, it may be a beneficial practice.

The application of manure to new laid down grass lands is seldom absolutely necessary: yet where they have not been returned to the state of sward under that degree of fertility and preparation which has been inculcated, it may, in many instances, be had recourse to with great advantage and improvement: as it is perhaps one of the best methods of preserving a good clove late of grass or sward, when properly employed. Mr. Maxwell states, in the third volume of Communications to the Board, that "though in general no manure will be wanted till the land has been mown for hay, there can be no doubt but that great additional improvement will be produced, where manure of any sort can be applied;" and that "the oftener the land is manured, the greater will be the improvement." Where lands have been laid to sward or grass with grain crops, the application of light dressings of manure in the following autumn may be of much utility in fixing and encouraging the growth of the young grass-plants, as has been seen; but in other cases, the latter end of the summer following, or very early in the autumn, are supposed by some to be the most beneficial and proper periods for the purpose: "but as at these times, in many instances, much loss of manure may be sustained both by evaporation and the washing of heavy rains and snows, it may be a better and more advisable practice to perform the business in the early spring months, especially where the lands are to be conducted under the scythe; as in this way the enriching material will be ready to exert its influence at the moment the young plants begin to fend forth their new shoots, and thus not only afford more assistance in thickening and invigorating the new sward, but be less in danger of being uselessly dissipated and waited." But "where manure cannot be spared for repeatedly dressing new grass lands, as the grasses are often, especially on lands not suited to their growth, liable to decline and become thin, in some instances, it is supposed, from the town grasses disappearing before the spontaneous ones have attained sufficient vigour and strength; but more generally, probably, from the grounds not having been in a proper state of fertility, or fineness of surface mould, at the time the seeds were put in; or the particular unfavourableness of the season, about the clove of the third summer after their being sown. It is believed by the Rev. Mr. Young, to be a better practice to defer the use of manure till that time, on such lays as are

pastured; and when they are under the scythe, till the hay crop has been taken from the ground. We have no doubt of the success of the application of dung top dressings at these periods, though they must evidently be made use of in a less economical manner than at a later season in the autumn, or an earlier one in the spring. And it is the most common opinion, that all the finer and more soluble kinds of top dressings are applied with the greatest benefits in the very early spring months, as about the latter end of February, or the beginning of the following month. The differences in the effects of these sorts of manure have perhaps not yet been fully ascertained, under different circumstances of application."

With the view of encouraging and supporting the growth of the natural grasses, when the sown ones decline, as about the third year, an experienced cultivator at Enfield, who seems to favour the opinion of manure being the most usefully laid on land early in the autumn, or on hay lands immediately after the crops have been taken off, states that "he has used coal-ashes with great success, to the amount of three chaldrons per acre. He has laid of this manure on grass land above fifty chaldrons in a year. About eight years ago, he laid down a field of twelve acres with broad clover principally, intending it to stand only for two years. In the summer it was mown twice; next year it was grazed: the clover was but weak. As he had particular reasons for altering his mind, and for wishing to continue it in grass, he resolved to try the effects of grazing it with sheep. On the fourth year it looked so very bad, the clover almost entirely disappearing, that he was tempted to plough it up. He, however, resolved to continue the grazing, and to give it a dressing of three chaldrons per acre of coal-ashes. The next year he observed the white clover and natural grasses beginning to form a clove turf; and the field is now an excellent piece of sward, without the aid of any hay-seeds." And it appears from the further trials of the same cultivator, that the following substances have much effect, not only in promoting the growth and rendering the herbage more fine and sweet, but in renovating the sward:—the scrapings of the road, sand drift, fold-yard liquor, and watering; and that the effects of other manures would seem to be chiefly in promoting the luxuriance of the grasses, and of course to be principally advantageous in increasing the quantity of produce; such as "tallow-chandlers' graves, when used in proportion of a ton an acre; and night-foil, when laid on to about three horse cart loads the acre. And that in fixing, producing, and rendering the white clover more permanent, marle, or strong cold land, and coal-ashes, on wet soils, have been highly beneficial. On the drier clayey lands in Cornwall, "sea-sand has been found to mellow the clay, and make them hold the grasses." And on what are termed stone brash lands, the use of marle is often found of great utility, when applied in the latter part of the summer of the first year of the lay. But it is necessary, to the success of this sort of application, that the ground be well covered with grass before it is applied; as where the surface is much exposed, the marle is liable to plaister and cake together, and the young grass-plants to be, in consequence, exposed to much injury from the heat of the summer. This substance seems to bring up the best sort of natural grasses; but in time it sinks below the reach of vegetation. About thirty cart-loads are sufficient for the acre. And chalk, on the deep loamy clays, was found by Mr. Davis an useful application the first year on new lays, in the proportion of about twenty loads to the acre. On the more sandy sorts of land, clayey marle may be of great advantage in establishing

blishing the grass; and on peaty or moory lands, marle and other similar materials will be found of advantage in rendering them more compact, and better fitted for preserving the grasses; as well as sand and road-stuff, for lining the herbage, and rendering it more palatable to the flock.

Though "foot has been much used as a top-dressing, it has not been found that its effects last beyond the first year. It has been tried to the amount of sixty bushels *per* acre, at *Sd. per* bushel; perhaps it should be used in larger quantity. Lime is nearly as dear, and of that 160 bushels have been used *per* acre on arable land. Soot should perhaps be laid on to that amount. Sugar-bakers' scum has been used with great success to the amount of two loads an acre, at half a guinea *per* load, which has been found a strong warm manure, highly serviceable on cold land, its effects being permanent. Lime is also found useful on the more friable red loamy soils, by fixing and rendering them more close, to keep the vegetation more to the surface, as well as to promote the growth of the natural grasses, and prevent their roots from being injured by the heat of the sun. And woollen rags, though not generally used as manure on grass-land, when chopped small, have been spread with advantage on young clovers before winter, to the amount of about 10 cwt. *per* acre," being useful in protecting and nourishing the young grass-plants in their more tender growth, but they are slow in producing their beneficial effects.

On applying, in order to compensate for an immediate crop of hay, and to thicken the sward on one part of a field, rotten dung about eight tons to the statute acre, on another part woollen rags chopped at the rate of 100 stones to an acre; and on a third a rich marle in the proportion of about 80 tons to the statute acre; Dr. Campbell found, on comparing their effects two years afterwards, that "the dung had produced the greater luxuriance. The woollen rags had a superior verdure, a deeper green: but as they had not yet been properly incorporated with the land, by the grass growing over them, their ultimate produce could not be ascertained." An acre of land may, it is supposed, "be manured by this means for about *3l.* effectually, should they be found to answer the purpose." The same is the case with "the marle, which having covered the ground into which it is not yet carried down by the rains, and the grass not having-grown through, it has at present rather done harm than good." On this account, he supposes that "marle is long in producing its beneficial effects, and the return of which cannot be looked for in less than two or three years."

It is evident from these facts, that different effects may be produced on grass-lands by the application of different sorts of substances or materials to them in the manner of top-dressings after they have been laid down to grass; and that "where fine herbage is the principal object in view, coal ashes and composts of the earthy kind formed from sand, mud, scrapings of roads, and other similar materials, intimately blended and incorporated with suitable proportions of well rotted dung, may be the most beneficial applications;" also that "the liquor of fold yards and watering may be useful in the same intention as well as those of restoring the grass-plants or swards, and promoting the luxuriance of the crops." But that "where the increase of produce is chiefly aimed at, good dung in a well reduced state, tallow-chandlers' graves, night soil, chopped rags, foot, scum of sugar, and other substances of the more animal kind, are the most effectual and proper." While in the intention "of establishing, preserving, rendering durable the different grasses, marle, lime, chalk, the folding of sheep, and other substances and practices of the same sort, will be the most proper for producing such effects." And that in "render-

ing the lands more firm and solid, the three last substances may perhaps be employed with the greatest success and advantage." See MANURE and GRASS Land.

LAYING-out Homesteads. See HOMESTEAD and FARM Buildings.

LAYING-out Lands, the manner of distributing the land of a farm or an estate. See FARM.

LAYING-out Roads, in *Rural Economy*, the mode of planning and laying out the lines of roads. See ROADS.

LAYING-down, or Laying-off, in *Ship Building*, delineating the ship to its full size from the given draught upon the mould-loft floor, for the purpose of making the moulds by which the several parts of the ship is provided.

LAYING, in *Ropemaking*, the closing of the strands together, to compose the rope.

LAYING-hook, the hook on which the strands are all hung together for laying or closing.

LAYKAN, in *Geography*, a small island in the East Indian sea, near the S.W. coast of Celebes. S. lat. 5° 52'. E. long. 119° 51'.

LAYMAN, a person not engaged in any order of ecclesiastics: accordingly, in the distribution of the people, *laity* is opposed to the *clergy*, and may be divided into three distinct states, *viz.* the *civil*, the *military*, and the *maritime*.

LAYMAN, among *Painters*, a little statue, or model, either of wax or wood, whose joints are so made, that it may be put into any attitude, or posture. Its chief use is for the casting and adjusting draperies, for the clothing of figures.

Some call it, after the French, *manequin*, q. d. *a little man*.

LAYMABAMBA, in *Geography*, a town of Peru, in the jurisdiction of Chacapayas.

LAYMOU, a town on the S. coast of the island of Ceram.

LAYR. See LAIR.

LAZA, in *Geography*, a town of Spain, in Galicia; 18 miles E.S.E. of Orense.

LAZANILLA, a town of the island of Cuba; 40 miles E.N.E. of Spiritu Santo.

LAZARE BUEY, a town of Spain, in New Castile; eight miles from Toledo.

LAZARETTO, a small island in the Mediterranean, near the N. coast of the island of Candy, formerly used by the Venetians as a lazaretto, but now deserted.

LAZARETTO *Vecchio*, *Il*, a small island in the neighbourhood of Venice, formerly called "St. Maria of Nazareth," from a church of that name built by Angustin Hermits in 1249. Since the year 1422, all ships coming from the Levant, are to perform quarantine in this island, for which purpose it was provided with the necessary inns, which were rebuilt and enlarged in 1565. Here all the ships and merchandise are closely inspected, under the direction of a deputate of the senate.

LAZARETTO, or *Lazar-house*, a public building, in manner of a hospital, for the reception of poor sick.

LAZARETTO, in some countries, is an office appointed for persons coming from places suspected of the plague, to perform quarantine. See QUARANTINE.

This is usually a large building, at a distance from any city, whose apartments stand detached from each other, &c. where ships are unladen, and their crew is laid up for forty days, more or less, according to the time and place of their departure.

We are indebted to John Howard, esq., the most distinguished philanthropist, who has appeared in this or any other country, and whose services in the cause of humanity

can never be forgotten, (see his biographical article,) for a particular account of all the principal lazarettos in Europe, with plans of the buildings, a detail of their chief regulations, and very important and useful hints for their improvement. With this view he determined, towards the end of the year 1785, notwithstanding the expence and danger which he thus incurred, to visit them in person. Accordingly, the first lazaretto which he inspected was that at Marcellis, which is situated on an elevated rock near the city, at the end of the bay, fronting the south-west, and commanding the entrance of the harbour. This is a spacious building, and its situation renders it very commodious for the great trade which the French carry on in the Levant. Within the lazaretto is the governor's house, a chapel, in which divine service is regularly performed, and a tavern, from which persons under quarantine may be supplied with necessaries. In order to prevent any communication, that is not allowed by the regulations of the establishment, there is a double wall round the lazaretto; and at the gate there is a bell for calling any person within this inclosure; and by the number and other modifications of the strokes, every individual knows when he is called. At Genoa, whither Mr. Howard next proceeded, the lazaretto is situated on the sea-shore, near the city, detached from other buildings, and encompassed by a double wall. Another lazaretto, belonging to the Genoese, stands on a rising ground at Varignano, near the gulf or noble port of Spezia. At Leghorn there are three lazarettos; one of which is new, having been erected in the year 1778. The lazaretto at Naples is very small; that at Messina lies on an island near the city. At Naples there are two kinds of quarant performed; one by ships with clean bills of health, and the other by ships with foul bills. The first, called the petty quarantine, lasts 18 days, and the ships which perform it lie at the entrance of the port near the health-office. The other, called the great quarantine, is performed at a lazaretto, situated on a peninsula near the city. The health-office at Zante is in the city at the water side. The old lazaretto is distant about half a mile from the city, and situated on a rising ground near the sea. There is another called the new lazaretto, which is appropriated to a numerous body of peasants, who pass over to the Morea to work in harvest time; on their return, they perform here a seven days' quarantine; and other persons perform 14 days' quarantine in the old lazaretto. The lazaretto at Corfu is finely situated on a rock surrounded with water, about a league from the city. The lazaretto of Castell-Nuovo, in Dalmatia, is on the shore, about two miles from the city; at the back of it there is a delightful hill, which belongs to a convent of friars. Persons in quarantine, after a few days, are allowed to walk there, and divert themselves with shooting, &c. In order to obtain the most complete and satisfactory information by performing the strictest quarantine, our author determined to go to Smyrna, and there to take his passage to Venice in a ship with a foul bill. He was thus enabled to give a particular account of his reception and accommodation in the new lazaretto of this city, which is chiefly assigned to Turks and soldiers, and the crews of those ships which have the plague on board; and this he thought to be the more necessary, as the rules and tariffs of the other lazarettos in Europe have been evidently formed from those established at Venice. The city of Venice has two lazarettos, appropriated to the expurgation of merchandise susceptible of infection, coming from suspected parts, and for the accommodation of passengers in performing quarantine; as also for the reception of persons and effects infected in the unhappy times of pestilence. The old lazaretto is two miles, and the new about five miles

distant from the city, both on little islands, separated from all communication, not only by broad canals surrounding them, but also by high walls; they are of large extent, being about 400 geometrical paces in circumference. Of these Mr. Howard has given a particular description, with an account of the regulations, and mode of government to which they are subject, and a plan of the old lazaretto. At Trieste there are two lazarettos; one new, but both clean, and a contrast to those which our author had seen at Venice. Of the new one he has given a plan. It is surrounded, at the distance of about 20 yards, by a double wall, within which are separate burying places for Roman Catholics, Greeks, and Protestants. Mr. Howard closes his account of the principal lazarettos in Europe, with the outlines of a proper lazaretto, and an engraved sketch of a plan for its construction. He has also subjoined, in minute detail, various pertinent remarks respecting quarantines and lazarettos in general; together with observations on the importance of a lazaretto in England, in its connection with the advantages which our commerce might derive from it. See "An Account of the principal Lazarettos in Europe, &c." by John Howard, F.R.A. Warrington 1789, 4to.

By 39 & 40 Geo. III. c. 80. § 23. is enacted, that if any found person shall enter any lazaret, he shall perform quarantine; and if he shall return from thence (unless duly licensed), or shall escape, or attempt to escape, he shall be guilty of felony without benefit of clergy. See QUARANTINE.

LAZARETTO, a name given to a hospital ship, which is for the reception of the sick, or persons supposed to be infectious. It is also the name of a place parted off at the fore part of the lower deck in some merchant ships, for the convenience of laying up the provisions, stores, &c. necessary for the voyage.

LAZAREVA, in *Geography*, a town of Russia, in the government of Irkutsk, on the Lena; 32 miles S.W. of Kirenk.

LAZARI MORBUS, a name given by some writers to the elephantiasis.

LAZARIA, in *Geography*, a town of Portugal, in the province of Beira; six miles S.E. of Lamego.

LAZAROLE, in *Botany*. See MEDLAR.

LAZARUS, St. or LAZARO, a military order, instituted at Jerusalem by the Christians of the West, when they became masters of the Holy Land; whose business was, to receive pilgrims under their care, guard them on the roads, and defend them from the insults of the Saracens.

Some say, this order was instituted in 1119.

The knights of this order, being driven out of the Holy Land in 1253, followed St. Lewis into France; who, in return for the services they had done him in the East, confirmed the donations made to them by his predecessors, put them into possession of several houses, commanderies, and hospitals, which he had built and endowed with ample privileges, and procured from Alexander IV. in 1255 a bull, confirming the order, and giving them permission to observe the rule of St. Augustine. In the year 1490, pope Innocent VIII. suppressed their order, and united them to the order of St. John of Jerusalem; but the bull issued for that purpose was not received in France. In 1572, pope Gregory XII. united those of the order in Italy with that of St. Maurice, (which see,) then newly instituted by Emanuel Philibert, duke of Savoy. And, in 1608, this order was united in France to that of our Lady of mount Carmel, which had been instituted by Henry IV., and it obtained some new advantages from Louis XIV. The knights of St. Lazarus, and those of our Lady of mount Carmel, are allowed to marry, and,

at the same time, to possess pensions charged upon ecclesiastical livings. The badge of this order is a cross (like that of Malta) of eight points, made of pure gold, edged with white enamel; the middle, or nucleus, of the cross is enamelled crimson, and on it is the image of the blessed virgin and child proper; the reverse has the middle enamelled green, on which is the figure of St. Lazarus; between the rays of the cross are four fleurs-de-lis, and on each of the points a small gold ball. The cross is fastened to a broad crimson ribbon, and is worn either on the breast or scarf-wife.

**LAZARUS**, *Fathers of St.*, called also *Lazarites*, a name given to certain regular clerks of a congregation instituted in France, in the seventeenth century, by M. Vincent.

They take the denomination from a house in the Faubourg St. Denis of Paris; they have a seminary in Paris, called the seminary *des bons enfans*. The vows they make are simple, and may be dispensed with on occasion.

**LAZICA**, in *Ancient Geography*, a country of Asia, S. of the Phasis, and N. of Armenia. This country was inhabited by a tribe of people called *Lazi*, who have to this day preserved their name, and are known among the Turks under the denomination of *Lazas*, and their country is called the country of the *Lazas*, or the province of *Trebizond*. In the time of Pliny, Arrian, and Ptolemy, the *Lazi* were a particular tribe on the northern skirts of *Colchos*. In the age of Justinian, they spread, or at least reigned, over the whole country. At present they have migrated along the coast towards *Trebizond*, and compose a rude sea-faring people, with a peculiar language. As the strength of the Roman empire was gradually impaired, the Romans stationed on the Phasis were gradually withdrawn or expelled about the beginning of the 2d century of the Christian era; and the tribe of the *Lazi*, whose posterity (as we have said) speak a foreign dialect, and inhabit the sea coast of *Trebizond*, imposed their name and dominion on the ancient kingdom of *Colchos*. Their independence, however, was soon invaded by a formidable neighbour, who had acquired, by arms and treaties, the sovereignty of *Iberia*. The dependent king of *Lazica* received his sceptre from the Persian monarch, and the successors of *Constantine* acquiesced in this injurious claim, which was proudly urged as a right of immemorial prescription. In the beginning of the sixth century (A.D. 522) their influence was restored by the introduction of Christianity. After the decease of his father, *Zathus* was exalted to the regal dignity by the favour of the great king; but the pious youth abhorred the ceremonies of the *Magi*, and sought, in the palace of *Constantinople*, an orthodox baptism, a noble wife, and the alliance of the emperor *Justin*. The king of *Lazica* was solemnly invested with the diadem, and his new patron soothed the jealousy of the Persian court, excusing the revolt of *Colchos*, by the venerable names of hospitality and religion. The common interest of both empires imposed on the *Colchians* the duty of guarding the passes of mount *Caucasus*, where a wall of 60 miles is now defended by the monthly service of the musqueteers of *Mingrelia*. But this honourable connection was soon corrupted by the avarice and ambition of the Romans. Degraded from the rank of allies, the *Lazi* were incessantly reminded, by words and actions, of their dependent state. At the distance of a day's journey beyond the *Aparus*, they beheld the rising fortresses of *Petra*, which commanded the maritime country to the south of the *Phasis*. Instead of being protected by the valour, *Colchos* was insulted by the licentiousness, of foreign mercenaries; the benefits of commerce were converted into base and vexatious monopoly; and *Gubazes*, the native prince, was reduced

to a pageant of royalty by the superior influence of the officers of *Justinian*. Disappointed in their expectations of Christian virtue, the indignant *Lazi* resented some confidence in the justice of an unbeliever, and after a private assurance that their ambassadors should not be delivered to the Romans, they publicly solicited the friendship of *Chosroes*. The sagacious monarch discerned the use and importance of *Colchos*, and meditated a plan of conquest. His ambition was fired by the hope of launching a Persian navy from the *Phasis*, of commanding the trade and navigation of the *Euxine* sea, of desolating the coast of *Pontus* and *Bithynia*, of distressing, perhaps of attacking, *Constantinople*, and of persuading the barbarians of *Europe* to second his arms and counsels against the common enemy of mankind. Accordingly he led his troops to the frontiers of *Iberia*; they were conducted by *Colchian* guides through the woods and along the precipices of mount *Caucasus*; and a narrow path was formed into a safe and spacious highway, for the march of cavalry and even of elephants. *Gubazes* laid his person and diadem at the foot of the king of *Persia*; his *Colchians* imitated the submission of their prince, and after the walls of *Petra* had been shaken, the Roman garrison prevented, by a capitulation, the impending fury of the last assault. But the *Lazi* soon discovered that their impatience had urged them to choose an evil more intolerable than the calamities which they strove to escape. The monopoly of salt and corn was effectually removed by the loss of those valuable commodities; the authority of a Roman legislator was succeeded by the pride of an oriental despot, who beheld, with equal disdain, the slaves whom he had exalted, and the kings whom he had humbled, before the footstool of his throne. The adoration of fire was introduced into *Colchos* by the zeal of the *Magi*; their intolerant spirit provoked the fervour of Christian people; and the prejudice of nature or education was wounded by the impious practice of exposing the dead bodies of their parents, on the summit of a lofty tower, to the crows and vultures of the air. The *Lazi* were also apprized that *Nushervan* had given secret orders for assassinating their king, for transplanting them into some distant land, and for fixing a faithful and warlike colony on the banks of the *Phasis*. In these circumstances the *Colchians*, apprized of the ruin that awaited them, solicited the clemency and succour of *Justinian*; who, from motives of policy, determined to expel the Persians from the coast of the *Euxine*. The siege of *Petra* (which see) was immediately undertaken. Thus commenced the *Colchian* or *Lazic* war, A.D. 549. Notwithstanding some splendid advantages obtained by the troops of *Justinian*, the Persians occupied the passes of *Siberia*; *Colchos* was enslaved by their forts and garrisons; they devoured the scanty sustenance of the people; and the prince of the *Lazi* fled into the mountains. At length, the prudence of *Chosroes* relinquished the prosecution of the *Colchian* war, under a persuasion that it is impossible to reduce, or at least to hold a distant country against the wishes and efforts of its inhabitants. The fidelity of *Gubazes* sustained trials of the most rigorous kind; he patiently endured the hardships of a savage life, and rejected, with disdain, the specious temptations of the Persian court. The king of the *Lazi* had been educated in the Christian religion; his mother was the daughter of a senator; he had served to years a silentary of the *Byzantine* palace; and the arrears of an unpaid salary were a motive of attachment and of complaint. The lieutenants of *Justinian* prejudiced the emperor against him; persuaded him that a second defection was meditated; an order was issued to send the king prisoner to *Constantinople*, and a treacherous clause was inserted in it, that he might be lawfully

fully killed in case of resistance; and Gubazes, without arms, or suspicion of danger, was stabbed in the security of a friendly interview. In the first moment of rage and despair, the Colchians would have sacrificed their country and religion to the gratification of revenge; but the counsel of the wiser men among them prevailed; and the emperor, anxious to avoid the imputation of so foul a murder, commissioned a judge of senatorial rank to enquire into the conduct and death of the king of the Lazis; and some satisfaction was granted to an injured people by the sentence and execution of the meaner criminals. After 20 years of destructive though feeble war, Chofros was persuaded to renounce his claim to the possession or sovereignty of Colchos and its dependent states. Gibbon's Decl. &c. of Rom. Emp. vol. vii. See COLCHIS, MINGRELIA, and TREBIZOND.

LAZISE, in *Geography*, a town of Italy, in the Veronese, on the E. bank of lake Garde, with a harbour, a custom-house, and a castle; five miles W. of Verona.

LAZIVRAD, in *Natural History*, one of the oldest names by which we find the lapis lazuli expressed in authors.

LAZULI LAPIS, or LAPIS LAZULI; *Azure Stone*, Jam.; *Lafuslein*, Wern.; *Lazulite* of Haüy and Delameth. (not of Werner); *Pierre d'Azur*, Broch.; *Lazulite outremere*, Brong.; *Lazurus orientalis*, Linn.

The colour of this mineral is azure blue, generally perfect, but also passing into Berlin blue and smalt blue, seldom into sky blue: some varieties shew a slight tint of greenish-blue.

It occurs generally massive, in rolled pieces and disseminated; also indistinctly crystallized. The regular crystal form mentioned by Lhermina, and other French mineralogists, is that of the garnet dodecahedron; but whether this be the primitive or a secondary form, or whether it belong at all to the real azure stone, is as yet undecided.

Its internal lustre is glistening and glimmering. Fracture uneven, fine-grained.

Fragments indeterminate angular, more or less sharp-edged, and slightly translucent on the edges.

It scratches glass, and is easily frangible.

Specific gravity of the Persian, (according to Brisson and Blumenbach), 2.771; 2.896, (Kirwan); of the Siberian 2.945, (Brisson).

It is infusible before the blowpipe; but at a still higher degree of heat its natural colour gives way to a bluish-grey, and it runs into a whitish enamel. Klaproth obtained a dark-coloured, semitransparent, glassy globule, covered with grains of iron. If previously calcined it forms a jelly with acids. This latter observation was first made by Marggraf, who, as early as the year 1788, published an analysis of the lapis lazuli, in which he shewed that its colour is by no means produced by copper; his analysis has been confirmed by Klaproth, who found also alumine as a constituent part, which had been overlooked by his celebrated predecessor. Its composition, as determined by Klaproth, is the following:

Silica	-	-	46
Alumine	-	-	14.50
Carbonate of lime	-	-	28
Gypsum	-	-	6.50
Oxyd of iron	-	-	3
Water	-	-	2
			100

100 Klapr. Beitr. i. p. 196.

The result of an analysis given by M. M. Clement and Deformes, differs from the preceding: they obtained

Silica	-	-	-	-	34
Alumine	-	-	-	-	33
Sulphur	-	-	-	-	3
Soda	-	-	-	-	22
Lofs	-	-	-	-	8
					100

They consider these constituents as essential, and look upon the 0.024 of lime, and the 0.015 of iron, which they have sometimes found, as accidental ingredients. These chemists have also observed some peculiarities in the characters of the earth, mentioned as pure silica in the above analysis. This discrepancy in the results of the analyses points out the necessity of submitting the lapis lazuli to new chemical examination, which may throw light on the nature of the matter that produces the vivid and intense colour of this substance.

But little is known respecting the geognostic situation of this mineral. We see it disseminated in, and mixed with, a fealy crystalline lime-stone; also with quartz, and nox frequently with iron pyrites. The Siberian azure stone (which is distinguished from that called the Persian by its less vivid colour) is said to be the production of a vein near the lake Baikal in Siberia, where it is accompanied with feldspar, garnets, and pyrites.

The finest azure-stone is found in China, Great Bucharia, and Siberia. The true lapis lazuli has not yet been found in Europe, except buried under the ruins of Rome. That mentioned by Tournefort, as occurring near Ergeron in Armenia, is probably a blue copper-ore; and that which, as Mr. Pennant states, is found in great quantities in the island of Hainan, in the Chinese sea, (whence it is sent to Canton, where they employ it in china painting,) may likewise turn out to be different from the true lapis lazuli.

M. Patrin was informed by a dealer in stones, whom he met at Ekaterineburg in Siberia, and who had been in Bucharia, that the lapis lazuli occurred there in granite; not in veins, but disseminated in all sorts of proportion: but that it was extremely rare to find masses, as thick as one's head, in which the blue generally predominated over the white and the grey. The blocks examined by Patrin had the appearance of being rolled: but he was informed they were taken from the quarry; and that their roundness was owing to their friction against each other in the carriage; though sometimes they were found by chance as boulders in torrents, and that these were of the most vivid blue.

According to Laxmann, who resided several years in Eastern Siberia, rolled pieces of lapis lazuli are found on the shore of the lake Baikal, in a kind of gulf to the southward, called the Koutouk; but he searched in vain for the mountains from which these blocks had been detached, and he could obtain no information on this subject from the Buret Tartars who inhabit that savage country. Patrin.

We have omitted mentioning Persia among the countries that furnish this valuable substance, because a traveller well versed in the study of precious stones denies its ever having been found there. "In the copper-mines of Persia," says Tavernier, "veins of lazur have been found; which colour is much used in the country for painting flowers on the ceilings and roofs of apartments. Before these were discovered, the Persians had no other lazur than the real kind which comes from Tartary, and is exceedingly dear. The Persian lazur is a sort of copper-ore, which, when pounded and sifted, forms a fine paint, which appears very bright and pleasant.

After this discovery, the Persians were no longer permitted to purchase the Tartarian lapis lazuli; and Mahomet Beg issued an order that painters should not use any but Persian blue. This prohibition, however, did not long continue: for the Persian pigment would not stand the effects of the atmosphere like the real kind, but, in the course of time, became dark and of a dismal colour. Sometimes it was full of scales, and would not adhere to the end of a soft hair brush; on which account it was soon neglected as a pigment, and the lapis lazuli of Tartary again introduced.

The lapis lazuli is susceptible of taking a good polish, and is therefore used for various ornamental and other purposes, such as the engraving of gems: (See GEMS.) The variety containing disseminated pyrites, which the ignorant frequently mistake for gold, is preferred for mosaics and other inlaid work, &c. Most profusely it was used for the last-mentioned purpose, in the magnificent marble palace which Catherine II. built at Petersburg for Orlov, her favourite, and which has some apartments completely lined with lapis lazuli brought from Great Bucharia.

Masses that contain much quartz are less esteemed by the lapidaries, and particularly by those who prepare from it the *ultramarine*, a beautiful blue colour, so called because it was originally brought from the trading towns of the Levant. See ULTRAMARINE.

Pliny distinctly describes the lapis lazuli, but as a variety of sapphire.

The lapis lazuli was formerly reckoned of some use in medicine: it was prepared by calcining and washing it several times; which done, it made an ingredient in the famous confection of alkermes.

The alchemical writers have given us processes for magisters, tinctures, and elixirs of lapis lazuli, but they are wholly out of use.

The method of making the Venetian counterfeit lapis lazuli is this; melt in a pot, in a glass-house furnace, equal quantities of the fairest lattimo, and the whitest crystalline glass; when this is in fusion, mix into it, by small parcels at a time, the blue smalt used by the painters; make frequent proofs of the colour, and when it is right let the whole stand twelve hours, and then work it. If the metal rise in the pot, put in a piece of leaf gold to keep it down. This makes a fine pale blue substance, representing the plain blue parts of the natural lapis lazuli. Neri's Art of Glass, p. 117.

A counterfeit lapis lazuli may be also made by fusing ten pounds of either of the compositions for hard glass (see *Colouring of Glass*) with an ounce and a half of zaffer, and half an ounce of magnesia, till a very deep transparent blue glass be produced. When the mass is cold, powder it, and mix with it three quarters of a pound of calcined bones, horn, or ivory, by grinding them together: then fuse this mixture with a moderate heat, till the ingredients are thoroughly incorporated, and form the melted mass into cakes by pouring it on a clean bright plate of copper or iron. In order to give it veins of gold, mix gold powder with an equal weight of calcined borax, and temper them with oil of spike: let the cakes be painted with this mixture with fresh veins as are desired, and then put into a furnace of a moderate heat.

LAZULITE, or LASULITE of Werner (not that of Haiüy, for which see the preceding article); *Azurite*, Jameson; *Siderite*, Tromsdorff.

Colour indigo blue, from which it passes into smalt blue. Is found massive, disseminated, and crystallized, as it would appear, in four-sided and six-sided prisms. Mr.

Bernhardi observed the same forms in the variety from Salzburg, but also the regular octahedron with truncated edges, passing into the regular rhomboidal dodecahedron. In general, the crystals are very indistinct and small; and they occur always imbedded.

It is glistening and shining, and of rather resinous lustre. Longitudinal fracture imperfectly foliated, cross fracture uneven. Fragments indifferently angular. Its hardness is inferior to that of common feldspar.

It is brittle, easily frangible, and not particularly heavy. The chemical characters of lazulite, which distinguish it from blue iron earth, are, according to Klaproth, first, its crumbling before the blowpipe into a whitish earthy mass; secondly, its giving a clear light wine yellow, glassy pearl, with borax, and a transparent white pearl with salt of phosphor; and, lastly, its not being operated upon either by acids, or caustic alkali.

Klaproth found the variety from Vorau, near Wienersdorf, Newstadt, in Stiria, to be composed of siliceous alumine, and iron, but could not, from the smallness of the quantity he operated upon, ascertain their proportions. An analysis of the same, by Heim, gave 0.65 alumine, and 0.30 iron.

Tromsdorff's analysis of the variety from Salzburg has given the following results:

Silex	-	-	10
Alumine	-	-	66
Magnesia	-	-	18
Lime	-	-	2
Oxyd of iron	-	-	2.5
Loss	-	-	1.5

100 Gehlen's Journal.

Mr. Tromsdorff thinks that alumine and magnesia must be considered as the essential parts of this mineral substance; hence Mr. Bernhardi is inclined to refer it to the spinelle ruby, with which Haiüy has already united the ceylanite, or pleonast, and which the lazulite resembles also with respect to its crystallization. But is not the hardness of the latter much inferior to that of spinelle?

To the above two localities where the lazulite has been found, we may add that of Krieglach; for, indeed, the substance known by the name of *blue feldspar of Krieglach* appears to agree in all its characters with those of Stiria and Salzburg. In all these places it is found in, and grown together with, white quartz, imbedded in a kind of mica slate.

LAZZI, a denomination given by the Saxons to that rank of people who were born to labour, and being of a more servile state than our servants, because they could not depart from their service without leave of the lord, but were fixed to the land where born and in the nature of slaves: hence the word *lazzi*, or *lazy*, signifies those of a servile condition. See EDHLING.

LE roy le oust, } See LE ROY.

LE roy s'advijera, }

LEA, in *Ancient Geography*, a small island of the Ægean sea. Pliny.

LEA, in *Geography*, a river of England, which rises in Bedfordshire, passes by Hertford, Ware, &c. and falls into the Thames a little below London.

LEA of Yarn, is used in some parts of England for a certain quantity of yarn. On a kilderminster it ought to contain two hundred threads, on a reel four yards about. Stat. 22 & 23 Car. II.

**LEACH-BRINE**, a word used by the English salt-workers to express the brine which runs out from the salt, when it stands in the basket to drain, immediately after being taken out of the pan; and also the liquor left in the pan, when no more salt will float. This is also called the *mother-brine*, and *bittern*. In the German salt-works they always throw this liquor away. In our brine-salt works in Cheshire they always preserve it, and add it to the next boiling; and in the Newcastle, and other sea-water salt-works, they save it for the making the bitter purging salt, called *Epsom salt*.

**LEAD**, in *Mineralogy*, *Plumbum*, Lat.; *Plomb*, Fr.; *Bly*, Germ.; *Saturnus*, Alchem. The colour of lead is of a blueish-white; when tarnished, it becomes yellowish-white, then blueish, and at last blueish black. Lustre, when untarnished, 3; hardness, 5; and specific gravity somewhere between 11 and 12. According to Brisson, it was 11.352; and a specimen tried by Gellert, which was found at Freyburg, was estimated at 11.445. Next to gold, platinum, and mercury, it is the heaviest metal, being upwards of eleven times heavier than an equal bulk of water. (See *SPECIFIC GRAVITY*.) The heaviest is reckoned the best. It stains paper and the fingers. Next to tin, it is the most fusible of all the metals. It is soluble in most of the acids, though more readily so in the nitrous diluted than the others. By exposure to the moist atmosphere, it rusts or oxyds. It is malleable, and unelastic, and its oxyd is easily fusible into a transparent yellow glass. Having given this general description, we shall now consider the several combinations under which it is found in nature.

*Ores of Lead.*

Sp. 1. *Lead Glance*. *Bleiglanz*. This species contains two subspecies: (1) *Common lead-glance*, the colour of which is of a lead-grey, of different kinds of intensity; in some varieties it inclines to a blackish cast. The lead-grey

frequently contains the greatest proportion of silver. It sometimes presents superficially an iridescent tarnish. It occurs massive, disseminated, in membranes, in angular pieces, and in grains: sometimes it is met with reticulated, specular, corroded, and amorphous; seldom cylindrical, but often crystallized. The crystalline form exhibits several varieties: 1, in the shape of a cube, in which the planes are either straight or spherical convex; 2, the cube having angles more or less deeply truncated; 3, the cube having its edges and angles truncated at the same time, but of these the latter the most deeply; 4, octahedron, either perfect or truncated on all its angles; 5, octahedron having its angles and edges truncated at the same time; 6, rectangular four-sided prisms, acuminate on both extremities by four planes, which are set on lateral edges; 7, six-sided prisms, acuminate by four planes; 8, three-sided tables, in which the terminal planes are bevelled. The crystals are usually small, or at most middle-sized, either grouped on one another, implanted, or solitary. The planes of the crystals are sometimes smooth, sometimes drusy, and sometimes rough. Internally it alternates from specular splendid to glittering; on the external surface it is less bright, but its lustre is metallic. Its fracture is more or less perfect foliated, and its fragments are cubical. In mass it is often composed of granular, and rarely of lamellar distinct concretions, which are much grown together, and whose fracture has a radiated aspect. It is soft, perfectly sectile, easily frangible, and the specific gravity is from 6.2 to 7.8 nearly. Before the blowpipe it flies to pieces, and emits a sulphureous odour. It is easily fusible, and may be readily reduced on coal before the blowpipe. When it is alternately heated and cooled, it at length disappears entirely; and if it contain silver, a globe of that metal remains behind. According to Vauquelin, lead-glance contains the following ingredients:

	From Kirchwald, in Deux Ponts.	Kampfflein.	Eckberg.	Kantenbach.	Cologne.
Lead - - -	54	69	68.69	64	63.1
Sulphur - - -	8	16	16.18	18	12.
Carbonated lime and silicx	38	15	16.13	18	19.67
Oxyd of iron - - -	0	0	0	0	3.33
	<hr/>	<hr/>	<hr/>	<hr/>	<hr/>
	100	100	101	100	98.1

Dr. Thomson gives the following as the result of his experiments:

Lead - - -	85.13
Sulphur - - -	13.02
Oxyd of iron - - -	0.5
	<hr/>
	98.65
Loss - - -	1.35
	<hr/>
	100

Hence, as is evident from the above tables, the proportion of lead varies from 54 to rather more than 85 per cent. The proportion of silver varies considerably also; and it appears to have an effect on the external aspect of the varieties. It sometimes also contains a small portion of iron; and gold has even been found in lead-glance. It is, next to pyrites, the most common of metallic ores, and is found in beds and veins in primitive, transition, and secondary mountains. It occurs almost always with blende and calamine, with which it appears to have a strong geognostic affinity. It is frequently

accompanied with silver ores, and sometimes with copper ores. To mention all the places in which it is found, would be to mention almost all the known mineral districts in the world. It is very abundant in Germany, and also in many places in our own country. The lead-mines in Britain are situated in Cornwall, Devonshire, and Somersetshire, in Derbyshire, Durham, Lancashire, Cumberland, and Westmoreland; in Shropshire, in Flintshire, Denbighshire, Merionethshire, and Montgomeryshire; at the lead-hills in Scotland, on the borders of Dumfriesshire and Lanarkshire, in Ayrshire, and at Strontian in Argyleshire. Lead-glance is also found at Konigsberg in Norway; in various parts of Lapland, and in Denmark and Sweden; in several districts of Saxony, Hungary, Transylvania; in France, Italy, and Spain. Most of the lead of commerce is procured from this ore; it is also used without farther preparation in the potteries for coarse work, and also in the smelting of silver ores. Lead-glance is now generally used as a scientific name, in preference to the less significant but common one *galena*, on account of its lustre, which forms a striking feature in the external aspect of this mineral. (2) The second subspecies

is *compact lead-glance*. The colour of this is very similar to that of the common lead-glance. It occurs in mafs, diffe-minated, and fpecular. The latter is externally fmoother, fhining, and fplendent; internally it is glimmering, and its luftre is metallic. Its fracture is even. It acquires a polifh by friction; its ftrcak is fhining, almofl fplendent; not fo eafily frangible as the preceding fubfpecies; but agrees with it in the other characters. Its fpecific gravity is about 7.4. It occurs in veins, and is ufually accompanied with the common lead-glance. When the two fubfpecies occur together, the compact always forms the fides of the vein, and this probably owing to its having been in a lefs perfect ftate of folution. It is accompanied with black blende, common iron pyrites, copper pyrites, quartz, and heavy fpar. It is found in the lead-hills in Lanarkfhire, and in Derbyfhire; in divers parts of Germany, and in the valley of Chamouni in Switzerland.

Sp. 2. *Blue lead ore. Blaubl-yerz*, Wern. *Mine de plomb bleu*, Broch. The colour of this fpecies is intermediate between dark indigo blue and lead-grey. It occurs mafive, and cryftallized in perfect fix-fided prifms, which are ufually fmall, low, fometimes bulging, with a furface rough and dull. Internally it is feebly glimmering, and its luftre is metallic. The fracture is even, paffing into the fine-grained uneven and flat conchoidal. Its fragments are indetermi-nately angular. It is opaque, gives a fhining metallic ftrcak, is foft, fertile, and eafily frangible. Its fpecific gravity is 5.46. It eafily melts before the blowpipe, burns with a weak blue flame, emits a ftrong fulphureous vapour, and is reduced to pure lead. It is conjectured to be a compound of lead, oxyd of lead, and fulphur; and is fuppofed by Werner to be intermediate between lead-glance and black lead ore. Klaproth difcovered in it phosphoric acid. It occurs in veins, accompanied with black lead ore, white lead ore, malachite, radiated copper azure quartz, fluor-fpar, and heavy fpar. It is not often to be met with, and has hitherto been found only at Zfchoppau in Saxony, at Schemnitz in Hungary, and Brittany in France.

Sp. 3. *Brown lead ore. Braun vleyerz*, Wern. *La mine de plomb brune*, Broch. Its colour is hair-brown, of different degrees of intensity, fometimes very pale, approaching to grey, and fometimes it paffes into a clove-brown. It occurs mafive, and is cryftallized in fix-fided prifms. The furface of the cryftals is blackifh and rough. Internally it is glitening, and its luftre is refinous. The fracture is fmall and fine-grained uneven, and fometimes paffes into fplintery. It is foft, not very brittle, but eafily frangible. Its fpecific gravity between 6.60 and 6.98. It melts eafily before the blowpipe, without being reduced; and, during the cooling, fhoots into acicular cryftals. It does not effervefce with acids. According to Klaproth, a fpecimen from Brittany contained,

Oxyd of lead	- -	78.58
Phofphoric acid	- -	19.73
Muriatic acid	- -	1.65
		<hr/>
Lofs	- - -	99.96
		4
		<hr/>
		100
		<hr/>

It is found at Miefs in Bohemia; alfo in parts of Hungary, Saxony, and Lower Brittany. In Bohemia it is ufually found accompanied with lead-glance, white, black, and green lead ores, copper pyrites, blende, quartz, heavy fpar, &c. It occurs in veins.

Sp. 4. *Black lead ore. Schwarz vleyerz*, Wern. *La mine de plomb-noir*, Broch. The colour of this fpecies is greyifh-black, of different degrees of intensity. It occurs in mafs, diffe-minated or cellular, or cryftallized in fix-fided prifms. It is externally fplendent, and internally only fhining. Fracture fmall-grained uneven, which fometimes paffes into imperfect conchoidal and fplintery. Fragments undeterminately angular; ftrcak greyifh white; rather brittle; eafily frangible. Specific gravity about 5.8. Before the blowpipe it decrepitates, and is quickly reduced to a metallic globule. According to Lampadius it confifts of,

Lead	- - -	72
Oxygen	- - -	7
Carbonic acid	- - -	18

		<hr/>

It occurs in veins, and is almofl always accompanied with white lead ore and lead-glance, and ufually in the upper part of veins, and in new lead-glance formations. It very frequently encrufts lead-glance, and is covered with white lead ore, and fometimes by green lead ore. It is found in the lead-hills of Scotland; in different parts of Bohemia, Saxony, Salzburg, Lower Brittany, and in Siberia. Previously to the analysis of Lampadius, Haiÿ fuppofed it was a phofphate of lead; and Werner fufpected that it was a compound of lead, carbonic, and fulphuric acids.

Sp. 5. *White lead ore. Wies-vleyerz*, Wern. *Mine de plomb blanche*, Broch. This is a carbonate of lead: its colour is a greyifh or yellowifh-white, with very many different fhades. It occurs mafive, diffe-minated, but moft frequently in a cryftallized ftate. The chief varieties are, 1, the cucuiform octahedron; 2, the pyramidal dodecahedron; 3, the preceding, with a fix-fided prifm interpofed between the pyramids; 4, the fame as variety 3, with fummits of the terminal pyramids replaced by a fix-fided plane; 5, a fix-fided prifm, with fummits compofed of four planes; 6, the fame, with fummits compofed of fix planes. The cryftals are ufually fmall. Externally, it is fpecular fplendent, feldom glitening; internally, it alternates from highly fplendent to glitening, and its luftre is adamantine, inclining fometimes to femi-metallic, and fometimes to refinous. The fracture is commonly fmall conchoidal, but it frequently paffes into fine-grained uneven, and even into fine fplintery. Fragments indetermi-nately angular. It alternates from tranf-lucent to tranfparent, and is duplicating. It is foft, brittle, and eafily frangible. Its fpecific gravity is from 6 to 7.24, according to the different fpecimens that have been analyzed. Before the blowpipe it flies to pieces, becomes red, yellow, and laftly melts into a globule of metallic lead. It makes a ftrong effervefce with acids. Its furface becomes black, when expofed to the vapour of fulphuret of ammonia. Its conftituent parts are as follow:

It is almost always accompanied with lead-glance, and occurs in a kind of repository. It occurs in veins that traverse transition rocks; though it is found with different minerals, in different parts of the world. It is not a rare mineral, but is seldom found in sufficient quantities to make it worth while to separate it from the adhering spar, for the purpose of melting. The finest specimens of this ore that are found in Britain come from the mines of Derbyshire, the Lead-hills in Scotland, and Minera in Denbighshire. It is also found on many parts of the continent.

Sp. 6. *Green lead-ore.* Grün Bleyerz, Wern. *La mine de plomb verte*, Broch. The colour of this species is grass-green, which passes on through the several shades into greenish-white. The olive and pistachio-green colours are the most common. It occurs massive, sometimes reniform, but most commonly crystallized. The varieties are, 1. Six-sided prisms, having sometimes the lateral and terminal edges truncated. 2. When the lateral edges of the prism converge towards their extremities, an acute, double, six-sided pyramid is formed. The crystals are small; externally smooth and shining; internally glistening; the lustre is resinous. Fracture small-grained, uneven. Fragments angular and blunt-edged: it is soft, rather brittle, and easily frangible. Specific gravity 6.27 to 6.94. Before the blowpipe it does not fly to pieces; it becomes white and melts easily into a greyish-globule, but without being reduced even with charcoal. It dissolves in acids without effervescence. Its constituent parts are, according to

Green lead-ore is, when of a pale colour, apt to be confounded with the preceding species; but it may be distin-

guished by the following characteristics: 1. The fracture in this species is fine-grained, uneven, but in white lead-ore it is more or less conchoidal. 2. Its lustre is resinous. 3. It is harder than white lead-ore. 4. It is of a greater specific gravity. 5. Its crystals are often aggregated; and 6. Its prisms are generally shorter than those of white lead-ore.

Sp. 7. *Red lead ore.* Roth Bleyerz, Werner. *Red lead-spar*, Kirwan. *La mine de plomb rouge*, Brochant. The colour of this mineral is of a hyacinth-red, sometimes inclining to aurora, or morning red. It occurs most commonly crystallized in broad four-sided prisms, and but rarely massive, disseminated, or in membranes. The crystals are middle-sized: the surface of the crystals is usually smooth, sometimes longitudinally streaked. Both externally and internally it is splendid, and its lustre is intermediate between adamantine and resinous. The fracture is foliated, and the fragments indeterminate angular. It sometimes inclines to transparency. It is soft, and in the intermediate state between very brittle and sectile: easily frangible, and its specific gravity is somewhere between 5.6 and 6.0. It melts before the blowpipe into a blackish scoria, and may be partly reduced with borax. Specimens have been analysed by

This mineral occurs in veins in gneiss and mica slate, where it is accompanied with lead-glance, green lead-ore, iron pyrites, brown iron-stone, native gold and quartz. It is found in Siberia; at Annaberg, in Austria; and at Upper Faucigny, in Savoy. It is much used as a pigment, on account of its beautiful colour, its durability in the atmosphere, and its mixing readily with oil.

Sp. 8. *Yellow lead-ore.* Gelbes Bleyerz, Werner. *Yellow lead-spar*, Kirwan and Hatchett. *Plomb molybdaté*, Haüy. *La mine de plomb jaune*, Brochant. In this species, which has long been known to mineralogists, the lead is mineralized by a particular metallic acid, called the molybdic acid. It occurs sometimes massive, more commonly crystallized in small crystals; the forms of which are rectangular tables of four sides, or of eight sides, bevelled; the cube, octahedron, equiangular eight-sided table, and double eight-sided pyramid. The tables are usually broad and thin, and alternate from small to very small, but are seldom middle-sized.

They

They are sometimes united, frequently intersect one another, and form thus the cellular external shape. Its colour is wax-yellow, and its lustre distinctly waxy: it is translucent, soft, and easily frangible. Its specific gravity is rather more than 5. It decrepitates before the blowpipe, then melts into a globule of a grey colour, in which are disseminated particles of metallic lead. It gives a bluish-white colour to borax: it occasionally produces a glass, which is greenish-blue, and sometimes deep blue. Its constituent parts are, according to

It occurs on compact lime-stone which is much traversed by veins of calc-spar, and is accompanied with molybdena and yellow lead-earth; sometimes, also, with lead-glance, white, black, and green lead-ore, calamine, blende, the calc and fluor spars. It is found principally in Carinthia; though it is met with at Annaberg, in Austria; also in Hungary, Silesia, Saxony, Burgundy, in France, and other places.

Sp. 9. *Lead vitriol, or sulphate of lead. Blei vitriol*, Werner. *Native vitriol of lead*, Kirw. *Plomb sulphaté*, Haüy. *Le vitriol de plomb natif*, Broch. The colour of this mineral is yellowish grey, passing to the greyish-white; the lighter varieties incline much to white. It occurs only in crystals, the form of which is rectangular octahedrons with obtuse pyramids. The pyramids are often variously truncated. Externally it is shining; internally it is splendent. The fracture is compact; it is more or less transparent: it is softish, rather brittle, and its specific gravity is about 6.3. It is easily reduced, when exposed to the flame of the blowpipe; and is insoluble in the nitrous acid. Specimens have been analysed by Klaproth; the constituent parts are as follow: viz. of that from

	Anglesea	Wanlock-head

	100.	100.

It occurs in lead-glance veins at Wanlock-head, and in brown iron-stone in the island of Anglesea. It has also been found in lead-glance veins in Andalusia in Spain.

Sp. 10. *Lead-earth. Bleyerde*, Wern. is divided into two

sub-species; 1, the coherent; and 2, the friable. 1. The coherent, or indurated, named *Verhärtete bleierde* by Werner, and *Le plomb endurci* by Brochant, is of a yellowish or greenish-grey colour. It is sometimes of a smoky-grey, and sometimes of a light brownish-red. It occurs in mass. Internally it is glittering, passing into glistening, and its lustre is resinous. Its fracture is fine-grained, uneven, passing into fine splintery and earthy, also into flat conchoidal. It is opaque, or, at most, slightly translucent on the edges. It gives a brownish streak, is soft, passing into friable, not brittle, but inclining to sectile, and heavy. It is easily reduced before the blowpipe, effervesces with acids, and becomes black with sulphuret of ammonia. It does not appear to have been hitherto analysed, but is supposed to be in intimate combination with white lead ore, alumine, and lime. It occurs with the other ores of lead, and is usually accompanied by iron pyrites, malachite, and quartz. The yellow varieties are found in Derbyshire, in some parts of Germany, at La Croix in France, and at Tschefink in Siberia. The other varieties are to be met with at Wanlock-head, in the Lead-hills in Scotland, in Saxony, Silesia, Poland, &c. 2. *Friable lead-earth. Zerrübbliche bleierde*, Werner. *Le plomb terreux friable*, Brochant, is of a yellowish-grey, approaching to sulphur-yellow. It occurs friable; sometimes massive and disseminated. It is composed of dull dusty particles, which are more or less cohering, and soil a little. It has a rough feel, and is heavy. It occurs on the surface, or in the hollows of other minerals, and is usually accompanied with lead-glance, and other ores of lead, and is found at Wanlock-head, and the Lead-hills of Scotland, at Zellerfeld in the Hartz, near Freyberg, in the electorate of Saxony, in the mountains of Cracow, Poland, at La Croix in France, and at Berefowskoï in Siberia. It is in some instances observed passing into solid lead-earth, and is probably formed by the decomposition of lead-glance, as it is frequently met with as a crust upon it.

Sp. 11. Another species is denominated a triple sulphuret of lead. Its colour is dark-grey inclining to black. It occurs crystallized. Its primitive figure is a rectangular tetrahedral prism, besides which it presents the following varieties. 1. The primitive crystal with solid angles replaced by triangular planes. 2. The same with lateral edges replaced by rectangular planes. 3. The same terminated by a very low and deeply truncated tetrahedral pyramid. 4. Four prisms with deeply truncated dihedral summits joined together at their bases, forming a rectangular cross. The crystals are large and middle-sized, with a splendent metallic lustre both externally and internally. Its fracture is coarse-grained and uneven. It is brittle and easily frangible. It leaves a faint black trace when rubbed on paper. Specific gravity 5.8 nearly. When suddenly heated before the blowpipe it crackles and splits; but if gradually heated it melts, and on cooling forms a globule of a dull metallic grey colour. According to an analysis made by Mr. Hatchett, it consists of

It is found in a mine at Huel-Boys in Cornwall.

The existence of native lead, which has been maintained by several mineralogists, is extremely doubtful. What has been regarded as a native oxyd of the metal, appears to be rather an earthy carbonate.

*Affay and Analysis of Lead Ores.*—The most common lead ore, galena, is very easily analysed, since it is in general composed of sulphur and lead only. Those ores in which the lead is combined with other metals, such as silver, copper, antimony, bismuth, or arsenic, are attended with more difficulty in their analysis. If the analysis be made with a view to smelt the ore, it will be proper to make the affay in the dry, as well as the humid way. The latter will not only give the proportion of lead, but its other constituents, by which the smelter is directed to use the most proper fluxes. When, however, the analysis is made for publication, it should be made by the humid process only, and with the greatest accuracy.

The common galena may be analysed by dissolving 100 grains in dilute nitric acid: the lead will be dissolved, and the residuum will be sulphur, which may be separated by washing. The solution of lead may now be treated with sulphat of soda. The lead will be precipitated, with the sulphuric acid in the state of sulphat of lead. The precipitate being collected, and dried at the temperature of 212, must be weighed, allowing for every 100 grains of the sulphat 69.85 of lead. The lead may be precipitated from the nitric acid, in the metallic, by means of a plate of zinc. The metallic lead will adhere to the plate, and may be scraped off and squeezed into lumps, after being washed in clean water. The lead obtained by this process is supposed to contain a small portion of the zinc. It will, therefore, be proper to digest the metallic precipitate, for a short time, in very dilute sulphuric acid, and then wash the lead with warm distilled water.

A specimen of galena containing silver was analysed by Vauquelin.

By slowly roasting a portion of this ore, he found it lost 12 per cent. of sulphur. Another portion was treated with dilute nitric acid, which dissolved the lead. The residuum was heated to redness, by which the sulphur was volatilized, leaving behind 16.75 of sulphur. To the solution in nitric acid was now added sulphat of soda, when the lead was precipitated in the state of sulphat. He obtained 63.1 per cent. of lead, allowing 100 of sulphat to contain 75.72 of metallic lead. He then saturated the liquor with ammonia, which threw down 3.3 per cent. of oxyd of iron, and obtained from the remaining liquor, by carbonat of potash, 5 per cent. of carbonat of lime.

A specimen of lead ore from Cornwall, consisting of lead, sulphur, antimony, and copper, was analysed by Mr. Hatchet.

To 200 grains of the ore, in a matrass, he added 2 oz. of muriatic acid. While the mixture was heated, he added, from time to time, small quantities of nitric acid, just to keep up an effervescence, till the metals were oxydated and dissolved. After being gently heated for an hour, the solution was complete, and of a green colour, owing to the presence of the copper. The sulphur was separated and floated on the liquid, which being collected was digested in muriatic acid. When dried it weighed 34 grains.

The above solution, and the muriatic acid in which the sulphur was digested, were mixed together, and diluted with six pints of distilled water. The mixture became turbid and milky, and on being filtered while hot, the pure oxyd of antimony was left on the filter, which being washed with more boiling water, was dried, and found to weigh 63 grains.

When the liquid, which had passed through the filter, including the washings, was cold, some muriat of lead was deposited in crystals, owing to the sparing solubility of that

salt. The whole was evaporated to a small quantity of liquid, sufficient to hold the copper in solution. This liquid, being separated from the solid muriat of lead, contained a small portion of that salt. A few drops of sulphuric acid being added, however, separated it in the state of sulphat of lead. The mass of muriat of lead left by evaporation, was now re-dissolved in boiling water, and decomposed by sulphat of soda. The sulphat of lead here formed was added to that produced from the separated liquid, which, on being washed and dried on a sand bath, weighed 120.2 grains. The green liquid containing the remainder of the mineral was now saturated with ammonia and an excess added, which redissolved the oxyd of copper, forming a vivid blue solution. A quantity of oxyd of iron now subsided, which, when separated, weighed 2.4 grains.

The solution of copper was now evaporated nearly to dryness, and boiled with pure potash, when the black oxyd of copper was left at the bottom of the vessel, which being washed, separated, and dried, weighed 32 grains.

In this analysis the sulphur is the only substance separated in a state of purity. The 63 grains of oxyd of antimony, allowing it to contain 23.08 per cent. of oxygen, would afford 48.46 of antimony. The 120.2 grains of sulphat of lead, allowing 70.9 to the 100, will give 85.22 of metallic lead. The 32 grains of oxyd of copper, reckoning the black oxyd of that metal to contain 25 in the 100, will yield 24 grains. If we reckon the 2.4 grains of iron at 1.2 of metal, the analysis will stand as follows, when reduced to 100.

Sulphur	-	-	-	17
Antimony	-	-	-	24.46
Lead	-	-	-	42.61
Copper	-	-	-	12
Iron	-	-	-	1.2
				<hr/>
				97.77
Loss	-	-	-	2.73
				<hr/>
				100
				<hr/>

If silver had been a constituent of the ore, the above process would have been a little varied. In the first operation the ore would have been dissolved in dilute nitric acid, the antimony would have been in part dissolved, and left at the bottom of the vessel in the state of white oxyd. When the sulphur and the antimony, by dilution with water, are separated, muriatic acid must be added. The lead will be in part, and the silver entirely precipitated. The muriat of lead may be separated, by boiling water, from the muriat of silver. The weight of silver may be rated at 77.52 in the 100 of muriat. The other metals may be separated as in the last process. Arseniated lead ore requires a still different treatment. It was analysed by Vauquelin as follows: 100 parts of ore were roasted for half an hour, occasionally adding a little tallow, which served to reduce the arsenic and facilitate its escape. By this treatment it lost 38 parts, which was presumed to be oxyd of arsenic; the remaining mass was boiled with strong muriatic acid for an hour. A quantity of oxy muriatic acid escaped, the liquid assumed a red colour, and white needle-formed crystals of muriat of lead were deposited. The lead by this means was converted into a muriat, which being dissolved in boiling water, and treated with sulphat of soda, affords sulphur of lead. This precipitate, being separated and dried, weighed 25 parts, which gave 20.2 of lead, allowing 80.8 to the 100 of sulphat. The liquid thus freed from lead being treated with pure ammonia, afforded a precipitate equal to 39 grains, consisting of oxyds of iron and arsenic. The circumstance of oxy muriatic acid being given out, when the oxyd of lead was digested

gested with muriatic, induced Vauquelin to conclude that it was in a state of peroxyd.

In this account the last part of the process appears incomplete, in the circumstance of the oxyds of arsenic and iron being mixed together. The former of these may be separated, boiling the two in nitromuriatic acid, which will convert the oxyd of arsenic into arsenic acid, and which may be separated by washing.

Carbonat of lead was analysed by Klaproth by the following process. He introduced 100 grains of this ore into 200 grains of nitric acid, and diluted it with 300 of water. The carbonic acid escaped in the form of gas, making a loss of weight equal to 16 grains. Into this solution was suspended a cylinder of zinc. In 24 hours the lead was precipitated in the metallic state, which weighed 77 grains, equal to 82 of oxyd.

Sulphat of lead has been analysed by the same chemist: 100 grains of the ore were first roasted at a red heat, and lost two grains, supposed to be water. The remainder was then heated to redness in a platina crucible, with 400 grains of carbonat of potash. By this treatment a yellow reddish mass was obtained, which, on being digested in water and filtered, afforded 72 grains of oxyd of lead. This was next dissolved in nitric acid, leaving a residuum of one grain of oxyd of iron. A cylinder of zinc was introduced into the solution, which precipitated the lead in the metallic form, in quantity equal to 66½ grains.

The alkaline matter which passed through the filter contained the sulphuric acid of the sulphat of lead, with excess of alkali; this excess was saturated with nitric acid, and the liquid acetat of barytes was added, which caused a precipitation of 73 grains of sulphat of barytes; this he allows to contain 25 grains of real sulphuric acid. Hence the result is

Oxyd of lead	72
Sulphuric acid	25
Oxyd of iron	1
Loss by roasting	2
	<hr/>
	100

We have also the analysis of phosphat of lead by the same ingenious experimenter.

One hundred grains of this native salt were dissolved in dilute nitric acid; into this solution nitrat of silver was dropped till it ceased to precipitate: the insoluble substance, which was muriat of silver, weighed 11 grains, indicating 17 grains of muriatic acid. Sulphuric acid was now added to precipitate the lead. The sulphat of lead weighed 106 grains, which contained 78.4 of oxyd of lead. The excess of sulphuric acid was separated by adding nitrat of barytes, and then nearly neutralized with ammonia. On adding acetat of lead, 82 grains of phosphat of lead were precipitated, containing 18.37 of phosphoric acid: muriatic acid was now added to the solution, and evaporated to dryness. The dry mass was digested with alcohol, which dissolved the muriat of iron, the presence of which was detected by prussiat of potash, and was found equal to 1/19th of a grain of the oxyd.

Molybdat of lead was analysed by Mr. Hatchett. He boiled a quantity of the ore in sulphuric acid, till it would dissolve no more. This formed sulphat of lead, while the molybdic acid was dissolved in the sulphuric acid. The sulphat of lead was boiled with carbonat of soda, and was afterwards washed: this appeared to be carbonat of lead. The nitric acid dissolved all but a small quantity, which was added to be flux. The lead was next precipitated by sulphuric acid. The solution of the molybdic acid in the sul-

phuric acid was diluted with 16 parts of water, and saturated with ammonia; when a little oxyd of iron was precipitated. The solution was now evaporated to dryness, and a strong heat given to sublime the sulphat of ammonia. The remaining mass, when boiled with nitric acid to dryness, afforded molybdic acid of a yellow colour.

Although the analysis of the different ores may have pointed out general methods for the separation of lead from other metals, some hints may, nevertheless, be necessary for the analysis of the alloys of lead. Lead is most frequently alloyed with tin, silver, antimony, or bismuth. The alloy of tin and lead may be dissolved in dilute nitric acid. The lead will be entirely taken up. Mott of the tin will be precipitated in the state of white oxyd, by the addition of water. If sulphuric acid be now dropped into the solution till the precipitation ceases, the lead, in a state of sulphat, will be obtained, while the remaining tin will be dissolved, which may afterwards be precipitated by an alkali. Lead may be separated from silver, when both those bodies are dissolved in pure nitric acid. The silver may be precipitated in the state of muriat, by adding muriat of soda. The lead may be afterwards precipitated by sulphuric acid.

To separate lead from bismuth, dissolve the alloy in nitric acid, then add a large quantity of water, which will precipitate the greatest part of the bismuth in the state of white oxyd. The lead must then be precipitated by sulphat of soda, and the remainder of the bismuth by potash.

The separation of lead from antimony may be performed by the same process used for separating tin.

It may be here noticed, that in all cases where sulphur is present in the ore or substance to be analysed, if the nitric acid be employed, it must be very dilute, otherwise the sulphur will combine with its oxygen, forming sulphuric acid. In order to know when this takes place, the solution must be tested with nitrat of barytes. If, however, lead be present, it will combine with the sulphuric acid as it is formed, and fall to the bottom of the vessel.

*Reduction of the Ores, or smelting of Lead.*—Two processes are employed for the smelting of lead, the one by means of a blast furnace, called an ore-hearth, and the other by means of a reverberatory furnace. The latter is used throughout Derbyshire and North Wales, and is undoubtedly the best, where coal is not very scarce. In the former of these methods the ore and the fuel are mixed together, and exposed to the blast. The heat dissipates the sulphuret, the ore being the common sulphuret of lead or galena. A portion of the lead is oxydated, which facilitates the vitrification of the earthy parts of the ore, and of the fuel. These together constitute the slag or scoria. The metallic lead falls into the lower part of the hearth, and is defended from the oxygen of the blast by the scoria, which is fluid upon its surface. The liquid lead is let off from time to time, always retaining a portion for the scoria to float upon. When the whole of the lead is to be drawn off, the blast must be stopped, and some lime thrown upon the liquid scoria, which renders it concrete, while the lead, being still liquid, can be run off.

The reverberatory furnace employed for smelting lead is made on the same plan with those commonly used for puddling iron, differing in size, and a few other particulars. The fire is made at one end, and the flame plays over the hearth, entering an oblique chimney at the end, which terminates in a perpendicular one, of considerable height. The length of the hearth, from the place where the fire enters, to the chimney, is 11 feet; two feet of this length next the fire constitutes the throat of the furnace; the width of the same is four feet, and its depth about six inches; the

length of the fire-place is four feet, equal to the width of the throat; its width two feet, and depth three feet, from the grate up to the throat of the furnace. The rest of the hearth is a concave surface, nine feet long, four and a half feet wide at the throat of the furnace, seven feet four inches wide at the distance of two feet from the throat, seven feet two inches in the middle of the hearth, five feet eleven inches at two feet distance from the chimney, and two feet ten where the flame enters the chimney at two apertures, each ten inches square. These apertures terminate in the oblique part of the chimney, the section of which is 16 inches square, which communicates with the main chimney, the section of which is twenty inches square, supporting a straight horizontal line, drawn from the lower plane of the throat of the chimney to the opposite side of the furnace; the lowest part of the concave hearth, which is in the middle of this cavity, is nineteen inches below this line, the roof of the furnace being seventeen inches above the same line; the rest of the hearth is conformably concave.

On each side of the furnace are three openings, each about ten inches square, provided with iron doors, to be removed as occasion may require. They are arranged at equal distances from each other, between the commencement of the hollow hearth and the entrance into the chimney. The lower part of these apertures is on a level with the horizontal line above alluded to, being for the purpose of stirring and raking the ore, &c. Besides the larger openings there are two small apertures, one below the large middle opening, and nearly on a level with the bottom of the furnace; the other under that next to the chimney, at some distance above the first aperture. The first is a tap-hole for the lead, and the second for the scoria. The ore is introduced by a vessel in the shape of a hopper, placed in the roof of the furnace.

Previous to the ore being smelted, it requires to be separated as much as possible from the earthy matter in which it is imbedded. Although galena, which is the ore used for smelting, is most frequently accompanied by sulphat of barytes, fluats and carbonat of lime, it is found to exist in crystallized distinct masses, and can be separated from it by mechanical means to a tolerable extent. The whole of the ore, with the earthy matter, is pounded to a certain degree with hammers, and is chiefly performed by women. In some places, however, it is broken down by passing it through iron rollers pressed together by great weights. After the ore has been thus reduced, the earthy matter is separated by washing. The powder to be washed is introduced into a sieve or riddle, and placed in a large tub full of water. By a certain motion given to the riddle, the lighter or earthy parts are thrown over the edge of the same, while the galena, by its greater specific gravity, is retained. This process requires great dexterity, which can be acquired by experience only. There are, however, some impurities which cannot be separated by this mechanical process, and are generally smelted with the ore. These are *blind*, or *black-jack*, called by the smelter *muck ore*; pyrites, or sulphuret of iron, named *Brasil* by the workmen. When the ore abounds much with these substances, the process of smelting is more difficult, and requires an extra assistance of flux to reduce it.

In the state above described, the ore is introduced at the hopper in the middle of the roof of the furnace, and spread upon the concave hearth, to expose it as much to the flame as possible, in order to facilitate the escape of the sulphur. This should be performed by a long continued heat which is not violent, in order that the sulphuret itself may not be volatilized, an effect which, more or less, always takes place. The moment the sulphur has left the lead it begins

to combine with oxygen. The oxyd of lead, thus formed, combines with the earthy matter, which it renders so fusible as to become liquid upon the sulphur of the melted lead, and defends it from the future action of the oxygen. At this stage of the process the fire is raised to separate as quickly as possible the melted lead from the liquid scoria. The latter is now let off at the upper tap hole, leaving a small portion still upon the lead to preserve it from the air. The fire at this period is lowered, and a quantity of coal-flask thrown in upon the melted mass. This serves as well to facilitate the cooling, and to cause the reduction of some oxyd of lead, which also tends to stiffen the melted scoria. This last effect, however, is not produced sufficiently, till a quantity of powdered lime is thrown into the furnace. By this treatment the remaining scoria becomes concrete, and is then broken to pieces and pushed to the opposite side by means of a rake, and taken out of the furnace at the different openings on the same side. The liquid lead is now let out, at its proper aperture, into a large iron pan, or cistern, from whence it is laded into moulds to cast into pigs. The furnace is now ready to be charged again. When the ore abounds with much impurity, the oxyd of lead is not sufficient to give the proper degree of liquidity to the scoria. In this case a certain quantity of flux of lime is added, which has the property of forming a very fusible compound with sulphat of barytes, an ingredient very common in the ore.

This flux has been used from time immemorial for the same purpose, and has no doubt derived its name from its properties as a flux. See *Flux of LIME*.

The concrete scoria, which is taken out of the furnace, is found to contain some lead, independent of that in the state of oxyd, and chemically combined. This is generally lodged in the cavities of the spongy mass. These masses are taken to a kind of blast furnace, called a slag-hearth. By this second fusion of the scoria, the lead drops through the liquid mass into the lower part of the hearth, where it is not acted upon by the blast, and from thence is let off and cast into pigs. This lead is said to be of an inferior quality. Some ores of lead contain silver. The great affinity of lead for that metal is such, that the whole of it is found in the lead (see *SILVER*), from whence it is afterwards separated.

*Physical and chemical Properties of Lead.*—Lead is of a bluish-white colour, when made as bright as possible. This is best effected by scraping and burnishing. This polish it soon loses by exposure to air.

Its softness is such, that a cylinder of one inch in diameter and twelve inches long, may be easily bent by a person of ordinary strength; indeed, it is the most soft and flexible of the metals. Its specific gravity, according to Brisson, is 11.3523, and so far from being increased by the hammer, agreeably to that change in other metals by the same effect, Mufchenbroeck asserts that it is diminished. It may be here proper to observe, that those metals which are susceptible of the most perfect crystallization, will undergo the greatest condensation by the hammer, provided the metal be sufficiently malleable. Hence we find this property the most conspicuous in brass, and in blistered steel. See *METAL*.

Lead, in common with its softness, is the least elastic of the metals; so which also may be attributed its little tenacity. Its hardness is increased by hammering, and its tenacity in a proportionate degree.

Lead is exceedingly malleable, which connected with its excessive softness, admits of its being rolled into thin sheets with little power. Its tenacity, according to Dr. Thomson,

Thomson, is such, that a wire of  $\frac{1}{12.6}$  of an inch will support only 18.4 pounds. Lead fuses at about 600° of Fahrenheit, and if raised to a much higher temperature, will be found to diminish by evaporation. If lead be melted and poured into an iron mould, while the middle part will be liquid for a short time. If this liquid part be poured off, or let out at a plug-hole at the bottom, the interior surface of the solid part will exhibit a crystalline form. The crystals will be larger and more distinct as the cooling is slower.

Lead is much employed in the arts, particularly for buildings and cisterns. For the former of these purposes it has many advantages. It is easily worked into any shape on account of its great softness, and is sufficiently malleable to fold two edges over each other, so as make it watertight without soldering. This is a very great advantage, since, when the pieces are folded together, the expansion and contraction, by a change of temperature, soon breaks it to pieces.

Although it is at present in general use for water-cisterns, pumps, and pipes for conveying water, serious objections have been made to it by different philosophers, particularly Dr. Lambe, so far as regards its effects on the human economy.

A very ingenious paper was some time ago published by Morveau, in which he shews that the water exposed to the leaden vessels would frequently be pernicious, if some sulphuric acid were not present, which never fails to precipitate lead from any of its solutions. Thus we see that lead is the least objectionable for mineral waters containing the sulphuric acid, which is very general in almost all springs.

Great mischief has been produced by the use of lead in dairies; although we lament to say that this practice is still followed up to a certain extent. If the milk runs into the slightest acidity, we must expect some lead to be dissolved, and its probable consequences if taken into the stomach.

The disease called the Devonshire colic, was proved by sir George Baker, in several excellent papers written by him, and published in the Philosophical Transactions of that time, to be occasioned by lead dissolved in the cyder, and which had been furnished from the cyder presses, which were lined with that metal; but was in consequence of this valuable discovery laid aside.

We have heard of a similar disease in the West Indies, acquired by drinking new rum. The rum was found to contain lead, which had been taken from the leaden worm used for the condensation of the spirituous vapour. What, however, is very singular, the rum lost its deleterious property by keeping about twelve months. This fact was not explained at the time, but it has lately been cleared up by a series of experiments made by the writer of this article. The new rum is generally put into oak casks, from whence the liquor extracts a quantity of tan and gallic acid. These substances combine with the lead in solution, forming a perfectly insoluble substance, which falls to the bottom of the cask. These facts shew that lead should not be used in any situation where fermented liquors are present, since in every stage of their existence, they contain more or less acetic acid. And it must not be forgotten, that all distilled spirits will contain the same acid, from the circumstance of its being volatile and coming over with the spirit.

We have, however, abundant satisfaction in knowing that the existence of lead and gallic acid in spirits, wine, or

other fermented liquors, are incompatible: and that all liquors which have been kept in oak casks for a certain time must be freed from lead. If we find the presence of gallic acid by a solution of iron, we may pronounce such liquid free from lead.

These observations, which may appear out of place, are given with a view to guide those who may be making or using vessels of lead, which, under some circumstances, are attended with deplorable consequences.

*Alloys of Lead formed with other Metals.*—One part of tin and two of lead form an alloy, fusible at about 350 of Fahrenheit, and used by tinmen and others under the name of soft folder. See **SOLDER**.

Lead forms an imperfect alloy with copper. The metal used for common brass-cocks is an alloy of these two metals. The lead is so imperfectly combined with the copper, that when a piece of the metal is exposed to a certain heat, the lead separates from the copper in bright globules of the former.

The alloy of antimony with lead is not uncommon. Sixteen of lead and one of antimony form the printers' type metal.

Lead easily combines with mercury, forming an amalgam. This is effected either by putting mercury into melted lead, or by putting lead, in small particles, to the mercury. See **AMALGAM**.

An alloy of silver and lead is easily formed. Indeed lead is frequently used to take silver from plated iron, which is afterwards got from the lead by cupellation.

We are indebted to Mr. Hatchett for some valuable facts relative to the alloys of lead and gold. One part of lead to eleven of gold forms a very brittle alloy, having a fracture of a pale brown colour, destitute of metallic lustre.

The alloys in any proportion have the singular property of being of less specific gravity than the mean, the very contrary of which is observed in most other compounds of metals. The following is a table given by Mr. Hatchett exhibiting these facts.

Metals.	Grains.	Specific Gravity of Alloy.	Bulk before Union.	Bulk after Union.	Expansion.
Gold Lead	442 38	18.08	1000	1005	5
Gold Copper Lead	442 19 19	17.765	1000	1006	6
Gold Copper Lead	442 30 8	17.312	1000	1022	22
Gold Copper Lead	442 34 4	17.032	1000	1035	35
Gold Copper Lead	442 37.5 .5	16.627	1000	1057	57
Gold Copper Lead	442 37.75 .25	17.039	1000	1031	31

When lead is exposed to the air for a little time, it soon appears of different colours, not unlike the prismatic colours. By a longer exposure, assited with moisture, it becomes covered with a white powder. This is the oxyd of lead combined with carbonic acid. This change is facilitated by heat, and fill more by the fumes of acetic acid or vinegar. It is by this means that the white lead of commerce is made, of which we shall treat hereafter.

If melted lead be exposed to the oxygen of the atmosphere, a greyish-yellow powder begins to form upon the surface. By keeping it exposed for some time, the powder becomes more yellow. In this state it is called *massicot*, or yellow oxyd of lead. It contains about 6.88 of oxygen.

This oxyd is made, in the large way, in a furnace not unlike a baker's oven. The middle of the hearth contains a recess for exposing the melted lead. On each side, and a little below the level of the hearth, is a fire, the flame of which passes slowly over the hearth, giving sufficient heat to keep the lead melted, and passes up a chimney near the mouth of the furnace. As soon as the lead is melted, a person is constantly employed to agitate it, in order to expose greater surface to the air. This manual operation is performed by a rake suspended from a chain, so that the perpendicular part of the rake dashes through a portion of the melted lead, by merely moving it backwards and forwards. By the same motion, the oxyd which is formed is pushed away from the surface of the lead, leaving it free to the action of fresh oxygen. This process being kept up, the lead is at length converted into a greenish-yellow powder, mixed with lumps of metallic lead. This powder is ground in a mill and then washed, by which means the metallic lead is separated, and the powder becomes of a more bright yellow. The green colour was therefore owing to a mixture of the blue particles of lead, mixed with the yellow oxyd. The yellow oxyd here produced is called *massicot*; which see.

This oxyd appears capable of combining with more oxygen by a second exposure. For this purpose the yellow powder, after being washed and dried, is returned into the furnace above-mentioned, or one of similar construction, kept for this second process only. The heat is kept uniform but not great, and the oxyd raked about to expose as much surface as possible. It gradually changes colour, and ultimately assumes a splendid red. In this state it is called *minium*; which see. Although during this process the oxyd appears gradually to pass through all the shades of orange colour from yellow to red, the two latter can only be considered as distinct oxyds, the intermediate tints being mixtures of the two.

If we consider the yellow as the first or protoxyd, the red will be the second, and the brown, yet to be treated of, the third and the peroxyd. Proust, however, has given some reason to believe that the yellow is not the first. The oxyd which is precipitated from the nitric acid when heated to redness, to drive off the water and carbonic acid, is found to be the yellow oxyd in a very perfect state. The author above-mentioned informs us, that if crystals of the common nitrat of lead be boiled with some pieces of metallic lead, scaly yellow crystals are formed. This salt, decomposed by potash, affords an oxyd which Proust supposes to contain less oxygen than the yellow. Dr. Thomson repeated his experiment; he found the oxyd not to differ in appearance from the yellow, and makes it to consist of lead, 91.5, lead, and 8.5 oxygen. This appears to be rather less oxygen than, according to his own analysis, is contained in the yellow. But there is reason to believe, that in Dr. Thomson's analyses of the yellow oxyd, the oxygen is rated too high. The

fame oxyd, according to Bucholz, is composed of 100 lead and eight of oxygen, equal to 7.4 per cent. This analysis appears to have been made under such circumstances as to entitle it to much credit. From the average of three analyses of the yellow oxyd, obtained from acetat of lead, the writer of this article made the oxygen 7.4 per cent. Hence we have abundant reason to doubt the existence of an oxyd below the yellow oxyd, since it appears, from Dr. Thomson's own account, that the oxyd, said to consist of less oxygen than the yellow, contains 8.5 per cent., being 1.1 more than Bucholz makes the yellow oxyd.

If nitric acid in sufficient quantity be added to the red oxyd of lead, nearly the whole will be dissolved;  $\frac{1}{3}$ th of the oxyd will remain at the bottom of the vessel, which, when collected and dried, is of a dark brown colour, and is called the brown oxyd of lead. The following process is given by Vauquelin: Mix a quantity of the red oxyd of lead with water in a Woulff's apparatus, and let the oxymuriatic acid gas pass through the mixture. The oxyd gradually becomes of a deeper colour, and is at last dissolved. From this solution the brown oxyd is precipitated by potash. From every 100 parts of the red oxyd 68 of the brown may be obtained.

This oxyd is of a flea-brown colour, having no smell or taste. It is insoluble in any of the acids. It converts the muriatic into oxymuriatic acid, by giving up a portion of its oxygen. When rubbed briskly in a mortar with powdered sulphur, the sulphur inflames, producing a strong smell of sulphurous acid. According to the analysis of Proust, this oxyd is composed of 79 lead and 21 oxygen. Dr. Thomson makes it 81.6 lead and 18.4 oxygen.

It appears highly probable that we have only three oxyds of lead, namely, the yellow, the red, and the brown. The first, according to Proust, contains 9 per cent.; Thomson, 10.3; Bucholz, 7.4; the writer of this article, 7.4: the average of all these being 8.5. The red oxyd, by Dr. Thomson's analysis, contains 12 per cent.: the brown, according to Proust, contains in the 100, 21 oxygen; Dr. Thomson makes 18.4: the mean of these is 19.7.

Agreeable to the average results of these different analyses, we cannot help being forcibly struck with the beauty of Mr. Dalton's hypothesis relative to the limited proportions with which bodies combine. He makes the atom of lead to weigh 95, or to be 95 times heavier than an atom of hydrogen; the atom of oxygen being 7 times heavier. In referring to the doctrine advanced by this ingenious chemist, it will be seen that he holds the necessity of bodies combining atom to atom, or in some multiple of the same; as, 2 to 1, 3 to 1, &c. The first oxyd of lead, agreeably to the above data, must be 1 to 1, or 95 to 7; the second oxyd, 95 to 14; and the third, 95 to 21. Hence these

proportions reduced to 100, will stand as follows:  $\frac{95 + 7}{7}$

$= \frac{100}{6.86}$ , or 6.86 in the 100, for the first oxyd. Then,

for the second,  $\frac{95 + 14}{14} = \frac{100}{12.84}$ , or 12.84 in the 100.

Lastly, for the third or peroxyd,  $\frac{95 + 21}{21} = \frac{100}{18.1}$ , or

18.1 in the 100. The proportions by analysis give, for the first, 8.5; second, 12; and the third, 19.7: by theory, 6.86, 12.84, and 18.1.

The second and third oxyds of lead give out oxygen, by exposure to heat in a crucible, and are reduced to the state of the first oxyd. If the heat be raised a little above redness,

ness, the yellow oxyd fuses into a glass, in which state it is called the vitreous oxyd of lead. It becomes so exceedingly fluid, as to run through the common crucibles. In this state it has the power of oxydating, and combining with the oxyds of all the metals which are oxydatic, by exposure to air with heat: and hence is employed to great advantage in the cupellation of the nobler metals. See SILVER.

When lead is oxydated at a high temperature, such as that employed in the separation of silver from lead, the yellow oxyd fuses as it is formed, and is blown from the surface of the lead by bellows. In this state it is called *libarge*; which see. It consists of the yellow oxyd, united to a portion of carbonic acid. For this part we are indebted to Dr. Thomson.

Lead combines with sulphur and phosphorus.

*Sulphur of lead* may be formed by projecting sulphur into melted lead, or by stratifying thin plates of the metal with the sulphur. The compound is very brittle, of a dark grey colour. It may be crystallized by slow cooling; under which form it exhibits a brilliant fracture, resembling the native sulphuret, or *galena*. This sulphuret, according to Dr. Thomson, consists of 86 lead and 14 sulphur. According to Dalton's hypothesis, it consists of one atom of lead to one of sulphur: the former atom being 95, and the

latter 13, will give  $\frac{95 + 13}{13} = \frac{100}{12}$ , or 12 to 100; which agrees with several other analyses very nearly.

Lead appears capable of combining with a second dose of sulphur, constituting a compound, which is more brilliant, and of a lighter colour. It may be easily distinguished from the common kind, by its burning in the flame of a candle.

It is called the *super-sulphuret of lead*, and, according to Dalton's hypothesis, must consist of one atom of lead and

two atoms of sulphur, which would give  $\frac{95 + 2 \times 13}{26} =$

$\frac{100}{21.5}$ , or 21.5 per cent. Dr. Thomson makes it 25 per cent.

It is to this chemist we are indebted for our knowledge of this substance.

*Phosphuret of lead* may be formed by mixing together equal parts of filings of lead and phosphoric glass; the mixture being fused in a crucible. It is of a silvery blueish-white colour. It possesses slight malleability, and may be cut with a knife. It is composed of 88 lead and 12 of phosphorus. Dalton makes the atom of phosphorus to weigh 9;

hence this compound of 1 to 1 will give  $\frac{95 + 9}{9} = \frac{100}{8.6}$ .

*Salts of Lead.*—Most of the acids combine with the yellow oxyd of lead, forming peculiar compounds. By far the greatest proportion of these compounds is insoluble in water. All those which are soluble have a sweetish taste, attended with a roughness which it leaves on the tongue, similar to that of red port, and some other wines. This property has caused it to be used for the villainous purpose of mixing with four wine, which does not only take up the acid, but adds a roughness and sweet vinous flavour, exceeding imping upon the palate. Some have suspended bags of it in the casks of wine; others have added common white lead.

Mankind are now so well acquainted with the different tests for lead, that it is very seldom found in those liquors. Water impregnated with sulphuretted hydrogen gas will

instantly turn wine muddy and black, which contains lead. A solution of iron be dropped into wine, and it turns black, the presence of gallic is indicated: and from what we before observed, the existence of lead and that acid are incompatible in the same liquid.

*Sulphat of Lead.*—Lead is scarcely acted upon by the fulphuric acid, in the cold. If the acid be boiled with the lead, fumes of fulphurous acid will be given out, and a portion of the lead oxydated, which combines with the acid, forming a whitish patty compound. If the acid be in excess, and the mass washed in water, the substance becomes divided into two portions, namely, the sulphat of lead, which is insoluble, and the super-sulphat, which is slightly soluble, and will be deposited in crystals.

It is from the circumstance of the infolubility of the sulphat of lead, that the metal can be used with such advantage for the lead-houses, used in making sulphuric acid, and for making vessels which have to hold this acid. The sulphat which first forms upon the surface defends the lead not only from the action of this acid, but from any other solvent of this pernicious metal. Sulphat of lead may be best formed by adding sulphat of soda to the acetat of nitrat of lead. A dense white precipitate is formed, which is sulphat of lead. This salt is produced in great abundance by the calcio-printers, in making acetat alumine, with alum and acetat of lead. It forms an excellent paint with oil, for standing the action of acids.

Kirwan gives the proportion of this salt at 23.37 acid, 75 acid yellow oxyd, 1.63 water in the 100; Bucholz, 24.72 acid, 75.28 oxyd; and Klaproth, 26.5 acid, and 73.5 oxyd: the mean of these is 24.86 acid, and 75.14 base. Calculated by Dalton's theory, the atom of ful-

phuric acid weighs 34: therefore,  $\frac{95 + 7 + 34}{34} = \frac{100}{25}$ ;

or, the acid is 25 in the 100: then,  $100 - 25 = 75$  the base.

*Sulphite of Lead.*—The sulphurous acid has no action upon lead: but it combines with the yellow oxyd, forming an insoluble compound, having no remarkable properties. When exposed to a red heat, the acid is disengaged, in the form of gas.

When the sulphurous acid is added to the red oxyd of lead, the acid takes oxygen from the oxyd, reducing it to the state of yellow oxyd. The acid is converted into the sulphuric, and combines with the oxyd, forming the sulphat of lead.

Dr. Thomson gives the proportions at

74.5 oxyd,  
25.5 acid.

100

*Nitrat of Lead.*—When the nitric acid is a little diluted, it acts with considerable rapidity upon lead. If it be a little assisted by heat, the whole will become speedily dissolved, forming nitrat of lead: This consists of the yellow oxyd of the metal united to a portion of the acid. If the solution be evaporated, it affords crystals of tin, in six-sided pyramids of a silvery white colour. This salt dissolves in  $\frac{7}{5}$  of boiling water. When the crystals are heated, they undergo a slight detonation: the same takes place when they are rubbed with sulphur in a hot mortar.

According

According to experiments of Dr. Thomson, this salt consists of,

66 oxyd,
34 acid.
—
100

When the crystals of the last salt are boiled with metallic lead, yellow fealy crystals are formed, constituting, according to Dr. Thomson, a subnitrat, consisting of

81.5 oxyd,
18.5 acid,
—
100

By Dalton's theory the weight of an atom of nitric acid is 19: in most of the nitrats he supposes one atom of the base to unite with two atoms of acid. The nitrat of lead, already described, should, according to the above analysis, consist of at least two atoms of acid to one of base, for  $\frac{102 + 2 \times 19}{38} = \frac{100}{27.14} = 27.14$  of acid, and 72.86 of base.

The acid here falls considerably short of that in the analysis of Dr. Thomson. The latter salt, which we have called the subnitrat, should have one atom less of acid.

Hence  $\frac{95 + 7 + 19}{19} = \frac{100}{15.7}$ , which gives 15.7 acid, and 84.3 of oxyd = 100.

*Muriat of Lead.*—Muriatic acid has a very feeble action on lead, but it readily dissolves the yellow oxyd, forming the muriat of lead. This salt may be also formed by adding muriat of soda to nitrat of lead. The precipitate which is formed is the salt in question. It dissolves in 22 parts of cold water. This is the fact only when no excess of this acid, or when no other acid is present; since the salt is soluble in most acids to a greater extent than in water. When this salt is mixed with the sulphat of lead, it may be separated from it by its solubility in the acetic acid. Muriat of lead is much more soluble in hot than in cold water. Hence, when a saturated hot solution is suffered to cool, the salt is deposited in crystals of a silvery-white colour. When heated they readily melt, and on cooling assume a slight transparency, from which it has been called *Plumbum cerneum*.

On the application of greater heat some of the salt evaporates in a white smoke, leaving behind a substance, which is said to be a submuriat of lead.

The composition of muriat of lead is, according to Klaproth,

Acid 13.5
Oxyd 86.5
—
100

By Kirwan's account,

Acid 17
Oxyd 83
—
100

The weight of the atom of muriatic acid being 22, we shall have by Dalton's theory  $\frac{95 + 7 + 22}{22} = \frac{100}{17.74}$ , by

which we have 17.74 acid, and 82.26 of oxyd, which comes very near to Kirwan. When the muriatic acid is poured on the red oxyd of lead, the lead gives up a part of its oxygen to the muriatic acid, constituting the oxymuriatic acid. The muriatic acid then unites with the yellow oxyd thus formed, while the oxygen is returned to the remaining red oxyd, forming the brown oxyd.

The substance above-mentioned, said to be a submuriat, appears rather ambiguous, and may, perhaps, be a mere mixture of the common muriat with the yellow oxyd of lead. There is, however, one argument in favour of its being a proper compound. It is said not to be soluble in water, or that the excess of oxyd is attached to the muriat, so as to prevent its being separated by the affinity of the water for the salt.

The common way of forming this substance is by adding to the muriat of soda a much larger quantity of litharge than would be necessary to saturate the acid of the salt. We are indebted to Vauquelin for the best account of the nature of this anomalous decomposition. At the same time the muriat of lead is decomposed by soda. We have the fact before our eyes, that an oxyd of lead will completely decompose the muriat of soda. If we state the experiment of Vauquelin we shall be better able to give an opinion. To one part of muriat of soda he added seven of litharge in fine powder, with as much water as made the mixture of the consistency of thin soup. This was frequently stirred for several hours. The litharge gradually lost its colour, and ultimately became white. It increased in bulk, and so much water was absorbed as to make it necessary to add more. At the end of four days the chemical action had entirely subsided, when the result was examined. The liquid part, when separated by the filtre, had a strong taste of soda, with a taste of muriat of lead, but no muriat of soda was present. The liquid afforded crystals of carbonat of soda by evaporation. The substance from which the liquor had been separated, when washed and dried, was of a dirty white colour, and was found to have increased in weight  $\frac{1}{4}$ th of the whole oxyd employed. When this substance was heated to a certain degree it assumed a fine yellow colour, by which it lost  $\frac{1}{27}$ th of its weight. This was, perhaps, carbonic acid and water.

Some caustic soda was added to a part of this substance, which changed its colour to that of a dirty yellow, and the residuum was found to be a mass of crystals of muriat of lead. By the test of an alkaline hydro-sulphuret, the soda appeared to hold a great quantity of the oxyd of lead in solution.

The one part of muriat of soda, used in this experiment, consisted of .44 of acid, and .56 of soda. The .44 acid would combine with 2.4 of the yellow oxyd to form 3.84 of muriat of lead, leaving  $7 - 2.4 = 4.6$  of oxyd of lead. This is supposing the true muriat to be formed; but if a submuriat were formed, it must consist of more than one atom of lead united to one of acid. Suppose it one of acid to two of oxyd, then  $.44 + 2 \times 2.4 = .44 + 4.8 = 5.2$  of submuriat, still there would be free oxyd left. But the author tells us that the yellow substance was insoluble in water, or that the water would not take the muriat from the excess of oxyd, although the nitric acid, as well as the soda, was capable of that effect. If there were no free oxyd when two atoms of lead were to one of acid, let us suppose them three to one, we shall then have  $.44 + 3 \times 2.4 = .44 + 7.2 = 7.64$  of a second submuriat. If, therefore, we are to rely upon the fact, that the muriat of lead could not be dissolved, leaving the excess of oxyd, we must regard this

this yellow substance as a legitimate compound. If the contrary be the case, we must regard it as a mixture of the true muriat mixed with the yellow oxyd of lead. This substance has been manufactured under a patent by Mr. Turner, of Newcastle-upon-Tyne, and is deemed a valuable pigment for painting.

*Phosphat of Lead.*—The phosphoric acid does not act upon lead in the cold, and but very feebly by heat. The result of this action is the formation of an insoluble compound, which is the phosphat of lead.

This salt may be more easily formed by adding together the solutions of phosphat of soda and the nitrat, or acetat of lead. A dense white powder subsides, which is the salt in question. This salt is insoluble in water, but it dissolves readily in nitric, and also, when assisted by heat, in the muriatic acid. On the latter solution cooling, crystals of muriat of lead are deposited; a proof that a partial decomposition takes place. It is also decomposed by the sulphuric acid, by the assistance of heat.

When this salt is heated it melts, and on cooling assumes a crystalline appearance.

It is from this salt that phosphorus is generally obtained; for when it is exposed to a great heat, in an earthen retort, with charcoal, both the lead and the phosphorus lose their oxygen, the latter being distilled over.

Mr. Dalton makes the atom of phosphoric acid to weigh 23, then  $\frac{95 + 7 + 23}{23} = \frac{100}{18.4}$ ; so that this salt, from these data, consists of 18.4 of acid, and 88.6 of oxyd, which is very near the proportions of the native salt.

*Carbonat of Lead.*—Carbonic acid does not act upon lead; but it combines with the yellow oxyd of lead, forming an insoluble white powder, which is manufactured under the name of *white lead*.

This salt may be formed by adding a carbonat of potash to the acetat or nitrat of lead. The precipitate, being washed and dried, is snowy-white powder, appearing to the eye well calculated to make a much finer white paint than that made in the common way. Although the carbonat formed by precipitation is, no doubt, chemically the same with the manufactured, their difference, in point of density, is very remarkable. The proportions of the constituents of this salt are, according to Bergman, 16 acid, 84 oxyd; to Chenevix, 15 acid, 85 oxyd; Proust, 16.15 acid, 83.85 oxyd; and Klaproth, 16.33 acid, 83.67 oxyd in the 100.

The manufacture of white lead has been known long before any idea was entertained of its composition, or the theory of the process; and it is rather singular that no more improvement has been made in the common process, which has long appeared to chemists as clumsy and uneconomical.

The process consists in exposing thin sheets of lead to the fumes of vinegar at a certain temperature. The lead is cast into sheets about two feet long, five or six inches broad, and about  $\frac{1}{4}$ th of an inch thick. These are coiled up, rather spirally, into a cylindrical shape, about five or six inches diameter. The vinegar is placed in the bottom of earthen pots, which are different in size at different manufactures; some holding three pints and others five or six. There is a ledge round the pot, in the inside, about an inch deep, for the purpose of supporting the cylindrical coil of lead, which stands upon it like a chimney. The pots thus fitted, with the lead and vinegar, are arranged in rows, upon a stratum of horse-litter, or, what is now used as being cheaper, the refuse bark of tanners. The ends of all the

cylinders of lead are covered with a plate of the same metal, to confine the whole as much as possible to the action of the vapour. The pots thus placed are covered over with litter or bark, and a new stratum of pots arranged in a similar way over them. Several tons of lead are sometimes exposed in this manner at one time. The heat arising from the fermentation of the vegetable or animal matter keeps up a certain temperature, by which the vinegar is slowly evaporated. The vapour oxydates the lead, and the oxyd combines with carbonic acid. This latter substance was formerly thought to be furnished by the fermenting substance in which the pots were imbedded: it is now, however, known, that the vinegar is decomposed, and furnishes the carbonic acid. White-lead works are at present carried on, both on the continent and in this country, in which the heat is furnished by artificial means only; and of course the carbonic acid can come from no other source than that of the vinegar.

After the lead has been exposed to the vapour of the vinegar for about six weeks or two months, the pots are withdrawn, and the coils of lead are found corroded to a considerable thickness. The white carbonat thus formed is very brittle and very hard. The sheets are now passed through rollers for the purpose of breaking the white lead from the uncorroded metallic lead. The powder is now taken to a pair of stones, and ground in a manner similar to corn. After this it is levigated to get it of the greatest possible fineness, and it is then gradually dried in stoves for the purpose.

Density and whiteness are the most valuable properties of white lead. These properties do not depend upon the proportions of its elements, but upon the mechanical treatment. The density in all probability will be greater, as it has been longer forming, by the action of the vinegar being slower. Some of the pieces of white lead, as they are separated from the sheet, are much harder than others, even in the same bed. This hardness and density are sometimes so great as to render the pieces sonorous. In this state it is the most valuable. Hence the whitest and densest pieces are selected for making the beautiful substance called *flake white*.

The value of white lead is easily ascertained by the painters, from the quantity of oil required to give it proper consistency. The greater the proportion of lead to the oil, the greater is said to be the body of the paint, and the greater will be its whiteness. The carbonat of lead made by precipitation, when in a dry state, is much whiter than the best white lead, made in the common way. If, however, equal weights of the two be mixed with oil to make them fit for painting, the precipitated specimen will be found to take a much greater quantity of oil than the other, and its whiteness much diminished. The common white lead will have lost so little of its whiteness, that the contrast will be very strikingly in favour of the latter. This fact is exceedingly apparent, on mixing together transparent media of different densities. The whiteness of snow depends upon the mixture of small particles of ice with air; for when the same are mixed with water, the whiteness disappears. All colourless transparent bodies become white on being reduced to powder. This is observed in powdered glass and in salts which lose their water of crystallization. Whiteness may therefore be said to arise from a confused refraction of light, rather than from reflection. See LIGHT.

*Fluat of Lead.*—Fluoric acid does not oxydate lead; but it is capable of combining with the yellow oxyd, forming this salt, which is an insoluble compound. It may be formed.

## L E A D.

formed better by adding the fluat of ammonia to nitrat or acetat of lead, the fluat of lead falling down in a flate of powder.

*Borat of Lead.*—Boracic acid does not act upon lead. This falt, however, may be formed by adding a solution of borat of soda to nitrat of lead. The borat of lead will be precipitated in the form of an infoluble white powder. This falt, from a vitreous flate which the acid is capable of afuming, melts into a colourless glafs before the blowpipe.

*Acetat of Lead.*—Acetic acid has little or no action upon lead when the metal is immerfed in it; but the fumes of the acid in contact with air is capable of oxydating lead, as we have shewn in the manufacture of white lead. The oxyd thus formed is easily taken up by the acetic acid, forming a foluble compound of a sweetish and atringent taste. If the solution be evaporated, an excefs of the acid being present, the falt is obtained in needle-formed crytals, and of the lultre of fatin. It diffoves in about four times its weight of water at 60°. It is fingular that this falt is decomposed by the carbonic acid. It is from this circumstance that we always find it decomposed, in some degree, by difolving it in water, which generally contains more or lefs of that substance. This falt is used in medicine, uncrystallized, under the name of *Goulard's extrañt*.

The acetat of lead is an article of extensive manufacture in England, France, and Holland.

Common diftilled vinegar is first saturated with the yellow oxyd of lead, which is sometimes from the carbonat or white lead, and frequently from litharge: the latter, however, is the cheapest process. The solution should have a little excefs of acid, else it does not form the real falt. By slow evaporation this solution crytallizes, in which flate it is used in abundance in the arts, particularly by the calico printers, for the purpose of getting the acetat of alumine, by double decomposition with alum.

The analysis of this falt, according to Dr. Thomson, is

26	Acid
58	Yellow oxyd
16	Water
<hr/>	
100	

From the combinations of the acetic acid, the earths, and alkalies, it appears that the weight of its atom is about 36.

We have hence  $\frac{102 + 36}{36} = \frac{100}{26}$ , which gives 26 of acid and 74 of yellow oxyd = 100.

*Subacetat of Lead.*—When the last falt is boiled for some time with the yellow oxyd of lead, a peculiar falt is formed, confisting of two atoms of oxyd, and one of acid. It is lefs foluble in water than the acetat. It was first noticed by Thenard, to whom we are indebted for the following analysis:

17	Acid
78	Oxyd
4	Water.

If it consists of two atoms of base to one of acid, its analysis, according to the data in the acetat, will be  $\frac{2 \times 102 + 36}{36}$

=  $\frac{100}{15}$ , which gives 15 acid, and 85 oxyd = 100.

*Oxalat of Lead.*—This falt is formed by difolving the oxyd of lead in oxalic acid. In all probability there are two falts of this species. That given by Dr. Thomson is formed

with the second oxyd, and an excefs of acid, and is the superacetat. According to Bergman's analysis it contains

41.2	Acid
58.8	Red oxyd
<hr/>	
100	

The weight of the atom of oxalic acid appears to be 39, and an atom of the oxyd in this falt 95 lead + 14 oxygen = 109, therefore supposing it the super falt  $\frac{95 + 14 + 39 \times 2}{39 \times 2}$

=  $\frac{100}{41.7}$ , which gives 41.7 acid, and 58.3 red oxyd = 100.

The proper oxalat of lead may, no doubt, be formed by an alkaline oxalat being added to the nitrat of lead, the falt being precipitated in a flate of infoluble powder. From the above data it ought to consist of 27.7 and 72.3 yellow oxyd.

*Tartrat of Lead.*—The tartaric acid does not act upon lead; but this falt may be formed by adding an alkaline tartrat to the acetat, or nitrat of lead. The tartrat of lead falls down in the form of white powder. Dr. Thomson gives the analysis of this falt at 37.44 acid, and 62.56 yellow oxyd.

*Cürat of Lead.*—This is an infoluble compound, formed by adding an alkaline citrat to a foluble falt of lead.

*Malat of Lead.*—Malic acid has no action on lead; but the acid combines with the oxyd, forming a compound infoluble in water, but foluble in acetic acid. Cyder, which contains an abundance of malic acid, would never contain lead, but from the presence of acetic acid. If acetat of lead be dropped into cyder, a copious precipitate falls down, but if free acetic acid be added, the precipitate is difsolved.

*Arseniat of Lead.*—The arsenic acid is capable of oxydating lead, and then combines with its oxyd, forming arseniat of lead, which is completely an infoluble compound. It may also be formed by adding the arseniat of potash to a foluble falt of lead. From the analysis of Chenevix it consists of 33 acid, 63 yellow oxyd, and 4 of water. According to Thenard, it is composed of 35.7 acid, and 64.3 of oxyd. See the native arseniat of lead under the mineralogical part of this article.

*Molybdat of Lead.*—The artificial falt of this species has been little examined. See the native falt.

*Chromat of Lead.*—This falt may be formed by adding an alkaline chromat to a foluble falt of lead. The falt is precipitated in the form of powder of a reddish-yellow colour. It is foluble in potash and soda, from which it may be precipitated without changing its properties. It is foluble in nitric acid, but it is decomposed by the muriatic and fulphuric acids. See native falt.

The other species of the falts of lead are not of importance.

The alkalies and some of the earths difsolve the oxyd of lead.

Potash and soda, when pure, difsolve the greatest proportion. By exposure to the air, however, the carbonic acid of the atmosphere combines with the oxyd of lead, as well as the potash. The lead is precipitated in a flate of carbonat.

These alkaline solutions of lead have the property of staining hair, wool, and horn. The tint commences with a light fawn colour, and ultimately becomes of a deep and beautiful reddish-brown. These colours are not permanent, being quickly faded by exposure to the light and the air.

Lime

Lime water, and probably solutions of barytes and strontian, dissolve the oxyd of lead, but in smaller quantity. A liquid formed by boiling lime and litharge in water, has also the property of staining wool, but the colour is somewhat different to that given by the alkaline solution. The brown colour has less of the red and more of the yellow tint. A composition of common pearl-ash, red lead, and quick-lime, is used to give horn the appearance of tortoise shell. In effect, this composition is a solution of the oxyd of lead in potash.

Lead, as we have already seen in the preceding part of this article, is much used in building, particularly for covering gutters, pipes, and in glass windows. For which uses, it is either cast into sheets in a mould, or milled; which last, some have pretended, is the least serviceable, not only on account of its thinness, but also because it is so exceedingly stretched in milling, and rendered so porous and spongy, that when it comes to lie in the hot sun, it is apt to shrink and crack, and consequently will not keep out the water. Others have preferred the milled lead, or flatted metal, to the cast, because it is more equal, smooth, and solid.

The lead used by glaziers is first cast into slender rods, twelve or fourteen inches long, called *canes*; and these, being afterwards drawn through their vice, come to have a groove on either side for the panes of glass; and this they call *turned lead*.

The method of paling or foldering lead for fitting on of inbossed figures, &c. is by placing the part whereon the figure is to be paled horizontal, and strewing on it some pulverized resin; under this they place a chafing-dish of coals till such time as the resin becomes reddish, and rises in pimples; they apply the figure, and rub some soft folder into the jointing; when this is done, the figure will be paled on, and as firm as if it had been cast on.

Lead is much used in varnishes and painting with oil, both as a colour and as a dryer. It is also used in the preparations of enamels and of porcelain as a flux, and makes the basis of the glazing of almost all pottery wares; and by means of lead the most perfect metals are refined and assayed.

**LEAD, in Medicine.** This metal is celebrated by some chemical writers for its great medical virtues; but after all it seems to be a metal which ought to be given internally with the greatest caution, and to be rather calculated for outward application. Its ore is so poisonous, that the steam arising from the furnaces where it is worked, infects the grass of all the neighbouring places, and kills the animals which feed on it. The poisonous quality of this ore is such, that the people who live in the countries where it is dug, and near the places where it is washed, can keep neither dog nor cat, nor any kind of fowl, but all die in a short time, and it has been known that a little house, in which lead ore had been kept for some time, though afterwards made very clean, and bedded with fern, infected calves which were put into it, so that all died in a very short time; and it is a too melancholy observation, that children often die strangely and suddenly about these places. *Philosophical Collections*, N<sup>o</sup> 2. p. 6.

Its best preparation is *saccharum saturni*, or the super-acetate of lead; which, though capable of doing great good in hæmorrhages, and some other cases, is apt, however, to bring on colics of so violent a kind, that the remedy often proves worse than the disease.

The internal use of lead is dangerous, on account of the colics and palsies that are occasioned by it. Culinary vessels, lined with a mixture of tin and lead, which is the usual

method, are apt to communicate to acid foods pernicious qualities, and require to be used with great precaution. The same thing has been also said of liquors kept in glazed ware, and of cyder made in vessels, where lead is used, and of wines adulterated with litharge, &c. See the article **LEAD**, *supra*, and **COLICA Pietsanum**.

M. Navier has lately discovered that the liver of sulphur, and particularly liver of sulphur of Mars, is an excellent antidote against the poison of lead; and he advises patients labouring under its pernicious effects to drink largely of acidulated liquors, to make afterwards the liver of sulphur the principal part of the cure, and to finish the cure with gentle purgatives.

The Dutch have been charged with correcting the more offensive expressed oils, as that of rape seed, so as to substitute them for oil olive or oil of almonds, by impregnating them with lead: in order to detect this abuse, mix a little of the suspected oil with a solution of orpiment made in lime-water: on shaking them together, and suffering them to rest, the oil, if it has any saturnine taint, will appear of an orange-red colour: if pure, of a pale yellowish. The lead is discovered in wines by the same sulphurous solution, which changes the colour of wines impregnated with this metal to a brownish red or a blackish hue. However, the various preparations of lead are applied externally with safety and great benefit, on account of its sedative, drying, and repellent qualities. The vinegar and sugar of lead, and all the ointments and plasters which contain ceruss, minium, or litharge, eminently possess these qualities. See the following articles and references.

For the laws relating to lead, and the stealing of it, see 27 Ed. III. stat. 2. c. 1. 3. 15. 38 Edw. III. stat. 1. c. 6. 4 Geo. II. c. 32. 29 Geo. II. c. 30. See **LARCENY**.

**LEAD, Black.** See **PLUMBAGO**.

Black lead in fine powder may be readily mixed with melted sulphur, and though the compound remains fluid enough to be poured into moulds, it looks nearly like the coarser sorts of black lead itself. This was probably the method by which prince Rupert is said to have made black lead run like a metal in a mould, so as to serve for black lead again. *Birch's Hist. Royal Soc.* vol. iii.

The German black-lead pencils, and those which are hawked about among us, are prepared in this manner: their melting or softening, when held in a candle, or applied to a red-hot iron, and yielding a blueish flame, with a strong smell like that of brimstone, discovers their composition. Pencils of this kind are hard and brittle, and cut or scratch the paper or wood instead of marking them. The true English pencils are formed of black lead alone, sawed into slips, which are fitted into a groove made of the softest wood, as cedar, and another slip of wood glued over them. These pencils, however, are of different quality, on account of different sorts of the mineral being fraudulently joined together in one pencil, the fore-part being commonly pretty good, and the rell of an inferior kind. To avoid these inconveniences, some take the finer pieces of black lead itself, which they saw into slips, and fix for use in port-crayons. *Lewis's Commerce of Arts*, p. 328.

By our laws, entering mines of black lead, with intent to steal it, is made felony. See 25 Geo. II. c. 10. See **LARCENY**.

**LEAD**, for the *manufacture of*, see **PLUMBERY**.

There are various preparations of lead, serving for various purposes, some of which are now disused, and others, under one form and name, or another, still continued.

**LEAD, Balsam of,** an external medicine, formerly famed for its effects in old and sharp ulcers. It is made by mixing one ounce of sugar of lead with two of oil of turpentine, and setting this mixture in a sand-heat till the salt is dissolved. By this means the oil acquires a red colour, and is called balsam of lead.

**LEAD, Burnt, plumbum ustum,** is a chemical preparation used in medicine, made of plates of lead, melted in a pot with sulphur, and reduced by fire into a brown powder.

Lead continued in fusion and stirred, so that fresh surfaces may be exposed to the air, will gradually change into a powdery dusky-coloured calx, bearing this name.

Burnt lead is only intended for external use. It has the same virtues ascribed to it, in ointments and plasters, as litharge or minium. Mixed into an unguent with lard alone, it makes a good ointment for the piles.

**LEAD, Butter of,** is a kind of liquid unguent made of vinegar and lead, incorporated with rosin oil, and commended for the cure of tetters. It is called *butyrum saturni*.

**LEAD, Calined, or calx of lead.** See CALX, CERUSE, GLASS OF LEAD, LITHARGE, MASSICOT, MINIUM, &c. and *Alloys of Lead*, supra.

**LEAD, Casting of.** See CASTING.

**LEAD, Cerate of Super-acetate, Ceratum plumbi super-acetatis,** the "Unguentum ceruffæ acetatæ" of P. L. 1787, is prepared in the following manner: Take of super-acetate of lead two drachms, white wax, two ounces, and olive oil, half a pint. Dissolve the wax in seven fluid-ounces of oil, then gradually add to it the super-acetate of lead, separately rubbed down with the remaining oil, and stir the mixture with a wooden lice, until the whole has united.

**LEAD, Compound cerate of.** See CERATUM lithargyri acetati compositum.

**LEAD, Cohesion of.** See COHESION.

**LEAD Dust** is a preparation used by the potters; made by throwing charcoal dust into melted lead, and stirring them a long time together: to separate the coal again, they only wash it in water, and dry it afresh. Its use is, to give a varnish and gloss to their works.

**LEAD, Extract of, or Saturn,** is prepared by simmering together as many pounds of the litharge of gold as quarts of vinegar for an hour and a quarter, and often stirring them; then taking it from the fire, and as soon as it is cool enough, pouring the clear liquor into bottles to be kept for use. If this liquor be made into the common consistence of an extract, it must boil yet longer after its separation from the mass, and will acquire a reddish colour. This is Goulard's extract (see LEAD, supra), and the basis of all his preparations of lead. It evidently differs in no respect from sugar of lead, and vinegar of litharge, but in the degree of concentration. The only circumstance in which the extract seems to have the advantage of sugar of lead, appears to be in the greater quantity of the acetous acid contained in it, which proves an excellent assistant in many cases, and the sugar of lead, when once crystallized, cannot be brought back to that state of solution in vinegar in which it was before; yet where a large quantity of watery menstruum is added, as in Mr. Goulard's saturnine water, it is as well to make a solution of sugar of lead in the water, and add the vinegar afterwards, as to mix them both together in the form of extract. Aikin's Obs. on the external Use of Preparations of Lead, &c. p. 2. See VINEGAR of Lead.

In the London Pharmacopœia of 1787, this was denominated "Aqua lithargyri acetati;" and in the last edition it is called "Liquor plumbi acetatis," or "solution of acetate

of lead," and it is directed to be prepared by mixing two pounds four ounces of semi-vitreous oxyd of lead, with a gallon of acetic acid, and boiling down to six pints, constantly stirring; then setting it by, that the feculencies may subside, and straining. This is a dense liquor, of a deep brown colour, and consists of a saturated solution of subacetate of lead. It was restored in the last Pharmacopœia, in consequence of the celebrity it had obtained under the name of "Goulard's Extract." The "Aqua lithargyri acetati composita" of P. L. 1787, called in the last edition "Liquor plumbi acetatis diluti," or "diluted solution of acetate of lead," is prepared by mixing a drachm of solution of acetate of lead, a pint of distilled water, and a fluid-drachm of weak spirit. When this mixture is made, even with distilled water, some precipitation takes place; and when, as is more common, ordinary water, containing any muriates or sulphates, is used, this is much more abundant from double decomposition, and gives the liquor a milky appearance when diffused through it. To this it owes its common name of "white wash."

**LEAD, Glass of.** See GLASS of Lead.

**LEAD, Magillery of,** is the calx of lead purified and sublimed. It is made of lead dissolved in aquafortis, pouring filtrated salt water into it; whence results a magillery extremely white, which, when softened by several lotions, is mixed with pomatums for the face and complexion.

**LEAD Mine.** See MINING.

**LEAD, Mock,** a name given to a glittering substance found in lead-mines. See GALENA inanis, and BLINDE.

**LEAD, Native.** See LEAD, supra.

**LEAD, Ointments of, Preparations of.** See UNGUENT.

**LEAD Plaster.** See EMPLASTRUM Commune.

**LEAD Pipes, Manufacture of.** The common method used for making lead pipes, consists in casting the lead upon a smooth steel mandril placed in a mould, also of metal, to form the outside. These pieces are about 18 inches long. They are afterwards joined together by a process, called *lining*.

A very great improvement has been made in the manufacture of lead pipes, by drawing them in a manner similar to wire. The lead to form the pipe is cast upon a mandril of the diameter of the inside the pipe, but of such a thickness as to equal the whole pipe in weight: it is then fastened upon one end of a cylindric steel mandril, and the lead is pulled through different sized holes, till the pipe is of sufficient length and thickness. These pipes can be drawn to the length of eight or ten feet. The power required, however, is very great, which is one objection to the method. They are also liable to flaws; for, if the casting happen to be imperfect, the imperfection is much increased and extended by the process of drawing.

This manufacture has been much improved by passing the lead upon the mandril, through grooved rollers of different sizes, following each other in succession. The power required is much less than that required for drawing; and the pipes are said to be superior in other respects. For a more particular account of this manufacture, see LEAD PIPES.

**LEAD, Red,** a preparation of mineral lead calcined and rubified; used by painters, potters, and surgeons. See MINIUM, and Oxyds of LEAD.

**LEAD, Salt or Sugar of, Saccharum saturni, Superacetat plumbi, superacetate of lead,** is an essential salt of vinegar, incorporated with the proper substance of lead, or ceruss, dissolved in spirit of vinegar. See SACCHARUM Saturni, and LEAD, supra.

**LEAD, Tincture of.** See *TINCTURA Saturnina*.

**LEAD, Vinegar of, or of Libarge.** See *VINEGAR*.

**LEAD, Water of, Aqua Saturni,** is called by Mr. Goulard vegeto-mineral water, who makes it by dropping into a quart of pure water a hundred drops of the extract of saturn, and then adding to them four tea-spoonfuls of brandy. This is his specific in external inflammations, particularly of the eye, for washing ulcers, cancers, serofulas, contusions, phlegmons, erysipelas, piles, chilblains, tetters, gaugrences, &c. But a solution of the saccharum saturni will have the same effect.

**LEAD, White.** See *CERUSE*, and *LEAD, supra*.

**LEAD Nails.** See *NAILS*.

**LEAD,** in the *Manege*, is a term used to express the part that begins any motion first. A horse going in a straight line always leads, or cuts the way with his right foot. This is called in French *entraier le chemin*.

**LEADWORT,** in *Botany.* See *PLUMBAGO*.

**LEADERS,** in the *Military Art.* See *FILE-leaders*,

*LEÛNA*, the lioness. See *LIONESS*.

**LEAF, (FOLIUM,)** in *Botany* and *Vegetable Physiology*, is a very general, but not universal, organ of the herbage of plants, of the first importance to vegetable life, being, in many respects, equivalent to the lungs of animals; inasmuch that when leaves are not present in the usual manner, their office must be performed by some other part, which is generally the stem. Leaves are, for the most part, remarkable for their expanded form, in which the object of nature is manifestly to present to the atmosphere as wide an extent of surface as possible, greatly exceeding that of all the rest of the plant. "Their colour is almost universally green, their internal substance pulpy and vascular, sometimes very succulent, and their upper and under surfaces commonly differ in hue, as well as in kind or degree of roughness."—How great a share the foliage of plants has in contributing to the beauty of the vegetable creation, and how widely their utility extends, in the sustenance they afford to the animal world, not to mention their various economical uses to mankind, is too evident to require much illustration. Their curious functions, and their real use to the plant that bears them, has not till lately been properly understood or justly appreciated. The science of chemistry was, for a long time, not sufficiently advanced to throw the necessary light upon this subject; and even at the present day, when applied to the physiology of vegetables, it serves rather to help us to conceive what *may be*, than to see clearly what *is*, transfused in their apparently simple, but truly elaborate, frame.

The first who attempted to reason upon the uses and properties of leaves was Cæsalpinus, who merely supposed them a sort of clothing, or protection against cold and heat. It is not worth staying to consider his reasons, for an opinion which is so inadequate to what it attempts to explain. This writer conceived the foliage of plants to originate from, or to be, a sort of expansion of, their bark.

Some of the first practical observations that tended to discover the importance of leaves, were made by gardeners, who, in their various treatment of fruit trees, soon found they were not to be stripped of their leaves, even partially, without caution, and that a general injury to the foliage infallibly ruined the fruit. They have also universally discovered, by experience alone, the benefit of removing decayed or sickly leaves; which all books on gardening have never failed to inculcate, though the writers had no idea of the manner in which the morbid secretions, or corrupted exhalations, of these bodies, might injure the growing plant.—

When gooseberry or currant bushes are stripped of their leaves, by the voracity of caterpillars, every body knows that the fruit, if not withered, is altogether tasteless. We cannot even yet precisely trace the mode in which this effect is produced, except that it evidently arises from a great, though only temporary, injury to the constitution of the shrub, caused by its premature and violent desolation. This injury is repaired in the ensuing season.

The absorption and perspiration of leaves could not long remain unobserved, when these organs came to be considered with any philosophical attention. Hales and Bonnet have made the best and most numerous experiments on this part of their functions. The former first suggested the probability of their imbibing air as well as moisture, nor did the action of light upon them escape his sagacity, though subsequent chemists and physiologists have pursued these subjects to a far greater extent. The fading of a leafy branch of any plant when gathered, and its revival, on being immersed for a short time in water, sufficiently evince the perspiring and absorbing powers of the leaves. Dr. Hales first determined the proportion of each, by experiments upon the great annual sun-flower, the vine, cabbage, &c. On the first-mentioned plant he bestowed particular attention, and the result of his observation was that it lost 1lb. 14 oz. weight in the course of a hot dry day, but in a dry night only three ounces. In a rainy night it gained two or three ounces by absorption. The surface of the plant, compared with that of its roots being, as nearly as could be calculated, in the proportion of five to two, it follows that the daily absorption by the roots was so much the more rapid, in order to make up the loss which took place in the herbage. Compared with the ordinary insensible perspiration of the human body, that of the sun-flower is only as 15 to 50; but the bulk or solid substance of the two being extremely different, that of the vegetable being so much more dilated, it is found the latter perspires seventeen times more, in proportion to its bulk, than the human frame. These proportions of course vary in both, according to circumstances. If the roots be plentifully watered, the evaporation by the leaves is the more copious and rapid. In newly removed plants, the absorption by the leaves supplies the wants of the vegetable body, till the roots have shot forth new fibres in order to obtain moisture in that their natural direction; but if such plants be immoderately watered, they may be killed by excess of moisture; for no evaporation by the leaves being allowed to take place, nothing can be imbibed by the roots. In certain states of the atmosphere, some plants are frequently exhausted by their perspiration, and droop for want of adequate supplies from the roots; while others are so constructed as to perspire very slowly, and therefore to resist the effects of the most parching air or sun. Such is the nature of the cuticle that covers the leaves of aloe, and of all succulent plants, more or less, that although they perspire but very slowly, they absorb with great facility. Hence these plants are admirably adapted to thrive on dry sunny rocks, or amid the moist and sandy deserts of Africa, where the rare and trivial supplies of rain which fall to their lot during a great part of the year, prove sufficient for their support in consequence of their tardy perspiration. It is truly worthy of remark, that this difference, in their powers of imbibing and giving out moisture, exists only while these plants retain their living principle. When killed by the application of great heat or cold, their leaves dry as quickly as any bodies of equal thickness. Evergreens are found to perspire much less than other shrubs, while the *Cornus mascula*, or Cornelian cherry, a plant with a thin dry leaf, was

found by Du Hamel to perspire to the amount of twice its whole weight in 24 hours.—See PERSPIRATION OF PLANTS.

The best observations on the absorbing power of leaves, and its difference in different plants, have been made by Bonnet, and are recorded in his book entitled *Recherches sur l'Usage des Feuilles*. By laying good, healthy, full-grown leaves of various herbs or trees upon the surface of water, some with the upper, and others of the same species with the under, side applied to the water, he observed in which situation they continued longest in health and vigour; and also how far different species differed from each other in this respect. In general, herbaceous plants sustained the longest this continual and copious application of wet to their upper surface, while various trees on which the same experiment was made, decidedly preferred absorption by their under side.

The absorption and evaporation in the leaves of aquatic plants; whether, like many species of *Potamogeton*, as well as the *Zannichellia*, the *Chara*, and all the submerged *Algae*, they are entirely under water; or whether, like the *Nymphaea*, they float on its surface; appear in general to be very rapid; such plants, however juicy, drying with great rapidity when taken into the air. They are, for the most part, highly vascular, and, no doubt, have an equal facility in imbibing and in giving out water.

Although most leaves are so formed as to have decidedly an upper and an under surface, the sword-shaped plants (see ESSAYS) are an exception. Their foliage is vertical, and has little or no upper surface, except where it embraces the stem; what is analogous to the under side of ordinary leaves, being in fact so circumstanced in these, as to constitute their whole surface. Other leaves are by cylindrical, that no difference of sides can be traced. In all these the absorbing vessels and the perspiring ones must be dispersed alike over the whole expansion of the leaf; as they are over stalks, and especially over the stems of plants that have no leaves at all, in which nevertheless all the known functions of leaves necessarily take place. This latter is the case in the whole genus *Staphelia*, and in many species of *Cistus*, as well as in several rush-like plants, and those singular productions the *Cuscuta* and *Cassipha*.

There are, in a very few instances, strange aberrations of configuration in leaves, declined to the accomplishment of some particular purpose. Thus, those of the *Dionaea*, (see that article,) bear an appendage like a rat-tail, the toothed lobes of which, when stimulated, close upon each other, and imprison any insect that may have happened to alight upon them. The leaves of the *Sarracenia* are tubular, and those of the *Nepenthes* bear each a tubular appendage with a lid. These are found for the most part full of water, that seems to be secreted or poured out by the vessels of the leaf, rather than received, as has commonly been supposed of the *Sarracenia*, from the atmosphere. This water is the resort of insects, who mostly perish in it, and the materials of their decomposing bodies are supposed to minister to the health of the plant. The *Drosera*, found in our bogs, entrap insects by the viscid and irritable hairs of their leaves, apparently for a similar purpose.

This leads us to consider the effects of air and light upon vegetables, through the medium of their foliage, which, in this point of view, is transcendently important.

Grew and Malpighi, independent of each other, but about the same period, detected, in the leaves of plants, abundance of vesicles full of air, as also the spiral-coated tubes or vessels of the stems, considered by their discoverers,

as well as by subsequent physiologists till very lately, in the light of air-vessels likewise, because, like the arteries of the animal frame, they appeared, on dissection, to be empty, or at least not occupied by the sap or juices of the plant. On the detection of these vesicles, physiologists theoretically supposed leaves to imbibe air, "which the spiral vessels were believed to convey all through the plant, in order that it might act on the sap as it does on the animal blood. The analogy thus understood was not correct, because air is conveyed no further than the lungs of animals; but without this hypothesis no use could be found for the supposed longitudinal air-vessels." Now it is proved that these longitudinal spiral-coated tubes do really transmit the sap from one part of the vegetable frame to another, finally conveying it into the leaves, where it is acted upon by the air, either of the above-mentioned vesicles, or of the atmosphere. The analogy with animal respiration holds good, therefore, much more correctly than the authors of the above hypothesis imagined. On this subject we need not repeat what is said under the article CIRCULATION of the Sap.

Dr. Hales's experiments with the air-pump, to prove the transmission of air through the vegetable body, are to be regarded with caution, as merely showing that air will pervade their longitudinal vessels, when a branch is cut, and its vital principle probably in some degree injured; at least when the natural movement of its sap is by no means going on, nor that fluid remaining in its natural situation. Air is obtained in abundance, by means of the air-pump, from every part of the vegetable body, as well as from recently extracted sap; and plants are found to perish very soon in an exhausted receiver. Hales rightly remarked, that air is not only taken in by plants very copiously along with their food, but also imbued by their bark, as well as through the surface of their leaves. Yet we cannot follow him when he adds, "especially at night, when they are changed from a perspiring to a strongly imbibing state." Such a difference between night and day seems merely to regard the watery absorption and perspiration of leaves, the introduction of air, or rather its action upon them, being doubtless carried on chiefly in the light, that body having a principal share in the result. Nor did this escape the sagacity of Hales, who, after concluding that "one great use of leaves is to perform in some measure the same office for the support of the vegetable life, that the lungs of animals do, for the support of the animal life; plants, very probably, drawing through their leaves some part of their nourishment from the air:" adds two pages further; "and may not light also, by freely entering the expanded surfaces of leaves and flowers, contribute much to the ennobling the principles of vegetables?"

Bonnet's experiments and enquiries, respecting leaves, principally elucidate their absorbing powers, proving them to be "furnished with a system of cuticular absorbents, which carry fluids into their sap-vessels, so as to enable them, in some degree, to dispense with supplies from the root." This philosopher has not improved upon the ideas of Hales, respecting the effects of air or light upon plants. He does not appear to have had any conception of leaves imbibing air and giving it out again; still less of their effecting any change in its properties. He was not aware that the bubbles he observed clinging to leaves, whether dead or living, when placed under water, and exposed to a bright sun, were separated, by the action of light, from the water itself; so that he has no right to be considered as the discoverer of the expiration of plants.

The great Dr. Priestley first pointed out a property in  
1 growing

growing vegetables, of absorbing carbonic acid gas, denominated by him fixed air, by the upper surface of their leaves, and of giving out by their under surface oxygen gas, or pure respirable air. Dr. Ingenhoufz improved upon this important discovery, by observing light to be necessary to these functions, remarking that in the dark leaves give out a bad or carbonic air, and that fruits and flowers almost invariably give out the last-mentioned kind of air, at all times, but especially in the dark. Aquatic or bog plants, as the *Epilobium* and *Nymphaea*, were found by these philosophers to excel remarkably in this faculty of purifying air, or of changing it from a carbonic to an oxygenous nature. This operation is, in most cases, performed very quickly. A vine-leaf in an ounce phial of carbonic acid gas, that immediately extinguished a candle, being set in the sun, without water, changed it to pure respirable air in an hour and a half. Dr. Priestley found some of the bog-plants to alter even unmix'd inflammable air, or hydrogen. Succulent leaves afford most of the purified air in question, because of the abundance of their cellular parenchymatous substance, in which the chemical operations of leaves are performed, and in which their green colour chiefly resides. This colour therefore does not exist in leaves never exposed to the light, in which consequently no such chemical operations ever take place. The sickly white observable in that part of celery stalks, or of the sprouts of asparagus, indeed of all plants, which is under the surface of the ground, is entirely owing to the absence of light; for when exposed to light such parts become green like the rest of the herbage. It is found that exposing plants to the action of hydrogen gas will produce the same green colour, even if they are kept in the dark.

Every person attentive to the growth of plants must have observed the constant direction of the upper surface of their leaves towards the light. When the situation of branches nailed to a wall is altered, and the position of their leaves disturbed, the latter resume their natural posture in a day or two, and the more speedily in proportion to the brightness of the weather. It has long been known that light acts beneficially upon the upper surface of leaves, and hurtfully upon their under side; for if the latter be repeatedly turned to the light, or forcibly kept in such an unnatural position, the leaves grow sickly, black or discoloured spots appear about the veins at their backs, and the cuticle scales off. Thus we have seen the *Magnolia grandiflora*, whose rigid leaves do not readily change their posture, very materially injured, by nailing it to a wall in hot and bright weather. The under surface of its foliage became spotted, and the colour of the other side sickly; the leaves fell prematurely, and the plant was long in recovering its health. One great use of footstalks to leaves appears to be to facilitate their turning to the light, and varying their position as the sun pursues his course; as may be seen in clover and other papilionaceous plants more especially. Leaves separated from their parent branch, and suspended delicately by a fine thread, turn to the light as effectually as if in their natural situations. This power, however, of turning to the light, is not equally obvious in all leaves. Such as are very much folded or plaited, necessarily presenting, on that account, about an equal portion of their surface to the sun in every position, are often less moveable; and this may account perhaps for the insensibility observed by Bonnet in the mallow. Sword-shaped leaves are always vertical, and do not alter their position. Those of the papilionaceous tribe are, as we have already hinted, among the most sensible. Light seems, in many instances, the sole

cause of their expansion, for when it is withdrawn, they fold together and droop as if dying; such a state of relaxation being very elegantly, and indeed, as it appears, very correctly, termed by Linnæus the sleep of plants, on which subject he has left us a curious dissertation in his *Annotates Academicæ*, v. 4. p. 333. He there justly remarks that the general aspect of a field, a garden, or a hot-house, is wonderfully changed during a summer's night in Sweden, so as to puzzle the most experienced botanist, owing to a general alteration in the posture of the foliage of plants. Some fold the two sides of the leaf together; others turn their leaves upward, so as to enclose the flowers, which they thus shelter from nocturnal dews that might interfere with their impregnation; and many press their foliage downwards, close to the stem or branch, whose buds they thus perhaps protect from cold. Such movements evince a portion of that irritability, dependent on life, which is more strikingly displayed in the sensibility of some leaves to the touch of any extraneous body. Several species of *Mimosa*, called for that reason sensitive plants, as well as a few others of different genera, fold up their leaves when any concussion is given to the plant. If any of their leaflets be shaken or injured, the irritation is communicated to the neighbouring ones, and thence, with accelerated velocity, to the rest, even to other leaves on the same branch or root. The leaves of the *Hedyfarum gyrans* of Bengal are remarkable for a spontaneous movement, apparently independent of external stimulation. They are ternate, and their small lateral leaflets move frequently, but irregularly, up and down, independent of light, requiring only, for the performance of this action, a warm and still air. This, like all other movements of leaves, is most conspicuous in such as are young.

In consequence of the observations of Priestley and Ingenhoufz, confirmed, variously extended, and explained upon the principles of improved chemistry by succeeding philosophers, the effects of light, heat, and atmospheric air upon leaves, and, where these are wanting, upon the green stems of plants, are now, as far as concerns all vegetables in common, tolerably well understood. It is agreed that in the day-time the parts in question imbibe from the atmosphere carbonic acid gas, which they decompose, absorbing the carbon as matter of nourishment, which is added to the sap, and emitting the oxygen. Plants absorb the same gas from water, when by the action of light it is separated from that fluid. Air contaminated with this gas by the burning of a candle, or the breathing of animals, serves therefore as food for vegetables, who in their turn purify it again, and render it fit for the support of animal life, by the oxygen given out from their leaves under the influence of light. Hence arises a mutual and essential dependence of the animal and vegetable kingdoms on each other, for the discovery of which, one of the most curious and beautiful in natural philosophy, we are principally indebted to Dr. Priestley, that great name from which fanaticism would gladly tear, if it could, even the laurels of science.

The above view of the functions of leaves exactly coincides with Mr. Knight's theory of vegetation, of which we have given an outline in our article *CIRCULATION of the Sap*. That gentleman has proved, that very little albumen, or new wood, is secreted when light is kept from the leaves. We are also thus enabled to understand how essential oils may be produced, which, as well as sugar, are known to be composed of oxygen, hydrogen, and carbon in different proportions. The various modifications of mucilage, detected and distinguished in the vegetable body by modern chemistry, are perhaps, as more dependant on the vital principle for  
their

their formation, more inexplicable by chemical laws. It is perhaps in vain to attempt to explain how any particular secretion is elaborated. Still less can we comprehend how different tribes of plants, growing in the same soil, even vegetating in the same distilled water, should regularly produce, as far as the health of the individuals under experiment will allow, their own peculiar secretions, ever preserving the most essential qualities of their species in this respect. How the nutritious sap, originally similar in these different plants, can be so operated upon, by the very same agents, in the thin and tender structure of the different leaves, as to produce substances so totally unlike each other as we meet with in plants, whence their various flavours and qualities originate; all this is inexplicable in our present state of knowledge, though transacted every moment before our eyes. The different secretions in various organs of the same individual vegetable body; the acrimony of the leaf, the bitter of the bark, the perfume of the blossom, the sweetness and acidity of the fruit; all these are no less wonderful. We understand enough indeed to conceive how the rest may be accomplished, and may congratulate ourselves on being allowed even a glimpse of those mysteries of nature, which our finite powers are inadequate fully to comprehend.

Having said so much on the physiology of leaves, it is necessary to consider them in another point of view, for the purposes of scientific botany. In discriminating the species of plants a knowledge of the various forms of leaves is of the utmost importance, nor are they entirely useless in the discrimination of natural tribes or orders. It is universal with grasses and the orchis family to have simple and undivided leaves; it is nearly as general for the papilionaceous or leguminous tribe to have compound ones. In some orders they are always opposite, in others alternate; in some genera evergreen, in others deciduous; but these latter circumstances are liable to various exceptions. Trees and shrubs of North America, and even those of Europe, generically related to them, have a general tendency to assume very brilliant colours in their foliage, as it verges towards decay. Grasses, on the other hand, are very uniform and constant in their green colour, which is seldom changeable. Evergreen leaves are commonly darker coloured, though more shining than others, and will often thrive with a less proportion of light than is necessary for other trees. The lower leaves of herbs that grow in lofty and windy stations, are frequently much less divided than the upper ones, while the reverse is the case with most aquatic plants, whose lower leaves, immersed in the water, are sometimes quite capillary, while the uppermost are broad, and float on its surface; witness the *Ranunculus aquatilis*, whose white flowers bespangle our ponds in summer. The action of a running stream appears to elongate the leaves of this, as well as of many other plants. The dilated form of leaves in general, by which they present so large a surface to the atmosphere, causes them to be the more easily dislodged by autumnal storms, when their connection with the branch or stem has already become gradually loosened by their approaching decay. See DECIDUOUS, and FALL of the Leaf.

Leaves are, in the first place, to be considered as to their situation and position.

*Folia radicalia*, radical leaves, spring from the root, as in the Primrose and Cowslip; *caulina*, stem-leaves, grow on the stem, as in the White Lily; *ramæ*, branch-leaves, if different from those of the main stem, require to be distinguished from them, as in Purple Cow-wheat, *Melampyrum arvense*.

*Alterna*, alternate leaves, stand solitarily on the stem or branches, as in Willows and many common plants; *opposita*, opposite ones are found in the Lilac, and many others equally common; *sparsæ*, are scattered without any order, as in the Orange and White Lilies; *confertæ*, are crowded together, as in the *Rhododendron* and *Azalea*.

*Bina*, are only two upon a plant, like those of the Lily of the Valley; *ternæ*, stand three together, as in the sweet *Verbena triphylla*, and often in the *Fuchsia*; *quaternæ*, *quina*, *sexa*, &c. are when four, five, six, or more, surround the stem in a whorl, as in some kinds of Heath; *verticillata*, whorled leaves, used without any reference to the number; expresses this mode of growth, as exemplified in the Wood-ruff, Madder, and many plants of the same as well as different families.

*Fasciculata*, tufted leaves, are seen in the Larch and Cedar; *imbricata*, lying like tiles upon a house, in the Common Ling; *decussata*, stand in pairs crossing each other, as in the Caper Spurge, *Euphorbia Lathyris*; *disticha*, two-ranked, spread in two directions, yet are not regularly opposite at their origin, as in the Yew; *secunda*, are unilateral, leaning all toward one side, as in the Solomon's Seal.

*Adpressa* are closely pressed to the stem, as in some kinds of *Xanthanum* and Spurge, in which case the back of each leaf only is presented to the light; *verticalia*, stand perpendicularly, with both sides equally at right angles with the horizon, like the *Laëuca Scariola*, but such a case is rare, except in sword-shaped leaves; *erecta*, are such as grow nearly upright, forming a very acute angle with the stem; *patentia* spread more in the usual manner; *horizontalia*, or *patentissima*, spread in the greatest possible degree; *reclinata* incline downward, the extremity of each being lower than the base, or point of insertion; *recurva*, are curved backward, as in *Erica vertora*; *incurva*, turn inward, as in *E. imperialis*; *obliqua*, are twisted, so that one part is vertical, the other horizontal; *reflexinata*, are so completely turned or reversed that the upper surface is become the under, as in *Aframoria peregrina*; *depressa*, are radical leaves pressed close to the ground, like the Hoary Plantain, *Plantago media*, or any succulent ones that are vertically flattened, in opposition to *compressa*, flattened laterally; *natantia*, float on the surface of water; *immersa*, *immersa*, or *submersa*, are plunged beneath it; *emorsa* are raised above the water, others upon the same plant being sunk below its surface.

The insertion of leaves means the mode in which they are connected with the parent plant.

*Petiolata*, stand on footstalks (*petioli*) either long or short, simple or compound; *petiata*, have the footstalks inserted, not into the base as usual, but into the middle of each leaf, like the arm of a man holding a shield, as in the Common Nauturium or *Tropæolum*; *sessilia*, sessile leaves, spring immediately from the stem, branch or root, without any footstalk, of which examples are frequent; *amplexicaulia*, clasp the stem with their more or less dilated base, being usually alternate; *connata*, or *connato-perfoliata*, are opposite leaves, united at the base, so that the stem runs through them; *perfoliata*, have the stem running through them in any way whatsoever, as *Eupleurum perfoliatum*, called Thorough-wax, from *coax* to grow, in allusion to this circumstance; *vaginantia*, are such as sheath the stem, or each other, with their base, which is exemplified in most grasses, and many liaceous plants that have no stem; *equitantia*, embrace each other with their compressed base, while they spread upwards in two ranks, of which the genus *Iris* affords many examples; *decurrentia*, decurrent,

run down the stem or branch in a leafy border or wing, as in many Thistles, and the Great Mullein; *florifera*, bear the flowers out of their disk or margin, as in *Rufcus* and *Xylophylla*.

With regard to form, the first thing to be considered is whether leaves are simple (*simplicia*) or compound (*composita*). Of the former kind are those of grasses, Orchises and Lilies, which are not only simple but undivided, while those of the Vine and Mallow are simple, but lobed; the Hop bears some leaves lobed, others undivided, as does *Laurus Sassafras*, and the Paper Mulberry. Compound leaves are observable in Roses, Jasmine, and the Un belliferous tribe in general, and consist of leaflets, or partial leaves, (*foliola*.) connected by a common stalk, and falling off along with it. In compound leaves the footstalk is either simple, as in the Jasmine and Rose, or compound, as in Parsley, Hemlock, and Fumitory. "In simple leaves the footstalk, if present, must of course be simple, while in compound ones it must always be present, though not always subdivided."

The following are the principal forms of simple leaves, considering their outline only.

*Orbiculatum*, as nearly a perfect circle as possible, of which infancs are very rare,

*Subrotundum*, roundish, is not uncommon.

*Ovatum*, the shape of an egg cut longitudinally, a very common form of leaves.

*Obovatum*, is the same figure reversed, the little end being downward.

*Ellipticum*, oval, of an equal breadth at each end.

*Oblongum*, of an indeterminate oblong shape, three or four times longer than broad.

*Spatulatum*, roundish, or obovate, with a long taper base, like a surgeon's spatula.

*Cuneiforme*, like a wedge, broad and abrupt at the extremity.

*Lanceolatum*, lanceolate, of a narrow oblong figure, tapering towards each end, very common, as in Willows, and *Plantago lanceolata*, or Ribwort.

*Lineare*, linear, narrow with the sides as nearly parallel as possible, such as the leaves of most grasses, the various species of *Narcissus*, the Rosemary, and many different plants. Linear-lanceolate leaves are of an intermediate shape between this and the last, or but slightly lanceolate, of which the gradations are numerous, often upon the same plant.

*Acrosum*, needle-shaped, linear and evergreen, mostly acute and rigid, almost peculiar to the Fir and Juniper tribe. Such leaves have usually a joint where they unite with the branch, at which they separate from it when they fall.

*Triangulare*, having three prominent angles, of whatever measurement or direction, as in Goosefoot, and some leaves of Ivy.

*Quadrangulare*, having four angles, as in the *Liriodendrum* or Tulip-tree, a very peculiar kind of leaf.

*Quinquangulare*, with five angles, like the Cyclamen, and Ivy.

*Deltoides*, deltoid, or trowel-shaped, having three angles, of which the terminal one is much further from the base than the two lateral ones, as in *Chenopodium Bonus-Henricus*. Linnæus in his *Philosopha Botanica*, p. 43, cites his fig. 58. of that work as an example of this leaf, which is a mistake, that figure being a representation of the succulent three-edged leaf, (*fol. trigonum*.) of *Mesembryanthemum deltoides*.

*Rhombicum*, rhomboid or diamond-shaped, approaching to a square, though the sides are scarcely ever equal. This is seen in *Trapa natans*, and the Stinking Goose-foot.

*Reniforme*, kidney-shaped, a short broad rounded figure, hollowed out at the base, as in *Afarabacca*.

*Cordatum*, heart-shaped, ovate hollowed out at the base, according to the vulgar idea of a heart; a form very frequent in leaves.

*Lunulatum*, crescent-shaped, like a half-moon, whether the points be directed backward, as in *Sagittaria obtusifolia* when its leaves are shorter than usual, or forward, as in *Pastiflora lunulata*, Sm. Ic. Pic. t. 1.

*Sagittatum*, arrow-shaped, like *Sagittaria sagittifolia*, and several species of Sorrel, *Rumex*. In the Great White Bindweed, *Convolvulus sepium*, the posterior angles are abrupt or lopped.

*Hastatum*, halberd-shaped, triangular, hollowed out at the base and sides, the lower lobes spreading horizontally, at right angles with the footstalk, as in Sheep's Sorrel, and the upper leaves of the Woody Nightshade, *Solanum Dulcamara*.

*Muriforme*, fiddle-shaped, oblong, blunt and dilated at each end, hollowed out at each side, of which remarkable figure the Fiddle Dock is a striking, and almost singular example.

*Runcinatum*, runcinate or lion-toothed, that is *re-uncinatum*, hooked backward, being cut into many transverse acute segments, whose points are directed backwards, like the Dandelion.

*Lyratum*, lyrate, so named in allusion to the antique lyre, but reversed. This leaf has a broad rounded extremity, with several transverse rounded segments, gradually lessening towards its base, as in *Erythronium Barbara*. It is most frequent in the Cruciferum and Compound classes, and by an occasional deep separation of the segments, often becomes a compound or lyrate-pinnate leaf.

*Fissum*, cleft or split, when the margins of the fissures and segments are straight, not rounded, as in the Ginkgo or Maidenhair-tree. *Bifidum*, *trifidum*, *multifidum*, &c. express the number of the segments, but these terms are also used with less limitation, to indicate the number of divisions, of whatever shape, when the latter circumstance does not come under consideration.

*Lobatum*, lobed, when the margins of the segments are rounded, as is most generally the case; witness the Hepatica. *Bilobum*, *trilobum*, &c. indicate the number of the lobes.

*Sinuatum*, sinuated, cut along the margin into deep, rounded, or wide openings, like *Statice sinuata*, *Mesembryanthemum pinnatifidum*, Curt. Mag. t. 67, and the Common Oak.

*Partitum*, deeply divided, almost to the base, like the Musk Mallow. *Bipartitum*, *tripartitum*, *multipartitum*, express the number of divisions.

*Laciniatum*, lacinated, cut, or as it were torn, into numerous irregular portions, which may be seen in various species of *Senecio*, denominated on that account Ragwort.

*Incisum* and *Dissectum*, cut or jagged, are nearly synonymous with the last, but express a less deep division of the whole leaf.

*Palmatum*, palmate or hand-shaped, cut into several oblong, nearly equal or uniform segments, about half way, or rather more, towards the base, leaving an entire space there, like the palm of the hand, as in the common Blue Passion-flower, whose leaves however are frequently still more deeply divided, and the Fig.

*Pinnatifidum*, pinnatifid, or wing-cleft, cut transversely into several oblong parallel segments, like several species of Thistle, *Carduus*, and on a smaller scale, though more deeply,

deeply, *Lepidium petreum* and *alpinum*; as well as *Coronopus didyma* of Fl. Brit.

*Bipinnatifidum*, doubly fo divided, as in the Long Rough-headed Poppy, *Papaver Argemone*, and *Eriocaula major*; see that article.

*Pinnatum*, pinnate, a fine and elegant sort of pinnatifid leaf, whose segments are so narrow and so regularly parallel, that they resemble the teeth of a comb, exemplified in the Water Violet, *Hoitonia palustris*.

*Inaequalis*, unequal, sometimes called oblique, is when the two halves of a leaf are manifestly unequal in dimensions, especially at the base, where they are not at all parallel. This is the case with most species of *Eucalyptus* and *Begonia*, but it is hardly observable in any British plants, except in a small degree.

*Integrum*, undivided, expresses a leaf or leaflet being destitute of all segment, division or lobe, without any reference to its margin, whether toothed or not.

The various terminations of leaves are thus distinguished.

*Folium truncatum*, an abrupt leaf, has the extremity cut off, as it were, transversely, by a straight line, as the Tulip-tree, *Liriodendrum tulipifera*.

*Praerorsum*, bitten, or jagged-pointed, is blunt with various irregular notches, a very unusual termination, but characteristic of Dr. Swartz's genus *Aerides*, a tribe of Indian *Orchideae*. *Hibiscus praerorsus*, Linn. Suppl. has a more dilated leaf with a similar termination.

*Retusum*, retuse, blunt with a broad shallow notch, like the Mountain Sorrel, *Rumex digynus*.

*Emarginatum*, emarginate or nicked, having a small acute notch at the summit, which is not uncommon.

*Obtusum*, blunt, terminating in a segment of a circle, like the Primrose leaf, and many others.

*Acutum*, sharp, ending with an acute angle, as is still more usual.

*Acuminatum*, pointed, having a taper point, like many grasses, and various other plants.

*Obtusum cum acumine*, blunt with a small point, like the Sea Lavender, *Statice Limonium*.

*Mucronatum*, or *Cuspidatum*, sharp-pointed, tipped with a rigid or pungent spine, like the Thistle tribe.

*Tridentatum*, three-toothed, when there are three terminal, nearly equal, points.

*Tricuspidatum* expresses the same thing.

*Cirrosium*, cirrose, tipped with a tendril, as in *Gloriosa* and *Flaellaria*, two Indian plants.

The different margins of leaves are defined as follows, and are very important to be well understood, and correctly applied, in forming specific characters of plants.

*Folium integerrimum*, an entire leaf, is destitute of all marginal teeth, notches or incisions, as in the *Orchelis* and *Lily* tribes. This term, alluding solely to the margin, has no reference to, or comparison with, *integrum*, which concerns the general figure, or disk, of the leaf.

*Spinosum*, spinous, beset with prickles, though otherwise perhaps entire, as in *Thistles*, and *Eryngos*. The veins and ribs are spinous in some kinds of *Solanum*, and many *Roses* and *Brambles*.

*Inermis*, unarmed, is opposed to spinous.

*Glandulosum*, glandular, bordered with pores that exude some peculiar fluid, as in *Salix pentandra*, the Bay-leaved Willow, and some others.

*Ciliatum*, fringed, bordered with soft parallel hairs, as in *Rhaleadendrum birtutum*.

*Cartilagineum*, cartilaginous, having a hard or horny edge, like several species of *Saxifrage*.

*Dentatum*, toothed, beset with directly projecting teeth,

of its own substance, as in some species of *Plantain* and *Hawkweed*.  
*Denticulatum*, finely toothed, is much more usual than the last.

*Serratum*, serrated, having sharp teeth pointing forward, like those of a saw, either in a simple row, like the *Nettle*, or with smaller intermediate serratures, as in the *Strawberry tree*, (*Arbutus Unedo*.) various *Roses*, and others. Such leaves are called *duplicato-serrata*, doubly serrated.

*Serrulatum*, minutely serrated, is used when the teeth are very fine, even so minute perhaps as to be scarcely perceptible but by the touch.

*Crenatum*, notched or crenate, when the indentations are blunted or rounded, and not directed towards either end of the leaf, which may be seen in *Ground-ivy*, and several *Saxifrages*, some of which are sharply crenate. The two British species of *Salvia* are examples of doubly crenate leaves.

*Erosum*, jagged, irregularly cut or notched, like some species of *Senecio* or *Ragwort*.

*Repandum*, wavy, bordered with small projections and shallow segments of circles alternately, as in *Fringed Water-lily*, *Menyanthes nymphaeoides*.

*Revolutum*, revolute, turned or rolled backwards, as in *Rosemary*. As this term always regards the margin only, in modern botanical phraseology, it is needless to lay marginic revolutum.

*Involutum*, involute, is the reverse of the last, as in *Butterwort* (*Pinguicula*).

*Conduplicatum*, folded, when the margins are clasped flatly together, as in *Rosacea purpurea*, Sm. Exot. Bot. t. 108, and the bases of sword-shaped leaves.

Terms descriptive of the surfaces of leaves, no less requisite to be clearly understood than the former, are as follows.

*Folium glabrum*, a smooth leaf, is used in contradistinction to all kinds of hairiness or pubescence.

*Laeve*, smooth and even, is opposed to all kinds of roughness and inequality whatever. Thus, the blistered leaf of a cabbage is *glabrum*, but not *laeve*; that of an *Orchis*, or of *Myrtle*, is both.

*Nitidum*, polished, smooth and shining, like *Laurel*.

*Viscidum*, viscid, exuding a clammy juice, as in *Butterwort*.

*Verrucosum*, warty, besprinkled with hard tubercles, like the *Pearly Aloe*, or some species of *Echium*; the warts of the latter mostly bearing rigid bristles.

*Papillosum*, papillary, covered with softer tubercles, like the *Ice-plant*.

*Scabrum*, rough to the touch, from any little rigid inequalities, opposed to *laeve*.

*Aasper*, is a greater degree of the last, of which one of the most eminent examples is *Symphytum asperinum*, Sims in Curt. Mag. t. 929.

*Hispidum*, bristly, beset with rigid or pungent bristles, like the *Borage*.

*Urens*, stinging, when each bristle discharges a venomous irritating fluid, as in the *Nettle*; see *Pilus* under the article *FULCRA*.

*Hirtum*, or *Pilosum*, hairy, clothed with soft hairs.

*Tomentosum*, downy, very soft to the touch, as in the *Marsh Mallow*, and others of that tribe.

*Villosum*, shaggy, clothed or besprinkled with long shaggy hairs, like *Hieracium villosum*, and others.

*Lanatum*, woolly, covered with dense, entangled, often branched hairs, as in several species of *Mullein* (*Verbascum*).

*Incanum*, hoary, whether arising from close silky depressed hairs, as in *Wormwood*, and the *White-Willow*, or from

from a scaly kind of mealliness, as in *Atriplex*, and some species of *Alyssum*.

*Gluceum*, glaucous, clothed with a fine mealliness, of a sea-green colour, which easily rubs off, as in the Cabbage, the *Chlora*, and many others.

*Maculatum*, spotted, besprinkled with spots or stains of a different colour from the prevailing green of the leaf. In *Lamium maculatum* these spots are white, in *Hypocheris maculata* they are of a dark purple.

*Coloratum*, coloured, is used when a leaf, or any part thereof, is of any other colour than green, as in *Amaranthus tricolor*.

*Punctatum*, dotted, either superficially, as in *Rhododendrum punctatum*, Andr. Repof. t. 36, or with pellucid cells filled with an essential oil, like *Hypericum perforatum*, and the whole natural order of Juslieu's *Aurantia*.

*Rugosum*, rugged, having the veins tighter than the intermediate spaces, so that the latter become tumid, as in the Garden Clary, and many other species of *Salvia*.

*Bullatum*, blistery, a more remarkable degree of the last, frequent in the Garden Cabbage.

*Platum*, plaited, when the disk of the leaf, especially towards the margin, is acutely folded up and down, as in Mallows, and Ladies' Mantle.

*Undulatum*, undulated, when the disk near the margin is waved obtusely up and down, in consequence of being more ample than the adjoining part, as in *Cyamus Nelumbo*; or than the rib, as in *Reseda lutea* and *alba*.

*Crispum*, curled, when the border is so much more dilated than the disk, that it necessarily becomes curled and twisted, which is the case with the Curled Mallow, and some varieties of Mint, for this mode of growth is justly suspected by Linnæus, to be but a variety, or preternatural luxuriance.

*Concavum*, hollow, depressed in the centre, owing to a tightness in some part of the circumference, as in *Cyamus Nelumbo*.

*Canaliculatum*, channelled, having a longitudinal depression, like several species of *Narcissus*.

*Venosum*, veiny, when the vessels by which the fluids are conveyed through the leaf, are branched, subdivided, and more or less prominent, frequently forming an elegant network, in which case the leaf is said to be reticulated, either on one or both its surfaces.

*Nervosum*, or *Costatum*, (see the latter article,) ribbed, when the vessels extend in simple lines from the base to the point, or towards it. The greater clusters of vessels are generally called *nervei* or *coste*, nerves or ribs, the smaller *vene*, veins, whether branched or simple.

*Avenium*, veinless, and *Enerve*, ribless, are opposed to the last-mentioned terms.

*Trinerve*, three-ribbed, is a leaf with three great or principal ribs, all alike distinct and separate from the very base, as well as remote from the margin, like the beautiful *Blakea trinervis*.

*Basi trinerve*, three-ribbed at the base, has the base cut away, as it were, close up to the lateral ribs, as in the Burdock, and Great Annual Sunflower.

*Triplinerve*, triply-ribbed, is when the side-ribs branch off from the middle one, at some distance above the base, as in *Laurus Cinnamomum* and *Campora*, and many species of Sunflower. The fine and ample South American genus *Melastoma*, is remarkable for the conspicuous ribs of its leaves, which are usually five, seven, or more, the lateral ones either branching off from the central, or all of them distinct to the base.

*Nudum*, naked, implies that a leaf is destitute of all kinds of clothing or hairiness, as in the Orchis.

*Variegatum*, variegated, is a sort of variety or disease, in which it differs from *coloratum*, the latter being natural, and proper to the species. Variegation of leaves consists in white or yellow irregular blotches, as in the Elder, Round-leaved Mint, Holly, and *Aucuba japonica*. Such plants are usually more tender, and difficult of increase, than when in their natural state, as gardeners experience in Geraniums.

The following terms express the substance, peculiar configuration, or some other circumstance relating to leaves, not included in the foregoing lists.

*Filium teres*, or *cylindraceum*, cylindrical, is seen in *Concium gibbosum*, and some others of that genus. See **CONCIUM**.

*Semieylindraceum*, semicylindrical, flat on one side, which is generally the upper, like *Salsola frutescens*, and *Chenopodium maritimum*.

*Subulatum*, awl-shaped, tapering from the base to the point, like *Salsola Kali*.

*Tubulosum*, tubular, ho'low within, as in the Onion, and some other species of *Allium*, some Rushes, &c. The tube is double in *Lobelia Dortmanna*.

*Carnosum*, fleshy, of a thick pulpy substance, as in all those called succulent plants, belonging mostly to the genera of *Sedum*, *Craffula*, *Aloe*, *Mesembryanthemum*, &c. Of the singular power in such leaves of resisting drought, we have already spoken. When bruised they soon dry or corrupt.

*Gibbum*, gibbous, swelling on one side or both, as in *Aloe retusa*.

*Compressum*, compressed, flattened laterally.

*Depressum*, depressed, flattened vertically, as already mentioned. Various kinds of *Mesembryanthemum* exemplify these.

*Carinatum*, keeled, when the back is longitudinally prominent, like the keel of a boat.

*Ensisforme*, sword-shaped, compressed, tapering to a point, slightly convex at each side, neither of which is properly the upper or under surface; as in *Iris* and its allies.

*Auceps*, two-edged, is nearly synonymous with the last.

*Acinaciforme*, scimitar-shaped, and *Dolabriforme*, hatchet-shaped, are two kinds of succulent leaves appropriated to two species of *Mesembryanthemum*, that bear the same names.

*Trigonum*, three-edged, has three longitudinal sides and as many angles, like *Mesembryanthemum deltoides*, Linn. Phil. Bot. f. 58.

*Trigretum* differs from the last only in being more precisely applied to a three-sided awl-shaped leaf.

*Tetragonum*, four-edged, has four prominent angles, as in *Iris tuberosa*.

*Linguletum*, tongue-shaped, is a thick oblong blunt figure, generally cartilaginous at the edges, as in *Saxifraga Cotyledon*, and some of its near relations.

*Membranaceum*, membranous, expresses a thin pliable sort of leaf, the reverse of succulent.

*Coriaceum*, leathery, is thick and tough, without being pulpy or succulent, like *Magnolia grandiflora*, *Aucuba*, Laurel, and many others.

*Sempervirens*, evergreen, permanent through one, two, or more winters, so that the branches are never stripped.

*Deciduum*, deciduous, (see that article,) such as falls off at the approach of winter, as in most trees and shrubs of cold climates.

*Alienatum*, alienated, when the first leaves of a plant give place to others totally different from them, as well as from the natural habit of the genus, as in many *Mimosa* of New Holland.

*Cucullatum*, hooded, when the edges meet in the lower part

part and expand in the upper, forming a sheath or hood, of which the genus *Sarracenia* is a curious example. The Common Lime, *Tilia europæa*, is liable to a variety in which the same thing takes place accidentally. A tree of this kind, of which we have a specimen, in the church-yard of Zedlitz in Bohemia, is vulgarly supposed to bear such hooded leaves, in consequence of a parcel of monks having once been hanged upon this tree. It is seldom we can so clearly trace the cause of any variety. Some might think the experiment worth repeating.

*Appendiculatum*, furnished with an appendage, or additional organ, for some purpose not essential to a leaf, as the irritable lobes at the end of the foliage of *Dionæa missipilla*; and the pouch with a lid, upon that of *Nepenthes distillatoria*; of both which we have already treated. *Athrovanda* and *Utricularia* bear numerous bladders on their leaves under water, which seem to secrete air for the purpose of floating the plants, especially perhaps at their flowering season.

*Folia composita*, compound leaves, consist of two or any greater number of partial leaves, connected by a common footstalk, whether simple or branched. Such partial leaves are termed *foliola*, leaflets.

*Folium articulatum*, a jointed leaf, consists of one leaflet, or pair of leaflets, growing out of the summit of another, with a sort of joint, as in *Fagara tragodes*.

*Digitatum*, fingered or digitate, has several leaflets at the top of one common stalk, as in many *Potentilla*.

*Binatum*, binate, consists of a pair of leaflets only on one footstalk, as in *Zygophyllum*, some *Mimosa*, the Great Everlasting Pea, and other species of *Lathyrus*.

*Ternatum*, ternate, has three leaflets, like the Trefoil and Strawberry.

*Quinatum*, quinate, has five.

*Pinnatum*, pinnate, a very common kind of leaf, is formed of several leaflets, ranged laterally along one footstalk, either with or without partial stalks, and in an opposite or alternate manner. There is usually a terminal leaflet, as in Roses, Jasmine, and Elder, which mode of growth is called *folium pinnatum cum impari*, and is that always underlood, when nothing is particularized; *abruptè pinnatum* means that there is no such terminal or odd leaflet. Sometimes its place is supplied by a tendril, as in Vetches and Peas, and such a leaf is termed *pinnatum circosum*. *Interruptè pinnatum*, interruptedly pinnate, is when the principal leaflets are ranged alternately with one or more intermediate series of smaller ones, as in our English *Spiræa*, and *Potentilla anserina*. *Articulatè*, jointedly, is when there are apparent joints in the common footstalk, as in *Weinmannia pinnata*. In the Japanese shrub *Nandina domestica* the leaflets all separate by a joint at their base, very soon after the leaf is gathered. *Decurvisè*, decurrently, is when the leaflets run down the footstalk at their base, like *Eryngium campostre*. *Lyratè*, in a lyrate manner, has the terminal leaflet largest, the rest gradually smaller, often with intermediate leaflets, as in *Geum*, and the Turnip. This and the true lyrate leaf often vary into each other, in the same plant or species. *Verticillatè*, in a whorled manner, has the leaflets cut into fine divaricated segments, embracing the footstalk, of which the curious *Stium verticillatum*, Fl. Brit. is an instance.

*Auriculatum*, an auricled leaf, bears a pair of leaflets at its base, that often indeed unite with it, as in the *Disfucus pilosus*, and *Salvia triloba*. *Hedysarum gyrans*, the Moving Plant, mentioned above, has properly an auricled leaf, rather than a ternate one, the auricles being what move up and down spontaneously.

*Conjugatum*, conjugate or yoked, consists of one pair of leaflets, and is much the same as *binatum*. *Bijugum*, *trijugum*, *quadrjugum*, *multijugum*, express particular numbers of pairs

of leaflets, as is sometimes necessary in the specific characters of *Mimosa*.

*Pedatum*, pedate or foot-like, is in the first instance ternate, but the two lateral leaflets are compounded in their fore part, which may be seen in *Helleborus fatidus* and *H. niger*. "There is an affinity between a pedate leaf, and those simple ones which are three-ribbed at the base."

The different degrees in which leaves are compounded are thus distinguished, without any reference to the mode.

*Folium compositum* is a simply compound leaf, as in Roses.

*Decompositum*, doubly compound, is exemplified in the Gout-weed (*Ægopodium*), and many other umbelliferous plants.

*Supradecompositum*, more than twice compounded, is seen in some common umbelliferous plants, as the Hemlock, and in some *Mimosa*.

The following terms express not only the degree but the mode.

*Bigeninatum*, twice paired, and *Tergeminatum*, thrice paired, are found in some *Mimosa*.

*Èternatum*, twice ternate, is seen in *Ægopodium*, and *Tri-èternatum*, thrice ternate, in *Femaria lutea*.

*Bipinnatum*, doubly pinnate, *Tri-pinnatum*, triply pinnate, are found in many exotic leguminous plants.

Some botanists, amongst whom Forskall seems to have taken the lead, use the word *lamina* for the expanded part of a leaf, that is, for the leaf itself, so that the term is entirely superfluous, and is besides appropriated to the border of the petals in a polypetalous corolla. (See LAMINA.) What is not leaf is footstalk (*petiolus*), the part which usually supports the leaf, and whose different kinds will be explained under the article PETIOLUS. Another appendage to leaves, but not always present, any more than the footstalk, is the *Stipula*. See FULCRUM and STIPULA.

In the use of the various terms above explained, it is often found necessary to combine two of them; in order either to express some intermediate figure, or to provide for that variety or mutability of shape, very frequent in the foliage of many plants. Thus, *ovato-lanceolatum* indicates a lanceolate figure, somewhat dilated towards the base, so as to approach towards ovate; as *elliptico-lanceolatum* implies a dilatation about the middle. Or such compound terms may express, that the foliage, generally lanceolate, occasionally verges towards either of those broader forms. But we must be careful not to combine terms which are incompatible, as *conjugato-pinnata*, and *digitato-pinnata*, employed by some writers in defining *Mimosa*; whereas their meaning is *conjugata*, or *digitata*, in the first instance, and *pinnata* as regarding the secondary divisions. *Sub* is commodiously prefixed to many terms, when our application of them is doubtful, or not precise, as *subrotundum*, roundish, *subfessile*, nearly fissile; but it should be sparingly used. It too often indicates a want of decision or perspicuity in the writer, rather than any uncertainty in his subject. An acute observer can generally seize what is essential, in parts that are the least variable, in each particular tribe; passing over what is doubtful; and above all, not dwelling on too many particulars in his definitions, when a few are sufficient. The leaves of plants afford, on the whole, the most commodious specific distinctions, as being obvious, most generally present, and independent of the parts of fructification, from which the generic characters are taken. In few cases are the leaves of any genus so uniform or similar in all the species, as not to exhibit abundance of clear specific differences, especially when their stipulas and footstalks are taken likewise into consideration.

The Leaves of Plants have, in one instance only, as far as we know, been resorted to for the purpose of forming

a system of botanical arrangement. The celebrated Dr. Sauvages of Montpellier published, in 1751, a *Methodus Floriarum*, or an arrangement of the wild as well as garden plants about Montpellier, according to their foliage. It is preceded by an epistle to Linnæus in French, and an introduction in the same language. His orders are eleven: *Aphyllæ*, *Cespititiæ*, *Angustifoliæ*, *Latifoliæ*, *Adversifoliæ*, *Verrucillatæ*, *Digitatæ*, *Palmatæ*, *Pinnatæ*, *Decompositæ*, and *Laciniatæ*. But they offer, in many instances, too much violence to nature, and are attended with so little, if any, advantage, that it is not worth while to detail their characters. We doubt much whether this system was ever expected to be prevalent; but if so, the author, truly able and excellent in other departments of science, and even of systematic arrangement, has, in this case, been totally disappointed.

**LEAF**, in *Agriculture*, such parts of trees and shrubs as are annually shed and fall to the ground. Where the leaves of trees or plants can be collected in large quantities, as in parks and woodlands, they may be highly useful in augmenting the manure-heaps of the farmer. And it is advised by Mr. Young, in his *CaleNDAR*, that, in wooded counties, all the leaves that can be had at little expence should be raked up in October, and carted to the yards and standing folds, for littering and making them into dung: he does "it," he says, "at three-pence per one-horse cart-load. They do not rot easily, but that is," he thinks, "no objection to them; they are a sponge to be saturated with urine, and if not touched previously to carting on the land, will convey to the field much of what might otherwise be lost; and they are extremely useful in aiding the main object of bedding the yards" in the autumn and winter season; and of course save straw where that article is scarce.

**LEAF**, in *Gardening*. Leaves are of great use in the garden where they can be collected in proper supplies for mixing in hot-beds and other preparations, where gentle heat is required. They are, likewise, beneficial as light coverings against frost and severe seasons in many cases. See **LEAF**, in *Botany*.

**LEAF-cared**, in *Rural Economy*, a provincial term applied to horses when their ears are low and badly placed.

**LEAF**, *Indian*, in *Botany*. See **TAMALAPATRA**.

**LEAF**, *Water*. See **HYDROPHYLLUM**.

**LEAF** is also applied to the finest and most beautiful parts of flowers, more properly called *petals*.

It is true, all flowers have not leaves or petals; and it is sometimes difficult to determine which is to be called the leaves, and which the calyx of the same flower.

To prevent confounding the leaves of the flower with those of the rest of the plant, the former are called by botanists *petala*, the latter *folia*.

**LEAVES**, in *Architecture*, are an ornament of the Corinthian capital, and thence borrowed into the Composite; consisting in the representation of a double row of leaves covering the vase, tympanum, or neck of the column.

These leaves are usually formed in imitation of those of the acanthus; sometimes of those of olive, and sometimes of laurel.

The leaves are divided; each making three ranges of lesser, and are bent at top one-third of their height.

**LEAF-gold**. See **GOLD-leaf**.

**LEAVES**, in clocks and watches, are used for the notches of their pinions.

**LEAF-silver**. See **SILVER**.

**LEAGUE**, an extent of ground, considered lengthwise; serving to measure the distances of one place from another; and containing more or less geometrical paces, according to the different usages and customs of countries.

The word comes from *leuca*, or *leuga*, an ancient Gaulish word, for an itinerary measure, and adopted in that sense by the Romans. Some derive the word *leuca* from *λευκο*, *white*; because the Gauls, in imitation of the Romans, marked the spaces and distances of their roads with white stones. The Gallic *leuca* was =  $1\frac{1}{2}$  Roman mile = 2415,522 yards.

A sea-league is usually reckoned 3000 geometrical paces, or three English miles; the large leagues of France are usually 3000, and in some places 3500 paces; the mean or common league is 2500 paces, and the little league 2000. Chorier observes, that the ancient Gaulish leagues were but 1500 paces; and the modern French league is = 2500 toises = 5328,75 English yards. The term *lieue*, or league, is applied in different parts of France to very different distances. The astronomical league of 25 to a degree measures 4865 English yards. The legal *lieues*, of two French miles, by which the highways were measured, contain each 4265 English yards. The marine league of 20 to a degree measures 6081 English yards.

The Spanish leagues are larger than the French, 17 Spanish leagues making a degree, or 20 French leagues, or 69 $\frac{1}{2}$  English statute miles. The league of Spain is = four ancient Roman miles = 6441,392 yards. The large league of Spain is = five ancient Roman miles = 8051,74 English yards. On roads made since 1766, the distances are laid down at the rate of 8000 varas to the league; that is, 7416 English yards; so that five such leagues = 21 English miles nearly. But the juridical league is 5000 varas, or 4635 English yards; so that eight of these are equal to 21 English miles. Marine leagues are reckoned at the rate of 20 to a degree. But in different parts of Spain, the leagues are very different. The leagues of Germany and Holland contain four geographical miles each. The German league, or that of Scandinavia, is = 9662,886 English yards. The mile or league of Germany is = 200 Rhenish yards = 8239,846 English yards.

The Persian leagues are nearly the same with the Spanish; that is, each is equivalent to four Italian miles; which come nearly to what Herodotus mentions of the parafanga, an ancient measure among the Persians, containing thirty *stadia*; eight of which, according to Strabo, make a mile.

The Persians mark their leagues by trees, as the ancient Romans did by stones, *lapides*; for which reason they are also called *zagas*, a Turkish word signifying a tree. In Japan, the league consists of 1800 fathoms. These are all distinguished by little hillocks, raised on purpose by the road-side. See the leagues of most countries reduced to the Roman foot, under **MILE**. See also **MEASURE**.

**LEAGUE** also denotes an alliance or a confederacy between princes and states for their mutual aid, either in attacking some common enemy, or in defending themselves. The word comes from *liga*; which, in the corrupt Latin, was used for a confederacy: "Qua quis cum alio ligatur."

There have been several holy leagues entered into by the Christians, against the Saracens and Infidels; called also *crusados*, or *crusades*.

The League, by way of eminence, denotes that famous one on foot in France, from the year 1576 to 1593. Its intent was to prevent the succession of Henry IV. who was of the Reformed religion, to the crown; and it ended with his abjuration of that faith.

The leaguers, or confederates, were of three kinds: the *zealous* leaguers aimed at the utter destruction, not only of the Huguenots, but also of the ministry. The *Spanish* leaguers

leaguers had principally in view the transferring of the crown of France to the king of Spain, or the infantia his daughter. The moderate leaguers aimed only at the extirpation of Calvinism, without any alteration of the government.

LEAGUE, in *Geography*. See GRISONS.

LEAGUE of *God's House*. See *God's House*.

LEAGUE, *Grey*. See GREY LEAGUE.

LEAGUE of the *Ten Jurisdictions*, one of the three leagues into which the Grisons are distributed. This league ought properly to be called, and is not infrequently denominated in Switzerland, the league of the *eleven jurisdictions*, from the number of communities that compose it; but as on its first union it was formed of *ten* only, the original appellation is still retained, although one of the jurisdictions has been since that period divided into two. This territory was formerly under the dominion of the Vats, whose authority was limited, as the people possessed very considerable privileges. On the death of Donatus, the last baron, the count of Toggenburg, who married his eldest daughter, succeeded to his possessions; and Frederic, one of his descendants, dying in 1436, without issue, the communities united, formed an offensive and defensive alliance, and erected themselves into a league. After some vicissitudes, the communities became free, and their independence was solemnly ratified by the emperor Ferdinand III., soon after the peace of Westphalia. For further particulars, see GRISONS.

LEAGUE, *Solemn*. See COVENANT

LEAK, in *Sea Language*, is a chink or breach in the decks, sides, or bottom of a ship, through which the water comes in. A ship is said to *spring a leak* when she begins to leak, or let in the water.

The manner of stopping a leak is, to put into it a plug wrapt in oakum, and well tarred, or in a tarpauling cloth, which keeps the water out; or nailing a piece of sheet-lead on the place. See CAULKING, and FOTHERING.

Seamen sometimes stop a leak by thrusting a piece of salt beef into it. The sea-water, says Mr. Boyle, being fresher than the brine imbibed by the beef, penetrates into its body, and causes it to swell so as to bear strongly against the edges of the broken plank, and thereby stops the influx of the water. Works Abr. vol. i. p. 147.

A ready way to find a leak in a ship, is to apply the narrow end of a speaking trumpet to the ear, and the other to the side of the ship where the leak is supposed to be; then the noise of the water issuing in at the leak will be heard distinctly, whereby it may be discovered. See Philos. Trans. No. 201.

LEAKAGE, the state of a vessel that leaks; that is, lets water, or other liquid, ooze in or out.

LEAKAGE also denotes an allowance of three barrels in thirty-six, both of strong beer or table beer and ale, and after that rate for any greater or less quantity, out of the excise, 43 Geo III. c. 69. s. 12. The said allowance to the common brewer of three upon every thirty-six barrels of beer or ale, shall be in full compensation for all waste or other losses whatsoever. s. 13.

LEAKE, JOHN, M. D., in *Biography*, was born of Scottish parents in Cumberland, and received his education at the grammar-school at Bishop-Auckland. This being finished, he set off for London, intending to engage in the military profession: but finding some promises, with which he had been flattered, were not likely soon to be realized, he turned his attention to medicine. After attending the hospitals, and being admitted a member of the corporation of surgeons, an opportunity presented itself of improving himself in foreign schools; he embarked for Lisbon, and afterwards visited Italy. On his return, he established himself as

a surgeon and accoucheur in the neighbourhood of Piccadilly; and about that time published "A Dissertation on the Properties and Efficacy of the Lisbon Diet-drink." Where he obtained his doctor's diploma is not known; but he became ere long a licentiate of the College of Physicians, and removed to Craven-street, where he began to lecture, as well as continued to practise, the oblietric art. In 1765, he purchased a piece of ground on a building lease, and afterwards published the plan for the institution of the Westminster Lying-in-Hospital; and as soon as the building was raised, he voluntarily, and without any consideration, assigned over to the governors all his right on the premises, in favour of the hospital. He enjoyed a considerable share of reputation and practice as an accoucheur, and as a lecturer; and was esteemed a polite and accomplished man. He added nothing, however, in the way of improvement, to his profession, and his writings are not characterized by any extraordinary acuteness, or depth of research; but are plain, correct, and practical. He was attacked, in the summer of 1792, with a disorder of the chest, with which he had been previously affected, and was found dead in his bed on the eighth of August of that year. He published, in 1773, a volume of "Practical Observations on Child-bed Fever;" and, in 1774, "A Lecture introductory to the Theory and Practice of Midwifery, including the History, Nature, and Tendency of that Science, &c." This was afterwards considerably altered and enlarged, and published in two volumes, under the title of "Medical Instructions towards the Prevention and Cure of various Diseases incident to Women, &c." The work passed through seven or eight editions, and was translated into the French and German languages. In the beginning of 1793, a short time before his death, he published "A practical Essay on the Diseases of the Viscera, particularly those of the Stomach and Bowels." Hutchinison Biog. Med.

LEAKE, RICHARD, was born at Harwich in the year 1629, and was bred to the sea-service. At the restoration he was made master-gunner of the Princess, a frigate of fifty guns; and in the first Dutch war distinguished himself by his skill and bravery in two very extraordinary actions, in one against fifteen sail of Dutch men of war, and another in 1667, against two Danish ships in the Baltic, in which, the principal officers being killed, the command devolved on him, though only master-gunner. In 1669, he was promoted to be gunner of the Royal Prince, a first rate man of war. In 1673, he was engaged, with his two sons Henry and John, in the battle against Van Tromp, when the ship had all her masts shot away, nearly four hundred men killed and disabled, and most of her upper tier of guns dismantled. As she lay like a wreck, a Dutch man of war and two fire-ships came down upon her, and captain Rooke, afterwards Sir George, conceiving it impossible to defend her, desired the men to save their lives, and strike the colours. Mr. Leake hearing this, ordered the lieutenant off the quarter-deck, and took the command, saying "the Royal Prince shall never be given up to the enemy, while I am alive to defend her." The undaunted spirit of the brave gunner inspired the small residue of the ship's company with resolution, they returned to the fight, and, under the direction of this valiant gunner and his two sons, sunk both the fire-ships, and obliged the man of war to sheer off, and having thus saved the Royal Prince, he brought her into Chatham. Mr. Leake's joy in obtaining this victory was miserably damped by the loss of his eldest son Henry, who was killed by his side. Mr. Leake, in consequence of his great merit, was made, in 1677, master-gunner of England, and store-keeper of the ordnance at Woolwich. He invented, among other things, the cushee;

piece) and contrived a new method of firing a mortar. He died in 1686. He had a surprising genius for all inventions relating to gunnery, and also in the composition of fireworks. He left a son.

LEAKE, JOHN, who was but sixteen years of age when he was engaged in the battle just referred to, and in which he took a conspicuous part. He was shortly after made captain, and performed many prodigies of valour, and, among others, he executed a desperate attempt of conveying some victuallers into Londonderry, which obliged the enemy to raise the siege; he was also at the battle of La Hogue. In 1702, being commodore of a squadron, he destroyed the French trade and settlements at Newfoundland, and restored the English to the possession of the whole island. On his return he was made rear-admiral, and, in a short time afterwards, he was created vice admiral of the blue, and received the honour of knighthood. In 1705, he saved the important fortrefs of Gibraltar from the combined attacks of France and Spain, and was engaged in the reduction of Barcelona. In the course of the following year he relieved that same city, when it was reduced to the last extremity, and obliged king Philip to raise the siege. Soon after this he took the cities of Carthagená, Alicante, and Joyce, and concluded the exploits of the year with the reduction of the city and island of Majorca. On his return home, he was presented by prince George of Denmark with a valuable diamond ring, worth 400*l.*, and from the queen he received 1000*l.* as a reward of his important services. On the death of admiral sir Cloudesly Shovel, in 1707, he was made admiral of the white, and commander-in-chief of her majesty's fleet. In the following year he surprized a convoy of the enemies corn, sent it to Barcelona, and thus saved the city and the confederate army from the danger of famine. He reduced the island of Sardinia to obedience to Charles king of Spain, and assisted lord Stanhope in the conquest of Minorca. Returning home, he was appointed one of the council to the lord high admiral, and in 1709 he was made rear admiral of Great Britain. He was several times chosen member of parliament for Rochester, and in 1712 conducted the forces to take possession of Dunkirk. On the accession of George I. he was superseded, and allowed a pension of 600*l.*, upon which he lived in a private manner till his death, which happened at his house in Greenwich, in 1720. He left no children, but was succeeded in his property by

LEAKE, STEPHEN MARTIN, who was son of captain Martin, the brother-in-law of admiral Leake. Inheriting the property of the admiral, he took his name in addition to that of his own. He went through the different ranks in the Herald's office, till he came to be Garter. He was the first person who wrote professedly on English coins. He published a history of British coins, under the title of "Nummi Britannici Historia:" he wrote also "The Life of Sir John Leake," of which only 50 copies were printed: and in 1766 he printed 50 copies of "The Statutes of the Order of the Garter." He died in 1773.

LEAM, a term sometimes used for a cut or canal.

LEAM, in *Geography*, a high mountain of the county of Galway, Ireland, situated on the south side of Lough Corrib, near the small town of Oughterard.

LEAM-KIEN-SAM, a town of Chinese Tartary; 42 miles S. of Poro.

LEAM-YOM-HOTUN, a town of Corea; 600 miles E.N.E. of Peking. N. lat. 42 20'. E. long. 128° 46'.

LEANDER, in *Biography*, a French Capuchin friar, was born at Dijon, where he died, in the year 1667. His writings are numerous, and by these he acquired a high reputation:

he is frequently referred to by Dupin, in his "Nova Bibliotheca Auctorum Ecclesiasticorum." One of his works is entitled "The Truths of the Gospel;" in two volumes folio. Moreri.

LEAO, in *Geography*, a river of China, which runs into the sea; 12 miles W. of Lai-tcheou

LEAO, or *Lebo*, a river of Chinese Tartary, formed by the union of several rivers, of which no one bears this name till after it has passed the barrier between Leao-tong and Tartary. It runs into the gulf of Leao-tong, about 12 miles W. of Yaot-tleou.

LEAO, in *Natural History*, a mineral substance, approaching to the nature of the lapis lazuli, found in the East Indies, and of great use in the Chinese porcelain manufacture, being the finest blue they are possessed of. This stone is found in the strata of pit-coal, or in those of a yellowish or reddish earth, in the neighbourhood of the veins of coal. There are often found pieces of it lying on the surface of the ground, and these are a sure indication, that more will be found on digging. It is generally found in oblong pieces of the size of a finger, not round, but flat. Some of this is very fine, and some coarse, and of a bad colour. The latter is very common, but the fine sort is scarce, and greatly valued. It is not easy to distinguish them at sight, but they are found by experiment, and the trying one piece is generally sufficient for judging of the whole mine; for all that is found in the same place is usually of the same sort.

Their manner of preparing it for use is this: They first wash it very clean, to separate it from the earth, or any other foulness it may have; they then lay it at the bottom of their baking furnaces; and when it has been thus calcined for three or four hours, it is taken out and powdered very fine in large mortars of porcelain, with pestles of stone faced with iron. When the powder is perfectly fine, they pour in some boiling water, and grind that with the rest; and when it is thoroughly incorporated, they add more, and finally pour it off, after some time settling. The remainder at the bottom of the mortar, which is the coarser part, they grind again with more water, and so on, till they have made the whole fine, excepting a little dirt or grit. When this is done, all the liquors are mixed together, and well stirred. They are suffered to stand two or three minutes after this, and then poured off, with the powder remaining in them. This is sufficed to suffice gradually, and is the fine blue they use in their best works, our common small serving for the blue of all the common low-priced China-ware. Observat. sur les Coutumes de l'Asie, p. 326.

It is plain that this stone is a sort of lapis lazuli; and the ultramarine blue, used by our painters, is made in a manner not wholly unlike this. It is much to be wished, that England were well searched for such a stone as this leao, since our mines in Derbyshire afford many blue substances, which have not been sufficiently considered; and if it should be found that either this, or any other European nation, produces it, it will be a fine discovery, as we should not only have the means of giving a fine colour to our own manufactures of this kind, but we might trade with it in China to a vast advantage. If England does not possess it, it is very probable that Germany does, the mines there affording an almost inexhaustible store of coloured stones; and this being certainly no other than the stony matter of some crystalline nodules, accidentally tinged with some particles of copper. See LAZULI Lapis.

LEAO-TONG, in *Geography*, a province of Chinese Tartary, more usually called Chen-yang, or Mougden. (See CHEN-YANG.) The province is extremely fertile; but it is too far distant from Peking, and from the centre of

the empire, to send its provisions thither. Beside, carriage is altogether impracticable, except in winter; in this season, great quantities of game, and fish preserved, or inclosed in ice, according to the Chinese expression, are carried from that country to the capital.

LEAO-TONG, *Gulf of*, or *Yellow Sea*, is a large bay or gulf of the Chinese sea, between the peninsula of Corea and China; about 400 miles from N. to S., and from 100 to 250 from E. to W. N. lat.  $34^{\circ} 45'$  to  $41^{\circ}$ .

LEAO-COU-HOTUN, a town of Corea, on the S. side of the Ya-lou river; 370 miles E. of Peking. N. lat.  $40^{\circ} 9'$ . E. long.  $125^{\circ} 4'$ .

LEAP, in *Agriculture*, a measure of capacity, signifying half a bushel, sometimes termed *lip*.

LEAP, in *Music*, is when the song does not proceed by conjoint degrees. For instance, when there is an interval of a third, fourth, fifth, &c. between two notes, the Italians call it a *leap, salto*.

It is to be observed, that there are two kinds of leaps, regular and irregular, called by the Italians *salii regolari* & *irregolari*.

The *regular* leaps are those of a third major or minor, whether natural or accidental, fourth, fifth, sixth minor, and octave, and these either ascending or descending.

*Irregular* leaps are the triton, sixth major, seventh major, the ninth, tenth, and, in general, all beyond the compass of an octave, at least in vocal music.

Besides these, there are others which may be used, but with discretion; such as the diminished fourth, the false fifth, and flat seventh. The difference between the *regular* and *irregular* leaps is, that the former are performed by the voice, without any great difficulty or effort; whereas, the latter require more attention and pains to execute.

LEAP, in *Fishing*, is used for a net, engine, or wheel, made of twigs, to catch fish in. Stat. 4 & 5 Will. & Mary. cap. 23.

LEAP, in the *Manege*, an air of a step and a leap.

LEAPING-HORSE, in the *Manege*, is one that works in the high manege, or one that makes his leaps with order and obedience between two pillars upon a straight line, in volts, caprioles, balorades, or croupades. Use excludes a gallop *a terra a terra*, and converts from the number of leaps; because the horse does not rise so very high in these. Each leap of the horse ought not to gain, or make above a foot and a half of ground forward.

LEAP-YEAR, the same with *Bissextile*; which see.

It is thus called, because, in the common year any fixed day of the month changes successively one day of the week; but in the leap-year, it skips or leaps over one day.

The common year hath three hundred and sixty-five days in it, but the leap-year three hundred and sixty-six days; and in this case February hath twenty-nine days; which, in the common year, hath but twenty-eight.

To find the leap-year, the rule is,

“Divide by 4, what’s left shall be,

For leap-year, 0: for pass, 1, 2, or 3.”

For example; is the year 1812 a leap-year, or common-year.

4)1812(453

There is 0 remainder, so that it is leap-year.

LEASBURG, in *Geography*, a town of America, being the capital of Caswell county, in North Carolina; containing a court-house, gaol, and a few houses.

LEASE, from the French *laiser, dimittere, to let*, in *Law*, a demise, or letting of lands, tenements, or hereditaments, unto another for life, term of years, or at will, for a rent reserved.

A contract for the possession of lands or tenements, for some determinate period, is an *estate for years* (see *ESTATE*); and it takes place where a man letteth them to another for the time of a certain number of years, agreed upon between the lessor, or person who granteth a lease, and the lessee, the person to whom it is granted, and the lessee enters thereon. (Litt. § 58.) If the lease be but for half a year, or a quarter, or any less time, this lessee is reputed as a tenant for years, and is so styled in some legal proceedings; a year being the shortest term which the law takes notice of in this case. A year is a determinate and well-known period, consisting commonly of 365 days. (See *BISSEXTILE*.) A month, (see *MONTH*) in law, is a lease month, or 28 days, unless otherwise expressed; and, therefore, a lease for “twelve months” is only for 48 weeks; but if it be for “a twelve-month” in the singular number, it is good for the whole year. (6 Rep. 61.) These estates for years were originally granted to mere farmers or husbandmen, who every year rendered some equivalent in money, provisions, or other rent, to the lessors or landlords; but, in order to encourage them to manure and cultivate the ground, they had a permanent interest granted them, not determinate at the will of the lord. Their possession, however, was deemed of so little consequence, that they were rather considered as the bailiffs or servants of the lord, who were to receive and account for the profits at a settled price, than as having any property of their own; and, therefore, they were not allowed to have a freehold estate; but their interest existed after their deaths in their executors, who were to make up the accounts of their testator with the lord, and his other creditors, and were entitled to the stock upon the farm. The lessee’s estate might also, by the ancient law, be at any time defeated by a common recovery suffered by the tenant of the freehold (Co. Litt. 46.); which annihilated all leases for years then subsisting, unless afterwards renewed by the recoverer, whose title was supposed superior to his by whom those leases were granted. Estates for years, whilst they continued precarious, were usually of short duration, like our leases upon rack-rent; and we are told (Mirror. c. 2. § 27. Co. Litt. 45, 46.), that by the ancient law no leases for more than 40 years were allowable, because any longer possession (especially when given without any livery declaring the nature and duration of the estate), might tend to defeat the inheritance. This law, if it did ever exist, was soon antiquated; for, in Madox’s “Collection of Ancient Instruments,” some leases for years, of a pretty early date, occur, which considerably exceed that period; and long terms, for 300 or 1000 years, were in use in the time of Edward III., and probably of Edward I. But when, by the statute 21 Hen. VIII. c. 15. the tennor (that is, he who is entitled to the term of years), was protected against these fictitious recoveries, and his interest rendered secure and permanent, long terms began to be more frequent than before; and were afterwards extensively introduced, being found extremely convenient for family settlements and mortgages; continuing subject, however, to the same rules of succession, and with the same inferiority to freeholds, as when they were little better than tenancies at the will of the landlord.

Every estate which must expire at a period certain and prefixed, by whatever words created, is an *estate for years*; and, therefore, this estate is frequently called a term, *terminus*, because its duration is limited and determined; for every such estate must have a certain beginning and certain end. (Co. Litt. 45.) But “id certum est, quod certum reddi potest;” therefore, if a man make a lease to another, for

for many years as J. S. shall name, it is a good lease for years (6 Rep. 35.); for though it is at present uncertain, yet when J. S. hath named the years, it is then reduced to a certainty. If no day of commencement is named in the creation of this estate, it begins from the making, or delivery, of the lease. (Co. Litt. 46.) A lease for so many years as J. S. shall live, is void from the beginning (Co. Litt. 45.); but a lease for 20 or more years, if J. S. shall so long live, is good, for a certain period is fixed, beyond which it cannot last, though it may determine sooner, on the death of J. S. An estate for life, even if it be *pur autre vie*, is a freehold; but an estate for 1000 years is only a chattel, and reckoned part of the personal estate. A lease for years may be made to commence *in futuro*, though a lease for life cannot. Because no livery of seisin is necessary to a lease for years, such lease is not said to be *seized*, or to have true legal seisin of the lands. Nor, indeed, does the bare lease velt any estate in the lessee; but only gives him a right of entry on the tenement, which right is called his "interest in the term," or *interesse termini*; but when he has actually so entered, and thereby accepted the grant, the estate is then, and not before, vested in him, and he is *possessed*, not properly of the land, but of the term of years (Co. Litt. 46.); the possession, or seisin of the *land* remaining still in him who hath the freehold. Thus, the word "term" does not merely signify the time specified in the lease, but the estate also and interest that passes by that lease; and, therefore, the "term" may expire during the continuance of the "time," as by surrender, forfeiture, or the like. See TENANT.

*Estates at will*, another species of estates not freehold, are those where lands and tenements are let by one man to another, to have and to hold at the will of the lessor; and the tenant by force of this lease obtains possession (Litt. § 68.) Such tenant hath no certain indefeasible estate, nothing that can be assigned by him to any other; because the lessor may determine his will, and put him out whenever he pleases. But every estate at will is at the will of both parties, landlord and tenant; so that either of them may determine his will, and quit his connection with the other at his own pleasure. If, indeed, the tenant at will sows his land, and the landlord, before the corn is ripe, or before it is reaped, puts him out, yet the tenant shall have the emblements, and free ingress, egress, and regress, to cut and carry away the profits. (Co. Litt. 56.) But it is otherwise, where the tenant himself determines the will; for in this case the landlord shall have the profits of the land. (Co. Litt. 55.) And if rent be payable quarterly, or half-yearly, and the lessee determines the will, the rent shall be paid to the end of the current quarter or half-year. (Salk. 414. 1 Sid. 339.) Upon the same principle, courts of law have of late years leaned as much as possible against construing demises, where no certain term is mentioned, to be tenancies at will; but have rather held them to be tenancies from year to year so long as both parties please, especially where an annual rent is reserved, in which case they will not suffer either party to determine the tenancy even at the end of the year, without reasonable notice to the other, which is generally understood to be six months. For another species of estates at will, see COPYHOLD. See also SUFFERANCE.

A lease is either written, called an *indenture deed-poll*, or lease in writing; or by word of mouth, called *lease-pareol*. See PAROL.

All estates, interests of freehold, or terms for years in lands, &c. not put in writing and signed by the parties, shall have no greater effect than as estates at will; unless it be of leases not exceeding three years from the making; wherein the rent reserved shall be two-thirds of the value

of the things demised. (Stat. 29 Car. II. cap. 3.) Leases exceeding three years must be made in writing, and if the substance of a lease be put in writing, and signed by the parties, though it be not sealed, it shall have the effect of a lease for years, &c. Wood's Int. 266.

But a lease in writing, though not under seal, cannot be given in evidence, unless it be stamped. (1 Term. Rep. 735.) Articles with covenants to make a lease to let and make a lease of lands, for a certain term, at so much rent, hath been adjudged a lease. (Cro. Eliz. 486.) In a covenant, with the words "have, possess, and occupy lands, in consideration of a yearly rent, without the word demise," it was held a good lease; and a licence to occupy, to take the profits, &c. which passeth an interest, amounts to a lease. (3 Bull. 204. 3 Salk. 223.) An agreement of the parties, that the lessee shall enjoy the lands, will make a lease; but if the agreement hath a reference to the lease to be made, and implies an intent not to be perfected till then, it is not a perfect lease till made afterwards. (Bridg. 13. 2 Shep. Abr. 374.) If a man, on promise of a lease to be made to him, lays out money on the premises, he shall oblige the lessor afterwards to make the lease; the agreement being executed on the lessee's part, where no such expence hath been, a bare promise of the lease for a term of years, though the lessee have possession, shall not be good without some writing. A lease for years may begin from a day past, or to come, at Michaelmas last, Christmas next, three or four years after, or after the death of the lessee, &c. though a term cannot commence upon a contingency which depends upon another contingency. (1 Inst. 5. 1 Rep. 156.) If one makes a lease for a year, and so from year to year, it is a lease for two years; and afterwards it is but an estate at will. (1 Mod. 4. 1 Lutw. 213.) And if from three years to three years, it is a good lease for six years; also, if a man make a lease for years, without specifying the number, it may be good for two years, to answer the plural number. (Wood's Int. 265.) Of all kinds of powers the most frequent is that to make leases. In the making of such leases all the requisites specified in the power must be strictly observed; and such leases must contain all such beneficial clauses and reservations as ought to be, for the benefit of the remainder-man; the principle being, that the estate must come to him in as beneficial a manner as the ancient owners held it. By stat. 29 Geo. II. c. 31. infants, lunatics, and femes-covert, may apply to the courts of chancery or exchequer, or to the courts of equity of the counties palatine of Cheiler, Lancaster, and Durham, or to the courts of great session of Wales, by petition or motion in a summary way, and by the order of these courts respectively, such persons may by deed only, without levying a fine, surrender leases for lives or years, and take new leases for lives or years of the premises comprised therein. Joint-tenants, tenants in common, and coparceners may make leases for life, years, or at will, of their own parts, which shall bind their companions; and in some cases, persons who are not seized of lands in fee, &c. may make leases for life or years, by special power enabling them to do it; when the authority must be exactly pursued. (Wood's Int. 267.) But there is a difference, where there is a general power to make leases, and a particular power. (8 Rep. 69.) If joint-tenants join in a lease, this shall be but one lease, for they have but one freehold; but if tenants in common join in a lease, it shall be several leases of their several interests. 3 Rol. Abr. 641. Com. Dig. title *Estates* (C. 6.) Bac. Abr. Leases (l. 5.) A lessee may take covenants on the tenement let for the rent; or may have action of debt for the arrears, &c. Tenants suffering houses to be uncovered, or in decay, taking away

waincot, &c. fixed to the freehold, unlets put up by the lessee, and taken down before the term is expired; cutting down timber trees to fell, permitting young trees to be destroyed by cattle, &c. ploughing up ground that time out of mind hath not been ploughed, not keeping banks in repair, &c. are guilty of wastes. (1 Inst. 52. Dyer 37. 2 Salk. 368.) Lessees are bound to repair their tenements, except the contrary be mentioned in the lease. Although a lessee for years is not obliged to repair the house let to him, which is burned by accident; if there be not a special covenant in the lease, that he shall leave the house in good repair at the end of the term; yet if the house be burnt by negligence, the lessee shall repair it, although there be no such covenant. (Pasch. 24 Car. B. R.) A lessee at will is not bound to sustain or repair, as tenant for years is. A lessee who covenants to pay rent, and to repair, with an exception of casualties by fire, is liable upon the covenant for rent, though the premises are burnt down, and not rebuilt by the lessor after notice. (1 Term Rep. 310.) A proviso in a lease for two years, that the landlord shall re-enter, on the tenant's committing any act of bankruptcy, on which a commission shall issue, is good. (2 Term Rep. 133.) An assignee of a bankrupt, a devisee, and a personal representative, are assignees in law to the purpose of being liable to actions on a covenant for rent in a lease to the bankrupt, devisee, or intestate. (Doug. 184.) Persons for whose lives estates are held by lease, &c. remaining beyond ten, or being absent seven years, if no proof be made of their being alive, shall be accounted dead. (See 19 Car. II. c. 6.) Where the term of a lease is to end on a precise day, then, there is no occasion for a notice to quit; because the lease of course is at an end, unless the parties come to a fresh agreement. In the case of a tenancy from year to year, there must be half a year's notice to quit, ending at the expiration of the year. Six calendar months' notice is not sufficient. And there is no distinction between houses and lands as to the time of giving notice to quit. 1 Term Rep. 54. 159. 162, 3. Blackf. Com. b. ii. Tomlins's Jacob, tit. Lease.

**LEASE BY STATUTE.** There are three kinds of persons, who may make leases for three lives or twenty-one years, and not exceeding this term, by statutes, that could not do so heretofore, *viz.* tenants in tail, binding their issue in tail, but not in remainder or reversion; husband and wife, of the wife's land; and persons seized of an estate in fee simple in right of the church, except parsons and vicars; by the stat. 32 Hen. VIII. c. 28. called the "enabling statute."

But this statute specifies several requisites in order to render the leases binding: they must be by indenture, and not by deed-poll, or parol. They must commence from the day of making, and not at any greater distance of time: the old lease, if there be any, must be first absolutely surrendered, or be within a year of expiring; it must be either for twenty-one years, or three lives, and not for both; it must not exceed the term of three lives, or twenty-one years, but may be for a shorter time: the lease must be of corporeal hereditaments, and not of such things as lie merely in grant; for no rent can be reserved out of these by the common law, as the lessor cannot resort to them to distrain; though now by 5 Geo. III. c. 17. a lease of tithes or other incorporeal hereditaments alone, may be granted by any bishop or ecclesiastical or eleemosynary corporation, and the successor shall be entitled to recover the rent by an action of debt, which, in case of a freehold lease, he could not have brought at the common law. The lease must also be of lands and tenements commonly letten for twenty years past; and the customary rent for that term reserved; and leases must not be made without impeachment of waste.

By 1 Eliz. c. 19. called the "disabling or restraining statute," it is enacted, that all grants by archbishops and bishops, other than for the term of twenty-one years or three lives from the time of making, or without reserving the usual rent, shall be void: but this statute did not extend to grants made by any bishop to the crown; however, these, as well as those made to any subject, were comprehended in the prohibition of the statute 1 Jac. I. c. 3. The restrictions of this statute were extended by 13 Eliz. c. 10. explained and enforced by 14 Eliz. c. 11. and 14. 18 Eliz. c. 11. and 43 Eliz. c. 29. to certain other inferior corporations, both sole and aggregate. From all these it is collected, that all colleges, cathedrals, and other ecclesiastical or eleemosynary corporations, and all parsons and vicars, are restrained from making any leases of any kind, of their land, unless under the following regulations: 1. They must not exceed twenty-one years or three lives from the making. 2. The accustomed rent, or more, must be yearly reserved upon them. 3. Houses in corporations or market-towns may be let for forty years; provided they be not the mansion-houses of the lessors, nor have above ten acres of ground belonging to them, and provided the lessee be bound to keep them in repair; and they may also be aliened in fee-simple for lands of equal value in recompence. 4. Where there is an old lease in being, no concurrent lease shall be made, unless where the old one will expire within three years. 5. No lease by the equity of the statute shall be made without impeachment of waste. (Co. Litt. 45.) 6. All bonds and covenants tending to frustrate the provisions of the statutes 13 and 18 Eliz. shall be void. The 13 Eliz. c. 20. together with all explanations, &c. of the same by 14th, 18th and 43d of Eliz. and much of 3 Car. I. which made them perpetual, are repealed by 43 Geo. III. c. 84. f. 10.

If a bishop have two chapters, as they may be two or more to one bishopric, both chapters must confirm leases made by the bishop. (1 Inst. 131.) A lease made by a bishop to begin presently for twenty-one years, when there is an old lease in being, is good, notwithstanding the stat. of 1 Eliz. c. 19. (Moor. Caf. 241.) But if such a lease is to commence at a future day, it will be void. (1 Leon 44.) Lease for three lives by a bishop of tithes is void against the successor, although the usual rent be duly received. (Moor. Caf. 1078.) Leases of a dean and chapter are good, without confirmation of the bishop. (Dyer, 273. 2 Nelf. Abr. 1096.) Where there is a chapter and no dean, they may make grants, &c. and are within the statute. (1 Mod. 204.) A prebendary's lease confirmed by the archbishop, who is his patron, is good, without confirmation of dean and chapter. (3 Bullstr. 290.) But where a prebendary made a lease for years of part of his prebend, and this was confirmed by dean and chapter; because it was not confirmed likewise by the bishop, who was patron and ordinary of the prebend, the lease was adjudged void. (Dyer 65.) If a prebendary hath rectories in two several dioceses, belonging to his prebend, and his lease of them is confirmed by the bishop, dean and chapter of the diocese of which he is prebendary, it is good, though not confirmed by the other. (Litt. 75.) A chancellor of a cathedral church may make a lease, and it is said it will be good against the successor, though not confirmed, &c. (Litt. 158.) If a parson or vicar makes a lease for life or years, of lands usually letten, reserving the customary rent, &c. it must be confirmed by patron and ordinary, for they are out of the statute 32 Hen. VIII. c. 28. And if the parson and ordinary make a lease for years of the glebe to the patron; and afterwards the patron assigns the lease to another, such assignment is good, and is a confirma-  
tion

tion of that lease to the assignee. (5 Rep. 15.) A lease for years of a spiritual person will be void by his death, if it is not according to the statute; and a lease for life is voidable by entry, &c. of his successor. (2 Cro. 173.) If a bishop be not bishop *de jure*, leases made by him to charge the bishopric are void, though all judicial acts by him are good. (2 Cro. 353.) And where a bishop makes a lease, which may tend to the diminution of the revenues of the bishopric, &c. which should maintain the successor, there the deprivation or translation of the bishop is the same with his death. 1 Inst. 324.

There is another restriction with regard to college leases, by stat 18 Eliz. c. 6. which directs, that one-third of the old rent, then paid, should for the future be reserved in wheat or malt, reserving a quarter of wheat for each *Gr. 8d.* or a quarter of malt for every *5s.*; or that the lessees should pay for the same according to the price that wheat and malt should be sold for, in the market next adjoining to the respective colleges, on the market-day before the rent becomes due. This money arising from corn rents is, *communibus annis*, almost double to the rents reserved in money.

But when a quarter of wheat is worth *50s.* and the colleges receive one-third of their rent in corn, *i. e.* a quarter of wheat, or its value for every *13s. 4d.* which they are paid in money, it follows that the corn rent will be in proportion to the money rent nearly as four to one. But these rents united are very far from the present value. Colleges, therefore, in order to obtain the difference, generally take a fine upon the renewal of their leases.

The leases of beneficed clergymen are farther restrained, in case of their non-residence, by statutes 13 Eliz. c. 20. 14 Eliz. c. 11. 18 Eliz. c. 11. 43 Eliz. c. 9. which direct, that if any beneficed clergyman be absent from his cure above fourscore days in any one year, he shall not only forfeit one year's profit of his benefice to be distributed among the poor of the parish; but that all leases made by him of the profits of such benefice, and all covenants and agreements of like nature, shall cease and be void; except in the case of licensed pluralists, who are allowed to demise the living, on which they are non-resident, to their curates only, provided such curates do not absent themselves above forty days in any one year. Blackt. Con. b. ii.

An *assignment* differs from a lease only in this; that by a lease one grants an interest less than his own, reserving to himself a reversion; in assignments he parts with the whole property, and the assignee stands to all intents and purposes in the place of the assignor.

If a lessor accepts of rent from an assignee, knowing of the assignment, it bars him from action of debt against the lessee; for the privity of contract is extinguished: but after such acceptance, the lessor or his assigns may maintain an action against the first lessee upon his covenant for payment of the rent. (1 Saund. 241. 3 Rep. 24.) But acceptance of rent from the assignee has been adjudged a sufficient notice of the assignment, so that the lessor could not resort to the first lessee. 2 Bulltr. 151.

**LEASES of the King.** Leases made by the king, of part of the duchy of Cornwall, are to be for three lives, or thirty-one years; and not to be made disposable of waste, whereon the ancient rent is to be reserved; and estates in reversion, with those in possession, are not to exceed three lives, &c. 13 Car. II. c. 4.

Leases from the crown of lands in England and Wales, and under the seals of the duchy of Lancaster, &c. for one, two, or three lives, or terms not exceeding fifty years, are

allowed time for inrollment, &c. by stat. 10 Ann. c. 18. Leases made by the prince of Wales of lands, &c. in the duchy of Cornwall, for three lives, or thirty-one years, on which is reserved the most usual rent paid for the greatest part of twenty years before, shall be good against the king, the prince, and their heirs, &c. and the conditions of such leases be as effectual as if the prince had been seized of an absolute estate in fee-simple in the lands. Stat. 10 Geo. II. c. 20.

**LEASE of Land, in the Economy of Agriculture,** a kind of contract or agreement for the letting of lands, tenements, &c. either for life, or a certain term of years, under a reserved rent. It has been stated by Mr. Marshall, that the different modes of holding land are first that of "the tenant holding at will, or until the customary notice be given, by either party to the other,—without any legal contract or written agreement,—the only tie between the owner and the occupier being the custom of the estate, or of the county in which it lies,—and the common law of the land." This, he conceives, may be considered as "the simple holding which succeeded the feudal or copyhold tenure; but which is now going fast into disuse." The second mode is that of "holding from year to year, under a written agreement, with specified covenants." This, which is a more modern usage, is, on the contrary, he thinks, becoming more and more prevalent; even where leases for a term of years were formerly granted." The third, is that of a "lease for a term of years; as seven, fourteen, twenty-one, or a greater number of years certain; but without the power of assignment, unless with the consent of the lessor." And the fourth, that of a "lease for lives; as one, two, three, or more, without the power of assignment, which he believes now are rarely granted in England, but in Wales they are still prevalent; the rent being there settled according to the value of the land at the time of letting, as on granting a lease for a term. And, in the western extremity of England, what are termed life leases are still common. But that they are in fact rather pledges for money taken up, or deeds of sale for lives, than leases; as nearly the whole of the estimated sale value of the land, during the life term, is paid down at the time of purchase, the seller reserving only a quit-rent or annual acknowledgment."

It is conceived by the same writer, that life leases may be considered in different points of view; as "to a tenant who holds at a moderate rent, a lease for life is gratifying, his farm becoming a sort of life estate, in which he is fixed for life; but that unless he is a prudent or a fortunate man, it may prove a source of misfortune to his family, who in the moment of their distress for his loss, may be liable to be turned out, penniless, from a house and home: a circumstance which can rarely happen, under holdings for certain terms of years." These sorts of leases have a much better effect, it is supposed, on agriculture than annual holdings; and that it is more than probable that life tenancy heretofore has assisted in the advancement of the art. "It is, however, a well ascertained fact, that the manifold and great improvements which have taken place in English agriculture, during the last half century, have not been effected in Devonshire nor in Wales, but in Norfolk, and in the midland counties under leases for terms of years." And "that in a political light, life leases have a favourable appearance, as tending to fill up a space between ordinary tenants and yeomanry or small proprietors, and giving their holders better stakes than less certain occupiers have, in the established order of things." But that "here it is the light in which life-holds appear to land proprietors that is entitled to the

chief attention," which "on whatever side they have been viewed by the owners of extensive estates during the last twenty or thirty years, have doubtlessly appeared in odious colours. For owing to the rapid depreciation of money there are proprietors who have been receiving, year after year, not more perhaps than one-half, or a less proportion, of the fair rental value of many of their lands. And for such as still hang on good lives, they may not receive more for many years to come." And further, that "owing to the perpetual bondage in which their lands are kept, no general work of arrangement can be effected, nor any individual improvement introduced by a proprietor, who can scarcely be said to have any authority either over his estate or its possessors." They have in fact been the bane of every useful improvement of the soil, and the great cause of its want of amelioration in every county where they have existed to any extent.

It may be noticed, that those sorts of holdings which are only for the year, "are, to a tenant, most discouraging; and to improvement in agriculture most unfriendly. In a public view they are of course highly impolitical: while to a proprietor they are most convenient, as he may be said to be in constant possession of his estate. He can lay out and execute general improvements, as embankments and drainage, extensive works of irrigation, the alteration of water-courses, roads and fences, and complete the arrangement of tenements without controul. It would be unwise, therefore, on an estate under this sort of tenancy, to alter it, until the requisite improvements were planned, and put in a train of being performed." It has, however, been further justly remarked, that "whatever discourages agriculture cannot be permanently profitable, either to a proprietor or the community." And in regard to present profit they must be highly disadvantageous to the proprietor or owner.

With respect to the third holding of land, as that of leases for terms of years, as "for twenty-one years, though they may be profitable at their commencement, they have, it is supposed, been found much otherwise before their expiration: owing to the great rise in the value of farm produce, during the terms. And while proprietors who were letting their lands from year to year, were profiting by this circumstance; the income of those whose lands were under long leases (whether of lives or years) were stationary; and this while the expences of living were advancing with the value of lands; which circumstances, added to their being controuled in the required arrangement, and perhaps annoyed during a length of years, by the improper conduct of ignorant, ill-disposed, purse-proud tenants (enriched by these very circumstances) have determined many persons in different parts of the kingdom to discontinue the practice of granting leases; giving written agreements from year to year only; which is much to be lamented for the interest of agriculture and the community in general." While others have shortened the terms of their leases to fourteen years. But such "has been the rapid depreciation in the value of money, and the nominal increase of the value of lands, that even this term has been found seriously inconvenient to a landlord; and the term of seven years (without a covenant of remuneration) is, it is believed, of little use to a tenant." These fixed leases are liable, it is conceived, to another objection. As "although a man of spirit and worth will not only give an advanced rent, in the first instance, but will, through the improvements he has made, be able and willing to give a still greater advance at the end of the term; yet, when a lease of this nature has been unfortunately or improvidently granted to a poor, an ignorant, an indolent, a resentful, or a dishonest man, the farm thus

let may be left at the end of the term in a much worse condition than it was in at the commencement." This renders it highly necessary for the manager of an estate to be careful in the choice of tenants. Where great and expensive improvements are required, it will be constantly necessary, however, to have long leases.

This may be remedied, in a great measure, by the renewal of leases before their terms are expired.

The above writer considers it useful, for owners or proprietors to come to clear understandings with their tenants, three years previously to the terminations of their respective leases. "For it is conceived, that, until about that period, a skilful tenant continues to keep his land in cultivation and condition, for his own interest; which, until then, may be said to go hand in hand with that of his landlord. And if, at that period of a lease, a fresh agreement were entered into, the ruinous consequences of an expiring term might be avoided." And that from proprietors objecting to give leases for long terms, "it occurred to him, that agreements for holding from three years to three years, instead of from year to year, would be an eligible species of tenancy. Or, which is precisely the same thing, granting leases for six years certain; with a condition, that if neither party give notice to quit before the expiration of the first three years, then the term to be prolonged to nine years; and so on, from three years to three years, (or in effect from six years to six years,) until three years after notice has been duly given by either party to the other," as by these means room is given for a tenant "to turn his hand in. He has, in reality, a fresh lease of six years granted him every third year. And this is sufficient to encourage him to keep his lands continually in the most husbandlike state. And if he execute any of the higher improvements, it is but reasonable that he should have, whenever he may quit his farm, an equitable remuneration for the remainder of such improvements. Thus the tenant is placed on sure ground; he may still manure and improve with much the same confidence, as if the lands in his occupation were his own property." And "in return for such advantages, the tenant cannot hesitate, it is supposed, to covenant, that, during the last three years of his term, he will manage his farm in a husbandlike manner, and at the end of the term leave it in such a state of cultivation and repair, as will induce a good tenant to take it at a full rent; or suffer the proprietor to put it in such a state, at his (the out-going tenant's) expence. An estate which is under lease on these principles, and under attentive management, cannot, it is conceived, be let down to an unprofitable state. It must continually remain under a regular course of husbandry, and in a state of cultivation and repair; and the more permanent improvements be kept up. If the acting manager do his duty, even the changing of tenants cannot interrupt its prosperity," while "the incoming tenant (under active management) steps into his farm, with the advantages that he would have enjoyed, had it been under his own direction, for the three preceding years." But "with a lease on this principle, and with a proper choice of tenants, removals can rarely happen. What proprietor, who knows the difficulty of procuring a good tenant, would wish to discharge him? And no such tenant would readily leave the farm he is settled upon, if he find proper treatment. Even should notice be given in consequence of any misunderstanding between the parties, three years allow time for reflection; and, before they expire, repentment may die away, and cordiality be restored. If, however, either party be dissatisfied, he has an easy way of dissolving the connection. Or if a proprietor is desirous to make fresh arrangements on his estate, or to regulate his rent-roll by the exit-

ing value of money, he need not wait many years to fulfil his desires; for if the tenant in occupancy will not agree to pay a fair rent, the owner has three years before him to choose one who will." It is thus evident, that "a lease on this principle has a decided preference, by a proprietor, to long leases. And its advantage over annual holdings is not less considerable. The lands of an estate are well worth from five to ten *per cent.* more to a tenant, under the former, than under the latter tenancy. So that beside the conveniences mentioned, a proprietor may be immediately adding very considerably to his income, by this principle of management." This has been proved in many cases in different parts of the kingdom.

*Covenants of Leases.*—It is suggested, that the necessary covenants,—the reservations, restrictions, obligations, penalties, and remunerations, that the lease (or form of a lease) of any landed estate contains, are (or ought to be) a code of private restraining laws, suited to the circumstances of that particular estate, in order to protect it from injury, and to promote its prosperity: an honest tenant considers the covenants of his lease merely as instructions to direct his steps, but which ought to restrain him no farther than to protect the farm or the estate from injury. But a worthless tenant, as a thief, is ever ready to break the laws which bind him; and the proprietor of an estate ought to have some means of punishing him for his fault. Penal covenants in leases are of course of the greatest importance to proprietors. But on account of "the great difficulty with which a general law of this nature would be framed, owing to the great diversity of soils, situations, and modes of culture, every estate, strictly speaking, requiring its own peculiar code to govern and defend it, (and of course the great difficulty which a court must find to decide with any sort of accuracy in cases of this kind,)—one would naturally imagine, it is said, that courts of law would rather be thankful to proprietors of estates, for furnishing them with ready and safe means of doing justice, than set their faces against any covenants, which have been formerly entered into, and legally confirmed by the parties before them. If penalties are excessive or oppressively severe, or have been surreptitiously imposed, it undoubtedly belongs to a court of law to mitigate or remove them. But severe restrictions, and excessive penalties, are highly impolitic, and altogether improper to be introduced into the lease or law of an estate, inasmuch as they tend to depress its character, and may prevent good tenants from settling upon it; or drive away those whom it may already possess; and of "course militating against one of the first principles of good management." But "where, by judicious restrictions and reasonable penalties, designing men are kept aloof, a general good is gained to the estate."

The particular covenants that are necessary, must be determined by the existing circumstances of the estate, or the particular farm for which it is intended; the modes of culture, cropping, &c. as it is obvious, that "a grass land farm requires a set of covenants differing from those which are proper for a farm under mixed cultivation. And an arable farm, situated near a great town, should have covenants differing in some respects from those of another, which lies in a replete district: while every part of an estate, and all estates on which hedge timber can be profitably raised, call for a series of regulations, which an untimbered estate, or one on which grown timber only is to be protected, does not require." And that, "much depends on the time of changing tenants. A spring and autumnal removal require very different stipulations respecting the states in which the lands of a farm are to be left; how the crops in the ground, and the produce on hand are to be disposed of; and by

whom the crops of the succeeding year are to be put in. Every district has its customary time or times of removal, and it can seldom be prudent in an individual to alter it (even though very improperly fixed) as he might thereby diminish his choice of tenants. Nevertheless, it is in the power of proprietors conjointly, to effect, in time, the required alteration. Michaelmas and Lady-day may be considered as the ordinary times of changing tenants in England. The former is not an ineligible time for removing in autumn, but the latter is extremely improper, as being in the middle of spring feed time, and falling at a time when the winter fodder is partially expended, and the crops of the preceding year are partially thrashed out." Mr. Marshall states, that "in the north of England (Cleveland, in Yorkshire, being the most northern district in which he has observed it,) a far more rational plan of removal is established. There, the arable lands are quitted at Candlemas; the pasture grounds (Cleveland being much of a dairy district) at Lady-day; and the mowing ground and the home-stall at old May-day." While, in Scotland, similar regulations prevail; but with a well judged difference, which naturally arises out of the different climates of the two situations. There, the premises are finally quitted at what is termed Whitsuntide, namely, the fifteenth of May old style." And it is the opinion of this writer, that, "for the more southern provinces of England, the first of May, new style, would be a proper time for removals in the spring."

*Forms of Leases.*—In respect to the forms of leases, those which are good do not, it is stated, "merely require a judicious selection of covenants, but that the several clauses should be properly digested; and be arranged, worded, and lettered in such a manner, as to be intelligible to plain countrymen,—to men for whose guidance and good government they are intended." And the plan, which experience entitles the above writer to recommend, is that "of printing leases on large folio sheets of firm paper, or sheets of parchment, folded in the folio manner; each page containing two columns, and each clause composing a distinct paragraph; with a blank page, or half page, to receive a sketch, or rough plan of the farm demised; as well as a particular, or schedule, of the different parcels of land of which it is composed: with the number, name, and measurement of each arranged in the column manner: in order that no doubt may at any time arise respecting their identity." It is useful to have a book in which all these, and some other circumstances, are regularly arranged and marked down.

Mr. Kent, in his "Hints to Gentlemen of Landed Property," states, that the ancient feudal tenures had undoubtedly a strong tendency to enslave mankind, by subjecting them to the controul and power of an arbitrary lord; but, like most other things, there were some advantages to be found in the system. Every man who held land had a certainty in it, as the tenant generally held his possession for life. When these tenures were discontinued by the more liberal spirit of modern law, some new compact became necessary, and terms of years were substituted in lieu of the former; for, as land properly managed requires great expence, and seldom answers that expence in one year, it was but reasonable that the man who applied his judgment, devoted his labour, and ventured his capital, should have some reasonable time allowed him to reimburse himself, and derive some proportionate reward for what he had done. In the course of time, this term began to be reduced into a certain number of years; and as moit of the land was formerly under the regulation of two crops and a fallow, the time allowed was from three to twenty-one years. And the latter in the end became the most general limitation,

and is the most prevalent term for leases at the present period.

There can be no doubt, it is supposed, but that leases are the first, the greatest, and most rational encouragement that can be given to agriculture; yet of late years there are very strong prejudices entertained against them.

Let any impartial man take a view of two districts, where it is the custom to grant leases, and where it is not: in the former he will generally find a respectable yeomanry, and a well cultivated country; in the other, an indigent spiritless race; following a contracted system of husbandry, calculated to answer no permanent purpose of advantage to themselves or landlords. Yet, there are many gentlemen who, to have such people at immediate command, prefer the continuance of a slovenly unproductive style of husbandry, to neatness and fertility. In some parts of England, the prejudice against leases is so strong, that some landlords will be tempted almost as soon to alienate the fee simple of their estates, as to grant a tenant a reasonable term in them. It is very unfortunate for a county where this abhorrence of leases prevails, as it keeps back an immense scene of improvement, which otherwise would take place, and robs the industrious occupier of a deal of comfort which might be bestowed upon him; and it can produce no other consolation to the owner than that of having the country more at command, and forcing a certain degree of respect from it, which is absurd to the last degree; for a landlord may, it is conceived, ensure as much real respect from a tenant on lease, as from a tenant at his immediate will and pleasure, and at the same time secure his property better, and stipulate for improvements to the extent of his inclination or desire.

It is noticed farther, that in the eastern counties, where it is more the custom to grant leases than in the midland parts of England, agriculture is upon the most respectable footing; and that within half a century there are many estates more than doubled in their value; which, without leases, where the means of improvement were heavy, could not have carried a third of the advance that has been put upon them. In short, it seems to him unreasonable to expect a man to employ the whole of his capital, and to devote the best part of his life upon an estate which, on the death or mere caprice of the landlord, he is liable to be turned out of at six months, or perhaps a shorter notice.

It is not, however, meant to imply, that leases ought not in any case to be withheld; there are certainly some exceptions against the practice he wishes to see established: for instance, if lands are situated very near a gentleman's house, part of which it may, perhaps, be an object, on some future occasion, to take into hand, or where a minor is very near coming of age, or where there is any immediate view of sale; in such cases, it would be imprudent to grant leases. But where none of these contingencies stand in the way, and where estates are under an entail, or in a family that has no idea of parting with them, leasing is unquestionably the most effectual means of raising the value of an estate, as it enables the owner to stipulate for improvements in what way and proportion he pleases, which he cannot do so well in any other manner.

And the author of the "Treatise on modern Agriculture" contends, that nothing gives such a spring to industry as the conviction, founded on the experience of ages, that in this country the fruits of the labours of the industrious man are secured to him. Hence, a farmer will be more or less active in proportion to the security he holds of reaping the fruits of his industry, skill, and capital.

And it is still further stated, that leases are certainly necessary and proper, as a compact between man and man; and

though the mode of cropping and general tenor of the lease must vary according to times and circumstances, yet no man who has thought seriously on the subject will deny that they are for the benefit of both parties, as they secure to the landlord the proper management of the land so leased, and to the tenant the additional profits which may be expected to arise from his superior cultivation of such lands or farms.

But as it is necessary to impose some degree of restraint upon tenants, the means of doing it in such a way that they may not be so fettered as to be prevented from making useful improvements, or left so much at liberty as to do mischief; are the point that forms the principal difficulty. Hence the circumstance to be chiefly guarded against by restrictive penal covenants, are those of preventing the breaking-up of old meadows, pastures, or other lands, the removing away hay, straw, or other materials convertible into manure; and the improving or destroying of timber trees. To enforce the leaving of green winter food; the keeping up of all sorts of fences; the cleansing of water-courses, ponds, pools, &c. and the preserving of buildings, gates, pens, and bridle roads in proper repair. To prevent the forming of rabbit-warrens, and the committing of waste of any kind. And, finally, to regulate the circumstances of the out-going and in-coming tenants with propriety.

But although it is not possible to form any particular lease, so as to include clauses that can apply to every kind of soil, mode of cropping, and general management; yet, as he has had opportunities of perusing a great variety of leases in different parts of England; and as he is in possession of one which is the most perfect of the kind he has seen, it is suggested that it may convey more information on the subject than any explanation that could be otherwise given of it.

*Form of Lease.*

"THIS Indenture, made the \_\_\_\_\_ day of \_\_\_\_\_ in the year of our Lord one thousand eight hundred and \_\_\_\_\_ between A. B. of \_\_\_\_\_ in the county of \_\_\_\_\_ of the first part, and C. D. of \_\_\_\_\_ in the county of \_\_\_\_\_ yeoman of the second part: Witnesseth, That for and in consideration of the rents and covenants, provisos and agreements, hereinafter reserved, expressed, and contained, and which, on the part and behalf of the said C. D., his executors and administrators, are to be paid, done, and performed, he the said A. B. hath demised, leased, setten, and to farm letten; and by these presents doth demise, lease, set, and to farm let unto the said C. D., his executors and administrators, all those messuages, tenements, or farms, called \_\_\_\_\_ situated in the parish of \_\_\_\_\_ and county of \_\_\_\_\_ now or late in the possession of \_\_\_\_\_ together with all and singular houses, out-houses, edifices, buildings, barns, cow-houses, cattle-sheds, stables, yards, garths, slack-garths, gardens, lands, feedings, ways, waters, easements, privileges, and appurtenances whatsoever, to the said demised premises belonging, or in anywise appertaining, except and always reserved out of this present demise, unto the said A. B., his heirs and assigns, all mines, minerals, and quarries, of what nature or kind soever the same may be, as well opened as not opened, lying, being, and remaining within or under the said premises, or which can or may be obtained, or gotten forth, or out of the same, or any part thereof, with liberty to dig brick-earth, and room to work, mould, dry, and burn the same into bricks, in and upon the said hereby demised premises, or any part thereof: And also with full and free liberty, power, and authority, to and for the said A. B., his heirs or assigns, and his and their agents, servants, and work-

L E A S E.

men, at reasonable times in the year, in the day-time, to search for all and every such mines, minerals, quarries, and brick-earth, and to sink pits or shafts, and to make trenches, groves, drifts, water-gates, canals, water-courses, and to direct or turn any water-course, brook, or river, for the winning and working such mines, minerals, and quarries, within the said demised premises, with sufficient ground-room and heap-room for laying the ores, metals, minerals, coals, stones, clay, earth, materials, and rubbish, to proceed, or to be obtained or gotten forth out of the same or any of them; together with full liberty and power to build and erect engines, machines, houses, hovels, lodges, stables, cabins, and other edifices and erections whatsoever, for the effectual winning and working the same: And also full and free liberty of way, leave, and passage in, through, and over the said premises, or any part thereof, to and from the said mines, minerals, quarries, and brick-kilns whatsoever, with carts, wains, waggons, and any other carriage or carriages necessary for leading ores, metals, minerals, coals, stones, cinders, bricks, lime, timber, or any other matter or thing whatsoever, and to make, lay, and place through, over, and upon the said premises, any road or roads, wagon-way or wagon-ways, rail-ways, or any way or ways, canal or canals, for the purpose aforesaid, and from time to time to repair the same, and to do all other acts and things needful or necessary for the winning, working, managing, and carrying on the said mines, quarries, and brick-making, as he or they shall think proper, with liberty to demise or grant to any persons all such liberties as herein before-mentioned: And also, except and reserved unto the said A. B., his heirs and assigns, all timber and other trees, woods, underwoods, and plantations, and the ground and soil thereof, now standing, growing, or being, or which shall hereafter at any time during the continuance of this demise, stand, grow, or be upon the said premises, with liberty to sell, cut down, or lop such timber trees, or other trees, woods, underwoods, and plantations, and to carry away the same, by any means whatsoever: He, the said proprietor, his heirs or assigns, or his or their grantee or lessee respectively, making reasonable satisfaction to the said tenant, his executors or administrators, for the damage or spoil of herbage or ground, to be occasioned by the use or exercise of all and every or any of the liberties aforesaid, such satisfaction to be from time to time fixed and ascertained by two indifferent persons, one to be named by and on the part of the said A. B., his heirs or assigns, and the other by and on the part of the said C. D., his executors or administrators: And also, except and reserved full power and authority for the said A. B., his heirs or assigns, and his and their stewards and agents, with workmen in their company, or without, in the day-time twice, or oftener, in every year during the term hereby demised, to enter in and upon the said premises, or any part thereof, to view the state and condition of the same: And also, except and reserved unto the said proprietor, his heirs and assigns, free liberty to hua, course, hawk, shoot, and fish, in, upon, through, and over all and every the said hereby demised premises, or any part thereof; to have and to hold the said messuage, tenement, or farm-hold, lands, grounds, and all and singular other the premises hereby demised, or mentioned, or intended so to be, with their and every of their appurtenances (except as before excepted), unto the said C. D., his executors and administrators, from the twelfth day of May, in the year of our Lord one thousand eight hundred and \_\_\_\_\_, for and during and unto the full end and term of twenty-one years, from thenceforth next ensuing, and fully to be complete and ended: yielding and paying yearly, and every year during the said term

of twenty-one years hereby demised unto the said A. B., his heirs or assigns, the clear yearly rent or sum of \_\_\_\_\_ of lawful money of Great Britain, by equal half-yearly payments, at two days or times in the year, that is to say, the twenty-second day of November, and the twelfth day of May in every year, by even and equal portions; the first half-yearly payment of the said yearly rent to begin and be made upon the twenty-second day of November next ensuing the commencement of the said term hereby demised: And also yielding and paying yearly and every year unto the said A. B., his heirs or assigns, on the several days and times aforesaid, over and above the said yearly rent of \_\_\_\_\_ the further rent or sum of \_\_\_\_\_ pounds an acre, for every acre of the said demised premises, that he the said C. D., his executors or administrators, shall, at any time or times during the continuance of this demise, break up, tear out, or convert into tillage, or have, or use, or employ in any course of husbandry, contrary to the covenants hereafter contained, without the licence and consent of the said proprietor, his heirs or assigns, in writing for that purpose first had and obtained, and so in proportion for a greater or less quantity than an acre; the first payment of the said additional rent to be made on the first of the aforesaid half-yearly days of payment, which shall happen next after the ploughing, breaking up, tearing out, converting into tillage, or having or using, or employing in any course of husbandry, contrary to the covenants hereinafter contained, any part of the said hereby demised premises, which said two several and respective rents are to be paid as above expressed and reserved, free and clear of all taxes, assessments, charges, and impositions whatsoever, as well parliamentary as parochial, or otherwise, which the said premises now are, or may hereafter be liable to answer or pay: Provided always, and upon condition, and it is the true intent and meaning of these presents, that if it shall happen that the said yearly and other rents herein and above reserved, or any of them, or any part thereof, be behind or unpaid, by the space of forty days next over or after either or any of the said days or times whereon the same ought to be paid as aforesaid, or in case the said C. D., his executors or administrators, shall neglect or refuse to do and perform all and every of the covenants or agreements herein mentioned and contained, on his and their parts, to be paid, done, and performed; or in case the said tenant, his executors or administrators, shall, or do, at any time or times during the term hereby demised, alien, let, or assign over the said premises, or any part thereof, unto any person or persons, without the licence and consent of the said A. B., his heirs or assigns, in writing for that purpose first had and obtained, that then, and in any of the said cases, it shall and may be lawful to and for the said A. B., his heirs or assigns, or such person or persons as shall be by him or them appointed for that purpose, into and upon the said demised premises, or into and upon any part thereof, in the name of the whole, wholly to re-enter, and the same to have again, re-possess, and re-enjoy, as in his and their first and former estate, and from and immediately after such re-entry made, the said term hereby demised shall cease, determine, and become utterly void and of none effect, any thing in these presents contained to the contrary thereof in anywise notwithstanding: And the said A. B. for himself, his heirs and assigns, doth hereby covenant, promise, and agree to, and with the said C. D., his executors and administrators, that it shall and may be lawful to and for the said C. D., his executors and administrators, (he and they paying the rents and performing the covenants and agreements herein reserved and contained, on his and their parts,

## L E A S E.

parts, and to be paid, done, and performed, according to the true intent and meaning of these presents,) peaceably and quietly to have, hold, use, occupy, possess, and enjoy all and singular the said premises, with their appurtenances hereby demised (except as before excepted), for and during the said term of twenty-one years, without the lawful let, suit, trouble, denial, hindrance, molestation, eviction, or interruption of him the said A. B., his heirs or assigns, or any other person or persons, claiming by, from, or under him, them, or any of them: And also, that it shall and may be lawful to and for the said C. D. his executors or administrators (he and they paying the rents and performing the covenants and agreements as aforesaid), in the harvest season next after the expiration of the said term hereby demised, peaceably and quietly to have, cut down, reap and lead the crop of corn or grain by him, them, or any of them, sown and then growing upon two-third parts of the lands then in ploughing or tillage (according to the covenants hereinafter contained, and the true intent and meaning of these presents), commonly called the way-going crop; and the same corn or grain to set in the stack-yards, and thrash the same in the barn or barns of and belonging to the said demised premises: And that he the said C. D., his executors or administrators, shall, for the purposes aforesaid, have the use of all the stack-yards, barns, and granaries of and belonging to the said demised premises, until the twelfth day of May next, after the determination of this demise; and the same corn and grain so thrashed (after payment of rents and arrears of rents then unpaid), shall and may carry away, sell, and dispose of, to and for his or their proper use and benefit, leaving and delivering all the straw of the said way-going crop, as soon as the same is thrashed (as hereinafter mentioned), in and upon the said premises, unto and for the use and benefit of the said A. B., his heirs and assigns, or his or their next succeeding tenant or tenants: And the said A. B., his heirs and assigns, or his or their next succeeding tenant or tenants, shall and will lead the said way-going crop from the lands where it grew to the barns or stack-yards, and fork the same from the loaded carts to the stacks: And also shall and will bear and pay one-half the expence of making and erecting new quick fences upon the said premises, and of cleaning, rearing, and preserving the same for seven years, after being first planted: And also, &c. [Here follow any other covenants on the part of the lessor for new buildings, &c. &c.]

And the said tenant, for himself, his heirs, executors, administrators, and assigns, doth covenant, promise, and agree to and with the said A. B., his heirs and assigns, by these presents, in manner following, that is to say, that the said C. D., his executors or administrators, shall and will well and truly pay, or cause to be paid, unto the said A. B., his heirs or assigns, the said yearly rent or sum of \_\_\_\_\_ and also the other casual or eventual rents herein above reserved, and payable on the days and times, and in manner above mentioned for payment thereof, according to the true intent and meaning of these presents: And also shall and will from time to time, and at all times during the term hereby demised, well and truly pay and discharge all and all manner of taxes, assessments, rates, charges, dues, tithes, and impositions, parliamentary or parochial, whatsoever, which now are, or at any time hereafter during the term hereby demised shall be, taxed, assessed, rated, charged, or imposed upon the said premises, or any part thereof: And also shall and will, from time to time, and at all times during the said term hereby demised, at his and their own charge and expence, repair, uphold, maintain, and keep, with all manner of needful and necessary reparations, all and singular the

houses, buildings, barns, cow-houses, cattle-fleeds, stables, offices, gates, liles, rails, fences, hedges, ditches, drains, and water-courses, of and belonging to the premises hereby demised, or which may at any time hereafter during the said term, be built, erected, or made upon the said premises or any part thereof: And at the end, expiration, or other sooner determination of the said term, shall and will deliver up all and singular the said houses, buildings, erections, barns, cow-houses, cattle-fleeds, stables, offices, gates, liles, rails, fences, hedges, ditches, drains, and water-courses, with their and every of their improvements unto the said A. B., his heirs or assigns, in good and sufficient repair and condition, together with the peaceable and quiet possession thereof: And also shall not, nor will not, at any time or times during the continuance of this demise, sell, dispose of, send or carry away, or permit to be sold or disposed of, sent or carried away from off the said premises hereby demised, any of the hay, straw, clover, turnips, cabbages, or other fodder, that shall grow or be produced from, or made thereon, but shall and will eat and consume the same (for the increase of manure) upon the said premises: And also shall and will, from time to time, during the continuance of this demise, at the proper seasons in every year, duly lay and spread upon the fallow grounds of the said premises (where most requisite and proper for the improvement thereof), in an even, regular, and uniform manner, all the manure, dung, and compost that shall be bred and made on the premises; except the manure, dung, and compost to be bred and made thereon in the year next before the determination of the said term; and which manure, dung, and compost, shall be left in the fold-yards, dung-hills, or midden-steads of the said premises, for the use and benefit of the said A. B., his heirs or assigns, or his or their next succeeding tenant or tenants: And also shall not and will not plant or sow any hemp, flax, or mustard, or any rape for seed\* upon the said premises, or any part thereof: And also shall not, and will not, at any time or times in the year next before the determination of this demise, depature or graze, or suffer to be depatured or grazed upon the said premises, or any part thereof, any larger stock of cattle or greater number of flints than were usually depatured or grazed thereon in the two years next preceding the said last year of the said term, or other sooner determination thereof: And also shall and will yearly, and every year during the said term hereby demised, catch and destroy the moles, and seals, mould, dres, and clean the grass-grounds of and belonging to the said demised premises: And also shall and will thrash the way-going crop, at the determination of the said term, in an uniform manner, so as to deliver a constant, regular, daily supply of straw to and for the use of the said A. B., his heirs or assigns, or his or their tenant or tenants: And also shall and will, from and after the first day of October preceding the termination of the said term, hain, free, and keep uncaten, all those fields or parcels of ground sown with grass-feed in the last fifteen months of the said term; save and except that it shall and may be lawful for the said C. D., his executors and administrators, from and after the first day of April next before the end of the said term, to depature, with not more than \_\_\_\_\_ sheep an acre, one-half of the said hained clover or new grass, which half shall be chosen and set out by the agent of the said A. B., his heirs or assigns, in the month of March preceding: And also shall and will permit the said A. B., his heirs or assigns, or his or their tenant or tenants, to sow with grass-seeds all or any part of the lands sown with corn or grain, for the way-going crop, and to roll in the same with a roller drawn

\* Rape for green food is allowed.

by hores, according to the custom of the country: And also shall and will permit and suffer the said proprietor, his heirs or assigns, or his or their servants, draughts, and workmen, from time to time, and at all times, from and after the first day of December preceding the determination of this demise, to enter into and upon all the then fallow grounds of the said premises, or the grounds which, according to the true intent and meaning of these presents, ought to be in true use, and the same to plough, sow, harrow, dress, manure, lime, and prepare for such course of agriculture as he or they shall think proper to convert the same into, without the let or hindrance of him the said C. D., his executors or administrators: And also shall not, and will not, have, use, or employ, in ploughing or tillage, a greater quantity of land than \_\_\_\_\_ acres of the said premises at any one time, or in any one year, during the term hereby demised: And also shall and will yearly, and every year during the term hereby demised, summer fallow † at least one-third part of the tillage, and plough the same at least

several times, at proper seasons in each year, and keep the same free and clear from quick-ins, wild oats, thistles, coltsfoot, runch, dead nettles, and every other pernicious plant or weed, and lay and spread upon every acre of such fallow, in an even and regular manner, at least

fother of well-turned clod-lime, or in lieu thereof twenty fother of good well-rotted dung, and so in proportion for a less quantity than an acre: And also shall not, and will not, have, keep, or continue in ploughing or tillage, any part of the said demised premises, more than \_\_\_\_\_ years at one time, that is from being ploughed out from grafs, to being laid down to grafs again: And also shall and will yearly, and every year, fow with grafs-seeds, and lay down to grafs, at least one-third part of the ploughing or tillage-lands, after a clean summer fallowing, and a crop of wheat, or a crop of turnips and white corn, and fow upon every acre thereof at least eight pounds of red clover seed, three pounds of white clover, three pounds of rib-wort plantain, and two pecks of rye-grass ‡ of the best quality; the quantity and quality to be ascertained by proper vouchers from the persons of whom the said seeds were bought, and by whom the said seeds were sown: And also shall and will, whenever any part of the ploughing or tillage lands are laid to grafs, keep and continue the same in grafs at least \_\_\_\_\_ years before the same, or any part thereof, be again ploughed out, or converted into tillage: And also shall and will, in the last three years of the said term, lay down to grafs as aforesaid, or have in grafs, and at the end thereof leave in grafs, all those fields or parcels of land, called \_\_\_\_\_ And also shall and will, during the whole of the said term, keep in grafs, and at the expiration thereof leave in grafs, all those fields or parcels of land § \_\_\_\_\_ And also all such lands as shall be converted into watered meadows: And also shall and will during the term hereby demised, bear and pay one-half the expence of making and erecting new quick fences upon

† On the fallow turnips should be sown, if a proper soil, or cabbages, or drilled beans, at thirty inches distance.  
‡ To these, upon light soils, are generally added three or four pounds of yellow hop-clover.  
§ This blank is sometimes filled up with two or one, according to soil, situation, and circumstances, and weak soils, improper for corn, generally continue in grafs five, six, or seven years, until it is thought they want refreshing by tillage, which is only used in such situations, as being subterfuge to rearing stock.

§ This covenant is used only in such situations where there are any rich old grazing lands.

the said premises, and of cleaning, rearing, and preserving the same for seven years after being first planted. [Here follow any other particular covenants that circumstances may require.]

In addition to this general form of lease, others with particular covenants become necessary for each particular sort of farm.

**LEASE, Valuation of,** the mode of finding out and ascertaining the value of leasehold property, in which the circumstances that are to be more particularly attended to are those of the peculiar nature or conditions of the lease, and the difference between the lease rent, and the full or actual rental value; as all sorts of leases, where the rent payable is not equal to the just or true rental value at the period of their being sold, lessen the value of the land, and are obviously an incumbrance in different points of view. The mode of managing this business with propriety, according to a late writer, is, after ascertaining the difference between the lease rent and the full rental value (incumbered with the same outgoings and repairs as the lease rent), to multiply it by the number of years that are unexpired, deducting the product in full from the value of the land free from such incumbrance; and from the product thus found, to further deduct half the interest thereof during the said number of years, together with that of one-half year over, where the rent is payable half yearly, and one year where it is payable annually; as all that a purchaser of this sort of property has a right to expect, is that of receiving the full rent for his land during the continuance of such lease or engagement. See *Valuation of Landed Property*.

**LEASE, in Agriculture,** a provincial term that implies grassy ground, meadow-ground, or any unploughed ground kept for the use of cattle.

**LEASE and Release, in Law,** is a conveyance of the fee-simple, right, or interest in lands or tenements, under the statute of Uses, 27 H. VIII. cap. 10. giving first the possession, and afterwards the interest, in the estate conveyed. This species of conveyance was first invented by Sir John Moore, soon after the statute of Uses, and it is now the most common of any, and not to be shaken. Though the deed of feoffment was the usual conveyance at common law; yet since the stat. of 27 Hen. VIII. of uses, the conveyance by lease and release has taken place of it, and is become a very common assurance to pass lands and tenements; for it amounts to a feoffment, the use drawing after it the possession without actual entry, &c. and supplying the place of livery and seisin, required in that deed: in the making of it, a lease, or bargain and sale for a year, or such like term, upon some pecuniary consideration, is first prepared and executed, to the intent that by virtue thereof the lessee may be in actual possession of the lands intended to be conveyed by the release, and thereby and by force of the statute 27 Hen. VIII. c. 10. for transferring of uses into possession, be enabled to take and accept a grant of the reversion and inheritance of the said lands, &c. to the use of himself and his heirs for ever. Upon which the release is accordingly made, reciting the lease and declaring the uses; and in these cases a pepper-corn rent in the lease for a year is a sufficient reservation to raise an use, to make the lessee capable of a release. (2 Vent. 35. 2 Mod. 262.) This is held to supply the place of livery of seisin; and so a conveyance by lease and release is said to amount to a feoffment. (Co. Lit. 270. Cro. Jac. 204.) Black. Com. b. ii. Tomlin's Jacob Dict. vol. ii. tit. LEASE and RELEASE. See BARGAIN and SALE, and CONVEYANCE.

The form of this conveyance is originally derived to us from the common law; and it is necessary to distinguish in what

what respect it operates as a common-law conveyance, and in what it operates under the statute of Uses. At the common law, where the usual mode of conveyance was by feoffment with livery of seisin, if there was a tenant in possession, so that livery could not be made, the reversion was granted, and the tenant attorned to the reversioner. As by this mode the reversion or remainder of an estate might be conveyed without livery, when it depended on an estate previously existing, it was natural to proceed one step further, and to create a particular estate for the express and sole purpose of conveying the reversion; and then by a surrender or release, either of the particular estate to the reversioner, or of the reversion to the particular tenant, the whole fee vested in the surrenderer or releasee. It was afterwards observed, that there was no necessity to grant the reversion to a stranger; and that if a particular estate was made to the person to whom it was propounded to convey the fee, the reversion might be immediately released to him, which release operating by way of enlargement, would give the releasee (or releasee as he is sometimes termed) a fee. In all these cases the particular estate was only an estate for years; for at the common law the ceremony of livery of seisin is as necessary to create even an estate of freehold, as it is to create an estate of inheritance. Still an actual entry would be necessary on the part of the particular tenant; for without actual possession the lessee is not capable of a release, operating by way of enlargement. But this necessity of entry for the purpose of obtaining the possession, was superseded or made unnecessary by the statute of Uses (27 Hen. VIII. c. 10. above alluded to); for by that statute the possession was immediately transferred to the *cestui que use*; so that a bargainee under that statute is as much in possession, and as capable of a release before or without entry, as a lessee is at the common law after entry. All, therefore, that remained to be done to avoid on the one hand the necessity of livery of seisin from the grantor, and to avoid on the other the necessity of an actual entry on the part of the grantee, was, that the particular estate (which, for the reasons above-mentioned, should be an estate for years) should be so framed as to be a bargain and sale within the statute. Originally it was made in such a manner as to be both a lease at the common law, and a bargain and sale under the statute; but as it is held, that where conveyances may operate both by the common law and statute, they shall be considered to operate by the common law, unless the intention of the parties appears to the contrary, it became the practice to insert, among the operative words, the words *bargain and sell* (in fact, it is more accurate to insert no other operative words); and to express that the bargain and sale, or lease, is made to the intent and purpose that thereby, and by the statute for transferring uses into possessions, the lessee may be capable of a release. The bargain and sale therefore, or lease for a year, as it is generally called, operates, and the bargainee is in the possession, by the statute. The release operates by enlarging the estate or possession of the bargainee to a fee. This is at the common law; and if the use be declared to the releasee in fee-simple, it continues an estate at the common law; but if the use be declared to a third person, the statute again intervenes, and annexes or transfers the possession of the releasee to the use of the person to whom the use is declared. It has been said, that the possession of the bargainee under the lease is not so properly merged in, as enlarged by, the release; but at all events it does not, after the release, exist distinct from the estate passed by the release. 1 Inst. 271. b. in n.

As the operation of a lease and release depends upon the lease, or bargain and sale; and if the grantor is a body corporate, the lease will not operate under the statute of Uses;

for a body corporate cannot be seized to an use, and therefore the lease of possession, considered as a bargain and sale under the statute, is void; and the release then must be of no effect for want of a previous possession in the releasee. In cases of this nature, therefore, it is proper to make the conveyance by feoffment, or by a lease and release with an actual entry by the lessee previous to the release; after which the release will pass the reversion. It may also be observed, that in exchanges, if one of the parties die before the exchange is executed by entry, the exchange is void. But if the exchange be made by lease and release, this inconvenience is prevented, as the statute executes the possession without entry; and all incidents annexed to an exchange at common law will be preserved. 1 Inst. 271. b. in n.

When an estate is conveyed by lease and release, in the lease for a year there must be the words, *bargain and sell* for money, and five shillings or any other sum, though never paid, is a good consideration, whereupon the bargainee for a year is immediately in possession on the executing of the deed, without actual entry: if only the words *demise, grant and to farm let* are used, in that case the lessee cannot accept of a release of the inheritance, until he hath actually entered, and is in possession. (2 Ld. Abr. 435.) But where Littleton says, that if a lease is made for years, and the lessor releases to the lessee before entry, such release is void; because the lessee had only a right, and not the possession; and such release shall not enure to enlarge the estate, without the possession: though this is true at common law, it is not so now upon the statute of Uses. (2 Mod. 250, 251.) And if a man make a lease for life, remainder for life, and the first lessee die; on which the lessor releases to him in remainder, before entry; this is a good release to enlarge the estate, he having an estate in law capable of enlargement by release, before entry had. 1 Inst. 270.

No person can make a bargain and sale, who hath not possession of the lands: but it is not necessary to reserve a rent therein; because the consideration of money raises the use. If a lease be without any such consideration, the lessee hath not any estate till entry, nor hath the lessor any reversion; and therefore a release will not operate, &c. (1 Inst. 270, 278. Cro. Jac. 169. 1 Mod. 263.) On lease at will, a release shall be good by reason of the privity between the parties; but if a man be only tenant at sufferance, the release will not inure to him; and as to the person who hath the reversion it is void, for such tenant hath not any possession, there being no estate in him. Lit. § 461, 462. Cro. Eliz. 21. Dyer 251.

In a lease and release, to make a tenant to the *precipe* to suffer a recovery, where the release is made to A. B., and his heirs (*viz.* the tenant to the *precipe*), it must be also said to the use of him the said A. B., and his heirs and assigns for ever; for the releasee must be absolute tenant of the freehold. (2 Vent. 312. Lil. Conveyance, 251.) And a release made on trust, must be to A. B., his heirs and assigns, to the only use and behoof of the releasee, his heirs and assigns for ever; in trust for C. D., who is to be a party to the deed, and the purchase-money to be paid by the *cestui que trust*. If the words *to the use*, &c. are not inserted in the release, the estate doth not execute by the statute of Uses, and the trust is void. Lil. Conv. 231, 251. See RECOVERY and TRUST.

A lease and release make but one conveyance, being in the nature of one deed. 1 Mod. 252. See RELEASE.

LEASEHOLD Tenure of Lands, in Agriculture, is that sort of tenancy which is held under lease or special agreement for any definite term, whether of lives or years; which also admits of several distinctions, as, where the term is for

for a great length of time, as a thousand years, and where it is for life, of which there are different kinds, as where the fine is certain, or under certain limitations on renewal, with an uncertain fine; payable to a proprietor or other superior, who has merely reserved a conventional rent, the tenant having given a sum of money to obtain the lease and the right of alienation; this is a practice common in the western counties: with an uncertain fine payable to a proprietor, who receives the full rent of the land at the time of granting the lease, the landlord having a power of alienation; this is a practice common in Wales, and some parts of this country: and where it is for an ordinary term, (as for less than 100 years,) with the power of alienation. They are all tenures, which give a sort of temporary property or interest in the lands, by which they are rendered liable to bargain or sale as other sorts of property by the holders of them. See TENANT and TENURE.

LEASH, or LEASHE, among *Sportsmen*, denotes three creatures of any kind; but chiefly greyhounds, foxes, bucks, and hares.

We say a leash of greyhounds, a couple and a half of hounds.

LEASING, or LESING. See GLEANING.

LEAT, is used for a trench to convey water to or from a mill. It is mentioned in the statute 7 Jac. I. cap. 19.

LEATHER, in *Commerce*, the skins of several sorts of beasts dressed and prepared for the use of various manufacturers, whose business is to make them up, according to their different employments. The butcher and others, who flay them off the carcasses, dispose of them raw or salted to the tanner and tawer; they to the shamoy, morocco, and other kind of leather-dressers, who prepare them according to their respective arts, in order to vent them among the curriers and leather-cutters, glovers, harness-makers, coach-makers, fadlers, breeches-makers, gilt-leather-makers, chair-makers, shoe-makers, book-binders, and all in any way concerned in the article of leather.

Leather has divers names according to the state wherein it is, and according to the different kinds of skins of which it is prepared, and its peculiar qualities when so prepared. 1. The skin is raw as it comes off the animal. 2. Some are salted with sea-salt and alum, or with natron, which is a species of salt-petre, or white salt-wort, to prevent corruption in keeping, or sending to distant tanneries during hot seasons.

Skins dried with the hair on, are commonly those of oxen and cows, or buffaloes, either tame or wild. Most of those in France come from foreign countries. The places which furnish the largest quantity, are Peru, the isle of St. Domingo, Barbary, Cape Verde Isles, the river Senegal in Africa, Muscovy, Ireland, the island of Cuba. Those of this latter place are the most esteemed; they are called Havana skins, from the name of the capital city of that island, whither they are carried in order to be sent to Spain, and from thence into other parts of Europe. After these skins are stripped of their hair, they are sold to the tanners. See CURRYING, TANNING, and SKINS.

The three principal assortments of leather are tanned or tawed, and oil and alum leather, all which are dressed in some yards.

The art of dressing leather in oil consists in first soaking the skins; then throwing them into the lime-pit; and when they are taken hence, pulling them and delivering them to the friezier; they are then struck with the oil, and sent to the mill; when they are milled sufficiently; they are thrown into the ditch to be scoured, and by some scudded, and afterwards hung upon the hooks to dry. When they have been

weighed and marked by the proper officers, in order to fix the excise duty, they are fit for sale. The sorts of skins dressed in oil are those of deer, sheep, and lambs, and some few of goat, and the oil used for this purpose is Newfoundland, or cod's liver oil. The alum leather-dressers' art consists in properly soaking, liming, wringing, (an operation sometimes omitted,) and striking them in a liquor composed of water, salt, and alum, and then drying them properly. The sorts of skins dressed in alum are those of sheep and lambs, and a large quantity of kid. Postleth. Dict. Com. art. *Leather*.

There are several statutes relating to leather; the 27 Hen. VIII. c. 14 directs packers to be appointed for leather to be transported: but the 18 Eliz. c. 9. prohibits the shipping of leather on penalty of forfeiture, &c. Though by 20 Car. c. 5. transportation of leather was allowed to Scotland, Ireland, or any foreign countries paying a custom or duty; which statute was continued by divers subsequent acts.

No person shall ingross leather to sell again, under the penalty of forfeiture. None but tanners are to buy any rough hides of leather, or calves' skins in the hair, on pain of forfeiture; and no person shall forsell hides, under the penalty of 6s. 8d. a hide. Leather not sufficiently tanned is to be forfeited. In London, the lord mayor and aldermen are to appoint and swear searchers and sealers of leather out of the company of cordwainers, &c. and also triers of the sufficiency of leather; and the same is to be done by mayors, &c. in other towns and corporations; and searchers allowing insufficient leather, incur a forfeiture of 40s. Shoemakers making shoes or boots of insufficient leather are liable to forfeit for every pair 3s. 4d. and the value thereof. (1 Jac. I. c. 22.) Red tanned leather is to be brought into open leather markets, and searched and sealed before it be exposed to sale, and on sale is to be registered, or shall be forfeited; and contracts for sale otherwise to be void. (13 & 14 Car. II. c. 7.) Hides of leather are adjudged the ware and manufacture of the currier, and subject to search, &c. All persons dealing in leather may buy tanned leather, searched in open market, and any person may buy or sell leather, hides, or skins, by weight. 1 W. & M. c. 33.

The first statute concerning leather, which it is necessary for us to refer to in this article, is the 1 Jac. c. 22, which reduces all preceding acts relating to that commodity into one; and therefore to this we shall have a retrospect in the progress of this article; premising that all forfeitures by this act, not otherwise specially directed, shall be divided, one-third to the king, one-third to him that shall sue, and one-third to the city, town, or lord of the liberty. By 9 Ann. c. 11. any two justices near the place where the forfeitures are incurred, or offence committed, may hear and determine the same. All forfeitures, by the act of 13 & 14 Car. II. c. 7. shall be recovered in any court at Westminster, or in any court of record in the city, &c. where the offence shall be committed; to be distributed half to the king, and half to the informer. By 39 & 40 Geo. III. c. 66. it is enacted that proper places and times for inspecting all raw hides and skins of cattle, sheep, horses, and hogs, shall be fixed by the mayor, bailiff, or head-officer of any city, town corporate, borough, or market-town, or any two magistrates acting for the same, or any two justices acting for the division within or nearest to such city, &c. The manner of appointing inspectors is also prescribed by the said acts. And by the same, butchers, &c. who are chargeable with willfully or carelessly injuring hides, so as to make them less valuable, are liable to penalties, not exceeding 5s. (47 Geo. III.) nor less than 1s. for the raw hide of every ox, bull,

## LEATHER.

bull, cow, or heifer, &c.; and not exceeding 2s. 6d. (41 Geo. III.) nor less than 6d. for the skin of every calf; and not exceeding 2s. 6d. (41 Geo. III.) nor less than 1s. for the hide of every horse, mare, or gelding; and not exceeding 6d. nor less than 3d. for the hide of every hog, pig, sheep, or lamb. Inspectors are required to take a prescribed oath, and are allowed certain fees for examining and inspecting hides. &c. (See also 43 Geo. III. c. 106.) These inspectors may impose penalties for damaging hides, &c.; which penalties shall be recovered before a justice, one-half of which, by 41 Geo. III. c. 53. shall be given to the inspector, and the other half applied to the purpose of better carrying on the objects of these acts. By the above-cited acts, 39 & 40 Geo. III. c. 66, the inspectors of raw hides shall provide proper stamps, and stamp the hides, not damaged or otherwise; and seize such hides or skins as have been damaged, and sell the same, provided the penalties be not paid in less than 48 hours after such seizure. Butchers or others neglecting to bring hides to be marked, shall forfeit not exceeding 5l. nor less than 40s. for every such hide. The regulations of this act shall extend to all hides found in Great Britain. (41 Geo. III. c. 53.) All disputes shall be settled by any five impartial and respectable persons concerned in the manufacture of leather, summoned by a magistrate, before whom such dispute shall be brought. All penalties and forfeitures shall be recovered before one justice or magistrate of any city, town, or place, where the offence shall be committed, upon conviction, confession, or the oath of one witness, and levied by distress; and for want of sufficient distress, the offending party shall be committed by such justice or magistrate to the common gaol or house of correction, for a time not exceeding one month. All penalties and forfeitures, not otherwise disposed of, shall go, half to the informer, and half to the execution of the purposes of the act. Persons aggrieved may appeal to the next sessions. (39 & 40 Geo. III. c. 66.) By the same and 41 Geo. III. c. 53, informations for offences against this act for wilfully or carelessly gashing raw hides, shall be laid within three days after the commission of the offence; and for any other offence within 14 days after the offence committed. By 43 Geo. III. c. 106, the provisions of 39 & 40 Geo. III. c. 66, and 41 Geo. III. c. 53, are extended to London, Westminster, and Southwark, and to all places within fifteen miles of the Royal Exchange. All raw hides within five miles of the Royal Exchange shall be brought to Leadenhall market, and the skins of sheep and lambs to one of the three sheep-skin markets in Southwark, the Whitechapel market, or the market at Wood's Clove. Proper places and hours for inspection are to be appointed within three months after the passing of this act. For the market at Leadenhall, eight inspectors are to be appointed; four from the company of butchers, two by the company of curriers, and two by the company of cordwainers; and besides, there shall be appointed four inspectors for the sheep market at Wood's Clove, two for Southwark, and two for the market of Whitechapel. One half of the inspectors at each of the three last-mentioned markets to be appointed by the company of butchers, and the other half at each of such markets in equal proportions by the companies of curriers and cordwainers. Provision is made for increasing their number and regulating their attendance. Inspectors for Leadenhall market are required to attend on the usual market days, from six in the morning till five in the afternoon, from the 25th of March to the 20th of September; and from seven in the morning until four in the afternoon, from the 30th of September till the 24th of March.

The distribution of fines and fees is prescribed, so that one-

half shall be equally divided between the inspectors, acting at the respective markets, and the remaining half-part shall be paid weekly to the arbitrator of the market, in respect to which they are received, and paid monthly by the said arbitrators to the respective persons appointed by the courts of assizants to receive the same. There is a penalty for impeding inspectors, not exceeding 5l. nor less than 10s. for each offence, and also a penalty not exceeding 20l. on inspectors receiving, and persons offering bribes. Salfemen are required to deliver an account of hides or skins sold, under a penalty for every offence of 10l. The lord-mayor of London is empowered to increase the fees of the inspectors, under the representation of the courts of assizants of the companies concerned, to any sum not exceeding 1d. for every hide, ½d. for every calf-skin, hog-skin, or pig-skin, and ¼d. for every sheep or lamb-skin. The respective courts of assizants are required to appoint annually four arbitrators, to settle disputes arising in any of the markets above-mentioned; and these arbitrators are empowered to fine inspectors, and also butchers and salfemen, for frivolous deceptions and exorbitant impositions. Inspectors and arbitrators are liable to be dismissed for misconduct in their respective offices, or to a fine not exceeding 5l. nor less than 10s. Buyers and sellers of unstamped hides or skins are liable to a forfeiture not exceeding 20s. nor less than 5s. for every hide; and not exceeding 5s. nor less than 1s. for every skin of hogs, pigs, or calves; and not exceeding 1s. nor less than 6d. for every sheep or lamb-skin. The treasurers are appointed by the respective courts of assizants to receive the sums collected by the arbitrators; one-half of which shall be paid to the treasurer appointed by the company of butchers, one-fourth to the officer of the company of curriers, and one-fourth to the officer of the company of cordwainers; which sums shall first of all be applied for the execution of the acts, and to the use of the poor of the said companies.

For particular regulations concerning *tanners* and *curriers* of hides, see these articles respectively. The mayor and aldermen of London (on pain of 40l. for every year they make default, half to the king and half to him that shall sue) shall yearly appoint eight freemen of some of the companies of cordwainers, curriers, salfers or girdlers, of whom one shall be a sealer, and keep a seal for the sealing of leather; they shall be sworn to do their office truly; and they shall search and view all tanned leather brought to market, whether it is thoroughly tanned and dried: and if it is, shall seal the same. Four of these officers shall be changed every year; no officer shall be continued above two years together, nor be re-elected till after the end of three years, on pain of 10l. a month. A similar regulation extends to other places. The wardens of the curriers shall search and seal curried leather, for which they are entitled to fees, to be paid by the currier; on pain of forfeiture for every hide not searched and sealed, 6s. 8d. If any searcher or sealer shall neglect his office or misbehave, he shall forfeit 40s.: if he shall take a bribe, or exact a fee not appointed, he shall forfeit 20l.; and if he shall refuse to execute his office, he shall forfeit 10l. If any person shall hinder the searcher in the execution of his office, he shall forfeit 5l. (1 Jac. c. 22.) The mayor of London (on pain of 5l. half to the king, and half to him that shall sue) shall, within six days after notice given of any seizure of any leather, red and unwrought, appoint six triers, two of the cordwainers, two of the curriers, and two of the tanners, using Leadenhall market, who, upon their oaths taken before him, shall, on the second or third market-day for leather, try the same, whether it be sufficient or not. The same regulation extends to other places. Triers not doing their duty shall forfeit 5l. The offering for sale of unsearched and

## LEATHER.

and unsealed leather incurs a forfeiture of the same, or its value, and for every hide or piece 6*s.* 8*d.*; and for every dozen of calves' skins, 3*s.* 4*d.*; but no person shall incur any penalty for selling or buying any sheep-skins, unsealed or unsealed. (1 Jac. c. 22. 4 Jac. c. 6.) All red tanned leather shall be bought only in the open fair or market, and not in any house, yard, shop, or other place, on pain of forfeiting the same, or its value, and rendering the contract void: and such leather shall be searched and sealed before sale, and on sale shall be registered, on pain of forfeiting the same, or its value. (13 & 14 Car. II. c. 7.) Searchers and sealers shall keep a register of all bargains made for leather, during the fair or market, with the prices; taking for searching, sealing, and registering of every ten hides, or butts, of the seller 2*d.*, and so in proportion; and for every six dozen of calves' skins, or sheep-skins, 2*d.*: and of the buyer after the same rate. Red tanned leather, brought into London, or within three miles of it, shall be brought to Leadenhall, to be viewed and registered by the searchers, with half such fees to be paid for tanned leather bought out of London, or within three miles, and searched and sealed before it be brought within the city; on pain that every person housing, or not bringing his leather to Leadenhall, shall forfeit for every hide or skin 6*s.* 8*d.* No person shall buy any tanned leather, unwrought, but who shall work the same into wares, on pain of forfeiting the same, or value. (1 Jac. c. 22.) But by 12 Geo. II. c. 25, all persons who deal or work in leather may buy all sorts of tanned leather in open fair or market, whether curried or uncurried, being first searched and sealed, and may cut the felt the same in any small pieces in their open shops. (See also 1 W. sess. 1. c. 33.) Within London, or within three miles, no person shall sell any wares appertaining to the mystery of any artificer cutting leather, but only in open shop, common fair, or market, whereby the wardens may have search thereof: on pain of forfeiting the same, and also 10*s.* 1 Jac. c. 22.

No shoemaker shall make any boots or shoes, or any part of them, except of leather, well and truly tanned and curried, or of leather well and truly tanned only; nor put into any part of any shoes or boots, any leather made of a sheep-skin, bull-hide, or horse-hide, &c. &c., on pain of forfeiting for every pair of shoes or boots 3*s.* 4*d.*, and the value. And if any artificer using leather do make any wares of any tanned leather insufficiently tanned, or of tanned and curried leather, not sufficiently tanned and curried, he shall forfeit the same, and value. If any shoemaker or cobbler within London, or three miles of it, shall put any tanned leather into any boots or shoes, or other things made of tanned leather, which shall not be well and perfectly tanned, or do put any curried leather into boots or shoes, or any things made of leather, which shall not be sufficiently tanned and curried, and also sealed; he shall forfeit the same and value. 1 Jac. c. 22.

All sorts of leather and skin, tanned or dressed, may be exported. 20 Car. II. c. 5. 9 Ann. c. 6.

By 43 Geo. III. c. 69, a duty is laid upon all hides and skins, vellum and parchment, imported; and drawbacks allowed on the exportation of them. Other duties are also imposed by 49 Geo. III. c. 98. for which we refer to the act, sched. A. After the duty on importation shall be paid, the officers of the customs shall cause every hide or skin to be marked, to denote the payment of the duty. (9 Anne. c. 11.) But by 15 Geo. III. c. 35, raw or undressed goatskins may be imported for five years, duty free; and this act was made perpetual by 31 Geo. III. c. 43. The several duties for and upon all hides and skins, and parts and

pieces of hides and skins, tanned, tawed, or dressed, to be paid by the tanners, tawers, and dressers of hides and skins respectively, and the duties upon vellum and parchment, to be paid by the respective makers thereof; and certain drawbacks are allowed on the exportation thereof. By tanned hides or skins, or pieces thereof, are meant only such as are tanned in wooze, made of the bark of trees, or slumack; and by hides and skins, dressed in oil, are meant such as are made into leather in oil, or with any materials, of which the chief ingredient shall be oil; and by tawed hides or skins, are meant such as are dressed or made into leather, in alum and salt, or meal, or other ingredients properly used by tawers of white leather. 9 Ann. c. 11. f. 3.

By 43 Geo. III. c. 69, every tanner shall take out a licence annually, for which he shall pay, if within the bills of mortality, 5*s.*, elsewhere 2*l.* 10*s.*, on pain of 30*l.* (24 Geo. III. c. 41. Sect. 2. § 1.) And every tawer shall take out a licence annually, for which he shall pay 1*l.* on the penalty of 10*l.* And every dresser of hides in oil shall take out a licence annually, for which he shall pay 2*l.* on the penalty of 20*l.* And every currier shall take out a licence annually, for which he shall pay 2*l.* on the penalty of 20*l.* And every maker of vellum or parchment shall take out a licence annually, for which he shall pay 1*l.* on the penalty of 10*l.* And every person who shall take out such licences shall renew them annually, ten days before their expiration, on the penalties above stated. Collar-makers, glovers, bridle-cutters and others, who dress skins or hides, or pieces thereof, in oil, alum, and salt, or meal, or other ingredients, and who cut and make the same into wares, shall be accounted tawers, or dressers. (2 Ann. c. 11. § 25.) Any hide or skin, which hath once paid the duty, shall not be charged under any other denomination (9 Ann. c. 11. § 3.) The commissioners of these duties, appointed by the commissioners of the treasury, shall have the same power as the commissioners of excise. Tanners, tawers, carriers, or dressers of hides or skins, and makers of vellum or parchment, are required to give notice in writing to the officer, of their names and places of abode, and of their tan-houses, yards, work-houses, mills, or other places where they intend to tan, taw, or dress hides or skins, or make vellum or parchment, before they use the same; on pain of 50*l.* Those who use such places without entry of them, shall forfeit 20*l.* and the goods found in them, or their value, shall also be forfeited. The officers, at all reasonable hours, shall enter and survey these places, and if the owner or occupier refuse them entrance, he shall forfeit 10*l.* And if any hide or skin, tanned, tawed, or dressed in oil, be found in any place not entered, without a stamp denoting that the duty has been charged, the same shall be forfeited and seized; and the persons in whose possession it shall have been found, shall for each offence forfeit 100*l.* (41 Geo. III. c. 91. § 10.) Tanners and others shall give two days notice to the proper officers of the removal of goods to the drying place, that an account of them may be taken; and before they are carried away from the drying place, two days notice shall be given; and they shall be entered with the officer with respect to their number and quality, and verified on oath before a justice of peace, collector or supervisor; nor shall they be removed, till the duty be first charged, entered and marked. The penalty for neglect is 20*l.* and forfeiture of the goods, or their value. Concealment of any hide or skin, vellum or parchment, in order to avoid the duty, incurs a forfeiture of 20*l.* and the goods or their value. If any tanner or other person shall shave any hide or calf-skin, before the same be thoroughly tanned, so as to impair it and diminish the duty, the same or its value shall be forfeited. Tanners or other such person shall keep

## LEBANON.

and Theodoret also states it to be the highest of all Palestine. Modern travellers concur in this account of its great height. "Scarcely," says Volney, "do we depart from Larnaca in Cyprus, which is 36 leagues distant, before we discover its summit capped with clouds. This is also distinctly perceivable on the map, from the course of the rivers. The Orontes, which flows from the mountains of Damascus, and loses itself below Antioch; the Kefnia, which, from the north of Balbec, takes its course towards Tyre; the Jordan, forced by the declivities towards the south, prove that this is the highest point." Although the height of this mountain has not been determined by the barometer, Volney deduces it from another consideration. In winter the tops of the adjoining mountains are entirely covered with snow from Alexandretta to Jerusalem; but after the month of March it melts, except on mount Lebanon, where, however, it does not remain the whole year, except in the highest cavities, and towards the N.E., where it is sheltered from the sea-winds and the rays of the sun. Since it is well known that snow in this latitude requires an elevation of 15 or 16 hundred fathoms, we may conclude, says Volney, that to be the height of Lebanon, and that it is consequently much lower than the Alps, or even the Pyrenées. Mount Blanc, the loftiest of the Alps, is estimated at 2488 fathoms above the level of the sea; and the peak of Ollian, in the Pyrenées, at 1000. Lebanon, which gives its name to the whole extensive chain of the Kefraouan, and the country of the Druzes, presents us every where with majestic mountains. At every step we meet with scenes, in which nature displays either taller grandeur, sometimes singularity, but always variety. When we land on the coast, the loftiness and steep ascent of this mountainous ridge, which seems to inclose the country, these gigantic masses, which shoot into the clouds, inspire astonishment and awe. Should the curious traveller then climb these summits which bounded his view, the wide extended space which he discovers becomes a fresh subject of admiration; but completely to enjoy this majestic scene, he must ascend the very point of Lebanon, or the "Sannin." There, on every side, he will view an horizon without bounds; while, in clear weather, the sight is lost over the desert, which extends to the Persian gulf, and over the sea, which bathes the coasts of Europe. He contemplates, besides rocks, woods, torrents, hill-sides, villages, and towns, which are nearer and more distinct objects, the valley obscured by stormy clouds, and smiles at hearing the thunder, which had so often burst over his head, growling under his feet; while the threatening summits of the mountains are diminished till they appear only like the furrows of a ploughed field, or the steps of an amphitheatre, and he feels himself flattered by an elevation above so many great objects, on which pride makes him look down with a secret satisfaction. Such is the picturesque description of Volney, which he pursues more in detail. Mount Lebanon is computed at about 100 leagues in compass, and is bounded by Mesopotamia on the E., Armenia on the N., Palestine on the S., and the Mediterranean on the W. It consists of four ridges of mountains, which rise one above the other; the first of these is very fertile in grain and fruit; the second is barren and rocky, producing nothing but briars and thorns; the third, though still higher, is said to enjoy a constant verdure and spring, its gardens and orchards producing such a variety of herbs, fruits, &c. that it hath been styled an earthly paradise; the last and loftiest is uninhabitable, by reason of its excessive coldness, being covered with deep snows almost all the year. It is mostly inhabited by the Maronites below,

and by the wild Arabs, called Amadea, of the feet of Hali, every where else but on the top. Here are several churches, convents, and chapels, and caverns cut into the rock. The Monks that inhabit it are very poor, but courteous to travellers, from whom they expect some token of beneficence. The convent, or cenobium, where the Maronite patriarch resides, lies almost in a bottom; the descent to it is very steep, narrow, and winding, and it has only that one avenue, which makes it so much the safer, as well as the more retired. It chiefly consists of fundry grotts, cut into the rock; of which the church is one of the largest. A river which empties itself at Tripoli, runs a little below it, and supplies it with water. Near the grott of St. Marina, who is reputed to have lived here as an hermit, in man's clothes, are some vines, which afford excellent wine; and fine young mulberry trees, as well as cedars, and other curiosities. Of the boasted cedars of Lebanon, there are no very magnificent remains; four or five of them only deserving notice: but the number of firs, oaks, brambles, mulberry trees, figs, and vines, is much more considerable. The wines of Lebanon have been much extolled by the Grecian and Roman epicures. It is probable, that the inhabitants of this territory have made no change in their ancient method of making wines, nor in the culture of their vines. They are disposed on piles of six or eight feet in height. They are not pruned as in France, which must certainly, says Volney, greatly injure both the quantity and quality of the crop. The vintage begins about the end of September. The convent of Mar-hanna makes about 150 rabia, or earthen jars, containing about 110 pints each. The price current in the country is about seven or eight sols (fourpence) the French pint. Of the numerous kinds of wine made in Syria, the chief is the Vino d'Oro, or "golden wine" of mount Lebanon. This is not boiled, as is the case in the preparation of other wines, but left to purify itself by keeping; the quantity produced is small. It is, as its name implies, of a bright golden colour, and is highly prized even on the spot. Several considerable rivers have their source in this mountain, viz. the Jordan, Rocham, Nahar-Rossian, and Nahar-Cadicha; besides many lesser streams, that run between the valleys; particularly that of Ahoval, which flows down into the "Romantic valley," so called, because it is surrounded on all sides with high rocks. These rivers, rushing down from such heights, form several beautiful cascades, like those of the Nile. This mountain has been, and is still to this day, a place of retreat and refuge for a great number of robbers, and other desperate people. The stone which composes the mountains of Lebanon and Antilebanon, and those of Syria in general, is a hard calcareous stone of a whitish colour, sonorous like free-stone, and disposed in strata variously inclined. Of this stone the inhabitants build their houses, and make lime.

LEBANON, a post-town of America, in York county, Maine, on the east side of Salmon-Fall river; 100 miles N. of Bolton. It was incorporated in 1767, and in 1790 contained 1275 inhabitants.—Also, a post-town in Windham county, Connecticut, settled in 1697. The soil is equal to almost any in the state, and the inhabitants are generally farmers, of whom many are rich. The number of inhabitants is 3652; 9 miles N. of Norwich.—Also, a post-town in Grafton county, New Hampshire, on Muscourey river, and on the east side of Connecticut, 2 miles below Dartmouth college; incorporated in 1761, and in the year 1800, containing 1574 inhabitants.—Also, a post-town of Pennsylvania, situated on the fourth side of Quatapehilla creek, in Dauphin county; containing about 300 houses regularly built.

built, many of them of brick and stone, a German Lutheran and a Calvinist church; 82 miles N.W. by W. from Philadelphia.

LEBANON, *New*, a village in Canaan, New York, pleasantly situated, partly on the declivity of a hill, and partly in a vale, and containing medicinal springs next in celebrity to those of Ball-town, Saratoga.

LEBE, a town of Germany, in the lordship of Lauenburg, in a lake near the Baltic; 15 miles N.W. of Lauenburg. N. lat. 54° 40'. E. long. 17° 20'.

LEBEDIAU, a town of Russia, in the government of Tambov; 100 miles W.N.W. of Tambov. N. lat. 53° 28'. E. long. 38° 50'.

LEBEDIN, a town of Russia, in the government of Charkov; 60 miles N.W. of Charkov.

LEBEDOS, in *Ancient Geography*, a town of the Ionians, situated in Lydia, upon an isthmus, north of Colophon, distant 120 stadia from this city. Lyfimaachus demolished it, and transported the inhabitants to Ephesus.

LEBERIS, in some *Medical Writers*, a word used to express the exuvia of serpents, or the skins which snakes cast off every year. These are by some greatly recommended for taking off freckles and sun-burns from the face.

LEBIALNA, in *Geography*, an island of Russia, in the Caspian sea. N. lat. 45° 55'. E. long. 53° 30'.

LEBIAR, a forest of Africa, in the country of Zehaga, affording great quantities of gum; 100 miles E.N.E. of Portendie.

LEBIDA, or LEBDA, a sea-port town of Africa, in the country of Tripoli, on the coast of the Mediterranean; 30 miles E.S.E. of Tripoli. N. lat. 32° 40'. E. long. 13° 56'.

LEBIEDA, a town of Lithuania, in the palatinate of Wilna; 10 miles S. of Lida.

LEBIEDZLOW, a town of Lithuania, in the palatinate of Wilna; 56 miles E.S.E. of Wilna.

LEBLANC, MICHAEL, in *Biography*, born at Dijon in the year 1653, entered into the order of the Jesuits, and was one of the fourteen mathematicians whom Lewis XIV. sent to the king of Siam in 1687. Leblanc went and resided with the priests of the country, to learn their language; but the revolution taking place, which deprived the king of his crown, put an end to the hopes of the missionaries, and he was obliged to return to Paris. He had the misfortune of being taken prisoner by the Dutch, and thrown into prison at Middleburg, in Zealand. In the year 1690 he was set at liberty, and returned to Dijon, where he was employed as professor of mathematics in the Jesuits' college. In 1691 he joined a new mission for China, and embarked at Lisbon. During the voyage he met with an accident, which put an end to his life at Mozambique, in the year 1693. As a writer he is principally known by "A History of the Revolution of the Kingdom of Siam in 1688, and of the present State of the Indies," 2 vols. 12mo. Moreri.

LEBNA, in *Scripture Geography*, a strong city of Palestine, in the tribe of Judah, situated on a narrow neck of land, which ran northwards between the tribes of Dan and Benjamin. Joshua took it and gave it to the Levites of this tribe, and it became a city of refuge. This had been an encampment of the Israelites in the Desert.

LEBNEK, in *Geography*, a town of Transylvania; 15 miles S.E. of Scheburg.

LEBNI, in the *Matéria Medica of the Ancients*, a name given by some to storax. Avicenna has treated of this drug in three separate chapters. The Greeks were very nice in

distinguishing the several kinds of storax, and the Arabians seem to have followed their example: nay, they have even borrowed some of the terms, by which they called the particular sorts. The soft, or liquid storax of the Greeks, seems to have been very common among these people, and they have called it *mel lebn*, the honey of storax. This was a common word with them to express any thing soft.

LEBO, in *Geography*, a river of Chili, which runs into the Pacific ocean, S. lat. 37° 50'.

LEBRILIA, a town or village of Spain, in the province of Murcia, containing about 1000 inhabitants; almost divided into two by a fort of long, broad, and deep bog, formed by rains, over which is a bridge; 11 miles from Murcia.

LEBRIXA, or LEBRIJA, a town of Spain, in the territory of Seville, situated formerly on a branch of the Guadalquivir, but now, in consequence of its being choked up, 6 miles from the river. It has a castle; and the environs produce olives, which afford some of the best oil in Spain; 20 miles S. of Seville.

LEBSKOI, a town of Russia, in the government of Archangel, near the union of the rivers Mezen and Pezna; 168 miles E. of Archangel.

LEBUS, a town of the Middle Mark of Brandenburg, situated on the Oder, containing about 14,000 inhabitants. Its site is low, and among hills, which intercept the view of it; 5 miles N.W. of Franckfort on the Oder. N. lat. 52° 26'. E. long. 14° 44'.

LECA, a town of the island of Samos.

LECANOMANTIA, Λεκανομαντία, in *Antiquity*, a kind of divination performed in a basin with wedges of gold or silver. See HYDROMANCY.

LECASELLO, in *Geography*, a town of the Ligurian republic; 20 miles N.E. of Genoa.

LECCE, ALETUM, a city of Naples, the capital of the province of Otranto, and sometimes giving name to the province. It is a large, well-built town, the see of a bishop, suffragan of Otranto. The wool produced in its environs was formerly much celebrated; and the adjacent country yields abundance of almonds and olives. It contains, besides the cathedral, three parish churches and several convents. It is the residence of the governor, and the number of inhabitants is estimated by some at 13,000, by others at 18,000; 24 miles from Brindisi, and as far from Otranto, and 8 miles from the eastern shore. N. lat. 40° 40'. E. long. 18° 8'.

LECCI, a town of the island of Corlica; 5 miles N. of Porto Vecchio.

LECCO, a town of Italy, and capital of the department of the Montagna, on the lake Como, whence a branch of the lake is called "the lake of Lecco; 14 miles E.N.E. of Como. N. lat. 45° 5'. E. long. 9° 23'.

LECETA, a town of Spain, in Navarre; 17 miles N.N.W. of Pamplona.

LECH, in *Metalurgy*, a term used by the miners to express the gold ore which has been powdered and washed, and afterwards run with the assistance of lime-stone. The lech is afterwards burnt in a fire of charcoal, in order to render it fit for the separation of the metal, by means of lead, which absorbing and scorifying the extraneous matter, renders the gold pure.

LECHEUM, in *Ancient Geography*, a town and promontory of Greece, on the gulf of Corinth, which served as a port to Corinth. It had a temple of Neptune, in which was a bronze statue of this deity. Venus had also a temple here.

LECHEA, in *Botany*, was so named by Linnæus, at the suggestion of Kalm, in honour of Professor John Leche, of Åbo in Finland. Member of the Stockholm Academy, several of whose memoirs, relating to zoology, botany, and rural economy, are found in the Transactions of that learned body. He has also left us three dissertations, published under his presidency: 1, *Primitia Flora Scandinavica*; 2, *Novæ Insectorum Species*, written by his pupil Udman, a piece highly valued for its merit and rarity; 3, *De Commoratione hybernali et peregrinationibus birundinum*. He died in 1764, aged 60. The name is pronounced *Lékéa*. Linn. Gen. 43. Schreb. 59. Willd. Sp. Pl. v. 1. 495. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 185. Juss. 303. Lamarck. Illust. t. 52. Gært. t. 129. Michaux Boreali-Amer. v. 1. 76.—Clafs and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllis*, Linn. Juss.

Gen. Ch. *Cal.* Perianth inferior, of three ovate, concave, spreading, permanent leaves. *Cor.* Petals three, oblong, narrower than the calyx, but about as long, concave. *Stam.* Filaments three, sometimes four or five, capillary, longer than the petals, lying over the pistil, equal; anthers roundish. *Pist.* Germen superior, ovate; styles none; stigmas three, feathery, spreading. *Peric.* Capsule ovate, slightly triangular, of three cells, and three valves, cohering at their base, with three central linear receptacles. *Seeds* solitary, ovate, angular at the inner side, where they are attached to each receptacle.

Ess. Ch. *Calyx* of three leaves. *Petals* three, oblong. *Capsule* superior, of three cells, and three half-distinct valves, with three central linear receptacles. *Seeds* solitary.

1. *L. minor*. Lesser Lechea. Linn. Sp. Pl. 133. Am. Acad. v. 3. 10. Lamarck. t. 52. f. 1? (*L. major*; Michaux n. 1, by the description.)—Hairs of the stem and branches spreading. Lower leaves whorled, elliptical, with a small point; upper alternate, lanceolate, acute. Flowers panicled, somewhat corymbose.—Gathered by Kalm in the dry sandy fir woods of Canada.—The root is perennial and woody. *Stems* several; the barren ones about a span long, lax, and spreading, with numerous, ternate or quaternate, short, leafy branches, all clothed with long, white, spreading hairs; flowering stems much taller and stouter, from one to two or three feet high, panicled, leafy, round, clothed with rather less spreading hairs. *Leaves* of the barren stems three or four in a whorl, on short stalks, spreading, a quarter of an inch long, broadly elliptical, entire, with a short point, the margin and rib fringed with long white spreading hairs; those of the flowering ones scattered, longer, and narrower. *Flowers* numerous, small, terminating the lateral branches, in small corymbose clusters, whose stalks are hairy, and more or less furnished with lanceolate bractæes. *Calyx-leaves* broad, keeled, very concave, smooth. *Capsule* polished.

This is certainly what Linnæus originally intended for *Lechea minor*, though he afterwards confounded other still smaller species with it, and the name being opposed to his *major*, which is a nonentity, is unmeaning, if not false. Less inconvenience, however, must arise from retaining than from changing it, unless we were furnished with more ample and certain materials for new modelling the whole genus. Our aim here is to correct such errors as we can, for the use of those who may take up the subject hereafter.

2. *L. major*. Greater Lechea. Linn. Sp. Pl. 133. Am. Acad. v. 3. 11. t. 1. f. 4; copied in Lamarck, f. 2.—“Leaves ovato-lanceolate. Flowers lateral, scattered.”—Native of dry situations in Canada. Linnæus, in his manuscripts and Syst. Veg. quotes for this, *Menandra ramis alternis*, Gron. Virg. ed. 2. 20, that is, *An Camerarie species, foliis latoribus oblongis, subtus argenteis, caule rubro, capsula*

*ampla trilobulari* of Clayton, who found his plant, flowering in August, on sandy hills at point Comfort, in the country of Gloucester, Virginia. It is described as shrubby, with the aspect of *Cistus Helianthemum* or of *Vaccinium Oxyococcu*, two plants between which it is difficult to find any point of resemblance; the *leaves* alternate, oblong, and entire. *Corolla* none. *Stamens* four, as long as the calyx, the two uppermost springing from the same point of the receptacle, the two lateral ones opposite. *Style* none. *Stigma* hipid. The rest of the account accords with the generic character. It must be observed that when Clayton guesses his plant to belong to *Cameraria*, he means that of Dillenius, which is the Linnæan *Montia*. Linnæus, in the *Amœnitates*, describes his *L. major* thus. “*Stems* purplish, round, with simple, alternate, distant branches. *Leaves* alternate, oval-lanceolate, rough above, downy beneath, reflexed at the margin, scarce perceptibly stalked. *Flowers* two, three or four from the small uppermost branches.” Now it happens that the specimen in the Linnæan herbarium is no other than *Cistus canadensis*, with the numerous stamens proper to that genus, and totally foreign to *Lechea*. The capsule also has imperfect partitions from the middle of the valves. The *seeds* indeed appear to be but one in each cell, and large, the only circumstance which could induce a reference of this *Cistus* to *Lechea*. Yet there can be no doubt of the description in the *Amœnitates* having been made from this plant, though the figure is unlike it, and more resembles *L. minor*, for which indeed, as well as for the *major*, it is quoted by Linnæus in Sp. Pl. and being in itself too imperfect to convey a precise idea of any thing, it can determine nothing in the present case. What is *L. major* of Kalm we know not, nor that of Hort. Kew. That of Michaux appears clearly to be our *minor*, whose lower leaves are indeed so much like *Oxyococcus*, while its upper are not very unlike *Helianthemum*, that Clayton might possibly have that species in view when he made the above description, but the “large capsule with three cells” agrees best with the above *Cistus*. Amid all this uncertainty we would rather strike out *L. major*, and give a new name, perhaps *heterophylla*, to our *minor*.

3. *L. racemulosa*. Many-clustered Lechea. Michaux Boreali-Amer. v. 1. 77. (Menandra ramis ternis; Gron. Virg. ed. 2. 21.)—Hairs close-pressed. Leaves linear-lanceolate, acute, hairy beneath. Flowers in numerous slender clusters. *Calyx* hairy.—Gathered by Clayton in the same place, at point Comfort, with the last. Specimens from him are in the Linnæan herbarium, answering to the account of Michaux, who also gathered his plant in Virginia. We have others, probably of the same species, from Kalm, and from the Rev. Dr. Muhlenberg of Lancaster in Pennsylvania. Those of Clayton have a panicled stem, a foot or two high, clothed with close-pressed, somewhat silky, hairs; the branches either ternate, opposite, or feathered. *Leaves* of the stem lanceolate; those of the branches linear, gradually smaller upwards, and often accompanying the *flowers*, but sometimes the *clusters* are leafless; they are elongated, slender, hairy or silky. *The calyx* also is hairy, and greatly resembles that of a little annual *Cistus*.

4. *L. thymifolia*. Thyme-leaved Lechea. Michaux Boreali-Amer. v. 1. 77, excluding the synonym. (*Capraria foliis integerrimis*; Gron. Virg. ed. 1. 75. Herb. Linn. from the author.)—Hairs close-pressed. Leaves lanceolate. Stem panicled. *Clusters* leafy. *Bractæes* linear, much longer than the flowers.—Gathered by Clayton in Virginia; by Michaux in dry exposed situations in North and South Carolina. *Stem* a foot high, round, reddish, rough with close-pressed hairs; simple and naked below; panicled and leafy above. *Leaves* opposite or scattered, various in size, slightly

slightly stalked, lanceolate, acute, the margin and rib fringed. *Flowers* in numerous, slender, hispid clusters, furnished with copious linear *bractææ*, two of which, extremely narrow and obtuse, accompany every flower at the base, and are twice as long as the *calyx*; which is likewise hairy or hispid.

5. *L. tenuifolia*. Slender-leaved Lechea: Michaux Bo-reali-Amer. v. 1. 77.—Stems bushy, decumbent, ascending, with spreading branches. Leaves linear-awl-shaped. Flowers ranged alternately, and rather remotely, along the branches. On sandy hills near the Santee river, flowering in April and May. We know nothing of this species but from Michaux, who describes it as of humble and bulky growth, with *cap-sules* rather larger, in proportion to the plant, than is usual in this genus.

6. *L. verticillata*. Whorled Lechea. Willd. n. 3.—Leaves elliptical, ferrated. Flowers whorled.—Sent by Dr. Rotter from Madras. The root seems, as in all the former, to be perennial. *Stems* several, spreading or decumbent, simple or branched, a span long, round, leafy, clothed with soft spreading hairs. *Leaves* opposite, stalked, half an inch long, elliptical, acute, finely and sharply ferrated, hairy, tapering at the base. *Flowers* numerous, in dense axillary whorls, sufficiently agreeing with the character of the genus, to which Willdenow has judiciously referred it. The ferrated *leaves*, however, are very peculiar.

Another species, *L. chinensis*, is mentioned in Loureiro, Cochinch. 60; but this, though adopted by professor Mar-tyr, cannot, in our opinion, have any right to a place here, the author's description shewing it evidently to be nearly allied to *Commelina*, consequently more remote, if possible, than even the above *Cissus canadensis* from *Lechea*. S.

LECHENAULTIA, named by Mr. R. Brown, in compliment to his friend Lechenault, an eminent French botanist and traveller, who has undertaken to illustrate the plants of the western coast of New Holland more especially, as well as those of Java and Timor. Brown Prodr. Nov. Holl. v. 1. 581. Class and order, *Pentandria Mono-gynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juss. *Goodenovicæ*, Brown.

Efl. Ch. Calyx superior. Tube of the corolla slit longitudinally on one side. Anthers coloring. Pollen of compound grains. Stigma obsolete, in the bottom of a two-lipped cover. Capsule prismatic, of two cells, and four opposite valves with central partitions. Seeds cubical or cylindrical, shelly. *Brown*.

Obs. The grains of pollen, in all the species, are composed of four combined globules, which mark, though minute, is esteemed by Mr. Brown very essential to distinguish this genus from all the rest of its natural order, and especially from its near ally *Anthotium*.

The species are generally shrubs of humble growth, rarely herbaceous, and are smooth, with narrow entire leaves. *Flowers* axillary or terminal, mostly solitary.

*Stk. 1.* Small shrubs, with heath-like leaves. *Flowers* axillary or terminal. Capsule valvular. Seeds cubical.

1. *L. formosa*. *Flowers* axillary, solitary, drooping, without *bractææ*. Corolla smooth, two-lipped.—Gathered by Mr. Brown on the south coast of New Holland.

2. *L. tubiflora*. *Flowers* nearly terminal, solitary, slightly stalked. Corolla tubular, curved, with a closed limb. Leaves awl-shaped, with a small pellicid point.—Native of the same country.

3. *L. expansa*. Corymbs axillary, of few flowers. Stalks with a pair of *bractææ* each. Corolla with one lip, in fringed segments.—Native of the same country.

*Stk. 2.* Herbaceous. Flower opposite to a leaf. Cap-

sule opening only when far advanced, its valves cohering by a narrow neck. Seeds cylindrical.

4. *L. filiformis*. Leaves alternate, thread-shaped, somewhat compressed.—Gathered by Mr. Brown in the tropical part of New Holland.

LECHERAINE, in *Geography*, a town of France, in the department of Mont Blanc; 10 miles N.N.E. of Cham-bery.

LECHIA, in *Ichthyology*, a name given by Paulus Jovius, and others, to the fish called by others *amia* and *glaucus*, and by the ancient Greeks *amia* and *troctus*. See SCOM-BER.

LECHLÄDE, or LEACHLADE, in *Geography*, a small market-town and parish in the hundred of Brightwells-bar-row, Gloucestershire, England, is situated, 76 miles distant from London, on the north side of the river Isis, or Thames, near the point where the counties of Berks, Oxford, and Gloucester unite; and not far from the place where the Leche rivulet empties itself into the Thames. From the latter circumstance Lechlade is said to have derived its name: *lade* being a contraction from the Saxon *ladean*, to unload or empty. In Domesday book is the mention of a fishery here of 175 eels. The manor, at the period of that survey, was the property of Henry de Ferrers, ancestor of the Ferrers, earls of Derby, from whom, by the marriage of Isabel, an heiress, it was conveyed to Roger Mortimer. A priory, or hospital for Black Canons, and consisting of a master and certain poor and infirm brethren, was founded here upon a piece of ground called Lade, near the ancient bridge over the Thames, given for that purpose by lady Isabel Ferrers. The hospital was suppressed in the year 1473, and its revenues applied to the foundation of a chantry of three priests in the parish church. Some foundations of buildings, supposed to have belonged to the priory, have been dug up near the bridge. The church is a handsome structure in the pointed style, and was erected, about the middle of the fifteenth century, at the joint expence of the then vicar, Conrad Ney, the inmates of the priory, and the inhabitants of the parish. The nave is spacious, and divided from the aisles by light pillars; at the west end is a square embattled tower, terminated by a well-proportioned spire: the pulpit is of sculptured stone. At this town the Thames becomes navigable; and here the junction of the Thames and Severn is completed by the canal. Moll of the Wilt-shire and Gloucestershire cheefe, consumed in the metropolis, is brought in waggons to this town, where it is put on board the vessels which convey it down the Thames. A weekly market is held on Tuesdays, for which the grant was obtained by Richard, earl of Cornwall: an annual fair, held on the ninth of September, is much frequented. According to the returns made in 1800, under the population act, the inhabitants of this parish amounted to 917; the number of houses to 193.

In a meadow near Lechlade, was lately discovered a large subterraneous building, supposed to have been a Roman bath: it was nearly fifty feet in length, forty in breadth, and four in height; the floor was supported by pillars of brick, and curiously inlaid with stones of variegated colours. Ridge's History, &c. of Gloucestershire, 2 vols. 8vo. Beauties of England and Wales.

LECHNICH, a town of France, in the department of the Roer, and chief place of a canton, in the district of Cologne. The place contains 1053, and the canton 11,462 inhabitants, in 31 communes.

LECHONES, Os, a cluster of small islands in the At-lantic, near the W. coast of Portugal; three miles N. from the

the mouth of the Duero. N. lat. 41° 43'. E. long. 8° 25'.

**LECHWAR**, a town of Hindoostan, in Bahar; 30 miles S. of Bahar.

**LECK**, a town of Denmark, in the duchy of Sleswick; 14 miles N. of Bredtede.

**LECKNESS**, a town of Norway; 22 miles W. of Christianfand.

**LE CLERC, DANIEL**, in *Biography*. See **CLERK**, DANIEL LE.

**L'ECLUSE**, in *Geography*. See **ECLUSE**.

**LE COQ, ANTHONY**, in *Biography*, a Parisian physician, graduated in the faculty of that city, and practised there with great reputation until his death, which took place on the 28th of March, 1550. He was elected dean of his faculty in 1538; and in the following year was called, in consultation with Fernel, to visit the French king, Francis I. who had contracted the venereal disease. He shewed his knowledge of the nature of the disease, by insisting, in opposition to Fernel, who was not disposed to employ any other remedy than his antivenerol opiate, that mercurial frictions were necessary; but his mode of proposing it evinced that he was a novice in the manners of a court. He observed to Fernel, speaking of the king, "C'est un vilain qui a gagné la vérole; frottetur comme un autre, et comme le dernier de son royaume, puisque il s'est gâté de la même manière." This was reported to the king, who laughed, and was pleased with his frankness. **Le Coq** left two works: 1. "De Ligno sacro non permiscendo in imperitos fucatoque medicos," Paris, 1548. 2. "Confilia de Arthritide," Francfort, 1540. The latter comprehended also some other treatises on the gout, especially those of Sylvius and Fernel; in conjunction with whom, **Le Coq** had been consulted on the subject by Louis of Flanders, and by Eleonora, queen of France. Eloy. Dict. Hist.

**LECTICA**, among the Romans, a litter, or vehicle, in which people were carried. The *sellæ* differed from the *lectica*, as being higher, and because people always sat in it; on which account the *sellæ*, from the time it was first brought into use, was esteemed the more honourable carriage of the two. See **LITTER**.

The *lectica* was also used as a bier for carrying out the dead, who were dressed in habits suitable to their quality and sex. Pitif. in voc. See **BURYING**.

**LECTICARII**, among the Romans, servants who carried the *lectica*.

**LECTICARIUS**, was also an officer in the Greek church, whose business it was to bear off the bodies of those who died, and to bury them. These were otherwise denominated *decani* and *copiate*.

**LECTIO, READING**. Considered in a medicinal view, it is said by Celsus, lib. i. cap. 4. to be bad, especially after supper, for those whose heads are weak: and in lib. i. cap. 8. he recommends reading with an audible voice, for such as have weak stomachs. It is also directed by Paulus Æginetus as an exercise, lib. i. cap. 19.

**LECTISTERNIUM**, a religious ceremony among the ancient Romans; being a festival prepared, and solemnly served up, in a temple, at a time of public calamity and danger.

And because, according to the customs of those times, they placed beds around the tables, and set the statues of the gods on those beds, in the same manner as men sat at meals, they called the solemnity *lectisternium*, from *lectus*, bed, and *sternere*, of *sterno*, to spread, prepare.

In this ceremony the Sibylline decemvirs presided, till

the year of Rome 558, and afterwards the Epulones. See **EPULO**.

Casaubon has observed, from a passage in the scholiast of Pindar, that the Greeks had also a sort of *lectisternium* in use.

Livy observes, that the first *lectisternium* seen in Rome, was that which held for eight days successively, in honour of Apollo, Latona, Diana, Hercules, Mercury, and Neptune; on occasion of a contagious disease which killed almost all their cattle, in the year of Rome 354; though Valerius Maximus mentions one before that.

**LECTORES**, among the Romans, servants in great men's houses, who were employed in reading while their masters were at supper. They were called by the Greeks *anagnostæ*.

**LECTOURE**, in *Geography*, a town of France, and principal place of a district, in the department of the Gers, seated on a mountain, having access only on one side, near the Gers, and well defended. Before the revolution it was the residence of a governor, and see of a bishop. The place contains 5433, and the canton 13,655 inhabitants, on a territory of 265 kilometres, in 17 communes; 16 miles S. of Agen. N. lat. 45° 56'. E. long. 0° 22'.

**LECTUM**, in *Ancient Geography*, *Cape Baba*, a promontory of Asia Minor, belonging to the Troades, situated between the isle of Lesbos to the south, and that of Tenedos to the north, at the extremity of Mount Ida. To the north it terminated the gulf of Adramyctium.

**LECTURERS**, in England, are an order of preachers in parish churches, distinct from the rector, vicar, and curate. They are chosen by the vestry, or chief inhabitants of the parish, supported by voluntary subscriptions and legacies, and are usually the afternoon preachers in the Sunday service. The term is also more generally applied to those who preach on Sunday, or on any stated day of the week, in churches, or other places of public worship. By 13 & 14 Car. II. cap. 4. lecturers in churches, unlicensed, and not conforming to the liturgy, shall be disabled to preach, and shall also suffer three months' imprisonment in the common gaol: and two justices, or the mayor, or other chief magistrate, in a town corporate, shall, upon certificate of the offence from the ordinary, commit them accordingly. Where there are lectures founded by the donations of pious persons, the lecturers are appointed by the founders, without any interposition or consent of rectors of churches, &c. though with the leave and approbation of the bishop: such as that of lady Moyer's at St. Paul's. But the lecturer is not entitled to the pulpit, without the consent of the rector or vicar, who is possessed of the freehold of the church.

**LECTURES**. See **BOYLE'S Lectures**.

**LECTURES of Divinity**, &c. in the universities. See **REGIUS Professors**.

**LECTUS IGNEUS**, among the Romans, a kind of instrument of torture first invented by Decius. The bottom of it was set with serrated teeth or spikes, and strewed with salt; while melted tallow was poured from above on the unhappy tortured person.

**LECTYTHIS**, in *Botany, so denominated by Læffing, from the Greek word *λεκτυς*; an oil jar, or large pot. He confounds it with *λεκτος*, the yolk of an egg. The latter has been used for the pea, alluding to the yellow colour of its internal substance: *λεκτος* applies to the form of the seed-vessel, which is that of a great pot with a cover. Læff. It. 189. Linn. Gen. 268. Schreb. 359. Willd. Sp. Pl. v. 2. 1172. Mart. Mill. Dict. v. 3. Jacq. Amer. 168.*

## LECYTHIS.

Juss. 327. Lamarck Illustr. t. 476.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Hesperideae*, Linn. *Myrii*, Juss.

Gen. Ch. *Cal.* Perianth superior, of six roundish, concave, permanent leaves. *Cor.* Petals six, very large, oblong, obtuse, flat, the two uppermost widely spreading. Nectary petal-like, of a single tongue-shaped leaf, flat and perforated at the base to admit the germen, bordered; its oblong part bent inwards and upwards from the bottom of the flower, linear, externally convex, thicker and ovate at the extremity, covering the pistil with the filaments. *Stam.* Filaments very numerous, inserted upon the disk of the base of the nectary at the inner side, very short, swelling upwards; anthers oblong, small. *Pist.* Germen inferior, depressed, pointed, encompassed with the receptacle of the flower, style very short; stigma bluntish, conical. *Peric.* Capsule woody, roundish at the base, abrupt at the top, encompassed with the remains of the calyx, cut round, and opening by a circular lid, imperfectly divided into four, sometimes two or six cells. *Seeds* few, polished, with rough edges.

Eff. Ch. Petals fix. Calyx of fix leaves. Nectary tongue-shaped, bearing the filaments. Capsule with a lid, and many seeds.

1. *L. ollaria*. Linn. Sp. Pl. 734. Loeffl. It. 189. (Jacapucaya; Marcgr. Bras. 128. Pfl. Bras. 135.)—Leaves sessile, ovate, somewhat heart-shaped, nearly entire.—Native of Brazil and the Caracacs. This, according to Laëfling, is a *vault tree*, with large unequal branches, bent in various directions, and a rough bark. *Leaves* about the ends of the branches, alternate, sessile, ovate inclining to heart-shaped, firm, smooth, nearly entire, slightly waved, of a brownish green. *Flowers* in terminal clusters, slightly drooping, on alternate, horizontal, somewhat angular stalks, with ovate, concave, soon deciduous bractees. *Corolla* white, with a yellow nectary.—Marcgraave says the *leaves* are serrated, the *fruit* like a pot with its cover, as big as a child's head, containing seeds like chestnuts, eatable either raw or roasted, and that the bark of the tree serves to make ink.

2. *L. minor*. Linn. Syst. Veg. ed. 14. 494. Jacq. Amer. 168. t. 109.—Leaves stalked, lanceolate, serrated.—Observed by Jacquin in woods near Carthagen, South America, flowering in June and July, ripening fruit in December. An elegant branching tree, 60 feet high. *Leaves* numerous, six inches long, alternate, spreading in two directions, lanceolate-oblong, pointed, serrated, smooth. *Spikes* terminal, each often accompanied by a smaller axillary one below, shorter than the leaves; the *flowers* nearly sessile, slightly feented. *Petals* and *nectary* white. *Stamens* yellow. *Fruit* very hard, brown, two inches wide. *Seeds* about eight. Jacquin thought he experienced a giddiness and sickness after eating one of them, though its taste proved very agreeable. Some persons told him these seeds were eatable, others reported them to be poisonous. Monkeys are said to be fond of them. The flowers are infested with a kind of black wasps, very troublesome to those who attempt to gather any.

3. *L. grandiflora*. Aubl. Guian. v. 2. 712. t. 283—285. (*L. Ollaria*; Linn. Am. Acad. v. 8. 258; Herb. Linn.)—Leaves stalked, obovate, entire. Clusters many times longer than the footstalks. Petals obtuse.—Native of Guiana and Surinam. A large tree. *Leaves* from four to seven inches in length, and two or three broad, obovate-oblong, with a little point, entire, slightly wavy, smooth, with one rib and many parallel transverse veins. *Footstalks* an inch long. *Clusters* about the ends of the branches, axillary, pendulous,

of numerous large rose-coloured flowers, whose partial stalks are an inch long, bearing a pair of blunt bractees, and whose blunt concave petals are nearly an inch and half in length. *Calyx-leaves* rounded, obtuse, flat. *Fruit* about seven inches long, and four wide; the opening about 2½. *Seeds*, according to Aublet, very good to eat: The flowers appear in January, the fruit is ripe in April.

4. *L. amara*. Aubl. Guian. 716. t. 286 and 285.—Leaves elliptic-oblong, pointed, entire. Clusters axillary and terminal, twice the length of the footstalks. Petals acute.—Found in the woods of Guiana, by Aublet, whose figure and description afford all the knowledge we have of this species. He says the *trunk* is 10 feet high, bearing at the top many straight and horizontal branches, whose subdivisions are pendulous and leafy. In his French description, which will generally be found the most original and authentic throughout his work, he says this is a very lofty tree. The flowers are small, yellow, with two or three scales upon their footstalks. *Fruit* the size of an egg, its coat thin though hard. *Seeds* bitter, but eaten by monkeys.

5. *L. Zalucajo*. Aubl. Guian. 718. t. 288.—Leaves elliptic-oblong, pointed, entire. Clusters terminal. Petals obtuse. Calyx-leaves lanceolate.—Gathered by Aublet in the desert woods of the interior of Guiana, flowering in March, and bearing fruit in July. We have from sir Joseph Banks a specimen of this species, gathered in Dutch Guiana by Mr. Alexander Anderson, which agrees well with Aublet's description, and helps us better to understand the distinctive characters, than professor Willdenow was able to do from his incorrect figure. The professor rightly expunges the quotations of Piso, which belong to the first; but it is unlucky that the specific name belongs to them, or rather perhaps is common to many species. This is a *vault tree*; its *trunk* 60 feet, or more, in height. *Wood* white, red in the centre. *Leaves* stalked, from six to ten inches long, and two or more in breadth. *Clusters* at the ends of the branches, pendulous. *Partial flower-stalks* an inch long, swelling upward. *Calyx-leaves* broadish at the base, tapering, concave, sharpish from the inflexion of their edges at the summit, fleshy, one-third of an inch in length, reddish when fresh. *Petals* large, rounded, fleshy, white bordered with rose-colour, two of them much bigger than the rest, being equal to those of *L. grandiflora*. The *fruit* is about four inches in diameter. *Seeds* sweet, eatable, preferable to our almonds.

6. *L. Idaitimon*. Aubl. Guian. 721. t. 289.—Leaves elliptical, pointed, entire. Clusters axillary. Stalks glandular. Calyx-leaves ovate, acute. Petals obtuse.—Native of wild forests in Guiana. A tree agreeing with the last in height, and in the general aspect of its leaves. *Clusters* axillary, with zigzag, glandular red stalks. *Flowers* rose-coloured, not half the size of the last, with broader calyx-leaves. *Fruit* little more than an inch in diameter. Aublet observed what he deemed a variety only, with yellow flowers.

7. *L. parviflora*. Aubl. Guian. 717. t. 287 and 285.—Leaves elliptic-oblong, pointed, entire. Clusters terminal, panicled. Petals acute. Capsule of two cells.—Found about the banks of rivers in Guiana. *Aublet*. A small tree, with drooping branches. *Leaves* three or four inches long. *Flowers* much smaller than even those of *L. amara*, bright yellow, and very fragrant. *Fruit* small, thin and brittle, of only two cells. *Seeds* solitary, bitter.

8. *L. multiflora*.—Leaves . . . Clusters terminal, panicled. Petals obtuse. Calyx-leaves broader than long, rounded, blunt, downy.—A native of Guiana, communicated by E. Rudge, esq. as a new species of *Lecythis*, which

which it really appears to be. The *leaves* are wanting in our specimen. *Clusters* plentifully terminating the little branches at the ends of the main ones, bearing many *flowers*, which are of a moderate size, and seem to be yellow, their petals rounded and blunt. The partial *stalks* are an inch long, swelling upwards, downy or glandular, naked. *Germs* hemispherical, downy, crowned with the six calyx-leaves, which are very short, rounded or heart-shaped, blunt, minutely fringed, very like those of a *Myrtus* or *Eugenia*.

9. *L. bracteata*. Willd. n. S. (Couroupita guianensis; Aubl. Guian. 708. t. 282. *Pekia fructu maximo globofo*; Barrere France Equinoxiale, 92.)—Leaves thick, obovate, pointed, entire. *Clusters* lateral. *Calyx* with a pair of acute bractæas at its base. *Fruit* of six cells.—Native of Cayenne, where the fruit is known by the name of the *cannon ball*. This is a large tree, with a thick rugged bark, and white soft and indifferent wood, red in the middle. The shape of the *leaves* seems most to approach those of *L. grandiflora*, and these two species agree also in having a pair of bractæas on each partial stalk, just below the calyx. These are acute in the present, blunt in the former. Both also have a deciduous bractæa at the base of each partial stalk. All this confirms the propriety of reducing them to one genus, though the *fruit* of that now under consideration has six cells, and its coats are separated by an intermediate pulpy and fibrous substance, which may also be the cause of its lid not falling off, as in all the above-described. *L. bracteata* is in flower and fruit nearly all the year round. Its *corolla* is of a full rose-colour, beautiful and fragrant. The *fruit* is as large as a cannon ball of 36 pounds, and Aublet remarks that its weight is such as to render it dangerous in falling. The pulp is red, acid, and not disagreeable, diffused, as the fruit ripens, through all the internal part, among the seeds.

LECYTHUS, in *Ancient Geography*, a town of Greece, in Eubœa. Thucydides.

LEZENZA, in *Geography*, a river of Africa, which runs into the Mozambique gulf, S. lat. 17° 20'.

LECZNA, a town of Poland, in the palatinate of Chelm; 24 miles N.W. of Chelm.

LEDA NEGUS, a town of Abyssinia, in the province of Gojam; 120 miles S.S.W. of Gondar.

LEDAH, a town of Hindoostan, in the circar of Gangpou; 20 miles S. of Gangpou.

LEDBURY, an ancient borough, and market town in the hundred of Radlow, and county of Hereford, England, is situated on a declivity within a small valley, formed by the Dog-hill and other eminences, about one mile west from the river Leddon, from which it derives part of its name. The town consists chiefly of two streets, crossing each other at right angles; the principal street runs north and south, and has a middle row near the old market house. This building is elevated on strong oak pillars, and composed of timber and lath plastered and white-washed; the beams being coloured black. This mode of building is prevalent in the more ancient parts of the town; and many of the houses have projecting stories: the modern houses are of red brick, and of a respectable appearance. The pavement, even in the high street, is very bad, and full of inequalities; the small stones that form it being pressed into the stiff clay, which is the general soil of the county. Ledbury formerly belonged to the see of Hereford; and bishop Bohun procured the charter of a market from king Stephen, to be held on Saturdays; but this having fallen into disuse, queen Elizabeth granted a new charter for a Tuesday market, and two annual fairs; the tolls arising from which were to be given to the poor. This borough had once the privilege of

sending two members to parliament, but surrendered the right, on the plea of inability to support them. The church, which is a large edifice, of Saxon origin, consists of a nave, side aisles, and chancel; a chapel called St. Catherine's, and a detached tower, terminated by a finely proportioned spire, about sixty feet high. Bishop Foliot founded an hospital in this town in the year 1232 for the maintenance of poor men and widows: it was refounded and further endowed by queen Elizabeth. The hospital is a very ancient timber and plaster building. Here are also a free-school, a charity-school, and several almshouses. The clothing trade was, at one period, very flourishing in this town; but the principal business now carried on is the manufacture of ropes, lines, and facks. The cyder trade is very considerable; great quantities being made in the vicinity. Ledbury is distant from London 121 miles; the inhabitants, as ascertained under the act of 1800, amounted to 3058; the number of houses being 618. The bishops of Hereford formerly had a palace here.

On the Dog-hill, to the north of Ledbury, is Hope End, the seat of sir Harry Vane Tempest, bart. About two miles south of the town is the Vineyard camp; the works of which have been almost defaced by the plough, and the area is cultivated. Beauties of England.

LEDER, a lake of the county of Tyrol; 18 miles W. of Trent.

LEDESMA, an ancient town of Spain, formerly called *Bletija*, in the province of Leon, situated four or five leagues from the mouth of the Tornices, and defended both by nature and art. In its jurisdiction are 380 villages, which have about 16,000 houses. To the E. of Ledesma and near it is a medicinal bath, made by a Moor for the use of the public. The water is moderately warm, and is reckoned good for the cure of different diseases, particularly the itch; 18 miles W. of Salamanca.

LEDETSCH, a town of Bohemia, in the circle of Czaflau; 13 miles S. of Czaflau. N. lat. 49° 40'. E. long. 15° 15'.

LEDETZ, a town of Bohemia, in the circle of Bolef-law; seven miles S.E. of Jung-Buntzel.

LEDGER. See BOOK and BOOK-KEEPING.

LEDGERS, among Builders. See PUTLOGS.

LEDGES, in a Ship, oak or fir scantling, used in framing the decks, which are let in the carlings athwart the ship. Those for gratings arch upwards, agreeable to the head ledges, which form the hatchways, &c.

LEDIANAIA, in *Geography*, a bay or gulf of the Frozen sea, on the coast of Nova Zembla. N. lat. 76° 40'. E. long. 59° 14'.

LEDIANOI, a cape on the N. coast of Nova Zembla. N. lat. 78°. E. long. 73° 24'.

LEDIGNAN, a town of France, in the department of the Gard, and chief place of a canton, in the district of Alais. The place contains 666, and the canton 3965 inhabitants, on a territory of 102½ kilometres, in 13 communes; 15 miles N.W. of Nîmes.

LEDON, in Gardning. See CISTUS.

LEDONG, in *Geography*, a town on the E. coast of the island of Borneo. N. lat. 4° 33'. E. long. 116° 42'.

LEDOREN, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 12'. E. long. 20° 56'.

LEDOYRA, a town of Spain, in Galicia; 12 miles N.E. of Santiago.

LE DRAN, HENRY FRANCIS, in *Biography*, a celebrated surgeon of the 18th century, was a native of Paris, where his father practised the same profession with considerable reputation, and was deemed the first operator of his

time. He soon equalled his father in reputation; and uniting with great dexterity, an excellent judgment and much acuteness of mind, learning, and experience, he not only practised with great success, but was the author of several works, which gave him a high rank among the surgeons of France. These are, "Parallele des différentes manieres de tirer la pierre de la vessie," Paris, 1730. "Observations de Chirurgie, auxquelles on a joint plusieurs Reflexions en faveur des Etudiants," Paris 1731, two vols. 12mo. Both these works were translated into other languages, and passed through several editions. "Traité des Operations de Chirurgie," *ibid.* 1731, 8vo. This was also a valuable work, was translated into English, and several times reprinted. "Reflexions sur les plaies d'armes à feu," *ibid.* 1737, &c. 12mo. A short treatise, but full of judicious and interesting observations, the result of the author's practical observation during several campaigns, in which he accompanied the French armies. "Suite du parallele de la taille," *ibid.* 1756, 8vo. "Consultations sur la plupart des maladies qui font du ressort de la Chirurgie," *ibid.* 1765; another judicious and valuable work, which contributed to support the eminent character of the author. But his last work, "Traité économique de l'Anatomie du corps humain," *ibid.* 1768, was inferior to the rest, his genius seeming to partake of the debility which age had now occasioned in his frame. Eloy. Dict. Hist.

**LEDUM**, in *Botany*, a name adopted from the Greeks, whose *λεδω* is generally believed to be a species of *Cistus*. Linnæus, in applying it to designate a not very dissimilar genus of shrubs, whose scent is so powerful as to be unpleasant and hurtful, offers an etymology expressive of that circumstance, *a ledendo*; but such explanations have scarcely more than the merit of a pun, and none in this case was wanting. Linn. Gen. 218. Schreb. 294. Willd. Sp. Pl. v. 2. 602. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 48. Juss. 159. Lamarck Illustr. t. 363. Gært. t. 112. Clafs and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendrea*, Juss.

Gen. Ch. Cal. Perianth inferior, minute, of one leaf, with five teeth, permanent. Cor. of one petal, wheel-shaped, regular, in five deep, ovate, concave, rounded segments. Stam. Filaments ten, thread-shaped, spreading, as long as the corolla; anthers ovate-oblong, vertical, opening by two terminal pores. Pist. Germen superior, roundish; style thread-shaped, the length of the stamens; stigma obtuse. Peric. Capsule roundish-oblong, of five cells, and five valves, separating from the base, their inflexed margins forming the partitions. Seeds numerous, oblong, narrow, their extremities acute and very thin, attached to five linear pendulous receptacles, proceeding from the central column. Eff. Ch. Calyx five-cleft. Corolla flat, in five deep regular segments. Capsule of five cells, splitting from the base; and partitions from the margin of the valves.

1. *L. palustre*. Marsh Ledum. Linn. Sp. Pl. 561. Fl. Lapp. ed. 2. 127. Ehrh. Arb. 113. Fl. Dan. t. 1031. (L. silesiacum; Clus. Pann. 69. Hist. v. 1. 83. Ger. em. 1288. Rosmarinum sylvestre; Camer. Epit. 546.)—Leaves linear, revolute, woolly beneath.—Native of spongy bogs in the north of Europe, very plentiful in Lapland. With us it flowers in April and May, being cultivated in bog earth, like the shrubs of North America. The stem is shrubby, erect, much branched in a determinate manner, about two feet high; the young branches woolly. Leaves scattered, numerous, stalked, an inch or more in length, linear, obtuse, entire, revolute; dark green and smooth above; clothed with dense rusty wool beneath. Flowers numerous, in dense, simple, terminal, bracted corymbs,

white and very pretty. The whole plant, especially when bruised, has a strong aromatic oppressive scent, somewhat like hops, instead of which the inhabitants of Dalecarlia are said by Linnæus sometimes to make use of it, but the consequences are a most pernicious kind of intoxication, with obstinate head-aches. The Swedes wash their oxen and swine with a decoction of it, to kill lice, and the settlers in Lapland frew its branches among their grain to drive away mice.—A procumbent variety, a span long, is said to be found at Hudson's bay, just as the birch grows humble, and almost prostrate, in the upper parts of Lapland.

2. *L. latifolium*. Labrador Tea, or broad-leaved Ledum. Ait. Hort. Kew. ed. 1. v. 2. 65. Jacq. Ic. Rar. t. 464. (L. groenlandicum; Fl. Dan. t. 567.)—Leaves elliptical, revolute, woolly beneath. Stamens scarcely more than five.—Native of bogs in Greenland, Labrador, Newfoundland, &c. Differs from the last chiefly in the broad form of its leaves and the very conspicuous dense rusty wool of their under side. The stamens are usually from five to seven or eight, seldom ten.

3. *L. busifolium*. Box-leaved Ledum. Bergius in Act. Petrop. for 1777. part 1. 213. t. 3. f. 2. *Dryand*. Leaves elliptical, smooth on both sides, nearly flat. Native of Carolina and New Jersey. Introduced to our gardens by the celebrated Peter Collinson in 1736. It is a much smaller shrub than either of the foregoing, with leaves resembling those of *Azalea procumbens* at first sight. They are about  $\frac{1}{2}$  of an inch long, elliptical or obovate, smooth on both sides, most shining above, their edges scarcely revolute, their midrib prominent underneath. Flowers white, about a quarter of the size of the first species.

**LEDUM**, in *Gardening*, comprehends plants of the hardy evergreen kind, as the marsh chisil, or wild rosemary. The species cultivated is the marsh ledum, (*L. palustre*.)

It has varieties with erect and decumbent branches.

*Method of Culture*.—These plants are increased by sowing the seeds in pots filled with boggy earth, or in shady borders of the same kind of mould, in the spring season. But the best method is to take up the plants in their native situations, with balls of earth about their roots, and plant them in borders of the above kind, keeping them well watered.

It is also found that layers of the young shoots will sometimes grow.

These plants afford variety in shady situations, where the soil is of the boggy kind.

**LEDYARD**, in *Biography*, a native of America, who seems from his youth to have indulged an invincible desire of acquainting himself with the unknown, or imperfectly discovered regions of the globe. His history is so extraordinary, that a detail of some of its leading particulars cannot be unamusing to our readers. Having lived for several years with the Indians of America, he had studied their manners, and had practised in their school the means of obtaining the protection, and of recommending himself to the favour of savages. In the humble situation of a corporal of marines, to which he submitted rather than relinquish his pursuit, he had made with captain Cook the voyage of the world; and feeling on his return an anxious desire of penetrating from the north-western coast of America, which Cook had partly explored, to the eastern coast, with which he himself was perfectly familiar, he determined to traverse the vast continent from the Pacific to the Atlantic ocean. His first plan for the purpose was that of embarking in a vessel, which was then preparing to sail, on a voyage of commercial adventure, to Nootka found, on the western coast of America; and with this view he expended in sea-torties the greatest part of the money with which he had been supplied by the liberality of fit

for Joseph Banks, who has eminently distinguished himself in this way on other occasions for the promotion of every kind of useful science. But this scheme was frustrated by the rapacity of a custom-house officer; and therefore Mr. Ledyard determined to travel over land to Kamtschatka, from whence the passage is extremely short to the opposite coast of America. Accordingly, with no more than ten guineas in his purse, which was all that he had left, he crossed the British channel to OÛtend, towards the close of the year 1786, and by the way of Denmark and the Sound, proceeded to the capital of Sweden. As it was winter, he attempted to traverse the gulf of Bothnia on the ice, in order to reach Kamtschatka by the shortest course; but finding, when he came to the middle of the sea, that the water was not frozen, he returned to Stockholm, and taking his course northward, walked to the Arctic circle, and passing round the head of the gulf, descended on its eastern side to Peterburg, where he arrived in the beginning of March 1787. Here he was noticed as a person of an extraordinary character; and though he had neither stockings nor shoes, nor means to provide himself with any, he received and accepted an invitation to dine with the Portuguese ambassador. From him he obtained twenty guineas for a bill, which he took the liberty, without being previously authorized, to draw on sir Joseph Banks, concluding, from his well known disposition, that he would not be unwilling to pay it. By the interest of the ambassador, as we may conceive to have been probably the case, he obtained permission to accompany a detachment of stores, which the empress had ordered to be sent to Yakutz, for the use of Mr. Billings, an Englishman, at that time in her service. Thus accommodated, he left Peterburg on the 21st of May, and travelling eastward through Siberia, reached Irkutsk in August; and from thence he proceeded to Yakutz, where he was kindly received by Mr. Billings, whom he recollected on board captain Cook's ship, in the situation of the astronomer's servant, but who was now entrusted by the empress in accomplishing her schemes of discovery. He returned to Irkutsk, where he spent part of the winter; and in the spring proceeded to Oczakow, on the coast of the Kamtschatkan sea, intending, in the spring, to have passed over to that peninsula, and to have embarked on the eastern side in one of the Russian vessels that trade to the western shores of America; but finding that the navigation was completely obstructed, he returned to Yakutz, in order to wait for the termination of the winter. But whilst he was amusing himself with these prospects, an express arrived, in January 1788, from the empress, and he was seized, for reasons that have not been explained, by two Russian soldiers, who conveyed him in a sledge through the deserts of Northern Tartary to Moscow, without his clothes, money, and papers. From Moscow he was removed to the city of Moialoff, in White Russia, and from thence to the town of Tolochin, on the frontiers of the Polish dominions. As his conductors parted with him they informed him, that if he returned to Russia he would be hanged, but that if he chose to go back to England, they wished him a pleasant journey. Distressed by poverty, covered with rags, infested with the usual accompaniments of such clothing, harassed with continual hardships, exhausted by disease, without friends, without credit, unknown, and reduced to the most wretched state, he found his way to Konigsberg. In this hour of deep distress, he resolved once more to have recourse to his former benefactor, and fortunately found a person who was willing to take his draft for five guineas on the president of the Royal Society. With this assistance he arrived in England, and immediately waited on sir Joseph Banks. Sir Joseph, knowing his disposition, and conceiving,

as we may well imagine, that he would be gratified by the information, told him, that he could recommend him, as he believed, to an adventure almost as perilous as that from which he had just returned; and then communicated to him the wishes of the Association for discovering the Inland Countries of Africa. Mr. Ledyard replied, that he had always determined to traverse the continent of Africa, as soon as he had explored the interior of North America, and with a letter of introduction by sir Joseph Banks, he waited on Henry Beaufoy, esq. an active member of the fore-mentioned association. Mr. Beaufoy spread before him a map of Africa, and tracing a line from Cairo to Sennar, and from thence westward in the latitude and supposed direction of the Niger, informed him that this was the route by which he was anxious that Africa might, if possible, be explored. Mr. Ledyard expressed great pleasure in the hope of being employed in this adventure. Being asked when he would set out? "Tomorrow morning" was his answer. The committee of the society assigned to him, at his own desire, as an enterprise of obvious peril and of difficult success, the task of traversing from east to west, in the latitude attributed to the Niger, the widest part of the continent of Africa. On the 30th of June, 1788, Mr. Ledyard left London; and after a journey of 36 days, seven of which were consumed at Paris, and two at Marfeilles, he arrived in the city of Alexandria. On the 14th of August, at midnight, he left Alexandria, and sailing up the Nile, arrived at Cairo on the 10th. From Cairo he communicated to the committee of the society all the information which he was able to collect during his stay there; and they were thus sufficiently apprized of the ardent spirit of inquiry, the unwearied attention, the persevering research, and the laborious, indefatigable, anxious zeal with which he pursued the object of his mission. The next dispatch which they were led to expect, was to be dated at Sennar: the terms of his passage had been settled, and the day of his departure was appointed. The committee, however, after having expected with impatience the description of his journey, received with great concern and grievous disappointment, by letters from Egypt, the melancholy tidings of his death. By a bilious complaint, occasioned probably by vexatious delay at Cairo, and by too free an use of the acid of vitriol and tartar emetic, the termination of his life was hastened. He was decently interred in the neighbourhood of such of the English as had ended their days in the capital of Egypt.

Mr. Ledyard, as to his person, scarcely exceeded the middle size, but he manifested very remarkable activity and strength; and as to his manners, though they were unpolished, they were neither uncivil nor unpleasing. "Little attentive to difference of rank," says his biographer, "he seemed to consider all men as his equals, and as such he respected them. His genius, though uncultivated and irregular, was original and comprehensive. Ardent in his wishes, yet calm in his deliberations; daring in his purposes, but guarded in his measures; impatient of controul, yet capable of strong endurance; adventurous beyond the conception of ordinary men, yet wary and considerate, and attentive to all precautions, he appeared to be formed by nature for achievements of hardihood and peril."—"They who compare the extent of his pilgrimage through the vast regions of Tartary with the scantiness of his funds, will naturally ask, by what means he obtained a subsistence on the road? All that I have ever learned from him on the subject was, that his sufferings were excessive, and that more than once he owed his life to the compassionate temper of the women. This remark is strongly confirmed by the following extract from his account of his Siberian tour: "I have always remarked, that women, in all countries, are civil, obliging, tender, and humane :

humane: that they are ever inclined to be gay and cheerful, timorous and modest; and that they do not hesitate, like men, to perform a generous action.—Not haughty, not arrogant, not supercilious; they are full of courtesy, and fond of society; more liable, in general, to err than man; but in general, also, more virtuous, and performing more good actions than he. To a woman, whether civilized or savage, I never addressed myself in the language of decency and friendship, without receiving a decent and friendly answer. With man it has often been otherwise. In wandering over the barren plains of inhospitable Denmark, through bonny Sweden and frozen Lapland, rude and churlish Finland, unprincipled Russia, and the wide-frold regions of the wandering Tartar, if hungry, dry, cold, wet, or sick, the women have ever been friendly to me, and uniformly so; and to add to this virtue (so worthy the appellation of benevolence), these actions have been performed in so free and so kind a manner, that if I was dry, I drank the sweetest draught; and if hungry, I eat the coarsest morsel with a double relish." Similar to this was the experience of Mr. Park. (See AFRICA.) Nevertheless, though Mr. Ledyard found frequent relief and assistance from female attention and kindness, he seems on many occasions to have endured the utmost pressure of distresses. "I am accustomed," said he, in his last conversation with the writer to whom we are indebted for this account of him, "to hardships. I have known both hunger and nakedness to the utmost extremity of human suffering. I have known what it is to have food given me as charity to a madman; and I have at times been obliged to shelter myself under the miseries of that character to avoid a heavier calamity. My distresses have been greater than I have ever owned, or ever will own to any man. Such evils are terrible to bear; but they never yet had power to turn me from my purpose. If I live, I will faithfully perform, in its utmost extent, my engagement to the society; and if I perish in the attempt, my honour will still be safe, for death cancels all bonds." Proceedings of the Association for promoting the Discovery of the Interior Parts of Africa. London, 1790.

LEE, NATHANIEL, son of a clergyman, was educated at Westminster school under Dr. Busby. He was admitted a scholar of Trinity college, Cambridge, in 1668, but quitted the university without a fellowship, and attempted to push his fortune at court. In this he was unsuccessful, and then began to write for the stage. His first piece was the tragedy of Nero, produced in 1675, and from this time, till 1681, he produced one tragedy every year, all which appear to have had temporary success. He made a trial of his talents as an actor, but did not succeed in the attempt. About the year 1684, he was bereaved of his understanding, an affliction which proved so severe as to baffle the powers of his medical friends, and which obliged his relatives to obtain for him an asylum in Bedlam. Here he remained about four years, during which he was able to write two tragedies. He died, in 1690, so poor, as to have been buried by the parish of St. Clement Danes. According to Addison, Mr. Lee was equal to any of his contemporaries in a natural genius for tragedy, but his impetuosity led him into a turgid style, approaching to bombast, and he was apt to bury his thoughts in such a cloud of words, that it was difficult to discern their beauty. He is reckoned to excel in representing the passion of love, which he sometimes touched with exquisite tenderness and force. Two of his pieces only are, at this time, ever brought on the stage, viz. his "Theodorus," and his "Rival Queens." Biog. Brit.

LEE, in Geography, a river of Ireland, which rises in the mountains, on the western border of the county of Cork,

and having passed Loughs Gougane-barra and Allun, flows eastward through the barony of Mulkerry. It receives in its way the rivers Sullane, Dripsey, Blarney, and Bride, with several smaller streams, and below the city of Cork, which is built chiefly on islands formed by it, it expands into that capacious and beautiful harbour, called Cork harbour. (See CORK.) There is also a small river of this name, which runs into Tralee bay, in the county of Kerry.

LEE, a county of Virginia in the S.W. corner of the state, bounded S. by North Carolina, and W. by Kentucky: its form is triangular, two sides being 60 miles long, and the other about 30. In this county is Powell's fertile valley, but a third part of the county is mountainous. It contains 3295 free inhabitants, and 243 slaves. The chief town is Jonesville.—Also, a small town in Stafford county, New Hampshire, about 12 miles N. of Exeter; formerly part of Dover and Durham; incorporated in 1766, and containing 978 inhabitants.—Also, a township in Berkshire county, Massachusetts; 140 miles W. of Bolton; incorporated in 1777, and containing 1267 inhabitants. Housatonic river runs towards the south through this town.

LEE, a term variously used at sea; though its general use be to signify the part towards, or opposite to the wind.

This expression is chiefly used when the wind crosses the line of a ship's course, so that all on one side of her is called to windward, and all on the opposite side, to lee-ward. Hence,

LEE-Shore is that on which the wind blows; so that to be under the lee of the shore, is to be close under the weather-shore, or under wind; or at a short distance from the shore which lies to windward.

A-LEE the Helm. See A-LEE.

LEE, Hard a. See HARD.

LEE-Hatch, take care of the, is a word of command to the man at the helm, to take care that the ship do not go to the lee-ward of her course.

To LEE-ward, denotes towards that part of the horizon which lies under the lee, or whither the wind bloweth.

LEE-ward Ship, is one that is not fall by the wind, or which doth not fall so near the wind, nor make so good way as she should; or which is much to leeward of her course, when sailing close-hauled.

LEE, To lay a Ship by the, or to come up by the Lee, is to bring her so, that all her sails may lie flat against her masts and shrouds, and that the wind may come right upon her broadside.

LEE-Rangs, are ropes reeved into the cringles of a yacht's or hoy's sails.

LEE-Larches, signify the sudden and violent rolls which a ship often takes to the leeward in a high sea, particularly when a large wave strikes her on the weather-side.

LEE-Side, denotes all that part of a ship or boat, which lies between the mast and the side farthest from the direction of the wind; or that half of a ship which is pressed down towards the water by the effort of the sails, as separated from the other half by a line drawn through the middle of her length; that part of the ship, which lies to the windward of this line, is accordingly called the weather-side. Thus, if a ship sails southward, with the wind at east, then is her star-board, or right side, the lee-side; and the larboard, or left, the weather-side.

LEE-Way, or Lee-ward Way of a Ship, is the angle made by the line on which the ship should run according to her course, or the point of the compass steered upon, and the real line of the ship's way occasioned by contrary winds, and a rough sea.

All ships are apt to make some lee-way; so that in casting

up the log-board, something must be allowed for lee-way. But the lee-way made by different ships, under the same circumstances of wind and sailing, will be different; and even the same ship, with different fails, will have more or less fail abroad, will make more or less lee-way. The ordinary rules of allowing for it are these: they were given by Mr. John Buckler to the late Mr. William Jones, who first published them about the year 1702.

1. When a ship is close-hauled, has all her sails set, the water smooth, and a moderate gale of wind, she is then supposed to make little or no lee-way. 2. Allow one point, when it blows fresh, that the small sails are taken in. 3. Allow two points, when the top-fail must be close-reefed. 4. Allow two points and a half, when one top-fail must be handed. 5. Allow three points and a half, when both top-fails are to be taken in. 6. Allow four points, when the fore-course is handed. 7. Allow five points, when trying under the main-fail only. 8. Allow six points, when both main and fore-courses are taken in. 9. Allow seven points, when the ship tries a-hull, or all fails are handed. When the wind has blown hard in either quarter, and shifts across the meridian into the next quarter, the lee-way will be lessened. But in all these cases, respect must be had to the roughness of the sea with the trim of the ship; and hence the mariner will be able to correct his course.

LEEA, in *Botany*, so named by Linnæus, at the suggestion of Professor David Van Royen of Leyden, in honour of the late Mr. James Lee, of the Vineyard at Hammer-smith, author of an Introduction to Botany, of which the first edition appeared in 1760, the fourth in 1810. This book, whose principles are borrowed from Linnæus, but which is particularly valuable for its glossaries and tables of synonyms, has been of primary use in making the Linnæan system popular here. Its author was one of the best practical botanists, and most experienced and successful cultivators. He loved to encourage and assist all who had a taste for natural history, and died generally esteemed, at an advanced age, in July 1795, leaving a son in every respect worthy to sustain and extend his reputation. Linn. Mant. 17. Schreb. 638. 796. Willd. Sp. Pl. v. 1. 1177. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 50. Juss. 153. (Aquilicia; Linn. Mant. 2. 146. Schreb. 154. 824. Juss. 266. Lamarck. Illust. t. 139. Gærtn. v. 1. 275. t. 57. f. 7.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Meliæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, bell-shaped, five-toothed, permanent. *Cor.* of one petal; tube the length of the calyx; limb in five ovate, acute, recurved segments. Nectary attached to the inside of the tube, erect, pitcher-shaped, shorter than the tube, with five notched lobes. *Stam.* Filaments five, connected with the nectary, between the lobes, a little way down, incurved; anthers ovate, versatile, cohering together before impregnation and covering the stigma. *Pist.* Germen superior, nearly globular; style simple, shorter than the nectary; stigma capitate. *Peric.* Berry orbicular, depressed, with five prominences, of one cell. *Seeds* five, gibbous at the outside, angular at the inner.

Efl. Ch. Corolla of one petal; limb in five segments. Nectary of one leaf attached to the tube, five-cleft, erect, bearing the stamens. Berry inferior, with five seeds.

1. *L. jambucina*. Elder-leaved Leea. Willd. n. 1. (Aquilicia jambucina; Linn. Mant. 2. 211. Cavan. Diff. 372. t. 218. Lamarck. Dict. v. 1. 217. Staphylea? indica; Burm. Ind. 75. t. 24. f. 2. Frutex aquosus fœmina; Rumph. Ambon. v. 4. 103. t. 45. Nalagu; Rheede Hort. Mal. v. 2. 43. t. 26.)—Stem furrowed and angular,

smooth. Leaves smooth, doubly pinnate; the terminal leaflet largest.—Native of the East Indies, from whence it was procured for the Kew garden, by Sir Joseph Banks, in 1790. It is a smooth shrub or small tree ten or twelve feet high, with the aspect of Elder; the branches timid at the insertion of the leaves, striated and more or less angular. *Leaves* alternate, large, doubly pinnate; leaflets stalked, opposite, elliptic-oblong, pointed, veiny, strongly serrated, very smooth, paler beneath; the odd ones largest. *Pavicles* cymose, opposite to the leaves, pubescent. *Flowers* small, whitish. *Berries* rather acid, the size of a pea, depressed, black, purplish internally. A decoction of the roots or wood seems, by the accounts given of its uses, to be a valuable tonic medicine.

2. *L. aquata*. Downy Leea. Linn. Mant. 124. (Cajoe toea of the Malays.)—Stem round, downy. Leaves doubly pinnate, rough.—Native of the East Indies, from whence Mr. Lee received and cultivated it before the year 1777. We find no figure of this species. Linnæus did not distinguish it from the former, but they are very different. In both the leaves are bipinnate, or rather ternate in their first division, pinnate in the second; but in this species the terminal leaflet is not larger than the rest, except in some of the lateral divisions, and all the leaflets, as well as their stalks, are rough with minute rather rigid pubescence. The serratures are less strong than in *L. jambucina*.

3. *L. crispata*. Wing-stalked Leea. Linn. Mant. 124. Meerburgh Ic. v. 1. t. 50. (*L. pinnata*; Andr. Repof. t. 355.)—Stem angular, with crisped wings. Leaves simply pinnate.—Native of the East Indies, not, as Linnæus supposed, of the Cape of Good Hope. The roots are tuberous. *Stem* scarcely shrubby, remarkably bordered, as are the leaf-stalks, with parallel, partly crisped, wings. *Leaves* pinnate, generally of two pair, with an odd one, of elliptical, pointed, strongly serrated and copiously veined leaflets, roughish to the touch when dry, but not pubescent. *Flowers* much as in the former, with channelled, angular, or winged stalks. Each segment of the corolla, according to Andrews, is hooded at the point. We have seen one leaf imperfectly bipinnate.

It appears, from the Linnæan herbarium, that Linnæus originally destined the name of *Hippia* for his *Leea*; but he afterwards applied the former to a very different genus. (See HIPPIA.) From the same source the identity of his *Leea* and *Aquilicia* was first discovered, and the latter name gives place, as being the more recent, to say nothing of the claims of the former respecting the person it commemorates.

LEEBYRAN, in *Geography*, a small island in the East Indian sea, near the north-east coast of Borneo. N. lat. 6° 1'. E. long. 118° 12'.

LEECH, in *Zoology*. See HIRUDO.

The history of this animal, and the structure of its parts, by means of which it becomes useful to us, in supplying very happily the place of the lancet, with every other particular circumstance of its life and food, have been very accurately given by Mr. Morand, in the Memoirs of the Academy of Sciences, in the year 1739.

The more vulgarly known particulars of this animal are briefly mentioned by this gentleman; such are the cutaneous annules of its outer coat, the beautiful arrangement of the several rays, the colours, the pyramids, and points, with which it is ornamented; the avidity with which this creature seizes the flesh of animals; the manner of its applying its mouth; the vermicular motion observed within it while sucking, which resembles the common motion of deglutition; the time they have been known to live in the water without

without any visible food; and the faculty they have, in common with many other animals, of moving when cut into several pieces: these the author supposes already sufficiently known, and passes on to what is less so, the structure of its inner parts.

The part of this animal, by which it pierces the skin of any creature to get at its blood, is generally called, simply, its *mouth*; but it really consists of five different parts, which are confounded under that general name. These are two regular lips, a cavity, which is properly the mouth, certain instruments to pierce with, others which serve it for sucking, and finally a sort of throat, or œsophagus, through which it swallows the blood. When the leech is in a state of rest, its upper lip forms a regular femicircle, and the lower a portion of a much larger circle.

When the creature lengthens its head to move, the femicircle of the upper lip becomes two oblique lines, the junction of which makes a salient angle, which the creature applies to whatever it would fix itself to. That angle is marked by a regular black spot on the outer edge of the lip. The extreme softness of the fibres of this part makes it very serviceable to the animal, in that it readily assumes any figure, according to the occasion of seizing any thing solid, in order to move the rest of its body; or on the flesh of an animal, to give opportunity to the piercing instruments to exert their force and action.

Whether it be for either of these purposes, that the creature fixes its mouth, the two lips regularly fix, and make in this state a sort of acetabulum, like the hollow of the tail. This may be seen in their fixing on the sides of a glass-vessel in which they are kept, and the mouth, or aperture between the lips, is distinctly seen. This mouth is formed, like the lips, of such extremely supple fibres, that it takes the figure of the part to which it is applied, and fixes perfectly close to it. When the lips are fixed on the flesh, in order to suck, this little mouth continues moveable under them, and searches over the compass of flesh, inclosed in the larger circle of the lips, for the spot where it will be easiest to draw much blood.

Within this mouth is placed the instrument for piercing the skin, which is more than the mere sucker of the gnat, or the like kind of flies; since the quantity of blood to be sucked by the leech, is much larger, and the aperture of the vessel must therefore also be larger. The shape of this weapon may be discovered by examining the wound it leaves. This is composed of three cuts, making three rays, and uniting in a centre, under equal angles. This structure of the wound is most distinctly seen when the swelling is gone down, and the skin is clean; and this is usually on the fourth day after the application. The three openings are then plainly seen not to be punctures, but absolute wounds, or cuts, as if made by a fine lancet. In examining the creature, the organ, destined for making the wound, is found to be placed between the aperture of the lips and the bottom of the mouth; and on cutting up the animal, and drawing the finger carefully over this part of it, there is felt a roughness like that of a fine file, which evidently is owing to some rough substance, of the hardness of bone. This is, in reality, a number of fine and sharp teeth; and when examined by a microscope, they are found to be disposed in three series on three ribs, or, as they may be called, jaws; each of which is placed along the middle of a strong muscle of its own length; and these corresponding regularly to a triangular opening, which the creature has in its mouth. When that has seized on a proper part for the getting blood, and is fixed, these muscles exert their action, and strike in the teeth through the skin.

These are the instruments which pierce the vessel which is to afford the blood; and for the receiving it into the body of the animal, there is between these rows of teeth, or in the common centre of the mouth, a small aperture; and within this there is a little body to be discovered, which by its motion seems very plainly to be a tongue, and which probably acts as a piston to take up the blood flowing from the triple wound, in the centre of which it naturally stands, while the larger circle of the lips, &c. perform the office of the body of the pump, and the blood is easily, by this means, conveyed into the body of the animal. Finally, between the root of the tongue and the beginning of the stomach, there is a space of two lines in length, in which it is easy to discover two different arrangements of fibres; the one set are flat and plain, the others are circular. These evidently have a power of widening or contracting the cavity of the pump, and by that means facilitate its office; the plane ones contracting in length, to enlarge the capacity, and the circular ones determining the blood towards the stomach, by their power of contracting the hollow, when the blood is received. The blood from hence enters into a membranaceous sort of sack, which serves the animal for the stomach and guts, and occupies the greatest part of the body of the creature. If the air is admitted into the body by the mouth, it may be seen to make its way down a longitudinal canal, and fill, as it goes, a number of sacks, or little bags, which are on each side. These vesicles receive the blood, and becoming filled with it, swell out the body of the animal to a great size. It remains here many months, and nourishes the creature; and if any thing is excreted from it, it must be merely by an insensible perspiration; since the creature has no anus, so far as can be yet discovered, nor any aperture which can supply the place of one.

Leeches are able to live in oil; and when removed out of this liquor into water again, they throw off a tender skin, or film, of the regular shape of their body, and resembling the skin of an eel in miniature. Their living in oil seems a proof, that their organs of respiration are not placed on the outside of their bodies, as they are in many small animals, which therefore die on being only rubbed over with oil. But the leech seems to respire by the mouth; and this may be the more plainly discovered, if the water, in which it is kept, be gently heated; for then the animal, being uneasy, breathes hard, and very visibly.

If a leech be kept in an eight-ounce glass phial, about three-fourths filled with water, it will indicate the changes of the weather, in the manner of a weather-glass. Thus, if the weather continues serene and beautiful, the leech lies motionless at the bottom of the phial, rolled in a spiral form: if it rains either before or after noon, it is found at the top of its lodging, where it will remain until the weather be settled: if we are to have wind, the leech gallops about its limpid habitation with amazing swiftness, and seldom rests until it begins to blow hard: if a remarkable storm of thunder or rain is to succeed, for some days before, it lodges almost continually without the water, and discovers great uneasiness, in violent throws and convulsive like motions. In frost, as in clear summer weather, it lies constantly at the bottom; and in snow, as in rainy weather, it dwells at the very mouth of the phial.

The phial should be covered at the mouth with a piece of linen rag, and the water should be changed once a week in the summer, and once a fortnight in the winter. *Gent. Mag.* vol. xxiii. p. 28.

LEECH, *Sca.* See *HIRUDELLA marina*.

LEECH is also a name given by Boccone to a very particular water-animal, which he found sticking to the sides of the *niphias*, or sword-fish.

He calls it *hirudo*, or *acus cauda utrinque pennata*, and observes, that it is slightly mentioned by Gesner, and by Johnson, in their books of fishes. It is about four inches long; the belly is white and cartilaginous, and transparent; there is no regular head to be seen, but only a hollow snout in the place of the head; this is covered with a very hard membrane, and differs extremely from the skin of the belly: this snout it thrusts up to the end into the body of the fish, and sucks its blood with it; it has a tail shaped like a feather, and under it two slender filaments of fibres, longer than its whole body. By means of these, when it is not fastened to the body of the fish, it clings to stones, or sea-plants, to prevent its being carried away by the motion of the water; and when it is on the body of the fish, these serve it to hold much more fastly with, than it otherwise could do. This creature miserably afflicts the sword-fish, but it is itself as much tormented by an animal that preys on its blood and juices. This is a sort of louse, which is always found upon it; it is of a brownish colour, and it is generally found fastened toward the tail of the creature, sticking as firmly as a limpet to a rock; it is nearly of the bigness of a pea, and when crushed a little, will thrust out several slender filaments. This leech is not found, so far as has yet been observed, on any other fish but the sword-fish; nor this louse among other creatures, besides this leech. Phil. Trans. N. 100.

LEECHES, *Utility of, in the Cure of Diseases.*—Bleeding, or the taking away of blood, for the alleviation and cure of diseases, is frequently one of the most powerful means to which the physician and surgeon can have recourse for the relief of their patients. It is divided into *general* and *topical*; the first signifying the evacuation, as made from a large vein in the arm, or the temporal artery, the external jugular vein, &c; the second denoting the evacuation of blood directly from the vessels of the part affected, or its vicinity, by scarifications, cupping, or leeches. In the article BLEEDING are described most of the surgical methods of taking away blood, with the exception of that by leeches, which more properly belongs to the present place, and of *Cupping* and *Scarifications*, for an account of which the reader is referred to these respective terms.

The *hirudo medicinalis*, as the term denotes, is the proper kind for medical purposes; and, when it has been caught in a clear piece of water, is not full of blood, and is hungry, in consequence of being kept for some time in a vessel of pure water, it is in the best condition for use. According to Schmucker, even the medicinal leech, if taken out of unclear, muddy, stagnant water, will cause pain, swelling, and inflammation, after being applied. *Vermischte Chir. Schriften*, vol. i. p. 86. edit. 2.

With respect to the art of collecting medicinal leeches, the best time for taking them is when they spawn in the earliest warm weather of the year. June and July are accounted favourable months, if there is a good deal of sun, and the wind is either very still, or blows gently from a southerly point. It would be in vain to endeavour to catch them in cold weather attended with northerly winds. The *hirudo medicinalis* inhabits clear lakes and ponds in warm situations, and streams flowing through vallies. In cold and woody countries, the horse leech can only be met with. The warmer the situation of the water is, and the fatter the soil, the thicker and larger are the leeches. Those which are caught in waters abounding with fish, do not bite and suck so well, as others taken out of poorer places. Fresh

ly leeches bite the most readily; but when they have been kept a long while, or have been put out of temperate into very cold water, they generally bite with less avidity.

With regard to the mode of applying leeches, the part on which they are about to be put may first be washed with some clean water and well dried. The leeches are then to be placed on it with the fingers, either one by one, or all of them together, by putting them first into a tumbler, and then applying this to the skin, in the manner of a cupping glass. The leeches should generally be suffered to fall off the part spontaneously, which they commonly do, as soon as they are well distended. But when the patient's weakness, or any other circumstance, requires them to be more speedily removed, they may easily be made to drop off by sprinkling them with a little salt or snuff. For the purpose of inducing leeches to bite with greater facility, some practitioners first wet the part on which they are to be put with a little milk, or milk and sugar.

On some occasions, the application of leeches will procure as copious an evacuation as phlebotomy itself. The quantity of blood which may sometimes be taken away by twelve leeches, would surprize the inexperienced. When the bites are exposed to the steam of warm water, or fomented after the leeches have dropped off, the bleeding may often be kept up for an extraordinary length of time. The writer of this article has known instances, where furcious have been detained for nearly twenty-four hours, in employing means to suppress the continuance of the bleeding from the bites of leeches on inflamed parts. In cases of hernia humoralis, where the scrotum has been much reddened and inflamed, he has often seen the hemorrhage, from the application of leeches, last a very unpleasant length of time. Indeed, the records of surgery prove, that the bleeding from the bites of leeches may even continue to a dangerous extent. Pelletan mentions a case, where an infant, four months old, bled to death, in consequence of the application of six leeches to the chest, some women who were in attendance having contented themselves with merely wiping away the blood with cloths, as fast as it flowed out. (See his *Clinique Chirurgicale*, tom. ii. p. 243.) In general, however, the bleeding, after leeches have dropped off, readily ceases, either of itself or on cold being applied; and it is only when the part is highly inflamed, or excessively vascular, as we know the skin of a very young infant to be, that the subsequent hemorrhage is disposed to continue long. In many instances, the continuance of the bleeding a certain time is a most desirable circumstance, as by this means a more effectual quantity of blood can be taken away than could otherwise be accomplished.

We learn from Galen, that Hippocrates was acquainted with the medical utility of leeches. (De *Hirudinibus* cum comment. Sebizio.) In inflammation of the liver, they were preferred by Aretæus, of Cappadocia, to cupping-glasses; and they are made frequent mention of in the writings of Dioscorides, Celsus, and Paulus Ægineta. Pliny thought, that leeches might be employed with several intentions, as, in plethoric cases, they extract the blood like cupping-glasses, and, according to his conjectures, also opened the pores. (Hist. Natural. l. xxxii. c. 10.) Horace has taken notice of these useful little animals in the following line of his satires.

“Non misura cutem nisi plena cruoris hirudo.”

The Arabian physicians well knew the usefulness of leeches, and were in the habit of directing them to be applied in melancholic and hypochondriacal cases. Rhazes, in particular, recites numerous cures which he effected with their assistance.

ance. Paracelsus used to apply them in cases of jaundice. By the chemical practitioners of medicine, leeches were not at all employed, because they were accustomed to reprobate all evacuations of blood as useless and hurtful; and Van Helmont would not suffer them to be applied to an hemorrhoidal swelling.

The use of leeches, in the practice of physic and surgery, appears to have been revived by Sennertus and Zacutus Lusitanus.

It would be almost an endless task to enumerate the great variety of medical and surgical cases in which leeches may be used with advantage. We may state, indeed, that in all inflammatory affections they are frequently of considerable service. In inflammations about the throat, in the abdomen, thorax, or cranium, or in the limbs and more superficial situations, the benefit derived from the application of leeches, can often be obtained by no other means. The great good which they often do in inflammatory diseases of the eye, joints, and testis, is acknowledged by every practitioner, as well as the relief which they speedily afford in cases of inflamed hemorrhoidal tumours. Their utility in inflammations of the breast, and in alleviating the pain, and even retarding the progress of scirrhous swellings of the same part, deserves also to be mentioned. That they sometimes prove even capable of curing and reducing many indurations of the breast, is a fact proved by daily experience. Nor must we forget the beneficial effects, frequently arising from the application of leeches in various examples of buboes, scrofulous and sympathetic, as well as venereal.

In the majority of cases, however, we are not to imagine that one application of three, four, or even a dozen leeches, is enough to try their efficacy; in general their application must be repeated from time to time, and, in some instances, once or twice a-day, according to the urgency of the symptoms.

In infants of tender years, and persons who have a particular dread of venesection, leeches may be used for the relief of all diseases which require blood to be taken away; and this method of bleeding has the advantage of not being likely to induce swooning, debility, and languor, by the blood being drawn too suddenly.

In many cases, where the practitioner is fearful of venturing upon general bleeding, the employment of leeches may often be tried with greater safety.

In painful affections of the ear and teeth, in inflammations and swellings of the gums, and in numerous inflammatory diseases affecting the parts about the neck and throat, topical bleeding with leeches proves of infinite service, either alone, or in conjunction with general bleeding, according to the nature and circumstances of the case.

In numerous instances of extravasations of blood under the skin, ecchymoses, contusions, &c. leeches are frequently applied with great benefit to the patient.

In cases of quinly, when deglutition has been quite obstructed, and repeated venesection has proved unavailing, Schmucker assures us, that he has found the application of leeches attended with an extraordinary degree of efficacy. The same experienced practitioner also observes, that in pleurifies, he has found topical bleeding with leeches even more useful than blisters.

Whitlows, which can so seldom be cured without suppuration, Schmucker has sometimes resolved, by applying to them leeches and the saturnine lotion in an early stage of the complaint.

This distinguished surgeon likewise confirms, how superiorly useful the application of sixteen or twenty leeches to the perineum frequently proves in cases of retention of

urine, when venesection, the warm bath, and other means alone are ineffectual. Vermischte Chirurgische Schriften, vol. ii. art. 2.

LEECH, or LEETCH of a Sail, in a Ship, the outward edge or skirt of the sail from the caring to the clew, or rather the middle of the fall between these two.

The leeches of all sails, whose tops and bottoms are parallel to the deck, and at right angles with the masts, are denominated from the ship's side, and the sail to which they belong, as the Starboard leech of the main-fail, the lee-leech of the fore-top-fail, &c. But the sails which are fixed obliquely upon the masts, have their leeches named from their situation with respect to the ship's length; as the fore-leech of the mizen, the after-leech of the jib, or fore-stay-fail, &c. Falconer.

LEECH, or Leech-lines, are certain ropes fastened to the leeches of the main-fail and fore-fail, and communicating with blocks under the opposite sides of the top, whence they pass downwards to the deck, serving to truss up those fails to the yard, as occasion requires. See BRAILS.

LEECH-ROPE, is a name given to that part of the bolt-rope, to which the border of a fail is sewed. In all sails, whose opposite leeches are of the same length, it is terminated above by the caring, and below by the clew. Falconer.

LEECHMAN, WILLIAM, in *Biography*, a learned and excellent Scotch divine, was born at Dolphinston, in Lanerkshire, in the year 1706. He was initiated in grammar-learning at his native place, from whence he removed to the university of Edinburgh. Here he distinguished himself by his great proficiency in different branches of learning. He began his theological studies in 1724, and in 1727 he was introduced into the western part of Scotland, which was destined hereafter to be the principal scene of his usefulness. He undertook the education of a young gentleman at Caldwell, in Renfrewshire, where he resided in the summer months, but during the remainder of the year he lived at Glasgow, and was honoured with the friendship of professors Hutcheson and Dunlop. About the beginning of 1731 he was licensed as a preacher, but it was not till the year 1736 that he had any prospect of preferment. He was now ordained minister of Beith, and remained in the discharge of the duties attached to that office during seven years. In 1740 he was elected moderator of a meeting of the synod at Irvine, and opened the assembly at Glasgow on the 7th of April, 1741, with a sermon to the clergy "On the temper, character, and duty of a minister of the gospel." This is thought to be one of the ablest charges ever delivered from the pulpit: it has passed through many editions, and is still in very high reputation. In 1743 he published a much longer discourse on "The Nature, Reasonableness, and Advantages of Prayer; with an Attempt to answer the Objections against it." This sermon, as well as that just noticed, excited great attention at the time of the publication, and it has been frequently reprinted since. He was, about this time, invited to settle with a congregation at Belfast, in Ireland, with the promise of a better salary than that which he enjoyed at Beith. This offer, upon due deliberation, he declined, and he was shortly after elected to the professorship of theology at the university of Glasgow; an honour which he obtained only by the casting vote of the president. The opposite party did all in their power to prevent his being fixed in the situation: they even commenced a process of heresy against him, which had a direct tendency to injure his reputation and usefulness, and to expose him to general odium. The charge was founded on the sermon on prayer, which his enemies considered as having laid too little stress on the atonement and intercession of Christ.

Christ. A paper of remarks was produced, consisting of eight articles, of what they deemed heretical omiffions. To each of the remarks the professor gave in written answers, which were neither deemed satisfactory to the committee nor to the presbytery, under whose authority they acted. Mr. Leechman appealed to a higher court, viz. the synod, the members of which, after hearing all that could be adduced on both sides of the question, almost unanimously determined, that there was no reason to charge him with any unsoundness in the passages of the sermon complained against. "Mr. Leechman's character, both as a preacher and professor, shone out the brighter after this cloud was dissipated. Some of those who had appeared his keenest adversaries in the church process, lived with him afterwards on terms of sincere friendship; even the prejudices of the common people in Glasgow gradually subsided; so that he came to be considered there, as he had always been in every other place, a very acceptable preacher." Soon after he had been established in the professorship, he took the degree of doctor in divinity. He continued in the theological chair seventeen years, vindicating and establishing the grand truths of natural and revealed religion, in answer to the principal objections made to them by Mr. Hume, lord Bolingbroke, and other sceptical writers. He had, in his lectures, a remarkable talent of selecting what was most important and striking on every subject that he handled: his arguments were solid, founded on indisputable facts; and they were urged with a degree of warmth which carried his auditors along with him; for they were addressed equally to the judgment and the heart. Dr. Leechman's fame extended far and wide, the Divinity-hall at Glasgow was crowded, in his time, with a greater number of scholars than any other in Scotland: and his numerous scholars, however they might differ in their sentiments on speculative theology and church government, were all cordially united in their affection and veneration for their master. In the year 1761, Dr. Leechman was raised to the office of principal of the university of Glasgow by a presentation from the king. He had previously to this been in a very bad state of health, and this change in his avocations was probably the means of prolonging his valuable life for five-and-twenty years. Though released from the more fatiguing part of his duties, he could not remain inactive, but entered warmly into every scheme for the benefit and improvement of the society, proposed by other professors, and prosecuted some schemes of his own suggestion. He gave a lecture, for some time, once a week, to the students in divinity, and weekly lectures to the whole university. Dr. Leechman's faculties remained in full vigour amidst the increasing infirmities of old age, and his taste for valuable knowledge continued as acute as ever. His mind seemed to be in a great measure independent of all bodily infirmities and connections. In September, 1785, he experienced a violent paralytic stroke, from the effects of which he speedily recovered: but a second shock of the same kind in the following month deprived him of the power of his whole left side. Still he continued in the full possession of his mental faculties, and was as intelligent, judicious, and even as acute as ever. Another attack carried him off on the third of December, 1785, when he was almost eighty years of age. Dr. Leechman committed nothing to the press, except nine sermons, which went through several editions during his life-time. These were re-published, with others, forming together two volumes, in the year 1789. To the first of these volumes is prefixed an account of the author, to which the reader is referred for more particulars relating to Dr. Leechman.

LEEDS, in *Geography*, a populous market-town in the

wapentake of Skyrack, in the West Riding of the county of York, England, is situated on the north side of the river Aire, over which is a handsome stone bridge. It is a place of great antiquity, and its name is registered in the Domesday survey. Here was formerly a strong castle, probably built by Ilbert de Lacy, which was besieged by king Stephen in 1139; and here the unfortunate Richard II. was confined about the year 1399. No vestige of this fortress remains; but its site is said to have been at a place called Mill-hill. Leeds has long been distinguished as a clothing town; though the pre-eminence it now enjoys is not of a very remote date. Leland says it is "a pretty market-town, subfitted chiefly by clothing, reasonably well builded, and as large as Bradford, but not so *quick* as it." Its growth, however, probably soon became considerable, as it was incorporated by king Charles I. At the commencement of the troubles of that reign, it was held for the king by sir William Saville; but after a sharp action, its fortifications were stormed by the forces which marched out of Bradford under sir Thomas Fairfax. A second charter was granted on the 13th of Charles II., under which the town is now governed. The trade in woollen cloth, which has raised Leeds to its present consequence, is carried on here to an extent unequalled in any place in the kingdom. The cloth-markets are held only on Tuesdays and Saturdays, and then only for an hour and a half each day; and the merchants are not allowed to buy, or even to look at cloth, but at these appointed hours. At six in the morning in summer, and seven in winter, the market-bell rings; and in a few minutes, without the least disorder, the whole market is filled, and all the benches are covered with cloth, each proprietor at the same time standing behind his own cloth. As soon as the bell has ceased the buyers enter, and having fixed on certain lots, or pieces of cloth, they proceed in a very expeditious and secret manner to bargain for the same. (A particular account of the modes of transacting business, &c. is given in the Monthly Magazine, vol. iii. p. 123, and vol. iv. p. 174.) In these places it is related that from ten to twenty thousand pounds worth of cloth, and sometimes more, is sold with a whisper only; the laws of the market are certainly more strictly observed than in any other place in England: the time of sale is terminated by another bell; and any merchant staying in the hall after the bell has ceased, forfeits five shillings. This extensive business, which used formerly to be carried on in the open street, is now conducted in two halls, which have been built for the accommodation of the clothiers. The Mixed-cloth Hall, which is the principal, was erected in 1758; it is a quadrangular building, inclosing an open area of about an hundred yards square, and is divided into seven partitions or streets, each of which contains four rows of stands; and these are the freehold property of separate manufacturers. The whole number of stands is 1770. The White-cloth Hall, built in 1775, is partitioned in a similar manner, and contains 1210 stands. Over the former building is an assembly-room, and over the latter a music-hall. The manufacture of broad cloth is now almost wholly performed by machinery, which has occasioned a considerable reduction in the price. By this means, very few hands are wanted in the first stages of the manufacture, particularly in carding and scribbling the wool, and in spinning it. This circumstance, on the first introduction of machinery, deprived great numbers of people of their customary employment.

Previous to the reign of Charles I. Leeds had but one church: here are now, however, several ecclesiastical edifices, appropriated to the established religion, and to different sects of Dissenters. The church of St. Peter, the original, is built

in the form of a cross, with a tower in the middle; and has a painting in fresco of the Ascension, by Parmentier, who presented the town with this specimen of his genius. -St. John's church was erected in 1634, at the sole expence of Mr. Harrison, who also built a free-school and a market-cross, and was in other respects a great benefactor to the town. The church of the Holy Trinity, which is an elegant structure, with a spire, was built in the eighteenth century. Eight other places of worship are appropriated to the several denominations of dissenters. Here are three almshouses, a charity-school, and an extensive work-house, in which children are taught the easy branches of the woollen manufacture. A spacious infirmary was built by subscription in the year 1786. The streets, in the upper part of the town, are narrow; but in the other parts they are broad, and the houses are mostly uniform, and many of them elegant. Here are several large open squares, the areas of which are in some cases planted, and in others used as tender grounds. The buildings are chiefly of brick, and covered with white slate; and every street has a flagged foot-way on each side. The civil government of the town is vested, by the charter of Charles II., in a mayor, twelve aldermen, and twenty-four common-council men.

Leeds is 192 miles distant from London, and 25 miles from York. In the year 1800, it contained, according to the return made to parliament, 11,599 houses, and 53,162 inhabitants: of the latter, 20,367 were slated to be employed in trade and manufacture, particularly that of woollen cloth. Two fairs are held annually; and two weekly markets, on Tuesdays and Saturdays, are well supplied with all kinds of provisions. A considerable pottery is established here, which furnishes large quantities of earthen ware, both for home consumption and exportation. By means of the rivers Aire and Calder, and the Canal Navigation, Leeds has communication with Wakefield, York, and Hull; from which latter place the woollen goods are usually shipped to foreign parts. The carriage of coals from the interior of Yorkshire is also a great source of traffic: these are carried in vessels from 45 to 60 tons burthen, to Selby, York, Howden, Hull, Beverley, and all the intermediate towns situated on the rivers Ouse and Humber. Three miles from this town are the grand and picturesque ruins of Kirkstall Abbey, seated on the banks of the river Aire. For an account of these, with an interesting print, see Day's Tour in Yorkshire, 8vo. 1805. West of the town is an ancient seat of the Vavaron family. Aikin's Description of the Country round Manchester, 4to, and Monthly Magazine.

LEEDS, a county of Upper Canada, bounded on the east by the county of Grenville, on the south by the river St. Lawrence, and on the west by the boundary line of the late township of Pittsburg, running north until it intersects the Ottawa or Grand river, and thence descending until it meets the north-westermost boundary of the county of Grenville. This county comprehends all the islands in the river St. Lawrence that are near it. The greater part of it lies fronting the St. Lawrence.—Also, a township in the county of Leeds, being the twelfth township in ascending the river St. Lawrence. It is watered by the Gananoque river, which has a good harbour at its entrance. There is a point of entry on the west bank of the Gananoque, near its mouth in the St. Lawrence.—Also, a town of America, in the eastern part of Gloucester county, New Jersey; 4 miles west of the mouth of Mullicus river.—Also, a town in Kennebeck county, on the east bank of Americkoggin river, opposite to the mouth of Twenty miles stream, in the town of Turner, in Cumberland county.—Also, a town, or

rather village, of Richmond county, Virginia, on the north bank of Rappahannock river; 70 miles N.E. of Richmond; near which is a famous course for horse-racing.

LEEDSTON, a post-town of Westmorland county, Virginia; 105 miles from Washington.

LEEGELLAN, a small island in the East Indian sea, near the east coast of Borneo. N. lat. 4° 10'. E. long. 118° 40'.

LEEHEEM, a small island nearly north-east of Borneo. N. lat. 6° 9'. E. long. 118° 16'.

LEEK, in *Botany, Gardening,* and the *Materia Medica.* See ALLIUM.

LEEK, in *Geography,* a small island of Pennsylvania, in Delaware river.

LEEK-Head, in the *Manege.* See WART.

LEEKE, or LEEK-in-the-Moorlands, formerly called Lee, in *Geography,* a market-town and parish in the hundred of Totmanlow, and county of Stafford, England, is seated at the northern extremity of that county, at the distance of 154 miles from London, and 31 from Manchester. Here are a weekly market on Wednesday, and seven annual fairs. In the year 1800, this parish contained 780 houses, and 3489 inhabitants. Many of them are employed in the manufacture of ribbons, silk-twist, and buttons; which may be considered the staple articles of the place. But of late years this latter branch has very much diminished, and at present the chief trade is in thrown silk, and the manufacture of bandana and other handkerchiefs. The cotton business has also been introduced, within these few years, into this town. The church here is a large building, with a lofty square tower. In the church-yard is an ancient stone-cross, the shaft of which is about ten feet in height. It has been called Danish, from "the imagery and fret-work," as Mr. Gough observes, with which it is ornamented. Near the town was formerly a Cistercian abbey, called Delacres, or Dieulacres, which was founded in the year 1214 by Ranulph, earl of Chester; to whom the lordship of this town formerly belonged. In the vicinity of Leeke are some lofty bare crags, called Leek-rocks and Henclouds. Blue-hills, in this neighbourhood, abound with coal-mines; and a fat-spring issues from one of these hills. Eight almshouses were endowed here in 1696, by Mrs. Elizabeth Aft, for as many widows.

LEER, in *Glass-making,* a sort of third furnace, intended to anneal and cool, by proper means, the vessels when made. See FURNACE and GLASS-HOUSE Furnace.

LEER, *Lebr,* or *Lier,* in *Geography,* a town of East Friesland, on a river of the same name, which soon after joins the Ems; 11 miles S. of Emden. N. lat. 53° 12'. E. long. 7° 20'.

LEERDAM, a town of Holland, on the river Linghe, which gave title of count to the noble house of Egmont, and afterwards to that of Nassau; 11 miles S. of Utrecht. N. lat. 51° 55'. E. long. 4° 59'.

LEERSIA, in *Botany,* a genus of grasses, received its appellation from Dr. Swartz, in order, with peculiar propriety, to honour the memory of John Daniel Leers, an apothecary at Herborn in Nassau, author of the *Flora Herbornensis*, published in 1775. This little octavo volume, now very rare, contains sixteen plates, in which all the grasses are engraved by the hand of the author, with such exquisite and minute precision, that they will bear inspection with a magnifier, almost like the plants themselves, and are unrivalled in natural history. A life of the author by his son is prefixed to this book, by which we learn that he died December 7, 1774, aged 47. The narrative contains few striking particulars, but the effusions of filial piety, with

which it abounds, must ever be interesting, and do honour both to the father and the son. A second edition of this work, from another hand, was published many years afterwards, of which the plates are extremely faulty and inaccurate copies of the first. Swartz. Prodr. 21. Ind. Occ. v. 1. 129. Schreb. 818. Willd. Sp. Pl. v. 1. 325. Mart. Mill. Dict. v. 3. Brown Prodr. Nov. Holl. v. 1. 210. Michaux Boreali-Amer. v. 1. 39. (Afprella; Schreb. 45. Homalocenchrus; Mieg. Act. Helvet. v. 4. 307. Hall. Helvet. v. 2. 201. Allion. Pedem. v. 2. 232. Ehrhartia; Wiggers Primit. 63.)—Clas and order, *Triandria Dignia*. Nat. Ord. *Gramina*, Linn. Juss.

Gen. Ch. Calyx none. Cor. Glume of two clofed, boat-shaped, concave, compressed flaves, often fringed with prickles at the back, and nearly equal in length; the outer one larger, oblong, pointed; inner but half as broad, linear, acute. Nectary of two lanceolate acute leaflets. *Stam.* Filaments three, in some cases one or fix, capillary, shorter than the corolla; anthers oblong. *Pist.* Germen superior, ovate, compressed; styles two, capillary, short; stigmas feathery. *Peric.* none except the permanent clofed corolla. *Seed* solitary, obovate, compressed.

Eff. Ch. Calyx none. Corolla of two clofed valves.

Obf. Homalocenchrus, the name given to this genus by Mieg, was jully, as compounded of another, thought exceptionable by Wiggers, who therefore preferred *Ehrhartia*; but the latter is now otherwise employed. (See *EHRHARTIA*.) Dr. Solander it seems originally distinguished this genus from *Phalaris*, and the name applied to it by Swartz, was adopted from his manuscripts. We cannot account for the error of Wiggers, who asserts it to be gynandrous, the stamens growing out of the top of the germen. We find no traces of any such insertion, which would be truly singular in a grass.

1. *L. oryzoides*. Swartz. Prodr. 21. Willd. n. 1. (*Phalaris oryzoides*; Linn. Sp. Pl. 81. Swartz. Obf. 31. Schreb. Gram. fasc. 2. 6. t. 22.—Panicle spreading. Flowers spreading, triandrous; their glumes fringed at the keel.—Native of watery places in Germany, France, Switzerland, Austria, Italy, and Persia. Seguer says it is frequent in the rice-fields about Verona, "in weeding which this grass is detected, in its youngest state, by its glaucous foliage, and, at a more advanced period, by the minute prickles at the edges of its leaves." The roughness arising from these prickles seems the origin of the Italian name, *Afprella*. The roots are perennial, with long runners. *Stems* four or five feet high, leafy, erect, smooth, with hairy joints. *Leaves* linear-lanceolate, pointed, striated, rough, especially at the edges, slightly glaucous; with long, striated, roughish sheaths; and a short notched stipula. *Panicle* at first enveloped in the upper sheath, then spreading, a span high, with numerous, drooping, compound, zigzag branches. *Flowers* light green, very much resembling those of rice, but smaller.

2. *L. virginica*. Willd. n. 2. (*L. oryzoides*; Michaux Boreali-Amer. v. 1. 39. *Oryza glumis carina hispida*; Gronov. Virgin. ed. 1. 153. *Phalaris oryzoides*; ed. 2. 11.)—Panicle loose. Flowers mostly triandrous, erect, close-pressed; their glumes fringed at the keel.—Found in Kentucky, Pennsylvania, and Carolina. Michaux. In marshes in Virginia, amongst *Smilacae* and *Rubi*, flowering in August. Clayton. Michaux thinks this is not specifically distinct from the former; but Willdenow, who has observed them both in a garden, says that, "though much alike, they are constantly different. The present has shorter and broader leaves; a shorter panicle, whose branches are not zigzag but

straight, and whose flowers are closely pressed to the stalks. The glumes are smaller, narrower, sparingly fringed. The panicle of this is never covered by a leaf, but always exposed and spreading." We have seen no specimen of this *Leersia*. Willdenow enquires "whether the Jamaica species be the same with it?" By this he seems to mean, whether *L. oryzoides* of Swartz, which he had already quoted with a doubt under the former, be this *L. virginica*. But Swartz no where mentions the *oryzoides* as a West Indian plant. He merely gives its character in italics, as usual in his *Prodromus*, to contrast it with his own new species, and thereby indicates it not to be a native of the West Indies.

3. *L. hexandra*. Willd. n. 4. Swartz. Ind. Occ. v. 1. 131.—Panicle nearly erect. Flowers alternate, close-pressed, hexandrous; their glumes fringed at the keel, roughish.—Native of watery places in the southern part of Jamaica, where it was gathered by Brown and Swartz. *Stem* two feet high, nearly erect, with hairy joints, but otherwise smooth, slender, leafy, sometimes a little branched. *Leaves* rather glaucous, lanceolate, acute, spreading, striated, rough at the edges. *Stipula* pointed, beardless. *Panicle* nearly erect, the branches a little spreading in every direction, by no means inclined to droop; the flowering part zigzag. *Flowers* alternate, crowded, erect, so as to approach the stalk, purplish, smaller than in *L. oryzoides*, but otherwise much like that species. The stamens however are constantly fix. It flowers in the spring.

4. *L. australis*. Brown Prodr. Nov. Holl. v. 1. 210.—Panicle loose, with alternate branches; the lower ones divided. Flowers hexandrous; their glumes fringed at the keel, finely toothed at their ribs; smooth at the sides.—Gathered by Mr. R. Brown at Port Jackson, as well as in the tropical part of New Holland. He thinks it to near the last, as to be doubtful of their being distinct.

5. *L. lenticularis*. Michaux Boreali-Amer. v. 1. 39.—Branches of the panicle nearly solitary, their secondary divisions spiked. Flowers imbricated; their glumes orbicular, fringed. Native of marshes in the country of the Illinois. Michaux describes the glumes as rather large, lenticular, and conspicuously fringed.

6. *L. monandra*. Willd. n. 3. Swartz. Ind. Occ. v. 1. 130.—Panicle simple, loose. Spikes remote, lax. Flowers monandrous, somewhat imbricated, single-ranked; their glumes roundish, smooth.—Observed by Swartz in chalky groves in Jamaica, flowering in the spring. He describes it as very different from all the other species known to him. The stem is two or three feet high. Leaves long, upright and smooth, of a bright green. Flowers the size of Millet-seed, green, smooth, with only one flamen in each.

LEERSIA, H. dw. Fund. v. 2. 88. See ENCALYPTA.

LEERSTRAND, in Geography, a town of Norway; eight miles S.W. of Drontheim.

LEES, the grossest and thickest parts of wine, oil, and other liquors; or the sediment found at the bottom of the vessel. See LIXIVUM.

The word comes from the French *lie*, and that either from *limus, mud*, or from *Lycus*, one of the surnames of Bacchus; or, according to Du-Cange, from *lia*, a corrupt Latin word, signifying the fame.

A kind of potash, called *cineres clavellati*, is made with the lees of wine burnt, and prepared, used by dyers, &c. which ought to be remembered by people troubled with the stone, &c.

The vinegar-makers make a great trade of the lees of wine dried, and made into cakes, after having squeezed out the remains of the liquor in presses.

All the various kinds of lees, such as those of wine, beer, ale, oil, &c. may be made use of as manures, when they can be had in sufficient quantities for the purpose.

**LEESBURG**, in *Geography*, a post-town of Maryland, in America; 25 miles from Fredericktown.—Also, a post-town of Virginia, and the capital of Loudon county; situated six miles S.W. of the Patowmac, and containing about 60 houses, a court-house, and gaol; 20 miles from Salisbury.

**LEESNITZ**, or **LEGNICA**, a town of Silesia, in the principality of Oppeln; 18 miles S.S.E. of Oppeln.

**LEET, JAMES**, in *Biography*, was born at Geneva in 1560. He received the early part of his education at home; studied law under Cujas, and, through the influence of Beza, obtained a chair in that faculty at Geneva in 1583. In the following year he was made counsellor of state, and the zeal and intelligence which he displayed in the public service caused him four times to be appointed to the syndicate, or first office in government, and likewise to be employed in important negotiations; one of which was with Elizabeth, queen of England, in order to obtain some pecuniary aid for the republic. He was employed upon a similar mission to Holland, and obtained a sum from the prince of Orange, and the states general, upon the condition that the academy of Geneva should be re-established. Leet supported this measure, and delivered an oration "De studiis liberalibus publica ob mala non defendis." He was employed to defend the rights of the republic with his pen against the duke of Savoy; and he vindicated the Protestant religion in opposition to the attacks of the president Favre. He was author of various publications in jurisprudence, and in polite literature. He died in 1611, highly respected by his countrymen as the model of a good citizen and magistrate. His principal works are, "Thefaurus Juris Romani, continens rariora meliorum Interpretum Opuscula;" five vols. folio. His other publications consist chiefly of poems, orations, pieces of biography, &c. Gen. Biog.

**LEET**, *Letas*, (*letb*, *letbe*, *letbe*), is a term of Saxon original, and seems to be no other than the court of the *letbe*; as the county court is the court of the county. For in ancient times the counties were sub-divided into *letbes*, rapes, wapentakes, hundreds, and the like; and the sheriff twice a year performed his *tourn* or perambulation, for the execution of justice through the county. Afterwards the power of holding courts was granted to divers great men, within certain districts. And from hence, these courts, holden within particular parts of the county, have descended unto us without variation, under the name of the *leet*, *letb*, or *letbe* courts. See *COURT-leet*, and *FRANK-pledge*.

**LEETAKOO**, in *Geography*, a large and populous city of Africa, the capital of a tribe of Kaffers called "Boo-hoanans," and the residence of their chief, situated at the distance of 16 days' journey beyond the Orange river in the direction of N.E. from the Cape of Good Hope. The palace of the chief, like the other houses in the town, was built in a circular form, being about 16 feet in diameter. The lower part, to the height of four feet from the ground, was stone laid in clay, and wooden spars erected at certain distances. On the east side of the circle, about the fourth part of the house was open, the other three-fourths entirely closed. A round pointed roof covered the whole in the form of a tent, well thatched with long reeds, or with the straws of the holcus. From the centre to the back part of the house, a circular apartment is made off, with a narrow entrance into it, where the head of the family takes his nightly rest; the other members of the family sleep in the fore part,

or between the large and small circles of the house. All the houses are enclosed with palisades; and the space between these and the dwelling serves for a granary, and store for their grain and pulc. These granaries are constructed in the form of oil-jars, of baked clay, the capacity of each being in the least 200 gallons; and they are supported on tripods, composed of the same material, which raise them about nine inches above the ground. They are covered with a round straw roof erected on poles, and sufficiently high to admit an opening into the jars, the upper edges of which are from five to six feet from the ground. Within and without the town are plantations of that species of Mimosa, which constitutes the principal food of the camelpardalis. The city in its circumference is estimated as large as Cape Town, with all the gardens of Table valley; but it is impossible to ascertain the number of houses, by a general survey, on account of the irregularity of the streets, and lowness of the buildings; but they are supposed to amount to between two and three thousand, of the same kind, but not so large, as that of the chief. The whole population, including men, women, and children, were estimated at between ten and fifteen thousand persons. The situation of Leetakoo was calculated to be S. lat. 26° 30', and E. long. 27°.

**LEEUWE**, or **LEEUWEN**, a town of France, in the department of the Dyle, called by the Flemings "Sout. Leeuwe," situated on the river Geeta, in the midst of a morass; formerly a place of strength, to which persons condemned to banishment were sent; 20 miles W.N.W. of Liege.

**LEEUWARD ISLANDS**, so called in contradistinction to the *Windward islands*, an appellation given to them from their situation in a voyage from the ports of Spain to Carthage, or Porto Bello. Those that lie to leeward extend from Porto Rico to Dominica.

**LEFCA**, a town of the island of Cyprus, the residence of an aga and a cadî. It was one of the four cities that bore the name of Arsinœ; 28 miles N.E. of Bassa.

**LEFKEH**, a town of Asiatic Turkey, in the province of Natolia; near it is a convent, which is the residence of a Greek bishop; 16 miles S.E. of Iznik.

**LEFOOGA**, one of the Friendly islands in the South sea, near Hapææ; in reality forming with three other islands, *viz.* Haanno, Foa, and Hoolava, a group, distinguished by the general name Hapææ. Each is about six or seven miles long, and of a similar height and appearance. Lefooga is joined by a reef to Foa. Lefooga is in several respects superior to Annamooka; its plantations were more numerous and more extensive. Towards the sea, indeed, on the east side, the country is still waste, which is probably owing to its sandy soil, as it is much lower than Annamooka and its surrounding isles. Towards the middle of the island the soil was better, and here were exhibited conspicuous marks of considerable population, and improved cultivation. The plantations were regularly fenced, and the fences, in a manner running parallel to each other, formed spacious public roads, not only convenient but ornamental. Large spots were covered with the paper mulberry trees, and the plantations were generally stocked with such roots and fruits as are the natural produce of the island. At one place was a house, four or five times as large as those of the common sort, to which, it is supposed, the people resort on certain public occasions. Near the landing place was observed a mount, two or three feet high, covered with gravel; and upon it stood four or five small huts, in which, as the natives said, the bodies of some of their principal people had been interred. This island is not above seven miles long; and, in  
 fone

some places, not above two or three broad. The reef on the east side, considerably broad, and on which the sea breaks with great violence, is a continuation of that which joins Lefooga to Foa, not above half a mile distant; and at low water, the natives can walk on this reef, which is then partly dry, from one island to the other. The shore itself is either a coral rock, six or seven feet high, or a sandy beach; but higher than the wet side, which is not, in general, more than three or four feet from the level of the sea, with a sandy beach through its whole length. S. lat. 19° 47'. E. long. 185° 40'.

LETT, a town on the N. coast of the island of Kishma; 12 miles N.E. of Kishma.

LEG, CRUS, in *Anatomy*. See EXTREMITIES.

LEG, *Amputation of*, in *Surgery*. See AMPUTATION.

LEG, *Dislocations of*. See LUXATION.

LEG, *Fractions of*. See FRACTURE.

LEG, *Mortification of*. See GANGRENE.

LEGACY, LEGATUM, in the *Civil Law*, a donation by testament; answering to what in common law is called a *donative*; and the person to whom it is given is styled the *legatee*.

Legacy is usually defined some particular thing given by a last will and testament; because if a man thus dispose, or transfer his whole estate to another, it is called *hereditas*; and he to whom it is given is called *heres*. Though in common law, the distinction is this: that he to whom all a man's lands and hereditaments descend by right of blood, is *heres natus*; the other, to whom it is bequeathed, is called *heres factus*.

This bequest transfers an inchoate property to the legatee; but the legacy is not perfect without the assent of the executor; for if I have a *general or pecuniary* legacy of 100*l.*, or a *specific* one of a piece of plate, I cannot in either case take it without the consent of the executor. (Co. Litt. 111. Aley. 39.) For all the chattels are vested in him; and it is his business first of all to see whether there is a sufficient fund left to pay the debts of the testator; the rule of equity being, that a man must be just before he is permitted to be generous, or, as Bracton expresses the sense of our ancient law, "de bonis defuncti primo deducenda sunt ea que sunt necessitatis, et postea que sunt utilitatis, et ultimo que sunt voluntatis." In case of a deficiency of assets, all the general legacies must abate in due proportion to pay the debts; but a specific legacy, as of a piece of plate, a horse, or the like, is not at all to abate, unless there be not sufficient without it. A specific legacy is where, by the assent of the executor, the property of the legacy will vest. As in one way there is a benefit to a specific legatee, that he shall not contribute, in case of a deficiency, to pay all the legacies, so there is a hazard in another way: *e. g.* if such specific legacy, being a *lease*, be evicted; or being *goods*, be lost or burnt; or, being a *debt*, be lost by the insolvency of the debtor; in all these cases, such specific legatee shall have no contribution from the other legatees, and therefore shall pay none towards them. (1 P. Wms. 539.) Hence a question of some importance has arisen, *viz.* whether a legacy was *specific* or *general*? A specific legacy (strictly speaking) is said by lord Hardwicke (1 Atk. 417.) to be a bequest of a particular chattel, *specifically* described and distinguished from all other things of the same kind; or, in other words, an *individual* legacy. Money, sufficiently distinguished, may be the subject of a specific bequest; as money in a certain chest, or a particular debt. So a bequest of a part of a specific chattel may be equally a specific legacy. (3 Atk. 103.) Legatees, however, of specific parts, though not liable to abatement with *general* le-

gates, must nevertheless abate proportionably among themselves, upon deficiency of the specific thing bequeathed (2 Vez. 563.); or on deficiency of the general assets for payment of debts. (1 P. Wms. 403.) And specific legatees of distinct chattels shall abate proportionably on a deficiency of general assets. 2 P. Wms. 382.

On the other hand, a mere bequest of *quantity*, whether of money or any other chattel, is a *general* legacy; as of a quantity of stock (1 Atk. 414. 2 Vez. 562.); and where the testator has not such stock at his death, it is a direction to the executor to procure so much stock for the legatee. (Tabl. 227.) The purpose to which a *general* legacy is to be applied will not alter its nature. (1 P. Wms. 539.) Personal annuities given by will are general legacies. 3 Atk. 693. 2 Vez. 417. See EXECUTOR and LEGATEE.

With regard to the payment of legacies, if a legacy when due be paid to the father of an infant, it is no good payment: and the executor may be obliged in equity to pay it again; and where any legacy is bequeathed to a *feme-covert*, paying it to her alone is not sufficient, without her husband. 1 Vern. 261.

Executors are not bound to pay a legacy without security to refund; and if sentence be given for a legacy in the ecclesiastical court, a prohibition lies, unless they take security to refund. (2 Ventr. 358.) As an executor is not obliged to pay a legacy without security given him by the legatee to refund, if there are debts, because the legacy is not due till the debts are paid, and a man must be just before he is charitable; so in some cases, the executor may be compelled to give security to the legatee for the payment of his legacy; as where a testator bequeathed 100*l.* to a person, to be paid at the age of 21, and appointed an executor, and died; afterwards the legatee exhibited a bill in equity against the executor, setting forth that he had wasted the estate, and praying that he might give security to pay the legacy when it should become due; and it was ordered accordingly. 1 Ch. Rep. 136. 257.

If a legacy is devised, and no certain time of payment is fixed, and the legatee is an infant, he shall have interest for the legacy from the expiration of one year after the testator's death; but if the legatee be of full age, he shall have no interest but from the time of the demand of his legacy. Where a legacy is payable at a day certain, it must be paid with interest from that day. (2 Salk. 415. 2 Nelf. Abr. 1114.) (See *Lapsed* LEGACY, and INTEREST on LEGACIES.) It has been decreed in equity, that although a legacy be devised to be paid at a certain time, it carries interest only from such time as it is demanded. A person having a legacy, of which he was unapprized till a great while afterwards, when the executors published it in the gazette; here chancery would allow no interest, but the bare debt. Pr. Chanc. 11.

As legacies are gratuities, and no duties, action will not lie at common law for the recovery of a legacy; but remedy must be had in the chancery or spiritual court. (Allen. 38.) If a legacy is payable out of the land, or its profits, an action on the case lies at common law; but the usual remedy is in chancery. (Sid. 44. 3 Salk. 223.) By chief justice Holt, a legatee may maintain an action of debt at common law, against the owner of land, out of which the legacy is to be paid; and since the statute of Wills gives him a right by consequence he shall have an action at law to recover it. (2 Salk. 415.) It is now, however, positively determined, that no action at law lies for a legacy; the court of chancery being the proper jurisdiction for that purpose. (5 Term Rep. 690.) An executor being in equity considered as a trustee for the legatee, with respect to his legacy, and as a

trustee in certain cases for the next of kin as to the undivided surplus, we hence derive the true ground of equitable jurisdiction in enforcing the payment of a legacy, or distribution of personal estate. (1 P. Wms. 544, 575.) The spiritual court administers redress in the case of subtraction, or the withholding or detaining of legacies, as a consequential part of their testamentary jurisdiction; but in this case the courts of equity exercise a concurrent jurisdiction, as incident to some other species of relief required; and as it is beneath the dignity of the king's courts to be merely auxiliary to other inferior jurisdictions, the cause, when once brought there, receives there also its full determination. Blackit. Com. b. iii.

Where a testator gives his debtor a legacy greater than his debt, it shall be taken in satisfaction of it; though where the legacy is less, it shall not be deemed as any part thereof; but as a legacy is a gift, the legatee has sometimes decreed both. (1 Salk. 155. 2 Salk. 508.) If a greater legacy is given by a codicil, to the same person that was legatee in the will, it shall not be a satisfaction, unless expressed. (1 P. Wms. 424.) Although a legacy is a gift, yet upon a principle already stated, that a man should be just before he is kind, a bequest of the same sum by the debtor to the creditor, shall be applied in satisfaction of the debt. (Pr. Ch. 394. 2 P. Wms. 130. 3 P. Wms. 354. 1 Ves. 123. 4 P. Wms. 616.) Yet when there are legatees, and the testator intended both, it may be as good equity to consider him as both just and kind; and the construction of making a gift a satisfaction has, in many cases, been carried too far. (1 Salk. 155. 4 P. Wms. 410. 2 P. Wms. 616.) Cases of this nature depend upon circumstances; and where a legacy has been decreed to go in satisfaction of a debt, it must be grounded upon some evidence, or at least a strong presumption that the testator did so intend it; for a court of equity ought not to hinder a man from disposing of his own as he pleases; and therefore the intention of the party is to be the rule; for where he says he gives a legacy, the court cannot contradict him, and say he pays a debt. (Treat. Eq. lib. 4. p. 1. c. 1. §. 5.) Jacob's Law Dict. by Tomlins, tit. Legacy. See WILL.

LEGACY, *Contingent*. See CONTINGENT.

LEGACIES, *Interest on*. See INTEREST.

LEGACY, *Lapsed*, is where the legatee dies before the testator, in which case the legacy shall sink into the residuum. (See CONTINGENT.) A legacy to be paid, when he attains the age of 21 years, is a *vested* legacy; an interest which commences in *presenti*, although it be *subdumum in futuro*; and if the legatee dies before that age, his representatives shall receive it out of the testator's personal estate, at the same time it would have become payable, in case the legatee had lived. But if such legacies be charged upon a real estate, they shall lapse for the benefit of the heir; for in regard to devises affecting lands, the ecclesiastical court hath no concurrent jurisdiction with chancery. And yet where 1000*l.* was given by a person out of lands to his daughter, and interest to be computed from his death, &c. here, though the legatee died before the time appointed for paying the same, it was held the legacy should be raised notwithstanding, and the lord chancellor said that this legacy was a vested one. (2 Vern. Rep. 617. Barnardist. 328. 330.) In case of a vested legacy, due immediately, and charged on land, or money in the funds, which yield an immediate profit, interest shall be payable thereon from the testator's death. See INTEREST on Legacies, and LEGATEE.

LEGACIES, *Subtraction of*. See SUBTRACTION.

LEGACY, in an *Ecclesiastical Sense*, was a soul-seat, a bequest to the church, or accustomed mortuary; which was

to hold good, even though the testament itself were declared null and invalid.

LEGAL *Column*, (*Economy*, *Subrogation*, and *Tutorage*. See the several substantives.

LEGALIS, *Homio*, in *Law*, a person who stands *relatus in curia*, not outlawed, nor excommunicated, nor infamous. And in this sense are those words so often used, *probi et legales homines*.

Hence, also, legality is taken for the condition of such a man.

LEGATA, fem. LEGATE, plu. in *Musiv*. See NOTES and SYNCOPATION.

LEGATE, a prelate, whom the pope sends as ambassador to any sovereign prince.

The term legate comes from *legatus*, which Varro derives from *legere*, to *choose*; and others from *legare*, *delegare*, to *send*, or *delegate*. Wicquefort.

There are three kinds of legates; *viz.* legates *a latere*, legates *de latere*, and legates *by office*, or *legati nati*.

Of these, the most considerable are the legates *a latere*; such are those whom the pope commissions to take his place in councils; who are thus called, because the pope never gives this office to any but his greatest favourites and confidants, who are always at his side, *a latere*; that is, to the cardinals.

A legate *a latere* may confer benefices without mandate, legitimate bastards to hold offices, and has a cross carried before him as the ensign of his authority.

The legates *de latere* are those who, not being cardinals, are yet entrusted with an apostolical legation.

LEGATES *by office*, *legati nati*, are those who have not any particular legation given them; but who, by virtue of their dignity, and place in the church, become legates. Such are the archbishop of Rheims and Arles. But the authority of these legates is much inferior to that of the legates *a latere*. The power of a legate is sometimes also given without the title; some of the nuncios are invested with it.

LEGATE, *Court of the*. See COURT.

LEGATEE, or LEGATARY, in *Law*, the person to whom a legacy is left; which every person is capable of being, unless particularly disabled by the common law or statutes, as traitors, and some others.

Formerly Papists were under several disabilities, both as to purchasing lands, and taking them by descent or devise; but in these more liberal and enlightened times, such disabilities are removed, and Papists, or as we should rather call them, Roman Catholics, are rendered capable of purchasing and devising lands, and having them by descent, purchase, and devise, on taking the oath prescribed to them by 18 Geo. III. c. 60.

It seems to be necessary that a legatee should be born at the time of making the will; and it has been adjudged, where legacies were given to a man's children, that those who were born afterwards should have no share. (1 Bull. 153.) But it has been otherwise decreed in chancery. (1 Ch. Rep. 301.) The general rule with regard to legatees is, that if the legatee die before the testator, or before the condition upon which the legacy is given be performed, or before it be vested in interest, the legacy is extinguished. (Treat. Eq. lib. 4. part 1. c. 2.) But a bequest may be so specially framed as to prevent the death of the legatee from occasioning a lapse of the legacy. (3 Atk. 572. 500.) Nor will the rule extend to a legacy bequeathed to two or more; for though, by the civil law, there is no survivorship among legatees, yet it is settled that a legacy to two or more is not extinguished by the death of one, but will vest in the survivor. (Gilb. Rep. 137. 2 Atk. 220.) Nor will

the rule extend to those cases where the legacy is given over after the death of the first legatee; for in such cases the legatee in remainder shall have it immediately. (1 And. 33, pl. 82. 2 Vern. 207. 1 P. Wms. 274. 3 P. Wms. 113. Pr. Ch. 37. Mofch. 319. 2 Vern. 378.) Nor will a legacy lapse by the death of the legatee in the testator's life-time, if he be to take as a trustee; (See 1 Vez. 140; and 2 Vern. 468.) in which latter case the point is doubted. When a father makes provision for a child by his will, and afterwards gives to such child, being a daughter, a portion in marriage; or, being a son, a sum of money to establish him in life, (such portion or sum being in amount equal to, or greater than, the legacy,) it is an implied adoption of the legacy; for the law will not intend that the father designed two portions to one child. (1 P. Wms. 680. 2 Ch. Rep. 85. 2 Vern. 115. 257. 2 Atk. 216. Ambl. 325. 2 Bro. C. R. 307.) But this implication will not arise, if the provision by the will be by bequest of the residue (2 Atk. 216.); or if the provision in the father's life-time be subject to a contingency (2 Atk. 491.), or be not *eiusdem generis* with the legacy (1 Bro. C. R. 425.); or if the testator be a stranger (2 Atk. 516. 2 Bro. C. R. 499.); and such implication is always liable to be refuted by evidence. 2 Atk. 516. 2 Bro. C. R. 165. 519.

A bequest of money to one at the age of 21, or day of marriage, without saying, *to be paid* at that time, the legatee dying before the term, is a lapsed legacy; and so it would have been, if the devise had been to her when she shall marry, or when a son shall come of age, and she die before. (Godb. 182. 2 Vent. 342.) But a devise of a sum of money, *to be paid* at the day of marriage, or age of 21 years, if the legatee die before either of these events happen, shall go to the legatee's administrator, because the legatee had a present interest, though the time of payment was not yet come; and it is a charge on the personal estate which was in being at the testator's death; and if it were discharged by this accident, then it would be for the benefit of the executor, which was never intended by the testator. (2 Vent. 366. 2 Lev. 207.) If the legacy be to the legatee *payable to him* at a certain age, and the legatee die before he attain that age, this is a vested and transferrable interest in the legatee. (2 Vent. 342. 2 Ch. Car. 155. 3 Vern. 462. 3 P. Wms. 138. 2 Vern. 199.) Otherwise, if the legacy be to the legatee generally, at or when he attains such age. (2 Vent. 342. 2 Salk. 415. 1 Eq. Ab. 259, 6. 1 Bro. C. R. 119.) If the legacy be made to carry interest, though the words *to be paid* or *payable* are omitted, it is a vested and transferrable interest. (2 Vent. 342. 2 Ch. Car. 155. 2 Vern. 673. 2 Vez. 263. 3 Atk. 645.) So if the bequest be to A. for life, and after the death of A. to B., the bequest to B. is vested upon the death of the testator, and will not lapse by the death of B. in the life-time of A. (2 Vent. 347. 1 P. Wms. 566. 2 Vern. 378. Ambl. 167. 1 Bro. C. R. 119. 181.) A person by will, &c. gives a portion or legacy to a child, payable at 21 years of age, out of a real and personal estate, and the child dies before the legacy becomes payable; in that case, so much of it as the personal estate will pay, shall go to the child's executors and administrators; but so far as the legacy is charged upon the land, it is said that it shall sink. (2 P. Wms. 613.) Jacob's Law Dict. by Tomlins, vol. ii. See LEGACY and EXECUTOR.

LEGATEE, *Residuary*, is the person to whom the residuum, or what remains of an estate, after funeral charges, debts, and legacies, are paid, is left by will. See EXECUTOR.

LEGATINE CONSTITUTIONS. See CONSTITUTIONS.

LEGATIS TENEMENTIS. See TENEMENTS.

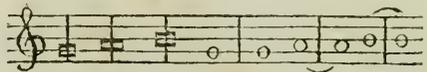

LEGATO, *Ital.*, in *Musick*, bound, tied, connected, sustained.

LEGATORY, or LEGATARY, a term used in speaking of the government of the ancient Romans: Augustus divided the provinces of the empire into consular, legatory, and provincial. The legatory provinces were those of which the emperor himself was governor, but where he did not reside, but administered affairs by his lieutenant, or legatus.

LEGATORY, or *Legatory*, the same with legatee of a will. (27 Eliz. cap. 16.) It is derived from the Latin *legatarius*.

LEGATUM, in an *Ecclesiastical Sense*, was a legacy given to the church, or accoutumed mortuary.

LEGATURA, *Ital.*, in *Modern Musick*, implies a binding note; as when the bar goes through the middle of the note, or two notes of the same kind are tied together by a femicircle.

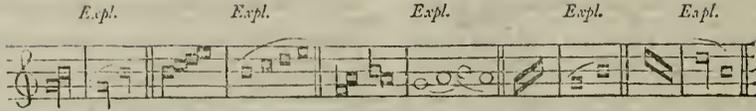

The bar is seldom drawn through the head of the note, except in *alla breve* time: notes of less value are linked together by a femicircle, or tie. See SYNCOPATION.

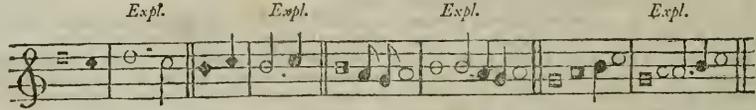

In old church music, before the use of bars, and when the notes were chiefly square, such as the *large*, the *long*, and the *breve*, the laws of ligature constituted the most difficult and tedious part of a practical musician's study. The value or length of a note, in the fifteenth or sixteenth centuries, was changed, by the position of the tail being upwards or downwards, on the left or right side of a note, or in the middle of a measure. In the music-school at Oxford, a set of mass books is preserved, containing compositions by Dr. Fairfax, Taverner, and other old English masters, of Henry VII.'s and Henry VIII.'s time, that are totally unintelligible, except to very curious and studious professors, who have made the ligatures their peculiar study.

Ligatures were used by the early contrapuntists, in vocal music, to connect such sounds as were to be sustained or sung to one syllable, as is done at present by femicircular marks, called binding-notes, and flurs. The rules for these are too numerous and vague to be explained without a long discussion, and their powers will perhaps be best comprehended in the examples of ancient composition of different parts, in partition, and barred. However, it may be useful to those who undertake to decypher such music, to remember that all the square notes in ligature, with tails on the *right hand*, *descending*, are long; on the *left*, *breves*; and all with tails on the *left*, *ascending*, are femibreves. Square notes, without tails, in ligature, are in general breves, though there are some exceptions to this rule, for which it is not easy to assign a cause.

Ligatures explained by equivalent Notes.

Black, square, and lozenge notes, when mixed with white, are diminished one-fourth of the value they have, while open or vacuete. And a note partially black, or demivacuete, is struck twice, in the following proportions :

LEGATUS, among the Romans, a military officer, who commanded as deputy of the chief general.

Of these there were divers kinds; *viz.* a legatus in the army under the emperor, or general, answering to our lieutenant-general; and a legatus in the provinces, under the proconsul, or governor.

When any considerable person among the Roman citizens had occasion to pass through any of the provinces, the senate gave him the title of legatus; that is, of envoy from the senate, to the end that he might be received with the greater respect, and that the cities and towns, through which he travelled, might defray his expences. This they called a *free legation, libera legatio*; because the person was not incumbered with any trust, and might lay it aside as soon as he pleased.

LEGAU, in *Geography*, a town of Bavaria, belonging to the abbey of Kempten; 2 miles N.N.W. of Kempten.

LEGE, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Nantes; 21 miles S. of Nantes. The place contains 2893, and the canton 5227 inhabitants, on a territory of 167½ kilometres, in 5 communes.

LEGEM, *ad communem, entry*, in *Law*, a writ of entry which lies where tenant for term of life, or for term of another's life, or by courtesy, &c. aliens and dies, when he in the reversion shall have his writ against any one that is in possession of the land. New Nat. Brev. 461. See ENTRY.

LEGEM *facere*, to make law, or oath; and *legem habere*, is to be capable of giving evidence upon oath. "Minor non habet legem." Selden's Notes on Heng. 133.

LEGEND, LEGENDA, was originally a book used in the old Romish churches, containing the lessons that were to be read in divine service.

Hence also the lives of saints and martyrs came to be called legends; because the chapters were read out of them at matins, and in the refectories of the religious houses.

The first Greek legend which is known is that of Simon Metaphrastes of the tenth century, who writ the lives of saints adapted to every day of the year. The first Latin legend is,

LEGEND, *Golden*, or a collection of the lives of the saints, compiled by James de Varase, better known by his Latin name of J de Voragine, vicar-general of the Dominicans, and afterwards archbishop of Genoa, who died in 1298.

It was received into the church with great applause, which it maintained for two hundred years; but, in effect, it

is so full of ridiculous and romantic accounts, that the Romans themselves are now generally ashamed of it. The word legend itself is, on that account, come into disrepute.

LEGEND is also used by authors to signify the words or letters engraven about the margins, &c. of coins.

Thus, the legend of a French crown is, SIT NOMIN DOMINI BENEDICTVM; that of a moidore, IN HOC SIGNO VINCES; on those of the last emperors of Constantinople, we find IESVS CHRISTVS BASILEVS BASILEON, HIS XPS NICA, IESVS CHRISTVS VINCIIT. For a brief historical account of the legend on coins, and the method of engraving it; see the article COINAGE.

LEGEND is also applied to the inscription of medals, which serve to explain the figures or devices thereof.

In strictness, the legend differs from the inscription; this last properly signifying words placed on the reverse of a medal, in lieu of figures. When the letters or words of a medal occupy the field, they are called an *inscription*; but when they run round the margin, on either side of the figures, or on the exergue, they are denominated a *legend*.

It seems as if the ancients had intended their medals should serve both as images, and as emblems: the one for the common people, and the other for persons of taste and parts; the images to represent the faces of princes; and emblems to represent their virtues, and great actions: so that the legend is to be looked on as the soul of the medal, and the figures as the body.

Every medal has properly two legends; that on the front, and that on the reverse. The first generally serves only to distinguish the person by his name, titles, offices, &c.; the latter is intended to express his noble and virtuous sentiments, his good deed; and the advantages the public has reaped by him. This, however, does not hold universally; for sometimes we find the titles shared between both sides, and sometimes also the legend.

In the medals of cities and provinces, as the head is usually the genius of the place, or, at least, some deity adored there, the legend is the name of the city, province, or deity, or of both together; and the reverse is some symbol of the city, &c. frequently without a legend; sometimes with that of one of its magistrates.

The ordinary subjects of legends are, the virtues of princes, the honours they have received, consecrations, signal events, public monuments, deities, public vows, privileges, &c.

Legends and inscriptions of medals are either in Latin or Greek. The Greek character, consisting of majuscule, or capital

capital letters, appears uniform on all the medals; no change or alteration being found in confronting the several characters; though it is certain there was in the ordinary use and pronunciation. All we observe on medals is sometimes a mixture of Greek and Latin letters.

Upon many of the coins struck in the Greek cities, we find the legend of the obverse in Latin, while that of the reverse is in Greek. The reason of this, suggested by Mr. Pinkerton, seems to be, that the magistrate of such country mint, not having any portrait of the emperor, sent to Rome for one, which was returned in a die ready cut with the legend. To this a reverse was made by the Greek artists; the magistrate inclining to save the expence of cutting another obverse. This opinion is confirmed by the fact, that few or no coins occur with Latin legends on the reverse, and Greek in front: besides, the dies are hastily done, and after the manner of different mints.

The character was preserved in all its beauty till the time of Gallienus.

From the time of Constantine, and for the space of five hundred years, the Latin tongue was alone used in the legends of medals, even in those struck at Constantinople. Michael began the first, whose legend was in Greek; and from his time the language, as well as the characters, began to alter for the worse. See MEDAL.

The Latin legends are all read from the left to the right; but the legends of some Greek medals are wrote the contrary way, from the right to the left. The letters of the circular legends are commonly placed with the bottoms inward; but sometimes with the bottoms towards the edge.

It is observed by Mr. Pinkerton in his excellent "Essay on Medals," that the legends of the earliest Greek writers are very brief, rehearsing only the initials of the city or prince: as  $\text{A}\Theta\text{E}$ , money of Athens;  $\text{C}\text{T}$ , money of Sybafis, &c.: afterwards,  $\text{A}$ , money of Archelaus, king of Macedon;  $\Phi$ , money of Philip. Afterwards the name was put at full length; as  $\text{O}\Lambda\text{I}\text{M}\text{P}\text{I}\text{O}\text{R}$ , coin of Philip of Macedon; and Alexander the Great has the title of  $\text{B}\alpha\text{S}\text{I}\Lambda\text{E}\text{T}\text{E}$ , or king. In process of time, the Syrian and Egyptian kings, the successors of Alexander, added some epithet of praise, as  $\text{E}\text{Y}\text{E}\text{P}\text{H}\text{E}\text{T}\text{I}\text{E}$ , beneficent, or the like, together with the year of their era in which the coin was struck. In this state the Greek coinage remained, till the Roman empire swallowed up all the kingdoms and cities which used that language. "Under the dominion of the Roman emperors, the Greek mint assumed more of the Roman form, then more perfect, as to legend, than their own. On the face they gave the Roman emperor or empress, with their titles; the founder of their city, with his name; the senate or the people of Rome, who had protected them; or the ideal bust of the genius of their city: while the reverse presents us with a legend indicative of the name of the magistrate under whom the money was struck; of some treaty entered into with one or more neighbouring states; of the river or deity represented, and the like." The Greek artists, as the same ingenious writer observes, to their honour, even when their mint was depressed by the Roman power, seldom or never explain by their legends the reverses of their coins; commonly, and almost universally, putting for the legend of the reverse the name of the city, frequently adding that of the magistrate. The symbols of their deities were familiar, and needed no explanatory legend. Personifications, rare on Greek coins, except of their cities and rivers, are commonly accompanied by an illustrative legend; and the Egyptian coins have also similar legends. The Grecian coins of cities seldom express more in their legends than the name of the town, generally contracted till the Roman

times. When the Roman empire swallowed up the Grecian, the legends on Greek coins were as much distinguished by their length as they had before been by their brevity. The titles of the emperors are translated from the Latin as literally as possible, as  $\text{A}\text{T}\text{T}\text{O}\text{K}\text{P}\text{A}\text{T}\text{O}\text{P}$  for Imperator,  $\text{K}\alpha\text{I}\text{C}\alpha\text{E}\text{A}\text{P}$  for Cæsar, &c. In order to express Latin sounds, the Greeks were often obliged to put their own enunciation of the same word, in characters very different from the Latin, as  $\text{K}\text{O}\text{I}\text{N}\text{O}\text{N}$  for Quintus. On the reverses of Greek imperial coins, the legends are very various; such are  $\text{K}\text{O}\text{I}\text{N}\text{O}\text{N}$ , the community;  $\text{O}\text{M}\text{O}\text{N}\text{O}\text{I}\text{A}$ , the alliance;  $\text{A}\text{T}\text{T}\text{O}\text{N}\text{O}\text{M}\text{O}\text{I}$ , living by their own laws;  $\text{L}\alpha\text{E}\gamma\text{G}\epsilon\text{O}\text{I}$ , free, &c. Inscriptions filling the whole field of the reverse are not so common in Greek coins. Some few, however, occur, particularly upon those of Smyrna. Our author further observes, that the noted S. C., signifying *Senatus Consulto*, by decree of the senate, and expressing the authority of the senate of Rome for striking any coin, never appears upon those of gold or silver, in the same sense as when it occurs upon those of brass. He suggests, that the Roman emperors had the sole disposal of the gold and silver coinage, but left that of brass entirely to the senate. The Roman legends resembled, for some time, in their simplicity those of the Greeks; but gradually proceeded to more explicit length, and in time from elegant and simple veracity degenerated into flattery. This remark is strictly applicable to the legends of the obverse; whereas those of the reverse began to flatter as soon as there was a prince, "an idol upon whose altar to burn the cloudy perfume." Clemency and moderation are found upon the medals of Tiberius, and equivalent virtues upon those of Titus. The reverses of the first imperial coins are not, however, wanting in adulation; which, says Mr. Pinkerton, is not to be wondered at, "when we consider that Virgil and Horace, men of the most enlightened minds, whatever may be decided of their claim to genius, were yet capable of even forgetting the sound dignity of poetry, and prostituting it at the bloody footstool of a tyrant. What Montfiquieu says of the English, that if ever they were reduced to be slaves, they would prove the meanest of all slaves, was exemplified in the conduct of the ancient Romans." In process of time, "a succession of virtuous monarchs authorized the reverses so foreign to most of their predecessors. S. P. Q. R. OPTIMO PRINCIPI, so common on the coins of Trajan, is not flattery, but glory. All the virtues appear without impropriety on the medals of Nerva, Trajan, Hadrian, and the Antonini. But in proportion as the empire declined, the more common are flattery and gross impropriety in the legends of the Roman coin." The Greeks also even surpassed the Romans themselves in the base art of adulation. "The legends of the Roman imperial coins are deservedly celebrated for their beautiful simplicity, and emphatic brevity, so as to be accounted models of the kind." Mr. Pinkerton has subjoined several instances to this purpose. The compass of a coin is so small, that artists have always been obliged to use abbreviations in the legends and inscriptions. This circumstance occasions considerable difficulty in interpreting them. Mr. Pinkerton, in the appendix to his valuable work, has furnished an explanation of those that most commonly occur.

Dr. Coningham, in his Tract on Modern Medals, cited by Mr. Pinkerton, enumerates five kinds of improper legends on modern medals; viz. poetical, impious, jingling, intricate, and abusive. Of the first kind he instances a French medal, struck on occasion of some advantage over the English at sea, *MATURATE FUGAM*, which, he says, reminds us of Virgil and not of the action. Mr. Addison, in his third dialogue on medals, vindicates poetical legends. But Mr. Pinkerton

justly observes, that medals are certainly meant to be historical, and that poetry has in it something alien to history and destructive of its reality; and he adds, that the ancients do not afford a single example of a poetical legend on a medal. Of the jingling kind of legend is that of Francis Morozini, Jupiter with an urn, GAUDET FLUMINE NON FULMINE, and also that of Richard Cromwell, NON DEFICIENT OLIVÆ, confounding the olive-tree with Oliver Cromwell. To the intricate kind is referred the chronological coin of Gustavus Adolphus, king of Sweden, CHRISTVS DVX ERGO TRIVMPHVS, the numeral letters making the year 1632. Of the abusive kind is the Dutch medal on their stadtholder, QVANTVM MUTATUS AB ILLO, and Louis XIV., VIRO IMMORTALI CUM FISTULA IN ANO. To these long legends might be added. The ancient legends are remarkable for simple brevity and energy; and the best of the modern class are formed on their model.

For further particulars we refer to Mr. Pinkerton's "Essay on Medals," 1789, vol. i. § 12, vol. ii. § 18. See MEDALS.

LEGER, ANTHONY, in *Biography*, a learned Piedmontese, was born in the year 1594. After pursuing his studies at Geneva, he entered the work of the ministry, the duties of which he discharged many years with great punctuality. In 1628 he went to Constantinople, as chaplain to the ambassador of the States-general in the Ottoman Porte, and there became intimately connected with the celebrated Cyrillus. On his return to Piedmont in 1637, he was chosen pastor of the church of St. John, a situation which he retained six years; during which he displayed much talent and learning in the defence of the Protestant faith. In 1643, he was proscribed by the duke of Savoy, and was obliged to seek for safety in Geneva, where he not only exercised his profession, but was elected professor of the Oriental languages, and of divinity. He died in 1661, at the age of sixty-seven. He published at Geneva an edition of the New Testament in two vols. 4to. in the Greek and French languages. He left a son of the same name, celebrated as an eloquent preacher, who died in 1719, and after his death five volumes of his sermons were published. Moreri.

LEGER, JOHN, nephew of Anthony, was born in 1615, and educated for the profession of the ministry, was chosen to succeed his uncle when he was obliged to fly for his life to Geneva. In this church he continued his labours till the year 1655, when the persecution of the WALDENSES (which see) broke out with great rage. Leger made his escape to France, and from thence he transmitted an affecting account of the cruelties perpetrated on the Protestants to Oliver Cromwell, who sent an extraordinary ambassador to the duke of Savoy, to remonstrate with him on those proceedings. Leger likewise applied to the king of France, and to the Protestant states, soliciting their interference in behalf of his countrymen. A treaty, now agreed on, seemed to promise future security and toleration. Leger was at the signing of this treaty, which being very shortly broke, and new oppressions and persecutions fell loose on the inhabitants of the valleys, he was appointed deputy general to several Protestant powers to solicit again their mediation with the duke of Savoy. This gave such offence to the court of Turin, that Leger was proclaimed a traitor, and his house ordered to be razed to the ground. He now became pastor of the Walloon church at Leyden, and in 1664, he visited secretly the valleys, carrying with him considerable sums of money collected from the Protestants, for the relief of his persecuted countrymen. He was author of a valuable history of the Evangelical churches in the valleys of Piedmont. Moreri.

LEGÈREMENT, *Fr.* in *Music*, indicates a movement more lively than gay; it is the mean between gay and quick, answering nearly to *vivace* in Italian.

LEGER-LINE is used to signify a line added to the staff of five lines, when the ascending and descending notes run very high or very low. We often meet with several of these lines both above and below the staff.

LEGGÉ, GEORGE, in *Biography*, baron of Dartmouth, and an eminent naval commander, was born about the year 1647. The family derive their origin from Italy, but have for several centuries been resident in this country. Thomas Legge, from whom George descended, was lord mayor of London in the years 1346 and 1353. The subject of this article, being intended early for the sea-service, was brought up under admiral Spragge, and at the age of twenty obtained the command of a ship. In 1673 he was appointed governor of Portsmouth, master of the horse, and held an office under the duke of York. In 1682 he was raised to the peerage, and in the following year was sent to raze the fortifications of Tangiers. By James II. he was appointed master of the horse, general of the ordnance, and constable of the Tower. He had also the command of the fleet at the time of the prince of Orange's invasion, but was prevented from acting by contrary winds. At the revolution he was committed to the Tower, where he died in 1691, at the age of 44. English Peerage.

LEGGÉ, ELIZABETH, the eldest daughter of Edward Legge, esq. an ancestor of the preceding, and also of the present earl of Dartmouth, was born in 1580. She studied the ancient and several of the modern languages, and had a fine poetical genius, but became blind by much study. She lived chiefly in Ireland, and died unmarried at the age of 105. Her family were remarkable for longevity. One of her brothers lived to 109, one sister to be more than 100, and another died in her 120th year.

LEGGIADRO, LEGGIADRAMENTE, *Ital.* in *Music*, implies *gayly, lively, briskly*. See ALLEGRO.

LEGHĒA, in *Geography*, a town of Nubia; 16 miles W.N.W. of Dongola. N. lat. 20° 6'. E. long. 29° 30'.

LEGHENICH, or LECKENICH. See LECKNICH.

LEGHĪ, a town of Arabia, in the province of Yemen; 56 miles E.N.E. of Aden.

LEGHORN, or LIVORNO, a considerable, regular, well-built, fortified and flourishing city and sea-port of Etruria (formerly the grand duchy of Tuscany); and, on account of its canals, called the *New Venice*. It is a bishop's see, defended by a castle, two small forts, and a broad ditch, situated in a marshy and insalubrious territory on the sea-coast, opposite to Malora, a small island, and distant about 14 miles from Pisa. The canals that intersect its environs have rendered the marsh fit for culture, and in some degree contributed to its greater salubrity. Its streets are straight, uniform, and spacious; and many of the buildings are not inelegant. The town is of a square form, and 12,790 feet in circuit, and contains a ducal palace, many religious houses, and from 40,000 to 50,000 inhabitants, of whom 15,000 are Jews, who live in a particular part of the city, are allowed a handsome synagogue, and though subject to heavy imposts, are in a prosperous state, as the greatest part of the commerce of the city is conducted by them. The Greeks and Armenians have each their peculiar church, most of them acknowledging the pope's supremacy. The free Turks and Turkish slaves have a mosque; but the Protestants are not permitted the public exercise of their religion, the English excepted, who are allowed to have a chaplain, because of all foreign nations they are the best customers to Leghorn. Other Protestants make use of chaplains of ships. Prostitutes are

restricted to a particular quarter, consisting of several streets. The heavy taxes payable to the government, from various necessities brought into the town from the continent, together with monopolies of brandy, tobacco, and salt, render provisions and other commodities very dear. The inhabitants carry on an extensive trade, which is much promoted by the freedom of the port; every bale of goods, great or small, paying only two pialres or feudi. The harbour, which is secure, is divided into the outward and inward; the latter serving merely for four or five galleys, which are sometimes sent to sea against the corsairs, under the command of a knight of St. Stephen. In the open place before this harbour stands a marble statue of Ferdinand I., and at the angles of the pedestal are four brazen statues, of a gigantic size, representing four Turkish slaves in chains. The outward harbour is formed by a mole or dam, 600 common paces in length, well paved, with a partition in the middle, that serves to shelter the shipping from the wind on one side. The mole serves also for an occasional promenade. The harbour has not sufficient water for large ships, which therefore lie out of the mole, moored to pillars and large iron rings; and they are thus safer than if they were in the harbour. The road, for a mile or two, is good, but not secure against winds and corsairs. Without the harbour on a rock is a light-house, where 30 burning lamps are contained in one lantern, and on the shore, not far from it, is a lazaretto, where quarantine is performed by persons and goods, that come from suspected places. (See LAZARETTO.) The power of the inquisition at Leghorn extends only to Roman Catholics, and comprehends only cases of religion. In June 1766 the French took possession of this town, and destroyed the fortifications. N. lat. 43° 32'. E. long. 10° 16'.

The principal monies of account at Leghorn are the lira and pezza; the former being chiefly used in domestic trade, and the latter in foreign commerce and exchanges. Each of these is divided into 20 parts called soldi, and the soldo is subdivided into 12 parts called denari. The pezza of Leghorn was originally the Spanish peso, and hence it is called the pezza de otto reali by the Italians, the piastra by the French, and dollars by the English. This pezza, valued in silver, is worth 46½d. sterling, but valued in gold, it is worth 49d. sterling; which is the intrinsic par between London and Leghorn, as bills in the latter place are paid in gold. The lira is either the lira moneta lunga, or the lira moneta buona; the former being an imaginary money of account, and the latter the real money of all Tuscany. The lira is, as in Florence, according to the rate of coinage, worth about 8d.

Accounts on Leghorn are understood to be in moneta lunga; and 23 lira moneta buona are worth 24 lira moneta lunga. The lira has its subdivisions. The pezza is worth 5½ lira moneta buona, or six lira moneta lunga. Foreign bills in Leghorn, unless particularly excepted, must be paid in gold, that is, in Florence sequins or ruspioni, by weight. No days of grace are allowed; but bills are paid three times a week at the "Stanza," a place where merchants meet on Mondays, Wednesdays, and Fridays. In freighting ships at Leghorn, 20 cheils of fruit, 26 barrels of oil, 44 barrels of wine, 5600lb. of alum, are reckoned one last, or two tons.. See Kelly's Universal Cambist. vol. i.

LEGHNAU, a town of Prussia, in the province of Ermeland; 22 miles S.E. Heilsberg.

LEGION, a kind of regiment, or body of forces, of a number of which the Roman armies were chiefly composed.

The word comes from the Latin *legere*, to choose; because

when the legions were raised they made choice of such of their youths as were the most proper to bear arms.

The number of soldiers and officers of which the legion consisted, was different at different times; but it is impossible to determine the precise time and manner of their alteration. In the time of Romulus, the institutor of this corps, each legion contained three thousand foot, and three hundred equites, or horse: these were divided into three bodies, which make as many orders of battle; each body consisting of ten companies, or maniples, ranged at some distance from each other, though in the same front. Each body had two general officers to command it, called *tribunes*; and each manipule, two centurions.

Under the consuls, the legion consisted of four thousand, or four thousand two hundred foot soldiers, who made four bodies, commanded by a consul, or one of his lieutenants; and each legion had its share of cavalry, which was three hundred horse.

About the year of Rome 472, it was composed of five thousand foot; which was the number of a legion during Julius Cæsar's wars with the Gauls. Under Augustus, each legion consisted of six thousand one hundred foot, and seven hundred and twenty-six horse. After his death, they were reduced to five thousand foot and six hundred horse. Under Tiberius, the legion was raised again to six thousand foot and six hundred horse. In the time of Septimius Severus, the legion was composed of five thousand men: under the following emperors, it was the same as it had been under Augustus.

In the time of Marius, those four divisions of the legion which had taken place under the consuls, were united into one, and augmented; and cohorts were appointed from five to six hundred men, each under the command of a tribune. Each cohort consisted of three companies of maniples, each manipule of two centuries, and the legion was divided into ten cohorts, who made as many distinct battalions, disposed in three lines; so that the legion, then, consisted of six thousand men.

Isidore tells us, that the legion consisted of six thousand men, and was divided into sixty centuries, thirty manipules, twelve cohorts, and two hundred troops. According to the French academy, the legion consisted of six thousand foot, and seven hundred and twenty-five horse. The legion consisted of four sorts of soldiers, who differed in their age, arms, and names: they were called *Velites*, *Hoplites*, *Principes*, and *Triarii*. (See ARMS.) Till the destruction at Cartilage, these were citizens of Rome, but after the Social War, the freedom of the city was granted to other towns in Italy, and legionary troops were raised which were called Roman, because as they shared the privilege of Roman citizens, they were incorporated in the republic.

The legions were by far the most considerable part of the Roman army; their number, in the time of Augustus, was thirty-three; they were composed wholly of Roman citizens. The allies formed a body of auxiliary forces. See the sequel of this article.

The standard borne by the legions was various; at first, a wolf, in honour of that which suckled Romulus; afterwards an hog; by reason, says Festus, war is only undertaken with a view to peace, which was concluded by sacrificing a hog. Sometimes they bore the minotaur, to remind their generals, that their designs were to be kept secret, and inaccessible as the minotaur in the labyrinth. They also bore a horse, a boar, &c. Pliny tells us, that Marius was the first who changed all these standards into eagles. See EAGLE.

The different legions were distinguished, according to the order.

## LEGION.

order in which they were raised, into first, second, and third, &c. by the names of the emperors who formed them into legio Augusta, Claudia, Flavia, Trajana, &c. by the provinces where they had served, as legio Parthica, Mædonica, &c. and by some famous exploit or display of valour.

We shall here subjoin some further particulars relating to the constitution and military services of the imperial legion. It was composed of infantry and cavalry. The heavy-armed infantry, which composed its principal strength, was divided into ten cohorts (see COHORT), and fifty-five companies, under the orders of a correspondent number of tribunes and centurions. The first cohort, which always claimed the post of honour, and the custody of the eagle, was formed of 1105 soldiers, the most approved for valour and fidelity. The remaining nine cohorts consisted each of 555; and the whole body of legionary infantry amounted to 6109 men. Their arms were uniform, and admirably adapted to the service which they were required to perform; they consisted of an open helmet, with a lofty crest, a breast-plate, and coat of mail; greaves on their legs; and an ample buckler on their left arm. The buckler was of an oblong and concave figure, four feet in length, and two and a half in breadth, formed of a light wood, covered with a bull's hide, and strongly guarded with plates of brass. Besides a lighter spear, the legionary soldier grasped in his right hand the formidable *pilum* (which see); and as soon as he had darted this from his hand, he drew his sword, and rushed forward to close with the enemy. His sword was a short well-tempered Spanish blade, that carried a double edge, and was alike adapted to the purpose of pushing or striking; but the soldier was always instructed to prefer the former use of his weapon, as his own body remained less exposed, while he inflicted a more dangerous wound on his adversary. See Veget. de Re Mil. l. ii. c. 1. Lipsius de Militia Romana. l. iii. c. 2.—7.

The legion was usually drawn up eight deep; and the regular distance of three feet was left between the files as well as ranks.

The cavalry, which was necessary for perfecting the force of the legion, was divided into ten troops or squadrons: the first, as the companion of the first cohort, consisted of 132 men; whilst each of the other nine amounted only to 66. The entire establishment formed a regiment, according to the modern expression, of 726 horse, naturally connected with its respective legion, but occasionally separated to act in the line, and to compose a part of the wings of the army. The cavalry of the emperors was not composed, like that of the ancient republic, of the noblest youths of Rome and Italy, who, by performing their military service on horseback, prepared themselves for the offices of senator and consul; and solicited, by deeds of valour, the future suffrages of their countrymen. Since the alteration of manners and government, the most wealthy of the equestrian order were engaged in the administration of justice and of the revenue; and whenever they embraced the profession of arms, they were immediately intrusted with a troop of horse, or a cohort of foot. Trajan and Adrian formed their cavalry from the same provinces, and the same class of their subjects, which recruited the ranks of the legion. The horses were bred, for the most part, in Spain or Cappadocia. The arms of the Roman troopers consisted in a helmet, an oblong shield, light boots, and a coat of mail. A javelin, and a long broadsword, were their principal weapons of offence. The use of lances and of iron maces they seem to have borrowed from the barbarians. Considerable levies were regularly made by the Romans among the provincials: and many dependent princes and communities, dispersed

round the frontiers, were permitted, for a while, to hold their freedom and security by the tenure of military service. Even select troops of hostile barbarians were compelled or persuaded to consume their valour in remote climates, and for the benefit of the state. All these were included under the general name of *auxiliaries*; and their number was seldom inferior to that of the legions themselves. By this institution each legion, to which a certain proportion of auxiliaries was allotted, contained within itself every species of lighter troops, and of missile weapons; and was capable of encountering every nation, with the advantages of its respective arms and discipline. Nor was the legion destitute of what, in modern language, would be styled a train of artillery. It consisted in ten military engines of the largest, and 55 of a smaller size; but all of which, either in an oblique or horizontal manner, discharged stones and darts with irresistible violence.

The camp of a Roman legion presented the appearance of a fortified city. See the description of it under CAMP. In their march, the legionaries carried their arms, and also kitchen furniture, instruments of fortification, and provision for many days. Thus laden, they advanced by a regular step, to which they were trained, near twenty miles in about six hours. On the appearance of an enemy, they threw aside their baggage; and by easy and rapid evolutions converted the column of march into an order of battle. The slingers and archers skirmished in the front; the auxiliaries formed the first line, and were seconded or sustained by the strength of the legions: the cavalry covered the flanks, and the military engines were placed in the rear.

As to the number of the legions, we may compute, that the legion, which was itself a body of 6831 Romans, might, with its attendant auxiliaries, amount to about 12,500 men. The peace establishment of Adrian and his successors was composed of no less than 30 of these formidable brigades; and most probably formed a standing force of 375,000 men. As to the position of the legions, they were encamped on the banks of the great rivers, and along the frontiers of the barbarians. As their stations were, for the most part, fixed and permanent, the troops may be considered as distributed in the following manner. Three legions were sufficient for Britain. The principal strength lay upon the Rhine and Danube, and consisted of sixteen legions, in the following proportions: two in the Lower and three in the Upper Germany; one in Rætia, one in Noricum, four in Pannonia, three in Mœsia, and two in Dacia. The defence of the Euphrates was entrusted to eight legions, six of which were planted in Syria, and the other two in Cappadocia. A single legion maintained the domestic tranquillity of each of the large provinces of Egypt, Africa, and Spain. Italy was not left destitute of a military force. About 20,000 chosen soldiers, distinguished by the titles of "City Cohorts" and "Prætorian Guards," watched over the safety of the monarch and the capital.

Under Constantine and his successors, the legions were very considerably reduced. When seven legions, with some auxiliaries, defended the city of Amida against the Persians, the total garrison, with the inhabitants of both sexes and the peasants of the deserted country, did not exceed the number of 20,000 persons. Hence we may infer, that the constitution of the legionary troops, to which they partly owed their valour and discipline, was dissolved by Constantine; and that the bands of Roman infantry, which still assumed the same names and the same honours, consisted only of 1000 or 1500 men. Nevertheless, the successors of Constantine indulged their love of ostentation, by issuing their orders to 132 legions, inscribed on the muster-roll of their

numeros

numerous armies. Under them the complete force of the military establishment was computed at 645,000 soldiers. Gibbon's Decl. &c. Rom. Emp. vol. i. and iii.

LEGION, *Square, legio quadrata*, was a legion consisting of four thousand men.

LEGIONUM, *Domestici*. See DOMESTICUS.

LEGION, *Thundering*. See THUNDERING.

LEGION, *Theban*, is a name given by some authors to a legion of Roman soldiers, who refusing not to sacrifice to idols, suffered martyrdom under the emperors Dioclesian and Maximilian, about the year of Christ 297. But the whole account of them seems to be fabulous.

LEGISLATOR, *LAWGIVER*, a person who frames the laws of a kingdom or state founded by him.

The principal ancient legislators are—Moses, legislator of the Hebrews; Mercurius Trimegistus, and Bocchyrus, of the Egyptians; Italus, of the Ænотrians; Theseus, Draco, and Solon, of the Athenians; Zoroaster, of the Bactrians; Charondas, of the Cappadocians; and Charondas, or Phaleas, of the Carthaginians; Andromadas, of the Chalcidians; Eudoxus, of the Cnidians; Phido, of the Corinthians; Mimos, of the Cretans; Pythagoras, of the Crotoniates, and most of the cities of the Græcia Major; Parmenides and Zeno, of Elea, in Lucania; Xamolxis, of the Getæ; Phoroneus, of the Greeks; Bacchus, of the Indians; Saturn, of Italy; Macarius, of the isle of Lesbos; Zaleucus, of the Locerians; Nicodorus Athleta, of the city of Mutina; Hippodamia, of Miletus; Charondas, of Rheggio; Lycurgus, of the Lacedæmonians; Archytas, of Tarentum; Philolaus, of the Thebans.

At Rome the people were in a great measure their own legislators; though Solon may be said, in some sense, to have been their legislator, as the decemviri, who were created for the making of laws, borrowed a great number from those of Solon.

With us the legislative power is lodged in the king, lords, and commons assembled in *parliament*; which see.

LEGITIMATE CHILD, a child born in lawful wedlock, or within a competent time afterwards. "Pater est quem nuptiæ demonstrat" is the rule of the civil law; and this holds with the civilians, whether the nuptials happen before, or after, the birth of the child. With us in England the rule is approved; for the nuptials must be precedent to the birth. See BASTARD.

LEGITIMATE *Delivery*. See DELIVERY and LABOUR.

LEGITIMATE *Tertian*. See FEVER.

LEGITIMATION, an act by which natural or illegitimate children are rendered legitimate. See BASTARD, &c.

By the French law, the father and mother, by marrying, render their children, begotten before marriage, legitimate; and this is called *legitimatio per subsequens matrimonium*.

The right of legitimation was a thing unknown to princes till the time of Constantine; but, since his time, has been exercised by most of them. The Greek emperors invented several kinds of legitimation.

Anastasis put it in the power of the father to legitimate his natural children by a bare adoption, provided he had no legitimate children. But Justin, by his constitution, and Justinian, by his Novel 74, abolished this legitimation, as fearing the too easy access to legitimation should encourage concubinage.

In lieu of this, he established a way of legitimation by the emperor's letters. This rendered bailards capable of attaining to honours, and even of succeeding to inheritances, provided the persons were legitimated with the consent of their father and mother; which is agreeable to the canon law.

LEGIUNCARA, in *Geography*, is a town of Naples, in the province of Bari; 21 miles N.W. of Matera.

LEGNA, *Λεγνα*, among the *Ancients*, a name given to the borders of the *toga* and *pallium*, that were on each hand; the extremities above and below being called *ora*.

LEGNANO, in *Geography*, a town of Italy, in the Veronese, on the Adige. The two divisions of this place are connected by a drawbridge; the eastern part is called Porto, and the western Legnano. It has several monasteries, and a playhouse. It is a populous town, and carries on a considerable trade by means of a corn-market held every Saturday, and a canal, running from Legnano to Obbligia, in the territory of Mantua. This was formed in 1762, between the Adige and the Po; and for the better security of its navigation, sluices have been constructed at both its ends. The French took possession of it in 1799; 22 miles E.S.E. of Verona. N. lat. 44° 50'. E. long. 11° 18'.

LEGNOTIS, in *Botany*, so named by professor Swartz, from *λεγνός*, fringed, because its petals are curiously lacinated and fringed. Schreb. 357. Swartz. Prod. 84. Ind. Occ. v. 2. 960. Willd. Sp. Pl. v. 2. 1171. Mart. Mill. Dict. v. 3. (Cassipourea; Aubl. Guian. v. 1. 528. t. 211. Juss. 432. Lamarck. Illustr. t. 406.)—Class and order, *Polyandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, four or five-cleft half way down, permanent; segments ovate, acute, erect. *Cor.* Petals four or five, longer than the calyx; claws slender, almost as long as the calyx, inserted into the receptacle; borders ovate, very much fringed, villose. *Stam.* Filaments sixteen or twenty, thread-shaped, equal, the length of the calyx, inserted into the receptacle; anthers oblong, erect. *Pist.* Germen superior, roundish; style cylindrical, as long as the stamens; stigma capitate. *Peric.* Capsule large, elastic, triangular, with three cells and three valves. *Seeds* solitary, convex on one side, angled on the other.

Obs. Sometimes the number of cells and valves in the fruit is liable to variation.

Eff. Ch. Capsule superior, of three cells. Petals inserted into the receptacle, very much fringed or torn.

1. *L. elliptica*. Swartz. Prod. 84. Willd. n. 1.—Leaves elliptical. Flowers on footstalks.—A native of lofty mountains in Jamaica, flowering in May and June.—This is a tree from ten to thirty feet in height, having a smooth, brown bark. Branches determinately subdivided, erect, smooth; the smaller ones slightly compressed. *Leaves* on footstalks, opposite, ovate-acuminate, or oblong-lanceolate, entire, scarcely nerve, smooth on both sides, somewhat rigid; footstalks short, flat above, roundish underneath. *Stipulas* small, ovate, membranaceous, downy, deciduous, between the footstalks. *Flower-stalks* axillary, from three to five, simple; scarcely so long as the leaf-stalks, with a few minute scales at their base. *Capsule* smooth, white and downy within. *Flowers* flesh-coloured, villose with white hairs.

Obs. The downy style becomes elongated to twice the length of the calyx, after flowering.

2. *L. Cassipourea*. Swartz. Prod. 84. Willd. n. 2. (Cassipourea guianensis; Aubl. Guian. t. 211.)—Leaves ovate. Flowers sessile.—A native of moist places in Cayenne, flowering in January.

A middling-sized tree, with a grey bark, about five feet in height, branched at the summit; smaller branches opposite, knotty. Its wood is white. *Leaves* issuing from the knobs, ovate, acute, smooth, entire, nearly sessile, accompanied at their base by two very minute stipulas. *Flowers* axillary, in tufts, white, sessile, situated between two opposite bractæas.

LEGOUZIA, Juss. 450, a name destined by M. Durand,

rande, for those *Campanule* which have a nearly flat, or wheel-shaped corolla, and an oblong prismatic capsule, which L'Heritier has likewise separated from *Campanula*, under the appellation of *Prismatocarpus*. See *CAMPANULA*, section \*.

**LEGRAD**, in *Geography*, a town of Croatia, at the union of the Muncer and Drave; 15 miles E. of Varadlin. N. lat. 46° 30'. E. long. 16° 54'.

**LE GRAND**, a considerable river of America, in the state of Ohio, which rises within a few miles of the W. extremity of lake Erie, and pursuing a N.N.W. course for nearly 100 miles, and then turning to the W., discharges itself into lake Michigan. At its confluence with the lake it is about 250 yards wide.

**LEGRENZI**, DON GIOVANNI, in *Biography*, an able master and fertile Italian composer of the seventeenth century. He was a native of Bergamo, and produced for the different theatres of Venice fifteen operas between the years 1664 and 1684. He was likewise a favourite composer of cantatas, of which he published at Venice two books: one of ten, in 1674; and a second book containing fourteen, in 1679. During his youth he was some time organist of Santa Maria Maggiore, in his native city of Bergamo; then maestro di cappella of the church Dello Spirito Santo, in Ferrara; and lastly of St. Mark's at Venice, and master of the Conservatorio de Mendicanti. He was the master likewise of the two great musicians, Lotti and Francesco Gasparini, both of whom are said to have resided in his house at Venice in the year 1684, in order to receive his instructions. He was also an instrumental composer, and among the most early trios for two violins and a bafe, may be numbered, "Suonate per Chiesa," by Legrenzi, published at Venice, 1655; "Suonate da Chiesa e Camna," 1656; "Una muta di Suonate," 1664; and "Suonate a due Violini e Violone," 1677. Of this last work we are in possession, and upon viewing it, find, that though Legrenzi has introduced into these pieces some of the best melody of the times, and there is considerable merit in the texture and contrivance of the parts, yet, for want of the knowledge of the bow, and the particular energies and expressions of the violin, these compositions have been long since justly superseded and effaced by superior productions of the same kind.

**LEGS**, the lower extremities of the bodies of most animals, serving them for support and motion. See *EXTREMITIES*. See also references under *LEG*.

**LEGS**, in the *Manege*, the members that support a horse's body, and perform the motion when he goes. Of the four legs, the two before have several parts, each of which has a peculiar name: so that by the name of fore-legs, we commonly understand that part of the fore-quarters that extends from the hough to the pattern-joint, and call it the *shank*; the part that corresponds to this in the hind-quarters is called the *instep*. But in common discourse we confound the fore and the hind-quarters; and without any distinction say the *four legs* of a horse. The French call a horse *droit sur les jambes*, i. e. straight-membered, or straight upon his legs, when the fore-part of the pattern falls perpendicularly upon the coronet, and the shank and the pattern are in a straight line. See *STRAIGHT* and *LONG-JOINTED*. See also *HORSE*.

The horseman's legs are likewise of singular concern in the manege, for the action of these given seasonably, and with a little judgment, constitutes one of the principal aids, which consists in approaching more or less with the calf of the leg to the horse's flank, and in bearing it more or less off as there is occasion. This aid a horseman ought to give very nicely, in order to animate a horse: and it is so much

the finer, that it is hidden and private: for in stretching the ham he makes the horse dread the spur, and this aid has as much effect as the spur itself. See *AIM*.

**LEGS**, in *Rural Economy*, are the extremities that form the support of animals. In horses they should have a due proportion to that of the body. The fore-legs are subject to many infirmities, as being the parts that suffer most, and are commonly the weakest. It is a mark of bad legs when they appear altogether straight, or, as if they were of one piece. A horse is said to be straight upon his legs, when from the knee to the fore-part of the coronet, the knees, shank, and coronet descend in a straight or plumb-line, and the pattern joint appears more, or at least as much advanced as the rest of the leg; such legs are like those of a goat, making a horse apt to trip and fall; so that in time the pattern is thrust quite forward out of its place, and the horse becomes lame and liable to stumble.

Horses which are straight upon their legs are quite contrary to those that are long-jointed, that is, whose patterns are so long and flexible, that in walking, they almost touch the ground with them. And it is a greater imperfection than the former, because some remedy may be applied to them; but there can be none for these: besides it is a sign of little or no strength, such horses not being fit for much fatigue. Some horses, though they be long-jointed, do not bend their patterns in walking; such horses gallop and run with greater ease to their riders than such as are short jointed.

In the language of the stable a horse is said to want the fifth leg when he is tired, and, bearing upon the bridle, lies heavy upon the rider's hand, so as to produce much fatigue.

**LEGS**, *Arched*. See *ARCIED*.

**LEGS**, *Compassee* of three. See *COMPASSES*.

**LEGS**, *Hyperbolic*. See *HYPERBOLIC*.

**LEGS**, *Long*, in *Natural History*. See *TYPULA*.

**LEGS** of the *Martinet*, in a *Ship*, are used for those small ropes which are put through the bolt-ropes of the main and fore-sail, in the leech of each. They are above a foot in length, and at either end are spliced into themselves; they have also a small eye, into which the martinet are fastened by two nitches, and the end is seized into the standing part of the martinet.

**LEGS** of a *Triangle*.—When one side of a triangle is taken as a base, the other two are called legs. See *TRIANGLE*.

**LEGUEVIN**, in *Geography*, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Toulouse; nine miles W. of it. The place contains 6689 and the canton 9549 inhabitants, on a territory of 117½ kilometres, in 10 communes.

**LEGUIGNO**, a town of the duchy of Parma; 18 miles S.S.E. of Parma.

**LEGUME**, in *Botany*, *legumen*, the pod proper to the pea or papilionaceous tribe of plants, thence termed, by some writers, *leguminosæ*. (See *LEGUMINOSÆ*.) The Latin word *legumen* is laid by the ancients themselves to be derived from *lego*, to gather; because such fruits are gathered or plucked from their stalks, not reaped nor mown. They are termed in English *pulse*.

This sort of seed-vessel is always solitary and simple, formed of two mostly oblong, equal, more or less coriaceous, parallel valves, without any distinct longitudinal partition, and bearing the seeds along one of its margins only. The top is terminated by the remains of the style, which is short, and placed obliquely, or out of the axis; the base is somewhat contracted towards the stalk. One of the margins, where the seeds are inserted, is generally rather shorter than the other, and externally more furrowed, the other being often rounded

rounded or wavy, and more compressed. There are, however, various shapes of legumes, some of which are peculiar to certain genera, as the spiral ones of different species of *Medicago* and *Scorpiurus*; the cylindrical, prismatic, or rhomboid ones of other genera. Such differ essentially from that kind of seed-vessel termed a *siliqua*, or pod properly so called, in having the seeds at one margin only, whereas the *siliqua* has them arranged along both. The furrowed edge of the legume, which bears the seeds, is called the future.

The capsules of *Helleborus*, and some other plants allied thereto, termed by Linnaeus rather incorrectly *multisiliquae*, are jully indicated by Gærtner as approaching to the definition of legumes. They differ, however, in consisting each but of one valve, and in not being solitary or single in each flower, except the instance of a few species of Larkspur, *Delphinium*, which differ from the natural character of their genus, in having one instead of three germens and seed-vessels; but analogy here teaches the true nature of the part in question. We are, indeed, obliged to have recourse to the same guide in a few papilionaceous genera, whose seed-vessel, otherwise a true legume, contains but one seed, as in most species of *Trifolium*, or whose valves do not separate, but become thickened and hard, as in *Pterocarpus*, or leathery, as in *Viminaria*.

When a legume is divided into several cells, it is either by an inflexion of its valves, as in *Astragalus* and *Mirbelia*, or by transverse constrictions, as in *Vicia* and *Genista*, or even membranous transverse partitions, as in *Securidaca* and *Cassia*. Some, however, are still more distinctly divided, separating as they ripen into distinct joints, each of which contains a single seed, and does not in general burst till that seed forces its way by vegetating, as in *Hedysarum*, *Scorpiurus*, and *Hippocrepis*. This latter kind of legume has lately been considered as a peculiar sort of pericarp, and called *lomentum*; but the gradations leading to it are so imperceptible, that unless a multitude of other distinctions were made, we do not see the eligibility of this.

Several legumes are internally spongy, fleshy, or pulpy, in which respects they vary greatly in the progress of their growth, as the bean (*Vicia Faba*), the Tamarind, the *Ceratonia*, the *Hymenaea*, &c.

Amid all the diversities of structure in this kind of pericarp, it is most difficult to admit as a legume the three-valved seed-vessel of Gærtner's *Moringa*; our HYPERANTHERA.

LEGUMINOSÆ, a natural order of plants, so called from the nature of their fruit. (See LEGUME.) It is the 93d order of Jussieu's system, the 11th of his 14th class, and embraces the Linnaean *Papilionacea* and *Lomentacea*.

For the detailed character of Jussieu's 14th class, see FICOIDEÆ. It has two cotyledons, many petals, and stamens inserted into some part of the calyx.

The *Leguminosæ* are thus defined.

Calyx of one leaf, variously divided. Corolla of many petals, rarely either wanting or monopetalous, inserted into the upper part of the calyx, below its divisions. Petals sometimes five, rarely fewer, regular and nearly equal; but more frequently four, and irregular, all together imitating the shape of a butterfly, whence the term papilionaceous flower; of these the upper and outer one is the standard, *ve.illum*, half embracing the rest, and mostly exceeding them in dimensions; the next two are the wings, *ala*, which are lateral; the lower and innermost is the keel, *carina*, which is either simple or divided. Stamens ten, rarely more or fewer, inserted into the calyx under the petals, their filaments sometimes distinct, or slightly united at their base, or more frequently diadelphous, (see DIADELPHIA,) that is,

consisting of nine united into a tube, which is slit lengthwise under the standard, with a tenth applied close to that fissure, or the whole are really monadelphous, the tube being undivided and decandrous; the anthers are distinct, often roundish and small, sometimes oblong and incumbent. Germen simple, superior; style one; stigma undivided. Fruit in a few instances capsular, of one cell, with scarcely more than one seed, either of two valves, or not bursting at all; in most it is leguminous, as the name of the order implies, longish, of two valves, (of three in *Moringa*, or *Hyperanthera*, of four in one species of *Mimosa*), the seeds affixed to one of the lateral futures; sometimes it is of a single cell, with one seed or several, sometimes of many cells separated by transverse partitions, each cell containing one seed, and all being occasionally pulpy. In the polypetalous irregular genera the radicle of the *corculum* or embryo inclines towards the lobes, and there is no perisperm or *albumen*; in those with more regular flowers the radicle is straight, and there is a perisperm, or thickish membrane, unfolding the embryo; the lobes of the seed are mostly changed into seminal leaves, according to the usual mode of dicotyledonous vegetables, but sometimes they remain distinct below the first leaves. The stem is either herbaceous, shrubby or arborescent, branched for the most part in an alternate manner. Leaves furnished with stipulas, alternate, in a very few instances imperfectly opposite, sometimes simple, but oftener ternate, or fingered, or once or more pinnate. The flowers are variously disposed.

The sections are eleven.

1. Corolla regular. Legume of many cells, mostly of two valves, with transverse partitions, the seeds solitary in each cell. Stamens separate. These are trees or shrubs, with abruptly pinnate leaves. The section contains *Mimosa*, *Gleditsia*, *Gynnocladus*, *Macrolobium* of Schreber, *Ceratonia*, *Tamarindus*, *Parkinsonia*, *Schotia* of Jacquin, and *Cassia*.—To these may be added *Azalia*, Smith Transf. of Linn. Soc. v. 4. 221.

2. Corolla regular. Legume of one cell, and two valves. Stamens ten, separate.—Trees or shrubs, with abruptly pinnate leaves. (In *Hyperanthera* they have terminal leaflets, and the legumæ has three valves.)

This comprehends *Hyperanthera*, (*Moringa* of Jussieu,) *Prosopis*, *Hematoxylum*, *Dimorpha*, of Schreber, *Cubæa* of the same, *Adenanthera*, *Poinciana*, *Casalpinia* (the two last being really one genus) and *Gulandina*.

3. Corolla somewhat irregular. Stamens distinct, or only connected at their base. Legume of one cell and two valves.—Trees or shrubs, with leaves either abruptly pinnate, or merely conjugate, or quite simple.

Here are *Dipteryx* and *Dimorpha* of Schreber, with *Cynometra*, *Hymenaea* and *Bauhinia* of Linnæus, and *GINANNIA* of the former. Jussieu admits *Vouapa* of Aublet, which Schreber unites to *Outea* of the same author, his own *Macrolobium*; see sect. 1.

4. Corolla irregular, papilionaceous. Stamens distinct, or rarely connected at their base. Legume mostly of one cell, and two valves.—Trees or shrubs; their leaves either simple, or ternate, or pinnate, with an odd leaflet.

Jussieu here enumerates only *Cercis*, *Rittrra* of Schreber, *Anagyris*, *Sophora*, *Mullera*, and *Coublandia* of Aublet, the character of which last is very puzzling. But to this section belongs a numerous tribe of New Holland genera, established by Dr. Smith, in the Annals of Botany, and in Tr. of Linn. Soc. v. 9. 245. These are *Putanea*, *Aotus*, *Gompholobium*, *Chorozema*, *Daviesia*, *Viminaria* (though the legume of this last does not burst), *Sphaerolobium*, *Dillwynia*, *Mirbelia* (though the legume has two cells), and *Calif-tachya*.

*tachya*. To these, moreover, are to be added several genera from the new edition of Hort. Kew. v. 3; *Edwardsia*, *Ormosia*, *Thermopsis*, *Virgilia* of Lamarck, *Cyclopia*, *Baptisia*, *Podalyria*, *Fodolobium*, *Oxylobium*, *Brachycyfa*, *Burtonia*, *Jackfonia* (see the latter in its place), *Eutaxia*, *Sclerobanauus*, *Glyrolobium* and *Euchus*.

5. Corolla irregular, papilionaceous. Stamens ten, diadelphous. Legume of one cell and two valves.—Shrubs or herbs; their leaves simple or ternate, or rarely fingered; the stipulas sometimes scarcely discernible, sometimes conspicuous, either attached to the bottom of the footstalk, or distinct from it.

This angle section contains *Ulex*, *Aspalathus*, *Borbonia*, *Liparia*, *Genista* (the latter including *Spartium* of Linnæus), *Cytisus*, *Crotalaria*, *Lupinus*, *Ononis*, *Acrachis*, *Anthyllis*, *Dalea*, *Pterocala*, *Trifolium*, *Melilotus*, *Medicago*, *Trigonella*, *Lotus*, *Dorobus*, *Platycolus*, *Erythrina*, *Urtica*, and *Glycine*.—Here are to be added *Platylobium*, *Boschia* and *Poirertia* of Smith in Tr. of Linn. Soc. v. 9. 301, also *Buta* of Kœnig and Roxburg, and *Haltia* of Thunberg, with doubtless many more.

6. Corolla, Stamens, and Legume as in the last. Herbs or shrubs, or small trees, whose leaves are pinnate with an odd leaflet. In a few the legume has two cells.

*Abrus*, *Amorpha* (remarkable for wanting both wings and keel), *Pisicida*, *Robinia*, *Caragana*, *Astragalus*, *Phaca*, *Biserrula*, *Colutea*, *Glycerhiza*, *Galgua*, and *Indigofera*.

7. Cor. Stam. and Legume as in the two last.—Herbs, with pinnate, or conjugate, or sometimes scarcely any, leaves, the common footstalk ending in a tendril; stipulas distinct from the footstalk.

*Lathyrus*, *Pisum*, *Orobus*, *Vicia*, *Faba*, *Ervum*, and *Cicer*.

8. Cor. and Stam. as in the three last. Legume composed of single-seeded joints.—Herbs or shrubs, rarely trees; leaves simple or ternate, or more frequently pinnate with an odd one; stipulas distinct from the leaf-stalk.

*Scorpiurus*, *Ornithopus*, *Hippocrepis*, *Coronilla*, *Hedysarum*, *Achyrocneme*, and *Diphysa*. Here belongs *Suañbia* of Ait. Hort. Kew. ed. 1.

9. Corolla as before. Stamens mostly ten, diadelphous. Legume capsular, of one cell, often not bursting, with scarcely more than one seed.—Trees or shrubs; leaves generally pinnate with an odd one; stipulas distinct from the footstalk, soon falling.

*Dalbergia*, *Amerimnon* of Browne's Jamaica, *Galegupa* of Lamarck, *Andira* of the same, *Geoffrea*, *Degubia* of Lamarck, *Nifolia*, *Dipteryx* of Schreber, *Acourea* of Aublet, and *Pterocarpus*, are the genera clasped here by Jussieu, which have all a general affinity to each other.

10. Corolla irregular (sometimes wanting). Stamens ten, distinct. Legume capsular, of one cell, generally not bursting, containing a single seed.—Trees or shrubs; leaves either pinnate with an odd one, or simple; stipulas distinct from the footstalk, soon falling.

*Crada* of Schreber, *Detarium* of Jussieu, *Copaifera*, and *Myrosylon*.—According to the definition of this section, *Fimbrinaria* belongs to it; but is too unlike the rest, and too closely allied in habit and character to the plants with which we have placed it in sect. 4, to be separated from them.

11. Jussieu concludes here with four genera, termed by him "akin to the leguminosa." These are *Securidaca*, which seems to belong properly to sect. 9, *Brownnea*, *Zygia* of Browne's Jamaica, and *Aruna* of Schreber.

It will easily be perceived that this arrangement requires much correction and reformation, in consequence of discoveries subsequent to its publication. The whole order is

so natural, that its subdivisions are proportionably difficult to be devised, and the same may be said of its generic distinctions. If Linnæus was obliged, by the laws of his artificial system, to offer great violence to this order, as Jussieu and others have not failed to observe, his class *Diadelphia* does honour to his penetration, and to the comprehensive systematic powers of his mind.

LEGUMINOUS FLOWERS. See FLOWER.

LEGUMINOUS Plants, in Gardening, a term applied to all such as are of the pulic kind, as those of the pea, bean, and other similar descriptions.

LEHE, in Geography, a town of the duchy of Bremen; 32 miles N. of Bremen.

LEHEIM, a town of Hesse-Darmstadt; 8 miles W. of Darmstadt.

LEHI, in Scripture Geography, a city of Palestine, in the tribe of Dan, near Eltak or Eltaka. This was a sacerdotal city, given to the sons of Cohath. Here Samson slew a thousand Philistines with the jaw-bone of an ass.

LEHI, *Lehigh*, or *Leche*, in Geography, a river of America, which rises in Northampton county, Pennsylvania, about 21 miles E. of Wyoming Falls, in Susquehanna river, and passing, by a circular course, through the Blue mountains, discharges itself into De'aware river, on the S. side of Eulton, 11 miles N.E. of Bethlehem. Its course is about 75 miles, and it is navigable 30 miles.

LEHMKUHLN, a town of Holstein; 8 miles S.W. of Lutzenberg.

LEHRBERG, a town of Germany, in the margravate of Anspach, on the Unter Retzat; 5 miles N.W. of Anspach.

LEHSO, a town of Arabia Deserta; 140 miles S. of Cathem.

LEHSTEN, or LEHESTEN, a town of Saxony, in the principality of Altenburg, celebrated for its quarries of slate; 45 miles S.S.W. of Altenburg. N. lat. 50° 25'. E. long. 11 35'.

LEHTIMAKI, a town of Sweden, in the government of Wafa; 65 miles E.S.E. of Wafa.

LEIBEN, a town of Austria; 10 miles W.N.W. of Crems.—Also, a town of Austria; 14 miles S.W. of Crems.

LEIBLINGEN, or LYPTINGEN, a town of Germany, in the lordship of Natenberg; 6 miles E. of Tuttingen.

LEIBNITZ, GODFREY WILLIAM DE, in Biography, an eminent German philosopher and mathematician, was born at Leipsic in the year 1646. He lost his father when he was very young, and of course the care of his education devolved on his mother. She placed him under able masters, who had been colleagues of his father in the university, of which he had been professor of moral philosophy, and secretary. The son made a very rapid progress in the different branches of science and learning. He not only became a deep classie, but availed himself of the advantages of a large and well chosen library, which his father had left him, and read all the books which it contained in regular order, as the poets, orators, historians, civilians, philosophers, mathematicians, and divines. Such was his application, that he could repeat the works of the principal poets, and so tenacious was his memory, that even in old age he could, without hesitation, run through the whole of the *Æneid*, without missing a line or a word. He had a talent for making verses, and is said to have composed three hundred in one day. When he was fifteen years of age he became a student in the university of Leipsic, where he profecuted, with great success, the various studies of the law, medicine, philosophy, and theology. Having finished his studies at Jena, the principal

cipal objects of his attention were history, law, and the mathematics. He was particularly attached to the writings of Plato and Aristotle, and is said to have spent whole days in meditation, in a forest near Leipzig. He principally devoted himself to the study of the law, and took his degree of bachelor in 1665, and in the following year he supplicated for his degree of doctor, which was refused, under the pretence that he was too young, being then only in his twentieth year, but it was imagined that the real cause was his having abandoned the tenets of Aristotle and the schoolmen. Offended at this treatment, he went to Altdorf, where he maintained a thesis, "De calibus perlexis," and in the disputations on this occasion, he displayed such uncommon abilities, that he had the degree of doctor instantly conferred upon him, and was even offered a professorship extraordinary in law, which he declined. He about this period published a work, entitled "Ars Combinatoria," intended to shew in what manner universal arithmetic may be applied to other sciences. This was accompanied with "A mathematical Demonstration of the Existence of God." From Altdorf Leibnitz went to Nuremberg, to visit the learned men in that university. He was at this place initiated in the mysteries of Alchemy. From Nuremberg he went to Mentz, and published, in 1668, "Nova Methodus Docendæ Discendæque Jurisprudentiæ," which gained him great applause. He next shewed himself as a politician, and wrote a treatise to induce the Poles to choose the elector-palatine their king, which so pleased the elector, that he invited the author to reside at his court, which invitation he would have accepted, had he not at the same time obtained the office of counsellor of the chamber of review in the chancery of Mentz. In 1670 he reprinted, with a preface and notes, the treatise of Marius Nizolius de Bersello, "De veris Principiis, et vera ratione Philosophandi contra Pseudophilosophos," to which he subjoined a letter, "De Aristotelæ recentioribus reconciliabili." In the year 1672, Leibnitz went to Paris, to manage some affairs at the French court: here he became acquainted with the greatest mathematicians in that metropolis, and made further and considerable progress in the study of mathematics and philosophy. Here also he met with Pascal's arithmetical machine, the defects of which he soon discovered, and to obviate these he invented a new one, which was highly approved by the minister Colbert, and the Academy of sciences. He was offered a seat in this body with a pension, and had the prospect of many other advantages if he would settle at Paris, but to attain this eminence he must embrace, or be supposed to embrace, the Catholic religion, which neither honours nor emoluments could induce him to do. In 1673 he came to England, and became acquainted with Mr. Oldenburg, the secretary, and Mr. Collins, a distinguished member of the Royal Society; from whom it was said he received some hints of the method of fluxions, which had been invented in 1664, or 1665, by Mr. Isaac Newton. Leibnitz improved these hints, and under the name of "calculus differentialis" he gave the same method of analysis with fluxions. (See KEIL and NEWTON.) While Mr. Leibnitz was in England he lost his patron, the elector of Mentz, and with him a pension which that prince had allowed him. He returned to France, whence he wrote to Frederic duke of Brunswic Lunenburg, informing him of his circumstances. This prince immediately appointed him a member of the Aulic council, with a regular salary, but he permitted him to remain at Paris, till his arithmetical machine should be perfected. When he entered upon his office at Hanover, one of his earliest cares was to furnish the prince's library with the best books in the various branches of science and literature. In 1677 he first mentioned his mathematical invention of diffe-

reentials to Newton, who had previously to this written to Leibnitz an account of his invention of fluxions; about the same period, he gave an account of some discoveries in optics and mechanics, describing a new method of polishing glasses. He became a constant contributor to the "Acta Eruditorum" of Leipzig, and among other pieces he published in this work "Thoughts on Knowledge, Truth, and Ideas." He next undertook a history of the house of Brunswic, and to render himself more competent to the task, he travelled over Germany and Italy, collecting materials. In passing from Venice to Mesola, a terrible storm arose, during which the pilot, imagining that he could not be understood by a German, whom, as a heretic, he regarded as the cause of the tempest, proposed to strip him of his clothes and money, and throw him overboard. Leibnitz, hearing the conversation, without the least emotion, drew a set of beads from his pocket, and began turning them over with great seeming devotion. The artifice succeeded; one of the sailors observing to the pilot, that since the man was not an heretic, he ought not to be drowned. Leibnitz returned to Hanover in 1690, where he pursued with great industry several objects of very different kinds. In a theological dispute he appeared the friend of toleration, and in 1693 he published a work on the law of nations, entitled "Codex Juris Gentium Diplomaticus." He next wrote his treatise "De ipsa natura, five Vi inîta," which was intended to improve and correct the philosophical notion of substance; and he likewise conceived the idea of a new science of forces, in which the laws of mechanics, and the measure of living forces might be clearly defined. This science he denominated *Dynamics* (which see), and insered a specimen of it in the "Acta Eruditorum." He published "Thoughts on Locke's Essay on the Human Understanding," in which he controverted that philosopher's opinions on innate ideas, substance, a vacuum, and other subjects; communicated to the world his ingenious invention of binary arithmetic; and wrote a reply to Dayle in defence of his doctrine of pre-established harmony. Without attempting to follow our author in all his publications, which were very numerous and important, we may observe that he spent much time in the invention of an universal language; but did not live to complete his design. In 1710 he published "A Dissertation on the Goodness of God, the Liberty of Man, and the Origin of Evil." The writings of Leibnitz had long rendered his name famous in every part of Europe: he had honours bestowed upon him by several other princes, besides the elector of Hanover and Brandenburg, and in 1711 he was made Aulic counsellor to the emperor, and at the same period the czar Peter the Great appointed him privy counsellor of justice, with a pension of a thousand ducats. In 1714 his patron, the elector of Hanover, was raised to the throne of Great Britain, and in a short time Leibnitz passed over to England, where he received new marks of favour and friendship, and frequently made his appearance at court. It was during this visit, that, at the desire of the prince of Wales, afterwards queen Caroline, he engaged in a dispute with the celebrated Dr. Samuel Clarke, upon the subject of free will and other important metaphysical topics. This controversy continued till the death of Leibnitz, which event took place in 1716. He was author of many other works besides those already mentioned. His intellectual abilities and attainments entitle him to be ranked among those universal geniuses which at once surprize and benefit the world. With great strength of understanding, an excellent faculty of invention, and a most capacious and retentive memory, he united an uncommon degree of industry. Hence he was enabled not only to acquire much general knowledge, but to become eminent in

attainments of various kinds. The improvements which he made in the higher geometry and algebra, rank him among mathematicians of the first class. He thoroughly understood the doctrines of philosophy, both ancient and modern, and cast new light upon almost every branch of knowledge. In theology he was well read in the writings of the Christian fathers, and in the controversies of his own times. On history and jurisprudence he wrote in such a manner as might lead a reader to suppose that these subjects were his chief or only study. The philosophy of Leibnitz is a system formed partly on the Cartesian, and partly in opposition to the Newtonian theory. After the dispute respecting the discovery of fluxions, he became the violent opposer of our great philosopher. He even charged his system with having an impious tendency, because it asserted that the fabric of the universe, and the course of nature, would not continue for ever in its present state, but would require, in process of time, to be re-established, or renewed by the hand of its former. According to his own principles, deduced, as he thought, from the wisdom and goodness of the deity, and his principle of a sufficient reason, he concluded the universe to be a perfect work, or the best that could possibly have been made; and that other things, which are evil or inconvenient, were permitted as necessary consequences of what was best; that the material system, considered as a perfect machine, can never fall into disorder, or require to be set right; and that to suppose that God interferes in it, is to lessen the skill of the author, and the perfection of his work. Among many other of his notions (for an account of which see *LEIBNITZIAN Philosophy*) we may add this, that the acts of the soul and body proceed by necessary laws: the soul in its perceptions and volitions, and the body in its motions, without affecting each other; but that each is to be considered as a separate independent machine. The volitions of the mind are followed instantly by the desired motions of the body, not in consequence of those volitions in the least, but of the nice and well-adjusted machinery of the body. The impressions produced in the sensory have no effect on the mind, but the corresponding idea arises at that precise time, in consequence of a chain of causes of a different kind. Moreri, Maclaurin, &c. See *LEIBNITZIAN Philosophy*.

*LEIBNITZ*, in *Geography*, a town of Saxony, in the margravate of Meissen; 4 miles S. of Dresden.—Also, a town of the duchy of Stiria, on the Sulm; 16 miles S. of Gratz.

*LEIBNITZIAN PHILOSOPHY*, or the philosophy of Leibnitz, is a system of philosophy formed and published by its author in the 17th century, partly in emendation of the Cartesian, and partly in opposition to the Newtonian. The basis of Mr. Leibnitz's philosophy was that of Des Cartes; for he retained the Cartesian subtle matter with the universal plenitude and vortices; and represented the universe as a machine that should proceed for ever, by the laws of mechanism in the most perfect state, by an absolute inviolable necessity, though in some things he differs from Des Cartes. After Sir Isaac Newton's philosophy was published in 1687, he printed an essay on the celestial motions (*Act. Erud.* 1689), where he admits of the circulation of the ether with Des Cartes, and of gravity with Sir Isaac Newton; though he has not reconciled these principles, nor shewn how gravity arose from the impulse of this ether, nor how to account for the planetary revolutions and the laws of the planetary motions in their respective orbits. That which he calls the harmonical circulation is the angular velocity of any one planet, which decreases from the perihelium to the aphelium in the same proportion as its distance from the sun increases;

but this law does not apply to the motions of the different planets compared together; because the velocities of the planets, at their mean distances, decrease in the same proportion as the square roots of the numbers expressing those distances. Besides, his system is defective, as it does not reconcile the circulation of the ether with the free motions of the comets in all directions, or with the obliquity of the planes of the planetary orbits; nor resolve other objections to which the hypothesis of the plenum and vortices is liable. Soon after the period just mentioned, the dispute commenced concerning the invention of the method of *fluxions* (which see), which led Mr. Leibnitz to take a very decided part in opposition to the philosophy of Sir Isaac Newton. See *LEIBNITZ*.

The perfection of the universe, by reason of which it is capable of continuing for ever by mechanical laws in its present state, led Mr. Leibnitz to distinguish between the quantity of motion and the force of bodies; and, whilst he owns, in opposition to Des Cartes, that the former varies, to maintain that the quantity of force is for ever the same in the universe, and to measure the force of bodies by the squares of their velocities. See *FORCE*.

This system also requires the utter exclusion of atoms, or of any perfectly hard and inflexible bodies; the advocates of it allege, that, according to the law of continuity, as they call a law of nature invented for the sake of the theory, all changes in nature are produced by insensible and infinitely small degrees; so that no body can, in any case, pass from motion to rest, or from rest to motion, without passing through all possible intermediate degrees of motion; whence they conclude that atoms or perfectly hard bodies are impossible: because if two of them should meet with equal motions, in contrary directions, they would necessarily stop at once, in violation of the law of continuity.

Mr. Leibnitz proposes two principles as the foundation of all our knowledge; the first, that it is impossible for a thing to be, and not to be, at the same time, which, he says, is the foundation of speculative truth: the other is, that nothing is, without a *sufficient reason* why it should be, rather than otherwise: and by this principle, according to him, we make a transition from abstracted truths to natural philosophy. Hence, he concludes, that the mind is naturally determined, in its volitions and elections, by the greatest apparent good, and that it is impossible to make a choice between things perfectly like, which he calls *indiscernibles*; from whence he infers, that two things perfectly like could not have been produced even by the Deity: and he rejects a vacuum, partly because the parts of it must be supposed perfectly like to each other. For the same reason also he rejects atoms, and all similar particles of matter: to each of which, though divisible in *infinitum*, he ascribes a *monad* (*Act. Lipsiæ* 1698, p. 435.), or active kind of principle, endued, as he says, with perception and appetite. The essence of substance he places in action or activity, or, as he expresses it, in something that is between acting and the faculty of acting. He affirms absolute rest to be impossible, and holds motion, or a sort of *nîsus*, to be essential to all material substances. Each monad he describes as representative of the whole universe from its point of sight; and after all, in one of his letters he tells us, that matter is not a substance, but a *substantiatum*, or *phenomenè bien fondé*. (See *MONAD*.) He frequently urges the comparison between the effects of opposite motives on the mind, and of weights placed in the scale of a balance, or of powers acting upon the same body with contrary directions. His learned antagonist Dr. Clarke denies that there is a similitude between a balance moved by weights, and a mind acting upon

upon the view of certain motives; because the one is entirely passive, and the other not only is acted upon, but acts also. The mind, he owns, is purely passive in receiving the impression of the motive, which is only a perception, and is not to be confounded with the power of acting after, or in consequence of, that perception. The difference between a man and a machine does not consist only in sensation and intelligence; but in this power of acting also. The balance, for want of this power, cannot move at all, when the weights are equal; but a free agent, he says, when there appear two perfectly alike reasonable ways of acting, has still within itself a power of choosing; and it may have strong and very good reasons not to forbear. Collection of Papers which passed between Mr. Leibnitz and Dr. Clarke in 1715 and 1716, &c. Svo. 1717, p. 121. See LIBERTY.

The translator of Mosheim's Ecclesiastical History observes, that the progress of Arminianism has declined in Germany and several parts of Switzerland, in consequence of the influence of the Leibnitzian and Wolfian philosophy. Leibnitz and Wolf, by attacking that liberty of indifference, which is supposed to imply the power of acting not only without, but against motives, struck, he says, at the very foundation of the Arminian system. He adds, that the greatest possible perfection of the universe, considered as the ultimate end of creating goodness, removes from the doctrine of predestination those arbitrary procedures and narrow views, with which the Calvinists are supposed to have loaded it, and gives it a new, a more pleasing, and a more philosophical aspect. As the Leibnitzians laid down this great end as the supreme object of God's universal dominion, and the scope to which all his dispensations are directed; so they concluded, that, if this end was proposed, it must be accomplished. Hence the doctrine of necessity, to fulfill the purposes of a predestination founded in wisdom and goodness; a necessity, physical and mechanical, in the motions of material and inanimate things, but a necessity, moral and spiritual, in the voluntary determinations of intelligent beings, in consequence of prepotent motives, which produce their effects with certainty, though these effects be contingent, and by no means the offspring of an absolute and essentially immutable fatality. These principles, says the same writer, are evidently applicable to the main doctrines of Calvinism; by them predestination is confirmed, though modified with respect to its reasons and its end; by them irresistible grace (irresistible in a moral sense) is maintained upon the hypothesis of prepotent motives and a moral necessity; the perseverance of the saints is also explicable upon the same system, by a series of moral causes producing a series of moral effects. Mosheim's Eccl. Hist. by Dr. Maclaine, vol. v. p. 464. Svo. edit.

For an account of Leibnitz's famous doctrine of a *pre-established HARMONY*, we refer to that article; and for his account of monads to MONADS.

See on the subject of this article Maclaurin's view of Sir Isaac Newton's Philosophical Discoveries, &c. book i. chap. 4. or p. 79, &c. 4to edit. Brucker's History of Philosophy, by Enfield, vol. ii. p. 556, &c.

LEICESTER, commonly pronounced *Lester*, in Geography, the county town of Leicestershire, England, was formerly written *Lege-cætria*, *Legeocæster*, and in the Saxon Annals *Leger-cæster*; and during part of the heptarchy it was a city. Without referring it to a British origin, or entering into a discussion respecting the derivation of its name, and of its civil privileges from king Leir, it will amply satisfy every rational enquirer to commence its history at that period when the Romans had settled themselves

in this island, and held the natives in military subordination. As those conquerors marched from the south-east, towards the central and northern parts of the country, they could not have obtained possession of this district, till the intermediate places between it and the sea were subjugated, and competent garrisons established. Having accomplished this, and overpowered the Coritani, they took possession of the chief town of that people. This town, or strong hold, was the seat of the present Leicester, and, at the time of its conquest, was denominated *Ratæ* in the Itineraries of Richard, Antoninus, and Ravennas; but *Ragæ* in other writings. "The real name, therefore," says Mr. Whittaker, "must be equally *Ratæ* and *Ragæ*; the former implying the town to be fixed upon the currents, the latter importing it to be the capital of the kingdom." That the Romans had a permanent station here is unequivocally manifested by the tessellated pavements, and other remains that have been discovered at different periods; and, according to Antoninus, *Ratæ* was one of their stipendiary towns. The fofs-road in its way from Londinio, London, to Lindum, Lincoln, came by Venone; whence to *Ratæ* was twelve miles, and thence to Verometum thirteen miles; and these distances very nearly correspond with those between Claycheſter, Leicester, and Willoughby. That this station was formed on the northern bank of the Soar, that an artificial channel was cut for the water to flow up to, and constitute one boundary of the station, and that the Romans were settled here for some length of time, are circumstances easily proved, as ample evidences remain, and are recorded in support of these inferences. Many tessellated pavements, coins, urns, and other domestic and military relics of the Romans, have been discovered at different times: some of which are still carefully preserved as memorials of ancient art, but many of the most interesting objects must have been destroyed during the ravages of war which Leicester experienced under the Saxons, Danes, and Normans. Of the Mosaic pavements, that which was found in a cellar nearly opposite the town-prison, in the year 1675, is the most worthy of notice. But the most curious relic of antiquity, and one that has provoked the most copious dissertations, is the *milliary*, or Roman milestone, which was discovered in 1771, on the side of the Fofs-road, at the distance of about two miles north of the town, and thence removed into the town at the expence of the corporation: by this stone the station of *Ratæ* is clearly defined. In different parts of the town, and at distant periods of time, a great number of Roman coins have been found: among which were several with the names of Titus, Trajan, Dioclesian, Constantine the Great, Constantine Junior, Constantian, Hadrian, Theodosius, Honorius, &c. Here is also a curious fragment of Roman architecture, commonly called the Jewry wall; consisting of a mass of brick-work, stones, and rubbish, with dilapidated arches turned entirely of tiles, bound together by a large quantity of mortar. About a quarter of a mile south of the Infirmary are some artificial banks, known by the name of *radynes*, or *rasudykes*: these were formerly about four yards in height, and consisted of two parallel mounds of earth, extending 67 yards in length, at the distance of fifteen yards from each other. If these remains are not peculiarly worthy notice as works of art, they are curious as vestiges of remote times, and of a particular people.

The history of Leicester, during the Saxon heptarchy, is very vague and uncertain, though, from the concurrent testimony of all writers, it was certainly a place of considerable note from the departure of the Romans to the time of the Norman conquest. According to Godwin, a bishop's see was transferred from Sidnaceſter to Leicester in the year

## LEICESTER.

737. At this period the Saxon kingdom of Mercia had, according to some authors, three episcopal sees: Lichfield, Dorchester, and Leicester. From the Saxon annals, it appears that Ethelfrid, king of Northumberland, being an avowed enemy to Christianity, marched an army to Leicester, where he made a great slaughter of the inhabitants. Jowallensis relates that Ethelred, king of Mercia, and his queen Elfreda, who was daughter of Alfred the Great, repaired the town about the year 907, and rebuilt and enlarged the walls, which were now made to inclose the castle; previous to that period the castle appears to have been on the outside of the town. On the conquest of England by William the Norman, Leicester soon became part of the royal demesne, and a castle was either newly erected, or enlarged and strengthened to ensure the submission of the inhabitants, and those of the surrounding country. On the death of the conqueror, Leicester citadel, being held by the adherents of duke Robert, was nearly demolished by the successful partizans of William Rufus. In the reign of Henry I. Robert, earl of Leicester, repaired, enlarged, and fortified the castle, which he made his principal residence. He was very liberal to the town; as was also his son Robert Boflu; but the arrogant behaviour of the latter to the king involved this place in broils and war; it being the practice in those times for sovereigns to revenge themselves, for the offences of the nobles, on the people and places immediately under the patronage of the offenders. This was fatally experienced in the reign of Henry II. when earl Robert Blanchmaius, leaguely with the king's son in his unnatural rebellion, Leicester, the chief resort of the disaffected, was, after a long siege, almost destroyed, and the castle reduced to a heap of ruins. Scarcely any thing now remains of the latter building, but an artificial mound, or the earth work of the keep, near which is a part of the town with some ancient buildings, called "the Newark," or New-work. This name appears to have been given to distinguish it from the castle with its original buildings, which was considered as the old works. The Newark is said to have been founded by Henry, third earl of Lancaster, and his son Henry, the first duke of that name. By these two noblemen some large buildings were erected here; and John of Gaunt, who was earl of Leicester, added considerably to the pile. When completed, the whole must have formed a grand display; but nearly all of these have fallen beneath the devastating hand of man, and the slowly devouring tooth of time. From the remains of the surrounding walls, it is presumed that the Newark was an inclosed area, bounded on the north by the castle, on the south by fields, to the west by a branch of the river Soar, and to the east by a street of the suburbs. At this side is still remaining a large castellated gateway, called the *magazine*, which name it obtained in 1682, when it was purchased by the county, and applied to the use of the train bands. Throby says it "was built with the New-works, by the founder of the hospital and collegiate church." This gateway has a large pointed arched entrance with a small postern door way, and communicates with an area nearly surrounded with buildings.

Among the ancient religious houses and foundations of this town, the abbey was formerly of great local importance; but its buildings are nearly levelled with the earth which covers the abies of its inhabitants. It is said to have been founded in the year 1143 by Robert Boflu, earl of Leicester, who became one of the regular canons on his own foundation. The abbey soon acquired celebrity, and obtained numerous privileges. It was possessed of lands in thirty-six parishes in and about Leicester, and in most of the manors in this and many other counties. Several kings

of England, and other distinguished personages, were entertained and lodged at this house in a grand and sumptuous style. The once great and magnificent cardinal Wolsey died at this abbey, November 29th, 1530.

In this town was formerly a *mintage*; and the series of coins that have been collected, prove that at the Leicester mint, a regular succession of coinage has been produced from the reign of the Saxon king Athelstan down to Henry II. This series has been engraved in Mr. Nichols's valuable history of this town.

The first charter granted to Leicester was by king John in the first year of his reign; and at the same time Robert Fitz-Parnel, earl of Leicester, invested the burgesses with the power of buying and selling lands, &c. A charter, granted in the following reign by earl Simon de Montfort, shews the peculiar intolerance of the times; it specifies that "no Jew, or Jewess, in my time, or in the time of any of my heirs, to the end of the world, shall inhabit, or remain in" the town of Leicester. Henry VII. by charter dated 1504, confirmed all the previous privileges, and empowered the justices to take cognizance of treasons, murders, felonies, &c. A charter by queen Elizabeth specifies that the borough of Leicester is very ancient and populous, and from remote times has been a borough incorporate; and the former liberties and immunities are specified and extended. The corporation are thereby empowered, among other privileges, to refuse the building of malt-kilns within the distance of thirty yards from any other building. This charter also grants a market for wool-yarn and worsted, and for other commodities. All fines and amerements were ordered to be applied to the use of the poor. The corporation consists of a mayor, recorder, steward, bailiffs, twenty-four aldermen, forty-eight common-councilmen, and a town clerk; the freemen are toll-free of all the markets and fairs in England. As a parliamentary borough, Leicester has returned two members to the national councils from the time of Edward I. One of the representatives was formerly elected by the "mayor and his brethren," and the other by the commonalty. This mode having excited much popular disturbance, Henry VII. ordained that "the mayor and his brethren should choose forty-eight of the most discreet inhabitants of the town," who should elect all officers for the borough, and members of parliament. Thus it continued till the reign of Charles II.; from which time the right of election has been vested in "the freemen, not receiving alms, and in the inhabitants paying foot and lot." The number of voters is about 2000.

At the time of the Norman conquest, there appear to have been six churches in this town; and it would be highly interesting to the architectural antiquary to ascertain if either of the present structures contains any part of the building then standing. Of the religious edifices now remaining, St. Nicholas's church is esteemed the most ancient. It stands contiguous to the Jewry wall, and appears to have been partly constructed with the bricks, tiles, &c. taken from the fallen parts of that building; whence some antiquaries have thought that they are both parts of the same structure, or built about the same period. The church of St. Mary, distinguished by the addition of *infra* or *juxta* castrum, is a large pile of irregular building, composed of various specimens, or styles of architecture, from a very early period to a late one, when all styles were disregarded. These varieties tend to mark "the disasters of violence, accident, and time," and prove that the neighbourhood of the castle, within the outer ballium, or precinct of which it stood, was often most dangerous. That there was a church on this spot in the Saxon times seems almost certain, from some bricks, apparently

apparently the workmanship of that people, found in the chancel; and the chevron work round the windows of the chancel proves that the first Norman earl of Leicester, Robert de Bellomont, constructed a church on a plan nearly like the present, and adorned it with the architecture of his time. The interior of this church is spacious; and on the south side of the nave is a singularly large semicircular arch, having a span of thirty-nine feet. The fourth aisle is said by Mr. Carte to have been built by John of Gaunt. At the east end of this aisle was a chapel, or choir, held by guild, or fraternity, called the Trinity guild. This was founded, in Henry VIIIth's reign, by sir Richard Sacheverele, and the good lady Hungerford. Respecting this guild, the following list of articles, bought in for the year 1508, will serve to shew the value of money, and prices of provisions at that period. "A dozen of ale, 20*d.*; a fat wether, 2*s.* 4*d.*; seven lambs, 7*s.*; fourteen goslings, 4*s.* 8*d.*; fifteen capons, 5*s.*; half a quarter of malt, 2*s.*; four gallons of milk, 4*d.*; a pig, 5*d.*" At the west end of the church is a handsome tower, surmounted by a lofty and elegant spire. The latter has twice suffered from storms. Near the north door of this church is a passage leading under an old building which forms a gateway to an area called the castle yard. Opposite this gateway is a building, partly ancient, partly modern, within which is a large hall seventy-eight feet in length, fifty-one in width, and twenty-four feet high. This hall, during the reign of Lancastrian princes, was the scene of frequent parliaments; at present it is used only for holding the assizes and other county meetings. The church of All Saints is a small modern structure, consisting of a nave and two aisles, all nearly of the same length. The church of St. Martin, formerly called St. Cross, is a large old building, consisting of a nave, three aisles, and a tower, with a lofty crocketed spire. This church, being the largest in the town, and even in the whole county, is used at all the public meetings of the district for the bishop, judges, &c. The churchwardens' accounts respecting this church and parish are copious and well preserved. They begin in 1544, and contain many curious notices, descriptive of the peculiar manners and customs of the different times. In this church was held St. George's guild, a fraternity which was invested with peculiar privileges, and annually ordained a sort of *jubilee* in the town, called "the Riding of St. George." It contained also another guild called Corpus Christi, which Mr. Throsby says, "was the most ancient and principal in Leicester." The register of this parish records the calamitous effects of a plague which raged here in the years 1610 and 1611, during which period 166 persons were buried. In the marriage register is an entry of the names of Thomas Tiley and Ursula Ruffel, the first of whom being "deafe and also dombe," it was agreed by the bishop, mayor, and gentlemen of the town, that certain signs and actions of the bridegroom should be admitted instead of the necessary words. St. Margaret's church, according to Leland's account, is "the fairest church in that place, which once was a cathedral church, and near which the bishop of Lincoln hath a palace, whereof little yet standeth." This edifice consists of a nave, side aisles, chancel, and a handsome tower, and was annexed as a *prebend* to the college of Lincoln by the bishop of that diocese, at the time when the other churches were given to the abbey. Besides these churches, here are chapels or meeting-houses for different sects of dissenters, presbyterians, independents, and baptists. The county gaol, erected in the year 1791, at the expence of six thousand pounds, occupies the site of an old prison, and is built after the plan recommended by Mr. Howard, with solitary cells, &c. The town gaol is a commodious stone building, de-

signed by Mr. Johnson, a native of this town, and executed by Mr. Firmadge in 1792. The other public buildings are a free grammar school of great antiquity; several charity schools; various hospitals; an asylum for indigent lunatics; an exchange for public business; the hotel, now used as assembly rooms; and a commodious theatre. Among the curiosities of the town, is the old wooden bedstead said to have belonged to king Richard, and on which he slept, or rather reclined, the night preceding the battle of Bosworth.

The principal, and almost only article of manufacture in Leicester, is that of stockings, which has been an established and staple commodity here for above two centuries. It finds employment for a great number of persons, as hosiery, stocking-makers, wool-combers, dyers, frame-smiths, comb-makers, winders, sizers, seamers, spinners, hobbiners, sinker-makers, stocking-needle-makers, &c. &c. Mr. Throsby states that in Leicester there were "upwards of seventy manufacturers, called hosiery, who, it is computed, employ 3000 frames; including the wrought goods they individually purchase; about 6000 persons being directly or indirectly employed in this great business." This town and its vicinity, with Nottingham and its neighbourhood, are the principal places in England for the manufacture of stockings; the latter is the most noted for silk, and the finer sort of goods, while the former is chiefly devoted to the coarser articles, of which a very large quantity is annually made. The trade at present is very flourishing, and in the "Walk through Leicester" it is stated "that 15,000 dozen per week" of stockings are made on an average. (See *STOCKINGS*.) Leicester is 97 miles distant from London: the market is held on Saturdays; and seven fairs annually; all on a very large scale. This town was returned to parliament in the year 1801 as containing 3290 houses, and 16,953 inhabitants.

Among the natives of this town, of literary eminence, is Dr. Richard Farmer, who was born in 1735, and died in 1797. Nichols's *History and Antiquities of Leicestershire*, seven vols. folio. A Walk through Leicester, 12mo. is an interesting and well written topographical work.

LEICESTER, a township of America, in Addison county, Vermont, situated on the east side of Otter creek, containing 522 inhabitants.

LEICESTER, called by the Indian natives *Towatid*, a considerable post-town in Worcester county, Massachusetts, containing 1103 inhabitants; situated upon the post-road from Bolton to Hartford, New York, and Philadelphia; 6 miles W. of Worcester, and 54 W. by S. of Bolton; settled in 1703, and incorporated in 1720 or 1721. It has three meeting-houses for Congregationalists, Anabaptists, and Quakers; and an academy incorporated in 1784, and well endowed. Wool-cards are manufactured in this town.

LEICESTERSHIRE, called in the Domesday Survey *Leicestre-shire*, is an inland county, situated nearly in the middle of England, and environed by the counties of Rutland and Lincoln to the east, Nottingham and Derby on the north, Staffordshire and Warwickshire to the west, whilst part of the latter county and Northamptonshire attach to the southern border. A part of the great Roman road, called Watling-street, appears to have formed a regular division between Leicestershire and Warwickshire. The district included within these boundaries was, at an early period, a part of the territory belonging to the Coritani. After the Romans had subjugated the Britons, and had established colonies in different parts of the island, this county was included within the province of Flavia Caesariensis, and had military stations established at Ratæ (Leicester); Veru-

## LEICESTERSHIRE.

metum, on the northern border of the county; Benouæ, near High-Crofs; and Manduëddum, at Mancester. Thefe ftations were connected by regular artificial roads, or military ways, known by the names of Watling-Street, Foffe-Way, and Via Devana. The firft enters this county at Dow-bridge or Dovebridge, on the Northamptonshire border, where the ftation called Tripontium was fixed: hence to Manduëddum it called nearly in a ftraight line, having the fmall ftation of Benouæ on its courfe. Near this place the Foffe-Way intersects it at right angles, and paffes on to Ræte; whence it continues in a northerly direction to Ver-nometum, and thence on to Margidunum, a ftation near Eaft Britford, in Nottinghamshire. After the Romans had evacuated the ifland, this diftrict became part of the kingdom of Mercia; and when the fubdivision of the Anglo-Saxon provinces into counties was eftablifhed, and bifhops' fees created, the town of Leicefter was conftituted the feat of the diocefan. The Mercian kingdom was divided into fouthern and northern; and the inhabitants of Leicefterfhire were denominated Mediterranean, or Middle Angles. They were frequently haraffed by the invading Danes, who entering the diftrict from the eaftern coaft, laid the whole country under contribution between the German ocean and Leicefter; and having conquered this place, eftablifhed themfelves here for fome length of time: indeed, Leicefter was confidered as one of their five chief cities in the ifland. After the Norman invafion in 1066, Leicefterfhire experienced a complete revolution in its civil and manorial privileges; as the conqueror divided it among his relations and adherents. Two hundred and twenty-eight lordfhips, the chief parts of the county, were allotted and parcelled out to different Norman chiefs; who again regranted various allotments to their followers and dependants, to be held of them by knight's fervice. The king, the archbifhop of York, and the bifhops of Lincoln and Conftance, were alfo poffeffed of landed property in the county; and fome was annexed to the abbies of Peterborough, Coventry, and Croyland. The Norman chiefs, in order to fecure their newly-acquired poffeffions, foon built, on their refpective eftates, ftrong and magnificent caftles, which might at once fecure themfelves, and keep the conquered English in awe. The feveral townfhips, in which fuch caftles are known to have been created, with the names of the founders, are Leicefter, Mount Sorel, Whitwick, and Shilton, founded by the earls of Leicefter; Groby and Hinckley, by Hugo de Grentemaignell; Donington, by Eulface baron of Halton; Melton, by Roger lord Mowbray; Ravenon, by Goeffrid Hanfelin; Sauvey, by lord Baffet of Weldon; and Thorpe, by Ernard de Bois. Moft of thefe caftles, during the unequal reigns of Henry II., John, and Henry III., being held by the rebellious barons, and rendered receptacles of thieves and freebooters, were, by command of the latter king, utterly demolifhed; and though fome of them were afterwards rebuilt, yet at this day there is not one of them remaining entire, and even the ruins of moft of them are entirely defaced. The Norman chiefs, after fettling their poffeffions, and fortifying themfelves within their refpective domains, next directed their attention to the religious habits and prejudices of the times; as to fecure the favour and influence of the monks, in an age when they were almoft omnipotent, or at leaft could command and intimidate the whole community, was a neceffary branch of military policy, which the provincial barons neither overlooked nor neglected. Accordingly, part of their eftates were appropriated to the foundation of abbies, priories, nunneries, and other monaftic eftablifhments. In this county were founded four abbies, at Croxton, Garendon, Leicefter, and Olvefton; twelve priories, at Belvoir,

Bradley, Bredon, Charley, Hinckley, Kirkby Beler, Laund; at Leicefter were four, for Eremites, Black Friars, Grey Friars, and Auftin Friars; and Ulvefton; two nunneries at Grace Dieu and Langley; two collegiate churches in Leicefter; and various free chapels, hofpitals, preceptories, and chantries, in different parts of the county.

At the time of compiling that great national work, the Domefday Survey, Leicefterfhire was divided into four wapentakes or hundreds; Framland, Guthlaxton, Gartre, and Gofcote: and thus it continued till the 20th of Edward III., when an additional hundred, Sparkenhoe, was taken out of Guthlaxton; and afterwards Gofcote was divided into two, denominated, from their fituations, Eaft and Weft Gofcote. In thefe fix hundreds are 196 parifhes, and 12 market-towns, *viz.* Leicefter, Aftby de la Zouch, Bofworth, Hal-laton, Harborough, Lutterworth, Melton Mowbray, Mount Sorel, Billefdon, Hinckley, Loughborough, and Waltham on the Wold. The whole county is within the ecclefiaftical jurifdiction of the fee of Lincoln, and in the province of Canterbury; under one archdeacon, and fix deaneries. Mr. Nichols ftates, from the Domefday Survey, that the whole county, at the time that record was compiled, contained 34,000 inhabitants. The number returned to parliament, under the population act of the year 1800, was 130,081; of whom 23,823 are ftated to be employed in agriculture, and 42,036 in trade and manufactures: the number of houfes being 26,734. The representatives in parliament are but four: two for the county, and two for the borough of Leicefter. The circumference and extent of the county have not been fatisfactorily defined. Mr. Nichols ftates the former to be "about 150 miles;" whilft Mr. Monk fetts the fame down at "about 96 miles." The fuperficial contents are eftimated at about 540,000 acres.

This county has not any rivers of importance; but thofe which pafs through it are convenient and ornamental. The chief are the Soar, the Swift, the Welland, the Avon, the Wreke, and the Anchor. The Soar, anciently called Leire, which is the largeft of thefe, rifes from two heads or fources in the fouth-weftern part of the county, and, after receiving a fmall tributary ftream near Whetstone, paffes by the weft and north fides of the town of Leicefter.

Leicefterfhire being more an agricultural than a commercial diftrict, and deprived of any particular mines, has not equally participated with many other English counties in canal navigation. Some plans for this purpofe have been projected at different periods, and a few have been executed. In 1782, a bill was brought into parliament for making a navigable canal from Chilver's Coton in Warwickfhire, to pafs through a great part of Leicefterfhire; but being opposed by a variety of interefts, it failed of fuccefs. In 1780, another bill was introduced for opening a canal communication between Loughborough and Leicefter; but it was thrown out on the fecond reading. In 1791, another application was made with better fuccefs; and an act was obtained for making the faid communication: the proprietors are ftyled in this act, "the company and proprietors of the Leicefter Navigation." In the fame year, another act was obtained for making navigable the rivers Wreke and Eye: and in 1793, a bill was paffed for making the "Oakham Canal," from a town of that name in Rutlandfhire, to Melton Mowbray.

The whole of Leicefterfhire preffents nearly a flat furface, and is chiefly appropriated to the grazing fystem. It has obtained peculiar celebrity, among agriculturifts, for a breed of fheep, diftinguifhed by the name of the Shire: and the late Robert Bakewell of Difhley, acquired for himfelf and the county much popularity, by the experiments and

and improvements he made in the breed of cattle and sheep. Among the different breeds of sheep in the county, the Old Leicester, the Forest, and the New Leicester, or Dishley, constitute the principal flocks, and of them the latter is in the highest repute. The extraordinary price for which many of the New-Leicester-sheep have been sold at public auctions, and the large fums for which some of the rams and bulls have been let out for the season, serve at once to shew their estimation in public opinion, and the laudable zeal that prevails for improving the breeds of cattle, &c. At an auction of ewes, belonging to Thomas Pagett, esq., in the year 1793, the following fums were given:—Five ewes, at 62 guineas each; five, at 52 guineas each; five, at 45 guineas each; ten, at 30 guineas; and several at 25, 20, and 16 guineas each. One of these sheep, which was killed at Walgrave in Northamptonshire, was of the following weight: the carcase 144lb., blood 5lb., fat 16½lb., head and entrails 12lb., skin 18lb.; making in the whole 195½lb. It is no uncommon thing to fald down the mutton as a substitute for bacon. In the year 1793, Mr. Pagett fold several bulls, heifers, cows, and calves, by public auction, when some were bought at the following very extravagant prices: a bull, called "Shakspere," described in the catalogue as "bred by the late Mr. Fowler) by Shakspere, off young Nell. Whoever buys this lot, the seller makes it a condition, that he shall have the privilege of having two cows bulled by him yearly"—Four hundred guineas: a bull calf 31 guineas; a three years old heifer 70 guineas; others at 35 and 32 guineas each; a two years old heifer at 84, and another at 60 guineas.

It will be difficult to define the soils of the whole county. Very little of the land can with propriety be called a mere sand or gravelly soil; nor is there any great quantity that may properly be called clay. The best soil is upon the hills; and the worst, or nearest approaching to the clay or cold lands, in the vallies; though there are many exceptions to this rule. The soil, or what the farmers generally call *mould*, is generally deep, which makes it very proper for grafs; such deep soils not being very soon affected by dry weather. About Lutterworth, some part is a light rich loam, excellent for turnips and barley; a part stiff, inclining to marle, or rich clay; the remainder, chiefly a fort of medium between both, with a subsoil inclining to marle, bearing excellent crops of oats and wheat, and good turnips also, though not so well adapted for being eat off the land by sheep. Molt of the land round Hinckley is a good mixed soil, bearing good crops of grafs. Ahyde-la-Zouch, and the northern parts of the county, exhibit various soils, sand, gravel, loam, and clay. In Melton Mowbray the soil is in general a heavy loam; and immediately underneath a very stiff impervious clay, mixed with small pieces of lime-stone. These lands are very wet in winter, and the turf so tender, as scarcely to be able to bear the treading of sheep, without injury. At Market Harborough the soil is in general a very strong clay, chiefly in grafs.

Since the commencement of the last century, cheese has become an article of some importance to the Leicestershire farmers; and a large cheese-fair is annually held in the county-town. Among the different sorts manufactured in the county, that called Stilton cheese is deemed the finest, and consequently obtains the highest price. It acquired the title of Stilton from a place of that name, on the great North road in Huntingdonshire, where it is well known to have been first publicly sold by retail. This cheese is sometimes called the Parmesan of England, and is usually formed in square vats. The cheeses seldom weigh more than twelve

pounds each, and from that to six pounds is the general average weight. They are sometimes moulded in nets, but this mode is not deemed so eligible as that of the vat. A considerable quantity of this cheese is made on the farms about Melton Mowbray.

Leicestershire is described by Mr. Marshall, in his "Rural Economy," as a very fertile district; and the only parts which are not absolutely in good cultivation, are Charnwood-Forest, also a tract of land in the northern part of the county, called the Wolds or Woulds, and another similar tract on the southern side. Nichols's History and Antiquities of Leicestershire, 7 vols. folio.

LEIDENS DORF, a town of Bohemia, in the circle of Leitmeritz; 20 miles W. of Leitmeritz.

LE JEUNE, in *Biography*. See CLAUDE.

LEIGE, See LIEGE.

LEIGH, Sir EDWARD, in *Biography*. See born at Shadwell, in Leicestershire, in the year 1602. He received the rudiments of learning at Walsal, in Staffordshire, and in 1616 was entered a commoner of Magdalen-hall, in the university of Oxford. From the university, he went to study the common law in the Middle Temple. When the plague broke out in 1625, he went into France for a short time, and returning thence, he applied himself most sedulously to his studies, which comprized not only the law, but divinity, history, and the learned languages. During the civil wars he was chosen member of parliament for the town of Stafford, and was one of the persons appointed to sit in the assembly of divines. He was greatly distinguished for the talents and learning which he displayed in the debates of that assembly. In the year 1648, when the Presbyterian party was excluded from the house by the army, he was in the number of proscribed members, and was for some time kept in confinement. From the period of his liberation till the restoration, he chiefly employed himself in prosecuting his literary studies, and in publishing various works, which discover profound erudition and general knowledge. He died in 1671, at the age of 69. He was author of "Selected and choice Observations concerning the twelve Cæsars;" "Analecfa Cæsarum Romanorum;" "A Treatise of divine Promises;" "Critica Sacra," in 2 vols. 4to; "Annotations on all the Books of the New Testament;" "A Philological Commentary, or an Illustration of the most obvious and useful Words in the Law;" "A System of Divinity;" "Annotations on the five poetical Books of the Old Testament, viz. Job, Psalms, Proverbs, Ecclesiastes, and Canticles;" "Choice Observations on all the Kings of England, from the Saxons to the Death of King Charles I." Gen. Biog.

LEIGH, CHARLES, a physician of the seventeenth century, was born at Grange, in Lancashire. He graduated at Cambridge, and afterwards practised in London with considerable reputation. He was admitted a member of the Royal Society in May 1685. He left the following works: "The Natural History of the Counties of Lancashire, Cheshire, and Derbyshire, &c." Oxford, 1630, folio. London, 1700, with plates. "Pththiologia Lancastrienfis, cum tentamine philosophico de Mineralibus Aquis in eodem comitatu observatis," London, 1694, 8vo. "Exercitationes quinque de Aquis Mineralibus, Thermis calidis, Morbis acutis, Morbis intermittentibus, Hydrope," ibid. 1697. "History of Virginia," drawn up from observations made during a residence in that country, London, 1705, 12mo.

LEIGH, *Wells*, in *Geography*, a market town in the hundred of West Derby, Lancashire, England, is situated six miles from Wigan, and 198 from London. The church

is a handsome structure, with a square tower; the body being supported by two rows of pillars. Leigh has a considerable manufacture of fustian and other cotton stuffs; and by its canal navigation, which communicates with the rivers Mersey, Dee, Ribbles, Ouse, Severn, Humber, Thames, Avon, &c. it carries on an extensive traffic. Coals are abundant; and the dairies round the town produce excellent cheese. The town, according to the official report in 1801, contained 277 houses, and 1429 inhabitants. A weekly market is held on Saturdays; and a fair on the 26th of April. The parish is of great extent, and contains the townships of Aitley, Bedford, Pennington, and Tyldesley, the hamlet of Shacklesley, and the chapelry of Chowbent, inhabited altogether by nearly 13,000 persons.

The chapelry of Chowbent has greatly increased in houses and population within the last 20 years. Its chapel, though regularly consecrated by the bishop of Sodor and Man, is exempt from episcopal jurisdiction, and the patronage is vested in the proprietor of Atherton Hall, which formerly was the seat of a family of that name, but is now the property of the Hon. T. Powis. The house, which was built by Gibbs, is large, and has a spacious cubical entrance hall. A plan of this mansion is given in the "Vitruvius Britannicus."

The township of Tyldesley has grown up with the manufactures of the county. A family of that name was seated here so early as the reign of Henry III. Of this family was Sir Thomas Tyldesley, who signalized himself during the troubles of Charles I.'s reign, and fell in the battle of Wigan lane, August 25, 1650. He was buried in Leigh church; and on a pillar near Wigan is fixed a brass plate, with an inscription to perpetuate his memory. Beauties of England, vol. ix.

LEIGH'S *Island*. See COCA-NUT *Island*.

LEIGHLIN, a bishopric of Ireland, in the province of Dublin, founded in 632, and united with Ferns in 1600. The united bishopric comprises the whole counties of Carlow and Wexford, with part of the Queen's county, Wicklow, and Kilkenny. There are 232 parishes in the union, forming 79 benefices, in which are 71 churches and six glebe houses. The cathedrals are small, and serve for parish churches. The residence of the bishop is at Ferns.

LEIGHLIN, *Old*, a village of Ireland, near the river Barrow, and in the county of Carlow, 2½ miles W. by N. from Leighlin bridge. It was incorporated in the year 1216, and continued to send members to parliament till the Union; and is still the seat of the cathedral church of the diocese.

LEIGHLIN *Bridge*, a post-town of Ireland, in the county of Carlow, on the river Barrow, over which it has a bridge, first built in the year 1320. It originated in a monastery, which, on the suppression of religious houses, was converted into a fort to protect the bridge; and lately, on account of the navigation of the Barrow, it has considerably increased, being now a thriving town. It is 45 miles S.S.W. from Dublin, on the Great Southern road, and six miles from Carlow.

LEIGHTON, ALEXANDER, in *Biography*, a Scotch presbyterian divine, was born at Edinburgh in 1587. He became noted for the sufferings which he endured in the reign of Charles I., on account of a work which he published, entitled "An Appeal to the Parliament; or Zion's Plea against Preacy." For this he was tried in the high-commission court, and being convicted, which, in those days, and in that court, was but another term for being accused, he was condemned to be imprisoned for life, and pay a fine

of 10,000*l.*: he was to be fet in the pillory twice, and to be whipt, have one of his ears cut off, one side of his nose slit, and be branded in the face with a double S.S. as a fower of sedition. When this savage sentence was passed on him, the cruel Laud exhibited signs of the most indecent joy, and publicly gave God thanks for it. Excepting the imprisonment for life, and the fine, the sentence was put into execution to the full extent. He was released by the Long Parliament after an imprisonment of ten years. His confinement and cruel usage had so impaired his health, that when he was released he had scarcely the power of walking, or seeing, or hearing. As a sort of remuneration for his troubles the parliament appointed him keeper of Lambeth palace, at that time converted into a prison. He died in 1644, infane. Toulmin's Neale's Hist. vol. ii.

LEIGHTON, ROBERT, a Scotch prelate in the seventeenth century, was son of the preceding. He was educated in Scotland, where he distinguished himself above his contemporaries, in all the branches of useful learning, particularly in the study of the scriptures. Having finished his course of academical studies he went to the continent for improvement, and spent some years in France. On his return he obtained Presbyterian ordination, and was chosen to a congregation at Newbattle, near Edinburgh. Very soon after his settlement at this place he conceived a dislike to the Presbyterian form and manner of church discipline, and chose rather a life of retirement than to attend at the presbytery. His main object was to instruct his flock in the principles and duties of religion and morality, urging them not to trouble themselves with religious and political disputes. In the year 1648, he declared himself for the engagement for the king, on account of which he would have exposed himself to much trouble, had not the earl of Lothian, who lived in his parish, proved his friend, and prevailed with the men in power not to molest him. At length, finding that he could no longer submit to the ecclesiastical impositions of the Presbyterians, and being unwilling to live in strife and contention, he resigned his parish in silence, and withdrew into retirement. Shortly after, he was chosen principal of the college of Edinburgh, the duties of which office he performed with great reputation during ten years. Upon the restoration, when it was determined to establish episcopacy in Scotland, Leighton was fixed on as a proper person for the mitre. He was consecrated, with other bishops, at Westminster; he would now gladly have promoted some plan for uniting the Presbyterians and Episcopalians, but was thwarted in all views on this subject. When he found that the government was determined to enforce conformity on the Presbyterians by the most rigorous measures, he laboured with all zeal to shew the impolicy of such proceedings; but he struggled ineffectually against the current, and all that he could do was to practise, in his own diocese, the moderation which he had recommended generally, and to set an edifying example to the rest of his dignified brethren. These, however, profited but little either from his advice or from the exemplary conduct which he manifested. He remonstrated with the king respecting the arbitrary proceedings of the ecclesiastical high-commission court, and more lenient measures were promised to be pursued with respect to Scotland. He begged permission to resign his see; but the king, so far from listening to the prayer of his petition, urged him to accept of the diocese of Glasgow, which was a more important bishopric, and one in which he might be more useful. To induce him to accept of this preferment, he was promised the assistance of the court in bringing about his favourite scheme of a comprehension of the Presbyterians. He accepted the see, but after a short time found himself

himself wholly unable to carry on his great designs of healing the divisions, and reforming the abuses in the church, and begged permission to retire into private life, which was at length granted him. He went to live in Suffex, where he occupied himself in doing all the good in his power. He died in 1634, at about the age of eighty. He was author of "Praelationes Theologicae:" "A Commentary on the first and second Chapters of the first Epistle of St. Peter;" and of "Sermons," including other pieces: to the volume of sermons, published in 1758, is prefixed a life of the author, to which the reader is referred for ample particulars of this excellent divine.

LEIGHTON, Sir WILLIAM, knight, one of the honourable pensioners, who seems to have been a dilettante of considerable erudition in music; he published, in 1614, "The Tears or Lamentations of a forrowful Soul," composed with musical airs and songs, both for voices and divers instruments. The best composers of the time contributed to this publication. See LAMENTATIONS.

LEIGHTON-BUZZARD, or *Beaufort*, in *Geography*, a market town and parish in the hundred of Manshead and county of Bedford, England, is situated on the banks of the river Ouse, 41 miles from London, and contained, according to the return made in 1800 to parliament, 387 houses and 1963 inhabitants, of whom 1014 were stated to be employed in trades and manufactures. The market, which is held on Tuesdays, is one of the most ancient in the county; the tolls were valued at 7*l.* per annum at the time of the Norman survey. Here are six annual fairs, of which two were granted in the year 1447. The principal antiquity in the town is a beautiful pentangular cross, built of stone, and situated in an open area near the market-house: it is supposed to have been erected about the beginning of the fourteenth century. It consists of two stories; and the whole height is thirty-eight feet. (For a particular description, with an engraving, see Britton's *Architectural Antiquities of Great Britain*, vol. i.) The church is a large antique building, which, from the various grotesque carvings, appears to have been built about the same time as the cross; and is constructed with the same sort of stone. It has a square tower, surmounted by a spire, the whole being 193 feet in height. A priory of foreign monks was established in the reign of Henry II at a place called Grovebury, within this parish: and here was also a house of Cistercian monks, which was a cell to Woburn abbey. About half a mile from the town are the remains of a Roman encampment; from which, and other corroborating circumstances, Leighton-Buzzard is supposed to be the Lygeanburg of the Saxon Chronicle, which, with several more towns, was taken from the Britons by Cuthwulph, A.D. 571. Lyfons's *Magna Britannia*, vol. i. 470.

LEIGNE-SUR-USSEAU, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Châtelleraut. The place contains 311, and the canton 5127 inhabitants, on a territory of 142½ kilometres, in 13 communes.

LEILAM, or LEYLAM, a town of the Arabian Irak; 30 miles N. of Bagdad.

LEIMA, a river of Russia, which runs into the Irtisch; 24 miles N. of Tobolsk.

LEINA, or LEINE, a river of Westphalia, which rises in the territory of Eichfeld, passes by Heiligenstadt, Göttingen, Hanover, &c. and joins the Aller about two miles below Zelle.

LEINA, a town of Germany, in the principality of Gotha; 4 miles S.S.W. of Gotha.

LEINE, a river of Germany, which runs into the Neffsa 4 miles N. of Gotha.

LEINEN ZEM, a town of Prussia, in the palatinate of Cullm; 9 miles E. of Thorn.

LEININGEN, or LINANGE, lately a county of Germany, bordering on the bishoprics of Worms and Spire, and almost surrounded by the palatinate. The soil is fertile in corn, fruit, and wine; the forest abounds with game, and it has also mines of copper and iron, and quarries of stone. By the peace of Luneville it was annexed to France.

LEININGEN, a town of France, in the department of Mont Tonnerre, the castle of which was demolished by the French; 11 miles S.W. of Worms. N. lat. 49° 30'. E. long. 8° 4'.

LEINLETTER, a town of Bavaria; 10 miles S.E. of Bamberg.

LEINSTER, the eastern province of Ireland, comprising twelve counties, viz. Louth, Dublin, Wicklow, and Wexford on the sea-coast; Meath, Westmeath, Longford, King's county, Queen's county, Kildare, Carlow, and Kilkenny. This was originally one of the kingdoms into which Ireland was divided at the time of the English invasion, and it was the sovereign of it who facilitated the conquest by soliciting aid from Henry II. and giving his daughter in marriage to earl Strongbow. The English pale was entirely within this province, and it is, on the whole, that which is most populous and best cultivated.

LEIOBATUS, in *Ichthyology*, a name given by Aristotle and Athenæus to a species of the ray-fish, called by many of the old authors *bat marinus*, and by the later authors *leisirraia*, or *raia oxyrynchus*; which see.

LEIOPODES, formed of *λεως*, light, and *πους*, foot, an epithet used by the old medical writers to express such persons who had feet perfectly smooth and even at the bottom, without the usual hollow between the heel and the fore part of the foot.

LEIPHEIM, in *Geography*, a town of Bavaria, in the territory of Ulm, on the S. side of the Danube; 11 miles N.E. of Ulm.

LEIPNIK, a town of Moravia, in the circle of Prerau; 6 miles N.E. of Prerau. N. lat. 49° 28'. E. long. 17° 35'.

LEIPODERMOS, from *λιπος*, to be deficient, and *δερμα*, the skin, one who has lost the prepuce.

LEIPSICK, or LEIPZIG, in *Geography*, a city of Saxony, and capital of a circle of the same name. This is one of the most celebrated towns in Germany, pleasantly situated in a fertile plain, on the river Pleisse. Its circuit is estimated at 89½ paces; and its suburbs are extensive, and consist of good buildings and gardens, being separated from the town by a fine walk of lime trees, which runs round the town, and in the town ditches are planted mulberry trees. Its university, which is famous, was founded in 1409, and contains six colleges, two good Latin schools, and two celebrated societies, viz. a German society, and another for the encouragement of the liberal arts. Leipsick is one of the principal trading towns in Germany, and it is in a peculiar degree the mart of German literature. Besides its foreign commerce, it has three celebrated fairs, at Easter, Michaelmas, and the beginning of the year, at which foreign and domestic wares afford an extensive trade. It has also a distinguishing privilege, consisting in the right of having all staple commodities, imported within the circuit of 60 miles, unladen here, and at least for three days offered for sale to the burghers of the place, and then carried away without being unladen any where else. In the citadel, called Pleiffenburg, situated on the Pleisse, are a mint, founded in

1752; and a chapel for the Roman Catholic worship. The market place, which is spacious, and the council-house, stand in the centre of the town. The exchange is a good building, and the roof of its hall is well painted. The city contains eight parish churches for Lutherans, and also a place of worship for Calvinists. The manufactures are various; consisting of gold, silver, silk, wool, and linen yarn, which are wrought here; and also of stuffs, velvets, stockings, cloths, and linen. Here are also houses for the dyeing of silk, the printing of cotton, and the making of tapestry. Leather, Prussian blue, &c. are prepared here, and the Orphan-house is appropriated to the culture of silk. In Leipzick are supposed to be 20 bookellers, 50 French and Italian merchants and tradesmen, 150 wholesale dealers, 250 retailers, and many dealers in cloth. According to Dithmar, in his Chronicle, this place subsisted, as a town, as long ago as the year 1015. The circle of Leipzick contains 33 towns, and more than 1000 villages. The city is 56 miles W.N.W. of Dresden. N. lat.  $51^{\circ} 13'$ . E. long.  $12^{\circ} 19'$ .

Leipzick, as well as Dresden and the whole of Saxony, keep accounts in six-dollars of 24 good groschen; each grosche being divided into 12 pfenings current. A specie six-dollar is reckoned at 15 six-dollar current, or 32 good groschen. For the coins, see SAXONY. Bills of exchange are paid at Leipzick, since 1786, in Saxon currency, or in August d'ors, Carl d'ors, Fredericks, &c. reckoned at five six-dollars. The time of payment of bills of exchange, presented for acceptance during the four first days of the fair, is during the five first days after the close of the fair is proclaimed; in default of which the bills must be protested before 10 o'clock at night, or the drawer is not liable.

During the fair, when Dresden was in its glory, serious operas were frequently performed at Leipzick by the best musicians, vocal and instrumental; and to the greatest personages in Germany. In 1774, the comic operas of M. Hiller, in the language of the country and without recitative, were the favourite amusements of that flourishing city. Every part of Europe, except Italy, seems unanimous in banishing recitative from their comic operas, indeed every nation has melodies of its own; but there is no recitative, except the Italian, which is fit for dramatic purposes.

LEISZNIG, a town of Saxony, in the circle of Leipzick, on the Mulda, containing two churches, and having manufactures of cloth, lace, stockings, &c. It has a citadel, called Milddenstein; 24 miles E.S.E. of Leipzick. N. lat.  $51^{\circ} 7'$ . E. long.  $12^{\circ} 50'$ .

LEITA, or LEYTHA, a river that rises in the S.W. part of Austria, and joins the Raab at Raab in Hungary; and afterwards, the united stream runs into a branch of the Danube; nine miles W. of Comorn.

LEITH, a sea-port town and burgh of barony, situated on the Frith of Forth, in the county of Midlothian, Scotland. It is about two miles distant from Edinburgh, and may not improperly be called the harbour of that northern metropolis. This town was originally denominated Inverleith; the word *inver*, prefixed to the name of a river, being a frequent appellation in Scotland, and implies a town near the mouth of that river, or its confluence with another. The etymology of this term is very uncertain, some alleging it to be of French, and others of Gaelic derivation.

The period at which Leith was first founded is unknown, but it is undoubtedly a place of great antiquity. It is mentioned by the name of Inverleith in the charter for erecting the abbey of Holyrood, which was built by David I. in the

year 1128. About a century afterwards the harbour of Leith and its mills were granted to the magistrates of Edinburgh by Robert I., and in 1298 they acquired all the other rights and privileges of it, with the exception of the superiority from Logan of Restalrig. Mary of Guise, queen regent of Scotland, constituted this town a burgh of barony in the year 1549. At this time the inhabitants of Leith were divided into four classes, or corporations; the mariners, maltmen, tradesmen, and traffickers, each of which still retains its original charters. In the same reign, the citizens purchased the superiority of their town from the descendants of Logan, but after the death of the queen, Francis and Mary, in violation of the private rights of the people, sold the superiority of the burgh to the magistrates of Edinburgh, to whom it has since been confirmed by several successive charters. Leith suffered considerably when the earl of Hartford invaded Scotland in the year 1541, being on that occasion pillaged and burnt by the English soldiers. After this, however, Leith was rebuilt and fortified anew, but soon after the expulsion of the French in 1560, the council of the kingdom, to prevent the danger arising to the liberties of the country, from the introduction of foreign troops, ordered the fortifications to be demolished. Oliver Cromwell once more raised fortifications for its defence. The citadel, which still remains, was built by that usurper. It then consisted of five bastions, but two of them were entirely demolished at the restoration of the English monarchy, and the site of the whole given to the duke of Lauderdale, then prime minister for Scotland, from whom the magistrates of Edinburgh were compelled to purchase it, at the enormous sum of 6000*l.* sterling. Since the alarm, excited by the appearance of Paul Jones in the Frith of Forth, a battery of nine guns has been erected a little to the westward of the citadel, for the defence of the port and shipping. A party of artillery constantly reside at this battery, which is kept in excellent order; and of late a considerable park of artillery has likewise been stationed here.

Leith is divided into two parishes by the river from which it derives its name. These are distinguished by the appellations of North and South Leith, and communicate with each other by means of two drawbridges, one of which has been very lately erected. The greater part of the town is situated in the parish of South Leith, which also extends over a considerable country district, and includes the ancient parish of Restalrig. North Leith is a much smaller parish, and consists of only about 170 acres. Both on the south and north side of the river, the streets of this town are extremely irregular, and of mean appearance. In the suburbs of South Leith, however, a number of respectable houses have been erected by the more opulent merchants, and may be said to vie, in internal accommodation and exterior appearance, with those of Edinburgh.

Prior to the year 1771, Leith was ill supplied with water, and the streets were neither properly cleaned nor lighted; in that year, however, an act of parliament was obtained to remedy these defects; and the great change which has taken place since that period shews the good effect of the act, and that it had been judiciously prepared and was carefully executed. At Restalrig are still extant some ruins of the old or mother church. This place is about a mile eastward of Edinburgh. The church was founded by king James III., and endowed by the three succeeding monarchs. It was highly ornamented with statuary and sculpture, representing many objects of religious worship. In 1650, the general assembly, in their zeal against Popery, ordered this church, as a monument of idolatry, to be pulled down and entirely demolished. In consequence of this mandate, the inhabitants of South Leith

Leith resorted for divine worship to the chapel of St. Mary, which was afterwards declared by authority of parliament to be the parish church of the district. It is a handsome spacious building; but being found insufficient to contain the inhabitants, a chapel of ease was erected in 1772. Here is also an episcopal chapel; and, as in all towns of any consequence in Scotland, some meetings of Presbyterian dissenters.

The civil government of Leith is vested in a magistrate sent from Edinburgh, having the power and title of admiral of Leith, and in two residing bailiffs, who are elected from the inhabitants of Leith by the town-council of Edinburgh.

The harbour of Leith, which is the chief source of wealth to the place, is formed by the conflux of the water of Leith with the sea. The depth of the water at the mouth of the harbour is at neap tides about nine feet, but in high spring tides about sixteen. It is entirely a tide harbour; the water in the river being too trifling to give any important aid towards the navigation. About the beginning of the last century, the magistrates of Edinburgh improved the harbour at a great expence, by extending a stone pier to a considerable distance into the sea. In the year 1777, they further improved it by erecting an additional stone quay towards its west side. It is accommodated with wet and dry docks, and other conveniences for ship-building, which is carried on to a considerable extent; and vessels come hither to be repaired from various parts of the eastern coast of Scotland. It has been thought advantageous to extend the harbour further into North Leith; and very considerable works are now carrying on for that purpose; which, when completed, will render it a very spacious, as well as a safe and convenient station for trading vessels of almost any burthen. Ships, indeed, can only enter at full tide; but the roads of Leith, which are about a mile from the mouth of the harbour, afford most excellent anchorage at all times.

Leith carries on a very considerable trade; the imports from the southern parts of Europe are wines, brandy, and fruits; from the West Indies and America, rice, sugar, rum, and dye-stuffs; but the principal traffic is with the Baltic, for which it is peculiarly well situated. The shipping of Leith causes a great demand for ropes and sail-cloth; of which articles here are several manufacturing companies. Two glass manufactories are established here, which, in the year 1790, wrought above nine million pounds weight of that article. The manufactures of soap and candles are also carried on to a very great extent; here are also a considerable carpet manufactory, and several iron forges. In 1784, the trade of Leith was estimated at half a million sterling, exclusive of glass-works and ship-building; and there is every reason to believe that, since that period, the amount has been doubled. In the year 1791 the population of North Leith was 2409, and of South Leith 11,432; total 13,841, which was an increase of 4436 since the year 1755. Beauties of Scotland, vol. i. Picture of Edinburgh.

**LEITH Water**, a river of Scotland, which runs into the Forth at Leith.

**LEITHEN**, a river of Scotland, which runs into the Tweed at Inverleithen.

**LEITMERTZ**, a city of Bohemia, in a circle of the same name, seated on the Elbe, well built, and populous; the see of a bishop, suffragan of Prague.

The circle, distinguished by its beauty and fertility, is called the "Bohemian Paradise;" and, independently of its own resources, it has ample supplies, by means of the Elbe, from other countries. It is famous for the wines, produced near Auzitz, and called "Podskalky," and for the

salubrious mineral waters of Topolitz. In this circle, which comprehends 89 feignories, estates, and feats, are tin and precious stones; 28 miles N.N.W. of Prague. N. lat. 50° 31'. E. long. 14° 15'.

**LEI RIM**, a county of Ireland, in the province of Connaught, which is bounded on the north by Donegal and Fermanagh; on the east by Cavan; on the south by Cavan, Longford, and Roscommon, and on the west by Sligo. In form somewhat like an hour-glass, it varies greatly in breadth, being in the widest parts 16, and in the narrowest only six miles across. Its length is 41 Irish, or 52 English miles. It contains 255,950 acres, or about 400 square miles (407,260 acres, or 652 square miles in English measure.) The parishes are 17 in number, partly in the diocese of Kilmore, and partly in that of Ardagh. There are very few unions, and a church in almost every parish. When Dr. Beaufort wrote, the number of houses was rated at 10,026, from which he estimated the population at upwards of 50,000; but Mr. Robertson in 1806, on what authority he has not stated, rates it at 76,630. Of the five baronies into which Leitrim is divided, the two northern are not as populous as the other three. Towards the sea there is an assemblage of wild and lofty mountains, which are divided from one another by deep vallies. These are the mountains of Sliebh-anewr and Dartry, the latter of which towers to an immense height above the level of the sea. Near the interior, the immense Sliebh an-Erin divides the mountainous from the level parts of the country. These great hills are far from unprofitable, for producing abundance of coarse grass, they annually pour forth immense droves of young cattle. The southern baronies are level. Few counties are so plentifully watered as this. The Shannon rises in a plain at the base of Quilca mountain, forming Lough Clean, a small lake, which is considered as the fountain of that noble river; from this it flows to Lough Allen, nearly in the centre of the county, which is 7 miles long and about 30 in circumference; and then, curling in a variety of forms, it glides by Carrick on Shannon, where it leaves the county, taking a southern direction. There are several other lakes and small streams, which are stored with trout, pike, eel, perch, and bream. The natural wants of this county seem abundantly outweighed by its numerous minerals. Iron ore is contained in great quantities in the high grounds. Deep and rich beds of it are also found on the lower grounds; and a vigorous search would undoubtedly discover it in almost every situation. Copper and lead are also met with, but not in such quantities. Coal in deep and rich strata is visible in many places. A variety of clays and plenty of limestone gravel are likewise found. The soil is exceedingly diversified. A rich dark soil on a limestone bottom, a ferruginous loam on the mountains, and an argillaceous stratum, are its chief characteristics. Great quantities of bog and moor tend to interrupt the general fertility of the county. The mode of agriculture adopted by the farmers is injudicious in many particulars. Potatoes, barley, rye, and wheat, are reared in small quantities; oats in abundance for home consumption. A considerable portion of the land is pasture. The farms are small, and generally occupied in common by a number of tenantry. Draining is greatly neglected. Manufactures are rapidly improving, particularly that of linen. There are several bleach-works. Potteries are numerous about Leitrim and Dromahare. The traveller who is anxious for variety, will no where find it in greater perfection than in Leitrim. Extensive tracts of waste may be contrasted with rich lands. The uniform and regular improvements of art are lost in the wild grandeur of picturesque natural disorder. The dale is frequently terminated by the stupendous mountain,

tain, and the beauties of the rich luxuriant woods on the demences, are enriched by the vicinity of beautiful sheets of water. Near a century ago, the county was a continued forest. Immense heaps of charred timber are seen at Dromthambo. A considerable time ago, great exertions were made to plant woods, and it now abounds with almost every variety which the nursery can afford. No town of any size ornaments the county. Carrick on Shannon is the shire town, but does not contain above 100 houses.

"The obstacles," says Mr. Robertson, "which have so long retarded the improvement of Leitrim, have been occasioned by the inhabitants, not by nature; she has made ample store for the exertions of their industry, by bestowing on them valuable minerals. These, however, have not been wrought with sufficient activity, and the public have as yet received little benefit from them. The want of water-carriage has likewise had a great effect; but this promises to be speedily obviated. Pasturage being pursued to a considerable extent, has in a great degree impeded the general improvement. The consequent want of population has retarded the cultivation of the bog and other waste land. But when the true interest of the people shall be sufficiently understood, the minerals will be wrought, pasturage will be supplanted by tillage, the bogs and moors will be covered with luxuriant crops, and in the end Leitrim will become one of the most wealthy counties in Ireland." Beaufort's Memoir; Robertson's Traveller's Guide.

LEITRIM, a small town of Ireland, which gives name to the county, but is not considerable enough to be a post-town. It is three miles N. by E. from Carrick on Shannon, and situated on the river Shannon.

LEITSHACH, a town of the duchy of Stiria; 13 miles N.W. of Marburg.

LEITURGI, *Athens*, among the *Athenians*, persons of considerable estates; who, by their own tribe, or the whole people, were ordered to perform some public duty, or supply the commonwealth with necessaries at their own expences.

LEITZKO, in *Geography*, a town of the Middle Mark of Brandenburg, insituated in the duchy of Magdeburg; 14 miles E.S.E. of Magdeburg.

LEIXLIP, a post-town of the county of Kildare, Ireland. It is beautifully situated on the banks of the river Liffey, and near it is a fine waterfall, called the Salmon Leap. It is eight miles W. from Dublin.

LEKEO, one of the Japan islands, about 120 miles in circumference; 20 miles S. of Ximo. N. lat. 31° 20'. E. long. 152° 40'.

LEKINPOUR, a town of Hindooftan, in the circar of Cattack; 12 miles N.E. of Cattack.

LEKNO, a town of the duchy of Warsaw; 28 miles N.N.W. of Gnesna.

LEKSAND, a town of Sweden, in Dalecarlia; 20 miles N.W. of Falun.

LELAND, JOHN, in *Biography*, was born in London about the end of Henry VIIIth's reign, and was educated at St. Paul's school, under William Lily, from whence he was sent to Christ's college, Cambridge. He removed from this university to All-souls, Oxford; and for farther improvement, especially in the Greek language, he went to Paris, cultivated an acquaintance with the principal scholars of the age, and acquired a knowledge of several modern languages. Upon his return he took orders, and was appointed one of Henry VIIIth's chaplains. The king conferred upon him the office of keeper of his library, and gave him the title of royal antiquary, which no other person in this kingdom before or after possessed. To the title was annexed a commis-

sion, empowering him to search after all objects of antiquity in the libraries of all cathedrals, abbies, priories, colleges, &c. He spent much time in travelling through England, and in visiting all the remains of ancient buildings and monuments of every kind, with the view of collecting every thing that could illustrate the history and antiquities of this nation. At the dissolution of the monasteries he made application to secretary Cromwell to get the MSS. which they contained conveyed to the king's library. He obtained considerable preferment in the church, the duties of which did not require much active service; he accordingly retired with his collections to his house in London, for the purpose of digesting them and preparing the publications he had promised the world; but either intemperate application, or some other cause, brought upon him a derangement of mind in the year 1550, from which he never recovered. He died in 1552. During his life, he published several Latin poems, and some tracts on antiquarian subjects. His MS. collections, after passing through many hands, came into the Bodleian library, furnishing very valuable materials to Camden, Dugdale, Burton, and others. After his decease in 1589, a volume of his small Latin poems was published by Mr. Thomas Newton of Cheshire, under the title of "Principum et illustrium aliquot et eruditorum in Anglia virorum Encomiz." From his collections, Anthony Hall published, in 1709, "Commentarii de Scriptoribus Britannicis." "The Itinerary of John Leland, the Antiquary," was published by Hearne at Oxford, in nine vols. 8vo. The same editor published "Joannis Lelandi Antiquarii de rebus Britannicis Collectanea," six vols. Biog. Brit.

LELAND, JOHN, a dissenting minister, was born at Wigan, in Lancashire, in the year 1691. While he was very young his father removed with his family to Dublin, where the son was seized with the small-pox of so malignant a nature, that it entirely deprived him of his understanding and memory. In this melancholy condition he remained twelve months, but after his recovery, he recommended himself to much notice by the quickness of his parts, and by the proficiency which he made in his learning. He was therefore educated for the Christian ministry among the Dissenters; and was, in due time, invited to become joint-pastor with the Rev. Mr. Weld, to which office he was ordained in 1716. He first appeared as an author in 1733, by publishing "An Answer to a late Book, entitled 'Christianity as old as the Creation &c.' in two volumes." In 1737, he embarked in a controversy with Dr. Morgan, by publishing "The divine Authority of the Old and New Testament asserted against the unjust Apeironists and false Reasonings of a Book, entitled The Moral Philosopher." The learning and abilities displayed by Mr. Leland in these publications, and the service which he rendered by them to the Christian cause, procured him many marks of respect and esteem from persons of the highest rank in the established church, as well as from the most eminent of his dissenting brethren; and from the university of Aberdeen he received, in the most honourable manner, the degree of doctor of divinity. In the year 1742, Dr. Leland published an answer to a pamphlet, entitled "Christianity not founded on Argument;" and in 1753, he distinguished himself still further as an advocate in behalf of Christianity, by publishing "Reflections on the late Lord Bolingbroke's Letters on the Study and Use of History; especially so far as they relate to Christianity and the Holy Scriptures." Dr. Leland was now justly considered a master in this branch of controversy, and at the desire of some valuable friends he sent to the press, in 1754, "A View of the principal deistical Writers that have appeared in England, in the last and present Century, with Ob-

versations, &c." The design of this work was to give some idea of the productions of the deistical writers, and of the several schemes which they have advanced, as far as the cause of revealed religion is concerned. In this work, the author ably maintained the reputation which he had acquired by his former productions, and it met with a very favourable reception. He afterwards published a supplement relating to the works of Mr. Hume and Lord Bolingbroke, and this was followed by a third volume, comprehending the author's additions and illustrations, with a new edition of his "Reflections upon Lord Bolingbroke's Letters, &c." The whole of this work is now comprised in three volumes; it secured the author general public approbation, and encouraged him to continue his exertions to a very advanced age. Accordingly, when he was upwards of seventy years old he published, in two volumes 4to. "The Advantage and Necessity of the Christian Revelation, shewn from the State of Religion in the ancient heathen World, especially with respect to the Knowledge and Worship of the one true God; a Rule of moral Duty, and a State of future Rewards and Punishments, &c." This work was afterwards reprinted in two volumes, 8vo. Dr. Leland died in his seventy-fifth year, on the 16th of January 1766; he was distinguished by considerable abilities, and very extensive learning; he had a memory so tenacious, that he was often called the "walking library." After his death a collection of his sermons was published in four volumes octavo, with a preface containing some account of the life, character, and writings of the author, to which our readers are referred for farther information respecting him.

**LELAND, Dr. THOMAS**, a divine of the church of England, was born at Dublin about the year 1702. Having received the elements of a good education, he was admitted a student, and afterwards became fellow of Trinity College, Dublin. He was author of "A History of Ireland," 4to.; "The Life of Philip of Macedon;" and "The Principles of human Eloquence." He also translated the orations of Demosthenes, in two volumes, 8vo., which came out separately, and were well received by the public. Dr. Leland died in 1785, at the age of eighty-three.

**LELCZA**, in *Geography*, a town of Russian Poland, in the palatinate of Volhynia; 60 miles N. of Zytomiers.

**LELEGES**, in *Ancient Geography*, a collection of people from different nations, as the supposed etymology of their name, derived from *λεγο*, *I assemble*, imports. They anciently occupied the territory adjoining to that of the people called by Homer Cilices or Cilicians; and when Achilles ravaged their country, which lay north-west of the gulf of Adramyttium, they passed over into Caria, and took possession of the environs of Halicarnassus. Their town was the metropolis of Caria, near Myfia. They were a kind of robbers and vagabonds, who resembled the Cilicians in their disposition and manners. The first king of Laconia, according to Pausanias, was Lelex; and the country took the name of Lelegia from these people.

**LELIAN**, in *Geography*, a town on the north coast of the island of Bourou.

**LELIT PATTAN**. See **PATTAN**.

**LELOW**, a town of Austrian Poland, in the palatinate of Cracow; 32 miles N.W. of Cracow.

**LELUNDA**, a river of Africa, which joins the Zaire, about 60 miles from its mouth.—Also, a town of Africa, in the kingdom of Congo, on the fore-mentioned river; 35 miles E. of St. Salvador.

**LELY, Sir PETER**, in *Biography*, the most excellent portrait-painter this country possessed, after the death of

Vandyke. Many of his works continue to be held in molt deserved estimation, and to be ranked amongst the classics of the art. He was born at Soest, in Westphalia, in 1617. His family name was Vander Vaas; but from the circumstance of his father, who was a captain of foot, being born in a perfumer's shop, whose sign was a lily, and receiving the appellation of captain Du Lys, or Lely, our artist obtained it as a proper name.

He was first instructed in the art by Peter Grebber at Haerlem; and having acquired a knowledge of its principles, and a very considerable degree of skill in execution, he came to England in 1641, and commenced portrait-painter. After the kingdom had sustained the irreparable loss of Vandyke, and the restoration was completed, he was appointed state-painter to Charles II., and continued to hold that office with great reputation till his death, which happened in 1680. He was seized by an apoplexy, while painting a portrait of the duchess of Somerset, and died instantly, at the age of sixty-three.

Though Lely's talents, as an artist, do not entitle him to hold a rank equal to that filled by his great predecessor; yet they justly claim very great respect and admiration. He fell short of Vandyke in two very essential parts of portraiture, *viz.* taste and expression. Of the former it must be acknowledged that he sometimes caught a glimpse; and, in the disposal of a piece of loose drapery, exhibited it with an enchanting style: but that high class of taste, which evidently sways the artist's mind who arranges, without apparent study, all the parts of a composition in an agreeable and effective manner, he does not appear ever to have felt or understood. It is in parts only that he wrought with taste: in the ringlets of the hair, for instance; seldom in the actions of his figures, and scarcely ever in the tout-ensemble of his pictures. As to the expression of his portraits, it is almost entirely deserted, at least in those of his females, by what the poet has said, that he

" ——— on animated canvas stole

The sleepy eye that spoke the melting soul."

The consequence is, that individual expression, the very essence of portrait-painting, is lost sight of; and a certain air of general resemblance is seen in them all.

Yet in spite of these great deficiencies, Lely's pictures, by the mastery of his execution, and his skill of imitation, where he pleased to employ it, will ever command admiration. He possessed the art of flattery more than most artists; and no doubt by that secured the approbation of his contemporaries, and consequently great practice. He painted drapery in a style peculiarly his own, with great richness and fulness of effect; and he understood fully the union of folds, though he did not always dispose them in just or agreeable shapes. His pencil is broad and full, and the markings of forms and features are free and decided in his pictures, which are to be found in almost every noble mansion in the kingdom; so great were the encouragement and employment he enjoyed.

By it he acquired a very considerable fortune, of which he employed a large portion to furnish himself with a collection of pictures and drawings. These, at his death, were sold by auction, and were so numerous, that forty days were consumed in the sale; and the product amounted to 26,000*l.*; besides which, he left an estate he had purchased, of 600*l.* per annum.

**LEMA**, in *Geography*, a small island in the Chinese sea. N. lat. 22°. E. long. 114° 17'.

**LEMA Islands**, a cluster of small islands in the East Indian sea,

fea, near the west coast of the island of Borneo. S. lat. 1° 10'. E. long. 108° 48'.

LEMAIRE, in *Biography*, is now generally supposed to have added, about the middle of the seventeenth century, the syllable *fi* to the hexachord, in order to furnish a name, in solmisation, to the sharp 7th of the key, and ease the students in singing of the embarrassments of the mutations. Many volumes have been written for and against the mutations. We believe that in the conservatorios at Naples and Venice they are still preserved, and by the organists of our cathedrals who teach the choristers; but in many other parts of Europe, besides France, the *fi* has been adopted. Though much has already been said on both sides the question, much still remains to be said by the champions of both methods. See MUTATION, SOLMISATION, HEXACHORD, and the syllable *Si*, in their several places.

LEMAN LAKE, in *Geography*. See GENEVA and LAKE.

LEMAN, *Department of*, one of the eleven departments of the eastern region of France, composed of Gex and Geneva, and the north part of Savoy, in N. lat. 46° 10', on the frontier of Switzerland, and so called from lake Lemman. It is bounded on the north by the lake, Switzerland, and the department of Jura; on the east by the Valais, and the departments of the Doria and Mont Blanc; on the south by the department of Mont Blanc; and on the west by the departments of the Ain and Mont Blanc. Its chief towns are Geneva, Thonon, and Bonneville. It contains 197 square leagues, and 215,884 inhabitants; and is divided into three circles or districts, including 23 cantons, and 276 communes; viz. Geneva, comprehending 103,550 inhabitants; Thonon, the inhabitants of which are 39,465; and Bonneville, including 72,869 inhabitants. Its contributions amount to 906,632 francs, and its expences to 200,427 francs, 66 cents. This department consists of hills, vallies, and plains; producing grain, wine, fruits, and pastures. It has forests and iron-mines.

LEMAVI, in *Ancient Geography*, a people of Spain, in the Tarragonensis. Their capital was Dactonium, according to Ptolemy.

LEMBA, a town of Asia, which Josephus classes in the number of those which the Jews possessed in the country of the Moabites.

LEMBA, in *Geography*, a town of Africa, in the kingdom of Congo.—Also, a town on the west coast of the island of Celebes. S. lat. 3° 15'. E. long. 119° 52'.

LEMBACH, a town of Austria; 9 miles S. of Aigen.

LEMBEECK, a town of France, in the department of the Scheldt; 8 miles S. of Ghent.

LEMBIGE, or LEMBAYE, a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the district of Pau; 15 miles N.E. of Pau. The place contains 960, and the canton 11,626 inhabitants, on a territory of 217½ kilometres, in 47 communes.

LEMBERG, or LEOPOLD, a city of Austrian Poland, and capital of Galicia, large and opulent, and well fortified with timber. It lies low on the banks of the river Peltew, which soon after joins the Berg; being surrounded with hills and mountains which command the town. It is the see of a Popish archbishop, and also of a Russian and Armenian bishop. It has two castles, one within and another without its walls; the latter standing on a high hill, and having the Carmelite monastery, which is fortified, for a citadel: and it carries on a considerable trade. Lemberg has a magnificent cathedral, several other churches, a gymnasium or seminary, an arsenal, a public granary, two Jewish schools,

&c. A provincial diet and court of judicature are held in this town. It is inhabited by a mixed people of different nations; but no Protestants are tolerated; 72 miles S.S.E. of Chelm. N. lat. 49° 51'. E. long. 23° 59'.

LEMBO, a town of Africa, in Congo, on the Zaire; 40 miles S.W. of Etrona.

LEMERY, NICHOLAS, in *Biography*, an eminent French chemist, was born at Rouen, in November 1645. His father, Julian Lemery, was a *procureur* in the parliament of Normandy, and of the Calvinist persuasion. Nicholas was brought up to the business of pharmacy, under an apothecary of Rouen; and he went to Paris in 1666, with the view of obtaining farther improvement, especially in the art of chemistry, which he perceived to be the basis of correctness in the processes of pharmacy. Here he studied under Glaser, demonstrator of chemistry in the royal garden; and afterwards spent six years in travelling, for the purpose of adding to his knowledge. He resided a considerable time at Montpellier, then famous for its apothecaries; and brought with him to Paris, where he settled in that capacity in 1672, all the knowledge in his department of the art which the kingdom at that time afforded. In order to give public proofs of his information and skill, he announced a course of lectures on chemistry, which his friend, M. Martin, apothecary to the prince of Condé, allowed him to deliver in his laboratory, at the hotel of that prince. He afterwards procured a laboratory of his own, which, though little better than a dark cellar, soon became the centre of attraction, not only to the first scientific characters in Paris, but to ladies, who resorted thither partly from a love of knowledge, and partly from fashion. Chemistry was then indeed coming into great vogue in that metropolis; and Lemery contributed greatly to its advancement, by treating it in a simple and perspicuous manner, divesting it of the jargon of mysticism in which it had been hitherto obscured, and, by the dexterity of his experiments, exhibiting the facts which it discloses to the comprehension of every understanding. By these means, Lemery established such a character for superior chemical skill, as enabled him to make a fortune by the sale of his preparations, which were in great request both in Paris and the provinces. One article in particular was the source of great profit, namely, the oxyd, or, as it was then called, the magistry of bismuth, and known as a cosmetic by the name of *Spanish white*, which no other person in Paris knew how to prepare. In 1675 he published his "Cours de Chymie," which was received with general approbation and applause, and passed through numerous editions: indeed feldom has a work on a subject of science been so popular. It sold, says Fontenelle, like a novel or a satire: new editions followed year after year; and it was translated into Latin, and into various modern languages. Its chief value consisted in the clearness and accuracy with which the processes and operations were detailed: the science was not yet sufficiently advanced for a rational theory of them. Indeed he seems to have worked rather with the view of directing apothecaries how to multiply their preparations, than as a philosophical chemist; and his materials are not arranged in the most favourable manner for the instruction of beginners in the science. Nor did he divulge the whole of his pharmaceutical knowledge in this treatise: he kept the preparation of several of his chemical remedies secret, in order to obtain the greater profit by their sale.

Hitherto our chemist, though openly professing Calvinistic principles, had not been interrupted by the spirit of persecution, which disgraced the latter part of the reign of Louis XV.; but in 1681, he received an order to discon-  
tinue

time his public lectures within a limited time. While under this interdiction, he was invited to Berlin by the elector of Brandenburg; but he preferred removing to England, where he was favourably received by Charles II., who had an attachment to chemical pursuits. Circumstances, however, did not accord with his expectations; and he returned to his own country, and took the degree of doctor of physic at Caen, with the hope of thus protecting himself from further persecution. He actually acquired considerable employment in his new character at Paris; but the revocation of the edict of Nantes, in 1685, by which the practice of physic was interdicted to Protestants, deprived him of his means of subsistence, and reduced him to such difficulties, that his constancy at length gave way, and, in the following year, he with his family was reconciled to the Catholic church. He then readily obtained letters patent, allowing him to resume his practice, and his office of public teacher; and he again derived considerable emolument from the sale of his medicines. In 1697 and 1698 he published two works of considerable value, but not without imperfections. These were, 1. "Pharmacopée universelle," containing a collection of the formulæ given in all the reputable dispensatories in Europe, with corrections and improvements. Like the pharmaceutical works of that time, it was overloaded with articles, but was superior to its contemporaries. 2. His "Dictionnaire universel des Drogues Simples;" which was a still more useful work than the former.

On the re-establishment of the Academy of Sciences in 1699, Lemery was appointed associate-chemist, and succeeded to the office of pensionary, on the death of Bourdin. He then read before that body the papers on the subject of antimony, which were printed in 1707, under the title of "Traité de l'Antimoine." Upon this subject he had a controversy with an anonymous critic, in which he was considered as not very successful. He was now advancing in years, and found the infirmities of age increasing upon him, when his life was suddenly terminated by a fit of apoplexy, on the 16th of June 1715. Lemery was one of the ablest chemists of his time, and indefatigable in his researches; having spent his life in his laboratory, or study, at the bed-side of the sick, or in the Academy. He was a man of great simplicity of manners, sincere in his friendships, and of the strictest integrity in the commerce of life. Eloy Dict. Hist. de la Med. Gen. Biog.

LEMERY, LOUIS, son of the preceding, was born at Paris in January 1677, and obtained a reputation for knowledge in chemistry and medicine worthy of his name. He was intended for the profession of the law; but he had imbibed from the pursuits of his father so great a taste for those sciences, that he entered the faculty of medicine of his native city, and received the degree of doctor in 1698. Two years afterwards he was admitted into the Academy of Sciences, and in 1708 he delivered lectures on chemistry in the royal garden. In 1710 he was appointed physician to the Hotel-Dieu, a post which he occupied during the remainder of his life. In 1712 he obtained the rank of associate in the Academy, and succeeded his father in that of pensionary in 1715. He purchased the office of king's physician in 1722; and in that capacity he accompanied the infants of Spain on her return from France, whither he had gone with the view of being married to Louis XV. Soon after his return to Paris, he was honoured by the queen of Spain with the title of her consulting physician. In 1731 he was appointed professor of chemistry in the royal garden, in the place of Geoffroy. At a subsequent period, he became particularly attached to the establishment of the dukes of Brunswick, whom he frequently visited in the palace of

Luxembourg; and he likewise obtained the patronage of the princefs of Conti, in whose hotel he regularly passed a part of every day, and there composed several of the chemical papers which he read before the Academy of Sciences. These papers treat of the subjects of iron, of nitre, and some other salts, of vegetable and animal analyses, of the origin and formation of monsters, &c. Louis Lemery died on the 9th of June 1743, and the loss of him was much regretted; for to the mild and polished manners of the gentleman, he united great sincerity and constancy in his attachments, and sentiments of liberality and generosity in all his proceedings.

In addition to the papers published in the Memoirs of the Academy, he left the following works: 1. "Traité des Alimens," Paris, 1702, which was frequently reprinted, and greatly augmented by Brühler in the edition of 1755, 2 vols. 12mo. 2. "Dissertation sur le Nourriture des Os," Paris, 1704, 12mo. In this work he maintains that the bones are nourished by a peculiar gelatinous fluid, deposited in their substance by the small arteries, and not by the marrow, as had been supposed by some. He likewise published three letters, on the generation of worms in the human body, in opposition to the treatise of Andry, with whom a sharp controversy was carried on upon this topic. Eloy Dict. Hist. Gen. Biog.

LEMEYBAMBA, in *Geography*, a town of Peru, in the diocese of Truxillo; 22 miles S.W. of Chacapoya.

LEMGO, or Lemgow, a town of Westphalia, in the county of Lippe, on a small river, near the Werra, divided into the Old and New Town, each of which has its own magistrates; formerly one of the Hanse towns; 17 miles S.S.W. of Minden. N. lat. 52° 2'. E. long. 8° 44'.

LEMIA, a small island in the Pacific ocean, near the coast of Chili. S. lat. 44° 6'.

LEMINGTON, a post-town of America, in York county, Maine; 610 miles N.E. from Washington.—Also, a township in Essex county, Vermont, on the W. bank of Connecticut river, and near the N.E. corner of the state. It contains 52 inhabitants.

LEMLANT, a small island in the Baltic, near the S.E. of Aland; about 20 miles in circumference. N. lat. 65° 4'. E. long. 19° 58'.

LEMLEM, a country of Africa, in the interior part of Negroland; 500 miles E.S.E. from Tombucou.

LEMLUM, a town of the Arabian Irak; 33 miles S.E. of Hellah. N. lat. 31° 43'.

LEMMA, in *Botany*, a name borrowed from the ancient Greek writers, whose *λεμμα* is supposed to have been so called from *λεμα*, a scale, bark, or membrane, and to have been either our Duckweeds, see LEMSA; or some other aquatic production, whether of the vegetable or the corolline kind, that adhered to shells. Juss. 16.—This name was given by Bernard de Jussieu to the proper *Marsilea* of Linnaeus, for which it seems difficult to give a good reason. We may indeed assent to the separation of Michx's *Salvinia* from that genus (see Jussieu); but this does not oblige us to abrogate a name long destined to commemorate a meritorious naturalist. See MARSILEA.

LEMMA, *λημμα*, of *λεμμα*, I assume, in *Mathematics*, denotes a previous proposition, laid down in order to clear the way for some following demonstration; and prefixed either to theorems, in order to render the demonstration of them less perplexed and intricate; or to problems, to make the resolutions of them more easy and short. Thus, to prove a pyramid one-third of a prism, or paralleloiped, of the same base and height with it, the demonstration of which, in the ordinary way, is difficult and troublesome, this lemma may

be premised, which is proved by the rules of progression, that the sum of the series of the squares, in numbers in arithmetical progression, beginning from 0, and going on, 1, 4, 9, 16, 25, 36, &c. is always subtriple of the sum of as many terms, each equal to the greatest; or is always one-third of the greatest term multiplied by the number of terms. Thus, to find the inflection of a curve line, this lemma is first premised, that a tangent may be drawn to the given curve, in a given point.

So, in physics, to the demonstration of most propositions, such lemmata as these are necessary first to be allowed: that there is no penetration of dimensions; that all matter is divisible; and the like. As also in the theory of medicine, that where the blood circulates, there is life, &c.

LEMMA, in the *Ancient Music*, a rest or pause of a *short* syllable in the catalectic rhythm. See RHYTHM.

LEMMA, λεμμας, in *Pharmacy*, a term used to express the hulk or shell of certain fruits, as the almond and the like; and, in general, whatever is taken off in decortication: thus, the hulks of oats, barley, &c. are the lemmata of those feeds.

LEMMER, TITE, in *Geography*, a sea-port of Friesland, near the Zuyder sea; 20 miles S. of Lewarden. N. lat. 52° 52'. E. long. 5° 30'.

LEMMER, or Lemming, in *Zoology*. See Sable Mouse.

LEMNA, in *Botany*, λεμμα or λεμμα of the Greeks; see LEMMA. Duckweed or Duck's meat. Linn. Gen. 478. Schreb. 620. Willd. Sp. Pl. v. 4. 193. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 956. Wiggerf. 66. Ehrh. Beitr. fasc. 1. 43. Brown Prodr. Nov. Holl. v. 1. 345. Lamarck Illustr. t. 747. (Lenticula; Juss. 19. Mich. Gen. 15. t. 11. Dill. Gen. 118. t. 6.)—Clafs and order, *Diandria Monogynia*. Nat. Ord. *Miscellanea*, Linn. *Naiades*, Juss. *Hydrocharitaceae*, Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, roundish, obtuse, obscurely two-lobed, soon disappearing. Cor. none. Stam. Filaments two, awl-shaped, spreading, more or less unequal, longer than the calyx; anthers terminal, of two round lobes. Pist. Germen superior, ovate; style columnar, shorter than the stamens; stigma simple, or slightly notched. Peric. Capsule roundish, of one cell, not bursting. Seeds few, oblong, striated, pointed at each end, vertical, ranged in a simple circular row.

Eff. Ch. Calyx of one leaf, inferior. Corolla none. Capsule of one cell, without valves. Seeds few, oblong.

Obs. The first person who ever observed the fructification of a *Lemma* appears to have been Valineri, whose essay on the subject, describing the flowers of *L. minor*, is published in the *Ephemerides Natura Curiosorum*, and in the Italian solo edition of his works, v. 2. St. t. 14, 15. His figure of the flower is borrowed by Dillenius, in the appendix to his *Plante Giffenses*, cited above. Micheli, several years after, published excellent representations of the flowers and fruit, observed in two or three species, to which he applied the generic name *Lenticula*; calling by that of *Lenticularia* such as he could not meet with in a flowering state. This is a distinction without a difference, and of the latter *L. trifolca* has since been found in perfection by Mr. Dawson Turner of Yarmouth, in June, 1801. Willdenow says it has been found by Wolf. Ehrhart, in his German *Beitrag*, fasc. 1. 43, has given an entertaining account of his examination of *L. gibba* in flower at Hanover, July 13, 1779. This was found near Lewes in Sussex, by Mr. W. Borrer in June 1803, as was *minor* by the same gentleman in 1802, so that three species being now distinctly figured in fructification, in Engl. Bot. t. 926, 1095 and 1233, we are no longer in the dark on the subject, and we venture to remove

the genus from *Monoclea* to *Diandria*, as suggested in Fl. Brit. 958. and Prodr. Fl. Grac. v. 1. 11. One British species still remains, the *polyrrhiza*, whose flowers appear to have been seen by one person only, Grauer, a young friend of Wiggerf., at Kiel, about 1780.

The calyx seems to be variable in this genus, and is probably soon evanescent. Some flowers also occasionally want the complete germen, but this is accidental, and they appear to be, in no species, truly monocleous, nor regularly polygamous.

1. *L. trifolca*. Ivy-leaved Duck-weed. Linn. Sp. Pl. 1376. Engl. Bot. t. 926. (Hederula aquatica; Lob. Ic. v. 2. 36. Ger. em. 830.)—Leaves stalked, lanceolate, proliferous.—Found throughout Europe, floating in clear still pools and ditches. Mr. R. Brown has observed it in New Holland. It is a pale-green, smooth, pellucid, annual herb, floating in fresh water, near or upon the surface, and consists of several lanceolate, ribbed, entire, sometimes waved or toothed, leaves, each, with its stalk, about an inch long. Each leaf throws out from its centre underneath a solitary simple root, descending, to more than the length of an inch, into the water, and tipped with a membranous sheath. From the same point whence the root originates, spring a pair of young divaricated flat leaves, looking like lobes of the old one. The flowers proceed solitarily from a marginal chink, at one or both sides of a leaf, and are scarcely perceptible but by their prominent yellowish anthers. Wolf, the author of a dissertation on *Lemma*, published at Altorf in 1801, and quoted by Willdenow, appears to have been the first who ever found the flowers of this species.

2. *L. minor*. Lesser Duck-weed. Linn. Sp. Pl. 1376. Engl. Bot. t. 1095. Michaux Boreali-Amer. v. 2. 163. (Lens palustris; Camer. Epit. 852. Ger. em. 829.)—Leaves sessile, nearly flat on both sides. Roots solitary.—Common and abundant in summer time, on the surface of stagnant pools throughout Europe. Michaux has also observed it in Carolina, and Brown in New Holland. This being the common species in Greece, Dr. Sibthorp justly presumed it to be the *φλωκος*, or *επι των τεταρτων* of Dioscorides; not that we would suppose this ancient sage accurate or attentive enough to have distinguished it from the two or three following, which may possibly grow likewise in the country he investigated. The leaves are obovate or elliptical, entire, slightly convex beneath, in consequence of the formation of air within, by which they become buoyant, and float in dense masses over the whole surface of the water, being much smaller and more crowded than in the former. They are, like that, in some measure proliferous. The roots are solitary from the centre of each beneath, and are temporary, not perennial, nor forming offsets. Flowers from marginal chinks, always, as far as we have seen, furnished with both itameus and pistil, and their calyx is more ample, as well as more evidently two-lobed, than in the above. The seeds when ripe doublets descend, and take root in the mud, as Valineri observed the young plants ascend in the form of a green soft pulp, full of air-bubbles, from the bottom to the surface, early in the spring, and soon after the waters were mantled with an entirely green covering of the perfect leaves, lying over each other.

Micheli's *Lenticularia media*, t. 11. f. 2, and *minor*, f. 3, both perhaps belong to this species.

3. *L. gibba*. Gibbous Duck-weed. Linn. Sp. Pl. 1377. Engl. Bot. t. 1233. (Lenticula palustris major. &c.; Mich. Gen. 15. t. 11. f. 1, not 2.)—Leaves sessile; slightly convex above; hemispherical beneath: Roots solitary—Less frequent by far than the last, in still pools of various parts of Europe. Hudson considered this as a variety only, but it differs

differs in being larger than *minor*, remarkably timid, succulent, and vascular. Its upper surface is convex, usually of a fine green, but often purplish; the lower almost hemispherical, and paler. *Roots* generally solitary, sometimes in pairs. Micheli says the *calyx* soon disappears; and Mr. Borrer's specimens were too far advanced to shew it, though the *stamens* and *style* were in perfection.

4. *L. polyrrhiza*. Greater Duck-weed. Linn. Sp. Pl. 1377. (Lenticularia major polyrrhiza, infernè atro-purpurea; Mich. Gen. 16. t. 11. f. 1.)—Leaves sessile, obovate, convex beneath. *Roots* clustered.—Native of ditches and pools in Europe; and Willdenow says of North America also. It is annual, flowering in July and August, but though the *leaves* are twice or thrice the size of the two last, the *flowers* have not been detected, except by the Danish naturalist Grauer above-mentioned, who accounts for this by his description of their situation. He says they are to be found at each side where one leaf is joined with the other, under the folding of its edge, and that the fruit agrees with that of *gibba*, except in being larger, and more flattened. The *leaves* are rounder and blunter; convex, and usually dark purple, underneath. The *roots* spring numerously in clusters from the centre of each.

5. *L. obcordata*. Heart-shaped Duck-weed. Vahl. Symb. v. 2. 95. Willd. n. 5.—“Leaves sessile, inversely heart-shaped. *Roots* clustered.”—Native of waters in the East Indies. Vahl, from whom alone we have any knowledge of this, says “the *leaves* are scarcely so long as the nail, of a bright green at the fore part of their upper side; purplish in the hinder part and underneath, as well as the *roots*. A longitudinal furrow runs along the leaf, sending off a branch to each lobe, which divides each nearly in two, to the extremity.” It does not appear why Willdenow defines the leaves as “proliferous at the apex.”

6. *L. arrhiza*. Rootless Duck-weed. Linn. Mant. 294. (Lenticularia omnium minima, arrhiza; Mich. Gen. 16. t. 11. f. 4.)—Leaves in pairs, without roots.—Observed by Micheli in fish-ponds near Florence. Duchesne found it in France; and we have specimens, both dried and in spirits, collected at Fontainebleau by the late Mr. Stephen de Lessert. This minute species is not bigger than an ordinary pin's head, and each plant consists of one larger *leaf* and one smaller, joined by their extremities; the former being elliptical, flatish on the upper side, very turgid below; the other nearly globose. No roots are discoverable, nor is any thing known of the fructification.

Micheli's *Lenticula media*, t. 11. f. 2, and *minima*, f. 3, remain undetermined by following writers. We venture to characterize them as follows.

7. *L. disperma*. Two-seeded Duck-weed. (Lenticula palustris media, pallide virens, infernè minus convexa, radicibus longissimis fructu dispermo; Mich. Gen. 15. t. 11. f. 2.)—Leaves sessile, obovate, convex beneath. *Roots* solitary, very long. Capsule with two seeds.—Found by Micheli in a place called the *Beccavivette* near Florence. He delineates the *leaves* about half the size of *L. gibba*, as well as much less convex beneath, and the *seeds* as but two in each capsule, whereas in *gibba* they are four, five, or six.

8. *L. atro-virens*. Dark-green Duck-weed. (Lenticula palustris minima atro-virens, utrinque pene convexa; Mich. Gen. 15. t. 11. f. 3.)—Leaves sessile, elliptic-oblong, convex on both sides. *Roots* solitary.—Found by the same author near Florence. This appears to be smaller than *L. minor*, with more oblong and darker *leaves*, whose upper side is as convex as the under one.

LEMNIAN EARTH, *Lemnia terra*, comprehends several

varieties of clay, mostly red and ferruginous, formerly preserved under this name, and employed in medicine. These were distinguished into the white, the yellow, and the red. They were brought from the Levant, mostly in the shape of small cakes, bearing the impression of a seal, whence the name of *Terra Sigillata*. Several of them are to be referred to *Bolz*; which see. The whitish kind, which appears to be the true Lemnian earth, and so highly valued by the ancients, on account of the alexipharmic virtues which they ascribed to it, is described under the article FULLER'S Earth.

The red earth is dug in a hill in the island of Lemnos, and in no other place, so far as is yet known; and the fine and true earth only in one pit, which used to be opened once every year, and no oftener, with great solemnity; and the earth, supposed sufficient for the year's demand, was taken out and sold to the merchants; some sealed with various figures, other quantities unsealed; but what was there bought unsealed, was generally formed into small masses, and sealed before it was offered to sale in Europe, the druggills always expecting to find Lemnian earth sealed.

This earth, to which imaginary virtues were attributed, was too often adulterated, frequently by the Turks upon the spot, either by mixing it with other earths, or another earth alone being sold in its place; but more frequently in Europe, where every wholesale dealer knew how to make a composition of our own clays, and properly tinge them with ochre, and afterwards give an impression resembling that of the genuine.

This earth was celebrated by the ancients as a sovereign remedy against poisons and the bites of reptiles: the Turks and Greeks still retain that notion, for the cups out of which the grand seignior drinks are made of this red earth, so that it is reserved chiefly for the sultan's use. But the alexipharmic and astringent property of this and the other boles is now in little or no esteem. (See BOLE.) It is also dug in the island of Lemnos, and was used in the German shops as an astringent and fudorific, and said to be of great efficacy in dysenteries, hemorrhages, and malignant fevers. The ancients knew this kind, but never used it in medicine, esteeming the other superior, but they employed it as the cimolia in cleaning linen and woollen cloths.

The yellow Lemnian earth is counterfeited two ways; the one by a yellow ochre, which may be discovered by its staining the hands, and the other by a yellow clay; but this is easily known by its want of the true florid colour, and having all the characters of a clay, not a bole. The genuine is found only in the island of Lemnos, and is the tiratum next above the red. It was formerly esteemed a fudorific, astringent, and vulnerary. Da Costa's Hist. of Fossils, p. 1. 14. and 22.

LEMNIS, in *Ancient Geography*, an island of Africa, in Mauritania Cæsariensis, E.N.E. of the mouth of the river Malva.

LEMNISCATE, in the *Higher Geometry*, is the name of a curve which has the form of the figure of 8. If we call  $A P, x$ , (Plate XI. *Analysis*, fig. 1.), and  $P M, y$ , and the constant line  $BC, a$ , the equation of the curve will be  $a y = x \sqrt{a a - x x}$ , or  $a^2 y^2 = a^2 x^2 - x^4$ , which is an equation of the fourth degree; it is also evident that a right line which passes through the double point  $A$  will cut this curve in four points, the double point being reckoned equal to two. See CURVE.

LEMNISCIA, in *Botany*, so called by Schreber, from  $\lambda\eta\mu\iota\sigma\kappa\alpha\iota$ ; a bandage, or fillet, in allusion to the shape of its petals. Schreb. 358. Willd. Sp. Pl. v. 2. 1172. Mart. Mill.

Mill. Dict. v. 3. (Vantanea; Aubl. Guian. v. t. 572. t. 220. Juss. 434. Lamarck. Illustr. t. 471.)—Clas and order, *Polyandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, five-toothed, acute, short. *Cor.* Petals five, linear, long, acute, recurved, adhering to the cup-shaped, fleshy, short nectary which encompasses the germen. *Stam.* Filaments numerous, from seventy to eighty, capillary, longer than the corolla, inserted into the nectary; anthers roundish, small. *Pist.* Cermen superior, roundish, immersed in the nectary; style thread-shaped, the length of the filaments; stigma obtuse. *Peric.* Capsule of five cells. *Seeds* solitary.

Eff. Ch. Calyx five-toothed. Corolla of five petals. Nectary cup-shaped, bearing the filaments. Capsule five-celled, with a seed in each cell.

t. *L. floribunda*. Willd. (Vantanea guianensis; Aubl. Guian. t. 229.)—Found at Guiana, where it is called *Jouantan*, whence Aublet derived his barbarous appellation *Vantanea*. It flowers in August. The trunk of this tree rises to the height of about fifteen or twenty feet, and is much branched. Bark brown and smooth. Wood whitish and compact. *Leaves* alternate, on short footstalks, smooth, oval, pointed, the larger ones about five inches long. *Flowers* forming large, handsome bunches at the extremity of the branches, of a red, coral colour. *Stamens* situated upon a yellow, fleshy disk, in the form of a cup, which almost covers the germen.

Obs. The long narrow petals of this plant greatly remind us of those in the neighbouring genus *Allagium*.

LEMNIUS, or LEMMENS, LÉVIN, in *Biography*, was born at Ziricksee, in Zealand, in May, 1565. He studied at Louvain, and by the advice of his friends applied both to medicine and theology. He principally distinguished himself, however, in the former of these sciences, and practised the profession for upwards of forty years, chiefly in his native place, where he settled in 1527. He obtained the full confidence of his patients by his knowledge and eloquence, and especially by a mild and humane expression of countenance and manner, which never failed to interest the sick. After the death of his wife, Lemnius became a priest, and was made a canon of the church of St. Lieven, at Ziricksee, where he died in July 1568. He was the author of several works, the style of which has some force and even elegance. These are; “*De Astrologia Libri unus, &c.*” *De termino vitæ Libri*. *De honesto animi et corporis oblectamento, &c. &c.*” Antwerp, 1554.—“*De oculitis naturæ miraculis Libri duo,*” *ibid.* 1559.—“*De oculitis naturæ miraculis Libri quatuor,*” *ibid.* 1564. These works contain many observations relative to natural philosophy, botany, physiology, and medicine, and especially concerning generation and monsters; but they also contain many fables. “*De Habitu et Constitutione corporis, quam triviales complexione vocant, Libri duo,*” *ibid.* 1561, and several subsequent editions. “*Similitudinum et parabolarum, quæ in Bibliis ex herbis atque arboribus defumuntur dilucida explicatio,*” *ibid.* 1569; many times reprinted and translated. “*De Zelandis suis Commentariolus,*” Leyden 1611. Eloy Dict. Hist.

LEMNOS, in *Ancient Geography*, an island situated in the Ægean sea. This island was consecrated to Vulcan in the time of Homer, probably on account of two volcanoes, which were here continually casting forth flames, and which were considered as the forges of the husband of Venus. No vestiges of these volcanoes now remain; but Sonnini thinks it probable that interior fires are still burning here; for he met with a spring of hot water, which has been brought to

supply baths, and another of aluminous water. Lemnos was celebrated amongst the ancients, on account of the fœnicœ which it afforded to the Argonauts; of which Apollonius Rhodius has given a particular account. As it was near Asia, it was almost always dependent on that province. The priests of Lemnos were reckoned famous for the cure of wounds. For this reason the Greeks, who went to the siege of Troy, left here Philoctetes, after he had been wounded in the foot by one of the arrows of Hercules. The efficacy of their skill depended, as it has been said, upon the quality of that bole under the denomination of *LEMNIAN earth*; which see. It is also said, that Galen made a voyage to Lemnos on purpose for ascertaining the virtues of this earth; and that he found a person who had availed himself of it as an antidote to the bites of reptiles, and to poison. The first inhabitants of this island were the Pelasgi, who expelled the descendants of the Argonauts, by whom it was previously occupied, and took possession of it about 1160 years before the vulgar era. This island retained the name of Lemnos, by which it is even now known; but navigators have given it the name of *Stalmene*. The island is lully, but extremely fertile; it yields corn, cotton, oil, and silk, with which a few light stuffs are manufactured. To be flourishing, says Sonnini, Lemnos wants only to be delivered from its oppressors. Nature has done every thing for it, and we lament the state of languor and wretchedness to which its destiny has reduced it. Its inhabitants were formerly much given to navigation, or at least to the carrying-trade; they are still trading mariners, because this kind of industry escapes more easily the cupidity of tyrants than affluence produced only by agriculture, or by a sedentary traffic. Some of its women are extremely beautiful. The whole east coast is inaccessible, on account of a shoal, which extends four leagues into the offing; the west coast affords to ships a few places of shelter against northerly winds. To the north is a large road; but there are no real harbours except on the south part, where are to be found two, at no great distance from each other, *viz.* Port *Cadia* and Port *Sant Antonio*. Sonnini's Travels in Greece and Turkey.

LEMO, in *Geography*, a town of Sweden, in the government of Abo; 12 miles N.W. of Abo.

LEMNON, or LIMON, in *Botany, Gardening, &c.* See CITRUS and CITRIC Acid.

LEMON-tree. See CITRUS *Medica*. The name is sometimes given by the Welsh to *Pyrus Aria* of Fl. Brit., the White Beam-tree, whence certain travellers have reported the lemon to be a native of the bleak cliffs of Penmaenawr!

LEMON, in the *Materia Medica*.

Lemons are cooling and grateful to the stomach, quenching thirst and increasing appetite; useful in fevers, as well common as malignant and pestilential; they also provoke urine. The juice, which is more acid than that of the orange, possesses similar medical virtues. (See ORANGE.) This juice, however, is always preferred, where a strong vegetable acid is required. Saturated with the fixed vegetable alkali, it is in frequent extemporaneous use in febrile diseases; and by promoting the secretions, especially that of the surface, proves of considerable service in abating the violence of pyrexia. Mixed with salt of wormwood, it is an excellent medicine to stop vomiting, and to strengthen the stomach. As an antiscorbutic, lemon juice is very generally taken on board ships, destined for long voyages. See CITRUS, and CITRIC Acid.

Whytt found the juice of lemons to allay hysterical palpitations of the heart, when various other medicines had proved

proved ineffectual; and this juice, or that of orange, taken to the quantity of four or six ounces a day, has sometimes been found a remedy in the jaundice. (See Sauanders's Elem. of the Practice of Physic, p. 170.) The yellow rind is a grateful aromatic, and commonly used in stomachic tinctures and infusions, and for rendering other medicines acceptable to the palate and stomach. The lemon peel, though less warm than that of the orange, possesses similar qualities, and is used with the same intentions. It is sometimes ordered to be candied. In distillation it yields an essential oil, extremely light, almost colourless, frequently employed as a perfume, and brought to us from the southern parts of Europe, under the name of "essence of lemons." This oil is an ingredient in the spiritus ammoniac compositus, or aromatic spirit of ammonia, and in other formulae. A mixture made by saturating six drams of the juice of lemons with about half a dram of fixed alkaline salt, with the addition of a small quantity of some grateful aromatic water or tincture, as simple cinnamon water, is given in cases of nausea and reachings, and generally abates, in a little time, the severe vomitings that happen in fevers, when most other liquors and medicines are thrown up as soon as taken. It is also used as a saline aperient in icterical, hydropical, inflammatory, and other disorders. A syrup made by dissolving fifty ounces of fine sugar in a quart or two pounds and a half of the depurated juice, is mixed occasionally with draughts and juleps, as a mild antiphlogistic, and sometimes used in gargarisms for inflammations of the mouth and tonsils. Lewis Mat. Med. Woodv. Med. Bot.

**LEMONADE**, a drink prepared of water, sugar, and citron, or lemon-juice.

This factitious liquor has been so popular in Paris, that it has given its name to a new established company called *lemonnaders*.

**LE MONNIER**, PETER CHARLES, in *Biography*, a French astronomer, member of the Academy of Sciences, and of the National Institute, was born at Paris in 1715, and accompanied Maupertuis in his tour to the north pole, for measuring a degree of the meridian. His principal works are: "Astronomical Institutions;" "Lunar Nautical Astronomy;" "Tables of the Sun, and Corrections of those of the Moon." He died in 1790. He had a brother, Lewis William, a very able experimental philosopher, who died in 1799. But neither of these is to be confounded with an abbé of that name, who translated Terence and Persius into French, and was author of fables, tales, and epistles. He died in 1796.

**LEMOS**, in *Geography*, a district of Spain, in Galicia, E. of Minho; the chief place is Montforte de Lemos.

**LEMOSANO**, a town of Naples, in the county of Molise; 8 miles N.E. of Molise.

**LEMOV**, NIZNEI, a town of Russia, in the government of Penza; 72 miles W. of Penza. N. lat. 53° 25'. E. long. 43° 34'.

**LEMOV**, *Verschnoi*, a town of Russia, in the government of Penza; 38 miles S.W. of Penza. N. lat. 53° 16'. E. long. 43° 14'.

**LEMPA**, a river of Mexico, which runs into the Pacific ocean, N. lat. 13° 36'.

**LEMPACH**, a town of Austria; 14 miles W.S.W. of Vienna.

**LEMPALA**, a town of Sweden, in Tavastland; 27 miles N.W. of Tavasthus.

**LEMPAS**, GRAND, a town of France, in the department of the Ière, and chief place of a canton, in the district of La-Tour-du-Pin; 18 miles N.W. of Grenoble. The place

contains 1680, and the canton 14,883 inhabitants, on a territory of 200 kilometers, in 17 communes.

**LEMPSTER**, an inconsiderable township of America, in Cheshire county, New Hampshire; incorporated in 1761, and containing, in 1800, 729 inhabitants.

**LEMPTA**, a sea-port town of Africa, on the E. coast of the kingdom of Tunis. It was the "Leptis parva" of the ancients; the other being in the kingdom of Tripoli. Lempta appears to have been a mile or more in circuit; but nothing now is left but the ruins of a castle; with a low shelf of rocks, that probably made the northern mound of the ancient Cothon; 60 miles S. of Tunis. N. lat. 35° 30'. E. long. 10° 54'.

**LEMPTA**, a desert country of Africa, inhabited by a barbarous and fierce people, who plunder the caravans that pass from Conflantia and other towns towards Nubia, situated about N. lat. 26° 30'. E. long. 9°.

**LEM-TCHIN**, a town of Thibet; 12 miles W.N.W. of Pitchan.

**LEMUI**, a small island in the Pacific ocean, between the island of Chiloe and the continent. S. lat. 44° 10'.

**LEMVIG**, a town of Denmark, in North Jutland, situated on the Lime-Fiord, or Lympfurd; 84 miles N. of Ripen. N. lat. 56° 44'. E. long. 8° 18'.

**LEMUR**, in *Zoology*, a genus of Primates. The fore-teeth in the upper jaw amount to four in number, the intermediate ones remote; those in the lower jaw to six, their form more elongated, extended, compressed, parallel, and approximate; grinders many, somewhat lobate, the foremost longer, and sharper.

The animals of the lemur genus approach the monkey tribe in the form of their feet, which in several of the species are furnished with flat and broad nails, resembling those of the human hand, excepting generally that of the first finger next the thumb, which is long and incurved; they have either two or four teats, and some of the species have the tail of considerable length, while others have none. Notwithstanding the resemblance these animals bear to the monkey race, they have nothing of the mischievous and petulant disposition of those creatures; they are mild and peaceable in their manners, at least when domesticated, and there are few species of the tribe that cannot readily be reduced to that state of docility by proper treatment. Some of the species feed on fruits, eggs, and small birds, others subsist entirely on the former. They inhabit chiefly the Indian islands, and the continent of South America.

#### Species.

**TARDIGRADUS**. Tail none; body somewhat tawny ash-Gmel. *Lemur tardigradus*, Erxleben. *Le loris grêle*, Audubert. *Slow lemur*, or *loris*.

Under the Linnaean specific name of tardigradus, the best authors appear to have confounded two, if not a greater number of distinct species. The little animal described by Erxleben under that title, is remarkable for the peculiar elegance of its figure, and the singularity of its conformation. The head is roundish; the muzzle projecting; the eyes extremely large and contiguous to each other; the ears large and round; instead of a tail a tubercle is situated in that part; and the whole body is covered with fine hair of a reddish-grey colour. The sexual organs of the female, according to the observations of Daubenton, present some curious particulars of interest to the comparative anatomist. This species inhabits Ceylon, is remarkable for its agility, is quick of hearing, and corresponds with the squirrel.

**ECAUDATUS**. Tail none; a dark-rusty line along the middle of the back from the rump to the forehead; orbits surrounded

## L E M U R.

fringed by a blackish line. *Lemur caudatus*, Linn. Gmel. *Loris tardigradus*, Audebert. *Parvifex pentadactyle de Bengale*, Voimacr. *Le loris de Bengale*, Buff.

The distinction between this and the preceding species has not been regarded with sufficient attention by all writers, and hence we sometimes find the description and history of one applied to and blended with the other. The latter is about thirteen inches in length, the head almost round, the muzzle very little pointed. The ears are small, oval, and straight, and almost entirely concealed under the woolly hair. The eyes are placed in front immediately above the nose, and are very close to each other; their form perfectly orbicular, their size remarkably large in proportion to the body, and of a brown colour. The nose is small, flat, and open at the sides; the teeth of the same form and number as in the former animal. The hair of the fur is long, fine, and woolly, but rough to the touch; the colour in general grey, or yellowish-ash, inclining rather more to reddish upon the flanks and limbs.

**INDRI.** Tailless, black; beneath greyish; rump whitish. *Lemur indri*, Gmel. *Indri*, Sonnerat. *Indri macaoco*, Penn.

This is a very large species; the colour entirely black, except on the face and beneath, which is greyish; and the space of white on the rump, or sometimes the face, is white. The muzzle is lengthened as in the dog tribe, the ears shortish and slightly tufted; the hair silky, thick, and in some parts curly. According to Sonnerat, its first describer, the height of this animal is three feet and a half; the tusks in each jaw are eight, the fore-teeth above two, beneath four; the feet five toed; nails flat and acute, those of the great toe large; the rudiment of a tail is sensible to the touch. It is said to be a gentle, docile animal, capable, like the dog, of being trained when young to the chase, and is commonly employed in hunting by the natives of Madagascar, the country it inhabits: its voice resembles the crying of an infant. At Madagascar it is known by the name of indri, which signifies the man of the wood. Geoffroy observes, that the cutting teeth in the upper jaw are four in number, instead of two, as mentioned by Sonnerat.

**RUFUS.** Yellowish-red; head at the summit, temples, cheeks, and tail beneath whitish. *Lemur rufus*, Audebert. *Maki-roux*, Desm.

This resembles the mongoz in size, and various other respects; it nevertheless differs in having the ears shorter, the tail longer, the hair in general shorter, and the colour of the fur yellowish-red instead of brown-grey; upon the summit of the head is a black line, and the tail at the extremity is brown. Whether allied to the following species or not seems difficult to determine.

**LANGER.** Tailed; above reddish-yellow, beneath white; tail uniformly tawny-brown. Gmel. *Maquis à bourres*, Sonn. *Flacky lemur*, Shaw.

A native of Madagascar; the length twenty-one inches; hair soft, curled, about the loins reddish tawny; face black; ears small; eyes large and greenish-grey; in the upper-jaw two fore-teeth, in the lower four; tail nine inches long; feet five-toed; nails long, great toe-nail rounded. There are two or three supposed varieties of this species.

**POTTO.** Sub-ferruginous; tail same colour. Gmel. *Potto*, Bosman.

Inhabits Guinea. An obscurely described species, conceived to differ from the indri only in the length of the tail. Bosman, who relates the supposed history of this animal, on the authority of the negroes (in his account of Guinea), attributes to it nearly the same manners as those of the European lloth.

**MONGOZ.** Tailed, fuscous-grey, the tail of the same colour. Linn. Erxleb. *Mongoz*, Edw. *Maki mongozes*, Desm. *Mongous*, Buff. *Woolly macaoco*, Penn. *Mongoz lemur*.

The mongoz is a larger species than the ring-tailed lemur, the size about that of the common or domestic cat; the upper part of an uniform dusky-brown colour, with the breast and belly whitish. The fur consists of silky curling hair. The nose is larger than in the ring-tailed lemur, and much resembling that of lemur macao, the colour black; the eyes are yellow, or orange, remarkably vivid, and are nearly surrounded by a circle of black placed at a small distance above and beneath each eye, then uniting between them, and passing down the middle of the front to the nose; the hands and feet are naked and dusky; the nails flat, except on the interior toe of the hind feet next the thumb, which is furnished with a sharp claw; and the tail, which is very long, covered with a thick fur.

No less than seven supposed varieties of this species are described by writers; in one kind the body is grey or brown, with the face and hands black; in another grey or black, with a black spot near the eyes; and in a third the body is brown, with the nose and hands white; the face is also sometimes black, the hands yellow, or varying from that to deep tawny, and the body grey; and again, others occur that are uniformly brown.

This animal is a native of Madagascar and some other Indian islands: it is an active animal, filthy in its dispositions, and feeding on fruits and leaves of trees; it constantly resides in woods: like some other animals, which nature has furnished with a tail of great length, it is observed occasionally to amuse itself by nibbling and biting the end of the tail, and is on this account sometimes found with that part destitute of the four or five extreme vertebrae.

The individual described by Buffon was neither of a gentle nor sportive disposition, and was necessarily confined by means of a chain to prevent its doing mischief; fruits, sugar, and comfits it devoured with apparent eagerness and satisfaction, besides which it was fed on bread; it almost incessantly uttered a low grunting noise, or when tired of being alone, croaked in the manner of the frog, and so loud as to be heard at a great distance. The tongue was rough like that of the cat; and Buffon observes, that when permitted it would lick a person's hand till the skin became inflamed; its caresses, usually concluding with a bite of its teeth upon withdrawing the hand from him. This individual was a male, and from its partiality to cats it was suspected its attachment might have been productive of an hybrid offspring; but these expectations were never realized.

**MACAO.** Tailed, black; collar bearded with a kind of ruff. *Lemur macao*, Linn. Erxleb. *Vari*, Buff. *Maki-vari*, Desm. *Black macaoco*, Edw. *Ruffed macaoco*, Penn. *Ruffed lemur*, Shaw.

An inhabitant of Madagascar, and the adjacent islands; its size exceeds that of the mongoz, and in the ferocity of its manners it very far surpasses that species. Travellers describe it as being scarcely less furious than the tiger; it is dangerous even to be met in the woods by two together, or even one, and yet they sometimes assemble to the amount of a hundred in company, when nothing can resist their attacks. Edwards is the only writer who speaks of it as an inoffensive creature, and the individual he mentions was in a state of captivity; he mentions it as "a very sociable, gentle, harmless-natured animal, not having the cunning, mischievousness, or malice of the monkey kind." The colours of this animal vary much in different individuals, yet are

## L E M U R.

are in general diversified with patches of black and white, though sometimes it appears they are totally white or brown. The voice of this animal is loud and terrible, and is by some compared with the roaring of the lion, or rather its cries resemble those of the howling-monkey of Brasil and Guiana; it delights in sun-shine, and sleeps in dark places. The fur of this animal is long, the muzzle large and rather long, the ears short and fringed with long hairs; and the eyes of such a deep orange as to appear of a fiery redness. The ruff, or cravat-like ring of long fur that surrounds the neck, is peculiarly striking in its appearance, and serves principally to characterize this species; besides which it may be observed, that the great hind-toes are almost subulate. It refuses eggs, flesh, and fish.

**CATTA.** Tail annulated with black and white. Linn. *Erxleb. Mococo*, Buff. *Maki-mococo*, or *maucoco*, Defm. *Maucauco*, Edw. *Ring-tailed maucuco*, Penn. *Ring-tailed lemur*, Shaw. Lev. Mu.

The mococo, says Buffon, is a beautiful animal, with a fine nature. Its size is rather smaller than that of the full-grown cat, the shape more slender; its colour above and on the outside of the limbs somewhat ferruginous, the under parts whitish, and the fur throughout remarkable for its lustre. The eyes are large, of a bright orange, inclining to hazel, and are surrounded by a distinct circle of black; the muzzle is black, and the hands and feet of the same colour; the fingers and toes furnished with round nails, the nails of the great toes not being longer or subulate as in most other species. The tail, which it always carries erect in a graceful position, is very long; the hair upon it longer than the rest of the fur, and marked with about thirty equi-distant or regular distinct circles of black and white.

The manners of this species are gentle and lively, in various respects resembling those of the monkey tribe, without its petulance and malice; when pleased it purrs like a cat. In a state of liberty these animals live in societies of thirty or forty together in the woods; in ascending trees they climb with all their feet like the ape; their food consists of fruits, herbs, and roots, and it is also asserted they will eat animal food; like the squirrel they sometimes feed sitting upright, and often extending their hands forwards, and in the same manner, when in a state of captivity, take their station before a fire to warm themselves. This species inhabits Madagascar.

**BICOLOR.** Blackish, beneath and heart-shaped spot on the forehead white; tail long. *Lemur bicolor*, Gmel. *Lemur albifrons*, Audebert. *Heart-marked maucauco*, Penn. *Heart-marked lemur*, Shaw. Gen. Zool.

Supposed to inhabit South America; the head is obtuse; nails subulate; toes white.

**PUSILLUS.** Grey; eyes large and broad. *Lemur pusillus*, Audebert. *Rat de Madagascar*, Buff. *Maki-nain*, Defm.

This species inhabits Madagascar; its length is five inches and a half from the tip of the nose to the base of the tail; the muzzle shorter than in most other species. An individual of this kind brought from its native country was preserved alive in France for some years. It evinced a remarkable degree of activity in its motions; its cry was feeble like that of the squirrel; and its food consisted of fruits and almonds. The history of this curious little species, as related by Buffon (under the title of *rat de Madagascar*), is erroneously placed by Mr. Pennant, in his work on quadrupeds, under the description of his *Murine maucauco*, by which means the two species are confounded together. Dr. Shaw, from his adherence to this writer, has also fallen into the same opinion in his *General Zoology*.

**MURINUS.** Cinereous; tail tawny. Gmel. *Lemur griseus*, Audebert. *Gristet. Maki-gris*, Defm.

This beautiful little animal is a native of Madagascar. The whole body, except the face, feet, and hands, are covered with greyish woolly hair; the tail is very long, and covered with short woolly hairs, like the rest of the body. It much resembles the lemur *catta* in its general appearance; and the posterior limbs are much higher than those before.

**GALAGO.** Tailed; whitish, beneath grey; tail ferruginous. *Galago*, Gvoff. *Adanson*, &c. *Galago senegalensis*, Audebert.

One of the smaller species of the tribe, measuring six or seven inches from the nose to the tail, the latter eight inches. The ears are very large, thin, upright, and rounded at the tip; the hind legs much longer than the anterior ones; the nails of the hands rounded, except that of the fore-finger of each, which consists of a sharp claw. These animals, according to Adanson, are of a peaceable disposition; they feed on insects, and live in trees. The negroes of Galam hunt them for the sake of their flesh, the flavour of which is, however, very indifferent.

**PSILODACTYLUS.** Rusty cinereous; tail extremely villose; middle finger of the fore-feet very long and naked. *Lemur psilodactylus*, Schreber Suppl. *Aye-aye*, Sonnerat. *Aye-aye squirrel*, Penn.

This is a species allied so nearly to the squirrel tribe, to which it is referred by Gmelin, that it admits of doubt whether Schreber is entirely correct in consigning it to the lemur tribe; and it also approaches very closely the family of monkeys. Its length is eighteen inches, the colour pale ferruginous grey, with a blackish cast on the back and limbs; the tail entirely black, sides of the head, neck, lower jaw, and belly greyish. The head is shaped like that of the squirrel; the ears large, round, and naked, their colour black; and in front of each jaw are two cutting teeth; the feet long; the interior toes of the hind feet short, and furnished with flat round nails. All the claws on the fore-feet sharp and crooked, the two middle ones in particular very long, extremely thin and naked, except at their base. It is a timid animal, uncommonly slow in its movements, and of a mild disposition. M. Sonnerat observes, that its eyes were of an ochre-colour, and resembled those of the owl, and like that bird the animal can scarce see distinctly by day. The individuals kept by Sonnerat lived only about two months; they slept almost continually, and were scarcely to be awakened but by shaking two or three times. Their nourishment consisted of boiled rice which they took up with their long fore-toes, in the manner that the Chinese use their eating sticks. It is a native of Madagascar, where it is rare. Fruits and insects appear to be its usual food.

Some indecision prevails among naturalists respecting the lemur genus, and its immediate affinities; the Linnæan and Gmelinian character is not altogether sufficiently precise, and thus embraces more than one distinct natural genus, of which the galeopithecus (*lemur-volvans*, Linn.) is a prominent example. The number of genera into which Geoffroy divides the lemures is considerable, amounting (independently of the galeopithecii) to no less than five, namely, lemur, indri, lorix, galago, and tarsius. This distribution, with some slight occasional deviations, is adopted by the latest French writers. The genus LEMUR (*maki*) is characterized as having the muzzle very long; four incisive teeth in the upper jaw, beneath six, inclining forwards; grinders tuberculated; ears short, or shortish; tail very long. Under this are retained the Linnæan lemur *catta*, *mongoz*, and *maucaco*; lemur *rufus* of Audebert; lemur *bicolor*.

bicolor (albifrons, Geoff.) and the two little species, called by Geoffroy griseus and pusillus. **INDRI**, the second new genus, consists at present but of two species, the Linnæan *lemur indri* and *laniger*; the former of which is *indri brevicaudatus* of Geoffroy; and the latter *indri longicaudatus* of the same author. There have the muzzle very long; in each jaw four incisive teeth; the upper ones standing distant in pairs; and grinders tuberculated; in other respects they resemble the *lemur*. In the genus **LORIS** the head is rounded, the muzzle short; incisive teeth in each jaw four, the lower ones directed forwards; eyes very open; ears moderate; nostrils situated on the sides of the nose; no tail, but in its place a tubercle; pectoral teats four; this consists of two species, *lemur tardigradus*, Linn.; and *lemur gracilis*, Geoff. **GALAGO**, the fourth genus, is distinguished by the rounded form of the head, short muzzle, two incisive teeth in the upper jaw, very remote; in the lower one six; grinders with pointed tubercles; nostrils placed at the sides of the nose; ears naked, sometimes very large; anterior legs short, posterior ones elongated; second finger of the hind feet shorter than the rest; tail longer than the body, and hairy; scrotum very large. This comprehends *galago senegalensis* of Geoffroy, and *le petit galago*, (*lemur minutus*, Cuvier.) **TARSIS** is the last of these new genera; its character consists in having the head rounded; muzzle a little prolonged; in the upper jaw four incisive teeth, in the lower only two; canine teeth several, and shorter than the incisive ones; the grinders with pointed tubercles; posterior shanks uncommonly long; tail long and tufted; ears large and naked. This genus, which can scarcely, perhaps with propriety, be referred to the *Gmelinian* *lemur*, although partially ascribed to by some authors, comprises *tarsius daubentonii* of Geoffroy (*lemur tarsius*, Pallas), and *didelphis macrotarsus*, Gmel.; with two others, one *lemur spectrum* of Pallas, the other *tarsus Fischerii*, Nob.; a species very recently described, and named *Fischerii* after professor Fisher, by whom it was first introduced to general observation.

**LEMURES**, in *Antiquity*, *sprites* or *hobgoblins*; restless ghosts of departed persons, who return to terrify and torment the living.

These are the same with *larvæ*, which the ancients imagined to wander round the world to frighten good people, and plague the bad. For which reason, at Rome they had *Lemuria*, or feasts instituted to appease the manes of the defunct. See **LARES**.

Apuleius explains the ancient notion of *manes* thus: the souls of men, released from the bands of the body, and freed from performing their bodily functions, become a kind of demons or genii, formerly called *lemures*. Of these *lemures*, those that were kind to their families, were called *lares familiares*; but those who, for their crimes, were condemned to wander continually, without meeting with any place of rest, and terrified good men, and hurt the bad, are vulgarly called *larvæ*.

An ancient commentator on Horace mentions, that the Romans wrote *lemures* for *remures*; which last word was formed from *Remus*, who was killed by his brother *Romulus*, and who returned to earth to torment him.

But Apuleius observes, that in the ancient Latin tongue *lemures* signifies the soul of a man separated from the body by death.

**LEMURIA**, or **LEMURALIA**, a feast solemnized at Rome on the ninth of May, to pacify the manes of the dead, or in honour of the *lemures*.

The institution of this feast is ascribed to *Romulus*, who, to rid himself of the phantom of his brother *Remus* (whom

he had ordered to be murdered) appearing always before him, ordained a feast, called after his name *Remuria*, or *Lemuria*.

In the *Lemuria*, they offered sacrifices for three nights together, during all which time all the temples of the gods were shut up, nor were any marriages permitted. There were many ceremonies in this feast, chiefly intended to exorcise the *lemures*, and prevent their appearing, or giving any disturbance to the living.

**LENA**, in *Geography*, the greatest river of Eastern Siberia. It takes its origin on the north-western side of the *Baikal*, in a morass; runs at first northwards, then to the district of *Yakutsk* eastwards, and lastly towards the north, where, after having divided itself into five great branches at its mouth, and thereby formed four considerable islands, it flows into the Frozen ocean. Its course is computed to be 5000 versts. Its source is in N. lat. 52° 30', its mouth in 73° lat., and the eastern arm in 153, and the western in 143° of longitude. This river has in general a very gentle current; its bottom is mostly sandy, and the shore only in the upper regions beset with hills and cliffs. Of the numerous rivers which it takes up in its course, the largest are the *Vitim*, the *Olekma*, the *Viluy*, and the *Aldan*. Out of the *Lena* travellers pass into the *Aldan*, from that into the *Maia*, from the *Maia* into the *Yadoma*, and from this they have but a short route to make by land to *Okhotsk*. *Tooke's Russ. Emp. vol. i.*

**LENA**, a harbour on the W. coast of *Mindanao*. N. lat. 6° 42'. E. long. 122° 12'.

**LENÆA**, *Λνωια*, in *Antiquity*, a festival of *Bacchus*, surnamed *Lenæus*, from *λενωια*, i. e. a wine-press. Besides the usual ceremonies at feasts sacred to this god, it was remarkable for poetical contentions, and tragedies acted at this time. *Potter's Archæol. lib. ii. cap. 20. tom. i. p. 412.*

**LENATO**, in *Geography*, a town of Italy, in the department of the *Olonæ*; 5 miles S. of *Milan*.

**LENBERAN**, a town of *Perlian* *Armenia*; 168 miles E. of *Erivan*.

**LENCLOISTRE**, a town of France, in the department of the *Vienne*, and chief place of a canton, in the district of *Châtelleraut*; 14 miles N. of *Poitiers*. The place contains 2114, and the canton 7350 inhabitants, on a territory of 182½ kilometres, in nine communes.

**LENCLOS**, ANNE, or **NINON DE**, in *Biography*, an illustrious woman, born at *Paris* in 1616, was daughter of the sieur *De l'Enclos*, a gentleman of *Touraine*, who had served with reputation in the army; her mother was a devotee. She lost both her parents at the age of fifteen, and being left mistress of a large fortune without any one to controul her, she determined to adopt a mode of life suited to her inclinations. She had already derived her philosophy from the works of *Charron* and *Montagne*: she was beautiful, and by much attention became very accomplished, and qualified for the company of the most cultivated persons of her time. Amorous in her constitution, and licentious by principle, she resolved to give free indulgence to the tender passion, without the shackles of a serious engagement. She never sold her favours; and her attachments seem partly to have been prompted by personal attractions, and partly by vanity, as they included persons of high rank and reputation, as well as men of gallantry and fashion. She was complimented and consulted by the most eminent writers of that time, and her friendship was sought by some of the most respectable of her own sex. She was intimate with *madame de Maintenon*, when the wife and widow of *Scarron*, who wished to engage *Ninon*

to live with her, when a partner in the throne, to dispel the dreadful enmity which was the price of her elevation. Ninon preferred her liberty to the prison of a palace, and as she retained her personal charms to a late period, and her mental attractions to the close of life, she was very long the object of admiration, and had the honour of forming more than one generation of young men of fashion. Mothers, so licentious was the age, were pleased to see their sons in her train, as she always promoted decorum, and the air of good company; and it was universally admitted that she was capable of disinterested friendship to those who confided in her. If she were an object of envy to bye-standers, she was, at the same time, conscious of having mistaken the way to true happiness; for in one of her letters to St. Evremont, she says, "Every one tells me that I have less to complain of time, than any other person. However that may be, if such a life, as I have spent, had been proposed to me as my lot, I would have hanged myself rather than have passed through it." She died at the age of eighty. She is reputed to have been the author of a set of letters to the marquis de Sevigné. Some of her real ones are contained in the works of St. Evremont. Moreri.

LENCZICZ, or LENTSCHITZ, in *Geography*, a town of the duchy of Warlaw, formerly capital of a palatinate of the same name in Poland; surrounded with a wall and moat, and defended by a castle placed on a rock. A provincial diet, a court of judicature, and provincial synods of the clergy, are held in this town; 60 miles W.S.W. of Warlaw. N. lat. 51° 52'. E. long. 19° 17'.

LENCZNA, a town of Poland, in the palatinate of Lublin; 16 miles N.E. of Lublin.

LENDAR, a town of Iltria; 19 miles E. of Capo d'Iltria.

LENDENARA, a town of Italy, in the Polse di Rovigo; containing two churches and four convents; 8 miles W. of Rovigo.

LENDORA, a town of Russia, in the government of Olonetz; 100 miles W.N.W. of Povenetz.

LENE LOUGH, a lake of Ireland, in the county of Westmeath, near the small town of Fore.

LENES, a small island in the North sea, near the coast of Norway. N. lat. 67° 40'.

L'ENFANT, DAVID, in *Biography*, a French Dominican friar, was born at Paris in the year 1603. He embraced the ecclesiastical life at the age of seventeen, and manifested a most ardent thirst for knowledge, together with very uncommon literary industry. He died in the year 1688, at the age of eighty-five. His principal work is "A General History of all Ages," in three vols.; which was afterwards extended to six volumes. He also published "Sancti Bernardi Abbatis Biblia," containing a collection of all the illustrations of texts of scripture dispersed throughout the works of that author; and similar works respecting biblical illustrations of St. Augustine, and St. Thomas Aquinas. Moreri.

L'ENFANT, JAMES, an eloquent as well as very learned French Protestant divine, was born at Bazoché in the year 1661. He pursued his theological studies at Saumur, under Lewis Cappel, professor of Hebrew, and afterwards at Geneva. In 1683 he left Geneva, and was admitted in the following year to the exercise of the ministry at Heidelberg, and ordained pastor of the French church in that place. Owing to his superior pulpit talents he was appointed chaplain to the dowager electress palatine. In 1688, on the invasion of the palatinate, he removed to Berlin, and was appointed pastor of one of the churches. He was in a short

VL. XX.

time nominated preacher to the queen of Prussia. In 1707 we find him in England, and nominated one of the chaplains to queen Anne, an honour which he declined on account of his great attachment to Berlin. He died in 1728, at the age of sixty-seven. His publications were numerous in divinity, ecclesiastical history, criticism, and polite literature. Those which are held in the highest estimation are his "Histories of the Councils of Pisa, Constance, and Basil." These histories are written with great ability and impartiality, and they abound with interesting facts and curious researches. L'Enfant, in conjunction with M. Beaufoire, published "The New Testament translated from the original Greek into French," in two volumes 4to. with notes, and a general preface, or introduction to the reading of the holy scriptures, useful for students in divinity. He is known also by his "De Inquirenda Veritate," which is a translation of Malebranche's "Search after Truth;" "The History of Pope Joan;" "Poggiana, or the Life, Character, Opinions, &c. of Poggio, the Florentine, with the History of the Republic of Florence," and other works. Moreri.

LENGA DE BAZARA, in *Geography*, a province on the coast of Caramania. N. lat. 36° 33'. E. long. 34° 11'.

LENGEFELD, a town of Saxony, in the circle of Erzgebürg; 12 miles S.E. of Chemnitz. N. lat. 50° 40'. E. long. 13° 7'.

LENGEFELD, or *Lengensfeld*, a town of Saxony, in the Vogtland; 10 miles S.S.W. of Zwickaw. N. lat. 50° 27'. E. long. 12° 22'.

LENGER, a town of Persia, in Khorasan; 162 miles N.N.W. of Herat.

LENGER *Kuran*, a town of Persia, in Ghilan; 120 miles N.W. of Reshd.

LENGFURT, a town of Germany, in the county of Wertheim; 12 miles S.S.W. of Wertheim.

LENGHIER, a town of Persia, in Khorasan; 70 miles E. of Herat.

LENGHIA, a town of Sweden, in West Gothland; 42 miles E. of Gothenburg.

LENGLET, DU FRESNOY, NICHOLAS, in *Biography*, was born at Beauvois in 1674. He applied himself particularly to the study of theology, and composed several works in a strain of freedom, which attracted the censure of the Sorbonne, and other established bodies. Disgusted with the opposition which he met with, he quitted divinity for politics, and in 1705 was sent by Torcy, minister for foreign affairs, to reside at the court of the elector of Cologne, as secretary for the Greek and Latin languages. He was entrusted with the management of the foreign correspondence with Brussels and Holland, by means of which he became acquainted with various plots against the French interest. Lenglet returned to France at the conclusion of the war, and employed himself in many literary works. In 1721 he went to Vienna, and was appointed librarian to prince Eugene, a post which he did not long retain, on account of some misconduct. Owing to this circumstance, he always remained in indignance, though he had friends that would have raised him to a better condition. Some of his writings were composed in so free a style as to cause the author to be imprisoned several times in the Bastille. He was accidentally burnt to death in the year 1755, in his eighty-second year. Of his various works we may notice those which are most esteemed, *viz.* "Méthode pour étudier l'Histoire, avec un Catalogue des principaux Historiens," 12 vols.; "Méthode pour étudier la Géographie," with maps; "Histoire de la Philosophie Hermetique," and "Tablettes Chronologiques de l'Histoire Universelle," two vols. 1744. An enlarged edition

edition of this work was published in 1777, by Bruyere, to which we have been indebted in the course of our inquiries. Mereri.

LENGO SPERANNO, in *Geography*, a town of Africa, in Congo; 45 miles S.S.W. of Bombi.

LENGTIL, in the *Manege*. *To passage a horse upon his own length*, is to make him go round in two treads, at a walk or trot, upon a spot of ground so narrow, that the horse's haunches being in the centre of the volt, his own length is much about the semidiameter of the volt; the horse still w-rings between the two heels, without putting out his croupe, or going at last faster or slower than at first.

LENGTHENING, in *Naval Architecture*, is the operation of separating a ship athwart the midships, and adding a certain portion to her length. It is performed by clearing all the fallings near the butts of those planks as may be retained, and the others are cut asunder. The after end is then drawn or lunched apart to the required distance. The keel is then made good, and a sufficient number of floors erected, and timbers raised to fill up the vacancy produced by the separation. The keelson is then replaced to give good shift to the carfs of the keel. The planks on the outside are then replaced with a proper shift, also the clamps and foot-waling inside. As many beams as are necessary are next placed athwart and kneed, the decks made good, and the ship completed in all respects as before. Sometimes ships are shortened in a similar manner.

LENGUR, in *Geography*, a town of Persia, in the province of Mazanderan; 15 miles N.W. of Amol.

LENHOFDA, a town of Sweden, in the province of Smaland; 30 miles N.W. of Calmar.

LENIOR, a county of America, in Newbern district, North Carolina, surrounded by Glasgow, Craven, Jones, and Dauphin; containing 3898 free inhabitants, and 1457 slaves. The chief town is Kingston.

LENIS SPIRITUS, in *Profody*. See SPIRIT.

LENITIVE, in *Physic*, sometimes denotes a softening, resolutive remedy, that moistens the parts diseased, and diffuses any sharp humour collected there.

LENITIVE is more frequently used for laxative.

LENITIVE Elixuary is more peculiarly used for a gentle purging electuary. See ELECTUARY of Senna.

LENKERAN, in *Geography*, a town of Persia, in the province of Ghilan, near the Caspian sea. N. lat. 28° 40'. E. long. 49°.

LENNAN, LA, a town of Peru, in the diocese of La Paz; 27 miles N. of Potofi.

LENNEP, a town of the duchy of Berg, inhabited for the most part by Lutherans; 20 miles E.S.E. of Dusseldorf. N. lat. 51° 0'. E. long. 7° 18'.

LENO, a harbour on the W. coast of the island of Mindanao.

LENNICK-SAINTE-MARTIN, a town of France, in the department of the Dyle, and chief place of a canton, in the district of Brussels. The place contains 1559, and the canton 10,606 inhabitants, on a territory of 120 kilometres, in 12 communes.

LENOS, in Hippocrates, denotes an old machine for reducing fractures and dislocations.

LENOX, in *Biography*. See RICHMOND, Duke of.

LENOX, in *Geography*, an island in the Mergui Archipelago, about five miles in circumference. N. lat. 6° 2'.

LENOX, the shire town of Berkshire county, Massachusetts; it is a pleasant and thriving town, and has a court house and a gaol. The river Housatonic traverses the town; 145 miles N. of Boston. The number of inhabitants is 1041.

LENOX Castle, a post-town of Buckingham county, North Carolina; 290 miles from Wallington.

LENS, in *Dioptrics*, properly signifies a small, roundish glass, of the figure of a *lentil*; but is extended to any detached portion of a transparent substance, of which the opposite sides are regular polished surfaces of such forms as may be described by lines revolving round a common axis; or to any optic glass, not very thick, which either collects the rays of light into a point, in their passage through it, or disperses them farther apart, according to the laws of refraction. A lens is generally supposed, in simple calculations, to be infinitely thin, and to be denser than the surrounding medium.

Lenses have various figures; that is, are terminated by various surfaces, from which they acquire various names. The lines that form them may be portions of circles, of ellipses, of hyperbolas, or of any other curves, or they may be right lines. But, in general, one of the sides is a portion of a spherical surface, and the other either a portion of a spherical surface or a plane. Hence some are plane on one side, and convex on the other; others convex on both sides; both which are ordinarily called *convex lenses*; though, when we speak accurately, the former are called *plano-convex*, and the latter, *double convex*. Again, some are plane on one side, and concave on the other; and others are concave on both sides, which are both usually ranked among the *concave lenses*; though, when distinguished, the former is called a *plano-concave*, and the latter, a *double concave*. Others, again, are concave on one side, and convex on the other; which are called *convexo-concave*, or *concavo-convex lenses*. The figures of all these are sufficiently described by their names (see also *Plate VI. Optics, fig. 5.*); except that the term *meniscus*, which properly implies a little moon or crescent, is applied in general to all lenses which are convex on the one side, and concave on the other, although they may be thicker at the edges than in the middle. Sometimes, however, a lens of this kind is distinguished by the term *convexo-concave*. See MENISCUS.

When the particular figure is not considered, a lens that is thickest in the middle is called a *convex lens*; and that which is thinnest in the middle is called a *concave lens*, without farther distinction.

It is to be here observed, that in every lens terminated in any of the aforementioned manners, a right line perpendicular to the two surfaces is called the *axis* of the lens; which axis, when both surfaces are spherical, passes through both their centres; hence it is manifest, that no lens, except the sphere, can have but one axis; and therefore all pencils of rays are oblique, excepting those whose foci are in the axis of the lens; but if one of them be plane, it falls perpendicularly upon that, and goes through the centre of the other. The points where the axis cuts the surface are called the *vertices* of the lens, and the middle point between them is called the *centre*. This is the case, when the lenses are thin, as they are usually supposed to be; but when the lens is pretty thick, and its surfaces of unequal curvatures, then the centre of the lens is nearer to one vertex than to the other; by as much as the radius of curvature of the former surface is less than that of the other.

For the explanation of other terms that pertain to lenses, and of their general effect, it is obvious, that if a ray of light falls perpendicularly upon the vertex of a lens, or coincides with its axis, it must pass straight through the lens without suffering any refraction; but when it falls obliquely upon it, it must emerge out of the lens in a direction inclined to its former direction. Thus, if the rays of light, which,

issuing from the luminous point A, (*Plate VI. Optics, fig. 6.*) fall upon the lens B E, the ray A C, which proceeds in the direction of the axis of the lens, must pass straight through it; but the ray A B, falling obliquely upon the surface of the lens, must be refracted, or bent, and if the lens be a plano-convex, or double convex, that ray must be bent inwardly, that is, towards the axis; consequently it must intersect the axis in some point, as F. This point F is called the *refracted focus* of that ray, or rather of the rays A B, A E, &c. which fall upon the lens at equal distances from the axis A C, and which all meet and cross at the same point F; but the point A from which they issue, is called the *radiant point*, or the *focus of incident rays*; and both these points, in reference to each other, are called the *conjugate foci*. If a lens be concave, as in *fig. 7*, then the oblique rays A B, A E, &c. will be bent outwardly, or from the axis; in which if the refracted rays be supposed to be continued backwards until they meet the axis as at F, then the point F is called the *virtual focus of the refracted rays*, being in fact the centre of divergency of the rays. In this case the conjugate foci are both on the same side of the lens; viz. the real focus of incident rays, and the virtual focus F of the refracted rays B G, D O, E S. It is to be observed, that all the rays which fall upon the surface of a lens, whether it be convex or concave, will not meet at one and the same point when the lens is convex, nor have a common virtual focus when it is concave: but those rays which are more distant from the axis, after the refraction, meet sooner than those which are nearer to the axis; and this effect is greater in proportion as the surfaces of the lens are farther from each other, and consist of larger spherical segments. Hence a glass globe renders the above-mentioned effect very conspicuous; and hence the lenses are made as thin as possible; but in all cases, a lens which consists of spherical surfaces, does never refract the rays which fall from a luminous point, precisely to the same focus. The rays which fall upon the edge of the lens have their refracted focus not only nearer to the lens, but also farthest from the axis, viz. on one side of it. Lines drawn through the refracted foci of the rays, which belong to one luminous or radiant point, form two curves, which make an angle with each other at the axis, or principal focus, and are called "caustics by refraction" (see CAUSTIC); which are real in convex lenses, but imaginary in those that are concave. When the lenses are thin, and their sphericity not very great, these caustics are so trifling that the eye does not perceive them; but lenses that are thick and of great convexity produce a considerable aberration of the rays, and an evident distortion of the object to an eye that looks through them. This aberration may be exhibited experimentally by covering one side of a glass globe or thick lens with a circular piece of brown paper, having a row of equidistant pin-holes in its diameter. Let the light which passes through these holes, and through the lens, fall upon a piece of white paper held perpendicular to the rays of light, and you will find that when the paper is held near to the globe or lens, the spots of light upon it are at equal distances from one another successively; but if the paper be gradually withdrawn from the lens, the intervals between the exterior spots grow less than the intervals between the interior, and soon unite. If the same operation be performed with a thick concave lens, the intervals between the exterior spots will be found to grow larger than the interior, &c. There is another aberration, resulting from the different refrangibility of the rays of light; and which causes a much greater imperfection in lenses. For an account of both, see ABERRATION. Notwithstanding these

aberrations, glass lenses, that are not very thick, are reckoned to have a determinate focus of refracted rays, originally issuing from a single radiant point; and the distance of that focus from the surface of the lens is called the *focal distance* of these rays. In order to prepare the way for determining their focal distance, it may be considered, that about the middle of the surface of every lens there is a point, upon which, if a ray falls and passes through the lens, the emergent part will be parallel to the incident; for the point of incidence and the point of emergence may be so situated, that if two planes touch the surfaces at these points, they may be parallel to each other. That ray or part of a pencil of light, which thus passes through the lens, without being bent, is called the *axis of that pencil*, and this axis passes through the *centre* of the lens. When rays of light fall upon the same lens with different inclinations, it is evident that after the refraction, they must have their foci at different distances from the lens. When rays of light come parallel to each other, such as those which come from a point of the sun's surface, or from any other distant point, and fall perpendicularly, or nearly so, upon the surface of a lens; then the focus of these rays, after refraction, is called the *geometrical focus*, or the *principal focus* of that lens, and its distance from the lens the *principal focal distance* of that lens. The principal focus of a lens may be found either experimentally or by computation. In a plano-convex, double-convex, or meniscus, the principal focus is real; in the other lenses the focus is virtual. See the *Theory of Lenses demonstrated under REFRACTION and DIOPTRICS*, and the application thereof under MICROSCOPE, TELESCOPE, BURNING-GLASS, and FOCUS.

Some confine lenses within the diameter of five or six lines, and will have such as exceed that diameter called *lenticular glasses*.

Lenses are distinguished, with regard to the manner of their preparation, into *ground* and *blown*.

LENSES, *Blown*, are little globules of glass, melted in the flame of a lamp, or taper. See MICROSCOPE.

LENSES, *Manner of grinding*. A little piece of copper is cemented to the end of the arbor of a lathe, and turned till it form a Dish, or bason, of the diameter of the lens required. Then a piece of clear glass is cemented, on one of its flat sides, to the end of a little maundrel, with black Spanish wax; and thus ground, on the side not cemented, on a grindstone, with water, till it hath nearly acquired a convex figure. It is finished in the lathe, by turning it in the bason, with fine wet sand, grit-stone, or emery. The grit must be often repeated fresh till the lens appear very round; when it is come to that point, they cease to take any fresh stone, but continue to turn it in the bason, till the remains of the sand are become so fine as to have polished it. This they perceive, when, upon wiping it, the image of the window of the place is seen painted on its surface; if it does not, it is wetted in water without any sand, and turned till it hath got a polish. The bason is then covered, within-side, with two or three folds of linen, and the polish finished with putty, or tripoly of Venice steeped in water. It is known to be perfectly polished, when, viewing it with a magnifier, there appear no scratches of the sand. The cement is then broken off, and the side polished cemented, to work and grind the other, as before, till the edges of the lens be become sharp, and it be perfectly polished on either side. When finished, it is washed in spirit of wine, to take off all remains of the wax.

According to the mode now generally practised, optical glasses are fixed on blocks by means of a cement, and ground with emery by a tool of proper convexity or concavity;

cavity; if they are small, a large number is fixed on the blocks at the same time. The tool is sometimes first turned round its axis by machinery, and when the lenses are to be finished, a compound motion is given to it by means of a crank; and in order to make it more smooth, the wheels turn each other by brushes instead of cogs. The point of the lens where its two surfaces are parallel, is determined by looking through it at a minute object, while it is fixed on a wheel with a tubular axis, and shifting it, until the object appears no longer to move; a circle is then described, as it revolves, in order to mark its outline. The dishes in which lenses are sometimes ground are of bell metal; and the emery is prepared by elutriation.

In the Philosophical Transactions we have the figure of a machine for grinding lenses spherically. It is a contrivance to turn a sphere at one and the same time on two axes, intersecting each other at right angles, with an equal velocity and pressure on each. See the Transactions, N<sup>o</sup> 459. sect. 1. See GRINDING of *Optic Glasses*.

LENSES, for convex, the laws of their refraction, and their effects depending thereon, are as follow.—1. A ray of light, E G, near the axis (*Plate VI. Optics, fig. 8.*), and parallel to it, striking on the plane surface of a plano-convex lens, directly opposite to the luminous body, after refraction concurs with the axis in the point F: and if C be the centre of the convexity, C F will be to F L, that is, the distance of the centre from the point of concurrence, or focus, will be to the distance of the centre, from the convex surface, in the ratio of the refraction.

For the plane surface being directly opposed to the luminous body, the ray E G is perpendicular to A B, and therefore will pass unrefracted to H: thus it strikes on A H B, still parallel to the axis; and therefore coming out of a denser medium into a rarer, it will meet with the axis of the lens in F: and so as that C F will be to F L in the ratio of the sine of the refracted angle to the sine of the angle of incidence: as will be demonstrated under the head REFRACTION.

And, therefore, C F — F L, or C L is to F L as the difference of these sines is to the sine of the angle of incidence; and C F — F L, or C L is to C F as the same difference is to the sine of the refracted angle.

If then the refraction be out of a glass lens into air, C F: F L :: 3 : 2, or C L: F L :: 1 : 2, and C L: C F :: 1 : 3; and therefore F L = 2 C L; that is, parallel rays, near the axis, will concur with it at the distance of the diameter. Moreover, if parallel rays pass out of air into glass, it will be C F: F L :: 2 : 3, and C L: F L :: 1 : 3; and C L: C F :: 1 : 2. It is evident from hence, that if C L be diminished, without any variation in the refracting power, F L would also be diminished. Again, if the refraction were out of a water lens, *i. e.* out of a plano-convex lens filled with water, C F: F L :: 4 : 3, or C L: F L :: 1 : 3; and therefore F L = 3 C L; *i. e.* parallel rays, near the axis, will concur with it at the distance of a diameter and a half. It is easy to deduce the effect of refraction out of air into water. So that if a lighted candle be placed in the focus of a plano-convex lens, that is, in the point F, distant from the surface of the lens A L B, by the length of the diameter; and from the surface of the water lens by a diameter and a half, its rays, after refraction, will become parallel.

2. If the ray K I, (*Plate VI. Optics, fig. 9.*) near the axis of a plano-convex lens, and parallel to it, strike on its convex surface A H B, after a double refraction, it will meet the axis in F; so as that H G will be to G C, and G D to F D, in the ratio of the refraction.

For the ray K I, parallel to the axis E G, by virtue of

the first refraction in I, will tend to the point G, so that G H will be to G C in the ratio of the sine of the angle of incidence to the sine of the refracted angle: therefore, by virtue of the second refraction in L, it will concur with the axis in F; so that G D will be to F D in the ratio of the sine of the refracted angle, to the sine of the angle of incidence. See REFRACTION.

So that the semidiameter, and thickness of the plano-convex lens, with the ratio of refraction, being given, we shall have a method of determining the focus of parallel rays striking on the convex surface. For, if the ratio of refraction be expressed by  $n : m$ , H G : G C ::  $n : m$ ;

therefore  $n - m : n :: H C : H G$ ; and  $H G = \frac{n}{n - m}$

× H C: from which subtracting the thickness of the lens,

D H, and G D =  $\frac{n}{n - m} \times H C - H D$ . Then since

the ratio of G D to F D is the given ratio of refraction,

F D =  $\frac{m}{n - m} C H - \frac{m}{n} H D$  = (rejecting the quantity

$\frac{m}{n} H D$  as very small)  $\frac{m}{n - m} C H$ .

Hence, if the lens be glass, F D = 2 C H —  $\frac{2}{3}$  H D. So that if two thirds of the thickness of the lens be inconsiderable, (as in practice it usually happens,) parallel rays meet with the axis at the distance of the diameter from the lens, even when they strike at a convex surface.

So that, as to the place of the focus, it is the same thing whether the plane surface, or the convex one, be turned to a luminary of parallel rays; though it appears, both from experience and trigonometrical calculations, that there are more rays united in a lens space, if the convex surface, than if the plane one, be turned towards the sun.

If the lens were full of water, F D = 3 C H —  $\frac{2}{3}$  H D, and therefore, if  $\frac{2}{3}$  H D be inconsiderable, F D = 3 C H, or if  $\frac{1}{4}$  H D be inconsiderable, F H = 3 C H. Parallel, and near rays, therefore, are united at the distance of a diameter and a half, if the refraction be in water, even when the convex surface is opposed to the luminous body.

3. Hence, also, arises a method of determining the focus of parallel rays striking on a lens convex on both sides, the two semidiameters, and the thickness of the lens, being given.

For if the ray H I, (*Plate VI. Optics, fig. 10.*) near the axis D G and parallel to it, fall on a lens convex on both sides, after a double refraction, it will meet the axis in F, provided that G E : G C and D K : D O have the ratio of refraction. And G D will be to G K as G O to G F. Since E G : G C in the ratio of refraction, the ray H I will tend to the point G; and if D K be to D O in the ratio of refraction, after the second refraction at its egress, it will meet the axis in F, and G D : G K :: G O : G F. See REFRACTION.

And therefore, G D : D K :: G O : F O. Let the ratio of refraction be that of  $n : m$ , then G E : G C ::  $n : m$ , and D K : D O ::  $n : m$ ; and, therefore,  $n - m : n :: C E : G E$ , and  $n - m : n :: K O : D K$ ; wherefore if the ratio of refraction and the semidiameters C E and K O are given, G E and D K may be found: and since G D = D K + E G — E K, and G K = G E — E K, and G O = G E + K O — E K, and G D : G K :: G O : G F; and G F may be found: moreover G E — G F = E F. If E K be rejected as very small, G D = D K + E G, G K = G E, and G O = G E + K O; and therefore, D K + E G : G E :: G E + K O : G F.

Hence, if the lens be glass, since  $GE = 3 CE$ , and  $DK = 3 KO$ ,  $3 KO + 3 CE : 3 CE :: 3 CE + KO : GF$ ; consequently  $KO + CE : CE :: 3 CE + KO : GF$ . And substituting for  $KO$ ,  $a$ ,  $CE$ ,  $b$ , and  $GF$ ,  $x$ ,

$$x = \frac{3bb + ab}{a + b}, \text{ and FE or FK, (rejecting E K) } = 3b - \frac{3bb + ab}{a + b} = \frac{3ab + 3bb - 3bb - ab}{a + b} = \frac{2ab}{a + b};$$

therefore the sum of the semidiameters  $KO + CE$  is to the double of one of them, or  $2 CE$ , as the other  $KO$  is to  $FK$  the distance of the focus from the lens.

If the glass lens were equally convex on both sides, then  $KO = CE$ , and  $2 CE : CE :: 4 CE : GF$ , and therefore,  $GF = 2 CE$ ; and  $FK = \frac{2a^2}{2a} = a = EC$ ; *i. e.*

the distance of the focus from the lens is equal to the radius of convexity.

If the lens were full of water, since  $GE = 4 CE$ , and  $DK = 4 KO$ ,  $4 KO + 4 CE : 4 CE :: 4 CE + KO : GF$ ; consequently  $KO + CE : CE :: 4 CE + KO : GF$ . Wherefore substituting as before  $x = \frac{4bb + ab}{a + b}$ ,

and  $FE$  or  $FK = 4b - \frac{4bb + ab}{a + b} = \frac{3ab}{a + b}$ ; consequently the sum of the semidiameters  $KO + CE$  is to the triple of either,  $3 CE$ , as the other  $KO$  is to  $FK$ , the distance of the focus from the lens.

If this lens were equally convex on both sides, we should have  $2 CE : CE :: 5 CE : GF$ ; therefore  $GF = \frac{5}{2} CE$ ; and  $FK = \frac{3aa}{2a} = \frac{3}{2} a$ ; *i. e.* the distance of the focus from the lens is  $\frac{3}{2}$  of the radius.

In order to find the principal focus of a plano-convex, or double convex lens experimentally, various methods have been devised and recommended. One is as follows: Measure exactly the thickness of the lens in the middle and at the edge, and also its breadth; then it will be, as the difference of the above thicknesses is to half the breadth, so is half the breadth to the focal length required. The following method will serve, according as the centres of the sides are on different sides or on the same side of the lens; as the sum or difference of the radii of the sides is to one of them, so is double the other to the focal distance from the lens. If the curvity of each side is the same, the radius of that curvity may be deemed the focal length; and if one side of the lens is plane, the focal length may be reckoned equal to twice the radius of the spherical side. The focal length of a convex lens may be also found by the following methods: darken a room, so that no light shall enter into it except through a tube in one of the window-shutters; then, placing the lens against and close to this hole, move a white paper behind it, till the picture of a particular object, directly facing the lens, appears most distinct, and there fix the paper; then measuring the distances betwixt the paper and the object from the lens respectively, there will be sufficient data for finding the focal length required. Let  $QP$  (*fig. 11.*) be the object without doors,  $A$  the lens in the window-shutter,  $qp$  the place of the paper where the image of  $QP$  is most distinct, and  $QAq$  the axis of the lens. Having measured the distances  $QA$ ,  $qA$ , it will be,  $Qq : QA :: QA : QF$ ; and  $QA - QF = AF$  the focal length required.

The focal length of any lens, it is observed, is in strictness the distance from its principal focus to the respective focal centre: in the example above given, the distances betwixt the focal centres of the lens should have been subtracted from  $Qq$ ; and for  $QA$  we should have taken the distance from  $Q$  to the nearest focal centre. But in experiments of this kind, these niceties would be superfluous. Moreover, in the above experiment, there will be a certain part of the axis, extending on each side of the geometrical focus  $q$ , within which, wherever the paper is placed, the picture as to sense will be equally distinct. Having found nearly the place of  $q$ , move the paper from thence both ways along the axis, till an indistinctness begins to be perceptible in a particular final part of the picture; and having noted these two places, the middle point between them may be taken for the focus  $q$ . Again, if the focal length of the lens does not exceed two or three feet, it may be found without darkening the room, by holding the lens at such a distance off, that the image of the window-shut may be distinct upon the opposite window: then computing as above, the window-shut being now the object. And for common purposes, when the focal length of a lens is but short, this length may be reckoned the distance from the lens to the place where the image of a remote object appears most distinct. For if the object be distant from the lens 100 or 1000 times the focal length, the image will be beyond the principal focus only the 100th or 1000th part of that focal length. The focal length of a lens may be found, without computation, by making the flame of a candle the object, thus: Move the lens or the candle, and the paper for receiving its image, so that, when the image is most distinct, the lens be exactly in the middle betwixt the other two; then half the distance betwixt the object or its image and the lens is the focal length required. Or if either the lens, or the candle, or the paper for receiving its image, be moved, while the other two are fixed; having measured the respective distances, the focal length may be found in the manner already stated. Or, if a small hole, of about one-fourth or one-eighth of an inch broad, be made in the window-shutter of a darkened room, and a lens and a paper be held behind this hole at proper distances; the place where the image of the hole is most distinct may be determined very accurately, and so the focal length of the lens may be found as above. Again, place the lens so that its axis may point as nearly as possible towards the sun; then holding a paper behind it, the burning point, or that in which the sun's image is smallest, and when its limb appears most distinct, is the focus of the lens. See these various methods illustrated more at large in Harris's Optics, book ii. § 4.

On the principles above illustrated is founded the structure of refracting burning-glasses, the sun's light and heat being exceedingly augmented in the focus of the lens, whether convex or plano-convex; since the rays, falling parallel to the axis of the lens, are reduced into a much narrower compass; so that it is no wonder they burn some bodies, melt others, and produce other extraordinary phenomena. See *BURNING GLASS*.

4. If a luminous body be placed in a focus behind a lens, whether plano-convex, or convex on both sides; or whether equally or unequally; the rays, after refraction, become parallel. In this case the refracted rays become the incident rays, and *vice versa*; and consequently the refracted are parallel. Hence, by means of a convex lens, or a little glass bubble full of water, a very intense light may be projected to a vast distance.

And this furnishes us with the structure of a lamp, or lantern, to project an intense light to an immense distance;

for a lens, convex on both sides, being placed opposite to a concave mirror, if in the common focus of both be placed a lighted candle, or wick, the rays reflected back from the mirror to the lens will be parallel to each other; and after refraction will converge, till they concur at the distance of the semi-diameter, after which they will again diverge. But the candle being likewise in the focus of the lens, the rays it throws on the lens will be parallel: and therefore a very intense light meeting with another equally intense, at the distance of the diameter from the lens, the light will be surprising; and though it afterwards decrease, yet the parallel and diverging rays going a long way together, it will be very great at a very great distance. Lanterns of this kind are of considerable service in the night-time to discover remote objects, and are used with success, by fowlers and fishermen, to gather their prey together, in order to take them.

If it be required to have the light, at the same time, transmitted to several places, as through several streets, &c. the number of lenses and mirrors is to be increased.

If the luminous body placed in the focus be of a larger extent, the rays, flowing from points sensibly distant from each other, cannot be parallel; but they will constitute several trains, or parcels of rays, parallel to each other.

5. The images of objects, opposed in any manner to a convex lens, are exhibited, invertedly, in its focus.

Hence, if a paper be applied to a convex lens (especially in a dark room) at the distance of its focus, the images of objects shining upon it will be represented distinctly, and in their natural colours, upon it: nor is the focus of the sun's rays any thing else, in effect, but the image of the sun. Hence in solar eclipses, the sun's image, eclipsed as it is, may be burnt by a large lens on a board, &c., and exhibit a very entertaining phenomenon.

Hence, also, if a convex lens, of any kind, be exposed both to nearer and remoter objects, and a paper at the same time be applied, so as to receive the images of objects distinctly, the distance of the focus from the lens, and thence the diameter of the convexity, may be determined. See the above.

6. If a concave mirror be so placed, as that an inverted image, formed by refraction through a lens, be found between the centre of the focus, or even beyond the centre, it will again be inverted by reflection, and so appear erect in the first case beyond the centre; and in the latter, between the centre and the focus. On these principles is constructed the *camera obscura*, which see.

7. The diameter of the image of an object delineated beyond a convex lens, is to the object itself in the ratio of the distance of the image to that of the object.

Since then the image of a remoter object is less distant from the lens than that of the nearer, the image of the more remote will be less than that of the nearer. And because the distance of the image from the lens is greater, if the lens be a segment of a greater sphere than of a less; hence the image will be greater in the former case than in the latter. The image therefore will be of such a magnitude, as it would be of, were the object to shine into a dark room through a little hole upon a wall, at the same distance from the hole at which the focus is from the lens. When an object is less distant from a lens than the focus of parallel rays, the distance of the image is greater than that of the object; otherwise the distance of the image is less than that of the object; in the former case, therefore, the image is greater than the object; in the latter less.

If the images be made greater than the objects, they will not appear distinctly; because in that case there are fewer

rays which meet after refraction in the same point; whence it happens, that rays proceeding from different points of an object terminate in the same point of an image, which is the cause of confusion. Hence it appears, that the same aperture of a lens may be admitted in every case, if we would keep off the rays which produce confusion. However, though the image is then more distinct when no rays are admitted but those near the axis, yet for want of rays the image is apt to be dim.

8. If the eye be placed in the focus of a convex lens, an object viewed through it appears erect, and enlarged in the ratio of the distance of the object from the eye, to that of the eye from the lens, if it be near; but infinitely, if remote.

The theory of real images may be thus illustrated by an experiment. Upon a long table draw the line B D (*Plate VIII. Optics, fig. 1.*) and over some point there as A, place the convex lens O, whose principal focuses are F, f; so that the axis F f of the lens be parallel to B D. In the line B D, take A E, A f, each equal to O F or O f in the axis O Q. On one side of A divide the line A B into the parts 1, 2, 3, 4, &c. each equal to A F; and on the other side take f 1 equal to A f or A F, and divide it into f' 1, f' 2, f' 3, &c. so that these parts be respectively equal to  $\frac{1}{2}$ ,  $\frac{1}{3}$ ,  $\frac{1}{4}$ , &c. of f 1 or A f. Then if the room be darkened, and a lighted candle be placed over any one of the divisions in the line A B, as at 2; the image of the candle will be seen distinct but inverted, upon a paper held over the corresponding fraction on the other side, as at  $\frac{1}{2}$ . If the candle be placed at the point 3 or 4, &c. the paper for receiving the image must be held over  $\frac{1}{3}$  or  $\frac{1}{4}$ , &c. So that if the candle be moved from 2 to an infinite distance, the whole motion of the image will be from  $\frac{1}{2}$  to f. If the candle be placed at 1, the image will be at 1, at the same distance from the lens on the other side. If the candle be brought nearer to F, the motions of the image and candle will now be reciprocal, to what they were before. But if the candle be placed any where between F and the lens, there will be no image formed.

Since an object placed at any distance, and its image, subtend equal angles at the focal centres *s, v*, of any lens; the angle under which any remote object appears being given, it will be easy to find the diameter of its image: let *q* (*fig. 2.*) be the principal focus of the convex lens O, and let the angle P s R (= *p v r*) be that under which the sun (or any other very remote object) appears to the naked eye: bisect the angle *p v r* with the line *v q*; then in the right-angled triangle *v q p* or *v q r*, we shall have the side *v q* and all the angles; whence it will be easy to find *q p* or *q r*, the semi-diameter of the image. See IMAGE and REFRACTION.

LENSES, *for concave*, their laws are as follow.—1. If parallel rays strike on a plano-convex lens K L, and F C be to F B in the ratio of refraction, the rays will diverge from the axis; and the point of divergency, or dispersion, called the *virtual focus*, will be F. See *Plate VII. Optics, fig. 3.* See FOCUS.

For the ray H I, parallel to the axis, is perpendicular to K L, and will therefore pass unrefracted to E. Wherefore F C being to F B in the ratio of refraction, F will be the virtual focus.

If then the lens be glass, F B = 2 B C; *i. e.* the virtual focus F will be distant from the lens K L by the space of the diameter 2 B C.

If the refraction be in water, F B = 3 B C; *i. e.* the virtual focus F will be distant from the lens K L a diameter and a half 3 B C.

2. If the ray  $A E$ , parallel to the axis  $F P$ , strike on a lens concave on both sides; and both  $F C$  be to  $F B$ , and  $I P$  to  $P H$  in the ratio of refraction; and  $F P : P H :: F B : B G$ ;  $G$  will be the point of dispersion, or the virtual focus. See *Plate VII. Optics, fig. 4.*

If, therefore, the ratio of the refraction be  $n : m$ ,  $C B = a$ , and  $I H = b$ ;  $F B = \frac{n a}{n - m}$ , and  $P I = \frac{n b}{n - m}$ ; consequently, disregarding the thickness of the lens,  $F P = F B + I P = \frac{n a + n b}{n - m}$ , and  $P H = P I - I H = \frac{n b}{n - m} - b = \frac{m b}{n - m}$ ; therefore,  $\frac{n \times a + b}{n - m} : \frac{m b}{n - m} :: \frac{n a}{n - m} : B G$ ; *i. e.*  $a + b : \frac{m b}{n - m} :: a : B G$ , or  $n - m \times a + b : m b :: a : B G$ ; *i. e.*  $\frac{n - m}{m} \times C B + I H : m I H :: C B : B G$ .

If, therefore, the refraction be in a glass lens, so that  $m \neq 2$ ,  $n = 3$ , and  $a + b : 2 b :: a : B G$ ; the sum of the semidiameters  $C B$  and  $I H$  will be to the diameter of the concavity of either,  $2 I H$ , as the semidiameter of the other  $C B$ , to the distance of the virtual focus from the lens,  $B G$ .

But if the semidiameters  $H I$  and  $C B$  are equal, or  $a = b$ ,  $B G = \frac{2 a^2}{2 a} = a$ ; or  $B G$ , the distance of the virtual focus from the lens, is equal to the semidiameter  $C B$  or  $H I$ . If the refraction be made in water,  $m = 3$  and  $n = 4$ , and, therefore,  $a + b : 3 b :: a : B G$ ; *i. e.* the sum of the semidiameters  $C B$  and  $H I$  will be to a diameter and a half of either concavity,  $3 H I$ , as the semidiameter of the other  $C B$  to  $B G$ , the distance of the virtual focus from the lens:

in this case, if  $a = b$ , or  $H I = C B$ ,  $B G = \frac{3 a^2}{2 a} = \frac{3}{2} a = \frac{3}{2} C B$ , *i. e.* the distance of the virtual focus from the lens  $B G$ , is to the semidiameter  $B C$  in a sesquilateral ratio.

Hence, the sun's rays striking on a concave lens, their light, after refraction, will be considerably weakened; so that the effect of concave lenses is opposite to that of the convex ones.

To find the focal length of a concave lens experimentally. Let the lens be covered with paper, having in it two small circular holes, as at  $O, v$  (*Plate VII. Optics, fig. 5.*); and on the paper for receiving the light, describe two small circles as  $a, b$ , whose centres are placed at twice the distance apart of the centres of  $O, v$ , and it will be best if their diameters are also double those of  $O, v$ . Thus, moving the paper to or fro, till the middle of the sun's light coming through the holes  $O, v$ , falls exactly on the middle of the circles  $a, b$ ; that distance of the paper from the lens will be the focal length required. For it is evident, that  $a b : O v :: a F : O F$ ; or, whatever is the distance of  $a, b$ , it will be,  $a b - O v : a O :: O v : O F$ , the focal length of the lens. Instead of the paper with the holes, small patches may be stuck on the lens.

The focus may be also found by candle-light; thus: let  $Q$  be the place of the flame;  $e, d$ , the bright spots upon the paper, and  $q$  the point where the lines  $v d, O c$ , produced, backwards, would intersect. To find the point  $q$ , it will be  $e d - O v : O v :: O c : O q$ . Then  $Q q : Q O :: Q O : Q a$ , and  $O a$  is the focal length required.

The focal length of a concave lens may be readily found by joining it to a convex one, having a shorter focus. Let  $q$  (*fig. 6.*) be the image of any object formed by the convex lens  $A$ , fixed at  $A$ ; and let  $Q$  be the image of the same object, when the concave lens  $O$  is joined to  $A$ . Having measured the distances  $Q q, q O$ , for finding the focal length of the concave lens, it will be (as before)  $Q q : Q O :: Q O : Q F$ ; then  $Q F - Q O = O F$ .

3. An object viewed through a concave lens appears erect, and diminished in a ratio compounded of the ratios of the space in the axis between the point of incidence, and the point to which an oblique ray would pass without refraction; to the space of the axis between the eye, and middle of the object; and the space in the same axis between the eye and the point of incidence, to the space between the middle of the object, and the point the oblique ray would pass to without refraction.

Though the properties of lenses have been here considered principally with regard to rays falling near the axis, and parallel to it; yet the reasoning will be easily transferred to rays remoter from the axis, and falling in any direction.— Thus we may say universally, that in a convex lens, all parallel rays become converging, and concur in a focus: that diverging rays either become less diverging, or run parallel, or converge; and that converging rays converge the more: all which alterations are more sensible in oblique rays than in perpendicular ones, because the angles of incidence in that case are greater.

In concave lenses all parallel rays become diverging, and all diverging rays diverge more; converging rays either converge less, or become parallel, or go out diverging; all which things hold of oblique as well as direct rays, but more sensibly in the first.

For the further illustration of this part of the subject of the article before us, we shall here subjoin two or three propositions; first premising, that all pencils of rays (see *PENCIL*), refracted by a lens, excepting that whose axis is perpendicular to both the surfaces, are said to be oblique, and are called "oblique pencils."

It "In every oblique pencil of rays, refracted by any lens, there is one ray whose incident and emergent parts are parallel; and this ray is the axis of that pencil, or that ray of it which undergoes the least refraction." In *Plate VII. Optics, fig. 7* to *12*, let  $R, r$ , be the centres of the spherical sides  $A, a$ ; and in *figs. 7, 8*, let  $r$  be the centre of the spherical side  $a$ . In the flattest side of any lens whatsoever assume any point  $B$ , at which let a ray of light be refracted, either at its entrance into the lens, or at its emergence out of it; draw  $R B$  perpendicular to that side, and parallel to it draw also  $r b$  perpendicular to the other side  $a$ ; join  $B b$ , then will  $B b$  be a ray, whose parts  $P B, p b$ , without the lens, will be parallel. For the ray  $B b$ , drawn between the two parallels  $R B, r b$ , is equally inclined to them both, and consequently  $P B, p b$  are also equally inclined to  $R B, r b$ , (by the law of refraction,) and therefore parallel to one another. After the same manner, wherever the point  $B$  is assumed, we can find a ray  $B b$ , that shall be equally inclined to both the surfaces; and therefore in every oblique pencil of rays there is one ray whose incident and emergent rays are parallel. It is evident also, that every other ray passing through  $B$  will be more refracted than the ray  $B b$ ; for a plane touching the lens in any other point besides  $b$  will be inclined to a plane touching it in  $B$ ; and, therefore, a ray passing through  $B$ , and any other point besides  $b$ , will be bent out of its course, more or less, according as these planes are more or less inclined. Whence the proposition is evident,  $Q q$  is the axis of an oblique pencil on the contrary side of

of the axis of the lens. Hence it appears, that the axis of any oblique pencil whatsoever is equally inclined to each side of the lens, and the less oblique is the pencil, the nearer the point B will be to the vertex A; and the less will be the distance between the parallel rays P B, *b*p.

2. In every oblique pencil of rays (figs. 7 to 12), the part B*b* of the axis within the lens, produced, if need be, will intersect the axis of the lens in the very same point O; and the point O divides the axis of the lens in such a manner, that A O : a O :: R : r; that is, 1. The point O is in the vertex of a plano-convex and plano-concave lens (figs. 7 and 8.) 2. In the double convex and double concave (figs. 9 and 10), the point O divides that part of the axis, which is within the lens, in the ratio of the radii of the sides, the shortest part being next that side which has the greatest curvity. 3. The line B*b* must be produced without a concavo convex lens (figs. 11 and 12), before it will intersect the axis; and the point O in the axis, where the said line B*b* produced intersects it, lies next to that side which has the greatest curvity; and its distance from the sides is as the radii of these sides respectively."

Let the radius of the flattest side A be called R, and the radius of the other side, r; and because the axis B*b* of any oblique pencil is equally inclined to both the sides of the lens (as we have above shewn), it necessarily follows: *Case 1.* In a plano-convex and plano-concave lens (figs. 7 and 8), the axis B*b* of any oblique pencil passes through the vertex *a*, and therefore the point O is also in *a*. For no perpendicular to the spherical side can be parallel to a perpendicular to the plane side, but that only which passes through the vertex *a*. Again, because R in this case is infinite, and O coincides with *a*; it will be R : r :: A O : a O. *Cases 2 and 3.* Because the radii R B, r*b* are parallel (by hyp.), the triangles R B O, r*b* o are similar; and, therefore, R B : r*b* :: R O : r o. Also R B ± r*b* : R B or r*b* :: R O ± r o : R O or r o. But the three first terms being invariable quantities, the 4th is so likewise; that is, in the same lens the point O is invariable. And from the position of the parallel radii R B, r*b*, it is plain that the point O must be within the double convex and double concave lens, and without the concavo-convex. Again, because R O : R A (R B) :: r o : r a (r*b*); we shall have A O (R O ∩ R A) : R A :: a O (r o ∩ r a) : r a; that is, A O : a O :: R : r; whence another part of the proposition is manifest.

Hence it follows; that the point O is in the middle of a double convex and double concave, whose sides are segments of the same sphere; and in every lens whatsoever, the greater proportion the greater radius bears to the lesser, the nearer will the point O be to the vertex *a* of that side which has the greatest curvity.

3. "If the axis B*b* (fig. 7 to 12.) of a pencil of rays is not very oblique to the axis of the lens; the points, *s*, *v*, where the parts without the lens, P B, *p*b, produced, of the axis of the oblique pencil, and the axis of the lens, divide that axis in such a manner, that A O : A s :: m : n :: a O : a v nearly." The angles, R B*s*, R B o, or their supplements, are the angles of incidence and refraction at the first side A; and therefore their sines are as *m* to *n*. In figs. 7 and 8, the angle R B*s* = A s B; and R B o = A O B. And in figs. 9 and 10, the difference between the angles, R B*s*, R B o, or their supplements, and the respective angles A s B, A O B, is equal to the angle A R B, as will appear by drawing *d*B parallel to the axis R A. And therefore the sines of these respective angles are pretty nearly in the same ratio; that is, sine < A s B : sine < A O B :: *m* : *n* nearly. But the sines of the angles, A s B,

A O B, are as the sides B O, B*s*; and when the point B is not very remote from A, B O and B*s* will be as A O and A*s* nearly; and therefore when the point B is the nearest of all to A, it will be A O : A s :: *m* : *n*. In figs. 7 and 8, the points *s*, *v*, and O, coincide; and in figs. 9 and 10, it might be proved as above, that when the point *b* is very near to *a*, it will be, a O : a v :: *m* : *n*. Hence the further the point B is from A, and *b* from *a*, the greater will be O*s* and O*v*. Let *s* and *v* be points belonging to pencils that have the least obliquity to the axis of the

lens; then will A*s* =  $\frac{n}{m}$  A O; and a v =  $\frac{n}{m}$  a O. Let the thickness, A*a*, of any lens be called *t*; then in a plano-

convex and plano-concave lens, A*s* =  $\frac{n}{m}$  *t*. And in a double convex and double concave, whose sides are segments

of the same sphere, A*s* = a v =  $\frac{n}{2m}$  *t*. Hence again, in

a plano-convex and plano-concave glass, A*s* =  $\frac{2}{3}$  *t*; and

in a double convex glass of equal convexities, and in a double concave glass of equal concavities, A*s* = a v =

$\frac{1}{3}$  *t*. It appears, moreover, that the focal length of any

lens is to be reckoned from the point *v*, if the flattest side is exposed to parallel rays; and from the point *s*, if the parallel rays are incident upon the most convex or concave side; the point *v*, in all cases, being the most remote from the flattest side, A, of the lens. The points, *s* and *v*, may occasionally be called the "focal centres" of the lens. Hence it follows, that the focal length of a convex lens is, properly, the distance between the principal focus and the next focal centre; and the focal length of a concave lens is to be reckoned from its principal focus to the farthest focal centre. As the axes of the several pencils that are not very oblique, are refracted from the same point *s* or *v* nearly; by the refraction of these axes causes no sensible confusion in the

image. Moreover, because A*s* =  $\frac{n}{m}$  A O, and a v =

$\frac{n}{m}$  a O, and because R : r :: A O : a O; it will be,

R ± r :  $\frac{R}{r}$  :: *t* (A O ± a O) :  $\frac{A O}{a O}$ ; therefore A O

=  $\frac{R t}{R \pm r}$ ; and a O =  $\frac{r t}{R \pm r}$ ; wherefore, A*s* =  $\frac{n}{m}$

×  $\frac{R t}{R \pm r}$ ; and a v =  $\frac{n}{m}$  ×  $\frac{r t}{R \pm r}$ ; and multiplying

one side of each equation by *m* ×  $\frac{R \pm r}{R \pm r}$ , it will be A*s* :

a v :: n R t : n r t.

4. "The foci of both direct and oblique pencils of parallel rays are nearly at the same distance from the focal centre (*s* or *v*, as the case is) of any lens." Let A*r*Q (Plate VIII. Optics, fig. 1 to 6.) be the axis of the lens, *r* the centre of the first surface *ab*, Q the principal focus of that surface, and F the focus of the lens. Let *p*B*B*P be the axis of any oblique pencil; and let the emergent part, B*P*, produced backwards cut the axis of the lens in *s*. Of all the rays parallel to the axis *p*B*B*P, there shall be one as D*d* which will fall perpendicular upon the first surface *a**d*; and therefore if the medium was continued, this ray (produced backwards from a concave lens, but continued through

through a convex lens) would pass through the centre  $r$ , and the geometrical focus of rays parallel to it would be at  $g$ , so that  $r q = r Q$ . This is plain, because  $d r q$  is perpendicular to the surface  $a$ , as well as  $a r Q$ . Again, of all the rays parallel to the axis  $p b$ , there shall be one as  $E e$  (if the lens is broad enough) which shall be refracted into  $e G$ , perpendicular to the second surface  $A B$ ; and therefore the focus of this ray shall be in  $s P$  produced, and in  $e G$  produced; that is, in the point of intersection  $f$ . Neglecting the aberration of the first surface  $a b$ ,  $e G$  would unite with the axis  $d r q$  in  $q$ . Hence we are to shew that  $s f = s F$  nearly.

*Cofe 1.* When one side of the lens is plain. (*Figs. 1, 2.*) Because  $s r$ ,  $f g$ , and  $s f$ ,  $r q$  are parallel;  $s f = r q = r Q = s F$ .

*Cafe 2.* When both sides of the lens are spherical. (*Fig. 3—6.*) Let  $R$  be the centre of the second surface  $A B$ , and because  $e G$  is perpendicular to this surface, it will pass through the centre  $R$ . And because  $r q$  is parallel to  $s f$ , it will be  $R r : R s :: r q : s f$ . The two first terms,  $R r$ ,  $R s$ , being invariable quantities, and  $r q$  being allowed to remain invariable,  $s f$  will also be invariable; that is,  $s F$  will describe the sector  $s F f$ , and  $s f = s F$ . But because of the aberration by the first surface  $d e$ , no ray, as  $E e$ , parallel to and remote from the axis  $D r q$ , can be refracted to the focus  $g$ ; but it will cut the axis  $r q$  in some point  $y$  between  $q$  and  $r$  (*fig. 1 to 6.*); and therefore a ray parallel to  $p b$ , that shall be refracted perpendicularly to the second surface  $A B$ , must be some ray  $b k$  between  $E e$  and the axis  $p b$ , if the centres,  $R, r$ , are on different sides (*figs. 3 and 4.*); otherwise  $b k$  will be farther from the axis than  $E e$  (*figs. 5 and 6.*); and consequently this ray will cut the axis  $s f$  in some point  $a$ , between  $f$  and  $s$ . But it has been already shewn, that if the lens had no aberration,  $f$  would be the focus of all the rays parallel to the axis  $p b B f$ ; and as the aberrations at the different surfaces are contrary, it is sufficiently evident that the focus of those rays which are nearest to the axis  $p b B f$ , will not be remote from  $f$ .

In every lens whatsoever, the true focus  $g$  of an oblique pencil of parallel rays is between  $f$  and  $s$ ; that is,  $s g$  will be less than  $s f$  or  $s F$ . Because if there was no aberration at either surface of the lens,  $s g$  would be equal to  $r F$  or  $s f$ ; and therefore it must follow, that if the aberrations at each surface were equal, they would destroy each other. (*Figs. 3, 4.*) Let rays of light be within the lens, on each side of the axis  $b B$ , and let their inclination to that axis be such, as that they would emerge at the side  $b$ , parallel to  $b p$ . It is plain, that a ray parallel to the oblique axis  $p b B P$ , and between the said axis and the perpendicular  $d r$ , will be more oblique to the emergent side  $A$  than to the incident side  $a$ ; and therefore, in this case, the aberration at the side  $A$  is the greatest, and this excess of the aberration contracts the focus nearer to  $s$  than  $f$ , as to  $g$ . In like manner, if the parallel ray be on the other side of the oblique axis, the greatest aberration will be on the incident side  $a$ ; and in the present case likewise, this excess of aberration contracts the focus nearer to the lens, as to  $g$ ; and it is plain, that the more oblique is the pencil, the greater will be  $f g$ ; whence the proposition is manifest.

5. "The focus of incident rays, either diverging or converging upon any lens, being given: to find the focus of the emergent rays." Let  $F f$  (*Plate VIII. Optics, fig. 7 to 12.*) be the axis of any lens  $B b$ , whose focal centres are  $s, v$ ; and principal foci are  $F, f$ . Let any point  $Q$  in the axis of the lens be the focus of incident rays, either diverging as  $Q B$ , or converging as  $M B$ ; and let  $f$  be the geo-

metrical focus of those rays parallel to the axis of the lens, whose incidence is on the same side with the ray  $Q B$ , or  $M B$ . To find the focus of the emergent rays, say  $Q F : F s :: v f (F s) : f g$ ; and placing  $g$  the same way from  $f$  that  $F$  is from  $Q$ , the point  $g$  thus found will be the focus required. Let the point of incidence  $B$  be not remote from the vertex of the lens; from the centre  $v$  describe the arc  $f d$ , and draw  $v d$  parallel to the incident ray  $Q B$ , or  $M B$ ; then will  $d$  be the point where the emergent ray intersects the axis  $v d$ ; and therefore the point  $g$ , where the emergent ray  $b d$  (or  $N b$ ) produced, intersects the axis of the lens, is the focus required. Again, draw  $s D$  parallel to  $g B$ ; then will the triangles,  $Q D s$ ,  $v d g$ , be equiangular, and therefore  $Q D : D s :: v d : d g$ . But  $D$  is a point where the incident ray  $Q b$ , or  $N b$ , after refraction by the lens, will intersect the axis  $s D$ , so that  $s D = s F$  nearly; and when the triangles,  $Q D s$ ,  $v d g$ , are vanishing, the point  $D$  will coincide with  $F$ , and  $d$  with  $f$ ; wherefore  $Q F : F s :: v f : f g$ . Hence it follows, 1. Because  $F s = v f$ ,  $F s$  or  $v f$  is a mean proportional between  $Q F$  and  $f g$ ; that is,  $Q F : F s :: F s : f g$ . 2.  $Q F : F s :: (v f : f g ::) Q s (Q F \div F s) : v g (v f \div f g)$ . 3.  $Q F : Q s :: (F s : v g ::) Q s (Q F \div F s) : Q s \div v g$ . Obf. When the

lens is not very thick in proportion to its focal length, the focal distances,  $S F$ ,  $v f$ , may, without sensible error, be reckoned from the point  $O$ , which bifects  $v s$ ; and then the preceding proportions will be convertible into the following: *viz.*  $Q F : F O :: F O (= O f) : f g$ ; and  $Q F : F O :: Q O : O g$ ; and  $Q F : Q O :: Q O : Q g$ . 4. If  $g$  be the focus of incident rays,  $Q$  will be the focus of the emergent rays. 5. The focuses,  $Q, g$ , move both the same way, and always lie contrary to  $F$  and  $f$ . And the distances,  $F Q, f g$ , vary reciprocally; that is, as one increases, the other decreases, but with a different velocity, according as they are differently situated. When  $Q$  coincides with  $F, g$  will be at an infinite distance; that is, the refracted rays will emerge parallel to the axis. And in *figs. 7, 8*, when  $Q O = 2 O F$ ,  $O g$  will be  $= O Q$ ; whence the difference of the focal distances of the refracted rays, when  $Q O = 2 O F$ , and when  $O$  is infinite, is only equal to  $O f$ . 6. When the focus  $Q$  of rays diverging upon a convex lens (*fig. 9.*) lies between  $A$  and the lens, the refracted rays ( $b N$  instead of crossing the axis) will diverge from the focus  $g$ . And if incident rays upon a concave lens converge towards the point that is nearer to it than  $F$  (as in *fig. 10.*), the lens in this case will have a real focus; that is, the refracted rays will cross the axis in  $g$ . And universally, 7. When the focuses,  $Q, g$ , lie both on the same side of the lens; if the incident rays diverge from  $Q$  (*fig. 9—12.*), the emergent rays will diverge from  $g$ . And if the incident rays emerge towards  $Q$  (*fig. 10, 11.*), the emergent rays will converge towards  $g$ . And in all these cases, the nearer  $Q$  is to  $O$ , the nearer also will  $g$  be to  $O$ ; and if one of these focuses be in  $O$ , the other also will coincide with it. And the contrary happens, when  $Q$  and  $g$  are on different sides of the lens; that is, rays diverging from  $Q$  (*fig. 7.*) will converge towards  $g$ ; and rays converging towards  $Q$  (*fig. 8.*) will diverge from  $g$ .

We have hitherto taken notice of the progress of a single pencil of rays, or such as come from a single point, through a lens; but it is easy to apply the same kind of reasoning to the various points of an object. Let  $D E$  (*Plate VII. Optics fig. 13.*) be an object,  $A B$  a double convex lens, whose centre is  $C$ ; and let us examine the pencils of rays which come from three points only of the object, since the situation

situation of the intermediate pencils; is evidently comprehended between those three. Of all the rays which proceed from each of these points, that which passes through the centre C of the lens must proceed, if the lens is not remarkably thick, in a straight line, so that DCI, FCH, and ECG, are straight lines; secondly, the focus of the rays DBA, after refraction, must be somewhere in the axis or straight line DCI; also that of the middle pencil, FBA, must be somewhere in FCH, and the focus of the third pencil must be in ECG. Thirdly, the refracted focus of each pencil must be on the contrary side of the axis of the lens, to what its incident or radiant focus is; for instance, the refracted focus I is below the axis of the lens, whilst its incident or radiant focus D is above it; and the refracted focus G is above the axis, whilst its radiant point E is below it: the consequence of which is, that if the object DE be sufficiently luminous, and a piece of white paper, or other flat and opaque body, be situated at GI, an image of the object DE will be formed upon it, but in an inverted position. If the opaque body be removed, then no image will be seen by a spectator situated on one side; for the rays of light, though they meet at their respective foci in IHG, yet they proceed divergingly beyond that place through the air or other transparent body, and none come to the lateral spectator. If the paper be situated nearer or farther from the lens than the place GI, then an imperfect image, or no image at all, will be formed upon it, because the rays of the respective pencils do not meet at any other place.

From what has been said above with respect to the conjugate foci of the same pencil, it will be clearly deduced, that if the object DE be brought nearer to the lens, the refracted foci, or the image GHI, will be formed farther from the lens, and *vice versa*. And from this it follows, that (since the angles DCE, GCI, formed at the centre of the lens by the axes of the two extreme pencils, are equal) when the distance of the object from the lens is equal to that of the image from the lens, then the size of the image is equal to that of the object; when the former distance is less than that of the latter, then the image is larger than the object; and when the former distance is longer than the latter, then the image is smaller than the object.

With respect to the brightness of that image it must be considered, that of the innumerable rays which are incessantly emitted in every direction from each point, for instance D, of the object, a considerable number, *viz.* DAB, fall upon the lens, and are converged to a single point I; therefore that point must be more or less bright in proportion as the surface of the lens is larger or smaller. Hence also a very remarkable property of those lenses is easily comprehended, which is, that when an image GHI is thus formed, if you cover part of the lens, be it the middlemost or some lateral part of it, the image IG will not thereby be rendered partly invisible,—the whole image will be seen as well as before, but it will appear less bright than before; for if we consider each indefinite part of the lens, we may easily perceive that rays of light from every point of the object must pass through that part, and must meet at the respective foci in GHI.

The above explanation of the progress of various pencils through a convex lens, may, *mutatis mutandis*, without much difficulty be adapted to explain the action of concave lenses. Newton's Optics. Smith's Optics. Harris's Optics. Cavallo's Philosophy, vol. iii.

LENS, or *Lenticula*, was the name of a kind of weight

among the Romans; being the hundred and eighth part of a drachm; equal to a grain and a half.

LENS, in *Anatomy*, a transparent body, nearly spherical in figure, placed in a depression in front of the vitreous humour of the eye. It is generally mentioned with the epithet crystalline. See EYE.

LENS, in *Botany*, the Lentil, *Ervum Lens* of Linnæus, but in reality a species of *Cicer*; see Sm. Fl. Brit. 776, and our article ERVUM. The Latin word lens is said to have originated from *lens*, mild, because those who fed on this sort of pulse were supposed to become mild and gentle in disposition.

LENS, *Palustris*. See DUCK'S MEAT.

LENS, in *Geography*, a town of France, in the department of Jennepe, and chief place of a canton, in the district of Mons. The place contains 1229, and the canton 13,714 inhabitants; on a territory of 237½ kilometres, in 19 communes.—Also, a town of France, in the department of the straits of Calais, and chief place of a canton, in the district of Bethune; seven miles N.W. of Douay. The place contains 2325, and the canton 13,246 inhabitants, on a territory of 152½ kilometres, in 21 communes.

LENSWYCK, a town of Norway; 20 miles W.N.W. of Dronthek.

LENT, QUADRAGESIMA, a time of mortification, during the space of forty days, wherein Christians are enjoined to fast, in commemoration of our Saviour's miraculous fasting so long in the desert, and by way of preparation for the feast of Easter.

In the ancient Latin church, Lent only consisted of thirty-six days. In the ninth century, to come somewhat nearer to the miracle, several took upon them to add four days more; which in time became a general practice: though the church of Milan is said still to take up with the ancient thirty-six.

According to St. Jerom, St. Leo, St. Augustine, and others, Lent must have been instituted by the apostles. Their way of reasoning is thus: whatever is generally received throughout the whole church, and whose institution we do not find in any council, must be esteemed to have been established by the apostles. Now such, they say, is the fast of Lent. Its institution is not spoken of in any council; but many of the ancient councils, particularly that of Nice, that of Laodicea, &c. and some of the oldest fathers, particularly Tertullian, speak of it as a thing of some standing.

The reformed, generally, hold Lent to be a superstitious institution, set on foot by some vain enthusiasts, who durst undertake to ape the miracles of Jesus Christ; as, in effect, it appears to have been from a passage of Irenæus quoted by Eusebius.

Some will have it to have been first instituted by pope Telephorus, in the second century: others, who own that there was a kind of abstinence observed in the ancient church before Easter, yet contend that it was entirely voluntary, and was never enjoined by any law till the third century. See FAST.

This religious season is said to have been first observed in England by our Saxon ancestors in the year 640. Anderson's Hist. of Commerce, vol. i. p. 25.

Political Lents have been often enjoined by statute and royal proclamation. See ABSTINENCE.

King James I. issued a proclamation against eating flesh in Lent in 1619, and another in 1625. A similar proclamation was also issued by Charles I. in 1627, and another in 1631.

There was some difference between the practice of the Greek

Greek and Latin churches, as to the business of Lent; the Greeks beginning it a week sooner, but at the same time allowing more days of intermission than the Latins: those who held it seven weeks did not fast on Saturdays, as those who observed but six did.

The ancient Latin monks had three Lents; the grand Lent before Easter, another before Christmas, called the Lent of St. Martin; and a third after Whit Sunday, called the Lent of St. John Baptist; each of which consisted of forty days.

The Greeks, besides that before Easter, observed four others; that of the Apostles, of the Assumption, of Christmas, and of the Transfiguration; but they reduced each of them to the space of seven days. The Jacobites added a fifth, which they called the Repentance of Nineveh; and the Maronites a sixth, called the Exaltation of the Holy Cross. By the ninth canon of the eighth council of Toledo, it is ordained, "That if any person, without evident necessity, eat flesh in Lent, they shall be deprived the use of it all the rest of the year."

By the fifth chapter of the fourteenth session of the council of Trent, confession is enjoined as peculiarly fit and acceptable at this season. Hard. Conc. tom. x. p. 93.

The forty days in Lent, say some, are observed in remembrance of the forty days wherein the world was drowned; or, as others say, of the forty years wherein the Jews wandered in the desert; others of the forty days allowed Nineveh for repentance; others of the forty stripes by which malefactors were to be corrected; or, the forty days during which Moses fasted at the receiving of the law; or the forty days fast of Elias; or finally, the forty days fast of our Saviour.

**LENTAGO**, in *Botany*, a name adopted by Cæsalpinus, (de Plantis, 76,) for the Laurustinus, *Viburnum Tinus* of Linnæus, and said to be of Tuscan origin. Linnæus has applied it to an American species of *Viburnum*.

**LENTELLA**, in *Geography*, a town of Naples, in Abruzzo Citra; 18 miles N.E. of Civita Borella.

**LENTEMENT**, *Fr.* in *Music*. This word is equivalent to *largo* in Ital., and implies a slow movement. Its superlative, *treslément*, very slow, is the slowest of all movements.

**LENTE**, in *Geography*, a town of Norway; 20 miles N. of Berga.

**LENTE** LAPIDÆÆ, *fossile lentis*, in *Natural History*, the name given by many writers to a very remarkable fossile substance, usually found immersed in hard stones, and of a roundish but flattened shape, resembling not unaptly a pea or lentil flattened by pressure. They generally lie in great quantities in the same mass of stone; and are of very different appearance when their sides or ends are seen, from that which they exhibit when their flat surfaces come in view.

They are generally supposed to be lentils petrified and bedded in stone, and as their sides come in view in some parts of the masses, they are not perceived to be a part of the same substance, but are called the remains of seeds of other plants, and the whole stone is usually named *lapis frumentarius*.

We are not to suppose, that so soft a body as the lentil seed, or a common pea, could be easily petrified and preserved in its own form in stone; since if these soft substances were readily capable of such a change, they are so very common in their recent state, that they must be expected to be found in this fossile condition very frequently also, and in great variety. This, however, is not the case. But this improbability is not all the reason we have to conjecture, that these are not what they are vulgarly supposed to be,

that is, fossile seeds; for a stricter examination of the things themselves proves this to be, impossible. Seeds, and other such things, are of some determinate growth; the size of which we know, and are well acquainted with their internal structure, which is only a farinaceous matter contained in a thick superficial skin or covering.

On the contrary, these fossils, when examined, prove to be of various sizes, from the minutest speck visible to the eye, to near an inch in diameter, a size that no lentil could be supposed to arrive at. They are of two kinds; the one convex on both sides, the other convex on one side only, and plane on the other. The first are thickest in the middle, and gradually lessen in thickness all round, till they terminate in a thin edge; the others are just like the halves of these when split horizontally. Those which are convex on both sides, have usually several crooked lines, rising from the umbilicus on each side, and tending towards the circumference; and the flat ones have usually on the flattened side a number of concentric circles surrounding the umbilicus, and one another to the edge. When these are broken, they are found to consist of a number of cases, or coats, one within another, all of the same shape with the outer one; and some of them are striated, or made up of transverse fibres. They are plainly of animal origin, though they differ from all the parts of animals hitherto known. Woodward's Cat. of Fossils. vol. ii.

Dr. Woodward, in one place, supposes them to have been the loose bones which are found in the heads of some fishes, and are supposed to serve for hearing; but that they belong to some fish at present unknown, or that has not been yet examined in this particular: there is, however, another much more probable opinion, which he mentions afterwards, that they may have been opercula of shell-fishes, of the nature of the umbilicus Veneris, of which the fishes we know afford us a great variety; and the many others we are yet unacquainted with, may furnish numbers of other kinds very different from all we do know.

These bodies are found in a hard greyish stone, and some of the large ones, which are flattened on one side, give great reason to judge that they are of this origin, as some of the large ones have on the flat side a reddish line, beginning at the centre, and thence continuing in a spiral form for eleven or twelve turns, till it reaches the edge of the stone. This is exactly the formation and lineation of the common umbilicus Veneris, only that it has fewer spires. The stone, called by authors *lapis numminalis*, is generally allowed to be of the nature of these opercula, and this differs very little from these large *lentes lapidææ*, as they are called.

**LENTHALL**, WILLIAM, in *Biography*, an English lawyer, and famous as a speaker in the Long Parliament, was born at Henley on Thames, in Oxfordshire, in 1591, and educated at Alban-hall, Oxford, from whence he removed to Lincoln's Inn, where he was called to the bar. In 1639 he was elected into parliament for Woodstock, and in 1640 was chosen speaker, in which capacity he was said to have made a considerable fortune by joining the ruling party. He was also master of the rolls, a commissioner of the great seal, and chancellor of the duchy of Lancaster. He was turned out by Cromwell in 1653, but in the following year he became speaker of the parliament called by the protector. At the restoration he was exempted from the act of indemnity, but obtained a pardon from the king. He died, it has been asserted, expressing great penitence for the part which he had borne in the rebellion, in 1662. Several of his speeches and letters have been printed.

**LENTIBULARIA**, in *Botany*. See **URICULARIA**.

**LENTICULA**, so called from the convex figure of its

little round leaves, which resembles that of the *Lens*, or Lentil seed. See LEMNA.

LENTICULA. See PETECHIA.

LENTICULAR SCALPEL, from *lenticulaire*, doubly convex, in *Surgery*, denotes an instrument usually placed among those which are considered necessary in the operation of the trepan. Its particular use is to cut off the irregularities which often present themselves at the edge of the perforation made with the trephine, and which might, if unremoved, cause irritation and injury of the dura mater. The shape of the instrument can hardly be conceived without ocular examination, or, at least, a reference to an engraving. (See the *Plate of Trepanning Instruments*.) We can only state, that one side of its blade is convex, the other concave, and one of its edges sharp. On the end of the blade is fixed a little shallow cup, with its concavity towards the handle of the instrument. This small cup-like part serves the purposes of receiving the little pieces of bone when detached, keeping the end of the blade from hurting the dura mater, and when applied under the margin of the perforation in the cranium, enables the operator to guide the instrument all round with steadiness and security. Dict. of Practical Surgery.

LENTICULARE, GANGLION, in *Anatomy*, a small ganglion in the orbit, from which the nerves of the iris are produced. See NERVE.

LENTICULARE OS, is a small round bone of the carpus, oftener described under the term pisiforme. See EXTREMITIES.

LENTICULARIA, in *Botany*. See LEMNA.

LENTIGO. See FRECKLES.

LENTIGO is also used by Dr. Quincy for a brown, scaly, or scurfy eruption upon the skin; such, especially, as is common to women in the time of child-bearing.

LENTIL, LENS, in *Botany*, a species of *Ervum*; which see.

Lentils are the best as well as cheapest food for pigeons.

The seeds of lentils are frequently the common food of the poor in some of the islands of the Archipelago, and other warm countries, when they can meet with no better fare. Another sort of lentil has of late years been cultivated in England, under the name of French lentil. This is the *lens major* of Caspar Bauhine; and being twice the size of the common lentil, is by so much the better worth cultivating. This is called *hills* in many parts of England. Miller's Gard. Dict.

The ancients affirm, that lentils, eaten with their skins on, bind the body, and stop a looseness; and yet at the same time, that the liquor they are boiled in loosens the belly. They are but rarely used in physic, though the flour of them may be used outwardly in cataplasms, for the same purposes as bean-flour.

LENTIL, in *Agriculture*, the name of a plant of the vetch or tare kind, which is cultivated in some places as fodder for cattle. Lentils grow a foot and a half in height, with stalks and leaves like those of tares, but smaller; and, like them, they bear their seeds generally three or four in little pods. These seeds are round, hard, smooth, and flat, but thicker at the sides. There are two sorts of lentils, the white and the yellow; but the latter affords the greater quantity of fodder. The seeds of this plant are commonly sown in March, where the land is dry; but in moist ground, April is a better season. The usual quantity of seed allowed to an acre of land is from one bushel and a half to two bushels. If these are sown in drills in the same manner as peas; they are said by some to succeed better than when they are sown broad-cast. The drills should be a foot and a

half asunder, to allow room for the hoe to clean the ground between; or if weeds are permitted to grow among them, they are apt to get above the lentils, and prevent them from being properly supported.

This is a crop not uncommon about Chesterford, in Essex, where they sow a bushel an acre on one ploughing in the beginning or middle of March. "It is there the custom," Mr. Young says, "to make hay of them, or feed them, for cutting into chaff for trough-meat for sheep and horses, and they sow them on both heavy and dry soils." It is added, that the whole country is of a calcareous nature; and likewise that attention should be paid not to water horses soon after eating this sort of food, as they are apt to have them. They are likewise asserted to be cultivated for the same purpose in Oxfordshire, and probably in other districts.

LENTILIUS. See LINSENBAUR.

LENTINI, in *Geography*, anciently *Leontini* or *Leontium*, which was a spacious, rich, and celebrated city of Sicily, and the rival of Syracuse, is now reduced to a population of 4000 persons, who occupy a very inconsiderable portion of the ruins of ancient Leontium. It is situated in Noto, on a river of the same name, about five miles from the sea. The air of the adjacent country, which abounds in marshes, is so insalubrious, that it prevents the increase of inhabitants, notwithstanding the fertility of the soil and the variety of its productions. Three miles from Lentini is a large lake, estimated at about 20 miles in compass, called "Bivieri," or the lake of Lentini, belonging to the prince de Butera, which produces 1500l. a-year; for the lease of the fishery, consisting of eels, tench, and cefaul, or a sort of barbel, that feeds in either fresh or salt water. The vicinity also yields great plenty and variety of game; 19 miles N.N.W. of Syracuse. N. lat. 37° 18'. E. long. 15°.

LENTISCASA, a town of Naples, in Principato Citra; nine miles S.W. of Policastro.

LENTISCUS, in *Botany*, the Mastic tree, supposed to have derived its name from *lentus*, and *lentisco*, alluding to the pliability and tenacity of its gum or resin. See PISTACIA.

LENTISK. See PISTACIA and MASTIC.

LENTISK, *African* and *Peruvian*, or *Indian MASTIC*. See SCHINUS.

LENTO, *Ital.*, a musical term for slow, or a movement between largo and grave:

LENTO, in *Geography*, a town of the island of Corfica; 11 miles S. of Oletta.

LENTON, JOHN, in *Biography*, a musician in the band of king William and queen Mary, whose instrument was the common flute. He composed and published, in conjunction with Tollet, a work entitled "A Conforte of Musick, in three parts," probably two flutes and a base-viol or arch-lute. At the beginning of the last century, the flute à bec, or common flute, was in much higher favour than the violin, or German flute, which was then hardly known in this country. There are catches of Lenton's composition printed in "The Pleasant Musical Companion."

LENTOR, in *Medicine*, a term employed by Boerhaave and his followers, to denote a supposed glutinous or viscid condition of the fluids of the living body, to which they ascribed the origin of many diseases.

It is scarcely necessary to enter at any length into the detail or refutation of an hypothesis, which was founded at the best upon a gratuitous and mistaken view of the operations of the animal economy, and which a better pathology has long ago exploded. Boerhaave, in his observations on diseases arising from a *spontaneous gluten*, (see his Aphorisms, § 69, et seq. and the commentary upon them in his "Praxis Medica,")

dica,") considers the direct effect of it to be an obstruction to the free circulation of the blood, especially through the small ramifications of the vessels. "Hence all the concoctions, circulations, secretions, excretions, all the vital, natural, and animal motions are disordered; whence arise suffocation and death." (3 pb. § 73.) Under this head, then, he readily includes not only inflammations, tumours, and concretions, but almost every species of chronic disease, especially where there is any change either in the qualities of the secretions, as the saliva, urine, &c. in the colour and complexion, as in chlorosis, leucophlegmatia, jaundice, &c.: or where any part, either external or internal, is altered in its form; as in all eruptive or cutaneous complaints, in scrofula, cancer, scirrhus, meliceris, or other species of swelling. But in all these instances, the asserted presence of a *gluten* or *lentos* is gratuitous; there is no evidence of any such change in the property of the circulating blood; and the morbid humour, where any such palpably exists, is found out of the course of the circulation, and is, in all probability, the result of a deranged action of the vessels in the part where it is found. Thus, in an abscess, following a phlegmous inflammation, (as in a common boil,) it is clear that there is no such thing as a purulent *lentos* in the mass of the blood; the pus is generated in the inflamed part, by an operation of the vessels, analogous to the secretion of bile or saliva, and is a new product, not a pre-existing matter. The argument, deduced from the appearance of the *buffy crust* on blood, drawn during the existence of inflammatory fever, is altogether fallacious; as this *buff* is but the ordinary coagulable lymph of the blood, somewhat more separated from the red globules. See BLOOD, and HUMORAL Pathology.

LENTZ, in *Geography*, a town of Prussia, in the territory of Ermeland; eight miles N.E. of Elbing.

LENTZBURG, an extensive bailiwick of Switzerland, in the canton of Berne, which was formerly a rich and powerful country. Its capital, of the same name, is one of the four municipal towns of the Aryan, having a considerable trade, and manufactures of flowered linens and cotton, tobacco, &c.; 16 miles W. of Zurich.

LENTZEN, a town of Brandenburg, in the mark of Prenzitz, near the Elbe; 74 miles N.W. of Berlin. N. lat. 53° 9'. E. long. 11° 36'.

LENZA, a small island in the Adriatic. N. lat. 44° 5'. E. long. 15° 31'.

LEO, LION, in *Astronomy*, the fifth of the twelve signs of the zodiac.

The stars in the constellation Leo in Ptolemy's Catalogue are 27, besides the inermes, which are eight; in Tycho's 30, in the Britannic Catalogue 95. See CONSTELLATION.

LEO I., in *Biography*, emperor of the East, succeeded Marcian, in the year 457, through the favour and interest of the patrician Aspar, who, on account of his Arian principles, was excluded from the empire. Leo was a native of Thrace, who had gradually risen in the Roman armies to the rank of military tribune, and was principal steward of Aspar's household. He received the imperial crown from the hands of the patriarch of Constantinople, which is the first instance of an ecclesiastical being employed in that ceremonial. Under Genferic the Vandals planted themselves in Africa, and Aspar favoured their cause. Leo became jealous of the influence and power of Aspar, and in the end caused him and his son to be put to death without the form of a trial, upon the mere charge of a conspiracy. The remaining parts of his family and friends attempted to revenge this treachery, and the Goths, attached to them, committed great disorders in Constantinople, which were suppressed by Zeno. The Arians, having lost their patron, were treated

with great rigour by Leo. From the Goths he was obliged to purchase a peace, which he did not long survive. He died in January 474, after a reign of nearly seventeen years. His moderation and love of justice have been praised, and several of his laws remain in the code of Justinian.

LEO III., surnamed the *Isaurian*, from Isauria, the place of his birth, was born of low and obscure parents. He entered the army, and became a guard to Justinian II. He attained the rank of general under Anastasius II. who took him in 717 as a coadjutor in the empire. The Saracens having ravaged Thrace, laid siege to Constantinople, which was bravely defended by Leo, who compelled them to retire. His reign was marked with acts of atrocious tyranny; he drove the patriarch Germanus from his place, and gave it to Anastasius. In the fifth year of his reign, he caused his son Constantine, surnamed Copronymus, to be solemnly crowned. In 726 he made his famous attack on image worship, which has rendered his reign memorable in ecclesiastical history. The destruction of objects long so much venerated, and especially of a statue of Jesus Christ placed over one of the gates of the city, struck the people with so much horror, that a serious insurrection was the consequence. Leo had authority sufficient to enforce his reform in the eastern empire, but in the West it encountered a more formidable opposition. Pope Gregory II. declared with great warmth against the imperial edict, and the people of Italy openly revolted. Leo sent a fleet to chastise the revolters, which was wrecked in the Adriatic, a circumstance that was interpreted as a divine interposition. The emperor, irritated by his want of success, inflicted great cruelties on the opposite party; the Saracens took advantage of these dissensions to make incursions into the bordering provinces. A dreadful earthquake added to the calamities of this reign. Leo died in 741, after a reign of twenty-four years.

LEO IV., the son of Constantine Copronymus, succeeded his father in 775, at the age of 25. The first object of his reign was to secure the succession of his son Constantine, whom he had by Irene, an Athenian lady of great accomplishments. He caused the youth to be solemnly crowned, and declared a partner in the empire. Leo IV. inherited his predecessor's enmity to images, and is on that account reckoned, by the Catholics, one of the impious "iconoclasts." He obtained some advantages over the Saracens, and initiated into the Christian religion a king of the Bulgarians, who, in the preceding reign, had inflicted great evils on the empire. He died in 780, and his death was imputed to an eruption on his head, which was said to have been excited by a crown that he wore, and which was studded with jewels, that he had sacrilegiously taken from the great church of Constantinople.

LEO V., the Armenian, son of a patrician, commanded an army against the Saracens in the reign of Michael I. His success, contrasted with the disgrace incurred by the emperor himself, caused a revolt of the army, and Michael himself quitted the throne, to which Leo succeeded, without opposition, in the year 813. He had been educated in the camp, and was ignorant of laws and letters; his administration, therefore, partook of severity and military discipline. In religion he followed the steps of the iconoclasts, and drew upon himself an excommunication from pope Paschal I. He attempted a reformation in the abuses of government, by which he made himself many enemies. At the head of these was Michael, formerly his fellow commander in the army, and a principal instrument of his elevation. Though he had been enriched and promoted by Leo, he was dissatisfied with his reward, and formed a conspiracy

spiracy against him. This was detected, and Michael was arrested, and condemned to die on Christmas day, but the holiness of the season caused a reprieve of the execution. In the interval, the friends of Michael assembled, and mingling with those who came to perform divine service in the imperial chapel, concealed themselves till the entrance of Leo. A signal was given, and an attack was made, by mistake, on the priest who led the devotions; perceiving their error, they instantly turned their fury upon the emperor, who had retired to the altar, and disregarding the cross which he held, they cruelly assassinated him. This event took place in 820, after Leo had reigned with reputation seven years and a half.

LEO VI., the philosopher, was the son and successor of Basil, the Macedonian, who had caused him to be crowned as his partner in the empire in 870. By the treachery of a monk he had nearly lost his eyes and his inheritance, but his friends zealously exerted themselves to procure his release, and restoration to favour. On the death of Basil in 886, Leo succeeded to the imperial throne, having a nominal partner in his brother Alexander, but he himself possessed the sovereign power. The Bulgarians, in this reign, renewed their usual hostilities against the eastern empire; and the ill success of the generals of the emperor, obliged him to submit to such terms of peace as they were pleased to impose. With the Saracens likewise several actions were fought by sea and land with various success. But he was chiefly harassed by conspiracies at home, and had more than once nearly lost his life. By his literary reputation he acquired the title of "philosopher," but his private conduct displayed an indolent and voluptuous character. He had in his theological zeal prohibited third marriages, whereas having himself lost three wives, he entered into the holy state a fourth time, which led to his excommunication. It has been urged, in excuse of his conduct, that he had no remaining issue by the first three marriages. He was, during his whole reign, much under the dominion of favourites; he was superstitious, and made pretensions to the art of foretelling future events by divination. A defeat of his fleet by the Saracens preceded his death, which happened in 911, after he had been on the throne twenty-five years. He bequeathed the empire to his brother Alexander, as a trust for his son. Leo had been educated under the learned Photius, from whom he derived an attachment to various kinds of erudition. He was supposed by some to have been the author of a collection of sermons or homilies; of a letter to the caliph Omar on the truth of the Christian religion; of a pastoral letter to his subjects; of a treatise on military discipline, and a collection of laws begun by his father. For farther particulars relating to the foregoing emperors, see Gibbon's Hist. and Univer. Hist.

LEO I. pope, surnamed "The Great," was a native either of Tuscany or Rome; at the latter place he was educated. Nothing certain is known of him till he was raised to the dignity of archdeacon of the Roman church under the pontificate of pope Celestine. He occupied the same post under Sixtus III. and acquired a very high reputation for piety, orthodoxy, eloquence, and prudence, in the management of business. He was employed to negotiate certain differences which had arisen in Gaul, between Aetius and Albinus, and succeeded in the object of his mission. While he was in Gaul, Sixtus III. died in 440, upon which the universal voice of the Romans proclaimed Leo his successor, and upon his return he was received with the greatest demonstrations of joy. He commenced his pontificate with the most zealous exertions of a Christian bishop, and he was particularly anxious for the advancement and grandeur of

the papal see. In the year 442, he extended the law of celibacy to the archdeacons, who nevertheless were not to abandon the wives whom they had married, while in inferior stations, but were in future to live with them as sisters. In the year 445, he quarrelled with Hilary, bishop of Arles, for opposing the power of the papal see, and obtained an edict from the emperor Valentinian, which put an end to the ancient liberties of the Gallican churches, and enforced those appeals to Rome which gradually subjected all the western churches to the jurisdiction of the pretended successors of St. Peter. About this time many of the Manicheans flying from Africa, after the conquest of Carthage by Geneseric, king of the Vandals, had repaired to Rome as a place of safety. The zeal of Leo would not suffer them long to enjoy tranquillity, but caused great numbers of them to be seized and imprisoned. Those who abjured their distinguishing tenets were admitted into communion, but those who steadily adhered to their principles were condemned to perpetual banishment. The pope found that many of the Manicheans had made their escape from Rome; he accordingly sent a circular letter to all bishops, exhorting them to be upon their guard against the said heretics, and when discovered, to prosecute them without mercy. His holiness was not contented with what he could do by the power with which he himself was armed, but he applied to the emperor Valentinian, for a law to exclude such persons from all civil and military employments, and to declare them incapable of giving or receiving any property by will or testament, or of making any contract. Leo was equally violent against the Priscillians, who pretended to high degrees of purity of life and manners, who practised great mortifications, and whose opinions were a compound of Gnosticism and Unitarianism. For propagating them, their leader, Priscillian, had been put to death, and was accordingly regarded as a saint and martyr. Leo now condemned the doctrines and practice of his followers as impious and detestable, and declared all those who tolerated heretics, no less guilty than those who embraced their opinions. The doctrine of Eutyches, which maintained that there was but one nature in Christ, roused the zeal of Leo, and after much discussion, concerning which our limits do not allow us to enlarge, he caused the heretic to be condemned, sent into banishment, and deprived of his sacerdotal dignity; and a decree was passed, that "in Christ there were two distinct natures united in one person, and that without any change, mixture, or confusion." During the pontificate of Leo the fourth general council was held, in which the famous canon was enacted, which rendered the see of Constantinople equal to the see of Rome in all respects, except precedence. This canon was evidently intended to check the growing power, and to oppose the daily encroachments of the bishop of Rome. When Leo was made acquainted with the determination of the council, he was filled with the utmost rage, and resolved to oppose it with all his might. He saw his rival but one step behind him, and was apprehensive he might soon get before him; he was, therefore, determined to dispute his power in every stage. Wishing, however, that he might be thought to be acting upon Christian motives, he pretended to be influenced only by a zeal for the decrees of the council of Nice, for the practice of antiquity, and for the rights and privileges of the patriarchal sees of Alexandria and Antioch. During the year 452, Attila, king of the Huns, made an irruption into Italy, soon became master of several important cities, and then bent his march towards Rome, hoping to enrich himself with the spoils of the metropolis. At this time the city was not in a condition to bear a siege, and the emperor sent a solemn embassy

embassy to Attila, with such proposals as might be acceptable to him and his army. Leo himself went at the head of the embassy, in which he was joined by two men of the first rank, and of long experience in negotiations. On their arrival with a grand and numerous retinue, at the enemy's camp, in the neighbourhood of Mantua, they were received by the king of the Huns in a very favourable manner, which the ecclesiastical writers ascribe to the fame of Leo's extraordinary sanctity. The terms which they proposed were readily agreed to by Attila, and a treaty of peace was soon concluded between him and Valentinian, in consequence of which he repassed the Alps, and retired beyond the Danube. In the year 453, Leo's zeal was directed towards the conversion of the monks of Palestine and Egypt, who denounced war against all the abettors of the council of Chalcedon, and massacred, without mercy, such of the clergy and laity, as had the courage to profess a belief in the two natures in Christ. In 455, Leo's attention was drawn off from the affairs of the East, by the calamities produced in Italy, in consequence of the death of Valentinian. That prince was murdered by Maximus, who not only usurped his throne, but obliged Eudoxia, the emperor's widow, to marry him. Determined to revenge the death of one whom she had loved with the greatest tenderness, and to deliver herself from the tyrant, she applied to Genesic, king of the Vandals, in Africa, who she well knew would be glad of any favourable opportunity of invading and plundering Italy. To him she dispatched a confidential messenger, conjuring him to come without delay and rescue her out of the hands of Maximus, assuring him that he would meet with no opposition, and promising to assist him to the utmost of her power. Genesic gladly seized the opportunity, and appeared in a short time with a very powerful army in the neighbourhood of Rome. His appearance struck the Romans with dismay, and instead of preparing for defence, they threw open their gates, and surrendered at discretion. In this extremity of distress, Leo went out to meet the enemy, and endeavoured by prayers and tears to mediate for the safety of the city. The pope could not prevail, and the army of Genesic plundered the city, and carried away the inhabitants into captivity. After spending fourteen days in ransacking the houses, churches, and public buildings, and stripping them of all their wealth, and valuable monuments, the Vandals re-embarked, and returned to Africa with an immense booty, and as many captives as they could carry on board the fleet. These troubles, and the mischiefs which they occasioned, engrossed much of Leo's care and attention to mitigate them, till, on the death of the emperor Marcian in 457, the Eutychians once more obtained the ascendancy in Egypt. The chief of this revolution was Timothy, surnamed *Ælurus*; who assembled his council, consisting of a small number of Eutychian bishops, in which he openly anathematized the council of Chalcedon, pope Leo, and the Catholic bishops. In virtue of this sentence, he excommunicated, deposed, and drove from their sees, all the bishops of the patriarchate of Alexandria, who refused to abjure the faith of Chalcedon, and in their room took care to place such as had distinguished themselves by their zeal for the Eutychian doctrine. In the year 458, the emperor invited Leo to Constantinople, that he might converse with him, in person, on the subjects of the decree of Chalcedon, and the intrusion of *Ælurus*. To this invitation his holiness replied in two letters; one containing his excuses for not undertaking such a journey, and the other intended to explain and confirm, with the testimony of the fathers, the doctrine of the two natures. The last named letter became very famous with the orthodox, and was often

quoted by the writers of that and succeeding ages. After this *Ælurus* gave the pope a public challenge to debate the points in discussion. But Leo refused to comply with the proposal, alleging that it was dangerous and unnecessary to examine anew, or to question what had already been examined and defined by an œcumenical council. From this time Leo continued his efforts, with unabated zeal, in defence of the Catholic cause, and omitted no opportunity of endeavouring to impress the emperor's mind with a sense of the heinousness and enormity of *Ælurus*'s crime. In 460, the bishops of the East united in the same cause with so much ardour, that an order was obtained from the emperor to expel and banish the heretic, which was carried into execution without delay. This event was followed by the election of a Catholic bishop to the see of Alexandria, and the restoration of those prelates who had been displaced for their adherence to the council of Chalcedon. The news of this important change afforded the highest satisfaction to Leo, but the pleasure was of short duration only, as he died in the year 461, having presided over the Roman church twenty-one years. Leo was a man of great learning, and of eminent abilities; but his ambition was unbounded, and with him every object, every consideration was made to yield to his predominant passion for aggrandizing his see, or, in other words, for extending his own power and authority. His works consist of 141 letters, and 96 sermons. The best edition of them was published at Paris in 1675, in two vols. 4to. which was reprinted in folio at Lyons, in the year 1700. The style of Leo's writings is energetic and elegant, though sometimes, in the pursuit of elegance, he renders his discourses too highly polished.

LEO II. pope, a Sicilian by birth, was raised to the papal dignity in the year 682. With the decree confirming his election, he received an account of the proceedings of the sixth general council, held at Constantinople, by which pope Honorius I. was anathematized as a monothelite. In reply to this letter, he says, that he had received this council as he received the five preceding general councils, and anathematized all whom the council anathematized. He also sent letters to the metropolitans of the different provinces of the West, acquainting them with the proceedings of this council, and requiring them to receive it, as well as to cause it to be received by the bishops in their respective jurisdictions. By this conduct he acquired so much interest at court, that he found the opportunity favourable for extending the power of the papal see, and procured an edict, subjecting for ever the see of Ravenna to that of Rome. He died in 683, after a pontificate of only ten months. Five of his letters may be seen in the sixth vol. of the Collect. Concil.

LEO III. pope, born at Rome, was in due time appointed to the office of presbyter in the church; and upon the death of Adrian, in 795, he was unanimously elected to the papal see. Upon his ordination, he wrote to Charlemagne, acquainting him with his promotion, and, at the same time, sending him the keys of the tomb of St. Peter, and the standard of the city of Rome, with other presents, and requesting him to send some fit person to receive the oath of allegiance from the Roman people. The answer of the king was conceived in equally civil and complimentary terms, and it was accompanied with immense treasures to be employed by Leo in repairing and adorning the churches of Rome, especially that of St. Peter. In the year 796, he restored the see of Canterbury to that jurisdiction over all the churches of England, which had been taken away by Offa. Towards the beginning of the year 799, Leo assembled a council at Rome, in which Felix, bishop of Urgella, and Eliphant, archbishop of Toledo, were condemned. During  
the

the same year, a conspiracy was formed against Leo, by two nephews of pope Adrian, who had been raised by him to high employments in the church, and governed all things at Rome, during his pontificate, with an absolute sway. To them, indeed, Leo had been greatly indebted for his election, and they supposed that gratitude would have led him to surrender all power into their hands. Leo, willing to shew his own authority, checked them in their designs, and in turn they resolved to put him to death. The attempt was made on the festival of St. Mark, when the pope was proceeding from the Lateran palace to join in an annual procession. The design did not succeed, though he was exposed to the most imminent danger, and was in fact thrown into a dungeon covered with wounds. From his prison he was rescued by the duke of Spoleto, who conveyed him safely into his own territory. From Spoleto the pope wrote to Charlemagne, to acquaint him with the cruel treatment he had met with, and soon after set out on a visit to that prince, to solicit protection against his enemies. Charlemagne received him with the greatest marks of respect and friendship, and after assuring him of his protection, sent him back to Rome, attended with several bishops, and a force sufficient to protect him against any farther attempt of his enemies. He entered the city amidst the loud acclamations of the people, and took possession once more of the Lateran palace, where the nobles and bishops who had accompanied him assembled, and to which all were summoned who had any cause of complaint against Leo, these being commissioned by the king to hear them and do them justice, if in any respect they had been injured by the pope or his ministers. Some did appear, and among these the nephews of Adrian, who accused him of several crimes; but not being able to substantiate the charge, they were sent to prison, tried, and sentenced to death for the conspiracy, in which they had been the principal actors. At the earnest solicitation of Leo their lives were spared, and their sentence exchanged to banishment. About this period, the title of emperor of the Romans was revived in the person of Charlemagne, who, on the proposition of the pope, was saluted Augustus by all classes of the Roman people, and on the day of his coronation received their homage, as well as that of Leo. In 803, the pope having expressed his wish to celebrate the nativity of Christ, with the emperor Charlemagne, the latter sent his son as far as St. Maurice, in the Valais, to meet his holiness, and went himself to Rheims, where he received Leo with extraordinary marks of esteem and friendship. From Rheims they proceeded to Quiercy, where they kept their Christmas, and then repaired to Aix-la-Chapelle. Here, after entertaining him for eight days, Charlemagne dismissed the pope with rich presents, and an escort, who were ordered to attend him as far as Ravenna. In 809, the dispute was revived in France on the question concerning the procession of the Holy Ghost: by the first council of Constantinople, an addition was made to the symbol of Nice, declaring that "The Holy Ghost proceeded from the Father." In the fifth and sixth centuries, the churches of Spain added to the symbol of Nice and Constantinople the word *filioque*, "and from the son," and their example was followed by most of the Gallican churches. The question now under discussion was, whether the expression "*filioque*" ought to be added or omitted. Leo was for the omission, though he adhered to the doctrine attached to it; because he said if it were received by the churches, it would be a fair plea for the addition of many other articles of equal importance. To them more decidedly that he did not approve it, he caused two tables of silver to be set up at the tomb of St. Peter, and the symbol to be engraved in Greek

on one, and on the other in Latin, without the words "and from the son," which, however, were afterwards added to the creed by his successors. Leo passed the remainder of his pontificate in tranquillity, till the death of Charlemagne, his great friend and protector, in 814: when the relations of pope Adrian and their partisans formed another conspiracy against him, with the design of deposing and murdering him. The plot he discovered in 815, some time before it was ripe for execution, and caused all who were concerned in it to be apprehended, and put to death without mercy. It has been said that he glutted his revenge by executing some of the conspirators with his own hands. His severity excited the displeasure of the new emperor Lewis, who commanded his nephew Bernard, king of Italy, to proceed immediately to Rome, and to take cognizance of the whole affair on the spot. The emperor was said to be perfectly satisfied with the pope's justification of his conduct, but the people, who felt for themselves and for their friends, who had been the victims of his cruelty, were not so easily appeased: they destroyed every thing belonging to his holiness that they could get at, and would have excited an insurrection, had they not been suppressed and dispersed by a body of troops under the duke of Spoleto. The pope died in June 816, after he had presided over the Roman church more than twenty years. He left behind him thirteen letters, which are to be found in the seventh vol. of the Collect. Concil. He has been celebrated for having enriched the churches of Rome with the most costly and valuable ornaments, for which he was chiefly indebted to the liberality of Charlemagne.

LEO IV., pope, was born at Rome, and educated in the monastery of St. Martin, ordained sub-deacon by Gregory IV., and presbyter of the Roman church by Sergius II. Upon the death of the latter, he was unanimously elected to the pontifical throne. The first object of his care was to restore to their former splendour, at an immense expence, the churches of St. Peter and St. Paul, which had been despoiled of their ornaments by the Saracens, and likewise to secure them against the future attempts of such plunderers. With this view he resolved to build a new city upon the Vatican, and to enclose it, as well as the church of St. Peter, by a strong wall. This resolution met with the approbation of the emperor, who not only contributed himself to the work, but engaged contributions from his brothers in support of the same cause. With this encouragement Leo set about the undertaking with the utmost diligence and ardour, performing in his own person the daily office of overseer, in all kinds of weather. In 849, he was interrupted in the work by a threatened attack upon the city by the Saracens. The attempt was made, but a storm arising, the enemy's fleet was driven on shore, and almost all the ships dashed in pieces, and those on board perished. Of the vessels that escaped the fury of the waves, some fell into the hands of the Romans, of which the greater part of the crews were hanged, and left on gibbets to strike terror into the minds of their countrymen, and the rest were put into irons, and forced to labour in the pope's new works. While the Romans were celebrating the victory obtained over their enemies, Lewis king of Italy arrived to be crowned emperor, in order that he might share the empire with his father. This was in 850, and in 852 Leo saw his new city completed, which was called, after the founder, the Leonine city. In the following year Leo assembled a council at Rome, for the purpose of restoring discipline, and banishing abuses that had crept into the church: among other things which they did, was the deposition of Anastasius, cardinal presbyter of the church, for absenting himself from his see five years. In the same year, the illustrious Alfred was sent

by his father to Rome, to be educated under the care and direction of the pope. The Saracens continued till to infest the court, notwithstanding their late defeat and consequent disasters: he accordingly fortified the cities on the coast to guard his people from their depredations, and he built a new city which he called Leopolis. Scarcely had he finished this city, when he was surprised with the intelligence that the emperor Lewis was arrived in the neighbourhood of Rome, at the head of a large army. Leo was soon informed of the design of his coming, which was to bring to trial Gratian, commander of the Roman militia, one of the pope's counsellors, who was accused of having solicited another commander to join him in driving out the French, and calling in the Greeks in their room. On the day of trial, the innocence of Gratian appeared perfectly clear, and the accuser was delivered up to be disposed of at pleasure. His life was, however, spared at the solicitation of the emperor. Leo died in 855, after a pontificate of eight years and upwards. He was, according to Anastasus, possessed of all the moral and Christian virtues, without the alloy of a single vice. He left behind him two letters, and a discourse, designed for the instruction of the clergy in the duties of their office, which are to be found in the eighth vol. of the Collect. Concil.

LEO V., pope, a native of Ardea, ascended the pontifical throne in the year 903, but scarcely had he attained to this distinguished honour, before he was deposed by one of his own priests, and thrown into prison, where he shortly died of grief.

LEO VI., pope, a Roman, was elected to the papal dignity on the death of pope John X., in the year 928. He held the high office but about six months, when he was deposed and imprisoned.

LEO VII., pope, a Roman, was raised to the pontifical throne by the unanimous vote of the clergy and people, on the death of John XI., in the year 936. He is highly commended for his zealous efforts to restore ecclesiastical discipline, to reform the monastic orders, and to correct the abuses which prevailed in the Roman and other churches. He died in 939, after having sat on the pontifical throne three years and a half. He has left three letters, inserted in the Collect. Concil.

LEO VIII., pope, though by others styled antipope, was born at Rome, and was chief secretary of the Roman church, an office in which he succeeded his father. Upon the deposition of John XII., in 963, Leo, on account of his excellent character, was elected to the pontifical dignity, with the approbation, if not by the influence, of the emperor Otho. He enjoyed his situation but a short time; the people, infligated by John, drove him from his elevated station, and Benedict was placed there in his stead, the partizans of whom bound themselves by the sanction of an oath, never to submit to Leo, whom they called the emperor's pope. Leo was, however, in a short time restored to his holy office, and died after a pontificate of fifteen months.

LEO IX., pope, was born at Toul, in Lorraine, in the year 1002, and being educated for the church, he was ordained deacon in 1025, and promoted to the bishopric of his native place in the following year. By his conduct in that see he acquired so high a reputation for learning, prudence, and piety, that on the death of pope Damasus II. in 1048, he was chosen as the most fit person to be his successor. He went from Toul in the habit of a pilgrim, and was received by the people at Rome with songs of joy and loud acclamations. An assembly of the clergy and people was convened, at which he informed them of his having been

nominated to the apostolic see by the emperor, but that he did not consider his election valid unless made by them, and that, therefore, they were at full liberty to choose or reject him; and that, if he were not unanimously chosen by them, he would return to his bishopric as willingly as he had unwillingly left it. This address was received with every demonstration of respect and satisfaction, and he was proclaimed sovereign pontiff under the title of Leo IX. In the year 1049 he assembled a council at Rome, which was attended by the Italian and Gallican bishops. By this council all simoniacal bargains were prohibited on pain of excommunication, and some bishops convicted of crimes were deposed from their high rank. When the council was broken up, Leo took a journey into Saxony to visit the emperor, with whom he celebrated the festival of St. Peter and St. Paul at Cologne, and having summoned the Gallican bishops and abbots to meet him at Rheims, he opened a council. At this council, among other excellent decrees, was restored to the people the right of choosing their own pastors. From Rheims Leo proceeded to Mentz, where he held another council of German prelates, at which the emperor, the chief lords and princes of Germany, assisted. Leo returned to Rome towards the close of the year 1049; and in the following spring he visited several Italian cities, restoring every where the decayed discipline of the church. Soon after this he held a council at Rome, which is chiefly memorable for the unjust sentence of condemnation which it passed upon the celebrated Berenger, without hearing him in his own defence, or so much as summoning him to attend. In 1053 he held another council at Rome, in which he condemned the practice of the Greeks, in administering the eucharist with leavened bread, which was one of the principal subjects of a letter addressed by him at this time to Michael Cerularius, patriarch of Constantinople. In the mean time Leo had conceived a jealousy of the Normans, who had made a conquest of Apulia, which they divided into twelve counties. He was strongly prejudiced against them by the Apulians, who represented that their government was cruel and tyrannical, and painted them as barbarians without either laws or religion: he was therefore determined to expel them from Italy, which was one grand object of his last journey into Germany, but the emperor was too much engaged in his own affairs to afford any material assistance in his project. Upon Leo's return he resolved to undertake the task himself. Having therefore assembled a numerous army, he marched with all possible expedition to the borders of Apulia, but before he could gain any decisive advantages, the Normans had put themselves into a posture of defence, and in the end they prepared for offensive measures; and put themselves under the command of Umfred, count of Apulia, Richard, count of Aversa, and the brave Robert Guiscard. These experienced warriors fell upon the pope's army with incredible fury, and after a bloody action entirely routed it with immense slaughter. The pope was now glad to fly, but was obliged in a short time to surrender at discretion. Leo now anticipated the most cruel treatment from those whom he had been accustomed to think, and to treat as barbarous enemies. His apprehensions were soon relieved: Umfred accosted him with all the respect due to his character, and conducted him, attended by the chief officers of the army, to his camp. There he entertained him with great magnificence, and set him at liberty, providing him with an escort. With this behaviour of the Normans, Leo was so greatly pleased, that he absolved them from all the censures which they had incurred, and even approved of the conquests which they had made, and likewise encouraged them to add the reduction of Ca-

labria to that of Apulia. The pope now received a letter from the emperor, in which he expressed a great desire to see the ancient union restored between the sees of Constantinople and Rome, and offered to contribute whatever lay in his power towards so good a work. Before any thing could be done to effect this, the pope was seized with a severe and fatal illness, which put an end to his life in the year 1054, at the age of fifty-two, after having governed the Roman church five years and two months. He was zealous in reforming abuses, and is highly commended for his prudence, his generosity, and his piety. For his attempts to aggrandize the holy see he has been honoured with a place among the saints in the Roman calendar. He was the first pope who made use of the Christian era in the date of his bulls, his predecessors having followed that of the Indictions. Nineteen of his letters are preserved in the ninth vol. of the Collect. Concil. and several of his homilies or sermons were published at Louvain in 1565.

LEO X., pope, born at Florence in December 1475, the second son of Lorenzo de Medici the Magnificent, bore the baptismal name of Giovanni, or John, was originally destined by his father for the church, and received the tonsure at the age of seven years. Being then declared capable of receiving ecclesiastical preferment, Lorenzo obtained two rich abbacies; and the list given of the preferments accumulated upon him at an early age, amounts to the number of twenty-nine, a proof of the great interest of his family, and of the scandalous corruption of the church. It was the great object of his father's ambition to decorate his house with the popedom, and upon the accession of Innocent VIII. to the pontificate, Giovanni, then thirteen years of age only, was nominated to the dignity of cardinal. Lorenzo was not wanting in exertions to make his son worthy of his premature advancement, and the disposition of the youth, which was grave and solid beyond his years, contributed to the success of his instructors. When he was nominated to the cardinalate, it was made a condition that he should spend three years at the university of Pisa in professional studies, before he was invested formally with the purple. In 1492 this solemn act took place, and he immediately went to reside at Rome as one of the sacred college. His father soon after died, and was succeeded in his honours in the Florentine republic by his eldest son Piero. The young cardinal's opposition to the election of pope Alexander VI. rendered it expedient for him to withdraw to Florence, from whence, at the invasion of Italy by Charles VIII. he and the whole family were expelled, and obliged to take refuge in Bologna. About the year 1500 he again fixed his residence at Rome, where he resided during the remainder of Alexander's pontificate, and likewise in the early part of that of Julius II. cultivating polite literature, and the pleasures of elegant society, and indulging his taste for the fine arts, for music, and the chase, to which latter amusement he was much addicted. The depression of his house occasioned frequent embarrassments in his finances, but his cheerful temper supported him under difficulties, and he extricated himself without loss of honour. In 1505 he began to take an active part in public affairs, and was appointed by Julius to the government of Perugia. By his firm adherence to the interest of the pope, the cardinal acquired the most unlimited confidence of his holiness, and was entrusted with the supreme direction of the papal army in the Holy League against the French in 1511, with the title of legate of Bologna. At the bloody battle of Ravenna, in 1512, he was made prisoner, and was conveyed to Milan, where the sacredness of his function caused him to be treated with great respect. The French in their retreat carried the cardinal with them,

but on his arrival at the banks of the Po he effected his escape. About this time the family of the Medici was restored to its former condition at Florence, and the popular constitution of that republic was overthrown. The cardinal contributed to this event, and remained at Florence, till the death of Julius II. called him suddenly to Rome. At the scrutiny for a new pontiff in 1513, the election was declared to have fallen on the cardinal de Medici, who was then only in the thirty-eighth year of his age. He assumed the name of Leo X. and ascended the throne with greater manifestations of good-will, both from Italians and foreigners, than most of his predecessors had enjoyed. One of his first acts was to interpose in favour of some conspirators against the house of Medici, at Florence, and he treated with great kindness the family of Soderini, which had long been at the head of the opposite party in that republic. He exhibited his taste for literature by the appointment of two of the most elegant scholars of the age, Beaubo and Sadoleti, to the office of papal secretaries. With regard to foreign politics, he pursued the system of his predecessor, in attempting to free Italy from the dominion of foreign powers; and in order to counteract the antipapal council of Pisa, which was assembled at Lyons, he renewed the meetings of the council of Lateran, which Julius II. had begun, and he had the good fortune to terminate a division which threatened a schism in the church. Lewis XII. who had incurred ecclesiastical censure, made a formal submission, and received absolution. Having secured external tranquillity, Leo did not delay to consult the interests of literature by an ample patronage of learned studies. He restored to its former splendour the Roman gymnasium or university, which he effected by new grants of its revenues and privileges, and by filling its professorships with eminent men invited from all quarters. The study of the Greek language was a very particular object of his encouragement. Under the direction of Lascaris a college of noble Grecian youths was founded at Rome for the purpose of editing Greek authors; and a Greek press was established in that city. Public notice was circulated throughout Europe, that all persons who possessed MSS. of ancient authors would be liberally rewarded on bringing or sending them to the pope. Leo founded the first professorship in Italy of the Syriac and Chaldaic languages: this was in the university of Bologna. With regard to the politics of the times, the pope had two leading objects in view, *viz.* the maintenance of that balance of power which might protect Italy from the over-bearing influence of any foreign potentate; and the aggrandizement of the house of Medici. When Francis I. succeeded to the throne of France, it was soon apparent that there would necessarily be a new war in the north of Italy. Leo attempted to remain neuter, which being found to be impracticable, he joined the emperor, the Swiss, and other sovereigns against the French king and the state of Venice. The rapid successes of the French arms soon brought him to hesitate, and even to stand aloof, and after the Swiss army had been defeated, the pope thought it expedient to detach his cause from that of his allies, and to form an union with the king of France. These two sovereigns, in the close of the year 1515, had an interview at Bologna, when the famous PRAGMATIC SANCTION (which see), was abolished, and a concordat established in its stead. The death of Leo's brother left his nephew Lorenzo the principal object of that passion for aggrandizing his family, which this pontiff felt full as strongly as any one of his predecessors. Under the influence of this passion, he found a pretext, in 1516, for issuing a monitory against the duke of Urbino, and upon his non-appearance, Leo issued an excommunication against him, and seized

his whole territory, with which, together with the dual title, he invested his nephew. In the same year a general pacification took place, though all the efforts of the pope were made to prevent it. In 1517, the expelled duke of Urbino collected an army, and, by rapid movements, completely regained his capital and dominions. Leo, excessively chagrined at this event, would gladly have engaged a crusade of all Christian princes against him. By an application, which nothing could justify, of the treasures of the church, he raised a considerable army, under the command of his nephew, and compelled the duke to resign his dominion, upon what were called honourable terms. The violation of the safe conduct, granted by Lorenzo to the duke's secretary, who was seized at Rome, and put to torture, in order to oblige him to reveal his master's secrets, imprints on the memory of Leo X. an indelible stain. In the same year his life was endangered by a conspiracy formed against him, in which the chief actor was cardinal Petrucci. The plan failed, and the cardinal, being decoyed to Rome, from whence he had escaped, was put to death; and his agents, as many as were discovered, were executed with horrid tortures. The conduct of Leo on this occasion was little honourable to his fortitude or clemency, and it was believed that several persons suffered as guilty who were wholly innocent of the crimes laid to their charge. To secure himself for the future, the pope, by a great stretch of his high authority, created in one day thirty-one new cardinals, many of them his relations and friends, who had not even risen in the church to the dignity of the episcopal office; but many persons also who, from their talents and virtues, were well worthy of his choice. He bestowed upon them rich benefices and preferments, as well in the remote parts of Christendom, as in Italy, and thus formed a numerous and splendid court attached to his person, and adding to the pomp and grandeur of the capital. During the pontificate of Leo X. arose the daring Luther, whose life will be given farther on; nevertheless, in this place, we must notice certain facts with which Leo and the reformation are closely connected. The unbounded profusion of this pope, in every object of expence attached to a taste for luxurious magnificence, had rendered it necessary to devise means for replenishing his exhausted treasury; and one of those which occurred was the sale of those indulgences which the church claimed a right of dispensing from the store of her spiritual wealth. The commissaries appointed for this traffic in Germany, exaggerated the efficacy of their wares in such very extravagant terms, as gave great offence to the pious and thoughtful. Luther, a public preacher at Wittemberg, warmly protested against this abuse in his discourses, and in a letter addressed to the elector of Mentz. He likewise published a set of propositions, in which he called in question the authority of the pope to remit sins, and made some very warm strictures on this method of raising money. His remonstrances produced considerable effect, and several of his cloth undertook to refute him. Leo probably regarded theological quarrels with contempt, and from his pontifical throne looked down upon the efforts of a German doctor with scorn; even when his interference was deemed necessary, he was inclined to lenient measures. At length, at the express desire of the emperor Maximilian, he summoned Luther to appear before the court of Rome. Permission was, however, granted for the cardinal of Saxa to hear his defence at Augsburg. Nothing satisfactory was determined, and the pope, in 1518, published a bull, asserting his authority to grant indulgences, which would avail both the living, and the dead in purgatory. Upon this, the Reformer appealed to a general council, and thus open war was declared, in which the

abettors of Luther appeared with a strength little calculated upon by the court of Rome. The sentiments of the Christian world were not at all favourable to that court. "The scandal," says the biographer, "incurred by the infamy of Alexander VI., and the violence of Julius II., was not much alleviated in the reign of a pontiff who was characterized by an inordinate love of pomp and pleasure, and whose classical taste even caused him to be regarded by many as more of a heathen than a Christian."

The warlike disposition of Selim, the reigning Turkish emperor, excited great alarms in Europe, and gave occasion to Leo to attempt a revival of the ancient crusades, by means of an alliance between all Christian princes; he probably hoped, by this show of zeal for the Christian cause, that he should recover some of his lost credit as head of the church. He had, likewise, another object in view, *viz.* that of recruiting his finances, by the contributions which his emissaries levied upon the devotees in different countries. By the death of Maximilian in 1519, a competition for the imperial crown between Charles V. and Francis I. took place. Leo was decidedly against the claims of both the rival candidates, and attempted to raise a competitor in one of the German princes, but he was unable to resist the fortune of Charles. At this period he incurred a very severe domestic misfortune in the death of his nephew Lorenzo, who left an infant daughter, afterwards the celebrated Catherine de Medicis, the queen and regent of France. The death of Lorenzo led to the immediate annexation of the duchy of Urbino, with its dependencies, to the Roman see, and to the appointment of Giulio, Leo's cousin, to the supreme direction of the state of Florence. (See CLEMENT VII.) The rapid progress of the Reformation forcibly recalled the attention of the papal court, and Leo, anxious for an amicable negotiation, employed a Saxon nobleman to treat in person with Luther, but the matter was, at this period, carried too far to admit of reconciliation. Luther appealed to the scriptures for his authority; and the pope insisted upon unqualified submission to the decrees of the Catholic church. The Reformer was persuaded to address a letter to his holiness; but, instead of expressions of humiliation, it contained much bitter invective against the court of Rome. It was, therefore, determined to condemn him and his doctrines; and a bull to that purpose was issued, June 15th, 1520, which occasioned a total separation between the papal see and the reformers. The writings of Luther were publicly burnt, an insult which he boldly retaliated by an equally solemn and public conflagration of the papal decrees and constitutions, and the bull itself. Leo was not satisfied with his own exertions, but was desirous of gaining on his side the Imperial court. Before, however, the emperor would condemn, he determined to hear, in person, what Luther had to say in his own justification, and a mandate was issued for his appearance at Worms. (See LUTHER.) We may observe here, that Leo conferred on Henry VIII. of England the title of "Defender of the Faith," for his appearance on the side of the church as a controversial writer. The tranquil state of Italy, at this period, allowed the pope to indulge his taste for magnificence in shows and spectacles, and in the employment of those great artists who have reflected so much lustre on his pontificate. His private hours were chiefly devoted to indolence, or to amusements, frequently of a kind little suited to the dignity of his high station. He was not, however, so much absorbed in them as to neglect the aggrandizement of his family and see. Several cities and districts in the vicinity of the papal territories, and to which the church had claims, had been seized by powerful citizens, or military adventurers; some of these

the pope summoned to his court to answer for their conduct; and in default of an exculpation of their crimes, he caused them to be put to death. His holiness next laid a plan to get into his possession the city and territory of Ferrara. He had set his heart upon this object, and being unable to attain it by open means, he had recourse to treachery, and it has been asserted that his plan included the assassination of the duke. The commander of a body of German troops was bribed to deliver up one of the gates to the papal forces, which were to be in readiness; but he took the pope's money, and apprized the duke of the plot, which was thus happily defeated. Another project, which entered deeply into the views of the pope, was the expulsion of the French from Italy. In 1521, he formed a treaty with the emperor for the re-establishment of the family of Sforza, in the duchy of Milan. He engaged a large body of Swiss in his service, who, under the pretence of different measures, made much progress against the French, and drove their troops before them; but in the midst of these successes, and while public rejoicings were making in Rome on account of them, the pope was seized with an illness, which at first was considered as a slight cold only, but which put an end to his life in a few days. This event happened on the 11th of Dec. 1521; when Leo was in the 46th year of his age, and the ninth of his pontificate. The people at large expressed much concern at his death, but the honours rendered to his memory were not such as might have been expected. An exhausted treasury was the pretext for an economical funeral, and amidst all the eminent scholars of his court, an illiterate chamberlain was appointed to pronounce his funeral oration. Leo was himself but moderately furnished with solid erudition: he afforded liberal encouragement to useful and reputable studies, but he also lavished his patronage upon productions and persons of an opposite character. The merit of a sovereign in promoting those ornamental arts by which alone he can display a magnificence superior to that of a private citizen, can rank no higher than an exertion of good taste; and this quality may be undoubtedly conceded to Leo. He was, however, rather the unfortunate inheritor, than the creator of great talents. Michael Angelo and Raphael had both risen to fame under his predecessor, Julius II., who had planned and made a commencement of the stupendous edifice of St. Peter's: the Vatican palace had likewise received some of its noblest ornaments in his and the former pontificates. But the reader who wishes to obtain an accurate view of the state of literature and the arts in Italy prior to, and during the reign of Leo, will have recourse to Mr. Roscoe's "Life and Pontificate of Leo X.," from which the foregoing facts are principally drawn. The character of this pontiff has been finely celebrated by Pope in the following lines:

But see! each muse, in Leo's golden days,  
Starts from her trance; and trims her wither'd bays;  
Rome's ancient Genius, o'er its ruins spread,  
Shakes off the dust, and rears his rev'rend head.  
Then sculpture and her sister arts revive:  
Stones leap to form, and rocks begin to live;  
With sweeter notes each rising temple rung,  
A Raphael painted, and a Vida sung.

LEO XI., pope, the son of Octavian de Medici, cousin of Cosmo, duke of Tuscany, was born in the year 1535. He was made archdeacon of Florence, and filled the post of ambassador from Francis, the great duke, at the court of Rome. He was created cardinal by Gregory XIII., and by Clement VIII. he was sent legate to Henry IV. of France, and he was successfully employed in adjusting the

terms of peace between Philip II., king of Spain, and the French monarch, and for his good offices he received from the latter a noble present. On the death of pope Clement VIII., in the year 1605, he was elected pope by the unanimous suffrages of the conclave when he took the name of Leo XI. The Romans and Florentines were highly delighted with his elevation on account of his distinguished talents and virtues, and because they knew that to his zeal for the interests of the church, he united a liberal spirit, a love of learning and learned men, and, as it were, an hereditary taste for the polite arts. On the day of the profection, when the pope commences his office with great pomp and form, the several orders of the city endeavoured to surpass each other in their demonstrations of joy on the occasion. Their satisfaction, however, was of very short continuance, and was speedily changed into grief and mourning, on account of his death, which happened on the 25th day after his election, in the 70th year of his age. Bower's Lives of the Popes. Bayle. Moreri. Lardner.

LEO ALLATIUS. See ALLATIUS.

LEO, the *Grammarians*, of whose personal history nothing is come down to us, was author of a continuation of the Chronicle of Theophanes, in the Greek language, comprising the lives of the seven emperors of the East, from the year 813 to 1013. It is annexed to Combes's edition of the chronicle, printed at Paris in 1655. Moreri.

LEO, JOHN, named *Africanus*, a traveller and geographer, was a native of Granada of Moorish extraction. When that city was taken by Ferdinand and Isabella, in 1492, he retired into Africa, and on that account obtained his surname. He studied the Arabic at Fez, was employed by the king as ambassador, and took several journeys into Europe, Lesser Asia, and Africa, of which he wrote a narrative in the Arabic language. He once fell into the hands of some pirates, and was sold as a slave to a master, who presented him to Leo X. The pontiff highly esteemed him on account of his learning and knowledge, and having persuaded him to renounce Mahometanism, gave him his own names of John and Leo at the time of his baptism. He now applied himself to the attainment of the Italian language, and translated into it his description of Africa. This work is reckoned one of the most curious of the early voyages and travels. The author describes what he had himself seen, chiefly on the northern and western coasts of that peninsula, and it supplies deficiencies from the relation of others; but as a geographical work it has various imperfections and defects. It has been translated into Latin and French. Leo probably died soon after he had rendered his work into the Italian language in 1526. He was author likewise of a treatise "De viis Philosophorum;" printed at Zurich in 1664. Moreri.

LEO of Orvieto, born in the territory of Orvieto, in Tuscany, became a monk of the Dominican or Franciscan order, who flourished towards the commencement of the fourteenth century. He was author of two "Chronicles," one of the popes, down to the year 1314; and the other of the emperors, terminating at the year 1308. They were brought into notice by John Lamy, who published them in his "Deliciae Eruditorum, seu Veterum Anecdota Opusculorum Collectanea," printed at Florence. Both the chronicles were published in 1737, in two volumes 8vo., with notes and illustrations. The second volume contains a sketch of the history of France, written by John de l'Isle, supposed to have been a monk of the abbey of St. Dennis, in the 15th century, entitled "de Gestis et Factis memorabilibus Francorum." Moreri.

LEO DE MODENA, a learned rabbi, whose Jewish name was

was R. Jehudah Arie, was born at Modeva, and flourished in the seventeenth century. He was for a considerable time chief of the synagogue, and esteemed a good poet both in Hebrew and Italian. He was author of a valuable work on the ceremonies and customs of the Jews, which is held in estimation by the learned of all nations. It is entitled "Iloria de Riti Hebraici, vita et Observanze de gli Hebrei di questi Tempi;" the best edition of this work was printed at Venice in 1638. It was translated into the French language in 1674, by Richard Simon, with supplements relating to the sects of the Karaites and Samaritans. Leo meant to have given an Italian translation of the Old Testament, but he was prohibited from pursuing it by the Inquisition. He compiled a Hebrew and Italian dictionary, entitled "The Mouth of the Lion." This work was published at Venice in 1612, and was afterwards reprinted in an enlarged form at Padua, in 1640. Leo died at Venice in 1654, in about the eightieth year of his age.

LEO DE ST JOHN, a French monk, born at Rennes in the year 1600. Before he entered into the religious profession, his name was John Macé. He was nominated to all the honourable and confidential posts of his order, and acquired the esteem of popes Leo XI., and Alexander VIII. and of several cardinals. He was an eloquent preacher, and had the honour of performing the duties of his office before Lewis XIII. and Lewis XIV. He was the friend of cardinal Richelieu, by whom he was patronized. He died in 1671, leaving behind him numerous works, the principal of which is entitled "Studium Sapientie Universalis," in three volumes folio. His "History of the Carmelites;" "Lives of different Romish Saints;" and "Journal of what took place during the last Sickness, and at the Death of Cardinal Richelieu," are well known and frequently referred to.

LEO, in *Botany*, a name used by some authors for the columbine, or *aquilegia*. Columella, besides others, calls it by this name. See *AQUILEGIA*.

LEO, the *Lion*, in *Zoology*. See *FELIS Leo*.

LEO, *Formica*. See *FORMICA Leo*.

LEO *Pulex*, a name given by M. Reaumur to a species of insects which feeds on the *pulex arboræus*, or common tree-lice, in the same manner that the creature called the *formica leo* does on the ants: this being also, like that, an animal, yet in an imperfect state, and finally to be changed into a different creature. This author has kept up the remembrance of this analogy between them, by giving this a similar name.

The *leo pulex* is usually bred among the herds of the pulices, which he devours most unmercifully. He is a worm of the hexapode, or six-legged kind, and very soon arrives at the time of his change; after which he becomes a green fly with four wings. Another animal of this kind, and not less destructive of this small race of animals, is a six-legged worm of a whitish colour, and smaller than the former, which finally becomes a round-bodied beetle. Another species of these devourers this author calls *vermis hystrix*, the porcupine-worm, from the vast number of spiculae, or tender prickles, with which he is armed. This also finally becomes a round and final beetle. Reaumur, Hist. Insect. tom. i. See *LION pueron*.

LEOBEN, or LEUBEN, in *Geography*, a town of the duchy of Stiria, on the Muehr; 68 miles S.W. of Vienna. At this town the preliminaries of peace between the emperor and the French republic, were settled on the 20th of April 1797. N. lat. 47° 22'. E. long. 14° 55'.

LEOBSCHUTZ, or LUBSCHUTZ, a town of Silesia, and capital of a circle, in the principality of Ingerndorf; 16 miles N. of Ratibor. N. lat. 50° 5'. E. long. 17° 44'.

LEOCROCOTTA, in *Natural History*, a name given by the ancients to an animal said to be the swiftest of all creatures in the world. It is described as a mongrel or bastard animal, unable to propagate its own species, being begotten upon the hioness by the male hyæna of some of the larger kinds: but is one of those animals, the existence of which is much to be doubted. The Latin authors have made some confusion between this creature and the mantichora, attributing the things that have been said of one to the other.

LEOGANE, in *Geography*, a sea-port town of the island of Hispaniola, or St. Domingo, on the N. coast. It was once the seat of the French government. Although its situation is not good, the air is salubrious, and the soil of the adjacent territory is fertile. In 1796, it was taken by the British. It is a place of considerable trade, N. lat. 18° 30'. W. long. 73° 25'. See *ST. DOMINGO*.

LEOGANE, *Bay* or *Bight* of, called also *Cul de Sac* of Leogane, lies at the W. end of the island of St. Domingo, and is formed by two peninsulas. It opens between Cape St. Nicolas at the W. end of the N. peninsula, and Cape Dame Marie, the N.W. point of the S. peninsula, 45 leagues apart. At the bottom of the bay, which embosoms a vast number of other fine bays, are the islands Gonave, and on the N. side of the S. peninsula the isles Refif and Caymite. The town of Leogane is situated on the N. side of the neck of the S. peninsula, in the bay of Leogane, at the head of a small bay which sets up E. from the bay of Grand Goave, four leagues N.E. of the town of that name. See *ST. DOMINGO*.

LEOMINSTER, or LEMSTER, a borough and market-town in the hundred of Wolphy, and county of Hereford, England, is situated in a very rich and fertile vale abounding with orchards, hop-yards, fine meadows, and arable lands. Its immediate site is, as Leland describes, "somewhat low, and all the ground very neere about it is farre lower." The river Lugg flows on its north and east sides; two smaller streams run through the town, and three other considerable rivulets pass it within half a mile. Its extent from north to south is nearly a mile; and from east to west about half a mile. "The towne of Leonminster," Leland says, "is metely large, and hath good buildinges of tymbre. The towne, by reason of their principall wool, use great draping of clothe, and thereby it flourished. Synes of latter days it chanced that the cittyes of Hereford and Worcester complained of the frequency of people that came to Lemster, in prejudice of bothe their marketts; whereupon the Saturday markett was removed from Lemster, and a markett on Friday newly assigned to it; synes that time the towne of Lemster hath decayed. The antiquity of the towne is most famous by a monastery of nunes, that Merwaldus, kinge of the Marches, built and endowed"—"There is but one paroch church in Leonminster; but it is large, somewhat dark, and of ancient building, inso much that yt is a greate likelihood that yt is the church that was afore the conquest. The common fame of the people about Lemster is, that king Merwald, and some of his successors, had a castle, or palace, on an hill side by the towne of Leonminster, half a mile off by east." In the year 1055, Leonminster was seized upon by the Welsh chieftains, who strengthened it by fortifications, the remains of which may be traced even at the present period. The town appears to have been a place of some consequence at the time of the Domesday survey; as that register records that the manor, with its appurtenances, consisting of sixteen dependent estates, had been assigned by Edward the Confessor to his queen Editha; and that it was governed by eight bailiffs,

eight beades, and eight free tenants. When the survey was made, the manor belonged to the king; great part of the customary rent was paid as composition for salt, fish, and cels. Here was also a wood fix miles in length, and three broad; but part of it was even then begun to be "afforded," and cleared for tillage; "an acree of hawks" is also mentioned in the same record. About the time of William Rufus, the fortifications of Leominster were strengthened and enlarged, the better to secure it against the incursions of the Welsh. In the reign of king John, William de Braose, lord of Brecknock, a turbulent and high-spirited baron, plundered this town, and burned great part of it, together with the priory and church. In Henry IV.'s reign, Leominster was for some time in the possession of Owen Glendour, after he had defeated the earl of March. In the next century, the inhabitants of this town took a decisive part towards the establishment of queen Mary on the throne; for which service she granted them the first regular charter of incorporation, with many valuable privileges. An annual fair had been granted in 1170, by Henry II.; two additional fairs, each of six days continuance, were granted by Edward I.

The church of Leominster, having been partly destroyed by fire March 18, 1700, was re-edified at the expence of nearly 17,000*l.*; the whole of that part used for divine service being entirely new. The church in its present state is irregular, both in its form and architecture. The most ancient parts are the east wall, the north side, the tower which stands at the north-west angle, the west end, and the wall and windows of the fourth side. In the interior the chief part is modern, excepting what is called the back aisle, which, as well as the lower part of the tower, is principally of Saxon workmanship. The exterior of the east end has three large buttresses, a high pointed window with intersecting mullions, and two smaller windows. On the north side is a very strong semi-circular arched door-way, with a smaller one within it. The upper part of the tower is in the pointed style and embattled; the lower part is Saxon; it displays a singularly rich entrance door-way on the west, having a recessed arch, with three pillars on each side, the capitals of which are ornamented with sculptures of foliage, a couchant man, a tyger, snakes entwined round branches, and birds. The mouldings supported by these pillars are slightly pointed, but are embellished with lozenges and zig-zag work. On the north side of the church is the nave and north side of the ancient structure, which are separated from each other by a range of massive circular columns, with round arches, over which are Saxon arcades; the arch of the tower which opens into this part is pointed, and reaches nearly to the roof. Besides the church, there are four places of religious worship in the town, for the respective denominations of Baptists, Presbyterians, Moravians, and Quakers. During the time of rebuilding the church, divine service was performed in a contiguous building, anciently called the Chapel in the Forbury, erected by Peckham, archbishop of Canterbury, about the end of the thirteenth century. It was afterwards appropriated to the purpose of tuition, and thence called the school-house; but has lately been converted into a regular theatre; it is a plain building, with pointed windows. The priory was situated to the north-east of the church, on the little river Pinstley; some of the buildings are yet standing, among which is the priory-house, which has undergone various alterations since the dissolution. The town-hall, or butter-cloze, as it is commonly termed, is a singular building, constructed of timber and plaster about the year 1633. The architect was the celebrated John Abel, who built the Shire-hall at Hereford,

in the year 1645. This fabric stands on twelve oak pillars, sustained on stone pedestals; the brackets and spandrels above the arches, and the upper parts of the building, display much carving. A new gaol was erected in the year 1750; and a market-house in 1803. Several improvements have been recently made in the town; the trade is flourishing, and many of the shops are respectable. The clothing and hat trade provide employment for a great number of the inhabitants. The wool grown in the vicinity is proverbially excellent; the cyder also, and the hops, are held in high estimation.

The corporation consists of a bailiff, chief steward, recorder, twenty-four capital burgesses, a chamberlain, and two serjeants at mace. Two representatives in parliament are chosen by the corporation and inhabitants paying scot and lot; the number of voters being about 500; the earliest return was in the twenty-third of Edward I.

Leominster is 137 miles distant from London; the population, as returned under the act of 1800, amounted to 3019; the number of houses to 736. The site of the castle or palace mentioned by Leland as belonging to Merwald, is supposed to be the mount to the eastward which overlooks the Hay lane.

Berrington, about four miles to the north-east, was the seat of the late Right Hon. Thomas Harley. About a mile to the south-east from the town is Eaton, formerly the seat of the Hackluys, a family of great antiquity and respectability. On the Brierley hills, about two miles south-westward from Leominster, is Ivinton camp, a strong fortification divided into two parts by an entrenchment more modern than the outer works. This is supposed, with great probability, to be the camp occupied by Owen Glendour. Price's History of Leominster, 8vo. Beauties of England and Wales, vol. vi.

LEOMINSTER, a post-town of America, in Worcester county and state of Massachusetts; 46 miles W. of Boston. It has a printing office and several neat buildings. This township was taken from Lancaster, incorporated in 1740, and contains 1486 inhabitants. On the streams that pass through this town are several mills of different kinds. About 200,000 bricks are annually made here. The manufacture of combs is also carried on in great perfection and with considerable profit.

LEON, in *Ancient Geography*, a promontory of Greece, in the isle of Eubœa.—Also, a promontory of the isle of Crete.—Also, a river of Phœnicia. Ptolemy.

LEON, in *Geography*, a province of Spain, called a kingdom, situated towards the N.W., and inclosed between Estremadura, Old Castile, Galicia, and Portugal. Its form is a kind of irregular long rectangular figure. Its mean length from N. to S. is estimated at about 52 leagues, and its mean breadth from E. to W. about 30 leagues. This is the country which was formerly inhabited by the Vettones, mentioned by Strabo. It is bounded on the E. by Old Castile; on the S.E. and S. by Estremadura; on the W. by the provinces of Beira, Tral-os-Montes in Portugal, and Galicia; and on the N. by the Asturias. Its capital has given name to the country, which was for a long time a separate monarchy; but its crown was united with that of Castile in 1069; but without losing the title of kingdom. Its territory is mountainous; nevertheless it contains many beautiful fields, good pastures, and large fertile vallies, which produce a great quantity of grain, as wheat, barley, &c. wine, and excellent flax, both in small quantities, vegetables, and good fruits. Its mountains are covered with different kinds of trees, and they afford iron and copper mines, mineral waters, &c. The mules bred in this country are of a super-

rior kind, and it furnishes a good number of sheep. The river Duero almost bisects the country. The kingdom of Leon contains six bishoprics, *viz.* those of Leon, Salamanca, Palencia, Zamora, Astorga, and Ciudad Rodrigo; six cathedral chapters, nine collegiate chapters, 2460 parishes, as well rectories as vicarages; 196 convents, 23 hospitals, five asylums, two military governments, four intendencies of provinces, a celebrated university, four superior colleges, 25 colleges of all classes, six cities, 539 towns or boroughs, 2005 villages or settlements, of which 76, formerly inhabited, are now deserted. Its mountains that are particularly distinguished are those that form part of the Sierras of Pico and Occa, formerly mount Idubeda; the former extends from the E. of the southern point of the kingdom of Leon to the W. of the southern point of Old Castile; the latter comes from the N. by E. point of Old Castile, and extends a little way into the kingdom of Leon, at the S. point of the E. Amongst its rivers, which are numerous, we may reckon the Sil, the Buroia, the Sabor, the Baeza, the Arago, the Xero, the Pisuerga, the Alagon, the Agueda, the Cea, the Exla, the Tuerta, the Obrega, and the Berneſga, almost all of which rise in Leon or near its confines; the Duero, the Carrion, the Erefina, Rio de Salamanca or Torme, &c. The principal towns of Leon are, on the N. of the Duero, Leon, Astorga, Zamora, Toro, Palencia, Medina-del-Rio-Secco, Tor-de-Sillas, Villa Pando, Duenas, Marſilla, Villa Franca, and Benevente; and on the S. of the Duero, Salamanca, Ciudad Rodrigo, Alva-da-Tornes, Pena-Aranda, Pena-de-Frania, Carpio, Medina-del-Campo, and Ledefma near Los Banos.

When the Gothic king Roderic was defeated by the Moors in the battle of Xeres de la Frontera, the fugitives dispersed to Galicia, Asturias, Lower Biscay, and the country at the foot of the Pyrenees; but their courage revived and they rallied their forces under prince Pelagius, who, in 717, obtained a signal victory over the Moors, and took possession of Oviedo, of which he was acknowledged king. Having regulated this little state, and gained new subjects, he again attacked the Moors, and retook from them the town of Leon, and some others. Thus was laid the foundation of this new kingdom, although Pelagius and his successors only took the title of kings of Oviedo or the Asturias, till Ordagno II. who in 915 assumed the title of king of Leon. The kingdom of Leon passed, in the year 1030, to Ferdinand, surnamed the Great, then king of Castile, by his wife. In the kingdom of Leon there are 5598 secular priests, 2064 monks, 1570 nuns, 196 convents, 2460 parish churches, 2695 villages, 31,540 nobles, 25,218 servants, and near 600,000 other inhabitants of all professions; which gives a total of about 665,000 persons. The agriculture of this country might be much improved, if the inhabitants availed themselves of the water which their rivers supply in the irrigation of the land. They are also negligent in the culture of fruit trees, and though they have fine rich pastures, their flocks are removed from one part of the country to another. The commerce of this province consists chiefly of importation, and it scarcely furnishes any thing to the neighbouring provinces. It sends to Galicia part of the serges and baize manufactured at Rio Seco; but this is very trifling compared with the goods which it is obliged to import. It traffics in some wines, some of which, of an excellent kind, are found in the country towards the S.E. Palencia had formerly considerable manufactories for cloth. At Zamora there is still a manufactory for hats; and they make some household cloths in the country. The English, by way of Portugal, carry away the madder of the environs of Ciudad Rodrigo, and of Medina-del-Campo. In the province of

Leon there are four springs of cold mineral waters. *viz.* at Amusco, about 31 leagues from Palencia, at Buron, at Bavila-Fuente, four leagues E. of Salamanca, and Aſudillo, nine leagues from Palencia. There are also four thermal springs, *viz.* near Almeyda, at Ledefma, at Bonar or Bonah, six leagues from Leon, and at Barnos, near the frontiers of Estramadura and Castile. The inhabitants of this province are very grave, and addicted to taciturnity; those who retain remains of the national manners of Spain, and who live in the mountains in the Mauregatos, near Astorga, wear pyramidal hats, a kind of ruff round the neck, a jacket or shirt, and close coat, wide breeches and spatterdashes. The women of Mauregatos wear large ear-rings, a kind of white turban, flat and widened like a hat, and their hair parted on the forehead. They have a chemise closed over the chest, and a brown corset buttoned, with large sleeves opening behind. Their petticoats and veils are also brown. Over all they wear immense coral necklaces, descending from the neck to the knee; twisting them several times round the neck, passing them over the shoulders, where a row is fastened that forms a kind of bandage over the bosom; another row is suspended lower than this; and also a third and even a fourth row at some distance from each other. The last falls over the knee, with a large cross on the right side. These necklaces or chaplets are ornamented with many silver medals, shaped with the figures of saints. These ornaments are chiefly worn on festivals. On the days of religious solemnities, particularly the Assumption, the fronts of the churches are illuminated, bonfires are made before them, musicians attend, and the people dance all night; the women play the castanets, and are accompanied by an instrument called "Panderero," which is a kind of tambour de basque. De Laborde's View of Spain, vol. ii.

LEON, *Legno*, the capital of the above province, or kingdom, is a very ancient town, founded before the reign of Galba; it was called by the Romans "Legio Septima Germanica," from the legion that bore that name being stationed there. This city is situated between the two sources of the Exla, which are called the rivers of Torio and Berneſja. This is one of the most famous and most ancient episcopal sees in Spain, and possessed, in the time of the Gothic kings, the privilege of appealing immediately to Rome. The bishop is suffragan to the archbishop of Compostella, without being in any respect dependent on its jurisdiction; this bishopric possesses a revenue of 22,000 ducats. Its diocese contains 823 villages, 883 parishes, 26 convents of monks, 11 of nuns, collegiate, and hospitals. When the kings resided here, till the 13th century, its population was considerable; but it is now much reduced. According to the statement of 1788, there were within the jurisdiction of the intendant of Leon 250,134 inhabitants. A great part of its walls consists of green marble. It contains 13 parish churches, one collegiate church, four convents of monks, five of nuns, and a number of hospitals and hermitages. Here are the royal houses of San-Isidoro and San-Marios of the order of St. James; and a chapter of noble canons, not cloistered, but who take the vows. This town was the first of any importance which the Christians retook from the Moors. Pelagius made himself master of it in 722, fortified it, and built a good castle, to defend the approaches to it.

It had the honour of being the capital of the first Catholic kingdom of Spain, and of being, for three centuries after the invasion of the Arabs, the residence of the kings. The palace which the duke of Alphonso built here at the end of the 12th century is still to be seen. Among its most splendid edifices we may reckon the cathedral church, which in beauty surpasses the most admired in Spain, and is one of the most attractive

attractive monuments of Gothic architecture. The hotel of the counts of Luna is also large and handsome. The town-house has a good appearance, with a tolerably regular front. The palace of the Guzman is magnificent, ornamented with a superb portal, and secured by very strong walls. Among the gates of the town one was formerly a famous prison; and at the bottom is the statue of king Don Pelagius, with an inscription. The Place Mayor has a beautiful appearance. There is a number of other squares and handsome fountains. Notwithstanding the antiquity and importance of this city it is very deficient in cleanliness. It is surrounded by trees, and the country about it is every where embellished; it has beautiful promenades, as well as broad and noble avenues of handsome trees. In the environs of the town the corn harvests are not abundant; but this deficiency is supplied by many excellent vegetables, fruits, flax, and verdant meadows, which furnish good pastures. At Leon there are several manufactories for different woollen articles; stockings, hosiery, leather, gloves, &c. are also made here. Leon is 150 miles N.W. of Madrid. N. lat. 42° 36'. W. long. 5° 37'.

LEON, a town of Spain, in Catalonia; 43 miles N.W. of Urgel.

LEON, a town of France, in the department of Stura; 4 miles N. of Savigliano.

LEON, *Isle of*, a kind of island four leagues from Xerez, in Andalusie, formed by a canal which furrounds it, ten miles long, and 24 feet deep in high water, and capable of admitting the largest ships. This island was entirely deserted in the seventeenth century, and there was scarcely a house upon it. At present the principal street of the town is two miles long, with rows of shops on each side, and containing upwards of 2000 inhabitants. Provisions are here abundant, and the place exhibits a moving scene. The island has an alcade-mayor for the administration of justice; a municipality composed of a number of regidores, and a manufacture of stained linen, resembling printed calico.

LEON, a river which falls into the gulf of Mexico, from the N.W., at the bay of St. Bernard.

LEON, a town of Mexico, in the province of Guadalarajara; 40 miles E. of Guadalajara.

LEON, a town of Mexico, and capital of the extensive province of Nicaragua, situated on a large lake of fresh water, abounding with fish. It is a bishopric, but a town of little importance. It has about 1200 houses, four churches, and several convents. Its situation near a mountain, in which is a volcano, renders it subject to earthquakes. The lake is said to ebb and flow like the sea. Realjo is a small entrenched town, with an excellent port, and serves Leon the capital.

LEON of *Caraccas*. See CARACCAS.

LEON of *Guanuco*. See GUANUCO.

LEON, *New*, one of the seven domains, called kingdoms, into which the Spanish dominions in North America are distributed. This name is restricted by the maps to a small province round the town of Monterey, which must not be confounded with another of the same name, to the N. of California. It is bounded on the N. by the Savage nations, on the E. by New Mexico Proper, on the S. by a part of Mexico, and on the W. by New Biscay. New Leon proper, a district ridiculously called a kingdom, is divided from Guadalcazar on the S. by the desert of Jaumave, and mountains of Tamalipa. It is very mountainous, produces little except lead, and is very thinly peopled. The other provinces of the domain of New Leon, besides New Leon proper, are Sootander and Coaguila, or New Estramadura.

LEONAN, a small island in the East Indian sea, near

the N.E. coast of Borneo. N. lat. 6° 39'. E. long. 117° 48'.

LEONARD of Pisa, in *Biography*, an Italian mathematician, who flourished at the commencement of the thirteenth century, was the first person who brought into Europe the knowledge of the Arabic cyphers and algebra. He gives an account of the fact himself, and says, that being at Bugia, a town in Africa, he was instructed in the Arabic method of keeping accounts, and that, finding it more convenient, and preferable to the European method, he had drawn up a treatise for the purpose of introducing it into Italy. From Italy the knowledge of the Arabic cyphers and algebra was afterwards communicated to the other countries of Europe. He was author of a treatise on surveying, preserved in the Magliabecchi library at Florence.

LEONARDO LEO, principal organist of the chapel royal at Naples, was not only admired and respected by his contemporaries, but his memory still continues to be held in reverence by every professor that is acquainted with his works. The first opera of his composition that we were able to find, is "Sofoniba," which was performed in Naples in 1718, and the last, "Siface," in Bologna, 1737. Between these he produced three operas for Venice, and four for Rome. Leo likewise set the "Olimpiade" of Metastasio, in which the duo, "Ne i giorni tuoi felice," and the air, "Non so donde viene," are admirable; as is "Per quel paterno amplesso," in Artaserse, the only air in that opera that we have seen. "Dirti hen mio voice," was in extreme high favour, as set by Leo, about the middle of the last century, in England, where it was sure to be heard at every musical performance, both public and private. Leo likewise set Metastasio's oratorio of "St. Elena al Calvario," of which we have seen some very fine airs. His celebrated "Miserere," in eight real parts, though imperfectly performed in London at the Pantheon, for Aniani's benefit, 1781, convinced real judges that it was of the highest class of choral compositions.

The purity of his harmony, and elegant simplicity of his melody, are no less remarkable in such of these dramas as we have been able to examine, than the judicious arrangement of the parts. But the masses and motets, which are carefully preserved by the curious, and still performed in the churches at Naples, have all the choral learning of the sixteenth century. There are likewise extant, trios, for two violins and a base, superior in correctness of counterpoint and elegance of design to any similar productions of the same period. This complete musician is equally celebrated as an instructor and composer; and the "Solfeggi," which he composed for the use of the vocal students, in the conservatorio over which he presided at Naples, are still eagerly sought and studied, not only in Italy, but in every part of Europe, where singing is regularly taught.

This great musician died about the year 1742, at the age of fifty-three. His death was unhappily precipitated by an accident which at first was thought trivial; for having a tumour, commonly called a *bur*, on his right cheek, which growing, in process of time, to a considerable magnitude, he was advised to have it taken off; but whether from the unskillfulness of the operator, or a bad habit of body, a mortification ensued, which cost him his life. After expressing the reverence which we have always had from our earliest youth, for the productions of this admirable composer, we shall transcribe a character of him from "L'Esai sur la Musique," drawn up with elegance, force, and feeling, which does not seem to flow from an exclusive admirer of Rameau, under the guidance of the intolerant preacher of the *triple progression*.

“Leonardo Leo, a Neapolitan, the first master, and most sublime genius for music of his time; who is never mentioned but with respect and admiration by every intelligent professor. They all aver that no compofer has given to music that interefing elevation, that impreffive dignity, which are the principal characteristics of the ftyle of Leo. A noble pathos always reigns in his compositions; his ferious and feeling character has intuitively guided his pen. This has made him partial to the chromatic, which he has fo ably treated. In fpite of the difficulty of compofing in this genus, he joins all the grace and sweetness which are fo delightful, even in the moft natural mufic. His tafte and expreffion will be always celebrated; as all thefe natural gifts were under the guidance of the moft profound knowledge of his art. In fhort, this wonderful man cannot be too highly prifed. His name and works are known to all Europe. He moft delighted in dramatic mufic, which, however, did not prevent him from enriching the church and chamber with innumerable productions of the moft finished kind. The following are fome of his operas: in 1720, *Cajo Gracco*; in 1722, *Tamerlane* and *Bajazet*; in 1723, *Timocrate*; 1728, *Argene*; in 1729, *Catone* and *Utica*; in 1735, *La Clemezza* di Tito; and in 1737, *Siface*. This truly great mufician died about the year 1742, at the age of 53.”

**LEONARDSTOWN**, in *Geography*, a poft-town of America, in the ftate of Maryland, and capital of St. Mary’s county, fituated on the E. fide of Britton’s brook, where it falls into Britton’s bay, five miles from its mouth in the Patowmac; and containing about 50 houfes, a court-houfe and gaol; 217 miles S.W. of Philadelphia. N. lat. 38° 18’.

**LEONBERG**, or **LEONSBURG**, a town of Wurtemberg, on the Glems; 6 miles W. of Stuttgart. N. lat. 48° 51’. E. long. 9° 7’.

**LEONE**, one of the Navigator’s ifles, about five miles in circumference, E. of Fanfoué, from which it is feperated by a channel.

**LEONES**, a fmall ifland in the Atlantic, near the coaft of Patagonia. S. lat. 50° 2’.

**LEONESSA**, a town of Naples, in Abruzzo Ultra; 19 miles N.W. of Aquila.

**LEONFORTE**, one of the largeft and handfomeft towns in Sicily, 10 miles from Argiro: fituated on an eminence. The number of inhabitants amounts to 12,000. The convent of Capuchins is as populous as the town.

**LEONI**, a town of Naples, in Principato Ultra; 12 miles W. of Couza.

**LEONICENUS**, **NICHOLAS**, in *Biography*, an eminent Italian phyfician, was born in one of the Venetian iflates in the year 1428. He was profefor of medicine at Ferrara during upwards of fixty years, and was the firft perfon who undertook to tranflate the works of Galen into Latin. In fact he was fo ftrongly attached to literary purfuits, and to the duties of his profeforfhip, that he gave up little time to the practice of his profefion: and when his negligence in this refpect was condemned, he faid, “I do more fervice to the public, than if I vifited the fick, by inftructing thofe who are to cure them.” He extended his attention alfo to the belles lettres, which he confidered as clofely connected with the proper ftudy of philofophy and medicine; he wrote fome refpectable poetry, and tranflated into Italian the hiftory of Dion Caffius, and the dialogues of Lucian. Until the age of thirty, Leoniceus was tormented with frequent attacks of epilepsy, which reduced him at times to melancholy and deffpair. This difeafe, however, afterwards left him, and, by means of great regularity and temperance,

he attained the age of ninety-fix years, and died in 1524, poffeffed of all his faculties. To one who inquired, with aftonifhment, by what feeret he had preferred this entire poffeffion of his faculties, together with an erect body, and vigorous health, at fo great an age, he replied, that it was the effect of innocence of manners, tranquility of mind, and frugality in diet. The duke and fonate of Ferrara erected a monument to his memory. He left feveral works, moft of which have been feveral times reprinted. “De Plinii et aliorum Medicorum in Medicina cronibus, &c.” Ferrari, 1492. In a pofthumous edition, printed at Bafle, in 1532, fome other opufcula were added, particularly “De Herbis, Fructibus, Animalibus, Metallis, Serpentibus, Tiro feu Viperâ.”—“Liber de Epidemia quam Itali Morbum Gallicum vocant, Galli verò Neapolitanum,” Venice, 1497. In feveral fubfequent editions, the title “De Morbo Gallico” was adopted.—“Præfationes in Libros Galeni a fe tranflatos,” ibid. 1508, folio, with fome other treatifes. “Opus de tribus doctriinis ordinatis fecundum Galeni fententiam,” ibid. 1508, fol. “Libri duo Galeni de curandi ratione ad Glauconem Latine verbi,” Paris, 1514, 4to. “Hippocratis Aphorifmorum Libri VII., Græce et Latine,” ibid. 1526, 8vo. “Converfio et explanatio primi Libri Ariftotelis de partibus Animalium,” Bafle, 1541, 8vo. “Galeni Ars Medica,” Venice, 1606. Eloy Dict. Hift. de Med.

**LEONICO**, **TOMEIO**, **NICHOLAS**, was born in Venice, of an Albanian family, in the year 1456. He ftudied Greek at Florence, and made fuch progrefs, that he became able to explain Ariftotle in the original language. For this purpofe he was invited to Padua in 1497. He was brought up to the church, and taught the learned languages at Venice, but in 1520 he returned to Padua, where he gave inftructions to cardinal Pole. He was much attached to the Platonic philofophy, and paffed his time remote from worldly purfuits, and fofoely intent upon his ftudies. Bembo, Giovio, and others, fpeak of him with great efteem, and Erafmus mentions him with honour, as a man equally refpectable for the purity of his morals and the profundity of his erudition. He died in 1531, and was buried in the church of St. Francis, at Padua. He tranflated feveral of the works of Ariftotle, Proclus’s Commentary on the Timæus of Plato, and other treatifes of the ancient philofophers. He wrote ten dialogues on fubjects philofophical and moral, a work, “De Varia Hiftoria,” and fome Italian poems.

**LEONIDAS** I., king of Sparta, fucceeded to the throne in the year 491, B.C. When Xerxes, king of Perfia, invaded Greece, Leonidas was appointed by the Lacedæmonians to the chief command of their forces to oppofe him. He marched at the head of 4000 men, to take poffeffion of the ftraits of Thermopylæ. Aware of the great danger of the enterprize, he confidered himfelf as one devoted to the fafety of the country. He pofted his fmall army fo fkillfully, that the Perfians, on arriving at the ftraits, found that it would be difficult to force them, and Xerxes endeavoured to bribe the commander to his intereft, by the offer of making him mafter of Greece. The propofal was rejected with indignation, and the monarch immediately fent a herald to order the Grecians to lay down their arms. “Let him come and take them,” was the reply of Leonidas. Thrice the Perfians were repulfed with great lofs; and when a treacherous Greek had led a chofen body of 10,000 Perfians by a feeret paffage to the rear of Leonidas, he was determined to afford a memorable example of what the Greeks could do when called upon to die for their country. Xerxes marched his whole army to the entrance of the ftraits, where Leonidas advanced to meet him. The efforts of valour, heightened

ed by despair, were terrible, and the Spartan king fell amidst a heap of slaughtered enemies. His friends defended his body, till the appearance of the foe in the rear caused the survivors to collect into one close band, facing every way. All these, overpowered by numbers, were left on the field of battle, having amply revenged their fall. The Persian tyrant, enraged at his loss, caused the body of the hero to be nailed to a cross; but the memory of his valour and patriotism could not be obliterated, and the defence of Thermopylae is consecrated among the noblest actions of antiquity. The gratitude of his country raised a splendid monument upon the spot to the fallen, and a funeral oration was for a long time annually pronounced amidst the celebration of martial games, over their tombs.

LEONINE, in *Poetry*, is applied to a kind of verses which rhyme at every hemistich, the middle always chiming to the end.

In this kind of verse we find several ancient hymns, epigrams, prophecies, &c. For instance; Muretus, speaking of the poetry of Lorenzo Gambara of Bresse, says,

“*Brixia vestrates, quæ condunt carmina vates  
Non sunt nostrates tergere digna vates.*”

The following one is from the school of Salernum :

“*Ut vites panam, de potibus incipe cenam.*”

The origin of the word is somewhat obscure : Pasquier derives it from one Leonius, or Leonius, who excelled in this way, and dedicated several pieces to pope Alexander III. ; others derive it from pope Leo; and others, from the beast called *lion*, because it is the loftiest of all verses.

M. Fauchet makes the leonine rhyme the same with what the French call the *rich*, and we the *double rhyme*, i. e. where two syllables have the same orthography, accentuation, and pronunciation, with two others.

LEONOTIS, in *Botany*, so called from λεων, a lion, and οvis, vites, the ear. Lion's-ear. Brown Prodr. Nov. Holl. v. 1. 504. Ait. Hort. Kew. ed. 2. v. 3. 409. (Leonurus; Tourn. t. 87.)—Clas and order, *Didymia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss. Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, oblong, with ten slight ribs, permanent; its orifice unequally toothed, with from six to ten teeth. *Cor.* of one petal, ringent; tube cylindrical, longer than the calyx; upper lip elongated, slightly concave, bearded, undivided; lower much smaller, in three nearly equal segments. *Stam.* Filaments four, concealed by the upper lip, two of them longer than the rest; anthers of two oblong divaricated lobes. *Pist.* Germen superior, four-lobed; style the length and position of the stamens; stigma cloven, acute, its upper segment shortest. *Peric.* none, except the permanent calyx. *Seeds* four, oblong, triangular.

Ef. Ch. Calyx with ten ribs; unequally toothed. Upper lip of the corolla elongated, bearded, undivided; lower much smaller, in three nearly equal segments. Lobes of the anthers divaricated. Upper segment of the stigma shortest.

1. *L. nepetifolia*. Catmint-leaved Lion's-ear. (Phlomis nepetifolia; Linn. Sp. Pl. 820. *Cardiaca americana annua, nepeta folio, floribus brevibus phnicicis villosis*; Herm. Lugd. Bat. 115. t. 117.)—Leaves heart-shaped, pointed. Calyx with eight spinous teeth; the upper one largest. Stem herbaceous.—Native of the East Indies, from whence sir Joseph Banks procured it for Kew garden in 1778. It is a tender annual, kept in the stove, and flowering in September and October. Hermann received the seeds from Suri-

nam; Linnæus from the East Indies, and it flowered in the Urial garden. The whole plant is hoary, with extremely soft minute pubescence. *Stem* four or five feet high, quadrangular, with opposite spreading branches. *Leaves* opposite, two or three inches long, and one or two broad, heart-shaped, veiny, deeply crenate or serrated, pointed, on stalks of their own length. *Flowers* in dense whorls, with linear spinous bractæ, and strongly spinous calyx-teeth. *Corolla* about an inch long, most elegantly clothed with dense scarlet hairs, paler at the edges.

2. *L. Leonurus*. Narrow-leaved Lion's-ear. Lion's-tail. (Phlomis Leonurus; Linn. Sp. Pl. 820. Curt. Mag. t. 478. Leonurus capitis bonæ spei; Breyn. Cent. t. 86.)—Leaves lanceolate. Calyx with ten regular teeth, five smaller than the rest.—Native of the Cape of Good Hope, from whence it was brought into the European gardens, for the sake of its beauty, early in the last century, and is still kept in greenhouses, being propagated by cuttings, and flowering abundantly in autumn. The stem is shrubby, seven or eight feet high. *Leaves* lanceolate, rather narrow, bluntly serrated, about two inches long, of a dull green, roughish, tapering down into short footstalks. *Flowers* large, in dense bracted whorls. *Calyx* downy, its teeth regular, very small, and scarcely spinous; the five alternate ones smaller than the rest. *Corolla* two inches long, slender, incurved, downy, of a fine tawny orange, or somewhat scarlet colour, the lower lip small and brown.

3. *L. Leonitis*. Round-leaved Lion's-ear. (Phlomis Leonitis; Willd. Sp. Pl. v. 3. 128. Ph. Leonotis; Linn. Mant. 83. Leonurus minor, capitis bonæ spei; Mill. Ic. t. 162. t. 1.)—Leaves ovate, blunt, crenate. Calyx with eight awned teeth; the upper one largest. Stem shrubby.—Native of the Cape of Good Hope, from whence it was brought early in the last century, but is less frequent in our greenhouses than the foregoing; from which it differs in its smaller size, roundish long-stalked small leaves, and rather shorter more obtuse corolla, besides the essential distinctions of the calyx.

LEONTARI, in *Geography*, a town of the Morea; 20 miles N.W. of Mifitra.

LEONTESERES, in the *Natural History of the Ancients*, the name of a species of agate, famous in early times for its imaginary virtues in taming the rage of wild beasts, and not a little esteemed among us for its beauty. It is the most variegated of all the agates. Its ground colour is yellow, and its variegations are flame-coloured, white, black, and green.

Sometimes it is one irregular congeries of all these colours, but more frequently it is very beautifully variegated with them in form of clouds and veins; the black and green particularly are usually disposed in concentric circles round one or more points. It is found only in the East Indies, and is very scarce.

LEONTIEVKA, in *Geography*, a town of Russia, in the government of Novgorod; 40 miles S.E. of Valdaï.

LEONTIASIS, in *Medicine*, a name given by the ancients to the elephantiasis, improperly called the Arabian leprosy, from a supposed resemblance of the tuberculated countenance of the patient, in some instances, to the visage of the lion (*leo*). See ELEPHANTIASIS.

LEONTICA, feasts, or sacrifices celebrated among the ancients, in honour of the sun.

They were called *leontica*, and the priests who officiated at them *leones*, because they represented the sun under the figure of a lion radiant, bearing a tiara, and gripping in his two fore-paws the horns of a bull, who struggled with him, in vain, to disengage himself.

The critics are extremely divided about this feast: some will have it anniversary, and to have made its return not in a solar, but in a lunar year; but others hold its return more frequent, and give instances where the period was not above 220 days.

The ceremony was sometimes also called *Mithriaca*; *Mithras* being the name of the sun among the ancient Persians.

There was always a man sacrificed at these feasts, till the time of Hadrian, who prohibited it by a law. Commodus introduced the custom afresh, after whose time it was again exploded.

**LEONTICE**, in *Botany*, a name adopted by Linnaeus from Pliny, as a substitute for *Leontopetalon* of Tournefort. (See **LEONTOPETALON**.) Lion's-leaf. Linn. Gen. 168. Schreb. 223. Willd. Sp. Pl. v. 2. 148. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 272. Sm. Prodr. Fl. Græc. Sibth. v. 1. 234. Juss. 287. Lamarck. Illust. t. 254. —Class and order, *Hexandria Monogynia*. Nat. Ord. *Corydalis*, Linn. *Berberidæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of six linear, spreading deciduous leaves, the intermediate ones smaller. Cor. Petals six, ovate, acute, twice as long as the calyx. Nectary of six half-ovate, spreading, equal, stalked scales, inserted into the base of the petals. Stam. Filaments fix, thread-shaped, very short, opposite to the petals; anthers erect, of two cells, and two valves, bursting from the base upwards. *Pist.* Germen superior, oblong-ovate; style short, nearly cylindrical, inserted obliquely upon the germen; stigma simple. *Peric.* Berry hollow, inflated, globose with a point, of one cell, but slightly succulent. *Seeds* few, globose.

Eff. Ch. Corolla of six petals. Nectary of six spreading stalked leaves, attached to the base of the petals. Calyx of six leaves, deciduous. Berry inflated, of one cell. *Seeds* few, globose.

1. *L. Chryfogonum*. Pinnated Lion's-leaf. Linn. Sp. Pl. 447. (*Leontopetalon* affinis, foliis quernis; Moris. v. 2. 285. fect. 3. t. 15. f. 7. *Chryfogonum* Diofcoridis; Rauw. It. t. 119. *Chryfogono* di Diofcorido; P. Bald. 141.)—Leaves radical, pinnated, deeply cut.—Native of corn-fields in Greece. Dr. Sibthorp gathered this species near Abydos. It is much to be regretted that so curious a plant, though cultivated by Miller, is now a stranger to our gardens, and that even dried specimens are so very rare. Whether it be really the *χρυσογόνος* of Diofcorides, his short description must ever leave doubtful. The leaves are not much like an oak, nor the flower like a Mullein, though the tuberous root may be compared to a turnip. He describes his as very red within. Authors represent our's as having a perennial, fleshy, somewhat conical root, producing several upright stalked leaves; there are about a span long, smooth, rather glaucous, simply pinnate; the leaflets not quite opposite, about nine or ten pair, sessile, oblong or roundish, either wedge-shaped or in some degree heart-shaped at the base, entire at the sides, but more or less deeply cut towards the top. In our specimens they are by no means so deeply divided as in the figures above quoted, which have led professor Willdenow to suppose them whorled. *Flower-stalks* one or two, radical, a little taller than the leaves, many-flowered, branched, corymbose, round, smooth, leafless. *Bractææ* elliptical, coloured, solitary at the base of each branch. *Flowers* yellow, somewhat like those of *Celandine*. *Anthers* ovate before they burst.

2. *L. Leontopetalum*. Common Lion's-leaf. Linn. Sp. Pl. 448. (*Leontopetalon*; Camer. Epit. 565. Ger. om. 236. Barrel. Ic. t. 1029, 1030. Moris. v. 2. fect. 3. t. 15.

f. 6.)—Radical leaves twice or thrice ternate; stem-leaves ternate.—Abundant in corn-fields in the Levant, flowering early in the spring, and ripening fruit in May. Gerard says, lord Zouch in his time brought a plant from Italy, but, as far as he knew, it perished. Miller, however, appears to have raised both this and the preceding from seed, but could not preserve them, on account of the unfavourable spring so usual here. *Root* tuberous, perennial. *Stem* solitary, erect, 12 or 18 inches high, branched, smooth, leafy. *Radical leaves* somewhat like those of a Columbine, on long stalks, twice or thrice ternate, the leaflets rounded or obtuse, entire, confluent or decurrent, veiny; those of the stem much smaller, and scarcely more than simply ternate. *Flower-stalks* corymbose, soon racemose, with ovate concave bractææ. *Flowers* yellow, copious, much like the last. *Fruit* an inch long, more or less ovate, soon becoming a dry, membranous, curiously reticulated bag, in the bottom of which are three or four large round seeds. The *Leontice incerta* of Pallas, in his Travels, v. 3. 726. t. V. f. 3, which Willdenow has adopted by the name of *L. vesicaria*, seems a mere variety, differing a little, as is perhaps usual, in the shape of the fruit, but otherwise agreeing exactly with the *Leontopetalum*. Pallas was in doubt respecting it, as having seen nothing of the flowers.

3. *L. altaica*. Fingered Lion's-leaf. Willd. n. 4. Pallas. Act. Petrop. for 1779. 257. t. 8. f. 1—3. Willd. Lamarck. f. 2.—Radical leaves twice compound; stem-leaves fingered, oblong.—Discovered by Pallas on exposed parts of the Altay mountains. We have never seen this species, but Willdenow, who examined a dry specimen, says, “the radical leaves have their stalk first three-cleft, and that each division bears five elliptic-lanceolate, entire leaflets at its summit; the stem-leaves are in like manner quinate, generally three together in a whorl. *Bractææ* elliptical, obtuse.” This latter part of the description accords with Lamarck's figure, copied, we presume, from Pallas.

4. *L. thalicroides*. Columbine-leaved Lion's-leaf. Linn. Sp. Pl. 448. (*Carophyllum thalicroides*; Michaux Boreali-Amer. v. 1. 205. t. 21.)—Stem-leaves twice or thrice ternate; terminal leaflets three-lobed, acute.—Native of North America. It was procured from thence by Peter Collinson before 1755, and is still preserved in some curious gardens, flowering in May. *Root* perennial. *Stem* a foot high or more, erect, simple, bearing one thrice compound leaf; and another, close to the flowers, twice compound, both sessile, but with long partial stalks; leaflets dark green above, glaucous beneath, rounded at the base, with two or three deep acute segments at their fore part; as the fruit advances they become more rounded and much enlarged, resembling some large kind of Meadow-rue, or Columbine. *Flowers* green, in a small, slightly compound, slender, stalked cluster, with little ovate acute bractææ. The whole plant is smooth. Michaux describes the fruit as more pulpy than in the above species, and single-seeded, like the drupa of the sloe, but this is hardly sufficient perhaps to establish, as he does, a new genus. We find the berry hollow, and apparently somewhat inflated, though far less than in the second species. American botanists must solve this difficulty.

5. *L. triphylla*. Three-leaved Lion's leaf.—Leaves radical, ternate, bluntly toothed. Stalk radical, simple. Flowers spiked.—Gathered by Mr. Archibald Menzies, on the west coast of North America. The root is perennial, somewhat creeping. *Leaves* solitary, on a slender, simple, upright, smooth footstalk, about ten or twelve inches high, with a few imbricated, elliptical, concave, ribbed scales at its base; leaflets three, sessile, two inches wide, smooth, pale green, beautifully reticulated with innumerable veins; ra-

ther wedge-shaped at their base, the side-ones dilated laterally; the outer margin of all wavy or bluntly toothed. *Flower-stalk* solitary, from the same bud with the leaf, but a little taller, simple, slender, naked. *Spike* terminal, about an inch long, of numerous, sessile, white *flowers*, of whose *calyx* or *corolla* we can find no traces, but the *filaments* agree so well with those of *L. Leontopetalum*, in their very peculiar structure, that we venture to refer our plant to this genus. The *filaments* are extremely slender at their base; the *germen* is ovate, with a thick, nearly sessile, oblique *stigma*.

LEONTICE is also a plant mentioned by the ancient Greeks, and called by them *caecalia*.

Dioscorides tells us it had these names in common, and that it was of great virtue in curing diseases of the *aspera arteria*, or wind-pipe.

This medicinal plant of the Greeks was very different from that we now call *caecalia*. Some have described it to have flowers like the oak, others like the olive-tree, but the old manuscripts of Dioscorides all say, the flowers were like those of bryony. Hence it could by no means be the *caecalia* of the moderns; nor is it easy to say, from such short and uncertain accounts, what it was. See the preceding article.

LEONTINI, or LEONTIUM, in *Ancient Geography*, a town of Sicily, called also, as Diodorus informs us, *Xutibia*, a name given probably to the small district in which it is situated. It was situated, according to Herodotus's account of it, between two rivers, which, after their junction, ran into the southern part of the gulf of Catania. One to the S. was called "Lisius," now Liso, and the other to the N. "Terias," called St. Leonard's stream. The town was built, at the same time with Catania, by the Chalcidians, under the conduct of Theocles, the Athenian, in the 11th year of the 13th Olympiad, as we are informed by Thucydides; in whose time it was defended by two strong citadels, one called the citadel of Phoece, the other the citadel of Bricinnia. The adjacent territory was so fruitful, that it yielded, according to Pliny, crops of corn an hundred fold, and Cicero calls it the grand magazine of Sicily. Its wines were the most delicious of the whole island, but the inhabitants perverted the benefit into an occasion of intemperance, so that it became a proverbial saying, "the people of Leontini are always at their cups." Leontium had its tyrants as well as Syracuse, and between these two cities there subsisted a constant rivalry and enmity. This was the birth-place of the celebrated rhetorician Gorgias, whose eloquence astonished even the Athenians, and who persuaded them to undertake the unfortunate expedition under Nicias. Leontium at length fell under the power of Syracuse, Dionysius the tyrant having removed the inhabitants thither. The situation of the castle, and the fertility of the country, rendered Leontium at all times a place of importance to the different nations which possessed Sicily. The earthquake of 1693 completed its destruction, and reduced it to its present state of wretchedness. The ancient city, built on four hills, presents to the observer nothing but a spot of ground torn by four ravines, which lay open a few wretched grottos, the sole remains of its former greatness. The castle stood on a detached rock, opposite to the city, which was originally hewn out of it, and has been successively built and rebuilt according to the style of different ages, and the prevailing modes of besieging and defending places. The rich country of Leontium, so luxuriant in corn, is now called the plain of Catania; it is 12 miles wide by 20 in length, and was formerly the country of the *Lætrigons*, divided and bathed by the "Simaethus," the largest river in Sicily, which rolls along in its stream a quantity of black

and yellow amber, which is sought for where it disgorges itself into the sea, and is washed up at Catania.

LEONTIUM, in *Biography*, an Athenian courtesan, at one time noted for the licentiousness of her life, and afterwards distinguished by her application to the study of the Epicurean philosophy. It has been asserted, that she did not desert from her intrigues after she was an attendant on Epicurus, but prostituted herself to the disciples of his school, and even to the philosopher himself. She became the wife of Metrodorus, one of the principal disciples of Epicurus, and had a son by him, whom Epicurus commended to the notice and regard of his executors. Leontium applied with great diligence to the study of philosophy, and wrote, in defence of the Epicurean doctrines, against Theophrastus, one of the principal of the Peripatetic sect. The book is acknowledged by Cicero to have been written in a polite and elegant style. Bayle. Moreri.

LEONTIUS, surnamed the *Sebolastic*, who flourished in the sixth century, was a native of Constantinople, was educated an advocate and afterwards became a monk. He lived till about the close of the century. The principal work of Leontius is "A Treatise on the Sects of Heretics," divided into ten discourses. It was published in Greek and Latin at Basil, in 1578. He was also author of various treatises against the Eutyrians, Nestorians, and Apollinarists; a discourse on the festival celebrated between Easter and Whit Sunday; and there are "Orations" and "Homilies" ascribed to him in the Bodleian and Vienna libraries. Moreri.

LEONTODERON, in *Natural History*, a name given by several authors to a species of agate, of a plain yellowish colour, without variegations.

LEONTODON, in *Botany*, derived from *λεων*, *λεω*'s, a lion, and *δον*, a tooth, and so called from a similarity in the shape of its jagged leaves to the teeth of a lion. Linnæus bestowed this name upon the genus in just preference to the compound one of *Dens Leonis* given by Tournefort. The English name *Dandelion*, which is a corruption of *Dent de Lion*, is expressive of the same idea, and might possibly have given rise to its botanical appellation. Dr. Smith has described the leaves of *Leontodon Taraxacum*, in his Introduction to Botany, p. 157, as runcinate or lion-toothed, cut into several traverse, acute segments, pointing backwards. A striking character of this sort, which, at first sight, suggests a name, borrowed from some familiar or popular resemblance, is always desirable, and is sufficiently apparent in this genus.—Linn. Gen. Coll. Schreb. 529. Willd. Sp. Pl. v. 3. 1544. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. v. 2. 822. Ait. Hort. Kew. v. 3. 120. Gaertn. t. 158. (Dens Leonis; Tournef. t. 266. Taraxacum; Juli. 169. Lamarck. Illust. t. 653.)—Class and order, *Synonymia Polygamia Æqualis*. Nat. Ord. *Compositæ Semibisulculosa*, Linn. *Ciboraceæ*, Juss.

Gen. Ch. *Common calyx* imbricated, oblong; its interior scales linear, parallel, equal; outer scales fewer in number, often reflexed at the base. *Cor.* compound, imbricated, uniform; the florets hermaphrodite, numerous, equal, each of one petal. ligulate, linear, abrupt, with five teeth. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen nearly ovate; style thread-shaped, as long as the florets; stigma two, revolute. *Peric.* none, except the oblong, straight, at length reflexed, calyx. *Seeds* solitary, oblong, rough; down capillary, stipitate. *Recept.* naked, dotted.

Ed. Ch. Receptacle naked. Calyx double, imbricated with rather lax scales. Down stalked, hairy.

1. *L. Taraxacum*. Common Dandelion. Linn. Sp. Pl.

1722. Engl. Bot. t. 510. Curt. Lond. fasc. 1. t. 58. —Outer scales of the calyx reflexed. Leaves lion-toothed, smooth. Perhaps the most common of all plants, in meadows, pastures, on rubbish and on all cultivated land, flowering from April to July. This troublesome though handsome weed, has a deep and branching perennial root. Leaves radical, runcinate, toothed, of a bright green colour, smooth. Flower-stalks simple, longer than the leaves, hollow, brittle, milky and single-flowered. Flower terminal, large, golden-coloured, closing in the evening. Styles hairy. Seeds obovate, furrowed, bearing on a long footstalk a tuft of simple, radiated down. The diuretic qualities of this plant, which caused it to be called *Pissinli* in French, procured it a similarly expressive name in this country, by which it is well known to the vulgar. The whole herb is milky and bitter, but like Lettuce or Celery becomes sweet by culture or blanching. Curtis remarks that the French are very partial to this species in their salads. It is especially used by the poorer sort of people, because it is so common and so easily prepared.

2. *L. palustris* Marsh Dandelion. Sm. Fl. Brit. 823. Lyons Fasc. 48. Engl. Bot. t. 553. (*L. lividus*; Willd. n. 3.) —Outer scales of the calyx shorter, upright, ovate. Leaves finned and toothed, nearly smooth. Found generally on moors and marshes. At Hinton Moor, in Cambridgeshire, by the Rev. Mr. Relhan, and at Heydon, Norfolk, by the Rev. Mr. Bryant. It flowers in June and July. Root perennial, spindle-shaped. Leaves not quite so distinctly lion-toothed as in *Taraxacum*, sometimes inclined to be hairy. Flower-stalks about as long as the leaves, sometimes decumbent. Calyx imbricated on all sides; its scales gradually smaller outwards, ovate, acute, all erect. Florets golden-coloured, the outer ones purplish at their back. Seeds and Down very similar to the former species. Indeed this was considered merely as a variety of that, till Dr. Smith established the present plant in his English Botany. The whole herbage is more delicate and slender than that of the common Dandelion.

3. *L. serotinus* Late-flowering Dandelion. Walldt. and Kitaib. Pl. Rar. Hung. v. 2. 119. t. 114. Willd. —Outer calyx spreading. Stalk single-flowered. Leaves runcinate rough, their teeth rounded and notched. A native of hills in Hungary. —Flower-stalk generally smooth, sometimes downy. The species is sufficiently marked as being distinct from *L. Taraxacum*, to which it is nearly allied in habit, from having the scales of its calyx spreading and sticking out in all directions; its leaves are also rough, their lobes rounded and toothed.

4. *L. levigatus* Smooth Dandelion. Willd. n. 4. —Outer calyx erect, close-pressed; scales ovate. Stalk single-flowered. Leaves deeply runcinate, toothed, smooth. A native of Spain. Radical leaves deeply runcinate, almost pinnatifid, very smooth and thin; teeth triangular, notched. Flower-stalks smooth, ascending. Scales of the outer calyx ovate, closely-pressed. It differs abundantly from *L. palustris* in having its leaves more slender, and deeply cut, with triangular notches.

5. *L. obovatus* Obovate Dandelion. Willd. n. 5. —Outer calyx spreading; scales ovate. Stalks single-flowered. Leaves obovate, rather obtuse, toothed. Found, like the last, in Spain. Leaves obovate, generally very obtuse, sometimes rather acute, toothed at the margin, smooth; their footstalks and mid-rib sometimes fringed. Calyx furnished with external, acute, spreading scales. This is decidedly distinguished from all the other species by the shape of its leaves.

This genus is much more ample as it stands in Linnæus. We have adopted all the species retained by Willdenow, who has removed the rest to different genera, as follows. *Leontodon bulbosus*, and *aureus*, are referred to *Hieracium*: *L. hiftilis*, *tuberosus*, *autumnalis*, *alpinus* and *bispitosus* to *Aparagia* of Schreber: *L. hirtus* to *Thrinicia* of Roth., and has followed Swartz in calling *L. tomentosus*, *Tufflago albicans*. We do not scruple following Willdenow in reforming the genus of *Leontodon*, especially as we have the authority of Jacquin and Smith for having done so in *Tragopogon*.

LEONTODON *Taraxacum*, or *Common Dandelion*, in the *Materia Medica*, &c. The young leaves of this plant in a blanched state have the taste of endive, and make an excellent addition to those plants eaten early in the spring as salads. At Gottingen the roots are roasted and substituted for coffee by the poorer inhabitants; who find that an infusion prepared in this way can hardly be distinguished from that of the coffee-berry. Dandelion is generally considered by medical writers as the most active and efficacious of the lacteic plants; the expressed juice is somewhat acrid, the root still more bitter, and possessing more medicinal power than any other part of the plant. *Taraxacum* has been long in repute as a mild detergent and aperient, and its diuretic effects may be inferred from the vulgar name it bears in most of the European languages, "quali lectingima et urinaria herba dicitur." Bergius recommends its use in obstructions of the liver, hypochondrials, and jaundice. We have various proofs of the good effects of the *Taraxacum* related by different authors, in jaundice, dropsy, pulmonary tubercles, and some cutaneous disorders. The leaves, roots, flower-stalks, and juice of dandelion have all been separately employed for medical purposes, and seem to differ rather in degree of strength than in any essential property; therefore the expressed juice, or a strong decoction of the roots, has been most commonly prescribed, from one ounce to four, two or three times a day. The plant should be always used fresh; for even extracts prepared from it appear to lose much of their power by keeping. Woodv. Med. Bot.

LEONTODONTOIDES, in *Botany*. See HYOSERIS.

LEONTOPETALO AFFINIS. See LEONTICE.

LEONTOPETALOIDES, the name of a genus of plants described by Dr. Amman, being a species of the *leontice* of Linnæus; which see. See also TACCA.

LEONTOPETALON, from λέων, *leōn*, a lion, and πτελον, a leaf. Lion's-leaf. Tourn. Cor. 49. t. 484. See LEONTICE.

LEONTOPODIUM, from λέων, a lion, and πους, *poūs*, the foot, has been applied as a name to several plants, whose thick and soft hairiness, enveloping their flowers or stalks, as the claws of a lion are enveloped, seems to have given rise to the idea. Among these are *Myosotis scorpioides*; several species of *Gnaphalium*, especially the elegant *Filago Leontopodium* of Linnæus, now restored by Willdenow, very justly, to *Gnaphalium*, where Linnæus at first placed it; *Alchemilla vulgaris*, called *Leontopodium* by Brunfelsius, v. 2. 53; and *Plantago cretica*, the *Leontopodium* of Clusius. What Dioscorides, the father of the name, intended by his *λεοντοπιδιον*, is very difficult to be guessed. Dr. Sibthorp thought it might be *Microtus creticus*, which is very common in Cyprus and several of the Greek islands; but it hardly answers to the description.

LEONTOPOLIS, or LEONTON, in *Ancient Geography*, a town of Egypt, and capital of a nome, which took the name of "Leontopolites nomos." Ptolemy.

LEONURUS,

**LEONURUS**, from *λεων*, a lion, and *ουρα*, a tail; a name given by Tournefort to some Linnaean species of *Phlomis*, (see *LEONOTIS*), but applied by Linnaeus to the *Cardiaca* of Tournefort, for which it is now retained. Motherwort.—Linn. Gen. 205. Schreb. 391. Willd. Sp. Pl. v. 3. 114. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 405. Sm. Fl. Brit. 637. Brown Prod. Nov. Holl. v. 1. 504. Juss. Fl. 14. Lamarck. Illustr. t. 509. (Cardiaca; Tourn. t. 87)—Clafs and order, *Didymium Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five angles, and five awl-shaped, spinous teeth, permanent. Cor. of one petal, ringed; tube narrow; limb gaping; throat long; upper lip longest, semicylindrical, concave, gibbous, fluggly, rounded and obtuse at the top, undivided; lower reflexed, in three deep segments, not quite equal. Stam. Filaments four, concealed under the upper lip, two of them shorter than the others; anthers oblong, incumbent, their lobes parallel, and near to each other, besprinkled with minute, globular, shining, elevated granulations. Pist. Germen superior, four-cleft; style thread-shaped, the length and situation of the stamens; stigma in two equal acute segments. Peric. none, the permanent calyx containing the seeds in its cavity. Seeds four, oblong, convex on one side, angular at the other.

Eff. Ch. Calyx with five teeth, pentagonal. Upper lip of the corolla concave, hairy, undivided; lower in three deep, rather unequal, segments. Anthers with parallel lobes. Stigma equally divided.

1. *L. crispus*. Cut-leaved Motherwort, Murray in Linn. Syst. Veg. ed. 14. 538. Nov. Comm. Goett. v. 8. 44. t. 4.—Leaves with three or five lobes, deeply toothed, rugged and wavy. Corolla longer than the calyx.—Native of Siberia. Said to have been cultivated in the Oxford garden in 1658. It has all the appearance of being a luxurious or monitrous variety of the following.

2. *L. Cardiaca*. Common Motherwort. Linn. Sp. Pl. 817. Engl. Bot. t. 286. Fl. Dan. t. 727. (Cardiaca; Ger. em. 705. Camer. Epit. 864. Rivin. Monop. Irr. t. 20. f. 1.)—Upper leaves lanceolate; three-lobed or undivided. Corolla longer than the calyx; the middle lobe of its under lip acute.—Native of waite ground in the more northern parts of Europe, not frequent in England. It loves a gravelly or calcareous soil, and is perennial, flowering in July and August. The herb is bitter, with a pungent unpleasant smell. Stem a yard high, purplish, square, regularly beset with numerous, opposite, stalked, roughish, dark-green leaves; of which the lower are broadest, three-lobed, and more or less deeply cut; the upper gradually narrower and less divided, till they become lanceolate, acute, and quite entire. Flowers numerous, in dense whorls. Bractees awl-shaped, pungent. Calyx-teeth spreading, rigid, nearly equal, broad at the base. Corolla purple, variegated; its upper lip elegantly villous with white hairs. The anthers are marked with shining points, but that is not peculiar to the genus.

3. *L. Marrubialtrum*. Small-flowered Motherwort. Linn. Sp. Pl. 817. Ehrh. Pl. Exicc. n. 157. Jacq. Austr. t. 405.—Leaves ovato-lanceolate, strongly serrated. Corolla scarcely longer than the calyx; the middle lobe of its under lip rounded, obtuse.—Native of Bohemia, Germany, Tartary and Siberia. The leaves vary in breadth, and are either strongly serrated or entire, but never cut or jagged like the preceding. The calyx-teeth also are narrower and longer; and the corolla totally different, scarcely exceeding the length of the calyx, but slightly downy, and the middle lobe of its under lip almost heart-shaped, or at least dilated

and very blunt. The roots moreover is said to be only annual, or biennial. The plant has little to excite notice, and is only kept in curious gardens.

4. *L. supinus*. Decumbent Motherwort. Willd. n. 5.—“Leaves mostly five-lobed; the lobes obtuse, toothed at the summit. Calyx sessile. Stems ascending.”—Native of Siberia, communicated to professor Willdenow by his friend Stephan. “Root perennial. Stems several, half a foot high, ascending, branched, square, downy. Leaves opposite, half an inch long, with three or five lobes, which are oblong, somewhat wedge-shaped and obtuse, furnished at the extremity with three or five obtuse teeth; downy on both sides, especially the under. Footstalks the length of the leaves. Whorls of four to six flowers, sessile. Bractees bristle-shaped, pointed, downy, shorter than the calyx. Calyx downy, its segments ovate, spinous. Corolla white, rather longer than the calyx, its lip three-lobed, obtuse.” Such is Willdenow’s description, made from the dried plant, which in almost every minute particular accords so well with our *Lamium palmatum*, (see *LAMNUM*), that we should conclude them to be the same, were it not for the bractees, of which our plant is certainly destitute.

5. *L. tataricus*. Tartarian Motherwort. Linn. Sp. Pl. 818. (Cardiaca foliis tenuiis et profundius incisfis glabra; Mill. Ic. v. 1. 53. t. 8c.)—Leaves in three deep divisions; their lobes jagged. Upper lip of the corolla flattened, upright, reflexed.—Native of Tartary. It differs from the following merely in the flower being smaller, with a more rounded upper lip, whose extremity is reflexed. Gmelin, who gathered both, thought them varieties, and we find no difference to be depended on.

6. *L. fibrificus*. Siberian Motherwort. Linn. Sp. Pl. 818. Sm. Exot. Bot. t. 94. (Ballote inodora, foliis coronopi; Amm. Ruth. 48. t. 8.)—Leaves in three deep divisions; their lobes jagged, bluntish. Upper lip of the corolla straight.—Native of Siberia, China, and the East Indies, a hardy annual in our gardens. Stem two or three feet high, branched. Leaves deeply cut in a three-fold manner, into various deep divisions, mostly narrow and bluntish, more or less downy. Flowers crimson, in dense whorls, with awl-shaped bractees. Calyx silky. Corolla twice as long as the calyx; its upper lip concave, but straight; lower in three lobes, the middle one dilated, heart-shaped. Mr. Sowerby found a double row of crimson glands in the mouth of the tube. The calyx is often spinous, but not always so.

For the *L. Galeobdolon* of Willdenow; see *GALEOBDELON*. **LEOPARD**, in Zoology, the English name of the long-tailed *felis*, or *FELIS pardus* of Linnaus; which see.

**LEOPARD’S PANE**, in Botany. See *DORONICUM*.

**LEOPOLD I.**, in Biography, emperor of Germany, son of Ferdinand III. was born in 1640. He was elected king of Bohemia in 1654, and of Hungary in 1655, and he succeeded to the imperial crown in July 1658. His reign was fruitful of important events. A war with the Turks, which broke out in 1661, was brought to a conclusion in 1664, in consequence of a victory obtained over the grand visier, at St. Gotthard, in Hungary. This was succeeded by a revolt of the Hungarians, excited by those infringements of their privileges which have been continually renewed under the princes of the house of Austria. The execution of the leaders in 1671, for a time, quelled the disorders, without removing the causes of discontent. In 1672 Leopold joined in a league with other powers to protect the Dutch against Lewis XIV.; at this crisis the Hungarian malecontents took the opportunity of shaking off the Austrian yoke and asserting

asserting their original independence. Headed by count Tekeli, and supported by the Turks, they again rose in arms, and obtained various successes against the Imperialists. In 1682 a new war broke out between the empire and France; and about the same time the breach of a truce by the Hungarian revolters, and the irruption of a vast Turkish army, reduced Leopold to the greatest danger. His general, the duke of Lorraine, was obliged to retire under the walls of Vienna, and the grand vizier laid siege to that capital, while the emperor with his court withdrew to Linz. A series of successes afterwards attended the imperial arms in Hungary, and all that had been lost was gradually recovered. The rebels were tried, the noblest blood was shed without mercy or remorse, and the Hungarians were so far humiliated, that an assembly of the estates, in 1687, declared the kingdom hereditary in the house of Austria, and elected for their king the archduke Joseph, then only nine years of age. Three years afterwards, Leopold procured the election of his son Joseph to the succession of the empire, as king of the Romans. The war with France was carried on with various success, till the general peace, concluded at Ryswick, in 1697. In 1699 a long truce was agreed on between the German and Turkish empires, on terms favourable to Leopold, whose arms had obtained great glory under the illustrious prince Eugene. The war, on account of the Spanish succession, plunged Europe again in blood. Leopold gained over the elector of Brandenburg to the party of the allies, by consenting to recognize him as king of Prussia. The events of the war were at first unfavourable to the emperor, but the decisive battle of Blenheim or Hochstet, in 1704, changed the face of affairs. Leopold did not long enjoy the brighter prospect which was opening upon him: he died in the following May, at the age of sixty-five, after a reign of forty-six years, leaving the power of his house much augmented in his hands. "His original education," says the historian, "which was that of an ecclesiastic, had coincided with his natural disposition, in producing a cold formality of character; and the narrowness of his ideas threw him into the power of favourites, whom his jealousy of authority led him frequently to change. The great objects of his policy were, however, pursued with a steadiness which ensured their final success." *Modern Univer. Hist.*

LEOPOLD II., emperor of Germany, born in 1747, son of the emperor Francis I. and the empress-queen Maria Theresa, was created grand duke of Tuscany about the year 1765; and during a reign of twenty-five years, displayed a constant regard and attention to the happiness and prosperity of his people. He carried into effect a number of improvements relative to all the branches of administration, which rendered that portion of Italy peculiarly flourishing. He diminished the taxes, and yet augmented the revenue; introduced an exact police; encouraged the arts, manufactures, and agriculture; freed industry from the fetters of numerous festivals, meliorated the condition of the public hospitals and prisons, and promulgated an entire new code of laws, characterized as well by their humanity as their simplicity. In the preface to this code he says, "We have considered the examination and reform of the criminal laws as one of our principal duties;" and after much experience he says with true patriotic exultation; "With the utmost satisfaction to our paternal feelings we have at length perceived, that the mitigation of punishments, joined to a most scrupulous attention to prevent crimes, and also a great dispatch in the trials, together with the suddenness of punishment to real delinquents, has, instead of increasing the number of crimes, considerably diminished that of the smaller ones, and rendered those of an atrocious nature very rare;" so rare, in-

deed, that during ten years not a single execution took place in his dominions. Leopold protected the lower ranks from the oppression of the higher, and his palace was ever accessible to the meanest supplicant. Though the father of his people, he was also their master, and would admit of no opposition to his will; though sincerely desirous of doing good, he was cold and saturnine. In 1790 the imperial crown, and the succession to the Austrian dominions, devolved to him on the death of his brother Joseph. The result of that unfortunate prince's schemes had been an absolute revolt of the Low Countries, the disaffection of Hungary, and the jealousy of all the surrounding states. Leopold, by employing the arts of conciliation, in conjunction with firmness and prudence, was able in a short time to recover the Low Countries, to quell the opposition of the Hungarian malcontents, to strengthen his house by splendid alliances, and to establish peace with the Ottoman Porte. He restored a good understanding between the courts of Vienna and Berlin, and concurred with England in checking the ambitious projects of Russia. Soon after the commencement of the French revolution, Leopold formed, at the congress of Pillnitz, a coalition with Prussia, for the avowed purpose of giving a government to France, and the subsequent invasion of that country by the united forces of the two powers is to be regarded as a consequence of this alliance. Leopold did not live long enough to witness the commencement of hostilities. He died in the month of March 1792, at the age of forty-four, leaving behind him a numerous progeny, of whom his eldest son Francis II. succeeded to the vacant throne. *Univer. Hist. New Ann. Regit. Edict of the grand duke of Tuscany, printed by the celebrated Mr. John Howard.*

Leopold was passionately fond of Italian poetry and music, and is said by Quadrio (*Storia d'Ogni Poesia, vol. i.*) not only to have been the constant patron of both, but to have composed masses and motets for his own chapel, and to have written, and set to music, himself, many beautiful canzonets and madrigals. This prince, early in his reign, retained in his service the Italian lyric poet Minato, and Antonio Draghi, to write and set operas for the imperial court at Vienna.

LEOPOLDSTADT, in *Geography*, one of the suburbs of Vienna, large and populous; situated on the N. side of the Danube, and communicating with the city by a bridge.

—Also, a fortified town of Hungary, on the river Waag; 56 miles E. of Vienna. N. lat. 48 28'. E. long. 17 54'.

LEOSTENIUS SINUS, in *Ancient Geography*, a gulf of Thrace, upon the Thracian Bosphorus, towards the northern part of the Hermean promontory.

LEOTAUD, VINCENT, in *Biography*, a French Jesuit, and able mathematician, was born at Laval-Louville, in the diocese of Embrun, and died in the year 1672. He published a work on the quadrature of the circle; "Arithmetical Institutions, in four books;" a treatise "On Cyclo-metry;" a work "On Magnetology," and a work "On the Primum Mobile."

LEOTIA, in *Botany*, perhaps so called from *λεως*, or *λαος*; the people, or *vulgar*; yet it does not appear to be either a common genus of fungi, nor vulgarly used as food, like many others. Its aspect indeed is ordinary enough, being that of a small Agaric without gills. *Perfoon. Syn. Fung. 611. Obs. Mycolog. v. 2. 21. t. 5. f. 1. 1. 6. f. 1. 2.*—Clafs and order, *Cryptogamia Fungi. Nat. Ord. Fungi.*

—Elt. Ch. Head roundish, reflexed at the margin and closely embracing the stalk, bearing seeds in its exposed surface.

The species enumerated by Perfoon are nine, four of which

which have a smooth conical or ovate head, three an orbicular one, and the other two arc esteemed doubtful.

Among the first is *L. Mitula*, the *Elvele acullata* of Batsch, f. 132, and probably *Clavaria ferruginea* of Sowerby's Fungi, t. 84; found in autumn growing copiously on decayed leaves of Scotch fir. The stalk is near an inch high. Head conical or ovate, of a pale cinnamon colour; white and spongy within.

In the second section is *L. lubrica*, (*Helvella gelatinosa*; Bulliard 296. t. 473. f. 2.) ; not unfrequent, after much rain, in beech woods. It is of a light greenish buff colour, and tender substance. Stalk two or three inches high, hollow, tumid in the lower part; and the cavity is continued into the head, which is rounded, depressed, undulated, and obscurely lobed, about an inch in diameter, composed as it were of two coats, with a hollow space between.

*Helvella Relbani*, Sowerby t. 11, is one of the doubtful species.

LEOVILLE, in *Geography*, a town of France, in the department of the Lower Charente; eight miles N. of Montlieu.

LEOWITZ, CYPRIAN, in *Biography*, a celebrated astronomer in the sixteenth century, was born in Bohemia, and was appointed mathematician to Otho Henry, elector palatine. He acquired a high reputation by his astronomical productions, of which the principal were "Ephemerides ab anno 1556, ad Ann. 1606;" "Expedita Ratio constituendi Thematæ celestis;" "Loca stellarum fixarum ab anno Dom. 1549, usque in Ann. 2029;" and "De Eclipsibus Liber." His celebrity occasioned Tycho Brahe to pay him a visit in the year 1569, when they had several conversations on their favourite subjects. Notwithstanding the great learning of Leowitz, he was weak enough to become the dupe of judicial astrology. He died in Swabia in 1574. He had predicted that the world would come to an end in 1584, and of this prophecy many priests and preachers took advantage as the important period approached, and enriched themselves at the expence of the fears of their people. Bayle. Moreti.

LEPA, in our *Old Writers*, a measure which contained the third part of two bushels. Whence we derive a *feed leap*.

LEPANTO, in *Geography*, a sea-port town of European Turkey, in the province of Livadia, situated in a bay formerly called the "gulf of Corinth," now the "gulf of Lepanto." This town is fortified and defended by a castle on an eminence. N. lat. 38 37'. E. long. 22 0'.

LEPAS, in *Conchology*, a genus of the multivalve order, the animal of which, according to the Linnæan system, is a triton, the shell affixed at the base, and consisting of many unequal erect valves. This genus, as defined by Linnæus and Gmelin, comprehends two very distinct genera, the union of which, under one title, is liable to much objection; though, for the sake of uniformity, we are not inclined in this article to separate them. One of these natural tribes, for example, has the shell of a conic form more or less tubular, the base firmly affixed upon rocks or other extraneous substances, without any tendinous tube; the shell is composed of six valves; and the truncated opening above is closed by a four-valved operculum. In the other genus the shell, instead of being conic, is broad, flattish and wedge-formed, and in many species resembling, in some degree, the spear or head of an arrow; it is besides composed, in general, of a much greater number of plates or valves, the aperture of which is lateral instead of being at the summit, and has no operculum; and lastly, the shell is not affixed by its testaceous base, but is placed at the extremity of a tendinous tube, the base of which unites it to the rocks or other substances to which, for convenience and security, the animal connects it-

self. The very obvious dissimilarity that prevails between these two genera attracted the particular attention of early writers, even before the time of our own countrymen Lüsler and Petiver, the term *Balanus* being adopted for the former, and *Concha anatifera* for the latter, and by these names the two tribes of shells are recognized in the writings of Gesner, Aldrovandus, and others. Linnæus, notwithstanding these authorities, however, consolidated them together. Da Costa was the first among the English authors who again separated them; he assigned to the first the original name of *balanus*, or *acorn shell*, at the same time that he retained the former under the name of *lepas*, or in English *bernaele*, a term preferable, no doubt, to that of *Concha anatifera*, which applied to a single species rather than the whole genus. The observations of Da Costa, as they militate in various respects against the conchological writings of Linnæus, have never perhaps been regarded in this country with sufficient attention, nor with ordinary liberality; he is not, we admit, on every occasion lucid, neither as a systematist does he deserve mention; yet, upon the whole, his remarks are often judicious, and almost constantly correct, and his strictures on the genus *lepas*, as proposed by Linnæus, are in particular satisfactory: he has restored both genera to their proper station. Among the collectors of shells in Britain, from the time of Da Costa to the present, the names of *balanus* and *lepas* have been almost constantly adopted, but the separation of them is ascribed to Dr. Solander, and the discrimination of earlier writers ceases to be remembered. In England, as before observed, the Linnæan term of *lepas* has been retained for one of the two genera; the continental writers, on the contrary, though they adopt this genus in the same form, reject the word *lepas*, and substitute that of *anatifera* in its place; the French call it *anatif*, and under the latter term it is distinguished by their bell writers. Having pointed out the leading character of the two genera into which the *lepas* of Linnæus and Gmelin is divided, it only remains to enumerate the species described by those and succeeding writers to the present time.

#### Species.

**BALANUS.** Shell conic, grooved; operculum, or lid acuminate. Linn. Fn. Succ. O. Fabr. *Balanus majusculus valvæ porcatæ* (*porcatæ*), Da Costa. *Ridged acorn shell*, Donovan. Brit. Shells.

Frequent on the British and other European shores, adhering in vast numbers to rocks, shells and stones; the colour generally whitish or greyish, and the form rather variable.

**BALANOIDES.** Shell conic, truncated, and smooth; operculum obtuse. Linn. *Balanus parvus vulgaris*, Petiv. *Balanus cinereus*, &c List. *Common acorn shell*, Donovan. Brit. Shells.

Found, like the former, in great abundance on the shores of Europe, and also those of the American and Indian seas. When affixed on an uneven surface, the base of this shell sometimes extends down into a pretty long rugged tubular stalk or root. This variety is noted by Pennant, and an extraordinary, but mutilated specimen, is shewn in one of the plates of Brit. Zool. Another occurs in Brit. Shells. Donovan. The colour is commonly greyish; the tips of the valves, as in the last-mentioned variety, greenish.

**INTERTEXTA.** Somewhat depressed; and ribbed obliquely. Donovan. Brit. Shells. *Lepas striata*, Penn.

"This rare species is the *lepas intertexta* of the Portland museum, and was fitted up at Weymouth, adhering to a valve of the *ostrea subrufus*, &c." Brit. Shells.

**COSTATA.** Somewhat conic and fulcated, the ridges equidistant

equidistant and divergent from the aperture; operculum sharp-pointed. *Donov. Brit. Shells.*

A new species found adhering to pieces of broken rocks on the coast of Pembrokehire.

**CONOIDES.** Shell conic, smooth, valves pointed at the tip, aperture very small. *Donov. Brit. Shells.*

A new species described as above, the specimen was found by Mr. Bryer, of Weymouth, affixed to a shell of the *lepas anatifera*.

**TINTINNABULUM.** Shell conic, or bell-shaped, obtuse, rugose, and fixed. *Lepas tintinnabulum*, Linn. *Balanus major*, Lillier. *Balanus major*, the conic centre shell, *Grew. Balanus maximus*, Petiver. *Balanus ore hiantis magnus*, Borlase. *Gland de mer clochette*, Davila. *B. tintinnabulum*, bell acorn shell, *Donov. Brit. Shells.*

Found adhering in large clusters to the bottoms of ships in moist seas. A supposed variety of a dirty whitish colour is mentioned by Chemnitz as a northern kind.

**TULIPA.** Shell subcubic, and smooth; operculum acute and transversely striated. *Müll. Zool. Dan.*

Inhabits the North seas.

**BOREALIS.** Shell erect, subconic, aperture quadrangular, operculum acute and transversely striated. *Donov. Brit. Shells.*

A new species, recorded as above stated. "A few small clusters, with some detached specimens of this curious species of *balanus*, were discovered about the year 1800, attached to the bottom of the Warfight ship of war, when taken into dock to be repaired, after lying in the harbour of Portsmouth for a great length of time. Mr. J. Hay of Portsmouth soon after found two or three shells of the same kind, by dredging in Portsmouth harbour. The species appears to be very rare; we have one specimen attached to the valve of an *ostrea rufus* brought from Newfoundland." *Vide Brit. Shells.*

**DIADEMA.** Shell subrotund, six-lobed and furrowed. *Gmel. Balanus polybalanus*, Walch. *Diadem acorn shell*, *Donov. Brit. Shells.*

A curious and rare species, about the size of a walnut, or sometimes larger; colour whitish. Inhabits the European and Indian seas.

**BALANARIS.** Shell somewhat conic; lobes six elevated wrinkled and four-parted; the operculum membranaceous and bidentated. *Müll. Chemnitz, &c. Whale acorn shell*, *Donov.*

Found adhering to the fins and pectoral wrinkles of the whale (*Balena boops*); its size resembles the last, but its form is very much depressed, colour the same as in *B. diadema*, as are also the furrows of the lobes. This is erroneously described by some authors as the *B. diadema* of Da Costa; we possess the example described by Da Costa under this name, and can in confidence affirm it to be the former species. *See Brit. Shells.*

**PALMIPES.** Shell erect, conic; operculum acute and transversely striated. *Olaf.*

Size of a pea, and smooth. Inhabits the ocean.

**GALEATA.** Shell helmet-form, with a lateral aperture. *Schroet.*

Discovered adhering to the gorgonia verrucosa, and ventrilarium; shell boat-shaped and smooth; aperture rhombic.

**MITELLA.** Shell compressed, erect, and irregularly striated. Linn. *Balanus Rondeletii*, *Gesl. Balanus chinensis striatus*, *Petiv.*

Native of the Indian seas.

**TESTUDINARIA.** Shell plano-convex; rays six excavated and striated. Linn.

Inhabits the depths of the ocean, and is usually found ad-

hering to other shells; the form resembles a globe cut off in the middle.

**SCALPELLUM.** Shell compressed, thirteen-valved, rather smooth, and seated on a scaly peduncle. Linn. *Ellis. Scaly lepas*, *Donov. Brit. Shells.*

A most curious and very elegant species, resembling in some measure the following kind, but rather smaller. *Gmelin* describes it as a native of the Norway seas, on the authority of a specimen met with by Dr. Pontoppidan, the bishop of North Bergen, and which is described by Mr. J. Ellis in the *Philosophical Transactions*, A.D. 1758. He found it sticking on the Norway sea-fan, and, from the peculiarity of its structure, was induced to call it the Norway sea-fan perknife. "This very rare shell is introduced into the British Fauna, on the authority of an example found attached to some sea-weeds, dredged up on the coast of Weymouth, which, after passing through the collections of the late dukes of Portland and Dr. Fordyce, is at present in our possession." *Vide Brit. Shells.*

**ANATIFERA.** Shell compressed, five-valved, smooth, and seated on a pedicle. Linn. *Concha anatifera*, *Merret. Balanus compressus, flat centre shell*, *Grew. Barnacle*, *Gerard. Lepas anatifera, anatiferos acorn shell*, *Donov. Brit. Shells.*

Found in moist seas, and is usually found affixed in clusters to the bottoms of ships, and pieces of decayed timbers floating in the water. The colour whitish, with a fine polish beneath the thin epidermis, and tinged with reddish or bluish-violet; the stems of the finest red.

The tentacula of these animals are long and pectinated like a feather, for which they were in fact mistaken in the sixteenth century; and hence arose the whimsical belief that the barnacle shell was the parent of the barnacle goose! Nor was this the vulgar opinion only; it was sanctioned by the grave details of learned naturalists of that time, and particularly by Gerard, whose observations are generally noticed by authors, in describing this singular marine production. *See BARNACLE Goose.* *See also Gerard's Herbal*, p. 1587.

There are several supposed varieties of *lepas anatifera*, in one of which the peduncle is black.

**ANSERIFERA.** Shell compressed, five-valved, striated, and seated on a peduncle. *Gmel. Donov. Brit. Shells.*

"A native of the American and Atlantic seas, and is chiefly distinguished from *lepas anatifera* by having the valves striated with elevated lines; the valves in the former being perfectly smooth. *Lepas anserifera* has been heretofore considered as a native of the American and Atlantic seas; but that it inhabits likewise the English coast is certain, the shell with the living animal having been dredged up at Weymouth." *Brit. Shells.*

**DILATA.** Shell compressed, five-valved, and thin; dorsal valve dilated at the base with an acute angle, and seated on a peduncle. *Donov. Brit. Shells. Lepas fascicularis*, *Ellis Zoophytes. Lepas sigillatum*, *Muf. Portl.?*

The first and only account we have of this kind of *lepas*, except that inserted in "British Shells," is that given by the late Mr. Ellis, from whom we merely learn that it is from St. George's Channel. The specimen appears to have been sent by Mr. Ellis to the late dukes of Portland, from whence it passed through the hands of the late Dr. Fordyce, and at his death came into our possession, under the title of *lepas sigillatum* of Solander. Unlike *lepas anatifera*, or *anserifera*, (though it is larger than either,) the valves of this shell are uncommonly thin and brittle, in a certain degree corneous, with the largest lateral valve rather crumpled in the usual course of the striae, and marked transversely with

obsolete rays. The shell is likewise covered with a fine pale brown skin, or epidermis. The acute prominent dilation at the base of the valve on the back is very singular. We must be excused for having expatiated with more than usual minuteness on local particulars, in describing the last-mentioned species; as it is principally, and in some instances entirely, on the authority of the individual examples mentioned, that the species are recorded, and their excellence ascertained.

**AURITA.** Shell membranaceous, ventricose, feated on a tube, eared; mouth eight-valved, and dentated. Seba, &c. *Lepas nuda comosa aurita*, Ellis.

Inhabits the North seas. Tube long.

**PETTACUS.** Shell falcated behind, six-valved, and wrinkled. Molina.

Native of Chili. Length an inch; the larger valves resembling the bill of a parrot.

**MINOR.** Shell reddish, six-valved, unequal; operculum pointed. Chemn.

An Indian species. Shell marked with transverse curved lines, dotted with white.

**VERRUCA.** Shell hemispherical, ferrated, six-valved; the four outer valves and the operculum plaited. Spengler.

Native of the North seas.

**ANGUSTATA.** Shell elongated, smooth, six-valved; the aperture narrow; operculum very minute. Chemn.

Country unknown.

**POROSA.** Shell granulated, striated, conic, and tubular; the operculum obtuse. Schroet.

Inhabits India. When living, the shell is green, becoming black after death. A supposed variety of a larger size, and broader in proportion, is described by Klein under the name of *balanus major latus*.

**ELONGATA.** Shell cylindrical, snowy, pellucid, six-valved, and cleft above; lid obtuse, grooved, and transversely striated. Chemn.

A small and very rare species, found in the Iceland seas.

**PATELLARIS.** Shell six-valved; externally violet variegated with white, and marked with fine longitudinal striae; within falcated; valves denticulated at the margin. Spengler.

Native of Coromandel. A rare species; teeth of the valves inserted in each other alternately.

**SPINOSA.** Shell conic, with twelve triangular valves, six of them more depressed, less, and whitish, with transverse striae; six purple, and longitudinally striated, and all armed with tubular recurved spines. Gmel.

Inhabits India.

**VIOLACEA.** Shell thick, glabrous, six-valved, and white, with rays of violet. Chemn.

Native of India. The shell slightly grooved within.

**POLLICIPES.** Shell compressed, erect, many-valved, smooth, and feated on a short, hard, scaly, coriaceous peduncle. Gmel.

Found in the Mediterranean. The four larger valves turned towards each other like the beak of a bird; lesser ones more than twenty.

**CYLINDRICA.** Cylindrical, slightly curved, with a very large oblique orifice; operculum horned. Gmel. *Balanus nasillaris*, Gronov. *Lepas sessilis capensis*, &c., Ellis.

Native of Africa under the torrid zone.

**CRISPATA.** Shell oval-truncated and conic, with six bluish valves shaded with white, and six elevated reddish ones purple and perpendicularly striated. Schroet.

Country unknown.

**CARIOSEA.** Shell solid, white, depressed with carious grooves; within unequally smooth. Pallas.

Native of the seas about the Kurile isles.

**STRÆMIA.** Conic-convex, with four ferrated striated valves; operculum two-valved. Müll.

Inhabits the Danish sea.

**LEPASTRUM**, derived from the Greek *λεπας*, a scale or plate, and *αστρα*, a star, in *Natural History*, the name of a genus of fossils, of the class of the selenites, composed of filaments arranged into broad plates, and those disposed in the form of a radiated star.

Of this genus there are two known species: the one a bright brownish-white kind, with thinner flakes; the other a white dull-looking kind, with thick flakes. They are both found on the shores of Sheppey Island in Kent, and form themselves in the cavities of the septaria, called by authors ludus Helmontii; and the septariae, with these affixed to them, have been accounted a separate species of that body, and called the *starred waxed vein*, or ludus Helmontii stellularis.

**LEPE**, in *Geography*, a town of Spain, in the province of Seville, celebrated for its grapes, figs, and wine; 10 miles E. of Ayamonte.

**LEPECHINIA**, in *Botany*, was named by Professor Willdenow, in his *Lortus Berolinensis*, as a tribute of respect to the labours of John Lepechin, Fellow of the Academy of Sciences at St. Peterburg, who published various tracts upon natural history in the Transactions of that Society. Many of these were botanical monographs; such as, 1. A description of *Iris Gildenstediana*. 2. *Novae species Menthae descripta*. 3. *Quatuor Encorum species descripta*. 4. Reflections on the necessity of studying the virtues of indigenous plants. He appears to have been an able chemist as well as naturalist, and to have travelled through various provinces of the Russian empire in the years 1768 and 1769. We are unable to discover either the time of his birth or of his death, though from the date of his Travels he must have lived about the middle of the last century. Willd. Hort. Berol. 21. Ait. Hort. Kew. ed. 2. v. 3. 390.—Class and order, *Didymia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Jusl.

Ess. Ch. Calyx two-lipped. Upper lip of the corolla cleft, lower one deeply divided into three nearly equal segments. Stamens spreading.

1. *L. spicata*. Ait. Hort. Kew. ed. 2. v. 3. 390.—“Spikes of flowers on bracteated footstalks. Leaves ovate, crenate, truncated at the base.”—The native country of this hardy, perennial plant is unknown. The species in question was introduced into the Royal Gardens at Kew in the year 1800, by Mr. John Hunneman, who received it from his friend Willdenow in Germany. By the above specific character we presume there are other species.

**LEPEIGA**, in *Geography*, a town of Hindoostan, in the circle of Gangpou; 30 miles S.S.W. of Gangpou.

**LEPEL**, a town of Russian Lithuania; 55 miles S.E. of Polotk.

**LEPERS.** See ELEPHANTIASIS and LEPROSY.

**LEPERS**, *Isle of*, in *Geography*, one of the New Hebrides, situated between Espirito Santo and Aurora island, eight leagues from the former, and three from the latter, in S. lat. 15° 22', and nearly under the same meridian as the south-east end of Mallicollo. It is of an egg-like figure, very high, and 18 or 20 leagues in circuit. In the north-east part there is anchorage half a mile from the land. It derived its name from Bougainville, who visited it in 1768, and found the inhabitants in general devoured with the leprosy. He describes the inhabitants as being of two colours, black and mulatto. Their lips are thick, their hair frizzled, and that of some is a kind of yellow wool: they are small, ugly, and

ill made. Few women were seen, but they were no less disgusting than the men. They were naked, hardly covering their waists with a mat. They carry their children on their backs in a kind of scarf; they wear ornaments in their nostrils; and have no beads.

**LEPIDIUM**, in *Botany*, is the *Λεπίδιον* of Theophrastus and other ancient writers, and is said by Professor Martyn to be derived from *λεπίς*, a scale, no doubt from the scaly appearance of its pods after their feed is discharged, but that is so usual a circumstance with plants of this tribe, that we are rather inclined with Ambrosius to consider the word *Lepidium* as derived from *λεπίδιον*, to be hot, or pungent, because other plants which have agreed with this genus in its quality of pungency, but in no other way whatever, have been distinguished by the same appellation, and hence its English name, Pepper-wort. Linn. Gen. 333. Schreb. 437. Willd. Sp. Pl. v. 3. 431. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 681. Ait. Hort. Kew. v. 2. 373. Juss. 241. Lamarek. Illust. t. 556. Gærtn. t. 141. Tournef. t. 103. (Nasturtium; Tournef. t. 102.)—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Crucifera*, Juss.

Gen. Ch. Cal. Perianth of four, ovate, concave, deciduous leaves. Cor. cruciform, of four equal obovate petals, twice as long as the calyx, with narrow claws. Stam. Filaments mostly six, awl-shaped, the length of the calyx, the two shorter ones opposite; anthers simple. Pist. Germen superior, cordate; style simple, as long as the stamens; stigma obtuse. Peric. Pouch heart-shaped, emarginate, compressed, acute at the margin, two-celled; valves boat-shaped, keeled; partition contrary, lanceolate. Seeds few, ovate, pointed, narrower at the base, pendulous.

Eff. Ch. Pouch notched, elliptical, with few seeds; valves keeled, contrary to the partition.

Obs. It is in some cases difficult to draw the line between the pouch of this and *Thlaspi*, even Gærtner considers them as of the same figure. He would retain in *Lepidium*, which he wishes to call *Nasturtium*, those which have solitary seeds, referring the others to *Thlaspi*. The regular corolla distinguishes this genus from *Iberis*, with which it is otherwise most closely allied. The number of stamens is few, in some species is fewer than six.

The species of *Lepidium*, in the fourteenth edition of Linnaeus's *Systema Vegetabilium*, are twenty; Willdenow has twenty-nine. Of these *L. didymum* belongs to the genus *Coronopus*, Fl. Brit. Three of the remainder are natives of England.

*L. petrum*. Mountain Pepper-wort. Linn. Sp. Pl. 899. Engl. Bot. t. 111. Jacq. Austr. t. 131.—Leaves pinnated, entire. Petals not longer than the calyx, slightly notched.—This rare English plant is found on St. Vincent's rocks near Bristol Hot-wells, which has been its habitat ever since the time of Ray. It is occasionally found in other places that are open and exposed, in the south of England, flowering in the early spring. Root biennial, fibrous. Stems two or three inches high, spreading, leafy, somewhat downy. Leaves alternate, unequally pinnatifid, of many pairs of smooth opposite segments, which are elliptical or spatulate, entire. Corymbs of many small, white, hexandrous flowers. Pouch elliptic-oblong, compressed, smooth. Seeds roundish, two in each cell.

*L. latifolium*. Broad-leaved Pepper-wort. Linn. Sp. Pl. 899. Engl. Bot. t. 182.—Leaves ovate-lanceolate, undivided, serrate.—This is also a scarce plant, found in moist saltish marshes, and on maritime cliffs, as at Sheringham, by Cromer, in Norfolk, flowering in July.—Root perennial,

branched, very long. Stems three feet high, erect, leafy, round, smooth, panicled, many-flowered. Leaves alternate, lanceolate or somewhat ovate, attenuated at the base, serrated more particularly in the middle. Flowers hexandrous, small, white. Pouch elliptical, with a sessile stigma. The whole plant is biting and disagreeable. An infusion of it is said by Dr. Withering to be emetic.

*L. ruderals*. Narrow-leaved Pepper-wort. Linn. Sp. Pl. 900. Engl. Bot. t. 1595.—Flowers with two stamens, without petals. Lower leaves pinnatifid, toothed; upper ones linear, entire.—A native of muddy and calcareous soils, which it prefers to find, in the neighbourhood of the sea. It keeps flowering from June to August. Root biennial, branched. Stem a foot high, erect, branched, leafy, wavy, round, hoary. Leaves fleshy, smooth. Flowers small, apetalous, diandrous; the clusters when in fruit becoming very long. Pouch elliptic or roundish, emarginate, smooth. Seeds generally solitary, pendulous, obovate. Dr. Smith mentions in his *Flora* that he never found any petals to this species, nor more than two stamens, though Withering describes the petals as "sometimes wanting," and that the stamens are either two or four.

As to the foreign species, we shall say a few words upon such as are more especially interesting.

*L. persfoliatum*. Various-leaved Pepper-wort. Linn. Sp. Pl. 897. Jacq. Austr. t. 346.—Lower leaves much divided in a pinnate manner; upper ones heart-shaped, embracing the stem, entire.—A native of Austria and the Levant. It flowers in July. Root annual. Stem a foot high, smooth, tinged with purple, dividing into various slender branches, at the end of which are corymbs of small and compressed flowers in long loose spikes. Calyx-leaves yellowish-green. Pouches orbicular, smooth, having a single, bay-coloured seed in each cell.

*L. vespicularium*. Bladdery Pepper-wort. Linn. Sp. Pl. 898. (L. orientale; Tourn. Cor. 15. Buxb. cent. v. 1. 17. t. 26.)—Leaves pinnate; segments linear. Stems inflated at their joints.—A native of Iberia, and the dry plains of Media, where, according to Buxbaum, it flowers in July and August. Dr. Smith has perhaps the only specimen of this species to be seen in this country, which was given him by the celebrated M. Le Monnier from his garden at Versailles in the year 1786. Stem two or three feet high, remarkably inflated at the joints. Leaves pinnate, with long, narrow leaflets. Flowers small, white. Pouch very similar to that of *L. ruderals*.

*L. alpinum*. Alpine Pepper-wort. Linn. Sp. Pl. 898. Jacq. Fl. Austr. t. 137.—Leaves pinnate, entire, smooth. Flower-stalks naked, ascending. Petals larger than the calyx. Pouches lanceolate, pointed.—A native of the German, Swiss, and Italian Alps, where it may be seen in flower from May to August. This pretty little perennial has a slender root. Stems very short, clothed with alternate leaves. Flower-stalks an inch or two in length, bearing a corymbose cluster. Leaves thick, dark green. Flowers milk-white; their petals roundish and entire. Pouch ovate or lanceolate, compressed, with the style at the end. The whole plant is smooth, and has the flavour of Cress.

*L. sativum*. Garden or Common Cress. Linn. Sp. Pl. 899. (Nasturtium hortense; Dod. Pempt. 711.)—Flowers tetradynamous. Leaves oblong, much cut and jagged.—The habitat of this plant so commonly cultivated was unknown, till Dr. Sibthorp discovered it in Greece. Root annual, white, spindle-shaped. Stem upright, smooth, from one to two feet in height, branched at the top. Stems and branches terminated by a spike of flowers. Lower leaves:

*hospites* much resembling those of Parsley; upper ones linear, or lanceolate. *Flowers* small, white. *Calyx* very small, greenish. *Pouch* roundish; valves winged. *Seeds* brown, solitary, tasting like Mustard. This is undoubtedly the *Καρβύσιος* of Dioscorides, and is in universal request for salads in the winter and spring. There are two varieties frequently to be met with, one of them having broad, the other curled leaves. It is said to act as a diuretic and antiscorbutic when taken largely.

*L. oleraceum*. Notch-leaved Pepper-wort. Willd. n. 16. Forst. EfcuL. 69. (*L. bidentatum*; Montin in Nov. Act. Nat. Cur. 6. 324. t. 5. a.)—Leaves elliptic-oblong, acute, serrated. Flowers tetrandrous.—A native of the sandy shores of New Zealand. *Root* perennial. *Stem* herbaceous, from one to three feet in height. *Leaves* scattered, alternate; the upper ones smaller, serrated only at the tip. *Flowers* white. *Pouches* ovate, or heart-shaped, compressed, containing an ovate, acute, reddish-yellow seed in each cell. Forster says that this plant, together with *Apium* or Smallage, and *Tetragonia balsimifolia*, was of considerable service to the ship's crews under Captain Cook, when they lay in Charlotte Sound.

*L. virginicum*, a native of the Caribbee Islands, is eaten by the natives in salads, like our Garden Cress.

*L. piscidium*, found in the South Sea islands, is made use of by the inhabitants for catching fish by incubrating them. It resembles *L. oleraceum*, and is esculent like that species.

LEPIDIUM, in Gardening, comprises a plant of the herbaceous annual kind, of which the species cultivated is the garden or common cress (*L. fativum*). But there are other species which may be cultivated for variety.

It has several varieties, as with broad leaves, with curled leaves, and the common sort with the leaves multifold.

*Method of Culture*.—These herbaceous plants are raised by sowing the seed as wanted for use, at different times of the year, as once a week or fortnight, where a constant succession of small herbs in their young growth is wanted for salads, when only a few days or a week or two old; or, where a constant supply of these small herbs is required in their young seedling growth, some seed, as just noticed, should be sown in succession every week or fortnight at firstest, all spring, summer, and autumn; and once a fortnight in the winter season.

The order of sowing them in the different seasons is, in a warm south border, or other similar situation, or under a frame, &c. in the early spring months; and as the warm season advances, in any open compartment, all in as light earth as the garden affords; but in summer, or hot dry weather, in somewhat shady borders, or in a free situation, shaded with mats from the scorching sun, and daily watered; and in winter, in the warmest situation, or in shallow frames defended with lights, and under hand-glasses; but in frothy or other very cold weather, in that season, on moderate hot-beds; and hot-bed sowings are also requisite during the colder part of the spring, or at any time in cold seasons, where a supply of these and other small salad herbs are required to be raised as quickly as possible. The method of sowing the seed, in all the cases, is very thick, as the plants are mostly used in small young growth, and generally in small, flat, shallow drills, about three inches asunder, so thick as almost to cover the earth, being lightly earthed over a quarter of an inch thick, or less; or on the plain surface, first raking it smooth, then sowing the seed thick as above, smoothing it down with the back of the spade, and either with the spade spreading some fine earth lightly over it as thinly as possible, or covering it by sifting earth over it

evenly a small depth, just to cover all the seed properly. This sort of salad herb should always be cultivated so as to grow as rapidly as possible, being cut while perfectly young, and in a crisp state. See *Small Salad HERBS*.

LEPIDOCARPODENDRON, in Botany, from *λεπις*, *λεπίδος*, a scale, *καρπος*, fruit, and *δένδρον*, a tree; a name given by Boerhaave in his Hort. Lugd. Bat. ed. 2. v. 2. 183, to the *PROTEÆ* with hemispherical heads of flowers, conspicuous for the ample and beautiful scales of their calyx, of which Linnæus composed his genus *Leucadendron*, in Gen. Pl. 46, but which he subsequently united to *Protea*. See LEUCADENDRON.

LEPIDOIDES, *Λεπίδοειδης*, formed of *λεπις*, scale, and *ειδος*, form, figure, or LEPIDOIDES, in Anatomy, a name of the squamous or scaly future of the cranium.

LEPIDOLITE, Wern., Jam. *Lepidolithe*, Häuy. *Lilalite* of some other mineralogists.

The colour of this mineral is generally pale peach-blossom red, or rose red, with an admixture of grey; but it also occurs of a pale violet and light cochineal red; sometimes the greyish-red variety passes into bluish and greenish; and a variety has been observed, in which the green approaches siskin green.

Occurs only massive; but its fragments are said sometimes to shew a tendency to adopting a prismatic form.

Its internal lustre is glistening, passing into shining; it appears sometimes between resinous and vitreous.

Fracture uneven, presenting fine-grained and scaly distinct concretions; fragments generally indeterminately angular, with pretty sharp edges, which are faintly translucent.

It is moderately hard, passing into soft; brittle; though not easily frangible.

Specific gravity, 2,854, Häuy; 2,816, Klaproth; 2,350, Gerhard.

Before the blowpipe the lepidolite, after a slight degree of intumescence, melts into a milk-white semi-transparent pearl. With borax it fuses more readily into a transparent colourless pearl.

Klaproth was the first who analysed this mineral. Among the results of his analysis was a deficiency of  $6\frac{1}{2}$  per cent., which a subsequent chemical examination, (made by the same chemist, with a view to ascertain the presence of potash, which he had a short time before discovered in the leucite) proved to be occasioned by the loss of the same alkali, till then unsuspected to enter the composition of mineral substances. Vauquelin afterwards found the same alkali, but in far greater proportion.

Silica	-	54.50	54.0

Klaproth Beitr. ij. Vauquelin J. d. M. N° 51.

The fluato of lime, in Vauquelin's analysis, is probably owing to particles of fluor spar that were adhering to the specimen examined by that chemist.

Lepidolite is found (exclusively, as it is supposed) on mount Radiceo, near Rozena in Moravia, in a kind of gneiss, which is said to pass into granite on one side, and into mica slate on the other. The accompanying minerals, with

with which it is also mixed, are quartz, feldspar, fluor spar, fluor-beryl, apatite, and common fluor.

Fichtel makes mention of a mass mixed of brownish-violet grains of quartz, whitish shining feldspar, and light and dark coloured lepidolite, which, (if the last-mentioned substance be considered as a substitute for mica, with which it is indeed nearly allied,) constitutes a particular kind of granite hitherto unnoticed.

Beyer has described a variety of lepidolite from Sudermanland, in Sweden; but some writers have doubted this to be real lepidolite.

The lepidolite was, by its discoverers and other mineralogists, referred to zeolite: it had also been mistaken for a variety of foliated gypsum. Klaproth, who determined its real nature, substituted for the nameless name of *lilalite*, that of *lepidolite*, derived from its scaly structure.

What has been described as crystallized lepidolite, is the red variety of fluor-beryl, or pinitic, which is likewise found at Rozena in Moravia, in a quartz matrix.

**LEPIDOPTERA**, from λεπίς, *a scale*, and πτερον, *wing*, in the *Linnean System*, an order of insects, with four wings, imbricated with scales: in the mouth is contained a spiral tongue, and the body is hairy. This order comprehends three genera, viz. the papilio or butterfly, the sphinx, and the phalaena or moth; and each genus includes a number of species.

**LEPIDOSARCOMA**, from λεπίς, *a scale*, and σαρξ, *flesh*. Severinus, a surgical author, implies by this term a sarcomatous and scaly tumour in the mouth.

**LEPIDOSPERMA**, in *Botany*, so called by Labillardiere, from λεπίς, *a scale*, and σπέρμα, *the seed*, because of the six permanent scales which invest the base of that part. Labillard. Nov. Holl. v. 1. 14. t. 11—17. Brown. Prodr. Nov. Holl. v. 1. 233.—Class and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoides*, Juss. *Cyperaceæ*, Brown.

Gen. Ch. *Cal.* Spikelet imbricated every way, of one or two flowers, and one seed; scales several, ovate, concave, acute, for the most part empty. *Cor.* none, except we so call the six flat, membranous, thickish scales, united at their base, which invest the bottom of the germen. *Stam.* Filaments three, capillary, projecting; anthers terminal, oblong, acute, pendulous. *Pistl.* Germen superior, very small; style cylindrical, erect, as long as the stamens, deciduous; stigmas three, equal, recurved, slender, downy, acute. *Peric.* none. *Nut* roundish, obtuse, hard, not burling, accompanied by the above-mentioned six scales, of one cell, with a single roundish kernel.

Ess. Ch. Spikelet of one or two flowers, and one seed. Glumes chafy, imbricated every way, most of them barren. Six flat combined permanent scales at the base of the germen. Style deciduous. Nut solitary, bald, obtuse.

This genus is allied to the *Cladium* of Browne's Jamaica, (confounded with *Schoenus* by Linnæus), but is distinguished by the six scales that accompany the germen. From the *Scleria* of Bergius it differs in the number of its glumes, and in having always androgynous spikelets, of which the upper flower is only male. Labillardiere describes and figures seven species; Mr. Brown defines 19, all from the colder parts of New Holland, or from Van Diemen's land. They are harsh rigid rushy plants, one or two feet high, with strong perennial roots, simple leafless stems, encompassed at the bottom with several long, narrow, mostly equitant, leaves, which are more or less compressed and acute, their edges either smooth or minutely serrated. The panicle or spike is terminal, mostly branched or divided.

Examples of this genus are

*L. gladiata*. Labill. Nov. Holl. v. 1. 15. t. 12.—Panicle dense, repeatedly compound. Stem compressed with an elevated rib at each side; its edges smooth, like those of the leaves. Glumes rather sharp.—Gathered by Mr. Brown at Port Jackson, as well as in Van Diemen's land, and the fourth part of New Holland. The stem is stout and rigid, from eighteen to twenty-four inches high. Leaves half an inch broad, smooth. Panicle upright, large, of numerous acute, oblong, scaly spikelets.

*L. tetragona*. Labill. Nov. Holl. v. 1. 17. t. 17.—Stem dense, somewhat compound. Leaves quadrangular. Stem bluntly angular.—Gathered by the author cited, in Van Diemen's land. The square leaves are very remarkable. It is a much smaller plant than the foregoing. The scales of each spikelet are from four to six only. The nut is elevated on a more conspicuous spongy base than in most of the other species.

Nothing can give a more unfavourable idea of the fertility, comfort, or beauty of a country, than the prevalence of such plants as these; slight examples of which may be seen in our *Schoenus nigricans*, *Nardus stricta*, and a few others, found on the most dreary and barren inland sands. Such of them as inhabit the sea-shore, answer the most valuable purpose possible, in forming a natural barrier against the encroachments of the ocean. See ELYMUS.

**LEPIDOTES**, in *Natural History*, the name of a stone bearing a resemblance to the scales of fishes. The word has been used by some, as the name of those stones which are composed of small flakes, or scales of talc, and by others to express the stones containing fish, or the impressions of fish, found in many parts of Germany.

**LEPIDUS**, M. ÆMILIUS, in *Biography*, a Roman triumvir, was descended from one of the most illustrious families in Rome, and rose to the highest employments of the state. On the death of Cæsar, Lepidus, who was zealously attached to his interests, thought it prudent to conceal himself. He afterwards joined Antony in driving away the conspirators, and obtained the dignity of chief pontiff, through the influence of that leader. Afterwards, when Antony was treated as a public enemy, Lepidus commanded an army of seven legions in Transalpine Gaul. Here Antony arrived in a very distressed situation, and conjured his friend to join his forces to those which he commanded. Lepidus refused, but assured him he would not act with hostility against him. Antony knowing in what estimation he was held by the army, rushed into the camp of Lepidus, where he was saluted with the loudest acclamations. Lepidus was now, in his turn, glad to supplicate the aid of his competitor. Antony treated him with apparent respect, left him the nominal command, while he himself exercised all the real authority. By this conduct, Lepidus lost the confidence of the senate; and in a short time he was declared a public enemy, and Octavianus and Decimus Brutus were sent out against him and Antony. In dividing the Roman world between three masters, Lepidus was allowed a place, principally by way of a connecting medium between the other two. He possessed a considerable family-interest, and was not destitute of military abilities; but he had neither capacity nor temper to take a leading part in political concerns. In the formation of the triumvirate, it was agreed, that while Antony and Octavianus should carry on war against Brutus and Cassius, Lepidus should remain at Rome with four legions, and maintain their authority in the capital. At the bloody proscription, and while the butchery was still raging, Lepidus had the unfeeling vanity to insult the public distress by a triumph, on account of some inconsiderable victories formerly obtained by him over the revolted Spaniards.

Spaniards. He was consul a second time, B. C. 42, with Manlius Plancus. The part of the empire which was allotted to Lepidus, after the TRIUMVIRATE (which see) was fully established, was Africa. In the war with Sextus Pompey, Lepidus brought a large force to Sicily, with which he joined Octavianus; and he shared in the victory obtained against that great general. The confidence he felt at being at the head of a large army, induced him to treat his colleague with haughtiness and neglect; but he had found the mortification to see himself deserted by all his troops, who joined Octavianus. He now supplicated his life of his rival, which being granted him, he retired into a kind of exile at Circeti, a small town in Latium, where he passed the remainder of his days in obscurity. Plutarch. Univer. Hist.

LEPINE, FRANCESCA MARGARITA DI. See MARGARITA.

LEPIOTA, in *Botany*, from *λεπις*, a thin membranous layer, or cuticle, the first section of the great genus *Agaricus* in Perizon's *Synopsis Methodica Fungorum*; the character of which is to have the gills dry and membranous, as the name expresses, not clouded nor footy, and the stalk encompassed with a ring. It includes twenty-nine species, of which *Agaricus procerus* is the first and most remarkable.

LEPISMA, in *Entomology*, a genus of aptera. Gmelin, after the Linnæan manner, defines it as having four feelers, two of which are fetaceous, and two capitated; the lip membranaceous, roundish, and emarginated; antennæ fetaceous; body imbricated with scales; tail ending in fetaceous bristles; legs six, and formed for running. The character of lepisma, as thus expressed, combines the more essential character of Fabricius with that of Linnæus. Lamarck and others propose some further alteration; and, lastly, Latreille, in whose arrangement they form the first family (lepismenæ) of the order thysanoura, divides them into two distinct genera: lepisma and machilis. The true lepisma, according to the new definition, has the antennæ inserted between the eyes, the body flat, and the tail ending in three equal bristles. This genus walks and runs. In the genus machilis, (which moves by skipping,) the antennæ are seated under the eyes, the body convex, and the middle bristle of the tail larger than those at the sides. The three first species are described by Linnæus; the other by Fabricius, and by Müller the author of *Zool. Dan.* All the species, except the first, are natives of Europe. In their various states of growth they prey on decayed wood, and moist or rotten substances; and are most commonly found in damp cellars, neglected water-courses, lead gutters, and similar situations. The larvæ, like the pupa and perfect state, are furnished with six feet, and are remarkable for their activity and swiftness.

#### Species.

SACCARINUM. Scaly, silvery; tail triple. Fabr. *Lepisma vulgare*, Scop. *Forbicina*, Aldrov. *Forbicina plana*, Geoffr. *Lepisma saccharinum*, Donovan. Brit. Inf.

Originally a native of America, from whence it has been introduced and naturalized in Europe. The body is oblong and tapering; antennæ as long as the body; tail terminating in three bristles, and two pair of smaller ones beneath. It secretes itself among old furniture, and runs, when disturbed, with great agility: is often found among fungus.

POLYPODA. Skipping; tail triple; segments of the abdomen villous each side beneath. Fabr. *Lepisma scutata*, *auda triplici*, Linn. Donovan. Brit. Inf.

Inhabits among stones and rubbish on sandy sea-shores, and possesses the faculty of leaping to a prodigious height,

by means of the springs under the tail; antennæ as long as the body.

TERRESTRIS. Naked; tail triple. Linn. Fn. Suec. Gmelin mentions the close affinity this indistinct species bears to the podura tribe, to which it may perhaps belong. It is entirely white and cylindrical, with obtuse antennæ half the length of the antennæ.

LINEATA. Tail triple; body brown, with two white fillets. Fabr.

Inhabits old walls in Helvetia. Antennæ as long as the body, which latter is brown above, with cinereous specks; legs short; thighs compressed.

VILLOSA. Brown, with a triple villous tail. Fabr. Native of China. The head villous-whitish; body beneath whitish; middle spine of the tail longer; legs short and white.

COLLARIS. Black, with a snowy band on the neck and end of the abdomen; tail triple and villous. Fabr.

An inhabitant of the South American islands. Antennæ as long as the body, and brown, with the base pale; head whitish; beneath the tail two short bristles; legs pale.

POLYPUS. Scutate; tail triple. Müll.

Native of Denmark.

MINUTUS. Yellow; tail of three bristles. Müll.

Inhabits same country as the latter. Appendages of the tail sometimes wanting.

LEPITA, in *Hindoo Mythology*, a name of Saraswati, spouse of Brahma, and goddess of literature, harmony, rhetoric, and the fine arts. See SARASWATI.

LEPIUM, one of Hill's names for a variety of gypsum.

LEPOIS, NICHOLAS, in *Biography*, a physician of celebrity in the sixteenth century, was born at Nancy, in 1527. He studied medicine at Paris under Sylvius, together with his elder brother, Anthony Lepois, who was afterwards first physician to Charles III. duke of Lorraine. In this office Nicholas succeeded his brother in 1578. He spent his whole time in sick-chambers, or in his closet, perusing the ancient authors from Hippocrates downwards. He drew up the result of his reading, corrected and corroborated by his personal observation, in an aphoristic form, chiefly with the view of being serviceable to his sons, Christian and Charles, whom he destined for the medical profession; but his friend the celebrated Fœsius, and several other persons, having seen his MS. prevailed upon him to publish it. It was first printed at Franckfort, in 1580, in folio, under the title of "De cognoscendis et curandis pæcipui internis humani corporis morbis, Libri tres, ex clarissimorum medicorum, tum veterum, tum recentiorum, monumentis non ita pridem collecti." Boerhaave had so high an opinion of this author, that he edited this work, adding a preface to it, at Leyden, 1736, in two volumes 4to. Eloy Dict.

LEPOIS, CHARLES, more generally known by his Latin name, *Carolus Pijo*, was son of the preceding, and born at Nancy in 1563. He was sent at the age of thirteen to the college of Navarre, at Paris, where he remained five years, and distinguished himself by his rapid advancement in the knowledge of the languages, belles lettres, and philosophy. He received the degree of Master of Arts in the university of Paris in 1581, and immediately commenced his career in the schools of medicine. After four years, spent in the faculty at Paris, he went to Padua in 1585, and visited the other schools and the learned men of Italy before he quitted that country. He returned to Paris in the beginning of 1588, and took his bachelor's degree in medicine, and two years afterwards became a licentiate; but he left Paris without having taken the degree of doctor, from inability

bility to defray the expences of that ceremony, in consequence of the small income left him by his father. He therefore returned to his native city, where duke Charles III. of Lorraine appointed him his consulting physician, and retained him near his person both at home and in his travels. Duke Henry II. likewise held him in the same estimation; and, among many other marks of his esteem for Lepois, he instituted a faculty of medicine at Pont-à-Mousson, and nominated him dean and first professor. In order to undertake these offices, he repaired to Paris, where he received the degree of M.D., which gave him the power of conferring the same degree upon others, and commenced the duties of his professorship in November 1598. He had now an opportunity of displaying the stores of knowledge, which his acquaintance with the Greek and Latin, Arabic, Hebrew, Italian, and Spanish languages had enabled him to obtain; he was indefatigable in his observation of diseases, and omitted no opportunity of examining by dissection the bodies of those who died; from which he justly anticipated the most important improvements would accrue to medicine. His reputation was elevated to the highest degree, so that he was the physician of all the honourable persons in Lorraine. His zeal in the practice of his profession continued unabated, and ultimately occasioned his death at the age of seventy; for he died of the plague at Nancy, whither he had gone to administer relief to those afflicted by the pestilence, in the year 1633. He left the following works, which have transmitted his reputation to posterity; particularly the first, entitled "Selectiorum Observationum et Consiliorum de præteritis hæcenus morbis, effectibusque præter naturam ab aquâ, seu serosâ colluvie et deluvio ortis, Liber singularis;" Pont-à-Mousson, 1618, in 4to. This work passed through several subsequent editions, one of which, (that of Leyden 1733) was published, with a preface, by the celebrated Boerhaave. A selection from, or an abridgment of it, was also printed in 1630, with the title of "Piso esucleatus," in 12mo. His other works were, "Physicum Cometæ Speculum," Ponte à Moationem, 1619, in 8vo.; and "Discours de la Nature, Causes, et Remèdes, tant curatifs que preservatifs, des Maladies populaires, accompagnées de Dysenterie et autres Flux de Ventre," ibid. 1623, in 12mo. He translated from the Spanish into Latin, "Ludovici Mercati Institutiones ad usum et examen eorum qui artem luxatoriâ exercent," Francofurti, 1625, in folio. He likewise published the following eulogy of his first patron, "Caroli III., Serenissimi, Potentissimique Ducis Lotharingiæ, &c., Mæcenasissimus, seu felicitatis et virtutum egregio Principe dignarum coronæ," 1690. Eloy Dict. Hist. de la Med.

LEPOMERO, in *Geography*, a town of New Mexico, in the province of Hiagui; 130 miles E.N.E. of Riochico.

LEPORARIA AQUILA, a name given by some authors to the *melanotos*, or black eagle, from his destroying great numbers of hares. See *FALCO melanotus*.

LEPORINUM LABIUM, in *Surgery*. See *HARE-LIP*.

LEPORINUM ROSTRUM, a term sometimes applied to the portion of flesh frequently observable between the margins of the fissure in cases of hare-lip. See *HARE-LIP*.

LEPORINUM GENUS, in *Zoology*, the name of a genus of animals, so called from their general resemblance to the hare in shape, and other particulars: the characters by which they are distinguished from other quadrupeds are these; they have feet divided into claws; they feed on vegetables; and they have two very long teeth in the fore-part of their mouths. Ray's Syn. Quad. p. 204.

LEPORINUS OCLUSUS, in *Surgery*. See *LACRIMETHALMIA*.

LEPOTI, in *Geography*, a town of the principality of Georgia, in the province of Kaketi; 22 miles S.E. of Kaketi.

LEPPOWIRTA, a town of Sweden, in the government of Kuopio; 24 miles S. of Kuopio.

LEPRA, λεπρα, quasi λεπρεν, squamula, from λεπτι, a scale; whence our English term *Leprosy*; which see.

LEPRA Lankeng, in *Geography*, a town of Thibet; 68 miles S.E. of Toudlong.

LEPRAS, in *Ichthyology*, the name of a sea-fish of the turdus, or wrasse kind, remarkable for the great variety and beauty of its colouring. It is seldom caught of more than five or six inches in length, and is considerably broad and flat. It sometimes grows to a foot long, but that only in the ocean, never in the Mediterranean sea, where it is usually caught; and even there very rarely. It is spotted all over like the body of a leopard. It is one of the most beautiful fish of the Mediterranean, but is not much esteemed at table, being of an intpid and watery tale.

LEPREUM, LEPREOS, or *Lepræum*, in *Ancient Geography*, a town of Triphlyia, near the confluence of the rivers Jordanus and Alcidon, N.W. of Chaa. It is said to have been founded by a person of the name of Lepros, a famous wrestler, who contended with Hercules, by whom he was vanquished and killed. In the time of Pausanias, the inhabitants of Lepreum assumed the appellation of Arcadians. In this town was a temple of Ceres, constructed of bricks, and near it was the fountain called Arené.

LEPRIA, an island on the coast of Ionia, mentioned by Pliny.

LEPROSO AMOVENDO, in *Law*, an ancient writ that lay to remove a leper, or *lazar*, who thrust himself into the company of his neighbours in any parish, either in the church or at other public meetings, to their annoyance. The writ lies against those lepers that appear outwardly to be such, by sores on their bodies, smell, &c. and not against others: and if a man be a leper, and keep within his house, so as not to converse with his neighbours, he shall not be removed.

LEPROSY, in *Medicine*, a denomination which has been given to a variety of chronic diseases, chiefly affecting the skin; but which has not been exclusively appropriated to those that are characterized by the formation of scales, as the origin of the term imports. Even the Greek writers themselves, and more especially the later ones, have not adhered uniformly to the proper import of the appellation; but the confusion which has prevailed in subsequent periods of medical history, in regard to the application of this term, almost bids defiance to the industry and discrimination of the inquirer. This is partly to be ascribed to the difficulty of conveying accurate notions of cutaneous appearances by verbal descriptions, partly to the extreme variety in which those appearances present themselves, and partly to the neglect of minute observation, where distinctions can only be detected by a careful and practised eye. Thus the latter Greek physicians applied the term *lepra* in a more extended sense than their predecessors, and rendered future discrimination more difficult. But this difficulty was exceedingly multiplied by the translators of the works of the Arabian physicians into Latin, after the revival of learning. The Arabians appear to have distinguished the lepra and elephantiasis of the Greeks, by appropriate terms in their own language: but the translators rendered the word which denoted the latter (*viz. juzam, and baras or albaras*) by the Greek term *lepra*; and the Arabic words (*albohak and alkouba*) which seem to have signified the same with the lepra, a phos, and psona of the Greeks, they translated by the terms *impetigo and morphaea*.

## LEPROSY.

*morphaea* respectively. (See Willan on Cutan. Diseases, 2d edit. p. 112. 117. and 126.) This produced the double confusion of applying the same appellation to a variety of diseases, and of denoting each disease by a variety of names; insofmuch that almost every severe chronic affection of the skin at length acquired the denomination of leprosy, which became rather the name of a class of diseases, than a specific term. This confusion was still farther increased, during the middle ages; when innumerable hospitals and places of resort, together with the means of subsistence, were provided for those who were afflicted by this prevalent malady; and when the epithet of *leprous* was a sufficient claim upon the charity of the Christian world. For every species of disease affecting the skin was represented as *leprosy*; and multitudes of idle and filthy persons obtained a subsistence by themselves in that class.

The same term, *leprosy*, has, moreover, been applied by the translators of the sacred writings, to a variety of cutaneous diseases, respecting the nature of which there has been some difference of opinion; none referring it to the scaly lepra of the Greeks, and others considering it as a variety of the elephantiasis of the same people; we mean the leuce, vitiligo, or albas alba.

In order to arrive at a tolerably clear-notion of the several varieties of signification, which have been given to the term, we must, therefore, consider it under four different heads; namely, the leprosy of the Arabians, of the Greeks, and of the Jews, and the leprosy of the middle ages.

*LEPROSY of the Arabians, or Lepra Arabum*, is the same with the *Elephantiasis* of the Greeks. See ELEPHANTIASIS.

Under that head, we have described at length the symptoms of this formidable disease, as detailed by Aretæus and the other Greek physicians; as well as the appearances, which it has been said to assume in the West Indies, in Arabia, and in other southern climates, in modern times. We must here, however, observe, that the appellation of *Arabian leprosy* has originated in error; and that the imputation of having misapplied the Greek term (*lepra*), which has been generally cast upon the Arabian physicians, appears to be altogether incorrect. This imputation arose from the misinterpretation of their translators, as above stated: and as the works of the Arabians were known only to European physicians, through the medium of these translations, into Latin, it was naturally inferred that the original writers had committed the error. Avicenna describes the elephantiasis under the title of *juzam*, or *aljuzam*, (the appellation which is still given to the disease in Arabia, according to Niebuhr,) and likewise distinctly treats of the *albers* or *albaras*, and the *alcheck* or *albohek* (morphaea of the translators). He carefully distinguishes, however, the albaras from the albohek, the former of which has several symptoms in common with the confirmed elephantiasis (*aljuzam*), and is said often to terminate in it. These symptoms are, a loss of sensibility in the parts affected; a change of colour in the hairs, which become white; and ultimately a loss of the hair; and a change in the colour and texture of the skin, and of the muscular flesh under it, which becomes white and bloodless, like that of oysters, and finally perishes and falls off. These symptoms have, in consequence of the mistakes of the translators of the Arabians, been transferred to the proper scaly lepra, and are conjoined, in the ordinary descriptions of the latter, with the symptoms properly belonging to it alone. But it seems obvious that the Arabian terms albohek and albaras are of nearly the same import as the Greek terms alphas and leuce, which both Hippocrates and Celsus have carefully distinguished; considering the former as a mere blemish of the skin, but the latter as a formidable and almost

incurable disease. See LEUCE. See also Hippoc. lib. *περὶ πιδωδω*. Celsus, lib. v. cap. 28, and Willan on Cutaneous Diseases, ord. ii. genus 1.

*LEPROSY of the Greeks, or Lepra Græcorum*, is principally characterized, as the term imports, by the formation of *scales* on the surface of the skin, which consist of morbid laminae of the cuticle, hard, thickened, opaque, and of a whitish colour, and appear in patches of different sizes, having always nearly a circular figure.

Such is the description of the disease which has been left us by the Greek writers, and which is given as the character of the *lepra* by the best writer on the subject in our own time; we mean Dr. Willan. Hippocrates has not left any circumstantial detail of the symptoms of *lepra*, but speaks of it, together with the *alphos*, *psora*, *hebenes*, &c. as an external blemish, rather than a disease. The later Greek writers, however, although brief in their description of *lepra*, have pointed out the distinctions between it and those similar affections, with which it was conjoined by their predecessors. Aëtius states, that it differs from the *leuce* (vitiligo, or white elephantiasis) in not penetrating deeper than the skin, and leaving the subjacent flesh sound; from the *alphos*, which, though scaly, is more superficial; and from the *psora*, in having large scales, like those of fish; whereas, in the latter, only scurf, or branny exfoliations, appear. (Aët. Tetrabib. iv. fermo i. cap. 134.) It must be here observed that the *psora*, simply, signifies a slight, scaly disease; and not the *scabies*, or itch, which is designated, together with the moist-tetter, by the epithet *ulcerating psora*, *λεπρα δλωδης*. (Aët. loc. cit. cap. 126, 127, and 130. Galen, Introd. Paul. lib. iv. cap. 2.) Paulus Ægineta, in a chapter "On Lepra and Psora," observes, that "both these diseases are characterized by roughness and itching, and a separation of a melancholic humour; but *lepra* affects the skin deeply, in circular patches, at the same time throwing off scales like those of large fishes; whereas *psora* is more superficial, variously figured, and throws off little bran-like substances." (Lib. iii. cap. 2.) Actuarius has given the same account of these diseases. (De Meth. Med. lib. ii. cap. 11.) This scaly *psora* will be afterwards considered, under the appellation of PSORIASIS, which Dr. Willan has appropriated to it, in order to avoid the confusion which would ensue in retaining the term *psora*, which has been applied by many of the moderns exclusively to *scabies*, or itch.

Three varieties of the scaly lepra are observed in this country, according to Dr. Willan, which he has denominated *LEPRA vulgaris*, *L. albidodes*, and *L. nigricans*.

1. The *lepra vulgaris* first shews itself in small, reddish, and shining elevations of the cuticle, on the tops of which thin white scales are seen within twenty-four hours from their appearance. After three or four days, the small elevations are flattened, and at the same time dilated, by an extension of their bases, to the size of a silver penny. These patches continue to enlarge gradually, until they become nearly of the size of a crown piece; they always retain a circular or oval form, are covered with dry scales, and surrounded by a red border. The scales often accumulate on them, so as to form a thick prominent crust, which is quickly reproduced, whether it fall off spontaneously, or have been forcibly detached. On its removal, the surface appears, through a magnifier, to be porous and irregular, or wrinkled; but the furrows do not coincide with the lines of the contiguous found cuticle. The eruption is not attended with any pain or uneasiness, excepting a slight degree of itching, felt when the patient becomes warm in bed, and a sensation of tingling upon

## LEPROSY.

upon any sudden change in the temperature of the atmosphere.

This species of *lepra* often appears first at the elbow, or on the fore-arm, but more generally about the knee; in the latter case, the primary patch forms immediately below the patella. Within a few weeks, several other scaly circles appear along the fore parts of the leg and thigh, increasing by degrees until they come nearly into contact. The disease is then often stationary for a considerable length of time: if it does advance farther, its progress is towards the hips and loins, afterwards to the sides, back, and shoulders, and about the same time to the arms and hands. In a great number of cases, the hairy scalp is the part last affected: although the circles formed on it remain for some time distinct, yet they finally unite, and cover the whole surface on which the hair grows with a scaly incrustation, producing, especially in hot weather, a troublesome itching. In some instances, the nails, both of the fingers and toes, are thickened, and deeply indented longitudinally; either the whole, or some part of each nail is harder, and more prominent than usual.

When the *lepra* extends to all the parts above-mentioned, it becomes highly disgusting in its appearance, and not only inconvenient, from the stiffness and torpor which it occasions in the limbs, but painful where the skin is red and tender, as it sometimes becomes, in the flexures of the joints. The disease, however, is seldom disposed to terminate spontaneously: it continues nearly in the same state for many weeks, or months, sometimes for several years, or even during the remainder of life, yet without being apparently connected with any disorder of the constitution. An appropriate course of medicine, with a regular diet, acts very slowly on the *lepra*, but will at length accomplish its cure; and it then proceeds to a termination in the following manner. First, the incrustation separates from about the centres of the patches, and is no longer reproduced. The scales being farther and farther removed, a circle of red flaking cuticle, deeply indented, appears within the original patch, which still retains a broad hard scaly ring, or border: this border continues till the cuticle within it assumes the usual colour and texture. It then gradually softens, and the cuticular lines being extended over it, every vestige of the disease is erased.

It may be observed, with respect to the scaly *lepra*, that the patches are generally situated where the bone is nearest to the surface, as along the skin, about the elbow, and upon the *ulna* in the fore-arm; along the spine, or *lumbo*, and shoulder-blade; and on the scalp. They rarely appear on the calf of the leg, on the fleshy part of the arm and thigh, or within the flexures of the joints. The disease almost constantly affects both sides, appearing at each elbow, or at each knee about the same time, and extending from thence along the limbs in a similar manner. But although fresh patches arise, from time to time, in different situations, there is no cessation of the complaint in the parts first affected, as happens in some cutaneous diseases; but when it is about to terminate, all the patches assume a favourable appearance at the same time, those nearest the extremities going off somewhat later than the rest. When the extremities, back, loins, and head, are all at the same time covered with dry crusts, it might be expected that the obstruction of the perspiration on so large a surface would produce disagreeable consequences; which, however, is not found to be the case.

The causes of the common *lepra* are not satisfactorily ascertained. Some writers maintain that the disease is both contagious and hereditary; but its contagious nature has probably been assumed from the erroneous notion of the

affinity between the *lepra vulgaris*, and the *elephantiasis*. Dr. Willan (to whose accurate observations we are indebted for the description of *lepra*), asserts, justly, that it is not a contagious disease. He admits, however, that an hereditary predisposition to it is occasionally transmitted from the parent to the offspring. A slow pulse, or a languid circulation of the blood, and, what must generally be connected with it, a harsh, dry, impermeable state of the skin and cuticle, appear to constitute a fundamental part of the pre-disposition. The morbid effects of such a state of the integuments are most likely to be felt in the decline of life: accordingly, the disease is of more frequent occurrence, and proves more inveterate after the age of forty, than at any earlier period; an observation made long ago by Hippocrates and Galen. Willan. loc. cit.

Among the exciting causes of this form of the *lepra*, particular kinds of diet, as dried meats, fish, oatmeal, and some incongruous mixtures of food, are usually mentioned, but not on sufficient authority: at least the disorder is very frequent in this metropolis and its environs, where the articles of diet just mentioned are little used. Nor does it appear that the general opinion, that *lepra* is more prevalent in fishing-towns on the sea-coast, than in other situations, rests upon any better foundation. Exposure to cold and moisture, and the accumulation of scordes on the skin, are the only exciting causes of this variety of *lepra* which Dr. Willan has been able to point out. From the last-mentioned cause, he says, it frequently arises in bakers, bricklayers, labourers, coal-heavers, dust-men, laboratory-men, and others who work among dry powdery substances; for these persons are not able to attend very carefully to personal cleanliness, from the want of public baths, and an imperfect supply of water in their own houses. For our own parts, however, we have seen the disease most frequently in females, where the last-mentioned circumstances had not operated.

2. *Lepra albaeoides*. In this form of *lepra*, the scaly patches are smaller than in the *lepra vulgaris*, and have their central parts a little depressed. The eruption usually begins about the elbow, with distinct, hard, protuberances, not much larger than pimples, and of a dull red colour. These, in a short time, dilate to nearly the size of a silver penny: two or three days afterwards the central part of them suffers a depression, within which minute white scales may be observed. The surrounding border, however, still continues to be raised, but it retains the same size, and the same red colour as at first. All the fore-arm, and in many cases the back of the hand, is spotted with similar patches, which seldom become confluent; but there is sometimes a white incrustation round the point of the elbow. This eruption appears in the same manner upon the joint of the knee, but without spreading far along the thigh or leg. It rarely, if ever, appears on the trunk of the body, or on the face.

This is a disease of long duration, and not less difficult to cure than the foregoing species of *lepra*: even when the scaly patches have been removed by a perseverance in the use of suitable applications, the cuticle remains for a long time red, tender, and brittle; but the small hairs of the skin are not destroyed, nor altered in their colour and texture, as some authors have stated, and as occurs in the *leuce*. This form of the disease seems to have been ranked by the ancients under the head of *rubite albos*, which Galen asserts is a slighter affection, and less rough than the common *lepra*. Celsus, indeed, has classed it (under the generic term *vitiligo*) with the *leuce*; but he points out with care the distinction between the slight *albos* and the incurable *leuce*.

The exciting causes of this form of the disease are probably

bably the same as those of the preceding species. It chiefly affects women and children; and is not infrequently seen, according to Dr. Willan, in those who are employed to dress flax, hair, or feathers.

3. The *lepra nigricans* does not differ much from the *lepra vulgaris*, with respect to its form or distribution; but chiefly in the colour of the patches, which are dark and livid. They appear first on the legs and fore-arms, extending afterwards to the thighs, loins, neck, back, and hands: their central part is not depressed, as in the *alpsides*. They are somewhat smaller than the patches of the *lepra vulgaris*, and have a livid or purplish border. The skin, likewise, appears of a livid colour through the scaly incrustations, which are seldom very thick. It is further to be observed, that the scales are more easily detached than in the other forms of lepra, and that the surface remains longer excoriated, discharging lymph, often with an intermixture of blood, till a new incrustation forms, which is hard, brittle, and irregular. This complaint is particularly troublesome when it covers the face.

The *lepra nigricans* affects soldiers, sailors, sculler-men, stage-coachmen, butchers, brewers'-labourers, and others, whose occupations are attended with much fatigue, and expose them to cold and damp, and to a precarious or improper mode of diet. Women, habituated to poor living, and constant hard labour, are also liable to this disease. It was probably comprised under the denominations of *black alphas* (*Μακρί*), by the Greeks, and of *black aloobak* by the Arabians (or *black morphaea* of their translators.) On comparing their accounts, however, it will be found that some of them represent the black alphas as smooth and shining, like the leuce; while others assert that it is rough and scaly. By this inaccuracy respecting the *black* as well as the *white* alphas, they have led succeeding writers to conjoin the lepra and elephantiasis, diseases generically different.

*Treatment of Lepra Græcorum.*—In the treatment of lepra, the Greek physicians always premised bleeding and strong purgative medicines; but they seem to have depended chiefly on external applications, such as alum, sulphur, nitre, lupines, cabbage-leaves, elm-bark, the dung of goats, mice, and foxes, human urine, and the gall of bears. They likewise used several vegetable and mineral substances, which had a corrosive or vesicating quality; as hellebore, colophonias, the roots of white lily, onion, bryony, asphodel, ranunculus, and anemone, the seeds of mustard, and horse-radish, quicklime, vitriol, &c. Remedies of this kind, or even blisters, are, however, found to have only a temporary effect, their operation being soon succeeded by a re-production of the scaly crusts. Liniments, composed of tar, or of some mercurial preparations, have been much employed, both in ancient and modern practice, with somewhat more beneficial effect.

Of all the *external remedies*, however, which can be employed in the two first species of lepra, frequent *balning* or *washing* is the most advantageous. Dr. Willis was averse to warm-bathing, or the external use of any mineral water, from some theoretical notions, and censures especially the Bath waters, as having converted many cases of slight eruption into a confirmed leprosy. (De Medicam. Operat. sect. iii. c. 7.) It is pretty well ascertained, however, from experience, that not only the waters of Bath, but also the sulphureous waters of Harrogate, Croft, Mofat, &c. used both externally and internally, prove very beneficial in many cases of the lepra. Where the skin is not very irritable, much advantage may be also derived from baths prepared with a solution of alkalinized sulphur, and muriate of soda; and when the surface is very tender,

simple ablution with warm water, or bran and water, has the effect of abating the tingling or itching of the skin, of encouraging the removal of the scales, and of rendering the skin softer and more pliable. Similar effects are produced by the use of the Bath waters, according to Dr. Falconer. (See Memoirs of the Med. Society of London, vol. iv.) "The method in general pursued," this respectable physician states, "is to order the patients to bathe twice or thrice a week, according to their age, strength, and other circumstances. This course is accompanied with a direction to drink the waters, which, at a medium, are taken in the quantity of about a pint daily, and are thought thus to second the good effects of the bath, by promoting an easy and gentle perspiration. If the amendment appears to proceed according to expectation, no other medicines are given, but occasionally such as are opening, if the body be costive." Dr. Falconer also states, that the whole number of persons admitted into the Bath hospital for this disease in the space of four years, from June 12th, 1775, was 83; of whom were discharged 52 "cleansed," and 24 "much better."

*Balning in sea-water.* Dr. Willan observes, is a certain auxiliary in the cure of lepra. "It is usual, and seems proper, first to use a bath of warm sea-water, till the skin be softened, and the scaly incrustations removed; after which a cure is soon obtained, especially in young persons, by bathing in the open sea. As the disease is apt to recur in winter, or in spring, the same plan may be requisite for several successive summers; but I have known it, by perseverance, finally eradicate the complaint. A simple warm-bath," the same physician observes, "with moderate friction, likewise contributes to remove the scales, and to produce a soft red skin, which, in time, regains the usual colour and texture. This plan is sufficient in the slighter cases of lepra, without the use of internal remedies. If the disease affects the extremities only, bathing the whole body is not necessary; it may be enough to apply steam, or warm-water, frequently to the disordered parts." Loc. cit.

Of the mercurial preparations employed externally, we learn from the same author, the muriate, (or sublimate,) and the unguentum hydrargyri nitrat, seem most efficacious in restoring the cuticle, after the leprosy crusts are removed. He does not, however, think the latter preferable to the tar-ointment, which Dr. Willis and others have recommended. This ointment should be well rubbed upon the parts affected every night, and carefully washed off, the following morning, with warm-water, or with a slight alkaline lotion. We may add, that in slight or incipient cases, where there is much dryness and an irritable state of skin, the scales may be often removed by a spirituous lotion; and that the thick crusts which sometimes form upon the patches, may be softened and removed by strong alkaline applications. The use of the decoctions of *solanum dulcamara*, or herb bitter-sweet, or of elm-bark, by way of lotion, has also been found of considerable service in several instances.

Many *internal remedies* have been employed and recommended for the cure of lepra, the efficacy of which has not been strongly established by subsequent experience. Respecting these, Dr. Willan remarks, that antimonials, sulphur, and nitre, have not alone any considerable efficacy; that decoctions of emollient herbs, of guaiacum-wood, sassaaparilla, mezereon, or of elm-bark, which have been recommended as specifics, by no means deserve that character; that calomel, *hydrargyri calcinatus*, *pitule hydrargyri*, or mercurial frictions, applied so as to produce salivation, do not remove the disease; and that the nitrous and muriatic acids, lately recommended in obstinate cutaneous eruptions,

though successful in some cases of lepra, have been given in other cases, for three or four successive months, without any manifest advantage. The tincture of *cantharides* has often been prescribed for the *lepra Græcorum*, as on the authority of Dr. Mead; but that physician recommended it only in cases of elephantiasis, or *lepra Arabum*; and it has been found totally useless in the scaly lepra. See Falconer, loc. cit. Willan, loc. cit.

The following substances may be mentioned, however, as having evinced considerable efficacy, when taken internally, in many cases of lepra. The corrosive *mercurate of mercury*, dissolved in spirit, and taken in small doses for a length of time, has sometimes proved useful; especially when its operation was assisted by some antimonial, given at the same time, with any of the decoctions above-mentioned. The caustic potash in solution, or *aqua kali puri* of the late dispensatories, given in the dose of twenty or thirty drops, thrice a day, in a cupful of any mild fluid, has also manifested some influence over the disease. But the preparations of *arsenic* have been employed with more considerable success, in obdurate cases of lepra, both in form recommended by the late Dr. Fowler, and in that of Dr. De Valangin. The doses of the solution prescribed by Dr. Fowler are larger than are necessary. Five or six drops taken three times a day will be generally sufficient for an adult. We have seen several cases in which the disease yielded readily to this remedy. See Dr. Willan's Treatise, 2d edit. p. 137; where is also an interesting communication on the subject, from Dr. Girdlestone, of Yarmouth.

Among the vegetable remedies, the tincture of *black hellebore* has been occasionally prescribed by Dr. Willan, its dose being regulated so as not to disorder the bowels, and he is of opinion that it has some efficacy; but not more than the mineral remedies already mentioned. The decoction of the twigs and leaves of the *Jolannum dulcamara* (Linn.), has also been found beneficial in the scaly lepra, when taken internally, as well as when applied externally as a wash. Out of twenty-three cases, in which it was employed by Dr. Crichton, two only resisted its action; all the others were cured. The decoction is now ordered in the pharmacopœia of the College, an ounce of the plant to be boiled in a pint and a half of water down to a pint. Of this decoction Dr. Crichton preferred two ounces, at first, to be taken every morning, noon, and evening, but the quantity was afterwards increased, until the pint was consumed every day; at the same time, the patient was ordered to wash the skin with a stronger decoction of the same plant, which considerably accelerated the cure. The remedy seldom begins to exhibit any evident good effects for the first eight days.

The remedies above-mentioned are applicable only to the two first species of lepra; none of them being particularly serviceable in the *lepra nigricans*. This form of the disease requires, in the first place, a regular and nutritive plan of diet, with moderate exercise; it may be afterwards wholly removed by the use of cinchona, and the mineral acids, seathing, &c. Willan, loc. cit.

It must be observed, before we conclude, that, in the venereal disease, circular patches sometimes appear, which resemble those of the *lepra nigricans* in size and colour, but which are not inherited. The dryness and hardness of the skin, so remarkable in the *lepra vulgaris* and *alboides*, do not occur in the venereal lepra; its patches, when somewhat advanced, being as soft and pliable as other parts of the skin. These patches are generally distinct, and at a distance from each other; they seldom exceed the size of a shilling; yet it is probable, Dr. Willan remarks, that they might acquire a greater magnitude, if the progress of the disease

were not early arrested by the use of mercury. As the disease yields to the influence of this remedy, a circular red spot appears for some time in the place of each declining patch, and a minute shallow depression, like a cicatrix, is left at the centre; but no permanent discolouration of the skin remains, as in some other cases. If no medicines were employed, these, like other syphilitic eruptions, would at length terminate in ulcerated blotches.

**LEPROSY of the Jews.** The nature of this disease, which appears from the writings of the Hebrew legislator to have prevailed extensively among that people, after they quitted Egypt under his guidance, has been the subject of much discussion, and of considerable difference of opinion. Some writers have referred it to one of the species of leprosy above-mentioned, and some to the other; and some again have considered it as a disease peculiar to the Hebrew people, differing from every malady with which other nations have been afflicted, and sent by Providence upon them, as a supernatural-punishment. Many of the ancient historians assert, that the Hebrews were expelled the Egyptian territories, in consequence of the general or even universal prevalence of the leprosy among them. Manethon, an Egyptian, who wrote a history of the religion of his ancestors, makes this assertion; and a similar account is given by Lysimachus, Plutarch, Justin, Tacitus, and others. The learned Jewish writer, Josephus, however, treats these accounts as altogether fabulous; and states some substantial arguments in proof of their absurdity and falsehood. (See Joseph. Antiq. Judaic. lib. iii. and contra Apion, lib. i.) The concurrent testimony of the historians, physicians, and poets of antiquity, indeed, goes to prove, that the inhabitants of Egypt, for many ages, were subject to elephantiasis, and that, in fact, the disease originated on the borders of the Nile; and modern observation has ascertained its more recent prevalence in the same countries. This circumstance seems to have led some writers to conclude, that the Hebrew leprosy was the elephantiasis, or *lepra Arabum*, as it has been called. But a consideration of the symptoms, enumerated by the divine lawgiver, sanctions the conclusion, which the majority of writers have drawn upon the subject, that it was neither the elephantiasis, in its ordinary tubercular form, on the one hand, nor the scaly lepra of the Greeks (which, however, it more nearly resembled in its external appearance) on the other; but that it was the *leuce* of the Greek writers, the *vithigo* of Celsus, and the *whitæ albaras* of Avicenna, and the other Arabian physicians. (See LEPRE.) See also Leon. Fuchsii, Paradox. lib. ii. cap. 16. Greg. Horst. Obs. Med. lib. vii. p. 330. Th. Campanella, Ord. Medic. lib. vi. cap. 23. art. 3. Foresti, Obs. Chirurg. lib. iv. Obs. 7. Raymond, Hist. de l'Elephantiasis, p. 64. Herder, vom Abendländischen Anstalt, p. 341.

It will be sufficient to compare the observations of Avicenna, when pointing out the distinction between the *whitæ albaras* and the *alguada* (*morphea* of the translators), with the marks of discrimination detailed in the book of Leviticus, respecting the *unclean* leprosy, and those forms of it which were not deemed unclean, in order to be convinced that the same disease is, in both cases, under the view of the writer. Avicenna states that "both species of *alguada* (*viz. albæ et melas* of the Greeks) are confined to the skin, and merely superficial; but the *albaras* affects both the skin and the flesh, even to the bones." And again; "there is this difference between the white *alguada* and the white *albaras*, that hairs grow upon the skin affected with the former, and they are of a black or brown colour: but those, which grow in the *albaras* are always white; and at the same time the skin is more depressed or sunk, than the rest of the sur-

face of the body. Some depression may, perhaps, occur in the *guada*, but it is very slight. Moreover, a puncture of the skin with a needle draws blood in the *guada*; but no blood follows it in the *baras*, only a watery humidity; and this is incurable." (Avicenna, Canon. Med. lib. iv. Fen. iii. tract. iii. cap. 9.) In the five or six species of leprosy described by Moses, namely, as commencing with a scab or bright spot, a swelling, a rawness of the flesh, a boil or ulcer, and a burning or inflammation, as well as the leprosy in the head, and that connected with baldness, it will be observed, that the two characteristic symptoms are the *whiteness of the hair*, and the *depression of the skin* conjoined, as in the quotation from Avicenna. The whiteness of the surface alone, without change of colour in the hair, or any depression (as it occurs in the *alphas*, *morphea*, or *lepra Græcorum*), is expressly asserted not to constitute an unclean leprosy. "When a man hath have in the skin of his flesh a rising, a scab, or bright spot, and it be in the skin of his flesh like the plague of leprosy, then shall he be brought unto Aaron the priest, or unto one of his sons the priests; and the priest shall look upon the plague in the skin of the flesh. And if the hair of the plague is turned white, and the plague in sight be deeper than the skin of his flesh, it is a plague of leprosy, and the priest shall look upon him and pronounce him unclean." But "if the bright spot be white in the skin of his flesh, and in sight be not deeper than the skin, and the hair thereof be not turned white; then the priest shall shut him up that hath the plague seven days," in order to ascertain the nature of the disease by future inspection. "And the priest shall look on him the seventh day; and behold, if the plague in his sight be at a stay, and the plague spread not in the skin, then the priest shall shut him up seven days more; and the priest shall look on him again on the seventh day: and behold, if the plague be somewhat dark, and the plague spread not in the skin, the priest shall pronounce him clean; if it is but a scab; and he shall wash his clothes, and be clean." Leviticus, chap. xiii.

Nay it appears that the whiteness of the skin, even when extending over the whole body, was not considered as constituting of itself the true leprosy, unless some excoriation, or appearance of "raw flesh," was conjoined with it, or the hair was changed to white, or the depression of surface was observed; and even after excoriation had occurred, if it were sealed over, or became white, nevertheless the person was declared clean. "And if a leprosy break out abroad in the skin, and the leprosy cover all the skin of him that hath the plague from his head even to his foot, where soever the priest looketh; then the priest shall consider; and, behold, if the leprosy have covered all his flesh, he shall pronounce him clean that hath the plague: it is all turned white: he is clean. But when raw flesh appeareth in him, he shall be unclean. And the priest shall see the raw flesh, and pronounce him to be unclean: for the raw flesh is unclean; it is a leprosy. Or, if the raw flesh turn again, and be changed into white, he shall come unto the priest, and the priest shall see him: and, behold, if the plague be turned into white, then the priest shall pronounce him clean that hath the plague; and he is clean." (Loc. cit.) And, in like manner, when the cutaneous disease originates from a "boil," or from a "hot burning," (*ibid.* vers. 18 and 24.) in either case, if, in the place of the boil or burning, there be "a white rising, or a bright spot, white, and somewhat reddish, and it be shewed to the priest; and if, when the priest seeth it, behold, it be in sight lower than the skin, and the hair thereof be turned white, the priest shall pronounce him unclean; it is a plague of leprosy broken out of the boil. But if the priest look on it, and, behold, there be no white

hairs therein, and if it be not lower than the skin, but be somewhat dark; then the priest shall shut him up seven days, &c.;" and if, in the mean time, it remains stationary, "it is a burning boil, and the priest shall pronounce him clean."

And, farther, when the hairy scalp, or the beard, is affected with leprosy, "if it be in sight deeper than the skin, and there be in it a yellow thin hair," the person is pronounced unclean; "it is a dry scall, even a leprosy upon the head or beard." But even if there should be no depression of the surface, yet if there be likewise no black and thick hair, (*i. e.* hair of the natural appearance,) it is still to be considered as "the plague of the scall," and the person is to be shut up for seven days, and to be shaven, for the purpose of more accurate investigation.

Lastly, when after these successive seclusions and examinations, at intervals of seven days, in any of the cases, the unclean leprosy is confirmed; then "the leper in whom the plague is, his clothes shall be rent, and his head bare, and he shall put a covering upon his upper lip, and shall cry 'unclean, unclean.' All the days wherein the plague shall be in him, he shall be defiled; he is unclean: he shall dwell alone; without the camp shall his habitation be."

It is to be inferred, from the preceding quotations, that the Hebrews, during their migration from Egypt to the land of Canaan, were subject to a variety of diseases of the skin and muscular solids, to which the appellation of leprosy was applied, as a general term; but that the most incurable and loathsome species, which was called the *leprosy*, by way of eminence, was that malady, which has been subsequently known in the countries which they traversed and inhabited, and on all the eastern shores of the Mediterranean, under the various denominations above mentioned, of *leuce*, *vittigo*, *albaras alba*, and *elephantia alba* (Plin. Hist. Nat. lib. xxv. cap. 5.) That it was not the elephantiasis of Aretæus, in which the face was deformed with tubercles, the lips thickened, the nose dilated, the ears enlarged and tuberosus, and the countenance distorted, with a reddish brown complexion tending to black; and ultimately with an ulceration of the rugous and tuberculated parts, (see ELEPHANTIASIS,) is obvious from a perusal of the foregoing description. The extreme *whiteness*, indeed, is mentioned in various parts of scripture, as characteristic of the leprosy, and is several times compared to that of snow. This colour is the only circumstance that is stated, in respect to the miraculous leprosy of the hand in Moses himself, as well as in that of Miriam and Gehazi; (see Exodus, chap. iv. ver. 6, also 2 Kings, chap. vi. v. 27. Numbers, chap. xii. v. 10.); and the bright and smooth surface and depression of the spots also afford a contrast to the prominent and rough tubercles of elephantiasis. Nevertheless the leuce has some affinity to the elephantiasis in the loss of sensibility in the integuments and muscles which are affected by it. It would seem, however, to be a legitimate inference from the silence of Moses, that the tubercular elephantiasis was either extremely rare, or not altogether unknown to the Hebrews, or that it was not deemed unclean or contagious.
